Guidelines for Environmental Infection Control in Health-Care Facilities

Recommendations of CDC and the Healthcare Infection Control Practices Advisory Committee (HICPAC)

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention (CDC)
Atlanta, GA 30329

2003
Updated: July 2019

⚠ **Ebola Virus Disease Update [August 2014]:** The recommendations in this guideline for Ebola has been superseded by these CDC documents:

- Infection Prevention and Control Recommendations for Hospitalized Patients with Known or Suspected Ebola Virus Disease in U.S. Hospitals (https://www.cdc.gov/vhf/ebola/healthcare-us/hospitals/infection-control.html)
- Interim Guidance for Environmental Infection Control in Hospitals for Ebola Virus (https://www.cdc.gov/vhf/ebola/healthcare-us/cleaning/hospitals.html)

See CDC's Ebola Virus Disease website (https://www.cdc.gov/vhf/ebola/index.html) for current information on how Ebola virus is transmitted.

⚠ **New Categorization Scheme for Recommendations [November 2018]**
In November 2018, HICPAC voted to approve an updated recommendation scheme. The category **Recommendation** means that we are confident that the benefits of the recommended approach clearly exceed the harms (or, in the case of a negative recommendation, that the harms clearly exceed the benefits). In general, Recommendations should be supported by high- to moderate-quality evidence. In some circumstances, however, Recommendations may be made based on lesser evidence or even expert opinion when high-quality evidence is impossible to obtain and the anticipated benefits strongly outweigh the harms or when then Recommendation is required by federal law. For more information, see November 2018 HICPAC Meeting Minutes [PDF - 126 pages] (http://www.cdc.gov/hicpac/pdf/2018-Nov-HICPAC-Meeting-508.pdf).

⚠ ***C. difficile* Update [April 2019]:** Recommendations E.VI.G. and E.VI.H. and the supporting text were updated to reflect changes in Federal regulatory approvals: LIST K: EPA's Registered Antimicrobial Products Effective against Clostridium difficile Spores (https://www.epa.gov/pesticide-registration/list-k-epas-registered-antimicrobial-products-effective-against-clostridium).

⚠ **Interim Measles Infection Control [July 2019]**
See Interim Infection Prevention and Control Recommendations for Measles in Healthcare Settings (https://www.cdc.gov/infectioncontrol/guidelines/measles)

Guidelines for Environmental Infection Control in Health-Care Facilities

Abstract

Background:
Although the environment serves as a reservoir for a variety of microorganisms, it is rarely implicated in disease transmission except in the immunocompromised population. Inadvertent exposures to environmental opportunistic pathogens (e.g., *Aspergillus* spp. and *Legionella* spp.) or airborne pathogens (e.g., *Mycobacterium tuberculosis* and varicella-zoster virus) may result in infections with significant morbidity and/or mortality. Lack of adherence to established standards and guidance (e.g., water quality in dialysis, proper ventilation for specialized care areas such as operating rooms, and proper use of disinfectants) can result in adverse patient outcomes in health-care facilities.

Objective:
The objective is to develop an environmental infection-control guideline that reviews and reaffirms strategies for the prevention of environmentally-mediated infections, particularly among health-care workers and immunocompromised patients. The recommendations are evidence-based whenever possible.

Search Strategies:
The contributors to this guideline reviewed predominantly English-language articles identified from MEDLINE literature searches, bibliographies from published articles, and infection-control textbooks.

Criteria for Selecting Citations and Studies for This Review:
Articles dealing with outbreaks of infection due to environmental opportunistic microorganisms and epidemiological- or laboratory experimental studies were reviewed. Current editions of guidelines and standards from organizations (i.e., American Institute of Architects [AIA], Association for the Advancement of Medical Instrumentation [AAMI], and American Society of Heating, Refrigeration, and Air-Conditioning Engineers [ASHRAE]) were consulted. Relevant regulations from federal agencies (i.e., U.S. Food and Drug Administration [FDA]; U.S. Department of Labor, Occupational Safety and Health Administration [OSHA]; U.S. Environmental Protection Agency [EPA]; and U.S. Department of Justice) were reviewed. Some topics did not have well-designed, prospective studies nor reports of outbreak investigations. Expert opinions and experience were consulted in these instances.

Types of Studies:
Reports of outbreak investigations, epidemiological assessment of outbreak investigations with control strategies, and *in vitro* environmental studies were assessed. Many of the recommendations are derived from empiric engineering concepts and reflect industry standards. A few of the infection-control measures proposed cannot be rigorously studied for ethical or logistical reasons.

Outcome Measures:

Infections caused by the microorganisms described in this guideline are rare events, and the effect of these recommendations on infection rates in a facility may not be readily measurable. Therefore, the following steps to measure performance are suggested to evaluate these recommendations:

1. Document whether infection-control personnel are actively involved in all phases of a healthcare facility's demolition, construction, and renovation. Activities should include performing a risk assessment of the necessary types of construction barriers, and daily monitoring and documenting of the presence of negative airflow within the construction zone or renovation area.

2. Monitor and document daily the negative airflow in airborne infection isolation rooms (AII) and positive airflow in protective environment rooms (PE), especially when patients are in these rooms.

3. Perform assays at least once a month by using standard quantitative methods for endotoxin in water used to reprocess hemodialyzers, and for heterotrophic, mesophilic bacteria in water used to prepare dialysate and for hemodialyzer reprocessing.

4. Evaluate possible environmental sources (e.g., water, laboratory solutions, or reagents) of specimen contamination when nontuberculous mycobacteria (NTM) of unlikely clinical importance are isolated from clinical cultures. If environmental contamination is found, eliminate the probable mechanisms.

5. Document policies to identify and respond to water damage. Such policies should result in either repair and drying of wet structural materials within 72 hours, or removal of the wet material if drying is unlikely within 72 hours.

Main Results:

Infection-control strategies and engineering controls, when consistently implemented, are effective in preventing opportunistic, environmentally-related infections in immunocompromised populations. Adherence to proper use of disinfectants, proper maintenance of medical equipment that uses water (e.g., automated endoscope reprocessors and hydrotherapy equipment), water-quality standards for hemodialysis, and proper ventilation standards for specialized care environments (i.e., airborne infection isolation [AII], protective environment [PE], and operating rooms [ORs]), and prompt management of water intrusion into facility structural elements will minimize health-care associated infection risks and reduce the frequency of pseudo-outbreaks. Routine environmental sampling is not advised except in the few situations where sampling is directed by epidemiologic principles and results can be applied directly to infection control decisions, and for water quality determinations in hemodialysis.

Reviewers' Conclusions:

Continued compliance with existing environmental infection control measures will decrease the risk of health-care associated infections among patients, especially the immunocompromised, and health-care workers.

Table of Contents

List of Abbreviations Used in This Publication

Abbreviation	Meaning
AAA	animal-assisted activity
AAMI	Association for the Advancement of Medical Instrumentation
AAT	animal-assisted therapy
ACGIH	American Council of Governmental Industrial Hygienists
ACH	air changes per hour
ADA	Americans with Disabilities Act
AER	automated endoscope reprocessor
AFB	acid-fast bacilli
AHA	American Hospital Association
AHJ	authorities having jurisdiction
AIA	American Institute of Architects
AII	airborne infection isolation
AmB	amphotericin B
ANC	absolute neutrophil count
ANSI	American National Standards Institute
AORN	Association of periOperative Registered Nurses
ASHE	American Society for Healthcare Engineering
ASHRAE	American Society of Heating, Refirgeration, and Air-Conditioning Engineers
BCG	Bacille Calmette-Guérin
BCYE	buffered charcoal yeast extract medium
BHI	brain-heart infusion
BMBL	CDC/NIH publication “Biosafety in Microbiological and Biomedical Laboratories”
BOD	biological oxygen demand
BSE	bovine spongiform encephalopathy
BSL	biosafety level
C	Centigrade
CAPD	continuous ambulatory peritoneal dialysis
CCPD	continual cycling peritoneal dialysis
CMAD	count median aerodynamic diameter
CDC	U.S. Centers for Disease Control and Prevention
CFR	Code of Federal Regulations
CFU	colony-forming unit
CJD	Creutzfeldt-Jakob disease
cm	centimeter
CMS	U.S. Centers for Medicare and Medicaid Services
CPL	compliance document (OSHA)
CT/EC	cooling tower/evaporative condenser
DFA	direct fluorescence assay; direct fluorescent antibody
DHHS	U.S. Department of Health and Human Services
DHBV	duck hepatitis B virus
DNA	deoxyribonucleic acid
DOP	dioctylphthalate
DOT	U.S. Department of Transportation
EC	environment of care (JCAHO)
ELISA	enzyme-linked immunosorbent assay
EPA	U.S. Environmental Protection Agency
ESRD	end-stage renal disease
EU	endotoxin unit
F	Fahrenheit

Abbreviation	Meaning
FDA	U.S. Food and Drug Administration
FIFRA	Federal Insecticide, Fungicide, and Rodenticide Act
FRC	free residual chlorine
ft	foot (feet)
FTC	U.S. Federal Trade Commission
GISA	glycopeptide intermediate resistant *Staphylococcus aureus*
HBV	hepatitis B virus
HCV	hepatitis C virus
HEPA	high efficiency particulate air
HICPAC	Healthcare Infection Control Practices Advisory Committee
HIV	human immunodeficiency virus
HPV	human papilloma virus
HSCT	hematopoietic stem cell transplant
HVAC	heating, ventilation, air conditioning
ICRA	infection control risk assessment
ICU	intensive care unit
ID 50	50% median infectious dose
IPD	intermittent peritoneal dialysis
JCAHO	Joint Commission on Accreditation of Healthcare Organizations
kg	kilogram
L	liter
MAC	*Mycobacterium avium* complex; also used to denote MacConkey agar
MDRO	multiple-drug resistant organism
MIC	minimum inhibitory concentration
µm	micrometer; micron
mL	milliliter
min	minute
mg	milligram
MMAD	mass median aerodynamic diameter
MMWR	"Morbidity and Mortality Weekly Report"
MRSA	methicillin-resistant *Staphylococcus aureus*
MSDS	material safety data sheet
N	Normal
NaCl	sodium chloride
NaOH	sodium hydroxide
NCID	National Center for Infectious Diseases
NCCDPHP	National Center for Chronic Disease Prevention and Health Promotion
NCCLS	National Committee for Clinical Laboratory Standards
ng	nanogram
NICU	neonatal intensive care unit
NIH	U.S. National Institutes of Health
NIOSH	National Institute for Occupational Safety and Health
nm	nanometer
NNIS	National Nosocomial Infection Surveillance
NTM	nontuberculous mycobacteria
OPL	on-premises laundry
OSHA	U.S. Occupational Safety and Health Administration
Pa	Pascal
PCP	Pneumocystis carinii pneumonia
PCR	polymerase chain reaction
PD	peritoneal dialysis

Abbreviation	Meaning
PE	protective environment
PEL	permissible exposure limit
PPE	personal protective equipment
ppm	parts per million
PVC	polyvinylchloride
RAPD	randomly amplified polymorphic DNA
RODAC	replicate organism direct agar contact
RSV	respiratory syncytial virus
RO	reverse osmosis
SARS	severe acute respiratory syndrome
SARS-CoV	SARS coronavirus
sec	second
spp	species
SSI	surgical site infection
TB	tuberculosis
TLV®-TWA	threshold limit value-time weighted average
TSA	tryptic soy agar
TSB	tryptic soy broth
TSE	transmissible spongiform encephalopathy
U.S.	United States
USC	United States Code
USDA	U.S. Department of Agriculture
USPS	U.S. Postal Service
UV	ultraviolet
UVGI	ultraviolet germicidal irradiation
VAV	variable air ventilation
vCJD	variant Creutzfeldt-Jakob disease
VISA	vancomycin intermediate resistant *Staphylococcus aureus*
VRE	vancomycin-resistant *Enterococcus*
VRSA	vancomycin-resistant Staphylococcus aureus
v/v	volume/volume
VZV	varicella-zoster virus

Executive Summary

The *Guidelines for Environmental Infection Control in Health-Care Facilities* is a compilation of recommendations for the prevention and control of infectious diseases that are associated with healthcare environments. This document

a. revises multiple sections from previous editions of the Centers for Disease Control and Prevention [CDC] document titled *Guideline for Handwashing and Hospital Environmental Control*;[1, 2]
b. incorporates discussions of air and water environmental concerns from CDC's *Guideline for the Prevention of Nosocomial Pneumonia*;[3]
c. consolidates relevant environmental infection-control measures from other CDC guidelines;[4–9] and
d. includes two topics not addressed in previous CDC guidelines — infection-control concerns related to animals in health-care facilities and water quality in hemodialysis settings.

Part I of this report, *Background Information: Environmental Infection Control in Health-Care Facilities*, provides a comprehensive review of the scientific literature. Attention is given to engineering and infection-control concerns during construction, demolition, renovation, and repairs of health-care facilities. Use of an infection-control risk assessment is strongly supported before the start of these or any other activities expected to generate dust or water aerosols. Also reviewed in Part I are infection-control measures used to recover from catastrophic events (e.g., flooding, sewage spills, loss of electricity and ventilation, and disruption of the water supply) and the limited effects of environmental surfaces, laundry, plants, animals, medical wastes, cloth furnishings, and carpeting on disease transmission in healthcare facilities.

Part II of this guideline, *Recommendations for Environmental Infection Control in Health-Care Facilities*, outlines environmental infection control in health-care facilities, describing measures for preventing infections associated with air, water, and other elements of the environment. These recommendations represent the views of different divisions within CDC's National Center for Infectious Diseases (NCID) (e.g., the Division of Healthcare Quality Promotion [DHQP] and the Division of Bacterial and Mycotic Diseases [DBMD]) and the consensus of the Healthcare Infection Control Practices Advisory Committee (HICPAC), a 12-member group that advises CDC on concerns related to the surveillance, prevention, and control of health-care associated infections, primarily in U.S. healthcare facilities.10 In 1999, HICPAC's infection-control focus was expanded from acute-care hospitals to all venues where health care is provided (e.g., outpatient surgical centers, urgent care centers, clinics, outpatient dialysis centers, physicians' offices, and skilled nursing facilities). The topics addressed in this guideline are applicable to the majority of health-care venues in the United States. This document is intended for use primarily by infection-control professionals (ICPs), epidemiologists, employee health and safety personnel, information system specialists, administrators, engineers, facility managers, environmental service professionals, and architects for health-care facilities.

Key recommendations include

a. infection-control impact of ventilation system and water system performance;
b. establishment of a multidisciplinary team to conduct infection-control risk assessment;
c. use of dust-control procedures and barriers during construction, repair, renovation, or demolition;
d. environmental infection-control measures for special care areas with patients at high risk;
e. use of airborne particle sampling to monitor the effectiveness of air filtration and dust-control measures;
f. procedures to prevent airborne contamination in operating rooms when infectious tuberculosis [TB] patients require surgery
g. guidance regarding appropriate indications for routine culturing of water as part of a comprehensive control program for legionellae;
h. guidance for recovering from water system disruptions, water leaks, and natural disasters [e.g., flooding];
i. infection-control concepts for equipment that uses water from main lines [e.g., water systems for hemodialysis, ice machines, hydrotherapy equipment, dental unit water lines, and automated endoscope reprocessors]);
j. environmental surface cleaning and disinfection strategies with respect to antibiotic-resistant microorganisms;
k. infection-control procedures for health-care laundry;

l. use of animals in health care for activities and therapy;
m. managing the presence of service animals in health-care facilities;
n. infection-control strategies for when animals receive treatment in human health-care facilities; and
o. a call to reinstate the practice of inactivating amplified cultures and stocks of microorganisms on-site during medical waste treatment.

Whenever possible, the recommendations in Part II are based on data from well-designed scientific studies. However, certain of these studies were conducted by using narrowly defined patient populations or for specific health-care settings (e.g., hospitals versus long-term care facilities), making generalization of findings potentially problematic. Construction standards for hospitals or other healthcare facilities may not apply to residential home-care units. Similarly, infection-control measures indicated for immunosuppressed patient care are usually not necessary in those facilities where such patients are not present. Other recommendations were derived from knowledge gained during infectious disease investigations in health-care facilities, where successful termination of the outbreak was often the result of multiple interventions, the majority of which cannot be independently and rigorously evaluated. This is especially true for construction situations involving air or water.

Other recommendations are derived from empiric engineering concepts and may reflect an industry standard rather than an evidence-based conclusion. Where recommendations refer to guidance from the American Institute of Architects (AIA), (AIA guidance has been superseded by the Facilities Guidelines Institute [FGI]) the statements reflect standards intended for new construction or renovation. Existing structures and engineered systems are expected to be in continued compliance with the standards in effect at the time of construction or renovation. Also, in the absence of scientific confirmation, certain infection-control recommendations that cannot be rigorously evaluated are based on a strong theoretical rationale and suggestive evidence. Finally, certain recommendations are derived from existing federal regulations. The references and the appendices comprise Parts III and IV of this document, respectively.

Infections caused by the microorganisms described in these guidelines are rare events, and the effect of these recommendations on infection rates in a facility may not be readily measurable. Therefore, the following steps to measure performance are suggested to evaluate these recommendations (Box 1):

Box 1. Environmental infection control: performance measures

1. Document whether infection-control personnel are actively involved in all phases of a health-care facility's demolition, construction, and renovation. Activities should include performing a risk assessment of the necessary types of construction barriers, and daily monitoring and documenting of the presence of negative airflow within the construction zone or renovation area.
2. Monitor and document daily the negative airflow in airborne infection isolation (AII) rooms and positive airflow in protective environment (PE) rooms, especially when patients are in these rooms.
3. Perform assays at least once a month by using standard quantitative methods for endotoxin in water used to reprocess hemodialyzers, and for heterotrophic and mesophilic bacteria in water used to prepare dialysate and for hemodialyzer reprocessing.
4. Evaluate possible environmental sources (e.g., water, laboratory solutions, or reagents) of specimen contamination when nontuberculous mycobacteria (NTM) of unlikely clinical importance are isolated from clinical cultures. If environmental contamination is found, eliminate the probable mechanisms.
5. Document policies to identify and respond to water damage. Such policies should result in either repair and drying of wet structural or porous materials within 72 hours, or removal of the wet material if drying is unlikely with 72 hours.

Topics outside the scope of this document include
a. noninfectious adverse events (e.g., sick building syndrome);
b. environmental concerns in the home;
c. home health care;
d. bioterrorism; and
e. healthcare-associated foodborne illness.

This document includes only limited discussion of
a. handwashing/hand hygiene;
b. standard precautions; and
c. infection-control measures used to prevent instrument or equipment contamination during patient care (e.g., preventing waterborne contamination of nebulizers or ventilator humidifiers).

These topics are mentioned only if they are important in minimizing the transfer of pathogens to and from persons or equipment and the environment. Although the document discusses principles of cleaning and disinfection as they are applied to maintenance of environmental surfaces, the full discussion of sterilization and disinfection of medical instruments and direct patient-care devices is deferred for inclusion in the *Guideline for Disinfection and Sterilization in Health-Care Facilities*, a document currently under development. Similarly, the full discussion of hand hygiene is available as the *Guideline for Hand Hygiene in Health-Care Settings: Recommendations of the Healthcare Infection Control Practices Advisory Committee and the HICPAC/SHEA/APIC/IDSA Hand Hygiene Task Force*. Where applicable, the *Guidelines for Environmental Infection Control in Health-Care Facilities* are consistent in content to the drafts available as of October 2002 of both the revised *Guideline for Prevention of Health-care Associated Pneumonia* and *Guidelines for Preventing the Transmission of Mycobacterium tuberculosis in Health-Care Facilities*.

This guideline was prepared by CDC staff members from NCID and the National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP) and the designated HICPAC advisor. Contributors to this document reviewed predominantly English-language manuscripts identified from reference searches using the National Library of Medicine's MEDLINE, bibliographies of published articles, and infection-control textbooks. Working drafts of the guideline were reviewed by CDC scientists, HICPAC committee members, and experts in infection control, engineering, internal medicine, infectious diseases, epidemiology, and microbiology. All recommendations in this guideline may not reflect the opinions of all reviewers.

Part I. Background Information: Environmental Infection Control in Health-Care Facilities

A. Introduction

The health-care environment contains a diverse population of microorganisms, but only a few are significant pathogens for susceptible humans. Microorganisms are present in great numbers in moist, organic environments, but some also can persist under dry conditions. Although pathogenic microorganisms can be detected in air and water and on fomites, assessing their role in causing infection and disease is difficult.[11] Only a few reports clearly delineate a "cause and effect" with respect to the environment and in particular, housekeeping surfaces.

Eight criteria are used to evaluate the strength of evidence for an environmental source or means of transmission of infectious agents (Box 2).[11, 12] Applying these criteria to disease investigations allows scientists to assess the contribution of the environment to disease transmission. An example of this application is the identification of a pathogen (e.g., vancomycin-resistant enterococci [VRE]) on an environmental surface during an outbreak. The presence of the pathogen does not establish its causal role; its transmission from source to host could be through indirect means (e.g., via hand transferral).[11] The

surface, therefore, would be considered one of a number of potential reservoirs for the pathogen, but not the "de facto" source of exposure. An understanding of how infection occurs after exposure, based on the principles of the "chain of infection," is also important in evaluating the contribution of the environment to health-care associated disease.[13] All of the components of the "chain" must be operational for infection to occur (Box 3).

Box 2. Eight criteria for evaluating the strength of evidence for environmental sources of infection*+

1. The organism can survive after inoculation onto the fomite.
2. The organism can be cultured from in-use fomites.
3. The organism can proliferate in or on the fomite.
4. Some measure of acquisition of infection cannot be explained by other recognized modes of transmission.
5. Retrospective case-control studies show an association between exposure to the fomite and infection.
6. Prospective case-control studies may be possible when more than one similar type of fomite is in use.
7. Prospective studies allocating exposure to the fomite to a subset of patients show an association between exposure and infection.
8. Decontamination of the fomite results in the elimination of infection transmission.

* These criteria are listed in order of strength of evidence.
\+ Adapted from references 11 and 12.

Box 3. Chain of infection components*

1. Adequate number of pathogenic organisms (dose)
2. Pathogenic organisms of sufficient virulence
3. A susceptible host
4. An appropriate mode of transmission or transferal of the organism in sufficient number from source to host
5. The correct portal of entry into the host

* Adapted from reference 13.

The presence of the susceptible host is one of these components that underscores the importance of the health-care environment and opportunistic pathogens on fomites and in air and water. As a result of advances in medical technology and therapies (e.g., cytotoxic chemotherapy and transplantation medicine), more patients are becoming immunocompromised in the course of treatment and are therefore at increased risk for acquiring health-care associated opportunistic infections. Trends in health-care delivery (e.g., early discharge of patients from acute care facilities) also are changing the distribution of patient populations and increasing the number of immunocompromised persons in nonacute-care hospitals. According to the American Hospital Association (AHA), in 1998, the number of hospitals in the United States totaled 6,021; these hospitals had a total of 1,013,000 beds,[14] representing a 5.5% decrease in the number of acute-care facilities and a 10.2% decrease in the number of beds over the 5-year period 1994–1998.[14] In addition, the total average daily number of patients receiving care in U.S. acute-care hospitals in 1998 was 662,000 (65.4%) – 36.5% less than the 1978 average of 1,042,000.[14] As the number of acute-care hospitals declines, the length of stay in these facilities is concurrently decreasing, particularly for immunocompetent patients. Those patients remaining in acute-care facilities are likely to be those requiring extensive medical interventions who therefore at high risk for opportunistic infection. The growing population of severely immunocompromised patients is at odds with demands on the health-care industry to remain viable in the marketplace; to incorporate modern equipment, new diagnostic procedures, and new treatments; and to construct new facilities. Increasing

numbers of health-care facilities are likely to be faced with construction in the near future as hospitals consolidate to reduce costs, defer care to ambulatory centers and satellite clinics, and try to create more "home-like" acute-care settings. In 1998, approximately 75% of health-care associated construction projects focused on renovation of existing outpatient facilities or the building of such facilities;[15] the number of projects associated with outpatient health care rose by 17% from 1998 through 1999.[16] An aging population is also creating increasing demand for assisted-living facilities and skilled nursing centers. Construction of assisted-living facilities in 1998 increased 49% from the previous year, with 138 projects completed at a cost of $703 million.[16] Overall, from 1998 to 1999, health-care associated construction costs increased by 28.5%, from $11.56 billion to $14.86 billion.[16]

Environmental disturbances associated with construction activities near health-care facilities pose airborne and waterborne disease threats risks for the substantial number of patients who are at risk for health-care associated opportunistic infections. The increasing age of hospitals and other health-care facilities is also generating ongoing need for repair and remediation work (e.g., installing wiring for new information systems, removing old sinks, and repairing elevator shafts) that can introduce or increase contamination of the air and water in patient-care environments. Aging equipment, deferred maintenance, and natural disasters provide additional mechanisms for the entry of environmental pathogens into high-risk patient-care areas.

Architects, engineers, construction contractors, environmental health scientists, and industrial hygienists historically have directed the design and function of hospitals' physical plants. Increasingly, however, because of the growth in the number of susceptible patients and the increase in construction projects, the involvement of hospital epidemiologists and infection-control professionals is required. These experts help make plans for building, maintaining, and renovating health-care facilities to ensure that the adverse impact of the environment on the incidence of health-care associated infections is minimal. The following are examples of adverse outcomes that could have been prevented had such experts been involved in the planning process:

a. transmission of infections caused by *Mycobacterium tuberculosis*, varicella-zoster virus (VZV), and measles (i.e., rubeola) facilitated by inappropriate air-handling systems in health-care facilities;[6]
b. disease outbreaks caused by *Aspergillus* spp., [17-19] *Mucoraceae*, [20] and *Penicillium* spp. associated with the absence of environmental controls during periods of health-care facility-associated construction;[21]
c. infections and/or colonizations of patients and staff with vancomycin-resistant *Enterococcus faecium* [VRE] and *Clostridium difficile* acquired indirectly from contact with organisms present on environmental surfaces in health-care facilities;[22–25] and
d. outbreaks and pseudoepidemics of legionellae,[26, 27] *Pseudomonas aeruginosa*, 28-30 and the nontuberculous mycobacteria (NTM)[31, 32] linked to water and aqueous solutions used in health-care facilities.

The purpose of this guideline is to provide useful information for both health-care professionals and engineers in efforts to provide a safe environment in which quality health care may be provided to patients. The recommendations herein provide guidance to minimize the risk for and prevent transmission of pathogens in the indoor environment.

B. Key Terms Used in this Guideline

Although Appendix A provides definitions for terms discussed in Part I, several terms that pertain to specific patient-care areas and patients who are at risk for health-care associated opportunistic infections are presented here. Specific engineering parameters for these care areas are discussed more fully in the text. **Airborne Infection Isolation (AII)** refers to the isolation of patients infected with organisms spread via airborne droplet nuclei <5 μm in diameter. This isolation area receives numerous air changes per hour (ACH) (≥12 ACH for new construction as of 2001; ≥6 ACH for construction before 2001), and is under negative pressure, such that the direction of the airflow is from the outside adjacent space (e.g., corridor) into the room. The air in an AII room is preferably exhausted to the outside, but may be recirculated

provided that the return air is filtered through a high efficiency particulate air (HEPA) filter. The use of personal respiratory protection is also indicated for persons entering these rooms.

Protective Environment (PE) is a specialized patient-care area, usually in a hospital, with a positive airflow relative to the corridor (i.e., air flows from the room to the outside adjacent space). The combination of HEPA filtration, high numbers of air changes per hour (≥12 ACH), and minimal leakage of air into the room creates an environment that can safely accommodate patients who have undergone allogeneic hematopoietic stem cell transplant (HSCT).

Immunocompromised patients are those patients whose immune mechanisms are deficient because of immunologic disorders (e.g., human immunodeficiency virus [HIV] infection, congenital immune deficiency syndrome, chronic diseases [such as diabetes, cancer, emphysema, and cardiac failure]) or immunosuppressive therapy (e.g., radiation, cytotoxic chemotherapy, anti-rejection medication, and steroids). Immunocompromised patients who are identified as **high-risk patients** have the greatest risk of infection caused by airborne or waterborne microorganisms. Patients in this subset include those who are severely neutropenic for prolonged periods of time (i.e., an absolute neutrophil count [ANC] of ≤500 cells/mL), allogeneic HSCT patients, and those who have received intensive chemotherapy (e.g., childhood acute myelogenous leukemia patients).

C. Air

1. Modes of Transmission of Airborne Diseases

A variety of airborne infections in susceptible hosts can result from exposures to clinically significant microorganisms released into the air when environmental reservoirs (i.e., soil, water, dust, and decaying organic matter) are disturbed. Once these materials are brought indoors into a health-care facility by any of a number of vehicles (e.g., people, air currents, water, construction materials, and equipment), the attendant microorganisms can proliferate in various indoor ecological niches and, if subsequently disbursed into the air, serve as a source for airborne health-care associated infections.

Respiratory infections can be acquired from exposure to pathogens contained either in droplets or droplet nuclei. Exposure to microorganisms in droplets (e.g., through aerosolized oral and nasal secretions from infected patients[33]) constitutes a form of direct contact transmission. When droplets are produced during a sneeze or cough, a cloud of infectious particles >5 μm in size is expelled, resulting in the potential exposure of susceptible persons within 3 feet of the source person.[6] Examples of pathogens spread in this manner are influenza virus, rhinoviruses, adenoviruses, and respiratory syncytial virus (RSV). Because these agents primarily are transmitted directly and because the droplets tend to fall out of the air quickly, measures to control air flow in a health-care facility (e.g., use of negative pressure rooms) generally are not indicated for preventing the spread of diseases caused by these agents. Strategies to control the spread of these diseases are outlined in another guideline.[3]

The spread of airborne infectious diseases via droplet nuclei is a form of indirect transmission.[34] Droplet nuclei are the residuals of droplets that, when suspended in air, subsequently dry and produce particles ranging in size from 1–5 μm. These particles can

a. contain potentially viable microorganisms,
b. be protected by a coat of dry secretions,
c. remain suspended indefinitely in air, and
d. be transported over long distances.

The microorganisms in droplet nuclei persist in favorable conditions (e.g., a dry, cool atmosphere with little or no direct exposure to sunlight or other sources of radiation). Pathogenic microorganisms that can be spread via droplet nuclei include *Mycobacterium tuberculosis*, VZV, measles virus (i.e., rubeola), and smallpox virus (i.e., variola major).[6] Several environmental pathogens have life-cycle forms that are similar in size to droplet nuclei and may exhibit similar behavior in the air. The spores of *Aspergillus fumigatus* have a diameter of 2–3.5 μm, with a settling velocity estimated at 0.03 cm/second (or about 1

meter/hour) in still air. With this enhanced buoyancy, the spores, which resist desiccation, can remain airborne indefinitely in air currents and travel far from their source.[35]

2. Airborne Infectious Diseases in Health-Care Facilities

a. Aspergillosis and Other Fungal Diseases

Aspergillosis is caused by molds belonging to the genus *Aspergillus*. *Aspergillus* spp. are prototype health-care acquired pathogens associated with dusty or moist environmental conditions. Clinical and epidemiologic aspects of aspergillosis (Table 1) are discussed extensively in another guideline.[3]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 1. Clinical and epidemiologic characteristics of aspergillosis

Modes of transmission	Airborne transmission of fungal spores; direct inhalation; direct inoculation from environmental sources (rare) [37]
Causative agents	*Aspergillus fumigatus* (90%–95% of *Aspergillus* infections among hematopoietic stem cell transplant (HSCT) patients; *A. flavus, A. niger, A. terreus, A. nidulans* [36–43]
Activities associated with infection	Construction, renovation, remodeling, repairs, building demolition; rare episodes associated with fomites [44–51]
Clinical syndromes and diseases	*Acute invasive:* pneumonia; ulcerative tracheobronchitis; osteomyelitis; abscesses (aspergillomas) of the lungs, brain, liver, spleen, and kidneys; thrombosis of deep blood vessels; necrotizing skin ulcers; endophthalmitis; and sinusitis *Chronic invasive*: chronic pneumonitis *Hypersensity*: allergic bronchopulmonary aspergillosis *Cutaneous*: primary skin and burn-wound infections [44, 45, 52–58]
Patient populations at greatest risk	Hematopoietic stem cell transplant patients (HSCT): immunocompromised patients (ie, those with underlying disease), patients undergoing chemotherapy, organ transplant recipients, preterm neonates, hemodialysis patients, patients with identifiable immune system deficiencies who receive care in general intensive care units (ICUs), and cystic fibrosis patients (may be colonized, occasionally become infected) [3 6, 59–78]
Factors affecting severity and outcomes	The immune status of the patient and the duration of severe neutropenia [79, 80]
Occurrence	Rare and sporadic, but increasing as proportion of immunocompromised patients increases; 5% of HSCT patients infected, <5% of solid organ transplant recipients infected [36, 37, 81–88]
Mortality rate	Rate can be as high as 100% if severe neutropenia persists; 13%–80% mortality among leukemia patients [5, 8, 83, 89, 90]

Aspergillus spp. are ubiquitous, aerobic fungi that occur in soil, water, and decaying vegetation; the organism also survives well in air, dust, and moisture present in health-care facilities.[91–93] The presence of aspergilli in the health-care facility environment is a substantial extrinsic risk factor for opportunistic invasive aspergillosis (invasive aspergillosis being the most serious form of the disease).[69, 94] Site renovation and construction can disturb *Aspergillus*-contaminated dust and produce bursts of airborne fungal spores. Increased levels of atmospheric dust and fungal spores have been associated with clusters of health-care acquired infections in immunocompromised patients.[17, 20, 44, 47, 49, 50, 95–98] Absorbent building materials (e.g., wallboard) serve as an ideal substrate for the proliferation of this organism if they become and remain wet, thereby increasing the numbers of fungal spores in the area. Patient-care items, devices,

and equipment can become contaminated with *Aspergillus* spp. spores and serve as sources of infection if stored in such areas.[57]

Most cases of aspergillosis are caused by *Aspergillus fumigatus*, a thermotolerant/thermophilic fungus capable of growing over a temperature range from 53.6°F–127.4°F (12°C–53°C); optimal growth occurs at approximately 104°F (40°C), a temperature inhibitory to most other saprophytic fungi.[99] It can use cellulose or sugars as carbon sources; because its respiratory process requires an ample supply of carbon, decomposing organic matter is an ideal substrate. (For AIA guidance on *Aspergillus* spp. see Table 2.)

Other opportunistic fungi that have been occasionally linked with health-care associated infections are members of the order *Mucorales* (e.g., *Rhizopus* spp.) and miscellaneous moniliaceous molds (e.g., *Fusarium* spp. and *Penicillium* spp.) (Table 2). Many of these fungi can proliferate in moist environments (e.g., water-damaged wood and building materials). Some fungi (e.g., *Fusarium* spp. and *Pseudoallescheria* spp.) also can be airborne pathogens.[100] As with aspergillosis, a major risk factor for disease caused by any of these pathogens is the host's severe immunosuppression from either underlying disease or immunosuppressive therapy.[101, 102]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 2. Environmental fungal pathogens: entry into and contamination of the healthcare facility

Fungal pathogen	Implicated environmental vehicle
***Aspergillus* spp.**	• Improperly functioning ventilation systems [20, 46, 47, 97, 98, 103, 104] • Air filters+ [17, 18, 105–107] Pigeons, their droppings and roosts are associated with spread of *Aspergillus, Cryptococcus,* and *Histoplasma* spp. There have been at least three outbreaks linked to contamination of the filtering systems from bird droppings[98, 103, 104] Pigeon mites may gain access into a health-care facility through the ventilation system.[119] • Air filter frames [17, 18] • Window air conditioners [96] • Backflow of contaminated air [107] • Air exhaust contamination+ [104] • False ceilings [48, 57, 97, 108] • Fibrous insulation and perforated metal ceilings [66] • Acoustic ceiling tiles, plasterboard [18, 109] • Fireproofing material [48, 49] • Damp wood building materials [49] • Opening doors to construction site [110] • Construction [69] • Open windows [20, 108, 111] • Disposal conduit door [68] • Hospital vacuum cleaner [68] • Elevator [112] • Arm boards [57] • Walls [113] • Unit kitchen [114] • Food [21] • Ornamental plants [21]
***Mucorales* / *Rhizopus* spp.**	• Air filter [20, 115] • False ceilings [97] • Heliport [115]
***Scedosporium* spp.**	• Construction [116]
***Penicillium* spp.**	• Rotting cabinet wood, pipe leak [21] • Ventilation duct fiberglass insulation [112] • Air filters [105] • Topical anesthetic [117]
***Acremonium* spp.**	• Air filters [105]
***Cladosporium* spp.**	• Air filters [105]
Sporothrix	• Construction (pseudoepidemic) [118]

+ The American Institute of Architects (AIA) standards stipulate that for new or renovated construction
  - exhaust outlets are to be placed >25 feet from air intake systems,
  - the bottom of outdoor air intakes for HVAC systems should be 6 feet above ground or 3 feet above roof level, and
  - exhaust outlets from contaminated areas are situated above the roof level and arranged to minimize the recirculation of exhausted air back into the building.[120]

Infections due *Cryptococcus neoformans*, *Histoplasma capsulatum*, or *Coccidioides immitis* can occur in health-care settings if nearby ground is disturbed and a malfunction of the facility's air-intake components allows these pathogens to enter the ventilation system. *C. neoformans* is a yeast usually 4– 8 μm in size. However, viable particles of <2 μm diameter (and thus permissive to alveolar deposition) have been found in soil contaminated with bird droppings, particularly from pigeons.[98, 103, 104, 121] *H. capsulatum*, with the infectious microconidia ranging in size from 2–5 μm, is endemic in the soil of the central river valleys of the United States. Substantial numbers of these infectious particles have been associated with chicken coops and the roosts of blackbirds.[98, 103, 104, 122] Several outbreaks of histoplasmosis have been associated with disruption of the environment; construction activities in an endemic area may be a potential risk factor for health-care acquired airborne infection.[123, 124] *C. immitis*, with arthrospores of 3–5 μm diameter, has similar potential, especially in the endemic southwestern United States and during seasons of drought followed by heavy rainfall. After the 1994 earthquake centered near Northridge, California, the incidence of coccidioidomycosis in the surrounding area exceeded the historical norm.[125]

Emerging evidence suggests that *Pneumocystis carinii*, now classified as a fungus, may be spread via airborne, person-to-person transmission.[126] Controlled studies in animals first demonstrated that *P. carinii* could be spread through the air.[127] More recent studies in health-care settings have detected nucleic acids of *P. carinii* in air samples from areas frequented or occupied by *P. carinii*-infected patients but not in control areas that are not occupied by these patients.[128, 129] Clusters of cases have been identified among immunocompromised patients who had contact with a source patient and with each other. Recent studies have examined the presence of *P. carinii* DNA in oropharyngeal washings and the nares of infected patients, their direct contacts, and persons with no direct contact.[130, 131] Molecular analysis of the DNA by polymerase chain reaction (PCR) provides evidence for airborne transmission of *P. carinii* from infected patients to direct contacts, but immunocompetent contacts tend to become transiently colonized rather than infected.[131] The role of colonized persons in the spread of *P. carinii* pneumonia (PCP) remains to be determined. At present, specific modifications to ventilation systems to control spread of PCP in a health-care facility are not indicated. Current recommendations outline isolation procedures to minimize or eliminate contact of immunocompromised patients not on PCP prophylaxis with PCP-infected patients.[6, 132]

b. Tuberculosis and Other Bacterial Diseases

The bacterium most commonly associated with airborne transmission is *Mycobacterium tuberculosis*. A comprehensive review of the microbiology and epidemiology of *M. tuberculosis* and guidelines for tuberculosis (TB) infection control have been published.[4, 133, 134] A summary of the clinical and epidemiologic information from these materials is provided in this guideline (Table 3).

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 3. Clinical and epidemiologic characteristics of tuberculosis (TB)*

Modes of transmission
- Airborne transmission via droplet nuclei 1–5 μm in diameter

Causative agents
- Mycobacterium tuberculosis, M. bovis, M. africanum

Patient factors associated with infectivity and transmission
- Disease of the lungs, airways, or larynx
- Presence of cough or other forceful expiratory measures
- Presence of acid-fast bacilli (AFB) in the sputum
- Failure of the patient to cover the mouth and nose when coughing or sneezing
- Presence of cavitation on chest radiograph
- Inappropriate or shortened duration of chemotherapy

Activities associated with infections
- Exposures in relatively small, enclosed spaces
- Inadequate ventilation resulting in insufficient removal of droplet nuclei
- Cough-producing procedures done in areas without proper environmental controls
- Recirculation of air containing infectious droplet nuclei
- Failure to use respiratory protection when managing open lesions for patients with suspected extrapulmonary TB135

Clinical syndromes and disease
- Pulmonary TB
- Extrapulmonary TB can affect any organ system or tissue
- Laryngeal TB is highly contagious

Patient populations at greatest risk
- Immunocompromised persons (eg, HIV-infected persons)
- Medically underserved persons, urban poor, homeless persons, elderly persons, migrant farm workers, close contacts of known patients
- Substance abusers, present and former prison inmates
- Foreign-born persons from areas with high prevalence of TB
- Health-care workers

Factors affecting severity and outcomes
- Concentration of droplet nuclei in air, duration of exposure
- Age at infection
- Immunosuppression due to therapy or disease, underlying chronic medical conditions, history of malignancies or lesions or the lungs

Occurrence
- Worldwide; incidence in the United States is 56 cases/100,000 population (2001)[136]

Mortality rate
- 930 deaths in the United States (1999)[136]

Chemoprophylaxis / treatment
- Treatment of latent infection includes isoniazid (INH) or rifampin (RIF)[4, 134, 137–139]
- Directly observed therapy (DOT) for active cases as indicated: INH, RIF, pyrazinamide (PZA), ethambutol (EMB), streptomycin (SM) in various combinations determined by prevalent levels of specific resistance[4, 134, 137–139]
- Consult therapy guidelines for specific treatment indications[139]

* Material in this table is compiled from references 4, 133–141.

M. tuberculosis is carried by droplet nuclei generated when persons (primarily adults and adolescents) who have pulmonary or laryngeal TB sneeze, cough, speak, or sing;[139] normal air currents can keep these particles airborne for prolonged periods and spread them throughout a room or building.[142] However, transmission of

TB has occurred from mycobacteria aerosolized during provision of care (e.g., wound/lesion care or during handling of infectious peritoneal dialysis fluid) for extrapulmonary TB patients.[135, 140]

Gram-positive cocci (i.e., *Staphylococcus aureus*, group A beta-hemolytic streptococci), also important health-care associated pathogens, are resistant to inactivation by drying and can persist in the environment and on environmental surfaces for extended periods. These organisms can be shed from heavily colonized persons and discharged into the air. Airborne dispersal of *S. aureus* is directly associated with the concentration of the bacterium in the anterior nares.[143] Approximately 10% of healthy carriers will disseminate *S. aureus* into the air, and some persons become more effective disseminators of *S. aureus* than others.[144–148] The dispersal of *S. aureus* into air can be exacerbated by concurrent viral upper respiratory infection, thereby turning a carrier into a "cloud shedder."[149] Outbreaks of surgical site infections (SSIs) caused by group A beta-hemolytic streptococci have been traced to airborne transmission from colonized operating-room personnel to patients.[150–153] In these situations, the strain causing the outbreak was recovered from the air in the operating room[150, 151, 154] or on settle plates in a room in which the carrier exercised.[151–153] *S. aureus* and group A streptococci have not been linked to airborne transmission outside of operating rooms, burn units, and neonatal nurseries.[155, 156] Transmission of these agents occurs primarily via contact and droplets.

Other gram-positive bacteria linked to airborne transmission include *Bacillus* spp. which are capable of sporulation as environmental conditions become less favorable to support their growth. Outbreaks and pseudo-outbreaks have been attributed to *Bacillus cereus* in maternity, pediatric, intensive care, and bronchoscopy units; many of these episodes were secondary to environmental contamination.[157–160]

Gram-negative bacteria rarely are associated with episodes of airborne transmission because they generally require moist environments for persistence and growth. The main exception is *Acinetobacter* spp., which can withstand the inactivating effects of drying. In one epidemiologic investigation of bloodstream infections among pediatric patients, identical *Acinetobacter* spp. were cultured from the patients, air, and room air conditioners in a nursery.[161]

Aerosols generated from showers and faucets may potentially contain legionellae and other gram-negative waterborne bacteria (e.g., *Pseudomonas aeruginosa*). Exposure to these organisms is through direct inhalation. However, because water is the source of the organisms and exposure occurs in the vicinity of the aerosol, the discussion of the diseases associated with such aerosols and the prevention measures used to curtail their spread is discussed in another section of the Guideline (see Part I: Water).

c. Airborne Viral Diseases

Some human viruses are transmitted from person to person via droplet aerosols, but very few viruses are consistently airborne in transmission (i.e., are routinely suspended in an infective state in air and capable of spreading great distances), and health-care associated outbreaks of airborne viral disease are limited to a few agents. Consequently, infection-control measures used to prevent spread of these viral diseases in health-care facilities primarily involve patient isolation, vaccination of susceptible persons, and antiviral therapy as appropriate rather than measures to control air flow or quality.[6] Infections caused by VZV frequently are described in health-care facilities. Health-care associated airborne outbreaks of VZV infections from patients with primary infection and disseminated zoster have been documented; patients with localized zoster have, on rare occasions, also served as source patients for outbreaks in health-care facilities.[162–166] VZV infection can be prevented by vaccination, although patients who develop a rash within 6 weeks of receiving varicella vaccine or who develop breakthrough varicella following exposure should be considered contagious.[167]

Viruses whose major mode of transmission is via droplet contact rarely have caused clusters of infections in group settings through airborne routes. The factors facilitating airborne distribution of these viruses in an infective state are unknown, but a presumed requirement is a source patient in the early stage of infection who is shedding large numbers of viral particles into the air. Airborne transmission of measles has been documented in health-care facilities.[168–171] In addition, institutional outbreaks of influenza virus infections have occurred predominantly in nursing homes,[172–176] and less frequently in medical and neonatal intensive care units, chronic-care areas, HSCT units, and pediatric wards.[177–180] Some evidence supports airborne

transmission of influenza viruses by droplet nuclei,[181, 182] and case clusters in pediatric wards suggest that droplet nuclei may play a role in transmitting certain respiratory pathogens (e.g., adenoviruses and respiratory syncytial virus [RSV]).[177, 183, 184] Some evidence also supports airborne transmission of enteric viruses. An outbreak of a Norwalk-like virus infection involving more than 600 staff personnel over a 3-week period was investigated in a Toronto, Ontario hospital in 1985; common sources (e.g., food and water) were ruled out during the investigation, leaving airborne spread as the most likely mode of transmission.[185]

Smallpox virus, a potential agent of bioterrorism, is spread predominantly via direct contact with infectious droplets, but it also can be associated with airborne transmission.[186, 187] A German hospital study from 1970 documented the ability of this virus to spread over considerable distances and cause infection at low doses in a well-vaccinated population; factors potentially facilitating transmission in this situation included a patient with cough and an extensive rash, indoor air with low relative humidity, and faulty ventilation patterns resulting from hospital design (e.g., open windows).[188] Smallpox patients with extensive rash are more likely to have lesions present on mucous membranes and therefore have greater potential to disseminate virus into the air.[188] In addition to the smallpox transmission in Germany, two cases of laboratory-acquired smallpox virus infection in the United Kingdom in 1978 also were thought to be caused by airborne transmission.[189]

⚠ **Ebola Virus Disease Update [August 2014]:** The recommendations in this guideline for Ebola has been superseded by these CDC documents:

- Infection Prevention and Control Recommendations for Hospitalized Patients with Known or Suspected Ebola Virus Disease in U.S. Hospitals (https://www.cdc.gov/vhf/ebola/healthcare-us/hospitals/infection-control.html)
- Interim Guidance for Environmental Infection Control in Hospitals for Ebola Virus (https://www.cdc.gov/vhf/ebola/healthcare-us/cleaning/hospitals.html)

See CDC's Ebola Virus Disease website (https://www.cdc.gov/vhf/ebola/index.html) for current information on how Ebola virus is transmitted.

Airborne transmission may play a role in the natural spread of hantaviruses and certain hemorrhagic fever viruses (e.g., Ebola, Marburg, and Lassa), but evidence for airborne spread of these agents in health-care facilities is inconclusive.[190] Although hantaviruses can be transmitted when aerosolized from rodent excreta,[191, 192] person-to-person spread of hantavirus infection from source patients has not occurred in health-care facilities.[193–195] Nevertheless, health-care workers are advised to contain potentially infectious aerosols and wear National Institute of Occupational Safety and Health (NIOSH) approved respiratory protection when working with this agent in laboratories or autopsy suites.[196] Lassa virus transmission via aerosols has been demonstrated in the laboratory and incriminated in health-care associated infections in Africa,[197–199] but airborne spread of this agent in hospitals in developed nations likely is inefficient.[200, 201] Yellow fever is considered to be a viral hemorrhagic fever agent with high aerosol infectivity potential, but health-care associated transmission of this virus has not been described.[202] Viral hemorrhagic fever diseases primarily occur after direct exposure to infected blood and body fluids, and the use of standard and droplet precautions prevents transmission early in the course of these illnesses.[203, 204] However, whether these viruses can persist in droplet nuclei that might remain after droplet production from coughs or vomiting in the latter stages of illness is unknown.[205] Although the use of a negative-pressure room is not required during the early stages of illness, its use might be prudent at the time of hospitalization to avoid the need for subsequent patient transfer. Current CDC guidelines recommend negative-pressure rooms with anterooms for patients with hemorrhagic fever and use of HEPA respirators by persons entering these rooms when the patient has prominent cough, vomiting, diarrhea, or hemorrhage.[6, 203] Face shields or goggles will help to prevent mucous-membrane exposure to potentially-aerosolized infectious material in these situations. If an anteroom is not available, portable, industrial-grade high efficiency particulate air (HEPA) filter units can be used to provide the equivalent of additional air changes per hour (ACH).

Table 4. Microorganisms associated with airborne transmission*

Evidence for airborne transmission	Fungi	Bacteria	Viruses
Numerous reports in health-care facilities	*Aspergillus* spp.+ *Mucorales* (*Rhizopus* spp.)[97, 115]	*Mycobacterium tuberculosis*+	Measles (rubeola) virus[168-170] Varicella-zoster virus[162-166]
Occasional reports in health-care facilities (atypical)	*Acremonium spp.*[105, 206] *Fusarium spp.*[102] *Pseudoallescheria boydii*[100] *Scedosporium spp.*[116] *Sporothrix cyanescens*¶[118]	*Acinetobacter spp.*[161] *Bacillus spp.*¶[160, 207] *Brucella spp.***[208-211] *Staphylococcus aureus*[148, 156] Group A *Streptococcus*[151]	Smallpox virus (variola)§[188, 189] Influenza viruses[181, 182] Respiratory syncytial virus[183] Adenoviruses[184] Norwalk-like virus[185]
No reports in health-care facilities; known to be airborne outside.	*Coccidioides immitis*[125] *Cryptococcus* spp.[121] *Histoplasma capsulatum*[124]	*Coxiella burnetii* (Q fever)[212]	Hantaviruses[193, 195] Lassa virus[205] Marburg virus[205] Ebola virus†[205] Crimean-Congo virus[205]
Under investigation	*Pneumocystis carinii*[131]	n/a	n/a

* This list excludes microorganisms transmitted from aerosols derived from water.
\+ Refer to the text for references for these disease agents.
§ Airborne transmission of smallpox is infrequent. Potential for airborne transmission increases with patients who are effective disseminators present in facilities with low relative humidity in the air and faulty ventilation.
¶ Documentation of pseudoepidemic during construction.
** Airborne transmission documented in the laboratory but not in patient-care areas
† **Ebola Virus Disease Update [August 2014]:** The recommendations in this guideline for Ebola has been superseded by these CDC documents:
- Infection Prevention and Control Recommendations for Hospitalized Patients with Known or Suspected Ebola Virus Disease in U.S. Hospitals (https://www.cdc.gov/vhf/ebola/healthcare-us/hospitals/infection-control.html)

3. Heating, Ventilation, and Air Conditioning Systems in Health-Care Facilities

a. Basic Components and Operations

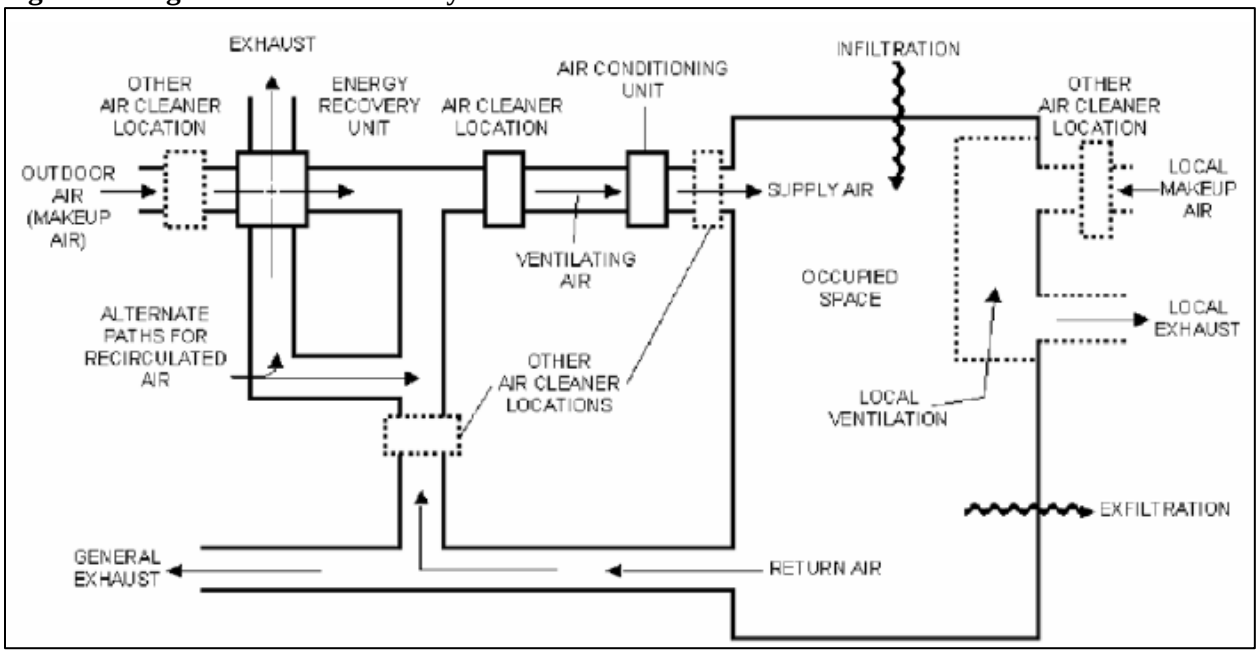
Heating, ventilation, and air conditioning (HVAC) systems in health-care facilities are designed to
a. maintain the indoor air temperature and humidity at comfortable levels for staff, patients, and visitors
b. control odors;
c. remove contaminated air;
d. facilitate air-handling requirements to protect susceptible staff and patients from airborne health-care associated pathogens; and
e. minimize the risk for transmission of airborne pathogens from infected patients.[35, 120]

An HVAC system includes an outside air inlet or intake; filters; humidity modification mechanisms (i.e., humidity control in summer, humidification in winter); heating and cooling equipment; fans; ductwork; air exhaust or out-takes; and registers, diffusers, or grilles for proper distribution of the air (Figure 1).[213, 214] Decreased performance of healthcare facility HVAC systems, filter inefficiencies, improper installation, and poor maintenance can contribute to the spread of health-care associated airborne infections.

The American Institute of Architects (AIA) has published guidelines for the design and construction of new health-care facilities and for renovation of existing facilities. These AIA guidelines address indoor

air-quality standards (e.g., ventilation rates, temperature levels, humidity levels, pressure relationships, and minimum air changes per hour [ACH]) specific to each zone or area in health-care facilities (e.g., operating rooms, laboratories, diagnostic areas, patient-care areas, and support departments).[120] These guidelines represent a consensus document among authorities having jurisdiction (AHJ), governmental regulatory agencies (i.e., Department of Health and Human Services [DHHS]; Department of Labor, Occupational Safety and Health Administration [OSHA]), health-care professionals, professional organizations (e.g., American Society of Heating, Refrigeration, and Air-Conditioning Engineers [ASHRAE], American Society for Healthcare Engineering [ASHE]), and accrediting organizations (i.e., Joint Commission on Accreditation of Healthcare Organizations [JCAHO]). More than 40 state agencies that license health-care facilities have either incorporated or adopted by reference these guidelines into their state standards. JCAHO, through its surveys, ensures that facilities are in compliance with the ventilation guidelines of this standard for new construction and renovation.

Figure 1. Diagram of a ventilation system*



Outdoor air and recirculated air pass through air cleaners (e.g., filter banks) designed to reduce the concentration of airborne contaminants. Air is conditioned for temperature and humidity before it enters the occupied space as supply air. Infiltration is air leakage inward through cracks and interstitial spaces of walls, floors, and ceilings. Exfiltration is air leakage outward through these same cracks and spaces. Return air is largely exhausted from the system, but a portion is recirculated with fresh, incoming air.

* Used with permission of the publisher of reference 214 (ASHRAE)

Engineering controls to contain or prevent the spread of airborne contaminants center on
a. local exhaust ventilation [i.e., source control],
b. general ventilation, and
c. air cleaning.[4]

General ventilation encompasses
a. dilution and removal of contaminants via well-mixed air distribution of filtered air,
b. directing contaminants toward exhaust registers and grilles via uniform, non-mixed airflow patterns,
c. pressurization of individual spaces relative to all other spaces, and
d. pressurization of buildings relative to the outdoors and other attached buildings.

A centralized HVAC system operates as follows. Outdoor air enters the system, where low-efficiency or "roughing" filters remove large particulate matter and many microorganisms. The air enters the distribution system for conditioning to appropriate temperature and humidity levels, passes through an additional bank of filters for further cleaning, and is delivered to each zone of the building. After the conditioned air is distributed to the designated space, it is withdrawn through a return duct system and delivered back to the HVAC unit. A portion of this "return air" is exhausted to the outside while the remainder is mixed with outdoor air for dilution and filtered for removal of contaminants.[215] Air from toilet rooms or other soiled areas is usually exhausted directly to the atmosphere through a separate duct exhaust system. Air from rooms housing tuberculosis patients is exhausted to the outside if possible, or passed through a HEPA filter before recirculation. Ultraviolet germicidal irradiation (UVGI) can be used as an adjunct air-cleaning measure, but it cannot replace HEPA filtration. [15]

b. Filtration

i. Filter Types and Methods of Filtration

Filtration, the physical removal of particulates from air, is the first step in achieving acceptable indoor air quality. Filtration is the primary means of cleaning the air. Five methods of filtration can be used (Table 5). During filtration, outdoor air passes through two filter beds or banks (with efficiencies of 20%–40% and ≥90%, respectively) for effective removal of particles 1–5 μm in diameter.[35, 120] The low-to-medium efficiency filters in the first bank have low resistance to airflow, but this feature allows some small particulates to pass onto heating and air conditioning coils and into the indoor environment.[35] Incoming air is mixed with recirculated air and reconditioned for temperature and humidity before being filtered by the second bank of filters. The performance of filters with ≤90% efficiency is measured using either the dust-spot test or the weight-arrestance test.[35, 216]

Table 5. Filtration methods*

Basic method	Principle of performance	Filtering efficiency
Straining	Particles in the air are larger than the openings between the filter fibers, resulting in gross removal of large particles.	Low
Impingement	Particles collide with filter fibers and remain attached to the filter. Fibers may be coated with adhesive.	Low
Interception	Particles enter into the filter and become entrapped and attached to the filter fibers.	Medium
Diffusion	Small particles, moving in erratic motion, collide with filter fibers and remain attached.	High
Electrostatic	Particles bearing negative electrostatic charge are attracted to the filter with positively charged fibers.	High

* Material in this table was compiled from information in reference 217.

The second filter bank usually consists of high-efficiency filters. This filtration system is adequate for most patient-care areas in ambulatory-care facilities and hospitals, including the operating room environment and areas providing central services.[120] Nursing facilities use 90% dust-spot efficient filters as the second bank of filters,[120] whereas a HEPA filter bank may be indicated for special-care areas of hospitals. HEPA filters are at least 99.97% efficient for removing particles ≥0.3 μm in diameter. (As a reference, *Aspergillus* spores are 2.5–3.0 μm in diameter.) Examples of care areas where HEPA filters are used include PE rooms and those operating rooms designated for orthopedic implant procedures.[35]

Maintenance costs associated with HEPA filters are high compared with other types of filters, but use of in-line disposable prefilters can increase the life of a HEPA filter by approximately 25%. Alternatively, if a disposable prefilter is followed by a filter that is 90% efficient, the life of the HEPA filter can be extended ninefold. This concept, called progressive filtration, allows HEPA filters in special care areas to be used for 10 years.[213] Although progressive filtering will extend the mechanical ability of the HEPA

filter, these filters may absorb chemicals in the environment and later desorb those chemicals, thereby necessitating a more frequent replacement program. HEPA filter efficiency is monitored with the dioctylphthalate (DOP) particle test using particles that are 0.3 μm in diameter.[218]

HEPA filters are usually framed with metal, although some older versions have wood frames. A metal frame has no advantage over a properly fitted wood frame with respect to performance, but wood can compromise the air quality if it becomes and remains wet, allowing the growth of fungi and bacteria. Hospitals are therefore advised to phase out water-damaged or spent wood-framed filter units and replace them with metal-framed HEPA filters.

HEPA filters are usually fixed into the HVAC system; however, portable, industrial grade HEPA units are available that can filter air at the rate of 300–800 ft^3/min. Portable HEPA filters are used to
a. temporarily recirculate air in rooms with no general ventilation,
b. augment systems that cannot provide adequate airflow, and
c. provide increased effectiveness in airflow.[4]

Portable HEPA units are useful engineering controls that help clean the air when the central HVAC system is undergoing repairs[219] but these units do not satisfy fresh-air requirements.[214]

The effectiveness of the portable unit for particle removal is dependent on
a. the configuration of the room,
b. the furniture and persons in the room,
c. the placement of the units relative to the contents and layout of the room, and
d. the location of the supply and exhaust registers or grilles.

If portable, industrial-grade units are used, they should be capable of recirculating all or nearly all of the room air through the HEPA filter, and the unit should be designed to achieve the equivalent of ≥12 ACH.[4] (An average room has approximately 1,600 ft^3 of airspace.) The hospital engineering department should be contacted to provide ACH information in the event that a portable HEPA filter unit is necessary to augment the existing fixed HVAC system for air cleaning.

ii. Filter Maintenance
Efficiency of the filtration system is dependent on the density of the filters, which can create a drop in pressure unless compensated by stronger and more efficient fans, thus maintaining air flow. For optimal performance, filters require monitoring and replacement in accordance with the manufacturer's recommendations and standard preventive maintenance practices.[220] Upon removal, spent filters can be bagged and discarded with the routine solid waste, regardless of their patient-care area location.[221] Excess accumulation of dust and particulates increases filter efficiency, requiring more pressure to push the air through. The pressure differential across filters is measured by use of manometers or other gauges. A pressure reading that exceeds specifications indicates the need to change the filter. Filters also require regular inspection for other potential causes of decreased performance. Gaps in and around filter banks and heavy soil and debris upstream of poorly maintained filters have been implicated in health-care associated outbreaks of aspergillosis, especially when accompanied by construction activities at the facility.[17, 18, 106, 222]

c. Ultraviolet Germicidal Irradiation (UVGI)

As a supplemental air-cleaning measure, UVGI is effective in reducing the transmission of airborne bacterial and viral infections in hospitals, military housing, and classrooms, but it has only a minimal inactivating effect on fungal spores.[223–228] UVGI is also used in air handling units to prevent or limit the growth of vegetative bacteria and fungi. Most commercially available UV lamps used for germicidal purposes are low-pressure mercury vapor lamps that emit radiant energy predominantly at a wave-length of 253.7 nm.[229, 230] Two systems of UVGI have been used in health-care settings – duct irradiation and upper-room air irradiation. In duct irradiation systems, UV lamps are placed inside ducts that remove air from rooms to disinfect the air before it is recirculated. When properly designed, installed, and maintained, high levels of UVGI can be attained in the ducts with little or no exposure of persons in the rooms.[231, 232] In upper-room air irradiation, UV lamps are either suspended from the ceiling or mounted on the wall.[4] Upper

air UVGI units have two basic designs:
a. a "pan" fixture with UVGI unshielded above the unit to direct the irradiation upward and
b. a fixture with a series of parallel plates to columnize the irradiation outward while preventing the light from getting to the eyes of the room's occupants.

The germicidal effect is dependent on air mixing via convection between the room's irradiated upper zone and the lower patient-care zones.[233, 234]

Bacterial inactivation studies using BCG mycobacteria and *Serratia marcescens* have estimated the effect of UVGI as equivalent to 10 ACH–39 ACH.[235, 236] Another study, however, suggests that UVGI may result in fewer equivalent ACH in the patient-care zone, especially if the mixing of air between zones is insufficient.[234] The use of fans or HVAC systems to generate air movement may increase the effectiveness of UVGI if airborne microorganisms are exposed to the light energy for a sufficient length of time.[233, 235, 237–239] The optimal relationship between ventilation and UVGI is not known.

Because the clinical effectiveness of UV systems may vary, UVGI is not recommended for air management prior to air recirculation from airborne isolation rooms. It is also not recommended as a substitute for HEPA filtration, local exhaust of air to the outside, or negative pressure.[4] The use of UV lamps and HEPA filtration in a single unit offers only minimal infection-control benefits over those provided by the use of a HEPA filter alone.[240] Duct systems with UVGI are not recommended as a substitute for HEPA filters if the air from isolation rooms must be recirculated to other areas of the facility.[4] Regular maintenance of UVGI systems is crucial and usually consists of keeping the bulbs free of dust and replacing old bulbs as necessary. Safety issues associated with the use of UVGI systems are described in other guidelines.[4]

d. Conditioned Air in Occupied Spaces

Temperature and humidity are two essential components of conditioned air. After outside air passes through a low- or medium-efficiency filter, the air undergoes conditioning for temperature and humidity control before it passes through high-efficiency or HEPA filtration.

i. Temperature
HVAC systems in health-care facilities are often single-duct or dual-duct systems.[35, 241] A single-duct system distributes cooled air (55°F [12.8°C]) throughout the building and uses thermostatically controlled reheat boxes located in the terminal ductwork to warm the air for individual or multiple rooms. The dual-duct system consists of parallel ducts, one with a cold air stream and the other with a hot air stream. A mixing box in each room or group of rooms mixes the two air streams to achieve the desired temperature. Temperature standards are given as either a single temperature or a range, depending on the specific health-care zone. Cool temperature standards (68°F–73°F [20°C–23°C]) usually are associated with operating rooms, clean workrooms, and endoscopy suites.[120] A warmer temperature (75°F [24°C]) is needed in areas requiring greater degrees of patient comfort. Most other zones use a temperature range of 70°F–75°F (21°C–24°C).[120] Temperatures outside of these ranges may be needed occasionally in limited areas depending on individual circumstances during patient care (e.g., cooler temperatures in operating rooms during specialized operations).

ii. Humidity
Four measures of humidity are used to quantify different physical properties of the mixture of water vapor and air. The most common of these is relative humidity, which is the ratio of the amount of water vapor in the air to the amount of water vapor air can hold at that temperature.[242] The other measures of humidity are specific humidity, dew point, and vapor pressure.[242]

Relative humidity measures the percentage of saturation. At 100% relative humidity, the air is saturated. For most areas within health-care facilities, the designated comfort range is 30%–60% relative humidity.[120, 214] Relative humidity levels >60%, in addition to being perceived as uncomfortable, promote fungal growth.[243] Humidity levels can be manipulated by either of two mechanisms.[244] In a water-wash unit, water is sprayed and drops are taken up by the filtered air; additional heating or cooling of this air sets the humidity levels. The second mechanism is by means of water vapor created from steam and added to filtered air in humidifying boxes. Reservoir-type humidifiers are not allowed in health-care facilities as per AIA guidelines and many state codes.[120] Cool-mist humidifiers should be avoided, because they can disseminate aerosols containing allergens and microorganisms.[245] Additionally, the small, personal-use versions of this equipment can be difficult to clean.

iii. Ventilation

The control of air pollutants (e.g., microorganisms, dust, chemicals, and smoke) at the source is the most effective way to maintain clean air. The second most effective means of controlling indoor air pollution is through ventilation. Ventilation rates are voluntary unless a state or local government specifies a standard in health-care licensing or health department requirements. These standards typically apply to only the design of a facility, rather than its operation.[220, 246] Health-care facilities without specific ventilation standards should follow the AIA guideline specific to the year in which the building was 120, 214, 241 built or the ANSI/ASHRAE Standard 62, *Ventilation for Acceptable Indoor Air Quality*.

Ventilation guidelines are defined in terms of air volume per minute per occupant and are based on the assumption that occupants and their activities are responsible for most of the contaminants in the conditioned space.[215] Most ventilation rates for health-care facilities are expressed as room ACH. Peak efficiency for particle removal in the air space occurs between 12 ACH–15 ACH.[35, 247, 248] Ventilation rates vary among the different patient-care areas of a health-care facility (Appendix B).[120]

Health-care facilities generally use recirculated air.[35, 120, 241, 249, 250] Fans create sufficient positive pressure to force air through the building duct work and adequate negative pressure to evacuate air from the conditioned space into the return duct work and/or exhaust, thereby completing the circuit in a sealed system (Figure 1). However, because gaseous contaminants tend to accumulate as the air recirculates, a percentage of the recirculated air is exhausted to the outside and replaced by fresh outdoor air. In hospitals, the delivery of filtered air to an occupied space is an engineered system design issue, the full discussion of which is beyond the scope of this document.

Hospitals with areas not served by central HVAC systems often use through-the-wall or fan coil air conditioning units as the sole source of room ventilation. AIA guidelines for newly installed systems stipulate that through-the-wall fan-coil units be equipped with permanent (i.e., cleanable) or replaceable filters with a minimum efficiency of 68% weight arrestance.[120] These units may be used only as recirculating units; all outdoor air requirements must be met by a separate central air handling system with proper filtration, with a minimum of two outside air changes in general patient rooms (D. Erickson, ASHE, 2000).[120] If a patient room is equipped with an individual through-the-wall fan coil unit, the room should not be used as either AII or as PE.[120] These requirements, although directed to new HVAC installations also are appropriate for existing settings. Non-central air-handling systems are prone to problems associated with excess condensation accumulating in drip pans and improper filter maintenance; health-care facilities should clean or replace the filters in these units on a regular basis while the patient is out of the room.

Laminar airflow ventilation systems are designed to move air in a single pass, usually through a bank of HEPA filters either along a wall or in the ceiling, in a one-way direction through a clean zone with parallel streamlines. Laminar airflow can be directed vertically or horizontally; the unidirectional

system optimizes airflow and minimizes air turbulence.[63, 241] Delivery of air at a rate of 0.5 meters per second (90 ± 20 ft/min) helps to minimize opportunities for microorganism proliferation.[63, 251, 252] Laminar airflow systems have been used in PE to help reduce the risk for health-care associated airborne infections (e.g., aspergillosis) in high-risk patients.[63, 93, 253, 254] However, data that demonstrate a survival benefit for patients in PE with laminar airflow are lacking. Given the high cost of installation and apparent lack of benefit, the value of laminar airflow in this setting is questionable.[9, 37] Few data support the use of laminar airflow systems elsewhere in a hospital.[255]

iv. Pressurization

Positive and negative pressures refer to a pressure differential between two adjacent air spaces (e.g., rooms and hallways). Air flows away from areas or rooms with positive pressure (pressurized), while air flows into areas with negative pressure (depressurized). AII rooms are set at negative pressure to prevent airborne microorganisms in the room from entering hallways and corridors. PE rooms housing severely neutropenic patients are set at positive pressure to keep airborne pathogens in adjacent spaces or corridors from coming into and contaminating the airspace occupied by such high-risk patients. Self-closing doors are mandatory for both of these areas to help maintain the correct pressure differential.[4, 6, 120] Older health-care facilities may have variable pressure rooms (i.e., rooms in which the ventilation can be manually switched between positive and negative pressure). These rooms are no longer permitted in the construction of new facilities or in renovated areas of the facility,[120] and their use in existing facilities has been discouraged because of difficulties in assuring the proper pressure differential, especially for the negative pressure setting, and because of the potential for error associated with switching the pressure differentials for the room. Continued use of existing variable pressure rooms depends on a partnership between engineering and infection control. Both positive- and negative-pressure rooms should be maintained according to specific engineering specifications (Table 6).

Table 6. Engineered specifications for positive- and negative pressure rooms*

Engineering characteristics	Positive pressure areas (e.g., protective environments [PE])	Negative pressure areas (e.g., airborne infection isolation [AII])
Pressure differentials	> +2.5 Pa§ (0.01″ water gauge)	> −2.5 Pa (0.01″ water gauge)
Air changes per hour (ACH)	>12	≥12 (for renovation or new construction)
Filtration efficiency	Supply: 99.97% @ 0.3 µm DOP (dioctylphthalate particles of 0.3 µm diameter) Return: none required (If the patient requires both PE and AII, return air should be HEPA-filtered or otherwise exhausted to the outside)	Supply: 90% (dust spot test) Return: 99.97% @ 0.3 µm DOP (dioctylphthalate particles of 0.3 µm diameter); HEPA filtration of exhaust air from AII rooms should not be required, providing that the exhaust is properly located to prevent re-entry into the building.
Room airflow direction	Out to the adjacent area	In to the room
Clean-to-dirty airflow in room	Away from the patient (high-risk patient, immunosuppressed patient)	Towards the patient (airborne disease patient)
Ideal pressure differential	> + 8 Pa	> −2.5 Pa

* Material in this table was compiled from references 35 and 120. Table adapted from and used with permission of the publisher of reference [35] (Lippincott Williams and Wilkins).

§ Pa is the abbreviation for Pascal, a metric unit of measurement for pressure based on air velocity; 250 Pa equals 1.0 inch water gauge.

Health-care professionals (e.g., infection control, hospital epidemiologists) must perform a risk assessment to determine the appropriate number of AII rooms (negative pressure) and/or PE rooms (positive pressure) to serve the patient population. The AIA guidelines require a certain number of AII rooms as a minimum, and it is important to refer to the edition under which the building was built for appropriate guidance.[120]

In large health-care facilities with central HVAC systems, sealed windows help to ensure the efficient operation of the system, especially with respect to creating and maintaining pressure differentials. Sealing

the windows in PE areas helps minimize the risk of airborne contamination from the outside. One outbreak of aspergillosis among immunosuppressed patients in a hospital was attributed in part to an open window in the unit during a time when both construction and a fire happened nearby; sealing the window prevented further entry of fungal spores into the unit from the outside air.[111] Additionally, all emergency exits (e.g., fire escapes and emergency doors) in PE wards should be kept closed (except during emergencies) and equipped with alarms.

e. Infection Control Impact of HVAC System Maintenance and Repair

A failure or malfunction of any component of the HVAC system may subject patients and staff to discomfort and exposure to airborne contaminants. Only limited information is available from formal studies on the infection-control implications of a complete air-handling system failure or shutdown for maintenance. Most experience has been derived from infectious disease outbreaks and adverse outcomes among high-risk patients when HVAC systems are poorly maintained. (See Table 7 for potential ventilation hazards, consequences, and correction measures.)

AIA guidelines prohibit U.S. hospitals and surgical centers from shutting down their HVAC systems for purposes other than required maintenance, filter changes, and construction.[120] Airflow can be reduced; however, sufficient supply, return, and exhaust must be provided to maintain required pressure relationships when the space is not occupied. Maintaining these relationships can be accomplished with special drives on the air-handling units (i.e., a variable air ventilation [VAV] system).

Microorganisms proliferate in environments wherever air, dust, and water are present, and air-handling systems can be ideal environments for microbial growth.[35] Properly engineered HVAC systems require routine maintenance and monitoring to provide acceptable indoor air quality efficiently and to minimize conditions that favor the proliferation of health-care associated pathogens.[35, 249] Performance monitoring of the system includes determining pressure differentials across filters, regular inspection of system filters, DOP testing of HEPA filters, testing of low- or medium efficiency filters, and manometer tests for positive- and negative-pressure areas in accordance with nationally recognized standards, guidelines, and manufacturers' recommendations. The use of hand-held, calibrated equipment that can provide a numerical reading on a daily basis is preferred for engineering purposes (A.Streifel, University of Minnesota, 2000).[256] Several methods that provide a visual, qualitative measure of pressure differentials (i.e., airflow direction) include smoke-tube tests or placing flutter strips, ping-pong balls, or tissue in the air stream.

Preventive filter and duct maintenance (e.g., cleaning ductwork vents, replacing filters as needed, and properly disposing spent filters into plastic bags immediately upon removal) is important to prevent potential exposures of patients and staff during HVAC system shut-down. The frequency of filter inspection and the parameters of this inspection are established by each facility to meet their unique needs. Ductwork in older health-care facilities may have insulation on the interior surfaces that can trap contaminants. This insulation material tends to break down over time to be discharged from the HVAC system. Additionally, a malfunction of the air-intake system can overburden the filtering system and permit aerosolization of fungal pathogens. Keeping the intakes free from bird droppings, especially those from pigeons, helps to minimize the concentration of fungal spores entering from the outside.[98]

Accumulation of dust and moisture within HVAC systems increases the risk for spread of health-care–associated environmental fungi and bacteria. Clusters of infections caused by *Aspergillus* spp., *P. aeruginosa, S. aureus,* and *Acinetobacter* spp. have been linked to poorly maintained and/or malfunctioning air conditioning systems.[68, 161, 257, 258] Efforts to limit excess humidity and moisture in the infrastructure and on air-stream surfaces in the HVAC system can minimize the proliferation and dispersion of fungal spores and waterborne bacteria throughout indoor air.[259–262] Within the HVAC system, water is present in water-wash units, humidifying boxes, or cooling units. The dual-duct system

may also create conditions of high humidity and excess moisture that favor fungal growth in drain pans as well as in fibrous insulation material that becomes damp as a result of the humid air passing over the hot stream and condensing.

If moisture is present in the HVAC system, periods of stagnation should be avoided. Bursts of organisms can be released upon system start-up, increasing the risk of airborne infection.[206] Proper engineering of the HVAC system is critical to preventing dispersal of airborne organisms. In one hospital, endophthalmitis caused by *Acremonium kiliense* infection following cataract extraction in an ambulatory surgical center was traced to aerosols derived from the humidifier water in the ventilation system.[206] The organism proliferated because the ventilation system was turned off routinely when the center was not in operation; the air was filtered before humidification, but not afterwards.

Most health-care facilities have contingency plans in case of disruption of HVAC services. These plans include back-up power generators that maintain the ventilation system in high-risk areas (e.g., operating rooms, intensive-care units, negative- and positive-pressure rooms, transplantation units, and oncology units). Alternative generators are required to engage within 10 seconds of a loss of main power. If the ventilation system is out of service, rendering indoor air stagnant, sufficient time must be allowed to clean the air and re-establish the appropriate number of ACH once the HVAC system begins to function again. Air filters may also need to be changed, because reactivation of the system can dislodge substantial amounts of dust and create a transient burst of fungal spores.

Duct cleaning in health-care facilities has benefits in terms of system performance, but its usefulness for infection control has not been conclusively determined. Duct cleaning typically involves using specialized tools to dislodge dirt and a high-powered vacuum cleaner to clean out debris.[263] Some duct-cleaning services also apply chemical biocides or sealants to the inside surfaces of ducts to minimize fungal growth and prevent the release of particulate matter. The U.S. Environmental Protection Agency (EPA), however, has concerns with the use of sanitizers and/or disinfectants to treat the surfaces of ductwork, because the label indications for most of these products may not specifically include the use of the product in HVAC systems.[264] Further, EPA has not evaluated the potency of disinfectants in such applications, nor has the agency examined the potential attendant health and safety risks. The EPA recommends that companies use only those chemical biocides that are registered for use in HVAC systems.[264] Although infrequent cleaning of the exhaust ducts in AII areas has been documented as a cause of diminishing negative pressure and a decrease in the air exchange rates,[214] no data indicate that duct cleaning, beyond what is recommended for optimal performance, improves indoor air quality or reduces the risk of infection. Exhaust return systems should be cleaned as part of routine system maintenance. Duct cleaning has not been shown to prevent any health problems,[265] and EPA studies indicate that airborne particulate levels do not increase as a result of dirty air ducts, nor do they diminish after cleaning, presumably because much of the dirt inside air ducts adheres to duct surfaces and does not enter the conditioned space.[265] Additional research is needed to determine if air-duct contamination can significantly increase the airborne infection risk in general areas of health-care facilities.

4. Construction, Renovation, Remediation, Repair, and Demolition

a. General Information

Environmental disturbances caused by construction and/or renovation and repair activities (e.g., disruption of the above-ceiling area, running cables through the ceiling, and structural repairs) in and near health-care facilities markedly increase the airborne *Aspergillus* spp. spore counts in the indoor air of such facilities, thereby increasing the risk for health-care associated aspergillosis among high-risk patients. Although one case of health-care associated aspergillosis is often difficult to link to a specific environmental exposure, the occurrence of temporarily clustered cases increase the likelihood that an environmental source within the facility may be identified and corrected.

Table 7. Ventilation hazards in health-care facilities that may be associated with increased potential of airborne disease transmission*

Problem§	Consequences	Possible solutions
Water-damaged building materials (18, 266)	Water leaks can soak wood, wall board, insulation, wall coverings, ceiling tiles, and carpeting. All of these materials can provide microbial habitat when wet. This is especially true for fungi growing on gypsum board.	1. Replace water-damaged materials. 2. Incorporate fungistatic compounds into building materials in areas at risk for moisture problems. 3. Test for all moisture and dry in less than 72 hours. Replace if the material cannot dry within 72 hours.
Filter bypasses (17)	Rigorous air filtration requires air flow resistance. Air stream will elude filtration if openings are present because of filter damage or poor fit.	1. Use pressure gauges to ensure that filters are performing at proper static pressure. 2. Make ease of installation and maintenance criteria for filter selection. 3. Properly train maintenance personnel in HVAC concerns. 4. Design system with filters down- stream from fans. 5. Avoid water on filters or insulation.
Improper fan setting (267)	Air must be delivered at design volume to maintain pressure balances. Air flow in special vent rooms reverses.	1. Routinely monitor air flow and pressure balances throughout critical parts of HVAC system. 2. Minimize or avoid using rooms that switch between positive and negative pressure.
Ductwork disconnections (268)	Dislodged or leaky supply duct runs can spill into and leaky returns may draw from hidden areas. Pressure balance will be interrupted, and infectious material may be disturbed and entrained into hospital air supply.	1. Design a ductwork system that is easy to access, maintain, and repair. 2. Train maintenance personnel to regularly monitor air flow volumes and pressure balances throughout the system. 3. Test critical areas for appropriate air flow
Air flow impedance (213)	Debris, structural failure, or improperly adjusted dampers can block duct work and prevent designed air flow.	1. Design and budget for a duct system that is easy to inspect, maintain, and repair. 2. Alert contractors to use caution when working around HVAC systems during the construction phase. 3. Regularly clean exhaust grilles. 4. Provide monitoring for special ventilation areas.
Open windows (96, 247)	Open windows can alter fan-induced pressure balance and allow dirty-to clean air flow.	1. Use sealed windows. 2. Design HVAC systems to deliver sufficient outdoor dilution ventilation. 3. Ensure that OSHA indoor air quality standards are met.
Dirty window air conditioners (96, 269)	Dirt, moisture, and bird droppings can contaminate window air conditioners, which can then introduce infectious material into hospital rooms.	1. Eliminate such devices in plans for new construction. 2. Where they must be used, make sure that they are routinely cleaned and inspected.
Inadequate filtration (270)	Infectious particles may pass through filters into vulnerable patient areas.	1. Specify appropriate filters during new construction design phase. 2. Make sure that HVAC fans are sized to overcome pressure demands of filter system. 3. Inspect and test filters for proper installation.

Problem§	Consequences	Possible solutions
Maintenance disruptions (271)	Fan shut-offs, dislodged filter cake material contaminates downstream air supply and drain pans. This may compromise air flow in special ventilation areas.	1. Budget for a rigorous maintenance schedule when designing a facility. 2. Design system for easy maintenance. 3. Ensure communication between engineering and maintenance personnel. 4. Institute an ongoing training program for all involved staff members.
Excessive moisture in the HVAC system (120)	Chronically damp internal lining of the HVAC system, excessive condensate, and drip pans with stagnant water may result from this problem.	1. Locate duct humidifiers upstream of the final filters. 2. Identify a means to remove water from the system. 3. Monitor humidity; all duct take-offs should be downstream of the humidifiers so that moisture is absorbed completely. 4. Use steam humidifiers in the HVAC system.
Duct contamination (18, 272)	Debris is released during maintenance or cleaning.	1. Provide point-of-use filtration in the critical areas. 2. Design air-handling systems with insulation of the exterior of the ducts. 3. Do not use fibrous sound attenuators. 4. Decontaminate or encapsulate contamination.

Construction, renovation, repair, and demolition activities in health-care facilities require substantial planning and coordination to minimize the risk for airborne infection both during projects and after their completion. Several organizations and experts have endorsed a multi-disciplinary team approach (Box 4) to coordinate the various stages of construction activities (e.g., project inception, project implementation, final walk-through, and completion).[120, 249, 250, 273–276] Environmental services, employee health, engineering, and infection control must be represented in construction planning and design meetings should be convened with architects and design engineers. The number of members and disciplines represented is a function of the complexity of a project. Smaller, less complex projects and maintenance may require a minimal number of members beyond the core representation from engineering, infection control, environmental services, and the directors of the specialized departments.

Box 4. Suggested members and functions of a multi-disciplinary coordination team for construction, renovation, repair, and demolition projects

Members

- Infection-control personnel, including hospital epidemiologists
- Laboratory personnel
- Facility administrators or their designated representatives, facility managers
- Director of engineering
- Risk-management personnel
- Directors of specialized programs (e.g., transplantation, oncology and ICU [intensive care unit] programs)
- Employee safety personnel, industrial hygienists, and regulatory affairs personnel
- Environmental services personnel Information systems personnel
- Construction administrators or their designated representatives
- Architects, design engineers, project managers, and contractors

Functions and responsibilities

- Coordinate members' input in developing a comprehensive project management plan.
- Conduct a risk assessment of the project to determine potential hazards to susceptible patients.
- Prevent unnecessary exposures of patients, visitors, and staff to infectious agents.
- Oversee all infection-control aspects of construction activities.
- Establish site-specific infection-control protocols for specialized areas.
- Provide education about the infection-control impact of construction to staff and construction workers.
- Ensure compliance with technical standards, contract provisions, and regulations.
- Establish a mechanism to address and correct problems quickly.
- Develop contingency plans for emergency response to power failures, water supply disruptions, and fires.
- Provide a water-damage management plan (including drying protocols) for handling water intrusion from floods, leaks, and condensation.
- Develop a plan for structural maintenance.

Education of maintenance and construction workers, health-care staff caring for high-risk patients, and persons responsible for controlling indoor air quality heightens awareness that minimizing dust and moisture intrusion from construction sites into high-risk patient-care areas helps to maintain a safe environment.[120, 250, 271, 275–278] Visual and printed educational materials should be provided in the language spoken by the workers. Staff and construction workers also need to be aware of the potentially catastrophic consequences of dust and moisture intrusion when an HVAC system or water system fails during construction or repair; action plans to deal quickly with these emergencies should be developed in advance and kept on file. Incorporation of specific standards into construction contracts may help to prevent departures from recommended practices as projects progress. Establishing specific lines of communication is important to address problems (e.g., dust control, indoor air quality, noise levels, and vibrations), resolve complaints, and keep projects moving toward completion. Health-care facility staff should develop a mechanism to monitor worker adherence to infection-control guidelines on a daily basis in and around the construction site for the duration of the project.

b. Preliminary Considerations

The three major topics to consider before initiating any construction or repair activity are as follows:

a. design and function of the new structure or area,
b. assessment of environmental risks for airborne disease and opportunities for prevention, and
c. measures to contain dust and moisture during construction or repairs.

A checklist of design and function considerations can help to ensure that a planned structure or area can be easily serviced and maintained for environmental infection control (Box 5) .[17, 250, 273, 275–277]

Specifications for the construction, renovation, remodeling, and maintenance of health-care facilities are outlined in the AIA document, *Guidelines for Design and Construction of Hospitals and Health Care Facilities*. [120, 275]

Box 5. Construction design and function considerations for environmental infection control

- Location of sinks and dispensers for handwashing products and hand hygiene products
- Types of faucets (e.g., aerated vs. non-aerated)
- Air-handling systems engineered for optimal performance, easy maintenance, and repair
- ACH and pressure differentials to accommodate special patient-care areas
- Location of fixed sharps containers
- Types of surface finishes (e.g., porous vs. non-porous)
- Well-caulked walls with minimal seams
- Location of adequate storage and supply areas
- Appropriate location of medicine preparations areas (e.g., >3 ft. from a sink)
- Appropriate location and type of ice machines (e.g., preferably ice dispensers rather than ice bins)
- Appropriate materials for sinks and wall coverings
- Appropriate traffic flow (e.g., no "dirty" movement through "clean" areas)
- Isolation rooms with anterooms as appropriate
- Appropriate flooring (e.g., seamless floors in dialysis units)
- Sensible use carpeting (e.g., avoiding use of carpeting in special care areas or areas likely to become wet)*
- Convenient location of soiled utility areas
- Properly engineered areas for linen services and solid waste management
- Location of main generator to minimize the risk of system failure from flooding or other emergency
- Installation guidelines for sheetrock

* Use of carpet cleaning methods (e.g., "bonneting") that disperse microorganisms into the air may increase the risk of airborne infection among at-risk patients, especially if they are in the vicinity of the cleaning activity.[111]

Proactive strategies can help prevent environmentally mediated airborne infections in health-care facilities during demolition, construction, and renovation. The potential presence of dust and moisture and their contribution to health-care associated infections must be critically evaluated early in the planning of any demolition, construction, renovation, and repairs.[120, 250, 251, 273, 274, 276–279] Consideration must extend beyond dust generated by major projects to include dust that can become airborne if disturbed during routine maintenance and minor renovation activities (e.g., exposure of ceiling spaces for inspection; installation of conduits, cable, or sprinkler systems; rewiring; and structural repairs or replacement).[273, 276, 277] Other projects that can compromise indoor air quality include construction and repair jobs that inadvertently allow substantial amounts of raw, unfiltered outdoor air to enter the facility (e.g., repair of elevators and elevator shafts) and activities that dampen any structure, area, or item made of porous materials or characterized by cracks and crevices (e.g., sink cabinets in need of repair, carpets, ceilings, floors, walls, vinyl wall coverings, upholstery, drapes, and countertops).[18, 273, 277] Molds grow and proliferate on these surfaces when they become and remain wet.[21, 120, 250, 266, 270, 272, 280] Scrubbable materials are preferred for use in patient-care areas.

Containment measures for dust and/or moisture control are dictated by the location of the construction site. Outdoor demolition and construction require actions to keep dust and moisture out of the facility (e.g., sealing windows and vents and keeping doors closed or sealed). Containment of dust and moisture generated from construction inside a facility requires barrier structures (either pre-fabricated or constructed of more durable materials as needed) and engineering controls to clean the air in and around the construction or repair site.

c. Infection-Control Risk Assessment

An infection-control risk assessment (ICRA) conducted before initiating repairs, demolition, construction, or renovation activities can identify potential exposures of susceptible patients to dust and moisture and determine the need for dust and moisture containment measures. This assessment centers on the type and extent of the construction or repairs in the work area but may also need to include adjacent patient-care areas, supply storage, and areas on levels above and below the proposed project. An example of designing an ICRA as a matrix, the policy for performing an ICRA and implementing its results, and a sample permit form that streamlines the communication process are available.[281] Knowledge of the air flow patterns and pressure differentials helps minimize or eliminate the inadvertent dispersion of dust that could contaminate air space, patient-care items, and surfaces.[57, 282, 283] A recent aspergillosis outbreak among oncology patients was attributed to depressurization of the building housing the HSCT unit while construction was underway in an adjacent building. Pressure readings in the affected building (including 12 of 25 HSCT-patient rooms) ranged from 0.1 Pa–5.8 Pa. Unfiltered outdoor air flowed into the building through doors and windows, exposing patients in the HSCT unit to fungal spores.[283] During long-term projects, providing temporary essential services (e.g., toilet facilities) and conveniences (e.g., vending machines) to construction workers within the site will help to minimize traffic in and out of the area. The type of barrier systems necessary for the scope of the project must be defined.[12, 120, 250, 279, 284]

Depending on the location and extent of the construction, patients may need to be relocated to other areas in the facility not affected by construction dust.[51, 285] Such relocation might be especially prudent when construction takes place within units housing immunocompromised patients (e.g., severely neutropenic patients and patients on corticosteroid therapy). Advance assessment of high-risk locations and planning for the possible transport of patients to other departments can minimize delays and waiting time in hallways.[51] Although hospitals have provided immunocompromised patients with some form of respiratory protection for use outside their rooms, the issue is complex and remains unresolved until more research can be done. Previous guidance on this issue has been inconsistent.[9] Protective respirators (i.e., N95) were well tolerated by patients when used to prevent further cases of construction-related aspergillosis in a recent outbreak.[283] The routine use of the N95 respirator by patients, however, has not been evaluated for preventing exposure to fungal spores during periods of non-construction. Although health-care workers who would be using the N95 respirator for personal respiratory protect must be fit-tested, there is no indication that either patients or visitors should undergo fit-testing.

Surveillance activities should augment preventive strategies during construction projects.[3, 4, 20, 110, 286, 287] By determining baseline levels of health-care acquired airborne and waterborne infections, infection-control staff can monitor changes in infection rates and patterns during and immediately after construction, renovations, or repairs.[3]

d. Air Sampling

Air sampling in health-care facilities may be conducted both during periods of construction and on a periodic basis to determine indoor air quality, efficacy of dust-control measures, or air-handling system performance via parametric monitoring. Parametric monitoring consists of measuring the physical periodic assessment of the system (e.g., air flow direction and pressure, ACH, and filter efficiency) can give assurance of proper ventilation, especially for special care areas and operating rooms.[288]

Air sampling is used to detect aerosols (i.e., particles or microorganisms). Particulate sampling (i.e., total numbers and size range of particulates) is a practical method for evaluating the infection-control performance of the HVAC system, with an emphasis on filter efficiency in removing respirable particles (<5 μm in diameter) or larger particles from the air. Particle size is reported in terms of the mass median aerodynamic diameter (MMAD), whereas count median aerodynamic diameter (CMAD) is useful with respect to particle concentrations.

Particle counts in a given air space within the health-care facility should be evaluated against counts obtained in a comparison area. Particle counts indoors are commonly compared with the particulate levels of the outdoor air. This approach determines the "rank order" air quality from "dirty" (i.e., the outdoor air) to "clean" (i.e., air filtered through high-efficiency filters [90%–95% filtration]) to "cleanest" (i.e., HEPA-filtered air).[288] Comparisons from one indoor area to another may also provide useful information about the magnitude of an indoor air-quality problem. Making rank-order comparisons between clean, highly-filtered areas and dirty areas and/or outdoors is one way to interpret sampling results in the absence of air quality and action level standards.[35, 289]

In addition to verifying filter performance, particle counts can help determine if barriers and efforts to control dust dispersion from construction are effective. This type of monitoring is helpful when performed at various times and barrier perimeter locations during the project. Gaps or breaks in the barriers' joints or seals can then be identified and repaired. The American Conference of Governmental Industrial Hygienists (ACGIH) has set a threshold limit value-time weighted average (TLV®-TWA) of 10 mg/m^3 for nuisance dust that contains no asbestos and <1% crystalline silica.[290] Alternatively, OSHA has set permissible exposure limits (PELs) for inert or nuisance dust as follows: respirable fraction at 5 mg/m^3 and total dust at 15 mg/m^3 .[291] Although these standards are not measures of a bioaerosol, they are used for indoor air quality assessment in occupational settings and may be useful criteria in construction areas. Application of ACGIH guidance to health-care settings has not been standardized, but particulate counts in health-care facilities are likely to be well below this threshold value and approaching clean-room standards in certain care areas (e.g., operating rooms).[100]

Particle counters and anemometers are used in particulate evaluation. The anemometer measures air flow velocity, which can be used to determine sample volumes. Particulate sampling usually does not require microbiology laboratory services for the reporting of results.

Microbiologic sampling of air in health-care facilities remains controversial because of currently unresolved technical limitations and the need for substantial laboratory support (Box 6). Infection-control professionals, laboratorians, and engineers should determine if microbiologic and/or particle sampling is warranted and assess proposed methods for sampling. The most significant technical limitation of air sampling for airborne fungal agents is the lack of standards linking fungal spore levels with infection rates. Despite this limitation, several health-care institutions have opted to use microbiologic sampling when construction projects are anticipated and/or underway in efforts to assess the safety of the environment for immunocompromised patients.[35, 289] Microbiologic air sampling should be limited to assays for airborne fungi; of those, the thermotolerant fungi (i.e., those capable of growing at 95°F–98.6°F [35°C–37°C]) are of particular concern because of their pathogenicity in immunocompromised hosts.[35] Use of selective media (e.g., Sabouraud dextrose agar and inhibitory mold agar) helps with the initial identification of recovered organisms.

Microbiologic sampling for fungal spores performed as part of various airborne disease outbreak investigations has also been problematic.[18, 49, 106, 111, 112, 289] The precise source of a fungus is often difficult to trace with certainty, and sampling conducted after exposure may neither reflect the circumstances that were linked to infection nor distinguish between health-care acquired and community-acquired infections. Because fungal strains may fluctuate rapidly in the environment, health-care acquired *Aspergillus* spp. infection cannot be confirmed or excluded if the infecting strain is not found in the health-care setting.[287] Sensitive molecular typing methods (e.g., randomly amplified polymorphic DNA (RAPD) techniques and a more recent DNA fingerprinting technique that detects restriction fragment length polymorphisms in fungal genomic DNA) to identify strain differences among *Aspergillus* spp., however, are becoming increasingly used in epidemiologic investigations of health-care acquired fungal infection (A.Streifel, University of Minnesota, 2000).[68, 110, 286, 287, 292–296] During case cluster evaluation, microbiologic sampling may provide an isolate from the environment for molecular typing and comparison with patient isolates.

Therefore, it may be prudent for the clinical laboratory to save *Aspergillus* spp. isolated from colonizations and invasive disease cases among patients in PE, oncology, and transplant services for these purposes.

Box 6. Unresolved issues associated with microbiologic air sampling*

- Lack of standards linking fungal spore levels with infection rates (i.e., no safe level of exposure)
- Lack of standard protocols for testing (e.g., sampling intervals, number of samples, sampling locations)
- Need for substantial laboratory support
- Culture issues (e.g., false negatives, insensitivity, lag time between sampling and recording the results)
- New, complex polymerase chain reaction (PCR) analytical methods
- Unknown incubation period for *Aspergillus* spp. infection
- Variability of sampler readings
- Sensitivity of the sampler used (i.e., the volumes of air sampled)
- Lack of details in the literature about describing sampling circumstances (e.g., unoccupied rooms vs. ongoing activities in rooms, expected fungal concentrations, and rate of outdoor air penetration)
- Lack of correlation between fungal species and strains from the environment and clinical specimens
- Confounding variables with high-risk patients (e.g., visitors and time spent outside of protective environment [PE] without respiratory protection)
- Need for determination of ideal temperature for incubating fungal cultures (95°F [35°C] is the most commonly used temperature)

* Material in this box is compiled from references 35, 100, 222, 289, 297.

Sedimentation methods using settle plates and volumetric sampling methods using solid impactors are commonly employed when sampling air for bacteria and fungi. Settle plates have been used by numerous investigators to detect airborne bacteria or to measure air quality during medical procedures (e.g., surgery).[17, 60, 97, 151, 161, 287] Settle plates, because they rely on gravity during sampling, tend to select for larger particles and lack sensitivity for respirable particles (e.g., individual fungal spores), especially in highly-filtered environments. Therefore, they are considered impractical for general use.[35, 289, 298–301] Settle plates, however, may detect fungi aerosolized during medical procedures (e.g., during wound dressing changes), as described in a recent outbreak of aspergillosis among liver transplant patients.[302]

The use of slit or sieve impactor samplers capable of collecting large volumes of air in short periods of time are needed to detect low numbers of fungal spores in highly filtered areas.[35, 289] In some outbreaks, aspergillosis cases have occurred when fungal spore concentrations in PE ambient air ranged as low as 0.9–2.2 colony-forming units per cubic meter (CFU/m^3) of air.[18, 94] On the basis of the expected spore counts in the ambient air and the performance parameters of various types of volumetric air samplers, investigators of a recent aspergillosis outbreak have suggested that an air volume of at least 1000 L (1 m^3) should be considered when sampling highly filtered areas.[283] Investigators have also suggested limits of 15 CFU/m^3 for gross colony counts of fungal organisms and <0.1 CFU/m^3 for *Aspergillus fumigatus* and other potentially opportunistic fungi in heavily filtered areas (≥12 ACH and filtration of ≥99.97% efficiency).[120] No correlation of these values with the incidence of health-care– associated fungal infection rates has been reported.

Air sampling in health-care facilities, whether used to monitor air quality during construction, to verify filter efficiency, or to commission new space prior to occupancy, requires careful notation of the

circumstances of sampling. Most air sampling is performed under undisturbed conditions. However, when the air is sampled during or after human activity (e.g., walking and vacuuming), a higher number of airborne microorganisms likely is detected.[297] The contribution of human activity to the significance of air sampling and its impact on health-care associated infection rates remain to be defined. Comparing microbiologic sampling results from a target area (e.g., an area of construction) to those from an unaffected location in the facility can provide information about distribution and concentration of potential airborne pathogens. A comparison of microbial species densities in outdoor air versus indoor air has been used to help pinpoint fungal spore bursts. Fungal spore densities in outdoor air are variable, although the degree of variation with the seasons appears to be more dramatic in the United States than in Europe.[92, 287, 303]

Particulate and microbiologic air sampling have been used when commissioning new HVAC system installations; however, such sampling is particularly important for newly constructed or renovated PE or operating rooms. Particulate sampling is used as part of a battery of tests to determine if a new HVAC system is performing to specifications for filtration and the proper number of ACH.[268, 288, 304] Microbiologic air sampling, however, remains controversial in this application, because no standards for comparison purposes have been determined. If performed, sampling should be limited to determining the density of fungal spores per unit volume of air space. High numbers of spores may indicate contamination of air-handling system components prior to installation or a system deficiency when culture results are compared with known filter efficiencies and rates of air exchange.

e. External Demolition and Construction

External demolition, planned building implosions, and dirt excavation generate considerable dust and debris that can contain airborne microorganisms. In one study, peak concentrations in outdoor air at grade level and HVAC intakes during site excavation averaged 20,000 CFU/m^3 for all fungi and 500 CFU/m^3 for *Aspergillus fumigatus*, compared with 19 CFU/m^3 and 4 CFU/m^3, respectively, in the absence of construction.[280] Many health-care institutions are located in large, urban areas; building implosions are becoming a more frequent concern. Infection-control risk assessment teams, particularly those in facilities located in urban renewal areas, would benefit by developing risk management strategies for external demolition and construction as a standing policy. In light of the events of 11 September 2001, it may be necessary for the team to identify those dust exclusion measures that can be implemented rapidly in response to emergency situations (Table 8). Issues to be reviewed prior to demolition include

a. proximity of the air intake system to the work site,
b. adequacy of window seals and door seals,
c. proximity of areas frequented by immunocompromised patients, and
d. location of the underground utilities (D. Erickson, ASHE, 2000).[120, 250, 273, 276, 277, 280, 305]

Table 8. Strategies to reduce dust and moisture intrusion during external demolition and construction

Item	Recommendation
Demolition site	• Shroud the site if possible to reduce environmental contamination.
Dust-generating equipment	• Prior to placing dust-generating equipment, evaluate the location to ensure that dust produced by the equipment will not enter the building through open doorways or windows, or through ventilation air intakes.
Construction materials storage	• Locate this storage away from the facility and ventilation air intakes.
Adjacent air intakes	• Seal off affected intakes, if possible, or move if funds permit.
HVAC system	• Consult with the facility engineer about pressure differentials and air recirculation options; keep facility air pressure positive to outside air.
Filters	• Ensure that filters are properly installed; change roughing filters frequently to prevent dust build-up on high-efficiency filters.
Windows	• Seal and caulk to prevent entry of airborne fungal spores.
Doors	• Keep closed as much as possible; do not prop open; seal and caulk unused doors (i.e., those that are not designated as emergency exits); use mats with tacky surfaces at outside entrances.
Water utilities	• Note location relative to construction area to prevent intrusion of dust into water systems. (Contamination of water pipes during demolition activities has been associated with health-care associated transmission of *Legionella* spp.[305])
Medical gas piping	• Ensure that these lines/pipes are insulated during periods of vibration.
Rooftops	• Temporarily close off during active demolition/construction those rooftop areas that are normally open to the public (e.g., rooftop atrium).
Dust generation	• Provide methods (e.g., misting the area with water) to minimize dust.
Immunocompromised patients	• Use walk-ways protected from demolition/construction sites; avoid outside areas close to these sites; avoid rooftops.
Pedestrian traffic	• Close off entry ways as needed to minimize dust intrusion.
Truck traffic	• Reroute if possible, or arrange for frequent street cleaning.
Education and awareness+	• Encourage reporting of hazardous or unsafe incidents associated with construction.

+ When health-care facilities have immunosuppressed patients in their census, telephoning the city building department each month to find out if buildings are scheduled for demolition is prudent.

Minimizing the entry of outside dust into the HVAC system is crucial in reducing the risk for airborne contaminants. Facility engineers should be consulted about the potential impact of shutting down the system or increasing the filtration. Selected air handlers, especially those located close to excavation sites, may have to be shut off temporarily to keep from overloading the system with dust and debris. Care is needed to avoid significant facility-wide reductions in pressure differentials that may cause the building to become negatively pressured relative to the outside. To prevent excessive particulate overload and subsequent reductions in effectiveness of intake air systems that cannot be shut off temporarily, air filters must be inspected frequently for proper installation and function. Excessive dust penetration can be avoided if recirculated air is maximally utilized while outdoor air intakes are shut down. Scheduling demolition and

excavation during the winter, when *Aspergillus* spp. spores may be present in lower numbers, can help, although seasonal variations in spore density differ around the world.[92, 287, 303]

Dust control can be managed by misting the dirt and debris during heavy dust-generating activities. To decrease the amount of aerosols from excavation and demolition projects, nearby windows, especially in areas housing immunocompromised patients, can be sealed and window and door frames caulked or weather-stripped to prevent dust intrusion.[50, 301, 306] Monitoring for adherence to these control measures throughout demolition or excavation is crucial. Diverting pedestrian traffic away from the construction sites decreases the amount of dust tracked back into the health-care facility and minimizes exposure of high-risk patients to environmental pathogens. Additionally, closing entrances near construction or demolition sites might be beneficial; if this is not practical, creating an air lock (i.e., pressurizing the entry way) is another option.

f. Internal Demolition, Construction, Renovations, and Repairs

The focus of a properly implemented infection-control program during interior construction and repairs is containment of dust and moisture. This objective is achieved by

a. educating construction workers about the importance of control measures
b. preparing the site;
c. notifying and issuing advisories for staff, patients, and visitors;
d. moving staff and patients and relocating patients as needed;
e. issuing standards of practice and precautions during activities and maintenance;
f. monitoring for adherence to control measures during construction and providing prompt feedback about lapses in control
g. monitoring HVAC performance;
h. implementing daily clean-up, terminal cleaning and removal of debris upon completion; and
i. ensuring the integrity of the water system during and after construction.

These activities should be coordinated with engineering staff and infection-control professionals.

Physical barriers capable of containing smoke and dust will confine dispersed fungal spores to the construction zone.[279, 284, 307, 308] The specific type of physical barrier required depends on the project's scope and duration and on local fire codes. Short-term projects that result in minimal dust dispersion (e.g., installation of new cables or wiring above ceiling tiles) require only portable plastic enclosures with negative pressure and HEPA filtration of the exhaust air from the enclosed work area. The placement of a portable industrial-grade HEPA filter device capable of filtration rate of 300–800 ft^3/min. adjacent to the work area will help to remove fungal spores, but its efficacy is dependent on the supplied ACH and size of the area. If the project is extensive but short-term, dust-abatement, fire-resistant plastic curtains (e.g., Visqueen®) may be adequate. These should be completely airtight and sealed from ceiling to floor with overlapping curtains;[276, 277, 309] holes, tears, or other perforations should be repaired promptly with tape. A portable, industrial-grade HEPA filter unit on continuous operation is needed within the contained area, with the filtered air exhausted to the outside of the work zone. Patients should not remain in the room when dust-generating activities are performed. Tools to assist the decision-making process regarding selection of barriers based on an ICRA approach are available.[281]

More elaborate barriers are indicated for long-term projects that generate moderate to large amounts of dust. These barrier structures typically consist of rigid, noncombustible walls constructed from sheet rock, drywall, plywood, or plaster board and covered with sheet plastic (e.g., Visqueen®). Barrier requirements to prevent the intrusion of dust into patient-care areas include

a. installing a plastic dust abatement curtain before construction of the rigid barrier
b. sealing and taping all joint edges including the top and bottom;
c. extending the barrier from floor to floor, which takes into account the space [approximately 2–8 ft.] above the finished, lay-down ceiling; and
d. fitting or sealing any temporary doors connecting the construction zone to the adjacent area. (See Box 7 for a list of the various construction and repair activities that require the use of some type of barrier.)

Box 7. Construction/repair projects that require barrier structures*

- Demolition of walls, wallboard, plaster, ceramic tiles, ceiling tiles, and ceilings
- Removal of flooring and carpeting, windows and doors, and casework
- Working with sinks and plumbing that could result in aerosolization of water in high-risk areas
- Exposure of ceiling spaces for demolition and for installation or rerouting of utility services (e.g., rewiring, electrical conduction installation, HVAC ductwork, and piping)
- Crawling into ceiling spaces for inspection in a manner that may dislodge dust
- Demolition, repair, or construction of elevator shafts
- Repairing water damage

* Material for this box was compiled from references 120, 250, 273, 276, 277.

Dust and moisture abatement and control rely primarily on the impermeable barrier containment approach; as construction continues, numerous opportunities can lead to dispersion of dust to other areas of the health-care facility. Infection-control measures that augment the use of barrier containment should be undertaken (Table 9).

Dust-control measures for clinical laboratories are an essential part of the infection-control strategy during hospital construction or renovation. Use of plastic or solid barriers may be needed if the ICRA determines that air flow from construction areas may introduce airborne contaminants into the laboratory space. In one facility, pseudofungemia clusters attributed to *Aspergillus* spp. and *Penicillium* spp. were linked to improper air flow patterns and construction projects adjacent to the laboratory; intrusion of dust and spores into a biological safety cabinet from construction activity immediately next to the cabinet resulted in a cluster of cultures contaminated with *Aspergillus niger*. [310, 311] Reportedly, no barrier containment was used and the HEPA filtration system was overloaded with dust. In addition, an outbreak of pseudobacteremia caused by *Bacillus* spp. occurred in another hospital during construction above a storage area for blood culture bottles.[207] Airborne spread of *Bacillus* spp. spores resulted in contamination of the bottles' plastic lids, which were not disinfected or handled with proper aseptic technique prior to collection of blood samples.

Table 9. Infection-control measures for internal construction and repair projects*+

Infection-control measure	Steps for implementation
Prepare for the project.	1. Use a multi-disciplinary team approach to incorporate infection control into the project. 2. Conduct the risk assessment and a preliminary walk-through with project managers and staff.
Educate staff and construction workers.	1. Educate staff and construction workers about the importance of adhering to infection-control measures during the project. 2. Provide educational materials in the language of the workers. 3. Include language in the construction contract requiring construction workers and subcontractors to participate in infection-control training.
Issue hazard and warning notices.	1. Post signs to identify construction areas and potential hazards. 2. Mark detours requiring pedestrians to avoid the work area.
Relocate high-risk patients as needed, especially if the construction is in or adjacent to a PE area.	1. Identify target patient populations for relocation based on the risk assessment. 2. Arrange for the transfer in advance to avoid delays. 3. At-risk patients should wear protective respiratory equipment (e.g., a high- efficiency mask) when outside their PE rooms.

Infection-control measure	Steps for implementation
Establish alternative traffic patterns for staff, patients, visitors, and construction workers.	1. Determine appropriate alternate routes from the risk assessment. 2. Designate areas (e.g., hallways, elevators, and entrances/exits) for construction-worker use. 3. Do not transport patients on the same elevator with construction materials and debris.
Erect appropriate barrier containment.	1. Use prefabricated plastic units or plastic sheeting for short-term projects that will generate minimal dust. 2. Use durable rigid barriers for ongoing, long-term projects.
Establish proper ventilation.	1. Shut off return air vents in the construction zone, if possible, and seal around grilles. 2. Exhaust air and dust to the outside, if possible. 3. If recirculated air from the construction zone is unavoidable, use a pre-filter and a HEPA filter before the air returns to the HVAC system. 4. When vibration-related work is being done that may dislodge dust in the ventilation system or when modifications are made to ductwork serving occupied spaces, install filters on the supply air grilles temporarily. 5. Set pressure differentials so that the contained work area is under negative pressure. 6. Use air flow monitoring devices to verify the direction of the air pattern. 7. Exhaust air and dust to the outside, if possible. 8. Monitor temperature, air changes per hour (ACH), and humidity levels (humidity levels should be <65%). 9. Use portable, industrial grade HEPA filters in the adjacent area and/or the construction zone for additional ACH. 10. Keep windows closed, if possible.
Control solid debris.	1. When replacing filters, place the old filter in a bag prior to transport and dispose as a routine solid waste. 2. Clean the construction zone daily or more often as needed. 3. Designate a removal route for small quantities of solid debris. 4. Mist debris and cover disposal carts before transport (i.e., leaving the construction zone). 5. Designate an elevator for construction crew use. 6. Use window chutes and negative pressure equipment for removal of larger pieces of debris while maintaining pressure differentials in the construction zone. 7. Schedule debris removal to periods when patient exposures to dust is minimal.
Control water damage.	1. Make provisions for dry storage of building materials. 2. Do not install wet, porous building materials (i.e., sheet rock). 3. Replace water-damaged porous building materials if they cannot be completely dried out within 72 hours.
Control dust in air and on surfaces.	1. Monitor the construction area daily for compliance with the infection-control plan. 2. Protective outer clothing for construction workers should be removed before entering clean areas. 3. Use mats with tacky surfaces within the construction zone at the entry; cover sufficient area so that both feet make contact with the mat while walking through the entry. 4. Construct an anteroom as needed where coveralls can be donned and removed. 5. Clean the construction zone and all areas used by construction workers with a wet mop. 6. If the area is carpeted, vacuum daily with a HEPA-filtered–equipped vacuum. 7. Provide temporary essential services (e.g., toilets) and worker conveniences (e.g, vending machines) in the construction zone as appropriate. 8. Damp-wipe tools if removed from the construction zone or left in the area. 9. Ensure that construction barriers remain well sealed; use particle sampling as needed. 10. Ensure that the clinical laboratory is free from dust contamination.

Infection-control measure	Steps for implementation
Complete the project.	1. Flush the main water system to clear dust-contaminated lines. 2. Terminally clean the construction zone before the construction barriers are removed. 3. Check for visible mold and mildew and eliminate (i.e., decontaminate and remove), if present. 4. Verify appropriate ventilation parameters for the new area as needed. 5. Do not accept ventilation deficiencies, especially in special care areas. 6. Clean or replace HVAC filters using proper dust-containment procedures. 7. Remove the barriers and clean the area of any dust generated during this work. 8. Ensure that the designated air balances in the operating rooms (OR) and protective environments (PE) are achieved before occupancy. 9. Commission the space as indicated, especially in the OR and PE, ensuring that the room's required engineering specifications are met.

* Material in this table includes information from D. Erickson, ASHE, 2000.

+ Material in this table was compiled from references 19, 51, 67, 80, 106, 120, 250, 266, 273, 276–278, 280, 285, 309, 312–315.

5. Environmental Infection-Control Measures for Special Health-Care Settings

Areas in health-care facilities that require special ventilation include

a. operating rooms
b. PE rooms used by high-risk, immunocompromised patients; and
c. AII rooms for isolation of patients with airborne infections (e.g., those caused by *M. tuberculosis*, VZV, or measles virus).

Interim Measles Infection Control [July 2019]
See Interim Infection Prevention and Control Recommendations for Measles in Healthcare Settings (https://www.cdc.gov/infectioncontrol/guidelines/measles)

The number of rooms required for PE and AII are determined by a risk assessment of the health-care facility.[6] Continuous, visual monitoring of air flow direction is required for new or renovated pressurized rooms. [120, 256]

a. Protective Environments (PE)

Although the exact configuration and specifications of PEs might differ among hospitals, these care areas for high-risk, immunocompromised patients are designed to minimize fungal spore counts in air by maintaining

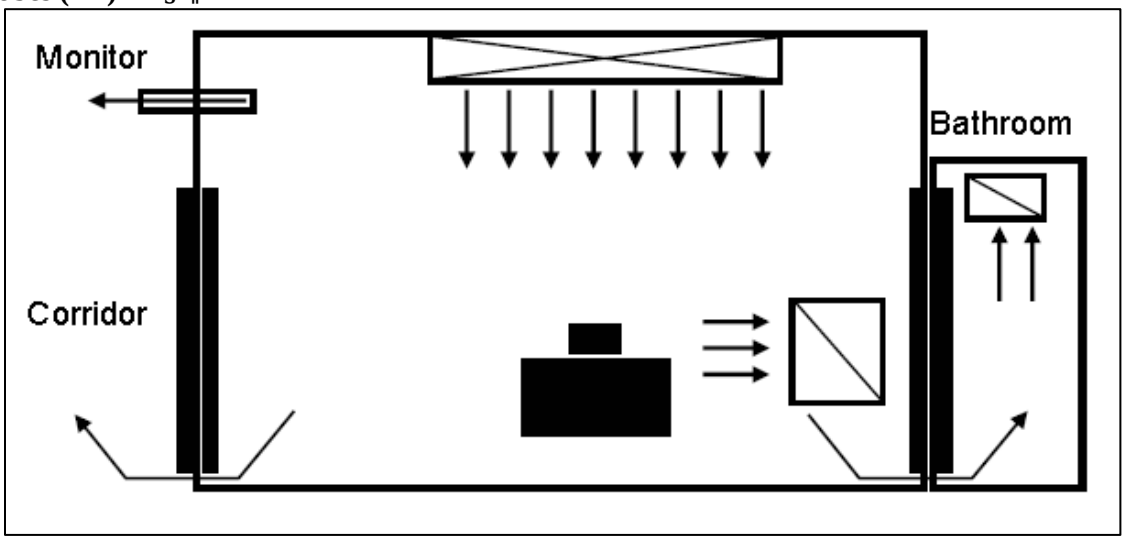
a. filtration of incoming air by using central or point-of-use HEPA filters
b. directed room air flow [i.e., from supply on one side of the room, across the patient, and out through the exhaust on the opposite side of the room];
c. positive room air pressure of 2.5 Pa [0.01" water gauge] relative to the corridor;
d. well-sealed rooms; and
e. ≥12 ACH.[44, 120, 251, 254, 316–319]

Air flow rates must be adjusted accordingly to ensure sufficient ACH, and these rates vary depending on certain factors (e.g., room air leakage area). For example, to provide ≥12 ACH in a typical patient room with 0.5 sq. ft. air leakage, the air flow rate will be minimally 125 cubic feet/min (cfm).[320, 321] Higher air flow rates may be needed. A general ventilation diagram for a positive-pressure room is given in Figure 2. Directed room air flow in PE rooms is not laminar; parallel air streams are not generated. Studies attempting to demonstrate patient benefit from laminar air flow in a PE setting are equivocal.[316, 318, 319, 322 - 327]

Air flow direction at the entrances to these areas should be maintained and verified, preferably on a daily basis, using either a visual means of indication (e.g., smoke tubes and flutter strips) or manometers. Permanent installation of a visual monitoring device is indicated for new PE construction and renovation.[120] Facility service structures can interfere with the proper unidirectional air flow from the

patients' rooms to the adjacent corridor. In one outbreak investigation, *Aspergillus* spp. infections in a critical care unit may have been associated with a pneumatic specimen transport system, a textile disposal duct system, and central vacuum lines for housekeeping, all of which disrupted proper air flow from the patients' rooms to the outside and allowed entry of fungal spores into the unit (M.McNeil, CDC, 2000).

Figure 2. Example of positive-pressure room control for protection from airborne environmental microbes (PE)* + § ¶



* Stacked black boxes represent patient's bed. Long open box with cross-hatch represents supply air. Open boxes with single, diagonal slashes represent air exhaust registers. Arrows indicate directions of air flow.

\+ Possible uses include immunocompromised patient rooms (e.g., hematopoietic stem cell transplant or solid organ transplant procedure rooms) and orthopedic operating rooms.

§ Positive-pressure room engineering features include positive pressure (greater supply than exhaust air volume); pressure differential range of 2.5–8 Pa (0.01–0.03-in. water gauge), ideal at 8 Pa; air flow volume differential >125-cfm supply versus exhaust; sealed room, approximately 0.5-sq. ft. leakage; clean to dirty air flow; monitoring; ≥12 air changes per hour (ACH); and return air if refiltered.

¶ This diagram is a generic illustration of air flow in a typical installation. Alternative air flow arrangements are recognized. Adapted and used with permission from A. Streifel and the publisher of reference 328 (Penton Media, Inc.)

The use of surface fungicide treatments is becoming more common, especially for building materials.[329] Copper-based compounds have demonstrated anti-fungal activity and are often applied to wood or paint. Copper-8-quinolinolate was used on environmental surfaces contaminated with *Aspergillus* spp. to control one reported outbreak of aspergillosis.310 The compound was also incorporated into the fireproofing material of a newly constructed hospital to help decrease the environmental spore burden.[316]

b. Airborne Infection Isolation (AII)

Acute-care inpatient facilities need at least one room equipped to house patients with airborne infectious disease. Every health-care facility, including ambulatory and long-term care facilities, should undertake an ICRA to identify the need for AII areas. Once the need is established, the appropriate ventilation equipment can be identified. Air handling systems for this purpose need not be restricted to central systems. Guidelines for the prevention of health-care acquired TB have been published in response to multiple reports of health-care associated transmission of multi-drug resistant strains.[4, 330] In reports documenting health-care acquired TB, investigators have noted a failure to comply fully with prevention

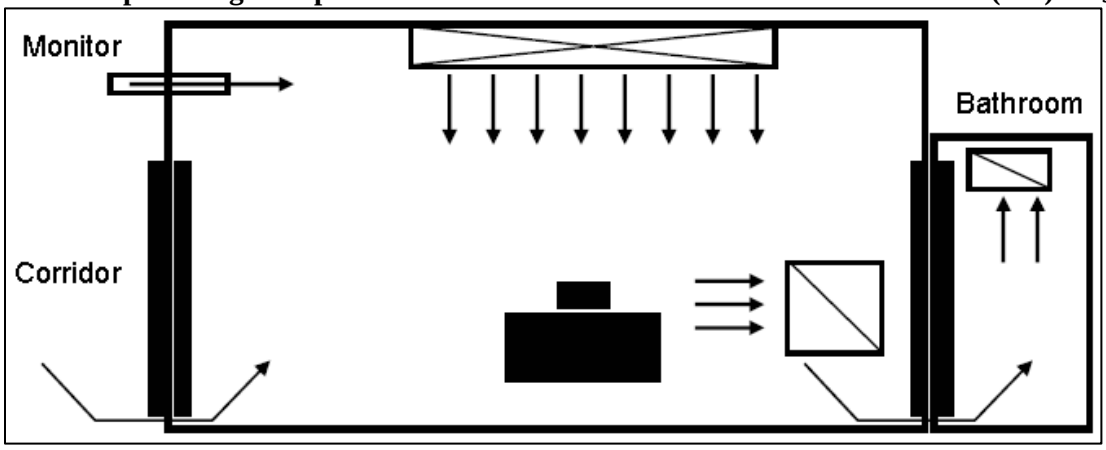
measures in established guidelines.[331 - 345] These gaps highlight the importance of prompt recognition of the disease, isolation of patients, proper treatment, and engineering controls. AII rooms are also appropriate for the care and management of smallpox patients.[6] Environmental infection control with respect to smallpox is currently being revisited (see Appendix E).

Salient features of engineering controls for AII areas include

a. use of negative pressure rooms with close monitoring of air flow direction using manometers or temporary or installed visual indicators [e.g., smoke tubes and flutter strips] placed in the room with the door closed
b. minimum 6 ACH for existing facilities, ≥12 ACH for areas under renovation or for new construction; and
c. air from negative pressure rooms and treatment rooms exhausted directly to the outside if possible.[4, 120, 248]

As with PE, airflow rates need to be determined to ensure the proper numbers of ACH.[320, 321] AII rooms can be constructed either with (Figure 3) or without (Figure 4) an anteroom. When the recirculation of air from AII rooms is unavoidable, HEPA filters should be installed in the exhaust duct leading from the room to the general ventilation system. In addition to UVGI fixtures in the room, UVGI can be placed in the ducts as an adjunct measure to HEPA filtration, but it can not replace the HEPA filter.[4, 346] A UVGI fixture placed in the upper room, coupled with a minimum of 6 ACH, also provides adequate air cleaning.[248]

Figure 3. Example of negative-pressure room control for airborne infection isolation (AII)* + §¶



* Stacked black boxes represent patient's bed. Long open box with cross-hatch represents supply air. Open boxes with single, diagonal slashes represent air exhaust registers. Arrows indicate direction of air flow.

\+ Possible uses include treatment or procedure rooms, bronchoscopy rooms, and autopsy.

§ Negative-pressure room engineering features include negative pressure (greater exhaust than supply air volume); pressure differential of 2.5 Pa (0.01-in. water gauge); air flow volume differential >125-cfm exhaust versus supply; sealed room, approximately 0.5-sq. ft. leakage; clean to dirty air flow; monitoring; ≥12 air changes per hour (ACH) new or renovation, 6 ACH existing; and exhaust to outside or HEPA-filtered if recirculated.

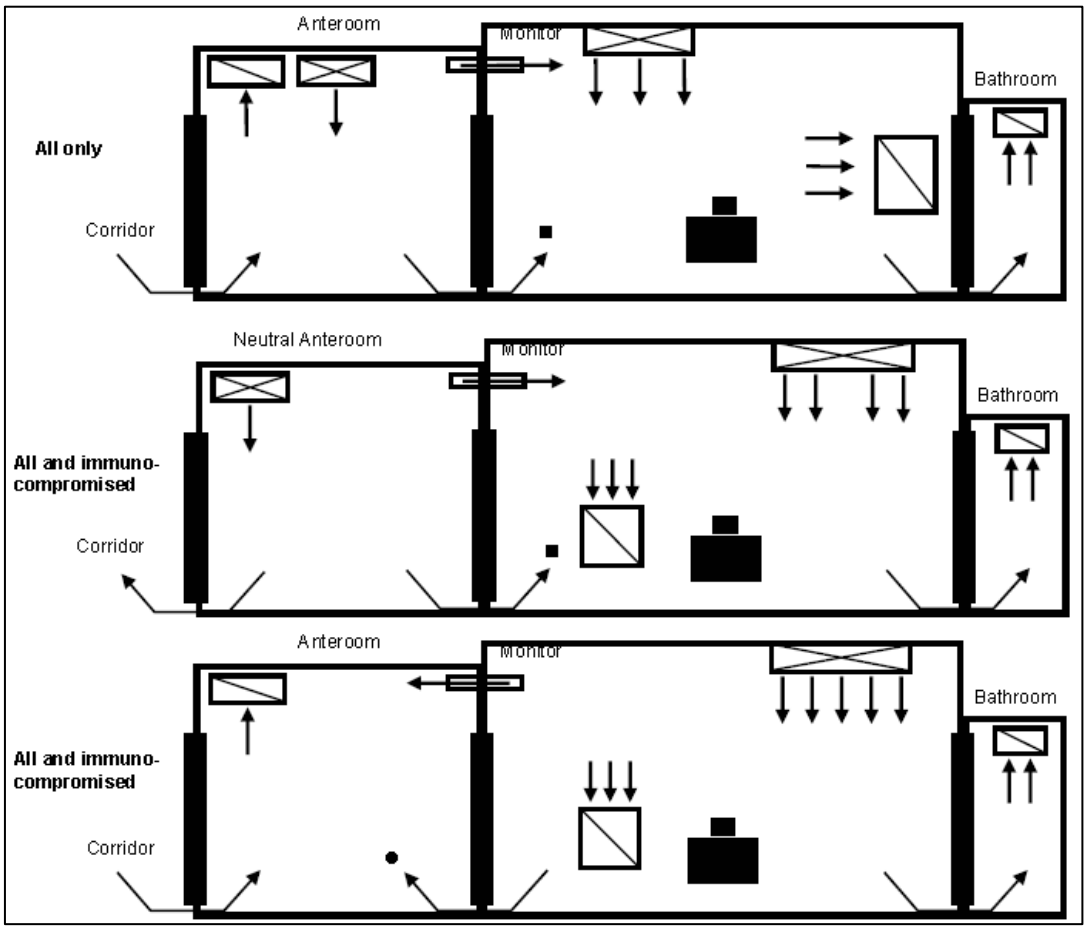
¶ This diagram is a generic illustration of air flow in a typical installation. Alternative air flow arrangements are recognized. Adapted and used with permission from A. Streifel and the publisher of reference 328 (Penton Media, Inc.)

One of the components of airborne infection isolation is respiratory protection for health-care workers and visitors when entering AII rooms.[4, 6, 347] Recommendations of the type of respiratory protection are dependent on the patient's airborne infection (indicating the need for AII) and the risk of infection to

persons entering the AII room. A more in-depth discussion of respiratory protection in this instance is presented in the current isolation guideline;[6] a revision of this guideline is in development. Cough-inducing procedures (e.g., endotracheal intubation and suctioning of known or suspected TB patients, diagnostic sputum induction, aerosol treatments, and bronchoscopy) require similar precautions.[348–350]

Additional engineering measures are necessary for the management of patients requiring PE (i.e., allogeneic HSCT patients) who concurrently have airborne infection. For this type of patient treatment, an anteroom (Figure 4) is required in new construction and renovation as per AIA guidelines.[120]

Figure 4. Example of airborne infection isolation (AII) room with anteroom and neutral anteroom* + §



* The top diagram indicates air flow patterns when patient with only airborne infectious disease occupies room. Middle and bottom diagrams indicate recommended air flow patterns when room is occupied by immunocompromised patient with airborne infectious disease. Stacked black boxes represent patient beds. Long open boxes with cross-hatches represent supply air. Open boxes with single, diagonal slashes represent air exhaust registers. Arrows indicate directions of air flow.

\+ AII isolation room with anteroom engineering features include

- pressure differential of 2.5 Pa (0.01-in. water gauge) measured at the door between patient room and anteroom;
- air flow volume differential >125-cfm. depending on anteroom air flow direction (pressurized versus depressurized);
- 38 sealed room with approximately 0.5-sq. ft. leakage;
- clean to dirty air flow
- monitoring;
- ≥12 air changes per hour (ACH) new or renovation, 6 ACH existing; and
- anteroom air flow patterns. The small ■ in panels 1 and 2 indicate the anteroom is pressurized

(supply versus exhaust), while the small • in panel 3 indicates the anteroom is depressurized (exhaust versus supply).

§ Used with permission of A. Streifel, University of Minnesota

The pressure differential of an anteroom can be positive or negative relative to the patient in the room.[120] An anteroom can act as an airlock (Figure 4). If the anteroom is positive relative to the air space in the patient's room, staff members do not have to mask prior to entry into the anteroom if air is directly exhausted to the outside and a minimum of 10 ACH (Figure 4, top diagram).[120] When an anteroom is negative relative to both the AII room and the corridor, health-care workers must mask prior to entering the anteroom (Figure 4, bottom diagram). If an AII room with an anteroom is not available, use of a portable, industrial-grade HEPA filter unit may help to increase the number of ACHs while facilitating the removal of fungal spores; however, a fresh air source must be present to achieve the proper air exchange rate. Incoming ambient air should receive HEPA filtration.

c. Operating Rooms

Operating room air may contain microorganisms, dust, aerosol, lint, skin squamous epithelial cells, and respiratory droplets. The microbial level in operating room air is directly proportional to the number of people moving in the room.[351] One study documented lower infection rates with coagulase-negative staphylococci among patients when operating room traffic during the surgical procedure was limited.[352] Therefore, efforts should be made to minimize personnel traffic during operations. Outbreaks of SSIs caused by group A beta-hemolytic streptococci have been traced to airborne transmission from colonized operating-room personnel to patients.[150–154] Several potential health-care associated pathogens (e.g., *Staphylococcus aureus* and *Staphylococcus epidermidis*) and drug-resistant organisms have also been recovered from areas adjacent to the surgical field,[353] but the extent to which the presence of bacteria near the surgical field influences the development of postoperative SSIs is not clear.[354]

Proper ventilation, humidity (<68%), and temperature control in the operating room is important for the comfort of surgical personnel and patients, but also in preventing environmental conditions that encourage growth and transmission of microorganisms.[355] Operating rooms should be maintained at positive pressure with respect to corridors and adjacent areas.[356] Operating rooms typically do not have a variable air handling system. Variable air handling systems are permitted for use in operating rooms only if they continue to provide a positive pressure with respect to the corridors and adjacent areas and the proper ACHs are maintained when the room is occupied. Conventional operating-room ventilation systems produce a minimum of about 15 ACH of filtered air for thermal control, three (20%) of which must be fresh air.[120, 357, 358] Air should be introduced at the ceiling and exhausted near the floor.[357, 359]

Laminar airflow and UVGI have been suggested as adjunct measures to reduce SSI risk for certain operations. Laminar airflow is designed to move particle-free air over the aseptic operating field at a uniform velocity (0.3–0.5 m/sec), sweeping away particles in its path. This air flow can be directed vertically or horizontally, and recirculated air is passed through a HEPA filter.[360–363] Neither laminar airflow nor UV light, however, has been conclusively shown to decrease overall SSI risk.[356, 364–370]

Elective surgery on infectious TB patients should be postponed until such patients have received adequate drug therapy. The use of general anesthesia in TB patients poses infection-control challenges because intubation can induce coughing, and the anesthesia breathing circuit apparatus potentially can become contaminated.[371] Although operating room suites at 15 ACH exceed the air exchanges required transmission of TB to operating-room personnel. If feasible, intubation and extubation of the TB surgical patient should be performed in AII. AIA currently does not recommend changing pressure from positive to negative or setting it to neutral; most facilities lack the capability to do so.[120] When

emergency surgery is indicated for a suspected/diagnosed infectious TB patient, taking specific infection-control measures is prudent (Box 8).

Box 8. Strategy for managing TB patients and preventing airborne transmission in operating rooms*

1. If emergency surgery is indicated for a patient with active TB, schedule the TB patient as the last surgical case to provide maximum time for adequate ACH.
2. Operating room personnel should use NIOSH-approved N95 respirators without exhalation valves.[347]
3. Keep the operating room door closed after the patient is intubated, and allow adequate time for sufficient ACH to remove 99% of airborne particles (Appendix B, Table B.1.):
   a. after the patient is intubated and particularly if intubation produces coughing
   b. if the door to the operating suite must be opened, and intubation induces coughing in the patient; or
   c. after the patient is extubated and suctioned [unless a closed suctioning system is present].
4. Extubate the patient in the operating room or allow the patient to recover in AII rather than in the regular open recovery facilities.
5. Temporary use of a portable, industrial grade HEPA filter may expedite removal of airborne contaminants (fresh-air exchange requirements for proper ventilation must still be met).+
6. Breathing circuit filters with 0.1–0.2 μm pore size can be used as an adjunct infection-control measure.[373, 374]

* Material in this table was compiled from references 4, 347, and 372–374.

\+ The placement of portable HEPA filter units in the operating room must be carefully evaluated for potential disruptions in normal air flow. The portable unit should be turned off while the surgical procedure is underway and turned on following extubation. Portable HEPA filter units previously placed in construction areas may be used in subsequent patient care, provided that all internal and external surfaces are cleaned and the filter's performance is verified with appropriate particle testing and is changed, if needed.

Table 10. Summary of ventilation specifications in selected areas of health-care facilities*

Specifications	AII room (includes bronchoscopy suites)	PE room	Critical care room§	Isolation anteroom	Operating room
Air pressure¶	Negative	Positive	Positive, negative, or neutral	Positive or negative	Positive
Room air changes	≥6 ACH (for existing rooms); ≥12 ACH (for renovation or new construction)	≥12 ACH	≥6 ACH	≥10 ACH	≥15 ACH
Sealed**	Yes	Yes	No	Yes	Yes
Filtration supply	90% (dust-spot ASHRAE 52.1 1992)	99.97% (Fungal spore filter at point of use (HEPA at 99.97% of 0.3 μm particles))	>90%	>90%	90%
Recirculation	No (Recirculated air may be used if the exhaust air is first processed through a HEPA filter.)	Yes	Yes	No	Yes

* Material in this table is compiled from references 35 and 120. Table used with permission of the publisher of reference 35 (Lippincott Williams and Wilkins).

§ Positive pressure and HEPA filters may be preferred in some rooms in intensive care units (ICUs) caring for large numbers of immunocompromised patients.
¶ Clean-to-dirty: negative to an infectious patient, positive away from an immunocompromised patient.
** Minimized infiltration for ventilation control; pertains to windows, closed doors, and surface joints.
¶¶ Table used with permission of the publisher of reference 35 (Lippincott Williams and Wilkins).

6. Other Aerosol Hazards in Health-Care Facilities

In addition to infectious bioaerosols, several crucial non-infectious, indoor air-quality issues must be addressed by health-care facilities. The presence of sensitizing and allergenic agents and irritants in the workplace (e.g., ethylene oxide, glutaraldehyde, formaldehyde, hexachlorophene, and latex allergens[375]) is increasing. Asthma and dermatologic and systemic reactions often result with exposure to these chemicals. Anesthetic gases and aerosolized medications (e.g., ribavirin, pentamidine, and aminoglycosides) represent some of the emerging potentially hazardous exposures to health-care workers. Containment of the aerosol at the source is the first level of engineering control, but personal protective equipment (e.g., masks, respirators, and glove liners) that distances the worker from the hazard also may be needed.

Laser plumes and surgical smoke represent another potential risk for health-care workers.[376–378] Lasers transfer electromagnetic energy into tissues, resulting in the release of a heated plume that includes particles, gases, tissue debris, and offensive smells. One concern is that aerosolized infectious material in the laser plume might reach the nasal mucosa of surgeons and adjacent personnel. Although some viruses (i.e., varicella-zoster virus, pseudorabies virus, and herpes simplex virus) do not aerosolize efficiently,[379, 380] other viruses and bacteria (e.g., human papilloma virus [HPV], HIV, coagulasenegative *Staphylococcus, Corynebacterium* spp., *and Neisseria* spp.) have been detected in laser plumes.[381–387] The presence of an infectious agent in a laser plume may not, however, be sufficient to cause disease from airborne exposure, especially if the normal mode of transmission for the agent is not airborne. No evidence indicated that HIV or hepatitis B virus (HBV) has been transmitted via aerosolization and inhalation.[388]

Although continuing studies are needed to fully evaluate the risk of laser plumes to surgical personnel, the prevention measures in these other guidelines should be followed:
a. NIOSH recommendations,[378]
b. the *Recommended Practices for Laser Safety in Practice Settings* developed by the Association of periOperative Registered Nurses [AORN],[389]
c. the assessments of ECRI,[390–392] and
d. the ANSI standard.[393]

These guidelines recommend the use of
a. respirators (N95 or N100) or full face shields and masks,[260]
b. central wall-suction units with in-line filters to collect particulate matter from minimal plumes, and
c. dedicated mechanical smoke exhaust systems with a high-efficiency filter to remove large amounts of laser plume.

Although transmission of TB has occurred as a result of abscess management practices that lacked airborne particulate control measures and respiratory protection, use of a smoke evacuator or needle aspirator and a high degree of clinical awareness can help protect healthcare workers when excising and draining an extrapulmonary TB abscess.[137]

D. Water

1. Modes of Transmission of Waterborne Diseases

Moist environments and aqueous solutions in health-care settings have the potential to serve as reservoirs for waterborne microorganisms. Under favorable environmental circumstances (e.g., warm temperature and the presence of a source of nutrition), many bacterial and some protozoal microorganisms can either

proliferate in active growth or remain for long periods in highly stable, environmentally resistant (yet infectious) forms. Modes of transmission for waterborne infections include

a. direct contact [e.g., that required for hydrotherapy];
b. ingestion of water [e.g., through consuming contaminated ice];
c. indirect-contact transmission [e.g., from an improperly reprocessed medical device];[6]
d. inhalation of aerosols dispersed from water sources;[3] and
e. aspiration of contaminated water.

The first three modes of transmission are commonly associated with infections caused by gram-negative bacteria and nontuberculous mycobacteria (NTM). Aerosols generated from water sources contaminated with *Legionella* spp. often serve as the vehicle for introducing legionellae to the respiratory tract.[394]

2. Waterborne Infectious Diseases in Health-Care Facilities

a. Legionellosis

Legionellosis is a collective term describing infection produced by *Legionella* spp., whereas Legionnaires disease is a multi-system illness with pneumonia.[395] The clinical and epidemiologic aspects of these diseases (Table 11) are discussed extensively in another guideline.[3] Although Legionnaires disease is a respiratory infection, infection-control measures intended to prevent healthcare-associated cases center on the quality of water—the principal reservoir for *Legionella* spp.

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 11. Clinical and epidemiologic characteristics of legionellosis/Legionnaires disease

Modes of transmission
- Aspiration of water, direct inhalation or water aerosols. [3, 394–398, 400]

Causative agent
- Legionella pneumophila (90% of infections); L. micdadei, L. bozemanii, L. dumoffii, L. longbeachii, (14 additional species can cause infection in humans). [395–399]

Source of exposure
- Exposure to environmental sources of *Legionella* spp. (i.e., water or water aerosols). [31, 33, 401–414]

Clinical syndromes and diseases

Two distinct illnesses: [397–399, 415–422]
- Pontiac fever [a milder, influenza-like illness]; and
- progressive pneumonia that may be accompanied by cardiac, renal, and gastrointestinal involvement [3]

Patient populations at greatest risk
- Immunosuppressed patients (e.g., transplant patients, cancer patients, and patients receiving corticosteroid therapy);
- Immunocompromised patients (e.g., surgical patients, patients with underlying chronic lung disease, and dialysis patients);
- Elderly persons; and
- Patients who smoke. [395–397, 423–433]

Occurrence
- Proportion of community-acquired pneumonia caused by *Legionella* spp. ranges from 1%–5%; estimated annual incidence among the general population is 8,000–18,000 cases in the United States; the incidence of healthcare-associated pneumonia (0%–14%) may be underestimated if appropriate laboratory diagnostic methods are unavailable. [396, 397, 434–444]

Mortality rate

- Mortality declined markedly during 1980–1998, from 34% to 12% for all cases; the mortality rate is higher among persons with health-care associated pneumonia compared with the rate among community-acquired pneumonia patients (14% for health-care associated pneumonia versus 10% for community-acquired pneumonia [1998 data]). [395–397, 445]

Legionella spp. are commonly found in various natural and man-made aquatic environments[446, 447] and can enter health-care facility water systems in low or undetectable numbers.[448, 449] Cooling towers, evaporative condensers, heated potable water distribution systems, and locally-produced distilled water can provide environments for multiplication of legionellae.[450–454] In several hospital outbreaks, patients have been infected through exposure to contaminated aerosols generated by cooling towers, showers, faucets, respiratory therapy equipment, and room-air humidifiers.[401–410, 455] Factors that enhance colonization and amplification of legionellae in man-made water environments include

a. temperatures of 77°F–107.6°F [25°C–42°C],[456–460]
b. stagnation,[461]
c. scale and sediment, [462] and
d. presence of certain free-living aquatic amoebae that can support intracellular growth of legionellae.[462, 463]

The bacteria multiply within single-cell protozoa in the environment and within alveolar macrophages in humans.

b. Other Gram-Negative Bacterial Infections

Other gram-negative bacteria present in potable water also can cause health-care associated infections. Clinically important, opportunistic organisms in tap water include *Pseudomonas aeruginosa, Pseudomonas* spp., *Burkholderia cepacia, Ralstonia pickettii, Stenotrophomonas maltophilia*, and *Sphingomonas* spp. (Tables 12 and 13). Immunocompromised patients are at greatest risk of developing infection. Medical conditions associated with these bacterial agents range from colonization of the respiratory and urinary tracts to deep, disseminated infections that can result in pneumonia and bloodstream bacteremia. Colonization by any of these organisms often precedes the development of infection. The use of tap water in medical care (e.g., in direct patient care, as a diluent for solutions, as a water source for medical instruments and equipment, and during the final stages of instrument disinfection) therefore presents a potential risk for exposure. Colonized patients also can serve as a source of contamination, particularly for moist environments of medical equipment (e.g., ventilators).

In addition to *Legionella* spp., *Pseudomonas aeruginosa* and *Pseudomonas* spp. are among the most clinically relevant, gram-negative, health-care associated pathogens identified from water. These and other gram-negative, non-fermentative bacteria have minimal nutritional requirements (i.e., these organisms can grow in distilled water) and can tolerate a variety of physical conditions. These attributes are critical to the success of these organisms as health-care associated pathogens. Measures to prevent the spread of these organisms and other waterborne, gram-negative bacteria include hand hygiene, glove use, barrier precautions, and eliminating potentially contaminated environmental reservoirs.[464, 465]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 12. *Pseudomonas aeruginosa* infections

Modes of transmission

- Direct contact with water, aerosols; aspiration of water and inhalation of water aerosols; and indirect transfer from moist environmental surfaces via hands of health-care workers. [28, 502–506]

Clinical syndromes and diseases

- Septicemia, pneumonia (particularly ventilator-associated), chronic respiratory infections among cystic fibrosis patients, urinary tract infections, skin and soft-tissue infections (e.g., tissue necrosis and hemorrhage), burn-wound infections, folliculitis, endocarditis, central nervous system infections (e.g., meningitis and abscess), eye infections, and bone and joint infections. [466–503]

Environmental sources of pseudomonads in healthcare settings

- Potable (tap) water, distilled water, antiseptic solutions contaminated with tap water, sinks, hydrotherapy pools, whirlpools and whirlpool spas, water baths, lithotripsy therapy tanks, dialysis water, eyewash stations, flower vases, and endoscopes with residual moisture in the channels. [28, 29, 466, 468, 507–520]

Environmental sources of pseudomonads in the community

- Fomites (e.g., drug injection equipment stored in contaminated water). [494, 495]

Patient populations at greatest risk

- Intensive care unit (ICU) patients (including neonatal ICU), transplant patients (organ and hematopoietic stem cell), neutropenic patients, burn therapy and hydrotherapy patients, patients with malignancies, cystic fibrosis patients, patients with underlying medical conditions, and dialysis patients.[28, 466, 467, 472, 477, 493, 506–508, 511, 512, 521–526]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 13. Other gram-negative bacteria associated with water and moist environments

Bacteria	Implicated contaminated environmental vehicle
Burkholderia cepacia	• Distilled water [527] • Contaminated solutions and disinfectants [528, 529] • Dialysis machines [527] • Nebulizers [530–532] • Water baths [533] • Intrinsically-contaminated mouthwash [534] (This report describes contamination occurring during manufacture prior to use by the health-care facility staff. All other entries reflect extrinsic sources of contamination.) • Ventilator temperature probes [535]
***Stenotrophomonas maltophlia, Sphingomonas* spp.**	• Distilled water [536, 537] • Contaminated solutions and disinfectants [529] • Dialysis machines [527] • Nebulizers [530–532] • Water [538] • Ventilator temperature probes [539]
Ralstonia pickettii	• Fentanyl solutions [540] • Chlorhexidine [541] • Distilled water [541] • Contaminated respiratory therapy solution [541, 542]
Serratia marcescens	• Potable water [543] • Contaminated antiseptics (i.e., benzalkonium chloride and chlorhexidine) [544–546] • Contaminated disinfectants (i.e., quaternary ammonium compounds and glutaraldehyde) [547, 548]
***Acinetobacter* spp.**	• Medical equipment that collects moisture (e.g., mechanical ventilators, cool mist humidifiers, vaporizers, and mist tents) [549–556] • Room humidifiers [553, 555] • Environmental surfaces [557–564]
***Enterobacter* spp.**	• Humidifier water [565] • Intravenous fluids [566–578] • Unsterilized cotton swabs [573] • Ventilators [565, 569] • Rubber piping on a suctioning machine [565, 569] • Blood gas analyzers [570]

Two additional gram-negative bacterial pathogens that can proliferate in moist environments are *Acinetobacter* spp. and *Enterobacter* spp. [571, 572] Members of both genera are responsible for healthcare–

associated episodes of colonization, bloodstream infections, pneumonia, and urinary tract infections among medically compromised patients, especially those in ICUs and burn therapy units.[566, 572–583]

Infections caused by *Acinetobacter* spp. represent a significant clinical problem. Average infection rates are higher from July through October compared with rates from November through June.[584] Mortality rates associated with *Acinetobacter* bacteremia are 17%–52%, and rates as high as 71% have been reported for pneumonia caused by infection with either *Acinetobacter* spp. or *Pseudomonas* spp.Multi-drug resistance, especially in third generation cephalosporins for *Enterobacter* spp., contributes to increased morbidity and mortality.[569, 572]

Patients and health-care workers contribute significantly to the environmental contamination of surfaces and equipment with *Acinetobacter* spp. and *Enterobacter* spp., especially in intensive care areas, because of the nature of the medical equipment (e.g., ventilators) and the moisture associated with this equipment.[549, 571, 572, 585]

Hand carriage and hand transfer are commonly associated with health-care– associated transmission of these organisms and for *S. marcescens*. [586] *Enterobacter* spp. are primarily spread in this manner among patients by the hands of health-care workers.[567, 587] *Acinetobacter* spp. have been isolated from the hands of 4%–33% of health-care workers in some studies,[585–590] and transfer of an epidemic strain of *Acinetobacter* from patients' skin to health-care workers' hands has been demonstrated experimentally.[591] *Acinetobacter* infections and outbreaks have also been attributed to medical equipment and materials (e.g., ventilators, cool mist humidifiers, vaporizers, and mist tents) that may have contact with water of uncertain quality (e.g., rinsing a ventilator circuit in tap water).[549– 556] Strict adherence to hand hygiene helps prevent the spread of both *Acinetobacter* spp. and *Enterobacter* spp.[577, 592]

Acinetobacter spp. have also been detected on dry environmental surfaces (e.g., bed rails, counters, sinks, bed cupboards, bedding, floors, telephones, and medical charts) in the vicinity of colonized or infected patients; such contamination is especially problematic for surfaces that are frequently touched.[557–564] In two studies, the survival periods of *Acinetobacter baumannii* and *Acinetobacter calcoaceticus* on dry surfaces approximated that for *S. aureus* (e.g., 26–27 days).[593, 594] Because *Acinetobacter* spp. may come from numerous sources at any given time, laboratory investigation of health-care associated *Acinetobacter* infections should involve techniques to determine biotype, antibiotype, plasmid profile, and genomic fingerprinting (i.e., macrorestriction analysis) to accurately identify sources and modes of transmission of the organism(s).[595]

c. Infections and Pseudo-Infections Due to Nontuberculous Mycobacteria

NTM are acid-fast bacilli (AFB) commonly found in potable water. NTM include both saprophytic and opportunistic organisms. Many NTM are of low pathogenicity, and some measure of host impairment is necessary to enhance clinical disease.[596] The four most common forms of human disease associated with NTM are

a. pulmonary disease in adults;
b. cervical lymph node disease in children;
c. skin, soft tissue, and bone infections; and
d. disseminated disease in immunocompromised patients.[596, 597]

Person-to-person acquisition of NTM infection, especially among immunocompetent persons, does not appear to occur, and close contacts of patients are not readily infected, despite the high numbers of organisms harbored by such patients.[596, 598–600] NTM are spread via all modes of transmission associated with water. In addition to health-care associated outbreaks of clinical disease, NTM can colonize patients in health-care facilities through consumption of contaminated water or ice or through inhalation of aerosols.[601–605] Colonization following NTM exposure, particularly of the respiratory tract, occurs when a patient's local defense mechanisms are impaired; overt clinical disease does not develop.[606] Patients may have positive sputum cultures in the absence of clinical disease.

Using tap water during patient procedures and specimen collection and in the final steps of instrument reprocessing can result in pseudo-outbreaks of NTM contamination.[607– 609] NTM pseudo-outbreaks of *Mycobacterium chelonae, M. gordonae,* and *M. xenopi* have been associated with both bronchoscopy and gastrointestinal endoscopy when

a. tap water is used to provide irrigation to the site or to rinse off the viewing tip *in situ* or
b. the instruments are inappropriately reprocessed with tap water in the final steps.[610– 612]

Table 14. Nontuberculous mycobacteria—environmental vehicles

Table 14a. Infections or colonizations

Pathogen	Vehicles associated with infections or colonizations
Mycobacterium abscessus	• Inadequately sterilized medical instruments [613]
***Mycobacterium avium* complex (MAC)**	• Potable water [614–616]
Mycobacterium chelonae	• Dialysis, reprocessed dialyzers [31, 32] • Inadequately-sterilized medical instruments, jet injectors [617, 618] • Contaminated solutions [619, 620] • Hydrotherapy tanks [621]
Mycobacterium fortuitum	• Aerosols from showers or other water sources [605, 606] • Ice [602] • Inadequately sterilized medical instruments [603] • Hydrotherapy tanks [622]
Mycobacterium marinum	• Hydrotherapy tanks [623]
Mycobacterium ulcerans	• Potable water [624]

Table 14b. Pseudo-outbreaks

Pathogen	Vehicles associated with pseudo-outbreaks
Mycobacterium chelonae	• Potable water used during bronchoscopy and instrument reprocessing [610]
Mycobacterium fortuitum	• Ice [607]
Mycobacterium gordonae	• Deionized water [611] • Ice [603] • Laboratory solution (intrinsically contaminated [625] • Potable water ingestion prior to sputum specimen collection [626]
Mycobacterium kansasii	• Potable water [627]
Mycobacterium terrae	• Potable water [608]
Mycobacterium xenopi	• Potable water [609, 612, 627]

NTM can be isolated from both natural and man-made environments. Numerous studies have identified [632] Some NTM species (e.g., *Mycobacterium xenopi*) can survive in water at 113°F (45°C), and can be isolated from hot water taps, which can pose a problem for hospitals that lower the temperature of their hot water systems.[627] Other NTM (e.g., *Mycobacterium kansasii, M. gordonae, M. fortuitum*, and *M. chelonae*) cannot tolerate high temperatures and are associated more often with cold water lines and taps.[629]

NTM have a high resistance to chlorine; they can tolerate free chlorine concentrations of 0.05–0.2 mg/L (0.05–0.2 ppm) found at the tap.[598, 633, 634] They are 20–100 times more resistant to chlorine compared with coliforms; slow-growing strains of NTM (e.g., *Mycobacterium avium* and *M. kanasii*) appear to be

more resistant to chorine inactivation compared to fast-growing NTM.[635] Slow-growing NTM species have also demonstrated some resistance to formaldehyde and glutaraldehyde, which has posed problems for reuse of hemodialyzers.[31] The ability of NTM to form biofilms at fluid-surface interfaces (e.g., interior surfaces of water pipes) contributes to the organisms' resistance to chemical inactivation and provides a microenvironment for growth and proliferation.[636, 637]

d. Cryptosporidiosis

Cryptosporidium parvum is a protozoan parasite that causes self-limiting gastroenteritis in normal hosts but can cause severe, life-threatening disease in immunocompromised patients. First recognized as a human pathogen in 1976, *C. parvum* can be present in natural and finished waters after fecal contamination from either human or animal sources.[638–641]

The health risks associated with drinking potable water contaminated with minimal numbers of *C. parvum* oocysts are unknown.[642] It remains to be determined if immunosuppressed persons are more susceptible to lower doses of oocysts than are immunocompetent persons. One study demonstrated that a median 50% infectious dose (ID50) of 132 oocysts of calf origin was sufficient to cause infection among healthy volunteers.[643] In a second study, the same researchers found that oocysts obtained from infected foals (newborn horses) were infectious for human volunteers at median ID50 of 10 oocysts, indicating that different strains or species of *Cryptosporidium* may vary in their infectivity for humans.[644] In a small study population of 17 healthy adults with pre-existing antibody to *C. parvum*, the ID50 was determined to be 1,880 oocysts, more than 20-fold higher than in seronegative persons.[645] These data suggest that pre-existing immunity derived from previous exposures to *Cryptosporidium* offers some protection from infection and illness that ordinarily would result from exposure to low numbers of oocysts.[645, 646]

Oocysts, particularly those with thick walls, are environmentally resistant, but their survival under natural water conditions is poorly understood. Under laboratory conditions, some oocysts remain viable and infectious in cold (41°F [5°C]) for months.[641] The prevalence of *Cryptosporidium* in the U.S. drinking water supply is notable. Two surveys of approximately 300 surface water supplies revealed that 55%–77% of the water samples contained *Cryptosporidium* oocysts.[647, 648] Because the oocysts are highly resistant to common disinfectants (e.g., chlorine) used to treat drinking water, filtration of the water is important in reducing the risk of waterborne transmission. Coagulation-floculation and sedimentation, when used with filtration, can collectively achieve approximately a 2.5 log10 reduction in the number of oocysts.[649] However, outbreaks have been associated with both filtered and unfiltered drinking water systems (e.g., the 1993 outbreak in Milwaukee, Wisconsin that affected 400,000 people).[641, 650–652] The presence of oocysts in the water is not an absolute indicator that infection will occur when the water is consumed, nor does the absence of detectable oocysts guarantee that infection will not occur. Health-care associated outbreaks of cryptosporidiosis primarily have been described among groups of elderly patients and immunocompromised persons.[653]

3. Water Systems in Health-Care Facilities

a. Basic Components and Point-of-Use Fixtures

Treated municipal water enters a health-care facility via the water mains and is distributed throughout the building(s) by a network of pipes constructed of galvanized iron, copper, and polyvinylchloride (PVC). The pipe runs should be as short as is practical. Where recirculation is employed, the pipe runs should be insulated and long dead legs avoided in efforts to minimize the potential for water stagnation, which favors the proliferation of *Legionella* spp. and NTM. In high-risk applications (e.g., PE areas for severely immunosuppressed patients), insulated recirculation loops should be incorporated as a design minimal loss.

Each water service main, branch main, riser, and branch (to a group of fixtures) has a valve and a means to reach the valves via an access panel.[120] Each fixture has a stop valve. Valves permit the isolation of a portion of the water system within a facility during repairs or maintenance. Vacuum breakers and other similar devices in the lines prevent water from back-flowing into the system. All systems that supply water should be evaluated to determine risk for potential back siphonage and cross connections.

Health-care facilities generate hot water from municipal water using a boiler system. Hot water heaters and storage vessels for such systems should have a drainage facility at the lowest point, and the heating element should be located as close as possible to the bottom of the vessel to facilitate mixing and to prevent water temperature stratification. Those hot or cold water systems that incorporate an elevated holding tank should be inspected and cleaned annually. Lids should fit securely to exclude foreign materials.

The most common point-of-use fixtures for water in patient-care areas are sinks, faucets, aerators, showers, and toilets; eye-wash stations are found primarily in laboratories. The potential for these fixtures to serve as a reservoir for pathogenic microorganisms has long been recognized (Table 15).[509, 654–656]

Wet surfaces and the production of aerosols facilitate the multiplication and dispersion of microbes. The level of risk associated with aerosol production from point-of-use fixtures varies. Aerosols from shower heads and aerators have been linked to a limited number of clusters of gram-negative bacterial colonizations and infections, including Legionnaires disease, especially in areas where immunocompromised patients are present (e.g., surgical ICUs, transplant units, and oncology units).[412, 415, 656–659]

In one report, clinical infection was not evident among immunocompetent persons (e.g., hospital staff) who used hospital showers when *Legionella pneumophila* was present in the water system.[660] Given the infrequency of reported outbreaks associated with faucet aerators, consensus has not been reached regarding the disinfection of or removal of these devices from general use. If additional clusters of infections or colonizations occur in high-risk patient-care areas, it may be prudent to clean and decontaminate the aerators or to remove them.[658, 659] ASHRAE recommends cleaning and monthly disinfection of aerators in high-risk patient-care areas as part of *Legionella* control measures.[661] Although aerosols are produced with toilet flushing,[662, 663] no epidemiologic evidence suggests that these aerosols pose a direct infection hazard.

Although not considered a standard point-of-use fixture, decorative fountains are being installed in increasing numbers in health-care facilities and other public buildings. Aerosols from a decorative fountain have been associated with transmission of *Legionella pneumophila* serogroup 1 infection to a small cluster of older adults.[664] This hotel lobby fountain had been irregularly maintained, and water in the fountain may have been heated by submersed lighting, all of which favored the proliferation of *Legionella* in the system.[664] Because of the potential for generations of infectious aerosols, a prudent prevention measure is to avoid locating these fixtures in or near high-risk patient-care areas and to adhere to written policies for routine fountain maintenance.[120]

Table 15. Water and point-of-use fixtures as sources and reservoirs of waterborne pathogens*

Reservoir	Associated pathogens	Transmission	Strength of evidence+	Prevention and control	References
Potable water	*Pseudomonas*, gram-negative bacteria, NTM	Contact	**Moderate:** occasional well-described outbreaks.	Follow public health guidelines.	(See Tables 12–14)
Potable water	Legionella	Aerosol inhalation	**Moderate:** occasional well-described outbreaks.	Provide supplemental treatment for water.	(See Table 11)

Reservoir	Associated pathogens	Transmission	Strength of evidence+	Prevention and control	References
Holy water	Gram-negative bacteria	Contact	**Low:** few well-described outbreaks	Avoid contact with severe burn injuries. Minimize use among immunocompromised patients.	665
Dialysis water	Gram-negative bacteria	Contact	**Moderate:** occasional well-described outbreaks.	Dialysate should be ≤2,000 cfu/mL; water should be ≤200 cfu/mL.	2, 527, 666– 668
Automated endoscope reprocessors and rinse water	Gram-negative bacteria	Contact	**Moderate:** occasional well-described outbreaks.	Use and maintain equipment according to instructions; eliminate residual moisture by drying the channels (e.g., through alcohol rinse and forced air drying).	669–675
Water baths	Pseudomonas, Burkholderia, Acinetobacter	Contact	**Moderate:** occasional well-described outbreaks.	Add germicide to the water; wrap transfusion products in protective plastic wrap if using the bath to modulate the temperature of these products.	29, 533, 676, 677
Tub immersion	Pseudomonas, Enterobacter, Acinetobacter	Contact	**Moderate:** occasional well-described outbreaks.	Drain and disinfect tub after each use; consider adding germicide to the water; water in large hydrotherapy pools should be properly disinfected and filtered.	678–683
Ice and ice machines	NTM, Enterobacter, Pseudomonas, Cryptosporidium Legionella	Ingestion, contact	**Moderate:** occasional well-described outbreaks. **Low:** few well-described outbreaks	Clean periodically; use automatic dispenser (avoid open chest storage compartments in patient areas).	601, 684–687
Faucet aerators	Legionella	Aerosol inhalation	**Moderate:** occasional well-described outbreaks.	Clean and disinfect monthly in high-risk patient areas; consider removing if additional infections occur.	415, 661
Faucet aerators	Pseudomonas, Acinetobacter, Stenotrophomonas, Chryseobacterium	Contact, droplet	**Low:** few well-described outbreaks	No precautions are necessary at present in immunocompetent patient-care areas.	658, 659, 688, 689
Sinks	Pseudomonas	Contact, droplet	**Moderate:** occasional well-described outbreaks.	Use separate sinks for handwashing and disposal of contaminated fluids.	509, 653, 685–693
Showers	Legionella	Aerosol inhalation	**Low:** few well-described outbreaks	Provide sponge baths for hematopoietic stem cell transplant patients; avoid shower use for immunocompromised patients when Legionella is detected in facility water.	656
Dental unit water lines	Pseudomonas, Legionella, Sphingomonas, Acinetobacter	Contact	**Low:** few well-described outbreaks	Clean water systems according to system manufacturer's instructions.	636, 694–696

Reservoir	Associated pathogens	Transmission	Strength of evidence+	Prevention and control	References
Ice baths for thermodilution catheters	Ewingella, Staphylococcus	Contact	**Low:** few well-described outbreaks	Use sterile water.	697, 698
Decorative fountains	Legionella	Aerosol inhalation	**Low:** few well-described outbreaks	Perform regular maintenance, including water disinfection; avoid use in or near high-risk patient-care areas.	664
Eyewash stations	Pseudomonas, amoebae, Legionella	Contact	**Low:** few well-described outbreaks **Minimal:** actual infections not demonstrated.	Flush eyewash stations weekly; have sterile water available for eye flushes.	518, 699, 700
Toilets	Gram-negative bacteria	n/a	**Minimal:** actual infections not demonstrated.	Clean regularly; use good hand hygiene.	662
Flowers	Gram-negative bacteria, Aspergillus	n/a	**Minimal:** actual infections not demonstrated.	Avoid use in intensive care units and in immunocompromised patient-care settings.	515, 701, 702

b. Water Temperature and Pressure

Hot water temperature is usually measured at the point of use or at the point at which the water line enters equipment requiring hot water for proper operation.[120] Generally, the hot water temperature in hospital patient-care areas is no greater than a temperature within the range of 105°F–120°F (40.6°C– 49°C), depending on the AIA guidance issued at the year in which the facility was built.[120] Hot water temperature in patient-care areas of skilled nursing-care facilities is set within a slightly lower range of 95°F–110°F (35°C–43.3°C) depending on the AIA guidance at the time of facility construction.[120] Many states have adopted a temperature setting in these ranges into their health-care regulations and building codes. ASHRAE, however, has recommended higher settings.[661] Steam jets or booster heaters are usually needed to meet the hot water temperature requirements in certain service areas of the hospital (e.g., the kitchen [120°F (49°C)] or the laundry [160°F (71°C)]).[120] Additionally, water lines may need to be heated to a particular temperature specified by manufacturers of specific hospital equipment. Hot-water distribution systems serving patient-care areas are generally operated under constant recirculation to provide continuous hot water at each hot-water outlet.[120] If a facility is or has a hemodialysis unit, then continuously circulated, cold treated water is provided to that unit.[120]

To minimize the growth and persistence of gram-negative waterborne bacteria (e.g., thermophilic NTM and *Legionella* spp.),[627, 703–709] cold water in health-care facilities should be stored and distributed at temperatures below 68°F (20°C); hot water should be stored above 140°F (60°C) and circulated with a minimum return temperature of 124°F (51°C),[661] or the highest temperature specified in state regulations and building codes. If the return temperature setting of 124°F (51°C) is permitted, then installation of preset thermostatic mixing valves near the point-of-use can help to prevent scalding. Valve maintenance is especially important in preventing valve failure, which can result in scalding. New shower systems in large buildings, hospitals, and nursing homes should be designed to permit mixing of hot and cold water near the shower head. The warm water section of pipe between the control valve and shower head should be self-draining. Where buildings can not be retrofitted, other approaches to minimize the growth of *Legionella* spp. include

a. periodically increasing the temperature to at least 150°F [66°C] at the point of use [i.e., faucets] and
b. adding additional chlorine and flushing the water. [661, 710, 711]

Systems should be inspected annually to ensure that thermostats are functioning properly.

Adequate water pressure ensures sufficient water supplies for
a. direct patient care;
b. operation of water-cooled instruments and equipment [e.g., lasers, computer systems, telecommunications systems, and automated endoscope reprocessors[712]];
c. proper function of vacuum suctioning systems;
d. indoor climate control; and
e. fire-protection systems.

Maintaining adequate pressure also helps to ensure the integrity of the piping system.

c. Infection-Control Impact of Water System Maintenance and Repair

Corrective measures for water-system failures have not been studied in well-designed experiments; these measures are instead based on empiric engineering and infection-control principles. Health-care facilities can occasionally sustain both intentional cut-offs by the municipal water authority to permit new construction project tie-ins and unintentional disruptions in service when a water main breaks as a result of aging infrastructure or a construction accident. Vacuum breakers or other similar devices can prevent backflow of water in the facility's distribution system during water-disruption emergencies.[11] To be prepared for such an emergency, all health-care facilities need contingency plans that identify
a. the total demand for potable water,
b. the quantity of replacement water [e.g., bottled water] required for a minimum of 24 hours when the water system is down,
c. mechanisms for emergency water distribution, and
d. procedures for correcting drops in water pressure that affect operation of essential devices and equipment that are driven or cooled by a water system [Table 16].[713]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 16. Water demand in health-care facilities during water disruption emergencies

Potable water use	Bottled, sterile water use
• Drinking water • Handwashing • Cafeteria services • Ice • Manual flushing of toilets • Patient baths, hygiene • Hemodialysis • Hydrotherapy • Fire prevention (e.g., sprinkler systems) • Surgery and critical care areas • Laboratory services • Laundry and central sterile services (Arrange to have a contingency provision of these services from another resource, if possible (e.g., another health-care facility or contractor).) • Cooling towers (Some cooling towers may use a potable water source, but most units use non-potable water.) • Steam generation	• Surgical scrub • Emergency surgical procedures • Pharmaceutical preparations • Patient-care equipment (e.g., ventilators) (This item is included in the table under the assumption that electrical power is available during the water emergency.)

Detailed, up-to-date plans for hot and cold water piping systems should be readily available for maintenance and repair purposes in case of system problems. Opening potable water systems for repair or construction and subjecting systems to water-pressure changes can result in water discoloration and dramatic increases in the concentrations of *Legionella* spp. and other gram-negative bacteria. The maintenance of a chlorine residual at all points within the piping system also offers some protection from entry of contamination to the pipes in the event of inadvertent cross-connection between potable and non-potable water lines. As a minimum preventive measure, ASHRAE recommends a thorough flushing of

the system.[661] High-temperature flushing or hyperchlorination may also be appropriate strategies to decrease potentially high concentrations of waterborne organisms. The decision to pursue either of these remediation strategies, however, should be made on a case-by-case basis. If only a portion of the system is involved, high temperature flushing or chlorination can be used on only that portion of the system.[661]

When shock decontamination of hot water systems is necessary (e.g., after disruption caused by construction and after cross-connections), the hot water temperature should be raised to 160°F–170°F (71°C–77°C) and maintained at that level while each outlet around the system is progressively flushed. A minimum flush time of 5 minutes has been recommended;[3] the optimal flush time is not known, however, and longer flush times may be necessary.[714] The number of outlets that can be flushed simultaneously depends on the capacity of the water heater and the flow capability of the system. Appropriate safety procedures to prevent scalding are essential. When possible, flushing should be performed when the fewest building occupants are present (e.g., during nights and weekends).

When thermal shock treatment is not possible, shock chlorination may serve as an alternative method.[661] Experience with this method of decontamination is limited, however, and high levels of free chlorine can corrode metals. Chlorine should be added, preferably overnight, to achieve a free chlorine residual of at least 2 mg/L (2 ppm) throughout the system.[661] This may require chlorination of the water heater or tank to levels of 20–50 mg/L (20–50 ppm). The pH of the water should be maintained at 7.0–8.0.[661] After completion of the decontamination, recolonization of the hot water system is likely to occur unless proper temperatures are maintained or a procedure such as continuous supplemental chlorination is continued.

Interruptions of the water supply and sewage spills are situations that require immediate recovery and remediation measures to ensure the health and safety of patients and staff.[715] When delivery of potable water through the municipal distribution system has been disrupted, the public water supplier must issue a "boil water" advisory if microbial contamination presents an immediate public health risk to customers. The hospital engineer should oversee the restoration of the water system in the facility and clear it for use when appropriate. Hospitals must maintain a high level of surveillance for waterborne disease among patients and staff after the advisory is lifted.[642]

Flooding from either external (e.g., from a hurricane) or internal sources (e.g., a water system break) usually results in property damage and a temporary loss of water and sanitation.[716–718] JCAHO requires all hospitals to have plans that address facility response for recovery from both internal and external disasters.[713, 719] The plans are required to discuss

a. general emergency preparedness,
b. staffing,
c. regional planning among area hospitals,
d. emergency supply of potable water,
e. infection control and medical services needs,
f. climate control, and
g. remediation.

The basic principles of structural recovery from flooding are similar to those for recovery from sewage contamination (Box 9 and 10). Following a major event (e.g., flooding), facilities may elect to conduct microbial sampling of water after the system is restored to verify that water quality has been returned to safe levels (<500 CFU/mL, heterotrophic plate count). This approach may help identify point-of-use fixtures that may harbor contamination as a result of design or engineering features.[720] Medical records should be allowed to dry and then either photocopied or placed in plastic covers before returning them to the record.

Moisture meters can be used to assess water-damaged structural materials. If porous structural materials for walls have a moisture content of >20% after 72 hours, the affected material should be removed.[266, 278, 313] The management of water-damaged structural materials is not strictly limited to major water catastrophes (e.g., flooding and sewage intrusions); the same principles are used to evaluate the damage

from leaking roofs, point-of-use fixtures, and equipment. Additional sources of moisture include condensate on walls from boilers and poorly engineered humidification in HVAC systems.

Box 9. Recovery and remediation measures for water-related emergencies*

Potable water disruptions

- **Contingency plan items**
  - Ensure access to plumbing network so that repairs can be easily made.
  - Provide sufficient potable water, either from bottled sources or truck delivery.
  - Post advisory notices against consuming tap water, ice, or beverages made with water.
  - Rope off or bag drinking fountains to designate these as being "out of service" until further notice.
  - Rinse raw foods as needed in disinfected water.
  - Disconnect ice machines whenever possible. (Ice machines should always be disconnected from the water source in advance of planned water disruptions.)
  - Postpone laundry services until after the water system is restored.
- **Water treatment**
  - Heat water to a rolling boil for ≥1 minute.
- **Remediation of the water system after the "boil water" advisory is rescinded**
  - Flush fixtures (e.g., faucets and drinking fountains) and equipment for several minutes and restart.
  - Run water softeners through a regeneration cycle.
  - Drain, disinfect, and refill water storage tanks, if needed.
  - Change pretreatment filters and disinfect the dialysis water system.

Sewage spills/malfunction

- **Overall strategy**
  - Move patients and clean/sterile supplies out of the area.
  - Redirect traffic away from the area.
  - Close the doors or use plastic sheeting to isolate the area prior to clean-up.
  - Restore sewage system function first, then the potable water system (if both are malfunctioning).
  - Remove sewage solids, drain the area, and let dry.
- **Remediation of the structure**
  - Hard surfaces: clean with detergent/disinfectant after the area has been drained.
  - Carpeting, loose tiles, buckled flooring: remove and allow the support surface to dry; replace the items; wet down carpeting with a low-level disinfectant or sanitizer prior to removal to minimize dust dispersion to the air.
  - Wallboard and other porous structural materials: remove and replace if they cannot be cleaned and dried within 72 hours. (Moisture meter readings should be <20% moisture content.)
- **Furniture**
  - Hard surface furniture (e.g., metal or plastic furniture): clean and allow to dry.
  - Wood furniture: let dry, sand the wood surface, and reapply varnish.
  - Cloth furniture: replace.
- **Electrical equipment**
  - Replace if the item cannot be easily dismantled, cleaned, and reassembled.

* Material in this box is compiled from references 266, 278, 315, 713, 716–719, 721–729.

An exception to these recommendations is made for hemodialysis units where water is further treated either by portable water treatment or large-scale water treatment systems usually involving reverse osmosis (RO). In the United States, >97% of dialysis facilities use RO treatment for their water.[721] However, changing pre-treatment filters and disinfecting the system to prevent colonization of the RO membrane and microbial contamination down-stream of the pre-treatment filter are prudent measures.

Box 10. Contingency planning for flooding

General emergency preparedness

- Ensure that emergency electrical generators are not located in flood-prone areas of the facility.
- Develop alternative strategies for moving patients, water containers, medical records, equipment, and supplies in the event that the elevators are inoperable.
- Establish in advance a centralized base of operations with batteries, flashlights, and cellular phones.
- Ensure sufficient supplies of sandbags to place at the entrances and the area around boilers, incinerators, and generators.
- Establish alternative strategies for bringing core employees to the facility if high water prevents travel.

Staffing Patterns

- Temporarily reassign licensed staff as needed to critical care areas to provide manual ventilation and to perform vital assessments on patients.
- Designate a core group of employees to remain on site to keep all services operational if the facility remains open.
- Train all employees in emergency preparedness procedures.

Regional planning among are facilities for disaster management

- Incorporate community support and involvement (e.g., media alerts, news, and transportation).
- Develop in advance strategies for transferring patients, as needed.
- Develop strategies for sharing supplies and providing essential services among participating facilities (e.g., central sterile department services, and laundry services).
- Identify sources for emergency provisions (e.g., blood, emergency vehicles, and bottled water).

Medical services and infection control

- Use alcohol-based hand rubs in general patient-care areas.
- Postpone elective surgeries until full services are restored, or transfer these patients to other facilities.
- Consider using portable dialysis machines. (Portable dialysis machines require less water compared to the larger units situated in dialysis settings.)
- Provide an adequate supply of tetanus and hepatitis A immunizations for patients and staff.

Climate control

- Provide adequate water for cooling towers. (Water for cooling towers may need to be trucked in, especially if the tower uses a potable water source.)

* Material in this box was compiled from references 713, 716–719.

4. Strategies for Controlling Waterborne Microbial Contamination

a. Supplemental Treatment of Water with Heat and/or Chemicals

In addition to using supplemental treatment methods as remediation measures after inadvertent contamination of water systems, health-care facilities sometimes use special measures to control waterborne microorganisms on a sustained basis. This decision is most often associated with outbreaks of legionellosis and subsequent efforts to control legionellae,[722] although some facilities have tried supplemental measures to better control thermophilic NTM.[627]

The primary disinfectant for both cold and hot water systems is chlorine. However, chlorine residuals are expected to be low, and possibly nonexistent, in hot water tanks because of extended retention time in the tank and elevated water temperature. Flushing, especially that which removes sludge from the bottom of the tank, probably provides the most effective treatment of water systems. Unlike the situation for disinfecting cooling towers, no equivalent recommendations have been made for potable water systems, although specific intervention strategies have been published.[403, 723] The principal approaches to disinfection of potable systems are heat flushing using temperatures 160°F–170°F (71°– 77°C), hyperchlorination, and physical cleaning of hot-water tanks.[3, 403, 661] Potable systems are easily recolonized and may require continuous intervention (e.g., raising of hot water temperatures or continuous

chlorination).[403, 711] Chlorine solutions lose potency over time, thereby rendering the stocking of large quantities of chlorine impractical.

Some hospitals with hot water systems identified as the source of *Legionella* spp. have performed emergency decontamination of their systems by pulse (i.e., one-time) thermal disinfection/superheating or hyperchlorination.[711, 714, 724, 725] After either of these procedures, hospitals either maintain their heated water with a minimum return temperature of 124°F (51°C) and cold water at <68°F (<20°C) or chlorinate their hot water to achieve 1–2 mg/L (1–2 ppm) of free residual chlorine at the tap.[26, 437, 709–711, 726, 727]

Additional measures (e.g., physical cleaning or replacement of hot-water storage tanks, water heaters, faucets, and shower heads) may be required to help eliminate accumulations of scale and sediment that protect organisms from the biocidal effects of heat and chlorine.[457, 711] Alternative methods for controlling and eradicating legionellae in water systems (e.g., treating water with chlorine dioxide, heavy metal ions [i.e., copper/silver ions], ozone, and UV light) have limited the growth of legionellae under laboratory and operating conditions.[728–742] Further studies on the long-term efficacy of these treatments are needed before these methods can be considered standard applications.

Renewed interest in the use of chloramines stems from concerns about adverse health effects associated with disinfectants and disinfection by-products.[743] Monochloramine usage minimizes the formation of disinfection by-products, including trihalomethanes and haloacetic acids. Monochloramine can also reach distal points in a water system and can penetrate into bacterial biofilms more effectively than free chlorine.[744] However, monochloramine use is limited to municipal water treatment plants and is currently not available to health-care facilities as a supplemental water-treatment approach. A recent study indicated that 90% of Legionnaires disease outbreaks associated with drinking water could have been prevented if monochloramine rather than free chlorine has been used for residual disinfection.[745] In a retrospective comparison of health-care associated Legionnaires disease incidence in central Texas hospitals, the same research group documented an absence of cases in facilities located in communities with monochloramine-treated municipal water.[746] Additional data are needed regarding the effectiveness of using monochloramine before its routine use as a disinfectant in water systems can be recommended. No data have been published regarding the effectiveness of monochloramine installed at the level of the health-care facility.

Additional filtration of potable water systems is not routinely necessary. Filters are used in water lines in dialysis units, however, and may be inserted into the lines for specific equipment (e.g., endoscope washers and disinfectors) for the purpose of providing bacteria-free water for instrument reprocessing. Additionally, an RO unit is usually added to the distribution system leading to PE areas.

b. Primary Prevention of Legionnaires Disease (No Cases Identified)

The primary and secondary environmental infection-control strategies described in this section on the guideline pertain to health-care facilities without transplant units. Infection-control measures specific to PE or transplant units (i.e., patient-care areas housing patients at the highest risk for morbidity and mortality from *Legionella* spp. infection) are described in the subsection titled *Preventing Legionnaires Disease in Protective Environments*.

Health-care facilities use at least two general strategies to prevent health-care associated legionellosis when no cases or only sporadic cases have been detected. The first is an environmental surveillance approach involving periodic culturing of water samples from the hospital's potable water system to monitor for *Legionella* spp. [747–750] If any sample is culture-positive, diagnostic testing is recommended for all patients with health-care associated pneumonia.[748, 749] In-house testing is recommended for facilities with transplant programs as part of a comprehensive treatment/management program. If ≥30% of the samples are culture-positive for *Legionella* spp., decontamination of the facility's potable water system is warranted.[748] The premise for this approach is that no cases of health-care associated legionellosis can occur if *Legionella* spp. are not present in the potable water system, and, conversely, cases of health-care associated legionellosis could potentially occur if *Legionella* spp. are cultured from the water.[26, 751]

Physicians who are informed that the hospital's potable water system is culture-positive for *Legionella* spp. are more likely to order diagnostic tests for legionellosis.

A potential advantage of the environmental surveillance approach is that periodic culturing of water is less costly than routine laboratory diagnostic testing for all patients who have health-care associated pneumonia. The primary argument against this approach is that, in the absence of cases, the relationship between water-culture results and legionellosis risk remains undefined.[3] *Legionnella* spp. can be present in the water systems of buildings[752] without being associated with known cases of disease.[437, 707, 753] In a study of 84 hospitals in Québec, 68% of the water systems were found to be colonized with *Legionella* spp., and 26% were colonized at >30% of sites sampled; cases of Legionnaires disease, however, were infrequently reported from these hospitals.[707]

Other factors also argue against environmental surveillance. Interpretation of results from periodic water culturing might be confounded by differing results among the sites sampled in a single water system and by fluctuations in the concentration of *Legionella* spp. at the same site.[709, 754] In addition, the risk for illness after exposure to a given source might be influenced by several factors other than the presence or concentration of organisms, including

a. the degree to which contaminated water is aerosolized into respirable droplets,
b. the proximity of the infectious aerosol to the potential host,
c. the susceptibility of the host, and
d. the virulence properties of the contaminating strain.[755–757]

Thus, data are insufficient to assign a level of disease risk even on the basis of the number of colony-forming units detected in samples from areas for immunocompetent patients. Conducting environmental surveillance would obligate hospital administrators to initiate water-decontamination programs if *Legionella* spp. are identified. Therefore, periodic monitoring of water from the hospital's potable water system and from aerosol-producing devices is not widely recommended in facilities that have not experienced cases of health-care associated legionellosis.[661, 758]

The second strategy to prevent and control health-care associated legionellosis is a clinical approach, in which providers maintain a high index of suspicion for legionellosis and order appropriate diagnostic tests (i.e., culture, urine antigen, and direct fluorescent antibody [DFA] serology) for patients with health-care associated pneumonia who are at high risk for legionellosis and its complications.[437, 759, 760] The testing of autopsy specimens can be included in this strategy should a death resulting from healthcare–associated pneumonia occur. Identification of one case of definite or two cases of possible healthcare–associated Legionnaires disease should prompt an epidemiologic investigation for a hospital source of *Legionella* spp., which may involve culturing the facility's water for *Legionella*. Routine maintenance of cooling towers, and use of sterile water for the filling and terminal rinsing of nebulization devices and ventilation equipment can help to minimize potential sources of contamination. Circulating potable water temperatures should match those outlined in the subsection titled *Water Temperature and Pressure*, as permitted by state code.

c. Secondary Prevention of Legionnaires Disease (With Identified Cases)

The indications for a full-scale environmental investigation to search for and subsequently decontaminate identified sources of *Legionella* spp. in health-care facilities without transplant units have not been clarified; these indications would likely differ depending on the facility. Case categories for health-care associated Legionnaires disease in facilities without transplant units include definite cases (i.e., laboratory-confirmed cases of legionellosis that occur in patients who have been hospitalized continuously for ≥10 days before the onset of illness) and possible cases (i.e., laboratory-confirmed infections that occur 2–9 days after hospital admission).[3] In settings in which as few as one to three health-care associated cases are recognized over several months, intensified surveillance for Legionnaires disease has frequently identified numerous additional cases.[405, 408, 432, 453, 739, 759, 760] This finding suggests the need for a low threshold for initiating an investigation after laboratory confirmation of cases of health-care associated legionellosis. When developing a strategy for responding to such a finding, however,

infection-control personnel should consider the level of risk for health-care– associated acquisition of, and mortality from, *Legionella* spp. infection at their particular facility.

An epidemiologic investigation conducted to determine the source of *Legionella* spp. involves several important steps (Box 11). Laboratory assessment is crucial in supporting epidemiologic evidence of a link between human illness and a specific environmental source.[761] Strain determination from subtype analysis is most frequently used in these investigations.[410, 762–764] Once the environmental source is established and confirmed with laboratory support, supplemental water treatment strategies can be initiated as appropriate.

Box 11. Steps in an epidemiologic investigation for legionellosis

- Review medical and microbiologic records.
- Initiate active surveillance to identify all recent or ongoing cases.
- Develop a line listing of cases by time, place, and person.
- Determine the type of epidemiologic investigation needed for assessing risk factors:
    - Case-control study,
    - Cohort study.
- Gather and analyze epidemiologic information:
    - Evaluate risk factors associated with potential environmental exposures (e.g., showers, cooling towers, and respiratory-therapy equipment).
- Collect water samples:
    - Sample environmental sources implicated by epidemiologic investigation,
    - Sample other potential source of water aerosols.
- Subtype strains of *Legionella* spp. cultured from both patients and environmental sources.
- Review autopsy records and include autopsy specimens in diagnostic testing.

The decision to search for hospital environmental sources of *Legionella* spp. and the choice of procedures to eradicate such contamination are based on several considerations, as follows:

a. the hospital's patient population
b. the cost of an environmental investigation and institution of control measures to eradicate *Legionella* spp. from the water supply;[765–768] and
c. the differential risk, based on host factors, for acquiring health-care associated legionellosis and developing severe and fatal infection.

d. Preventing Legionnaires Disease in Protective Environments

This subsection outlines infection-control measures applicable to those health-care facilities providing care to severely immunocompromised patients. Indigenous microorganisms in the tap water of these facilities may pose problems for such patients. These measures are designed to prevent the generation of potentially infectious aerosols from water and the subsequent exposure of PE patients or other immunocompromised patients (e.g., transplant patients) (Table 17). Infection-control measures that address the use of water with medical equipment (e.g., ventilators, nebulizers, and equipment humidifiers) are described in other guidelines and publications.[3, 455]

If one case of laboratory-confirmed, health-care associated Legionnaires disease is identified in a patient in a solid-organ transplant program or in PE (i.e., an inpatient in PE for all or part of the 2–10 days prior to onset of illness) or if two or more laboratory-confirmed cases occur among patients who had visited an outpatient PE setting, the hospital should report the cases to the local and state health departments. The hospital should then initiate a thorough epidemiologic and environmental investigation to determine the likely environmental sources of *Legionella* spp.[9] The source of *Legionella* should be decontaminated or removed. Isolated cases may be difficult to investigate. Because transplant recipients are at substantially

higher risk for disease and death from legionellosis compared with other hospitalized patients, periodic culturing for *Legionella* spp. in water samples from the potable water in the solid-organ transplant and/or PE unit can be performed as part of an overall strategy to prevent Legionnaires disease in PE units.[9, 431, 710, 769] The optimal methodology (i.e., frequency and number of sites) for environmental surveillance cultures in PE units has not been determined, and the cost-effectiveness of this strategy has not been evaluated. Because transplant recipients are at high risk for Legionnaires disease and because no data are available to determine a safe concentration of legionellae organisms in potable water, the goal of environmental surveillance for *Legionella* spp. should be to maintain water systems with no detectable organisms.[9, 431] Culturing for legionellae may be used to assess the effectiveness of water treatment or decontamination methods, a practice that provides benefits to both patients and health-care workers.[767, 770]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 17. Additional infection-control measures to prevent exposure of high-risk patients to waterborne pathogens

- Restrict patients from taking showers if the water is contaminated with *Legionella* spp. [407, 412, 654, 655, 658]
- Use water that is not contaminated with *Legionella* spp. for patients' sponge baths. [9]
- Provide sterile water for drinking, tooth brushing, or for flushing nasogastric tubes. [9, 412]
- Perform supplemental treatment of the water for the unit. [732]
- Consider periodic monitoring (i.e., culturing) of the unit water supply for *Legionella* spp. [9, 431]
- Remove shower heads and faucet aerators monthly for cleaning. (These measures can be considered in settings where legionellosis cases have occurred. These measures are not generally recommended in routine patient-care setting.) [661]
- Use a 500–600 ppm (1:100 v/v dilution) solution of sodium hypochlorite to disinfect shower heads and faucet aerators. (These measures can be considered in settings where legionellosis cases have occurred. These measures are not generally recommended in routine patient-care setting.) [661]
- Do not use large-volume room air humidifiers that create aerosols unless these are subjected to cleaning and high-level disinfection daily and filled with distilled water. [3]
- Eliminate water-containing bath toys. (These items have been associated with outbreaks of *Pseudomonas*.) [30]

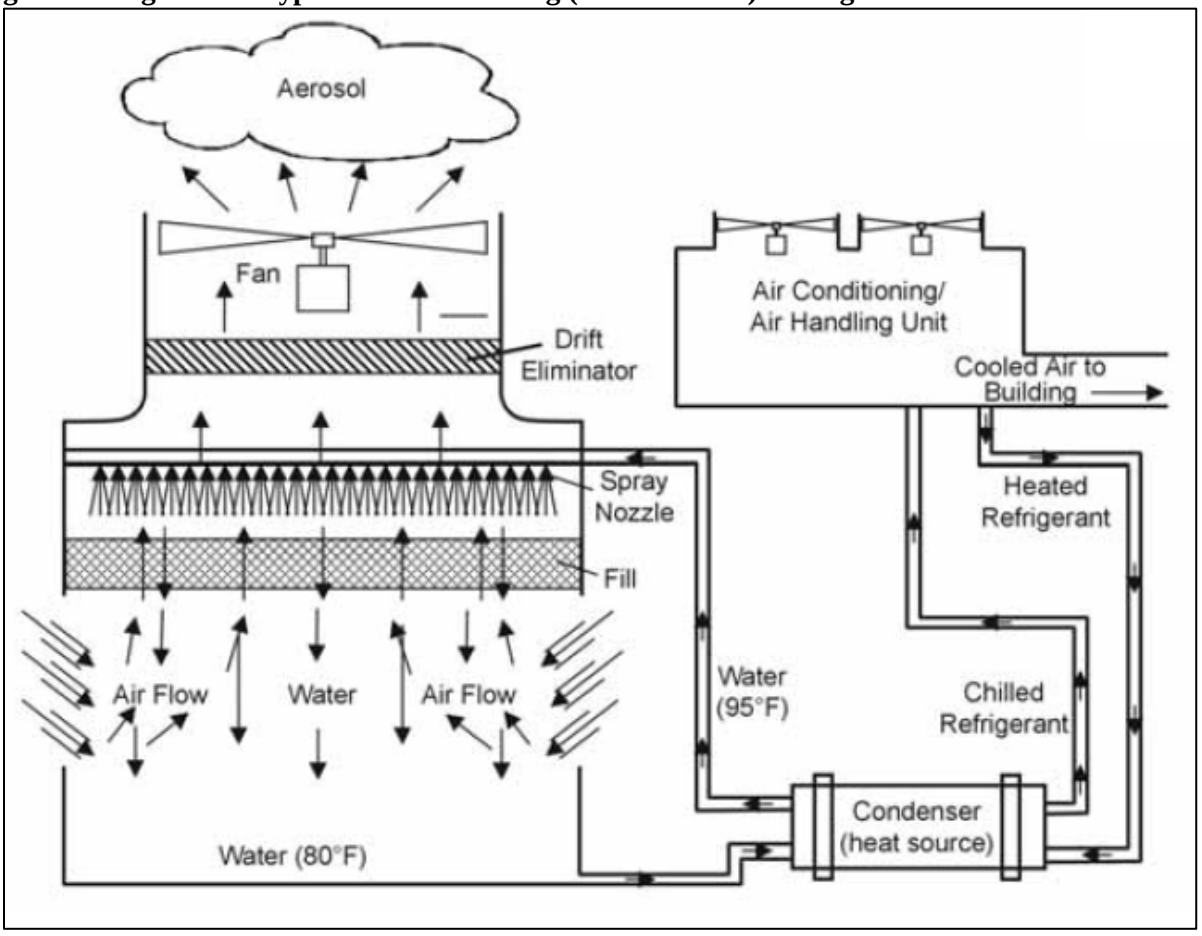
Protecting patient-care devices and instruments from inadvertent tap water contamination during room cleaning procedures is also important in any immunocompromised patient-care area. In a recent outbreak of gram-negative bacteremias among open-heart-surgery patients, pressure-monitoring equipment that was assembled and left uncovered overnight prior to the next day's surgeries was inadvertently contaminated with mists and splashing water from a hose-disinfectant system used for cleaning.[771]

5. Cooling Towers and Evaporative Condensers

Modern health-care facilities maintain indoor climate control during warm weather by use of cooling towers (large facilities) or evaporative condensers (smaller buildings). A cooling tower is a wet-type, evaporative heat transfer device used to discharge to the atmosphere waste heat from a building's air conditioning condensers (Figure 5).[772, 773] Warm water from air-conditioning condensers is piped to the cooling tower where it is sprayed downward into a counter- or cross-current air flow. To accelerate heat transfer to the air, the water passes over the fill, which either breaks water into droplets or causes it to spread into a thin film.[772, 773] Most systems use fans to move air through the tower, although some large industrial cooling towers rely on natural draft circulation of air. The cooled water from the tower is piped back to the condenser, where it again picks up heat generated during the process of chilling the system's refrigerant. The water is cycled back to the cooling tower to be cooled. Closed-circuit cooling towers and evaporative condensers are also evaporative heat-transfer devices. In these systems, the process fluid

(e.g., water, ethylene glycol/water mixture, oil, or a condensing refrigerant) does not directly contact the cooling air, but is contained inside a coil assembly.[661]

Figure 5. Diagram of a typical air conditioning (induced draft) cooling tower*



* This figure is reprinted with permission of the publisher of reference 773 (Plenum Medical).

Water temperatures are approximate and may differ substantially according to system use and design. Warm water from the condenser (or chiller) is sprayed downward into a counter- or cross-current air flow. Water passes over the fill (a component of the system designed to increase the surface area of the water exposed to air), and heat from the water is transferred to the air. Some of the water becomes aerosolized during this process, although the volume of aerosol discharged to the air can be reduced by the placement of a drift eliminator. Water cooled in the tower returns to the heat source to cool refrigerant from the air conditioning unit.

Cooling towers and evaporative condensers incorporate inertial stripping devices called drift eliminators to remove water droplets generated within the unit. Although the effectiveness of these eliminators varies substantially depending on design and condition, some water droplets in the size range of <5 μm will likely leave the unit, and some larger droplets leaving the unit may be reduced to ≤5 μm by evaporation. Thus, even with proper operation, a cooling tower or evaporative condenser can generate and expel respirable water aerosols. If either the water in the unit's basin or the make-up water (added to replace water lost to evaporation) contains *Legionella* spp. or other waterborne microorganisms, these organisms can be aerosolized and dispersed from the unit.[774] Clusters of both Legionnaires disease and Pontiac fever have been traced to exposure to infectious water aerosols originating from cooling towers and evaporative condensers contaminated with *Legionella* spp. Although most of these outbreaks have been community-

acquired episodes of pneumonia,[775–782] health-care associated Legionnaires disease has been linked to cooling tower aerosol exposure.[404, 405] Contaminated aerosols from cooling towers on hospital premises gained entry to the buildings either through open windows or via air handling system intakes located near the tower equipment.

Cooling towers and evaporative condensers provide ideal ecological niches for *Legionella* spp. The typical temperature of the water in cooling towers ranges from 85°F–95°F (29°C–35°C), although temperatures can be above 120°F (49°C) and below 70°F (21°C) depending on system heat load, ambient temperature, and operating strategy.[661] An Australian study of cooling towers found that legionellae colonized or multiplied in towers with basin temperatures above 60.8°F (16°C), and multiplication became explosive at temperatures above 73.4°F (23°C).[783] Water temperature in closed-circuit cooling towers and evaporative condensers is similar to that in cooling towers. Considerable variation in the piping arrangement occurs. In addition, stagnant areas or dead legs may be difficult to clean or penetrate with biocides.

Several documents address the routine maintenance of cooling towers, evaporative condensers, and whirlpool spas.[661, 784–787] They suggest following manufacturer's recommendations for cleaning and biocide treatment of these devices; all health-care facilities should ensure proper maintenance for their cooling towers and evaporative condensers, even in the absence of *Legionella* spp (Appendix C). Because cooling towers and evaporative condensers can be shut down during periods when air conditioning is not needed, this maintenance cleaning and treatment should be performed before starting up the system for the first time in the warm season.[782] Emergency decontamination protocols describing cleaning procedures and hyperchlorination for cooling towers have been developed for towers implicated in the transmission of legionellosis.[786, 787]

6. Dialysis Water Quality and Dialysate

a. Rationale for Water Treatment in Hemodialysis

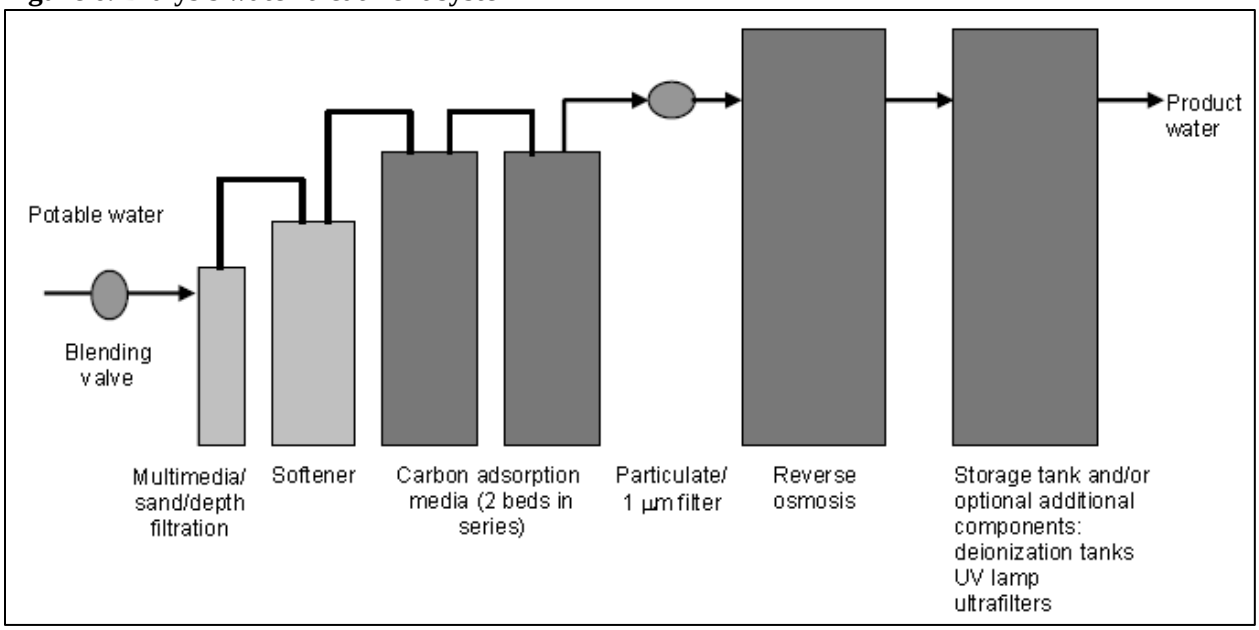
Hemodialysis, hemofiltration, and hemodiafiltration require special water-treatment processes to prevent adverse patient outcomes of dialysis therapy resulting from improper formulation of dialysate with water containing high levels of certain chemical or biological contaminants. The Association for the Advancement of Medical Instrumentation (AAMI) has established chemical and microbiologic standards for the water used to prepare dialysate, substitution fluid, or to reprocess hemodialyzers for renal replacement therapy.[788–792] The AAMI standards address:

a. equipment and processes used to purify water for the preparation of concentrates and dialysate and the reprocessing of dialyzers for multiple use and
b. the devices used to store and distribute this water. Future revisions to these standards may include hemofiltration and hemodiafiltration.

Water treatment systems used in hemodialysis employ several physical and/or chemical processes either singly or in combination (Figure 6). These systems may be portable units or large systems that feed several rooms. In the United States, >97% of maintenance hemodialysis facilities use RO alone or in combination with deionization.[793] Many acute-care facilities use portable hemodialysis machines with attached portable water treatment systems that use either deionization or RO. These machines were exempted from earlier versions of AAMI recommendations, but given current knowledge about toxic exposures to and inflammatory processes in patients new to dialysis, these machines should now come into compliance with current AAMI recommendations for hemodialysis water and dialysate quality.[788, 789] Previous recommendations were based on the assumption that acute-care patients did not experience the same degree of adverse effects from short-term, cumulative exposures to either chemicals or microbiologic agents present in hemodialysis fluids compared with the effects encountered by patients during chronic, maintenance dialysis.[788, 789] Additionally, JCAHO is reviewing inpatient practices and

record-keeping for dialysis (acute and maintenance) for adherence to AAMI standards and recommended practices.

Figure 6. Dialysis water treatment system*



* See text for description of the placement and function of these components.

Neither the water used to prepare dialysate nor the dialysate itself needs to be sterile, but tap water can not be used without additional treatment. Infections caused by rapid-growing NTM (e.g., *Mycobacterium chelonae* and *M. abscessus*) present a potential risk to hemodialysis patients (especially those in hemodialyzer reuse programs) if disinfection procedures to inactivate mycobacteria in the water (low-level disinfection) and the hemodialyzers (high-level disinfection) are inadequate.[31, 32, 633] Other factors associated with microbial contamination in dialysis systems could involve the water treatment system, the water and dialysate distribution systems, and the type of hemodialyzer.[666, 667, 794–799] Understanding the various factors and their influence on contamination levels is the key to preventing high levels of microbial contamination in dialysis therapy.

In several studies, pyrogenic reactions were demonstrated to have been caused by lipopolysaccharide or endotoxin associated with gram-negative bacteria.[794, 800–803] Early studies demonstrated that parenteral exposure to endotoxin at a concentration of 1 ng/kg body weight/hour was the threshold dose for producing pyrogenic reactions in humans, and that the relative potencies of endotoxin differ by bacterial species.[804, 805] Gram-negative water bacteria (e.g., *Pseudomonas* spp.) have been shown to multiply rapidly in a variety of hospital-associated fluids that can be used as supply water for hemodialysis (e.g., distilled water, deionized water, RO water, and softened water) and in dialysate (a balanced salt solution made with this water).[806] Several studies have demonstrated that the attack rates of pyrogenic reactions are directly associated with the number of bacteria in dialysate.[666, 667, 807] These studies provided the rationale for setting the heterotrophic bacteria standards in the first AAMI hemodialysis guideline at ≤2,000 CFU/mL in dialysate and one log lower (≤200 CFU/mL) for the water used to prepare dialysate.[668, 788] If the level of bacterial contamination exceeded 200 CFU/mL in water, this level could be amplified in the system and effectively constitute a high inoculum for dialysate at the start of a dialysis treatment.[807, 808] Pyrogenic reactions did not appear to occur when the level of contamination was below 2,000 CFU/mL in dialysate unless the source of the endotoxin was exogenous to the dialysis system (i.e., present in the community water supply). Endotoxins in a community water supply have been linked to the development of pyrogenic reactions among dialysis patients.[794]

Whether endotoxin actually crosses the dialyzer membrane is controversial. Several investigators have shown that bacteria growing in dialysate-generated products that could cross the dialyzer membrane.[809, 810] Gram-negative bacteria growing in dialysate have produced endotoxins that in turn stimulated the production of anti-endotoxin antibodies in hemodialysis patients;[801, 811] these data suggest that bacterial endotoxins, although large molecules, cross dialyzer membranes either intact or as fragments. The use of the very permeable membranes known as high-flux membranes (which allow large molecules [e.g., β2 microglobulin] to traverse the membrane) increases the potential for passage of endotoxins into the blood path. Several studies support this contention. In one such study, an increase in plasma endotoxin concentrations during dialysis was observed when patients were dialyzed against dialysate containing 10^3–10^4 CFU/mL *Pseudomonas* spp.[812] *In vitro* studies using both radiolabeled lipopolysaccharide and biologic assays have demonstrated that biologically active substances derived from bacteria found in dialysate can cross a variety of dialyzer membranes.[802, 813–816] Patients treated with high-flux membranes have had higher levels of anti-endotoxin antibodies than subjects or patients treated with conventional membranes.[817] Finally, since 1989, 19%–22% of dialysis centers have reported pyrogenic reactions in the absence of septicemia.[818, 819]

Investigations of adverse outcomes among patients using reprocessed dialyzers have demonstrated a greater risk for developing pyrogenic reactions when the water used to reprocess these devices contained >6 ng/mL endotoxin and $>10^4$ CFU/mL bacteria.[820] In addition to the variability in endotoxin assays, host factors also are involved in determining whether a patient will mount a response to endotoxin.[803] Outbreak investigations of pyrogenic reactions and bacteremias associated with hemodialyzer reuse have demonstrated that pyrogenic reactions are prevented once the endotoxin level in the water used to reprocess the dialyzers is returned to below the AAMI standard level.[821]

Reuse of dialyzers and use of bicarbonate dialysate, high-flux dialyzer membranes, or high-flux dialysis may increase the potential for pyrogenic reactions if the water in the dialysis setting does not meet standards.[796–798] Although investigators have been unable to demonstrate endotoxin transfer across dialyzer membranes,[803, 822, 823] the preponderance of reports now supports the ability of endotoxin to transfer across at least some high-flux membranes under some operating conditions. In addition to the acute risk of pyrogenic reactions, indirect evidence in increasingly demonstrating that chronic exposure to low amounts of endotoxin may play a role in some of the long-term complications of hemodialysis therapy. Patients treated with ultrafiltered dialysate for 5–6 months have demonstrated a decrease in serum β2 microglobulin concentrations and a decrease in markers of an inflammatory response.[824–826] In studies of longer duration, use of microbiologically ultrapure dialysate has been associated with a decreased incidence of β2 microglobulin-associated amyloidosis.[827, 828]

Although patient benefit likely is associated with the use of ultrapure dialysate, no consensus has been reached regarding the potential adoption of this as standard in the United States. Debate continues regarding the bacterial and endotoxin limits for dialysate. As advances in water treatment and hemodialysis processes occur, efforts are underway to move improved technology from the manufacturer out into the user community. Cost-benefit studies, however, have not been done, and substantially increased costs to implement newer water treatment modalities are anticipated.

To reconcile AAMI documents with current International Organization for Standardization (ISO) format, AAMI has determined that its hemodialysis standards will be discussed in the following four installments: RD 5 for hemodialysis equipment, RD 62 for product water quality, RD 47 for dialyzer reprocessing, and RD 52 for dialysate quality. The Renal Diseases and Dialysis Committee of AAMI is expected to finalize and promulgated the dialysate standard pertinent to the user community (RD 52), adopting by reference the bacterial and endotoxin limits in product water as currently outlined in the AAMI standard that applies to systems manufacturers (RD 62). At present, the user community should continue to observe water quality and dialysate standards as outlined in AAMI RD 5 (Hemodialysis Systems, 1992) and AAMI RD 47 (Reuse of Hemodialyzers, 1993) until the new RD 52 standard becomes available (Table 18).[789, 791]

Table 18. Microbiologic limits for hemodialysis fluids*

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 18a. Present standard

Hemodialysis fluid	Maximum total heterotrophs (CFU/mL) (colony forming units per milliliter)	Maximum endotoxin level (EU/mL) (endotoxin units per milliliter)
Product water - Used to prepare dialysate	200	No standard
Product water - Used to reprocess dialyzers	200	5
Dialysate	2,000	No standard

Product water presently includes water used to prepare dialysate and water used to reprocess dialyzers

Table 18b. Proposed standard**

Hemodialysis fluid	Maximum total heterotrophs (CFU/mL) (colony forming units per milliliter)	Maximum endotoxin level (EU/mL) (endotoxin units per milliliter)
Product water	200	2
Dialysate	200	2

** Dialysate for hemodialysis, RD 52, under development, American National Standards Institute, Association for the Advancement of Medical Instrumentation (AAMI).

* The material in this table was compiled from references 789 and 791 (ANSI/AAMI standards RD 5-1992 and ANSI/AAMI RD 47-1993).

The current AAMI standard directed at systems manufacturers (RD 62 [Water Treatment Equipment for Hemodialysis Applications, 2001]) now specifies that all product water used to prepare dialysate or to reprocess dialyzers for multiple use should contain <2 endotoxin units per milliliter (EU/mL).[792] A level of 2 EU/mL was chosen as the upper limit for endotoxin because this level is easily achieved with contemporary water treatment systems using RO and/or ultrafiltration. CDC has advocated monthly endotoxin testing along with microbiologic assays of water, because endotoxin activity may not correspond to the total heterotrophic plate counts.[829] Additionally, the current AAMI standard RD 62 for manufacturers includes action levels for product water. Because 48 hours can elapse between the time of sampling water for microbial contamination and the time when results are received, and because bacterial proliferation can be rapid, action levels for microbial counts and endotoxin concentrations are reported as 50 CFU/mL and 1 EU/mL, respectively, in this revision of the standard.[792] These recommendations will allow users to initiate corrective action before levels exceed the maximum levels established by the standard.

In hemodialysis, the net movement of water is from the blood to the dialysate, although within the dialyzer, local movement of water from the dialysate to the blood through the phenomenon of back-filtration may occur, particularly in dialyzers with highly permeable membranes.[830] In contrast, hemofiltration and hemodiaflltration feature infusion of large volumes of electrolyte solution (20–70 L) into the blood. Increasingly, this electrolyte solution is being prepared on-line from water and concentrate. Because of the large volumes of fluid infused, AAMI considered the necessity of setting more stringent requirements for water to be used in this application, but this organization has not yet established these because of lack of expert consensus and insufficient experience with on-line therapies in the United States. On-line hemofiltration and hemodiafiltration systems use sequential ultrafiltration as the final step in the preparation of infusion fluid. Several experts from AAMI concur that these point-of-use ultrafiltration systems should be capable of further reducing the bacteria and endotoxin burden of solutions prepared from water meeting the requirements of the AAMI standard to a safe level for infusion.

b. Microbial Control Strategies

The strategy for controlling massive accumulations of gram-negative water bacteria and NTM in dialysis systems primarily involves preventing their growth through proper disinfection of water-treatment systems and hemodialysis machines. Gram-negative water bacteria, their associated lipopolysaccharides (bacterial

endotoxins), and NTM ultimately come from the community water supply, and levels of these bacteria can be amplified depending on the water treatment system, dialysate distribution system, type of dialysis machine, and method of disinfection (Table 19).[634, 794, 831] Control strategies are designed to reduce levels of microbial contamination in water and dialysis fluid to relatively low levels but not to completely eradicate it.

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 19. Factors influencing microbial contamination in hemodialysis systems

Water supply—Source of community water

- **Ground water**
  Contains endotoxin and bacteria
- **Surface water**
  Contains high levels of endotoxin and bacteria

Water treatment at the dialysis center

- **None**
  Not recommended
- **Filtration: Prefilter**
  Particulate filter to protect equipment; does not remove microorganisms
- **Filtration:Absolute filter (depth or membrane filter)**
  Removes bacteria, however, unless the filter is changed frequently or disinfected, bacteria will accumulate and grow through the filter; acts as a significant reservoir of bacteria and endotoxin
- **Filtration:Activated carbon filter**
  Removes organics and available chlorine or chloramines; acts as a significant reservoir of bacteria and endotoxin

Water treatment devices

- **Deionization/ion-exchange softener**
  Both softeners and deionizers are significant reservoirs of bacteria and do not remove endotoxin.
- **Reverse osmosis (RO)**
  Removes bacteria and endotoxin, but must be disinfected; operates at high water pressure
- **Ultraviolet light**
  Kills some bacteria, but there is no residual; ultraviolet-resistant bacteria can develop if the unit is not properly maintained
- **Ultrafilter**
  Removes bacteria and endotoxin; operates on normal line pressure; can be positioned distal to deionizer; must be disinfected

Water and dialysate distribution system (Distribution pipes)

- **Size**
  Oversized diameter and length decrease fluid flow and increase bacterial reservoir for both treated water and centrally-prepared dialysate.
- **Construction**
  Rough joints, dead ends, unused branches, and polyvinyl chloride (PVC) piping can act as bacterial reservoirs.
- **Elevation**
  Outlet taps should be located at the highest elevation to prevent loss of disinfectant; keep a recirculation loop in the system; flush unused ports routinely.
- **Storage tanks**
  Tanks are undesirable because they act as a reservoir for water bacteria; if tanks are present, they must be routinely scrubbed and disinfected.

Dialysis machines

- **Single-pass**
  Disinfectant should have contact with all parts of the machine that are exposed to water or dialysis fluid.
- **Recirculating single-pass or recirculating (batch)**
  Recirculating pumps and machine design allow for massive contamination levels if not properly disinfected; overnight chemical germicide treatment is recommended.

Two components of hemodialysis water distribution systems – pipes (particularly those made of polyvinyl chloride [PVC]) and storage tanks – can serve as reservoirs of microbial contamination. Hemodialysis systems frequently use pipes that are wider and longer than are needed to handle the required flow, which slows the fluid velocity and increases both the total fluid volume and the wetted surface area of the system. Gram-negative bacteria in fluids remaining in pipes overnight multiply rapidly and colonize the wet surfaces, producing bacterial populations and endotoxin quantities in proportion to the volume and surface area. Such colonization results in formation of protective biofilm that is difficult to remove and protects the bacteria from disinfection.[832] Routine (i.e., monthly), low-level disinfection of the pipes can help to control bacterial contamination of the distribution system. Additional measures to protect pipes from contaminations include

a. situating all outlet taps at equal elevation and at the highest point of the system so that the disinfectant cannot drain from pipes by gravity before adequate contact time has elapsed and
b. eliminating rough joints, dead-end pipes, and unused branches and taps that can trap fluid and serve as reservoirs of bacteria capable of continuously inoculating the entire volume of the system.[800]

Maintain a flow velocity of 3–5 ft/sec.

A storage tank in the distribution system greatly increases the volume of fluid and surface area available and can serve as a niche for water bacteria. Storage tanks are therefore not recommended for use in dialysis systems unless they are frequently drained and adequately disinfected, including scrubbing the sides of the tank to remove bacterial biofilm. An ultrafilter should be used distal to the storage tank.[808, 833]

Microbiologic sampling of dialysis fluids is recommended because gram-negative bacteria can proliferate rapidly in water and dialysate in hemodialysis systems; high levels of these organisms place patients at risk for pyrogenic reactions or health-care associated infection.[667, 668, 808]

Health-care facilities are advised to sample dialysis fluids at least monthly using standard microbiologic assay methods for waterborne microorganisms.[788, 793, 799, 834–836] Product water used to prepare dialysate and to reprocess hemodialyzers for reuse on the same patient should also be tested for bacterial endotoxin on a monthly basis.[792, 829, 837] (See Appendix C for information about water sampling methods for dialysis.)

Cross-contamination of dialysis machines and inadequate disinfection measures can facilitate the spread of waterborne organisms to patients. Steps should be taken to ensure that dialysis equipment is performing correctly and that all connectors, lines, and other components are specific for the equipment, in good repair, and properly in place. A recent outbreak of gram-negative bacteremias among dialysis patients was attributed to faulty valves in a drain port of the machine that allowed backflow of saline used to flush the dialyzer before patient use.[838, 839] This backflow contaminated the drain priming connectors, which contaminated the blood lines and exposed the patients to high concentrations of gram-negative bacteria. Environmental infection control in dialysis settings also includes low-level disinfection of housekeeping surfaces and spot decontamination of spills of blood (see Environmental Services in Part I of this guideline for further information).

c. Infection-Control Issues in Peritoneal Dialysis

Peritoneal dialysis (PD), most commonly administered as continuous ambulatory peritoneal dialysis (CAPD) and continual cycling peritoneal dialysis (CCPD), is the third most common treatment for end-stage renal disease (ESRD) in the United States, accounting for 12% of all dialysis patients.[840] Peritonitis is the primary complication of CAPD, with coagulase-negative staphylococci the most clinically significant causative organisms.[841] Other organisms that have been found to produce peritonitis include *Staphylococcus aureus, Mycobacterium fortuitum, M. mucogenicum, Stenotrophomonas maltophilia, Burkholderia cepacia, Corynebacterium jeikeium, Candida* spp., and other fungi.[842–850] Substantial morbidity is associated with peritoneal dialysis infections. Removal of peritoneal dialysis catheters usually is required for treatment of peritonitis caused by fungi, NTM, or other bacteria that are not cleared within the first several days of effective antimicrobial treatment. Furthermore, recurrent episodes of peritonitis may lead to fibrosis and loss of the dialysis membrane.

Many reported episodes of peritonitis are associated with exit-site or tunneled catheter infections. Risk factors for the development of peritonitis in PD patients include

1. under dialysis,
2. immune suppression,
3. prolonged antimicrobial treatment,
4. patient age [more infections occur in younger patients and older hospitalized patients],
5. length of hospital stay, and
6. hypoalbuminemia.[844, 851, 852]

Concern has been raised about infection risk associated with the use of automated cyclers in both inpatient and outpatient settings; however, studies suggest that PD patients who use automated cyclers have much lower infection rates.[853] One study noted that a closed-drainage system reduced the incidence of system-related peritonitis among intermittent peritoneal dialysis (IPD) patients from 3.6 to 1.5 cases/100 patient days.[854] The association of peritonitis with management of spent dialysate fluids requires additional study. Therefore, ensuring that the tip of the waste line is not submerged beneath the water level in a toilet or in a drain is prudent.

7. Ice Machines and Ice

Microorganisms may be present in ice, ice-storage chests, and ice-making machines. The two main sources of microorganisms in ice are the potable water from which it is made and a transferral of organisms from hands (Table 20). Ice from contaminated ice machines has been associated with patient colonization, blood stream infections, pulmonary and gastrointestinal illnesses, and pseudoinfections.[602, 603, 683, 684, 854, 855]

Microorganisms in ice can secondarily contaminate clinical specimens and medical solutions that require cold temperatures for either transport or holding.[601, 620] An outbreak of surgical-site infections was interrupted when sterile ice was used in place of tap water ice to cool cardioplegia solutions.[601]

⚠ **Format Change [November 2016]:** The format of this section was changed to improve readability and accessibility. The content is unchanged.

Table 20. Microorganisms and their sources in ice and ice machines

From potable water

- *Legionella* spp. [684, 685, 857, 858]
- Nontuberculous mycobacteria (NTM) [602, 603, 859]
- *Pseudomonas aeruginosa* [859]
- *Burkholderia cepacia* [859, 860]
- *Stenotrophomonas maltophilia* [860]
- *Flavobacterium* spp. [860]

From fecally-contaminated water

- Norwalk virus [861–863]
- *Giardia lamblia* [864]
- *Cryptosporidium parvum* [685]

From hand-transfer of organisms

- *Acinetobacter* spp. [859]
- Coagulase-negative staphylococci [859]
- *Salmonella enteriditis* [865]
- *Cryptosporidium parvum* [685]

In a study comparing the microbial populations of hospital ice machines with organisms recovered from ice samples gathered from the community, samples from 27 hospital ice machines yielded low numbers (<10 CFU/mL) of several potentially opportunistic microorganisms, mainly gram-negative bacilli.[859] During the survey period, no health-care associated infections were attributed to the use of ice. Ice from community sources had higher levels of microbial contamination (75%–95% of 194 samples had total heterotrophic plate counts <500 CFU/mL, with the proportion of positive cultures dependent on the incubation temperature) and showed evidence of fecal contamination from the source water.[859] Thus, ice machines in

health-care settings are no more heavily contaminated compared with ice machines in the community. If the source water for ice in a health-care facility is not fecally contaminated, then ice from clean ice machines and chests should pose no increased hazard for immunocompetent patients. Some waterborne bacteria found in ice could potentially be a risk to immunocompromised patients if they consume ice or drink beverages with ice. For example, *Burkholderia cepacia* in ice could present an infection risk for cystic fibrosis patients.[859, 860] Therefore, protecting immunosuppressed and otherwise medically at-risk patients from exposure to tap water and ice potentially contaminated with opportunistic pathogens is prudent.[9]

No microbiologic standards for ice, ice-making machines, or ice storage equipment have been established, although several investigators have suggested the need for such standards.[859, 866] Culturing of ice machines is not routinely recommended, but it may be useful as part of an epidemiologic investigation.[867–869] Sampling might also help determine the best schedule for cleaning open ice-storage chests. Recommendations for a regular program of maintenance and disinfection have been published.[866–869] Health-care facilities are advised to clean ice-storage chests on a regular basis. Open ice chests may require a more frequent cleaning schedule compared with chests that have covers. Portable ice chests and containers require cleaning and low-level disinfection before the addition of ice intended for consumption. Ice-making machines may require less frequent cleaning, but their maintenance is important to proper performance. The manufacturer's instructions for both the proper method of cleaning and/or maintenance should be followed. These instructions may also recommend an EPA-registered disinfectant to ensure chemical potency, materials compatibility, and safety. In the event that instructions and suitable EPA-registered disinfectants are not available for this process, then a generic approach to cleaning, disinfecting, and maintaining ice machines and dispensers can be used (Box 12).

Ice and ice-making machines also may be contaminated via improper storage or handling of ice by patients and/or staff.[684–686, 855–858, 870] Suggested steps to avoid this means of contamination include

a. minimizing or avoiding direct hand contact with ice intended for consumption,
b. using a hard-surface scoop to dispense ice, and
c. installing machines that dispense ice directly into portable containers at the touch of a control.[687, 869]

Box 12. General steps for cleaning and maintaining ice machines, dispensers, and storage chests*+

1. Disconnect unit from power supply.
2. Remove and discard ice from bin or storage chest.
3. Allow unit to warm to room temperature.
4. Disassemble removable parts of machine that make contact with water to make ice.
5. Thoroughly clean machine and parts with water and detergent.
6. Dry external surfaces of removable parts before reassembling.
7. Check for any needed repair.
8. Replace feeder lines, as appropriate (e.g., when damaged, old, or difficult to clean).
9. Ensure presence of an air space in tubing leading from water inlet into water distribution system of machine.
10. Inspect for rodent or insect infestations under the unit and treat, as needed.
11. Check door gaskets (open compartment models) for evidence of leakage or dripping into the storage chest.
12. Clean the ice-storage chest or bin with fresh water and detergent; rinse with fresh tap water.
13. Sanitize machine by circulating a 50–100 parts per million (ppm) solution of sodium hypochlorite (i.e., 4–8 mL sodium hypochlorite/gallon of water) through the ice-making and storage systems for 2 hours (100 ppm solution), or 4 hours (50 ppm solution).
14. Drain sodium hypochlorite solutions and flush with fresh tap water.
15. Allow all surfaces of equipment to dry before returning to service.

* Material in this box is adapted from reference 869.

\+ These general guidelines should be used only where manufacturer-recommended methods and EPA-registered disinfectants are not available.

8. Hydrotherapy Tanks and Pools

a. General Information

Hydrotherapy equipment (e.g., pools, whirlpools, whirlpool spas, hot tubs, and physiotherapy tanks) traditionally has been used to treat patients with certain medical conditions (e.g., burns,[871, 872] septic ulcers, lesions, amputations,[873] orthopedic impairments and injuries, arthritis,[874] and kidney lithotripsy).[654] Wound-care medicine is increasingly moving away from hydrotherapy, however, in favor of bedside pulsed-lavage therapy using sterile solutions for cleaning and irrigation.[492, 875–878] Several episodes of health-care associated infections have been linked to use of hydrotherapy equipment (Table 21). Potential routes of infection include incidental ingestion of the water, sprays and aerosols, and direct contact with wounds and intact skin (folliculitis). Risk factors for infection include

a. age and sex of the patient,
b. underlying medical conditions,
c. length of time spent in the hydrotherapy water, and
d. portals of entry.[879]

Table 21. Infections associated with use of hydrotherapy equipment

Microorganisms	Medical conditions	References
Acinetobacter baumanii	Sepsis	572
Citrobacter freundii	Cellulitis	880
Enterobacter cloacae	Sepsis	881
Legionella spp.	Legionellosis	882
Mycobacterium abscessus, Mycobacterium fortuitum, Mycobacterium marinum	Skin ulcers and soft tissue infections	621–623, 883
Pseudomonas aeruginosa	Sepsis, soft tissue infections, folliculitis, and wound infections	492, 493, 506, 679, 884–888
Adenovirus, adeno-associated virus	Conjunctivitis	889

Infection control for hydrotherapy tanks, pools, or birthing tanks presents unique challenges because indigenous microorganisms are always present in the water during treatments. In addition, some studies have found free living amoebae (i.e., *Naegleria lovaniensis*), which are commonly found in association with *Naegleria fowleri,* in hospital hydrotherapy pools.[890] Although hydrotherapy is at times appropriate for patients with wounds, burns, or other types of non-intact skin conditions (determined on a case-by-case basis), this equipment should not be considered "semi-critical" in accordance with the Spaulding classification.[891] Microbial data to evaluate the risk of infection to patients using hydrotherapy pools and birthing tanks are insufficient. Nevertheless, health-care facilities should maintain stringent cleaning and disinfection practices in accordance with the manufacturer's instructions and with relevant scientific literature until data supporting more rigorous infection-control measures become available. Factors that should be considered in therapy decisions in this situation would include

a. availability of alternative aseptic techniques for wound management and
b. a risk-benefit analysis of using traditional hydrotherapy.

b. Hydrotherapy Tanks

Hydrotherapy tanks (e.g., whirlpools, Hubbard tanks and whirlpool bath tubs) are shallow tanks constructed of stainless steel, plexiglass, or tile. They are closed-cycle water systems with hydrojets to circulate, aerate, and agitate the water. The maximum water temperature range is 50°F–104°F (10°C–40°C). The warm water temperature, constant agitation and aeration, and design of the hydrotherapy tanks provide ideal conditions for bacterial proliferation if the equipment is not properly maintained, cleaned, and disinfected. The design of the hydrotherapy equipment should be evaluated for potential infection-

control problems that can be associated with inaccessible surfaces that can be difficult to clean and/or remain wet in between uses (i.e., recessed drain plates with fixed grill plates).[887] Associated equipment (e.g., parallel bars, plinths, Hoyer lifts, and wheelchairs) can also be potential reservoirs of microorganisms, depending on the materials used in these items (i.e., porous vs. non-porous materials) and the surfaces that may become wet during use. Patients with active skin colonizations and wound infections can serve as sources of contamination for the equipment and the water. Contamination from spilled tub water can extend to drains, floors, and walls.[680–683] Health-care associated colonization or infection can result from exposure to endogenous sources of microorganisms (autoinoculation) or exogenous sources (via cross-contamination from other patients previously receiving treatment in the unit).

Although some facilities have used tub liners to minimize environmental contamination of the tanks, the use of a tub liner does not eliminate the need for cleaning and disinfection. Draining these small pools and tanks after each patient use, thoroughly cleaning with a detergent, and disinfecting according to manufacturers' instructions have reduced bacterial contamination levels in the water from 10^4 CFU/mL to <10 CFU/mL.[892] A chlorine residual of 15 ppm in the water should be obtained prior to the patient's therapy session (e.g., by adding 15 grams of calcium hypochlorite 70% [e.g., HTH®] per 100 gallons of water).[892] A study of commercial and residential whirlpools found that superchlorination or draining, cleaning, disinfection, and refilling of whirlpools markedly reduced densities of *Pseudomonas aeruginosa* in whirlpool water.[893] The bacterial populations were rapidly replenished, however, when disinfectant concentrations dropped below recommended levels for recreational use (i.e., chlorine at 3.0 ppm or bromine at 6.0 ppm). When using chlorine, however, knowing whether the community drinking-water system is disinfected with chloramine is important, because municipal utilities adjust the pH of the water to the basic side to enhance chloramine formation. Because chlorine is not very effective at pH levels above 8, it may be necessary to re-adjust the pH of the water to a more acidic level.[894]

A few reports describe the addition of antiseptic chemicals to hydrotherapy tank water, especially for burn patient therapy.[895–897] One study involving a minimal number of participants demonstrated a reduction in the number of *Pseudomonas* spp. and other gram-negative bacteria from both patients and equipment surfaces when chloramine-T ("chlorazene") was added to the water.[898] Chloramine-T has not, however, been approved for water treatment in the United States.

c. Hydrotherapy Pools

Hydrotherapy pools typically serve large numbers of patients and are usually heated to 91.4°F–98.6°F (31°C–37°C). The temperature range is more narrow (94°F–96.8°F [35°C–36°C]) for pediatric and geriatric patient use.[899] Because the size of hydrotherapy pools precludes draining after patient use, proper management is required to maintain the proper balance of water conditioning (i.e., alkalinity, hardness, and temperature) and disinfection. The most widely used chemicals for disinfection of pools are chlorine and chlorine compounds – calcium hypochlorite, sodium hypochlorite, lithium hypochlorite, chloroisocyanurates, and chlorine gas. Solid and liquid formulations of chlorine chemicals are the easiest and safest to use.[900] Other halogenated compounds have also been used for pool-water disinfection, albeit on a limited scale. Bromine, which forms bactericidal bromamines in the presence of ammonia, has limited use because of its association with contact dermatitis.[901] Iodine does not bleach hair, swim suits, or cause eye irritation, but when introduced at proper concentrations, it gives water a greenish-yellowish cast.[892]

In practical terms, maintenance of large hydrotherapy pools (e.g., those used for exercise) is similar to that for indoor public pools (i.e., continuous filtration, chlorine residuals no less than 0.4 ppm, and pH of 7.2–7.6).[902, 903] Supply pipes and pumps also need to be maintained to eliminate the possibility of this equipment serving as a reservoir for waterborne organisms.[904] Specific standards for chlorine residual and pH of the water are addressed in local and state regulations. Patients who are fecally incontinent or who have draining wounds should refrain from using these pools until their condition improves.

d. Birthing Tanks and Other Equipment

The use of birthing tanks, whirlpool spas, and whirlpools is a recent addition to obstetrical practice.[905] Few studies on the potential risks associated with these pieces of equipment have been conducted. In one study of 32 women, a newborn contracted a *Pseudomonas* infection after being birthed in such a tank, the strain of which was identical to the organism isolated from the tank water.[906] Another report documented identical strains of *P. aeruginosa* isolates from a newborn with sepsis and on the environmental surfaces of a tub that the mother used for relaxation while in labor.[907] Other studies have shown no significant increases in the rates of post-immersion infections among mothers and infants.[908, 909]

Because the water and the tub surfaces routinely become contaminated with the mother's skin flora and blood during labor and delivery, birthing tanks and other tub equipment must be drained after each patient use and the surfaces thoroughly cleaned and disinfected. Health-care facilities are advised to follow the manufacturer's instructions for selection of disinfection method and chemical germicide. The range of chlorine residuals for public whirlpools and whirlpool spas is 2–5 ppm.[910] Use of an inflatable tub is an alternative solution, but this item must be cleaned and disinfected between patients if it is not considered a single-use unit.

Recreational tanks and whirlpool spas are increasingly being used as hydrotherapy equipment. Although such home equipment appears to be suitable for hydrotherapy, they are neither designed nor constructed to function in this capacity. Additionally, manufacturers generally are not obligated to provide the health-care facility with cleaning and disinfecting instructions appropriate for medical equipment use, and the U.S. Food and Drug Administration (FDA) does not evaluate recreational equipment. Health-care facilities should therefore carefully evaluate this "off-label" use of home equipment before proceeding with a purchase.

9. Miscellaneous Medical/Dental Equipment Connected to Main Water Systems

a. Automated Endoscope Reprocessors

The automated endoscopic reprocessor (AER) is classified by the FDA as an accessory for the flexible endoscope.[654] A properly operating AER can provide a more consistent, reliable method of decontaminating and terminal reprocessing for endoscopes between patient procedures than manual reprocessing methods alone.[911] An endoscope is generally subjected to high-level disinfection using a liquid chemical sterilant or a high-level disinfectant. Because the instrument is a semi-critical device, the optimal rinse fluid for a disinfected endoscope would be sterile water.[3] Sterile water, however, is expensive and difficult to produce in sufficient quantities and with adequate quality assurance for instrument rinsing in an AER.[912, 913] Therefore, one option to be used for AERs is rinse water that has been passed through filters with a pore size of 0.1–0.2 μm to render the water "bacteria-free." These filters usually are located in the water line at or near the port where the mains water enters the equipment. The product water (i.e., tap water passing through these filters) in these applications is not considered equivalent in microbial quality to that for membrane-filtered water as produced by pharmaceutical firms. Membrane filtration in pharmaceutical applications is intended to ensure the microbial quality of polished product water.

Water has been linked to the contamination of flexible fiberoptic endoscopes in the following two scenarios:

a. rinsing a disinfected endoscope with unfiltered tap water, followed by storage of the instrument without drying out the internal channels and
b. contamination of AERs from tap water inadvertently introduced into the equipment.

In the latter instance, the machine's water reservoirs and fluid circuitry become contaminated with waterborne, heterotrophic bacteria (e.g., *Pseudomonas aeruginosa* and NTM), which can survive and persist in biofilms attached to these components.[914–917] Colonization of the reservoirs and water lines of the AER becomes problematic if the required cleaning, disinfection, and maintenance are not performed on the equipment as recommended by the manufacturer.[669, 916, 917] Use of the 0.1–0.2-µm filter in the water line helps to keep bacterial contamination to a minimum,[670, 911, 917] but filters may fail and allow bacteria to pass through to the equipment and then to the instrument undergoing reprocessing.[671–674, 913, 918] Filters also require maintenance for proper performance.[670, 911, 912, 918, 919] Heightened awareness of the proper disinfection of the connectors that hook the instrument to the AER may help to further reduce the potential for contaminating endoscopes during reprocessing.[920] An emerging issue in the field of endoscopy is that of the possible role of rinse water monitoring and its potential to help reduce endoscopy/bronchoscopyassociated infections.[918]

Studies have linked deficiencies in endoscope cleaning and/or disinfecting processes to the incidence of post-endoscopic adverse outcomes.[921–924] Several clusters have been traced to AERs of older designs and these were associated with water quality.[675, 914–916] Regardless of whether manual or automated terminal reprocessing is used for endoscopes, the internal channels of the instrument should be dried before storage.[925] The presence of residual moisture in the internal channels encourages the proliferation of waterborne microorganisms, some of which may be pathogenic. One of the most frequently used methods employs 70% isopropyl alcohol to flush the internal channels, followed by forced air drying of these channels and hanging the endoscope vertically in a protected cabinet; this method ensures internal drying of the endoscope, lessens the potential for proliferation of waterborne microorganisms,[669, 913, 917, 922, 926, 927] and is consistent with professional organization guidance for endoscope reprocessing.[928]

An additional problem with waterborne microbial contamination of AERs centers on increased microbial resistance to alkaline glutaraldehyde, a widely used liquid chemical sterilant/high-level disinfectant.[669, 929] Opportunistic waterborne microorganisms (e.g., *Mycobacterium chelonae*, *Methylobacterium* spp.) have been associated with pseudo-outbreaks and colonization; infection caused by these organisms has been associated with procedures conducted in clinical settings (e.g., bronchoscopy).[669, 913, 929–931] Increasing microbial resistance to glutaraldehyde has been attributed to improper use of the disinfectant in the equipment, allowing the dilution of glutaraldehyde to fall below the manufacturer's recommended minimal use concentration.[929]

b. Dental Unit Water Lines

Dental unit water lines (DUWLs) consist of small-bore plastic tubing that delivers water used for general, non-surgical irrigation and as a coolant to dental handpieces, sonic and ultrasonic scalers, and air-water syringes; municipal tap water is the source water for these lines. The presence of biofilms of waterborne bacteria and fungi (e.g., *Legionella* spp., *Pseudomonas aeruginosa,* and NTM) in DUWLs has been established.[636, 637, 694, 695, 932– 934] Biofilms continually release planktonic microorganisms into the water, the titers of which can exceed $1H10^6$ CFU/mL.[694] However, scientific evidence indicates that immunocompetent persons are only at minimal risk for substantial adverse health effects after contact with water from a dental unit. Nonetheless, exposing patients or dental personnel to water of uncertain microbiological quality is not consistent with universally accepted infection-control principles.[935]

In 1993, CDC issued guidelines relative to water quality in a dental setting. These guidelines recommend that all dental instruments that use water (including high-speed handpieces) should be run to discharge water for 20–30 seconds after each patient and for several minutes before the start of each clinic day.[936] This practice can help to flush out any patient materials that many have entered the turbine, air, or waterlines.[937, 938] The 1993 guidance also indicated that waterlines be flushed at the beginning of the clinic day. Although

these guidelines are designed to help reduce the number of microorganisms present in treatment water, they do not address the issue of reducing or preventing biofilm formation in the waterlines. Research published subsequent to the 1993 dental infection control guideline suggests that flushing the lines at the beginning of the day has only minimal effect on the status of the biofilm in the lines and does not reliably improve the quality of water during dental treatment.[939–941] Updated recommendations on infection-control practices for water line use in dentistry will be available in late 2003.[942]

The numbers of microorganisms in water used as coolant or irrigant for non-surgical dental treatment should be as low as reasonably achievable and, at a minimum, should meet nationally recognized standards for safe drinking water.[935, 943] Only minimal evidence suggests that water meeting drinking water standards poses a health hazard for immunocompetent persons. The EPA, the American Public Health Association (APHA), and the American Water Works Association (AWWA) have set a maximum limit of 500 CFU/mL for aerobic, heterotrophic, mesophilic bacteria in drinking water in municipal distribution systems.[944, 945] This standard is achievable, given improvements in water-line technology. Dentists should consult with the manufacturer of their dental unit to determine the best equipment and method for maintaining and monitoring good water quality.[935, 946]

E. Environmental Services

1. Principles of Cleaning and Disinfecting Environmental Surfaces

Although microbiologically contaminated surfaces can serve as reservoirs of potential pathogens, these surfaces generally are not directly associated with transmission of infections to either staff or patients. The transferral of microorganisms from environmental surfaces to patients is largely via hand contact with the surface.[947, 948] Although hand hygiene is important to minimize the impact of this transfer, cleaning and disinfecting environmental surfaces as appropriate is fundamental in reducing their potential contribution to the incidence of healthcare-associated infections.

The principles of cleaning and disinfecting environmental surfaces take into account the intended use of the surface or item in patient care. CDC retains the Spaulding classification for medical and surgical instruments, which outlines three categories based on the potential for the instrument to transmit infection if the instrument is microbiologically contaminated before use.[949, 950] These categories are “critical,” “semicritical,” and “noncritical.” In 1991, CDC proposed an additional category designated “environmental surfaces” to Spaulding’s original classification[951] to represent surfaces that generally do not come into direct contact with patients during care. Environmental surfaces carry the least risk of disease transmission and can be safely decontaminated using less rigorous methods than those used on medical instruments and devices. Environmental surfaces can be further divided into medical equipment surfaces (e.g., knobs or handles on hemodialysis machines, x-ray machines, instrument carts, and dental units) and housekeeping surfaces (e.g., floors, walls, and tabletops).[951]

The following factors influence the choice of disinfection procedure for environmental surfaces:
a. the nature of the item to be disinfected,
b. the number of microorganisms present,
c. the innate resistance of those microorganisms to the inactivating effects of the germicide,
d. the amount of organic soil present,
e. the type and concentration of germicide used,
f. duration and temperature of germicide contact, and
g. if using a proprietary product, other specific indications and directions for use.[952, 953]

Cleaning is the necessary first step of any sterilization or disinfection process. Cleaning is a form of decontamination that renders the environmental surface safe to handle or use by removing organic matter, salts, and visible soils, all of which interfere with microbial inactivation.[954–960] The physical action of

scrubbing with detergents and surfactants and rinsing with water removes large numbers of microorganisms from surfaces.[957] If the surface is not cleaned before the terminal reprocessing procedures are started, the success of the sterilization or disinfection process is compromised.

Spaulding proposed three levels of disinfection for the treatment of devices and surfaces that do not require sterility for safe use. These disinfection levels are "high-level," "intermediate-level," and "low level." [949, 950]

The basis for these levels is that microorganisms can usually be grouped according to their innate resistance to a spectrum of physical or chemical germicidal agents (Table 22). This information, coupled with the instrument/surface classification, determines the appropriate level of terminal disinfection for an instrument or surface.

Table 22. Levels of disinfection by type of microorganism*

Disinfection level	Bacteria (vegetative)	Bacteria (Tubercle bacillus)	Bacteria (spores)	Fungi†	Viruses (lipid and medium size)	Viruses (nonlipid and small size)
High	+	+	+ High-level disinfectant chemicals possess sporicidal activity—only with extended exposure time are high level disinfections capable of killing high numbers of bacterial spores in laboratory tests.	+	+	+
Intermediate	+	+	– Some intermediate-level disinfectants (e.g., hypochlorites) can exhibit some sporicidal activity; others (e.g., alcohols and phenolics) have no demonstrable sporicidal activity.	+	+	± Variable killing effect Some intermediate-level disinfectants, although they are tuberculocidal, may have limited virucidal activity.
Low	+	–	–	Variable killing effect	+	± Variable killing effect

+ indicates that a killing effect can be expected when the normal use-concentrations of chemical disinfectants or pasteurization are properly employed

- indicates little or no killing effect

* Material in this table compiled from references 2, 951.

† This class of microorganisms includes asexual spores but not necessarily chlamydospores or sexual spores.

The process of high-level disinfection, an appropriate standard of treatment for heat-sensitive, semi-critical medical instruments (e.g., flexible, fiberoptic endoscopes), inactivates all vegetative bacteria, mycobacteria, viruses, fungi, and some bacterial spores. High-level disinfection is accomplished with powerful, sporicidal chemicals (e.g., glutaraldehyde, peracetic acid, and hydrogen peroxide) that are not appropriate for use on housekeeping surfaces. These liquid chemical sterilants/high-level disinfectants are highly toxic.[961–963] Use of these chemicals for applications other than those indicated in their label instructions (i.e., as immersion chemicals for treating heat-sensitive medical instruments) is not appropriate.[964] Intermediate-level disinfection does not necessarily kill bacterial spores, but it does inactivate *Mycobacterium tuberculosis* var. *bovis*, which is substantially more resistant to chemical germicides than ordinary vegetative bacteria, fungi, and medium to small viruses (with or without lipid envelopes). Chemical germicides with sufficient potency to achieve intermediate-level disinfection include chlorine-containing compounds (e.g., sodium hypochlorite), alcohols, some phenolics, and some iodophors. Low-level disinfection inactivates vegetative bacteria, fungi, enveloped viruses (e.g., human immunodeficiency virus [HIV], and influenza viruses), and some non-enveloped viruses (e.g., adenoviruses). Low-level disinfectants include quaternary ammonium compounds, some phenolics, and

some iodophors. Sanitizers are agents that reduce the numbers of bacterial contaminants to safe levels as judged by public health requirements, and are used in cleaning operations, particularly in food service and dairy applications. Germicidal chemicals that have been approved by FDA as skin antiseptics are not appropriate for use as environmental surface disinfectants.[951]

The selection and use of chemical germicides are largely matters of judgment, guided by product label instructions, information, and regulations. Liquid sterilant chemicals and high-level disinfectants intended for use on critical and semi-critical medical/dental devices and instruments are regulated exclusively by the FDA as a result of recent memoranda of understanding between FDA and the EPA that delineates agency authority for chemical germicide regulation.[965, 966] Environmental surface germicides (i.e., primarily intermediate- and low-level disinfectants) are regulated by the EPA and labeled with EPA registration numbers. The labels and technical data or product literature of these germicides specify indications for product use and provide claims for the range of antimicrobial activity. The EPA requires certain pre-registration laboratory potency tests for these products to support product label claims. EPA verifies (through laboratory testing) manufacturers' claims to inactivate microorganisms for selected products and organisms. Germicides labeled as "hospital disinfectant" have passed the potency tests for activity against three representative microorganisms – *Pseudomonas aeruginosa, Staphylococcus aureus,* and *Salmonella cholerae suis*. Low-level disinfectants are often labeled "hospital disinfectant" without a tuberculocidal claim, because they lack the potency to inactivate mycobacteria. Hospital disinfectants with demonstrated potency against mycobacteria (i.e., intermediate-level disinfectants) may list "tuberculocidal" on the label as well. Other claims (e.g., "fungicidal," "pseudomonicidal," and "virucidal") may appear on labels of environmental surface germicides, but the designations of "tuberculocidal hospital disinfectant" and "hospital disinfectant" correlate directly to Spaulding's assessment of intermediate-level disinfectants and low-level disinfectants, respectively.[951]

A common misconception in the use of surface disinfectants in health-care settings relates to the underlying purpose for use of proprietary products labeled as a "tuberculocidal" germicide. Such products will not interrupt and prevent the transmission of TB in health-care settings because TB is not acquired from environmental surfaces. The tuberculocidal claim is used as a benchmark by which to measure germicidal potency. Because mycobacteria have the highest intrinsic level of resistance among the vegetative bacteria, viruses, and fungi, any germicide with a tuberculocidal claim on the label (i.e., an intermediate-level disinfectant) is considered capable of inactivating a broad spectrum of pathogens, including much less resistant organisms such the bloodborne pathogens (e.g., hepatitis B virus [HBV], hepatitis C virus [HCV], and HIV). It is this broad spectrum capability, rather than the product's specific potency against mycobacteria, that is the basis for protocols and OSHA regulations indicating the appropriateness of using tuberculocidal chemicals for surface disinfection.[967]

2. General Cleaning Strategies for Patient-Care Areas

The number and types of microorganisms present on environmental surfaces are influenced by the following factors:

a. number of people in the environment,
b. amount of activity,
c. amount of moisture,
d. presence of material capable of supporting microbial growth,
e. rate at which organisms suspended in the air are removed, and
f. type of surface and orientation [i.e., horizontal or vertical].[968]

Strategies for cleaning and disinfecting surfaces in patient-care areas take into account

a. potential for direct patient contact,
b. degree and frequency of hand contact, and
c. potential contamination of the surface with body substances or environmental sources of microorganisms (e.g., soil, dust, and water).

a. Cleaning of Medical Equipment

Manufacturers of medical equipment should provide care and maintenance instructions specific to their equipment. These instructions should include information about

a. the equipments' compatibility with chemical germicides,
b. whether the equipment is water-resistant or can be safely immersed for cleaning, and
c. how the equipment should be decontaminated if servicing is required.[967]

In the absence of manufacturers' instructions, non-critical medical equipment (e.g., stethoscopes, blood pressure cuffs, dialysis machines, and equipment knobs and controls) usually only require cleansing followed by low- to intermediate-level disinfection, depending on the nature and degree of contamination. Ethyl alcohol or isopropyl alcohol in concentrations of 60%–90% (v/v) is often used to disinfect small surfaces (e.g., rubber stoppers of multiple-dose medication vials, and thermometers)[952, 969] and occasionally external surfaces of equipment (e.g., stethoscopes and ventilators). However, alcohol evaporates rapidly, which makes extended contact times difficult to achieve unless items are immersed, a factor that precludes its practical use as a large-surface disinfectant.[951] Alcohol may cause discoloration, swelling, hardening, and cracking of rubber and certain plastics after prolonged and repeated use and may damage the shellac mounting of lenses in medical equipment.[970]

Barrier protection of surfaces and equipment is useful, especially if these surfaces are

a. touched frequently by gloved hands during the delivery of patient care,
b. likely to become contaminated with body substances, or
c. difficult to clean. Impervious-backed paper, aluminum foil, and plastic or fluid-resistant covers are suitable for use as barrier protection.

An example of this approach is the use of plastic wrapping to cover the handle of the operatory light in dental-care settings.[936, 942] Coverings should be removed and discarded while the health-care worker is still gloved.[936, 942] The health-care worker, after ungloving and performing hand hygiene, must cover these surfaces with clean materials before the next patient encounter.

b. Cleaning Housekeeping Surfaces

Housekeeping surfaces require regular cleaning and removal of soil and dust. Dry conditions favor the persistence of gram-positive cocci (e.g., coagulase-negative *Staphylococcus* spp.) in dust and on surfaces, whereas moist, soiled environments favor the growth and persistence of gram-negative bacilli.[948, 971, 972] Fungi are also present on dust and proliferate in moist, fibrous material.

Most, if not all, housekeeping surfaces need to be cleaned only with soap and water or a detergent/disinfectant, depending on the nature of the surface and the type and degree of contamination. Cleaning and disinfection schedules and methods vary according to the area of the health-care facility, type of surface to be cleaned, and the amount and type of soil present. Disinfectant/detergent formulations registered by EPA are used for environmental surface cleaning, but the actual physical removal of microorganisms and soil by wiping or scrubbing is probably as important, if not more so, than any antimicrobial effect of the cleaning agent used.[973] Therefore, cost, safety, product-surface compatibility, and acceptability by housekeepers can be the main criteria for selecting a registered agent. If using a proprietary detergent/disinfectant, the manufacturers' instructions for appropriate use of the product should be followed.[974] Consult the products' material safety data sheets (MSDS) to determine appropriate precautions to prevent hazardous conditions during product application. Personal protective equipment (PPE) used during cleaning and housekeeping procedures should be appropriate to the task.

Housekeeping surfaces can be divided into two groups – those with minimal hand-contact (e.g., floors, and ceilings) and those with frequent hand-contact ("high touch surfaces"). The methods, thoroughness, and frequency of cleaning and the products used are determined by health-care facility policy.[6] However, high-touch housekeeping surfaces in patient-care areas (e.g., doorknobs, bedrails, light switches, wall areas around the toilet in the patient's room, and the edges of privacy curtains) should be cleaned and/or disinfected more frequently than surfaces with minimal hand contact. Infection-control practitioners

typically use a risk-assessment approach to identify high-touch surfaces and then coordinate an appropriate cleaning and disinfecting strategy and schedule with the housekeeping staff.

Horizontal surfaces with infrequent hand contact (e.g., window sills and hard-surface flooring) in routine patient-care areas require cleaning on a regular basis, when soiling or spills occur, and when a patient is discharged from the facility.[6] Regular cleaning of surfaces and decontamination, as needed, is also advocated to protect potentially exposed workers.[967] Cleaning of walls, blinds, and window curtains is recommended when they are visibly soiled.[972, 973, 975] Disinfectant fogging is not recommended for general infection control in routine patient-care areas.[2, 976] Further, paraformaldehyde, which was once used in this application, is no longer registered by EPA for this purpose. Use of paraformaldehyde in these circumstances requires either registration or an exemption issued by EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). Infection control, industrial hygienists, and environmental services supervisors should assess the cleaning procedures, chemicals used, and the safety issues to determine if a temporary relocation of the patient is needed when cleaning in the room.

Extraordinary cleaning and decontamination of floors in health-care settings is unwarranted. Studies have demonstrated that disinfection of floors offers no advantage over regular detergent/water cleaning and has minimal or no impact on the occurrence of health-care associated infections.[947, 948, 977–980] Additionally, newly cleaned floors become rapidly recontaminated from airborne microorganisms and those transferred from shoes, equipment wheels, and body substances.[971, 975, 981] Nevertheless, healthcare institutions or contracted cleaning companies may choose to use an EPA-registered detergent/disinfectant for cleaning low-touch surfaces (e.g., floors) in patient-care areas because of the difficulty that personnel may have in determining if a spill contains blood or body fluids (requiring a detergent/disinfectant for clean-up) or when a multi-drug resistant organism is likely to be in the environment. Methods for cleaning non-porous floors include wet mopping and wet vacuuming, dry dusting with electrostatic materials, and spray buffing.[973, 982–984] Methods that produce minimal mists and aerosols or dispersion of dust in patient-care areas are preferred.[9, 20, 109, 272]

Part of the cleaning strategy is to minimize contamination of cleaning solutions and cleaning tools. Bucket solutions become contaminated almost immediately during cleaning, and continued use of the solution transfers increasing numbers of microorganisms to each subsequent surface to be cleaned.[971, 981, 985] Cleaning solutions should be replaced frequently. A variety of "bucket" methods have been devised to address the frequency with which cleaning solutions are replaced.[986, 987] Another source of contamination in the cleaning process is the cleaning cloth or mop head, especially if left soaking in dirty cleaning solutions.[971, 988–990] Laundering of cloths and mop heads after use and allowing them to dry before re-use can help to minimize the degree of contamination.[990] A simplified approach to cleaning involves replacing soiled cloths and mop heads with clean items each time a bucket of detergent/disinfectant is emptied and replaced with fresh, clean solution (B. Stover, Kosair Children's Hospital, 2000). Disposable cleaning cloths and mop heads are an alternative option, if costs permit.

Another reservoir for microorganisms in the cleaning process may be dilute solutions of the detergents or disinfectants, especially if the working solution is prepared in a dirty container, stored for long periods of time, or prepared incorrectly.[547] Gram-negative bacilli (e.g., *Pseudomonas* spp. and *Serratia marcescens*) have been detected in solutions of some disinfectants (e.g., phenolics and quaternary ammonium compounds).[547, 991] Contemporary EPA registration regulations have helped to minimize this problem by asking manufacturers to provide potency data to support label claims for detergent/disinfectant properties under real- use conditions (e.g., diluting the product with tap water instead of distilled water). Application of contaminated cleaning solutions, particularly from small-quantity aerosol spray bottles or with equipment that might generate aerosols during operation, should be avoided, especially in high-risk patient areas.[992, 993] Making sufficient fresh cleaning solution for daily cleaning, discarding any remaining solution, and drying out the container will help to minimize the degree of bacterial contamination. Containers that dispense liquid as opposed to spray-nozzle dispensers (e.g., quart-sized dishwashing liquid bottles) can be used to apply detergent/disinfectants to surfaces and then to cleaning cloths with minimal aerosol generation. A pre-mixed, "ready-to-use" detergent/disinfectant solution may be used if available.

c. Cleaning Special Care Areas

Guidelines have been published regarding cleaning strategies for isolation areas and operating rooms.[6, 7] The basic strategies for areas housing immunosuppressed patients include

a. wet dusting horizontal surfaces daily with cleaning cloths pre-moistened with detergent or an EPA-registered hospital disinfectant or disinfectant wipes;[94, 98463]
b. using care when wet dusting equipment and surfaces above the patient to avoid patient contact with the detergent/disinfectant;
c. avoiding the use of cleaning equipment that produces mists or aerosols;
d. equipping vacuums with HEPA filters, especially for the exhaust, when used in any patient-care area housing immunosuppressed patients;[9, 94, 986] and
e. regular cleaning and maintenance of equipment to ensure efficient particle removal.

When preparing the cleaning cloths for wet-dusting, freshly prepared solutions of detergents or disinfectants should be used rather than cloths that have soaked in such solutions for long periods of time. Dispersal of microorganisms in the air from dust or aerosols is more problematic in these settings than elsewhere in health-care facilities. Vacuum cleaners can serve as dust disseminators if they are not operating properly.[994] Doors to immunosuppressed patients' rooms should be closed when nearby areas are being vacuumed.[9] Bacterial and fungal contamination of filters in cleaning equipment is inevitable, and these filters should be cleaned regularly or replaced as per equipment manufacturer instructions.

Mats with tacky surfaces placed in operating rooms and other patient-care areas only slightly minimize the overall degree of contamination of floors and have little impact on the incidence rate of health-care–associated infection in general.[351, 971, 983] An exception, however, is the use of tacky mats inside the entry ways of cordoned-off construction areas inside the health-care facility; these mats help to minimize the intrusion of dust into patient-care areas.

Special precautions for cleaning incubators, mattresses, and other nursery surfaces have been recommended to address reports of hyperbilirubinemia in newborns linked to inadequately diluted solutions of phenolics and poor ventilation.[995–997] These medical conditions have not, however, been associated with the use of properly prepared solutions of phenolics. Non-porous housekeeping surfaces in neonatal units can be disinfected with properly diluted or pre-mixed phenolics, followed by rinsing with clean water.[997] However, phenolics are not recommended for cleaning infant bassinets and incubators during the stay of the infant. Infants who remain in the nursery for an extended period should be moved periodically to freshly cleaned and disinfected bassinets and incubators.[997] If phenolics are used for cleaning bassinets and incubators after they have been vacated, the surfaces should be rinsed thoroughly with water and dried before either piece of equipment is reused. Cleaning and disinfecting protocols should allow for the full contact time specified for the product used. Bassinet mattresses should be replaced, however, if the mattress cover surface is broken.[997]

3. Cleaning Strategies for Spills of Blood and Body Substances

Neither HBV, HCV, nor HIV has ever been transmitted from a housekeeping surface (i.e., floors, walls, or countertops). Nonetheless, prompt removal and surface disinfection of an area contaminated by either blood or body substances are sound infection-control practices and OSHA requirements.[967]

Studies have demonstrated that HIV is inactivated rapidly after being exposed to commonly used chemical germicides at concentrations that are much lower than those used in practice.[998–1003] HBV is readily inactivated with a variety of germicides, including quaternary ammonium compounds.[1004] Embalming fluids (e.g., formaldehyde) are also capable of completely inactivating HIV and HBV.[1005, 1006] OSHA has revised its regulation for disinfecting spills of blood or other potentially infectious material to include proprietary products whose label includes inactivation claims for HBV and HIV, provided that such surfaces have not become contaminated with agent(s) or volumes of or concentrations of agent(s) for which a higher level of disinfection is recommended.[1007] These registered products are listed in EPA's

List D – *Registered Antimicrobials Effective Against Hepatitis B Virus and Human HIV-1*, which may include products tested against duck hepatitis B virus (DHBV) as a surrogate for HBV.[1008, 1009] Additional lists of interest include EPA's List C –*Registered Antimicrobials Effective Against Human HIV-1* and EPA's List E – *Registered Antimicrobials Effective Against Mycobacterium spp., Hepatitis B Virus, and Human HIV-1*.

Sodium hypochlorite solutions are inexpensive and effective broad-spectrum germicidal solutions.[1010, 1011] Generic sources of sodium hypochlorite include household chlorine bleach or reagent grade chemical. Concentrations of sodium hypochlorite solutions with a range of 5,000–6,150 ppm (1:10 v/v dilution of household bleaches marketed in the United States) to 500–615 ppm (1:100 v/v dilution) free chlorine are effective depending on the amount of organic material (e.g., blood, mucus, and urine) present on the surface to be cleaned and disinfected.[1010, 1011] EPA-registered chemical germicides may be more compatible with certain materials that could be corroded by repeated exposure to sodium hypochlorite, especially the 1:10 dilution. Appropriate personal protective equipment (e.g., gloves and goggles) should be worn when preparing and using hypochlorite solutions or other chemical germicides.[967]

Despite laboratory evidence demonstrating adequate potency against bloodborne pathogens (e.g., HIV and HBV), many chlorine bleach products available in grocery and chemical-supply stores are not registered by the EPA for use as surface disinfectants. Use of these chlorine products as surface disinfectants is considered by the EPA to be an "unregistered use." EPA encourages the use of registered products because the agency reviews them for safety and performance when the product is used according to label instructions. When unregistered products are used for surface disinfection, users do so at their own risk.

Strategies for decontaminating spills of blood and other body fluids differ based on the setting in which they occur and the volume of the spill.[1010] In patient-care areas, workers can manage small spills with cleaning and then disinfecting using an intermediate-level germicide or an EPA-registered germicide from the EPA List D or E.[967, 1007] For spills containing large amounts of blood or other body substances, workers should first remove visible organic matter with absorbent material (e.g., disposable paper towels discarded into leak-proof, properly labeled containment) and then clean and decontaminate the area.[1002, 1003, 1012] If the surface is nonporous and a generic form of a sodium hypochlorite solution is used (e.g., household bleach), a 1:100 dilution is appropriate for decontamination assuming that

a. the worker assigned to clean the spill is wearing gloves and other personal protective equipment appropriate to the task,
b. most of the organic matter of the spill has been removed with absorbent material, and
c. the surface has been cleaned to remove residual organic matter.

A recent study demonstrated that even strong chlorine solutions (i.e., 1:10 dilution of chlorine bleach) may fail to totally inactivate high titers of virus in large quantities of blood, but in the absence of blood these disinfectants can achieve complete viral inactivation.[1011] This evidence supports the need to remove most organic matter from a large spill before final disinfection of the surface. Additionally, EPA-registered proprietary disinfectant label claims are based on use on a pre-cleaned surface.[951, 954]

Managing spills of blood, body fluids, or other infectious materials in clinical, public health, and research laboratories requires more stringent measures because of

a. the higher potential risk of disease transmission associated with large volumes of blood and body fluids and
b. high numbers of microorganisms associated with diagnostic cultures.

The use of an intermediate-level germicide for routine decontamination in the laboratory is prudent.[954] Recommended practices for managing large spills of concentrated infectious agents in the laboratory include

a. confining the contaminated area,
b. flooding the area with a liquid chemical germicide before cleaning, and
c. decontaminating with fresh germicidal chemical of at least intermediate-level disinfectant potency.[1010]

A suggested technique when flooding the spill with germicide is to lay absorbent material down on the spill and apply sufficient germicide to thoroughly wet both the spill and the absorbent material.[1013] If using a solution of household chlorine bleach, a 1:10 dilution is recommended for this purpose. EPA-registered germicides should be used according to the manufacturers' instructions for use dilution and contact time. Gloves should be worn during the cleaning and decontamination procedures in both clinical and laboratory settings. PPE in such a situation may include the use of respiratory protection (e.g., an N95 respirator) if clean-up procedures are expected to generate infectious aerosols. Protocols for cleaning spills should be developed and made available on record as part of good laboratory practice.[1013] Workers in laboratories and in patient-care areas of the facility should receive periodic training in environmental-surface infection-control strategies and procedures as part of an overall infection-control and safety curriculum.

4. Carpeting and Cloth Furnishings

a. Carpeting

Carpeting has been used for more than 30 years in both public and patient-care areas of health-care facilities. Advantages of carpeting in patient-care areas include

a. its noise-limiting characteristics
b. the "humanizing" effect on health care; and
c. its contribution to reductions in falls and resultant injuries, particularly for the elderly.[1014–1016]

Compared to hard-surface flooring, however, carpeting is harder to keep clean, especially after spills of blood and body substances. It is also harder to push equipment with wheels (e.g., wheelchairs, carts, and gurneys) on carpeting.

Several studies have documented the presence of diverse microbial populations, primarily bacteria and fungi, in carpeting;[111, 1017–1024] the variety and number of microorganisms tend to stabilize over time. New carpeting quickly becomes colonized, with bacterial growth plateauing after about 4 weeks.[1019] Vacuuming and cleaning the carpeting can temporarily reduce the numbers of bacteria, but these populations soon rebound and return to pre-cleaning levels.[1019, 1020, 1023] Bacterial contamination tends to increase with higher levels of activity.[1018–1020, 1025] Soiled carpeting that is or remains damp or wet provides an ideal setting for the proliferation and persistence of gram-negative bacteria and fungi.[1026] Carpeting that remains damp should be removed, ideally within 72 hours.

Despite the evidence of bacterial growth and persistence in carpeting, only limited epidemiologic evidence demonstrates that carpets influence health-care associated infection rates in areas housing immunocompetent patients.[1023, 1025, 1027] This guideline, therefore, includes no recommendations against the use of carpeting in these areas. Nonetheless, avoiding the use of carpeting is prudent in areas where spills are likely to occur (e.g., laboratories, areas around sinks, and janitor closets) and where patients may be at greater risk of infection from airborne environmental pathogens (e.g., HSCT units, burn units, ICUs, and ORs).[111, 1028] An outbreak of aspergillosis in an HSCT unit was recently attributed to carpet contamination and a particular method of carpet cleaning.[111] A window in the unit had been opened repeatedly during the time of a nearby building fire, which allowed fungal spore intrusion into the unit. After the window was sealed, the carpeting was cleaned using a "bonnet buffing" machine, which dispersed *Aspergillus* spores into the air.[111] Wet vacuuming was instituted, replacing the dry cleaning method used previously; no additional cases of invasive aspergillosis were identified.

The care setting and the method of carpet cleaning are important factors to consider when attempting to minimize or prevent production of aerosols and dispersal of carpet microorganisms into the air.[94, 111] Both vacuuming and shampooing or wet cleaning with equipment can disperse microorganisms to the air.[111, 994] Vacuum cleaners should be maintained to minimize dust dispersal in general, and be equipped with HEPA filters, especially for use in high-risk patient-care areas.[9, 94, 986] Some formulations of carpet-cleaning chemicals, if applied or used improperly, can be dispersed into the air as a fine dust capable of

causing respiratory irritation in patients and staff.[1029] Cleaning equipment, especially those that engage in wet cleaning and extraction, can become contaminated with waterborne organisms (e.g., *Pseudomonas aeruginosa*) and serve as a reservoir for these organisms if this equipment is not properly maintained. Substantial numbers of bacteria can then be transferred to carpeting during the cleaning process.[1030] Therefore, keeping the carpet cleaning equipment in good repair and allowing such equipment to dry between uses is prudent.

Carpet cleaning should be performed on a regular basis determined by internal policy. Although spills of blood and body substances on non-porous surfaces require prompt spot cleaning using standard cleaning procedures and application of chemical germicides,[967] similar decontamination approaches to blood and body substance spills on carpeting can be problematic from a regulatory perspective.[1031] Most, if not all, modern carpet brands suitable for public facilities can tolerate the activity of a variety of liquid chemical germicides. However, according to OSHA, carpeting contaminated with blood or other potentially infectious materials cannot be fully decontaminated.[1032] Therefore, facilities electing to use carpeting for high-activity patient-care areas may choose carpet tiles in areas at high risk for spills.[967, 1032] In the event of contamination with blood or other body substances, carpet tiles can be removed, discarded, and replaced. OSHA also acknowledges that only minimal direct skin contact occurs with carpeting, and therefore, employers are expected to make reasonable efforts to clean and sanitize carpeting using carpet detergent/cleaner products.[1032]

Over the last few years, some carpet manufacturers have treated their products with fungicidal and/or bactericidal chemicals. Although these chemicals may help to reduce the overall numbers of bacteria or fungi present in carpet, their use does not preclude the routine care and maintenance of the carpeting. Limited evidence suggests that chemically treated carpet may have helped to keep health-care– associated aspergillosis rates low in one HSCT unit, [111] but overall, treated carpeting has not been shown to prevent the incidence of health-care associated infections in care areas for immunocompetent patients.

b. Cloth Furnishings

Upholstered furniture and furnishings are becoming increasingly common in patient-care areas. These furnishings range from simple cloth chairs in patients' rooms to a complete decorating scheme that gives the interior of the facility more the look of an elegant hotel.[1033] Even though pathogenic microorganisms have been isolated from the surfaces of cloth chairs, no epidemiologic evidence suggests that general patient-care areas with cloth furniture pose increased risks of health-care associated infection compared with areas that contain hard-surfaced furniture.[1034, 1035] Allergens (e.g., dog and cat dander) have been detected in or on cloth furniture in clinics and elsewhere in hospitals in concentrations higher than those found on bed linens.[1034, 1035] These allergens presumably are transferred from the clothing of visitors. Researchers have therefore suggested that cloth chairs should be vacuumed regularly to keep the dust and allergen levels to a minimum. This recommendation, however, has generated concerns that aerosols created from vacuuming could place immunocompromised patients or patients with preexisting lung disease (e.g., asthma) at risk for development of health-care associated, environmental airborne disease.[9, 20, 109, 988] Recovering worn, upholstered furniture (especially the seat cushion) with covers that are easily cleaned (e.g., vinyl), or replacing the item is prudent; minimizing the use of upholstered furniture and furnishings in any patient-care areas where immunosuppressed patients are located (e.g., HSCT units) reduces the likelihood of disease.[9]

5. Flowers and Plants in Patient-Care Areas

Fresh flowers, dried flowers, and potted plants are common items in health-care facilities. In 1974, clinicians isolated an *Erwinia* sp. post mortem from a neonate diagnosed with fulminant septicemia, meningitis, and respiratory distress syndrome.[1038] Because *Erwinia* spp. are plant pathogens, plants brought into the delivery room were suspected to be the source of the bacteria, although the case report

did not definitively establish a direct link. Several subsequent studies evaluated the numbers and diversity of microorganisms in the vase water of cut flowers. These studies revealed that high concentrations of bacteria, ranging from 10^4–10^{10} CFU/mL, were often present, especially if the water was changed infrequently.[515, 702, 1039] The major group of microorganisms in flower vase water was gram-negative bacteria, with *Pseudomonas aeruginosa* the most frequently isolated organism.[515, 702, 1039, 1040] *P. aeruginosa* was also the primary organism directly isolated from chrysanthemums and other potted plants.[1041, 1042] However, flowers in hospitals were not significantly more contaminated with bacteria compared with flowers in restaurants or in the home.[702] Additionally, no differences in the diversity and degree of antibiotic resistance of bacteria have been observed in samples isolated from hospital flowers versus those obtained from flowers elsewhere.[702]

Despite the diversity and large numbers of bacteria associated with flower-vase water and potted plants, minimal or no evidence indicates that the presence of plants in immunocompetent patient-care areas poses an increased risk of health-care associated infection.[515] In one study involving a limited number of surgical patients, no correlation was observed between bacterial isolates from flowers in the area and the incidence and etiology of postoperative infections among the patients.[1040] Similar conclusions were reached in a study that examined the bacteria found in potted plants.[1042] Nonetheless, some precautions for general patient-care settings should be implemented, including

a. limiting flower and plant care to staff with no direct patient contact,
b. advising health-care staff to wear gloves when handling plants,
c. washing hands after handling plants,
d. changing vase water every 2 days and discharging the water into a sink outside the immediate patient environment, and
e. cleaning and disinfecting vases after use.[702]

Some researchers have examined the possibility of adding a chemical germicide to vase water to control bacterial populations. Certain chemicals (e.g., hydrogen peroxide and chlorhexidine) are well tolerated by plants.[1040, 1043, 1044] Use of these chemicals, however, was not evaluated in studies to assess impact on health-care associated infection rates. Modern florists now have a variety of products available to add to vase water to extend the life of cut flowers and to minimize bacterial clouding of the water.

Flowers (fresh and dried) and ornamental plants, however, may serve as a reservoir of *Aspergillus* spp., and dispersal of conidiospores into the air from this source can occur.[109] Health-care associated outbreaks of invasive aspergillosis reinforce the importance of maintaining an environment as free of *Aspergillus* spp. spores as possible for patients with severe, prolonged neutropenia. Potted plants, fresh-cut flowers, and dried flower arrangements may provide a reservoir for these fungi as well as other fungal species (e.g., *Fusarium* spp.).[109, 1045, 1046] Researchers in one study of bacteria and flowers suggested that flowers and vase water should be avoided in areas providing care to medically at-risk patients (e.g., oncology patients and transplant patients), although this study did not attempt to correlate the observations of bacterial populations in the vase water with the incidence of health-care associated infections.[515] Another study using molecular epidemiology techniques demonstrated identical *Aspergillus terreus* types among environmental and clinical specimens isolated from infected patients with hematological malignancies.[1046] Therefore, attempts should be made to exclude flowers and plants from areas where immunosuppressed patients are be located (e.g., HSCT units).[9, 1046]

6. Pest Control

Cockroaches, flies and maggots, ants, mosquitoes, spiders, mites, midges, and mice are among the typical arthropod and vertebrate pest populations found in health-care facilities. Insects can serve as agents for the mechanical transmission of microorganisms, or as active participants in the disease transmission process by serving as a vector.[1047–1049] Arthropods recovered from health-care facilities have been shown to carry a wide variety of pathogenic microorganisms.[1050–1056] Studies have suggested that the diversity of microorganisms associated with insects reflects the microbial populations present in the indoor health-care

environment; some pathogens encountered in insects from hospitals were either absent from or present to a lesser degree in insects trapped from residential settings.[1057–1060] Some of the microbial populations associated with insects in hospitals have demonstrated resistance to antibiotics.[1048, 1059, 1061–1063]

Insect habitats are characterized by warmth, moisture, and availability of food.[1064] Insects forage in and feed on substrates, including but not limited to food scraps from kitchens/cafeteria, foods in vending machines, discharges on dressings either in use or discarded, other forms of human detritis, medical wastes, human wastes, and routine solid waste.[1057–1061] Cockroaches, in particular, have been known to feed on fixed sputum smears in laboratories.[1065, 1066] Both cockroaches and ants are frequently found in the laundry, central sterile supply departments, and anywhere in the facility where water or moisture is present (e.g., sink traps, drains and janitor closets). Ants will often find their way into sterile packs of items as they forage in a warm, moist environment.[1057] Cockroaches and other insects frequent loading docks and other areas with direct access to the outdoors.

Although insects carry a wide variety of pathogenic microorganisms on their surfaces and in their gut, the direct association of insects with disease transmission (apart from vector transmission) is limited, especially in health-care settings; the presence of insects in itself likely does not contribute substantially to health-care associated disease transmission in developed countries. However, outbreaks of infection attributed to microorganisms carried by insects may occur because of infestation coupled with breaks in standard infection-control practices.[1063] Studies have been conducted to examine the role of houseflies as possible vectors for shigellosis and other forms of diarrheal disease in non-health–care settings.[1046, 1067] When control measures aimed at reducing the fly population density were implemented, a concomitant reduction in the incidence of diarrheal infections, carriage of *Shigella* organisms, and mortality caused by diarrhea among infants and young children was observed.

Myiasis is defined as a parasitosis in which the larvae of any of a variety of flies use living or necrotic tissue or body substances of the host as a nutritional source.[1068] Larvae from health-care acquired myiasis have been observed in nares, wounds, eyes, ears, sinuses, and the external urogenital structures.[1069–1071] Patients with this rare condition are typically older adults with underlying medical conditions (e.g., diabetes, chronic wounds, and alcoholism) who have a decreased capacity to ward off the flies. Persons with underlying conditions who live or travel to tropical regions of the world are especially at risk.[1070, 1071] Cases occur in the summer and early fall months in temperate climates when flies are most active.[1071] An environmental assessment and review of the patient's history are necessary to verify that the source of the myiasis is health-care acquired and to identify corrective measures.[1069, 1072] Simple prevention measures (e.g., installing screens on windows) are important in reducing the incidence of myiasis.[1072]

From a public health and hygiene perspective, arthropod and vertebrate pests should be eradicated from all indoor environments, including health-care facilities.[1073, 1074] Modern approaches to institutional pest management usually focus on

a. eliminating food sources, indoor habitats, and other conditions that attract pests
b. excluding pests from the indoor environments; and
c. applying pesticides as needed.[1075]

Sealing windows in modern health-care facilities helps to minimize insect intrusion. When windows need to be opened for ventilation, ensuring that screens are in good repair and closing doors to the outside can help with pest control. Insects should be kept out of all areas of the health-care facility, especially ORs and any area where immunosuppressed patients are located. A pest-control specialist with appropriate credentials can provide a regular insect-control program that is tailored to the needs of the facility and uses approved chemicals and/or physical methods. Industrial hygienists can provide information on possible adverse reactions of patients and staff to pesticides and suggest alternative methods for pest control, as needed.

7. Special Pathogen Concerns

a. Antibiotic-Resistant Gram-Positive Cocci

Vancomycin-resistant enterococci (VRE), methicillin-resistant *Staphylococcus aureus* (MRSA), and *S. aureus* with intermediate levels of resistance to glycopeptide antibiotics (vancomycin intermediate resistant *S. aureus* [VISA] or glycopeptide intermediate resistant *S. aureus* [GISA]) represent crucial and growing concerns for infection control. Although the term GISA is technically a more accurate description of the strains isolated to date (most of which are classified as having intermediate resistance to both vancomycin and teicoplanin), the term "glycopeptide" may not be recognized by many clinicians. Thus, the label of VISA, which emphasizes a change in minimum inhibitory concentration (MICs) to vancomycin, is similar to that of VRE and is more meaningful to clinicians.[1076] According to National Nosocomial Infection Surveillance (NNIS) statistics for infections acquired among ICU patients in the United States in 1999, 52.3% of infections resulting from *S. aureus* were identified as MRSA infections, and 25.2% of enterococcal infections were attributed to VRE. These figures reflect a 37% and a 43% increase, respectively, since 1994–1998.[1077]

People represent the primary reservoir of *S. aureus*. [1078] Although *S. aureus* has been isolated from a variety of environmental surfaces (e.g., stethoscopes, floors, charts, furniture, dry mops, and hydrotherapy tanks), the role of environmental contamination in transmission of this organism in health care appears to be minimal.[1079–1082] *S. aureus* contamination of surfaces and tanks within burn therapy units, however, may be a major factor in the transmission of infection among burn patients.[1083]

Colonized patients are the principal reservoir of VRE, and patients who are immunosuppressed (e.g., transplant patients) or otherwise medically at-risk (e.g., ICU patients, cardio-thoracic surgical patients, patients previously hospitalized for extended periods, and those having received multi-antimicrobial or vancomycin therapy) are at greatest risk for VRE colonization.[1084–1087] The mechanisms by which cross-colonization take place are not well defined, although recent studies have indicated that both MRSA and VRE may be transmitted either

a. directly from patient to patient,
b. indirectly by transient carriage on the hands of health-care workers,[1088–1091] or
c. by hand transfer of these gram-positive organisms from contaminated environmental surfaces and patient-care equipment.[1084, 1087, 1092–1097]

In one survey, hand carriage of VRE in workers in a long-term care facility ranged from 13%–41%.[1098] Many of the environmental surfaces found to be contaminated with VRE in outbreak investigations have been those that are touched frequently by the patient or the health-care worker.[1099] Such high-touch surfaces include bedrails, doorknobs, bed linens, gowns, overbed tables, blood pressure cuffs, computer table, bedside tables, and various medical equipment.[22, 1087, 1094, 1095, 1100–1102] Contamination of environmental surfaces with VRE generally occurs in clinical laboratories and areas where colonized patients are present,[1087, 1092, 1094, 1095, 1103] but the potential for contamination increases when such patients have diarrhea[1087] or have multiple body-site colonization.[1104] Additional factors that can be important in the dispersion of these pathogens to environmental surfaces are misuse of glove techniques by healthcare workers (especially when cleaning fecal contamination from surfaces) and patient, family, and visitor hygiene.

Interest in the importance of environmental reservoirs of VRE increased when laboratory studies demonstrated that enterococci can persist in a viable state on dry environmental surfaces for extended periods of time (7 days to 4 months)[1099, 1105] and multiple strains can be identified during extensive periods of surveillance.[1104] VRE can be recovered from inoculated hands of health-care workers (with or without gloves) for up to 60 minutes.[22] The presence of either MRSA, VISA, or VRE on environmental surfaces, however, does not mean that patients in the contaminated areas will become colonized. Strict adherence to hand hygiene/handwashing and the proper use of barrier precautions help to minimize the potential for spread of these pathogens. Published recommendations for preventing the spread of vancomycin resistance address isolation measures, including patient cohorting and management of patient-care items.[5]

Direct patient-care items (e.g., blood pressure cuffs) should be disposable whenever possible when used in contact isolation settings for patients with multiply resistant microorganisms.[1102]

Careful cleaning of patient rooms and medical equipment contributes substantially to the overall control of MRSA, VISA, or VRE transmission. The major focus of a control program for either VRE or MRSA should be the prevention of hand transfer of these organisms. Routine cleaning and disinfection of the housekeeping surfaces (e.g., floors and walls) and patient-care surfaces (e.g., bedrails) should be adequate for inactivation of these organisms. Both MRSA and VRE are susceptible to several EPA-registered low- and intermediate-level disinfectants (e.g., alcohols, sodium hypochlorite, quaternary ammonium compounds, phenolics, and iodophors) at recommended use dilutions for environmental surface disinfection.[1103, 1106–1109] Additionally, both VRE and vancomycin-sensitive enterococci are equally sensitive to inactivation by chemical germicides,[1106, 1107, 1109] and similar observations have been made when comparing the germicidal resistance of MRSA to that of either methicillin-sensitive *S. aureus* (MSSA) or VISA.[1110] The use of stronger solutions of disinfectants for inactivation of either VRE, MRSA, or VISA is not recommended based on the organisms' resistance to antibiotics.[1110–1112] VRE from clinical specimens have exhibited some measure of increased tolerance to heat inactivation in temperature ranges <212°F (<100°C);[1106, 1113] however, the clinical significance of these observations is unclear because the role of cleaning the surface or item prior to heat treatment was not evaluated. Although routine environmental sampling is not recommended, laboratory surveillance of environmental surfaces during episodes when VRE contamination is suspected can help determine the effectiveness of the cleaning and disinfecting procedures. Environmental culturing should be approved and supervised by the infection-control program in collaboration with the clinical laboratory.[1084, 1087, 1088, 1092, 1096]

Two cases of wound infections associated with vancomycin-resistant *Staphylococcus aureus* (VRSA) determined to be resistant by NCCLS standards for sensitivity/resistance testing were identified in Michigan and Pennsylvania in 2002.[1114, 1115] These represented isolated cases, and neither the family members nor the health-care providers of these case-patients had evidence of colonization or infection with VRSA. Conventional environmental infection-control measures (i.e., cleaning and then disinfecting surfaces using EPA-registered disinfectants with label claims for *S. aureus*) were used during the environmental investigation of these two cases;[1110–1112] however, studies have yet to evaluate the potential intrinsic resistance of these VRSA strains to surface disinfectants.

Standard procedures during terminal cleaning and disinfection of surfaces, if performed incorrectly, may be inadequate for the elimination of VRE from patient rooms.[1113, 1116–1118] Given the sensitivity of VRE to hospital disinfectants, current disinfecting protocols should be effective if they are diligently carried out and properly performed. Health-care facilities should be sure that housekeeping staff use correct procedures for cleaning and disinfecting surfaces in VRE-contaminated areas, which include using sufficient amounts of germicide at proper use dilution and allowing adequate contact time.[1118]

b. Clostridium difficile

Clostridium difficile is the most frequent etiologic agent for health-care associated diarrhea.[1119, 1120] In one hospital, 30% of adults who developed health-care associated diarrhea were positive for *C. difficile*.[1121] One recent study employing PCR-ribotyping techniques demonstrated that cases of *C. difiicile*-acquired diarrhea occurring in the hospital included patients whose infections were attributed to endogenous *C. difficile* strains and patients whose illnesses were considered to be health-care– associated infections.[1122] Most patients remain asymptomatic after infection, but the organism continues to be shed in their stools. Risk factors for acquiring *C. difficile*-associated infection include

a. exposure to antibiotic therapy, particularly with beta-lactam agents;[1123]
b. gastrointestinal procedures and surgery;[1124]
c. advanced age; and
d. indiscriminate use of antibiotics.[1125–1128]

Of all the measures that have been used to prevent the spread of *C. difficile*-associated diarrhea, the most successful has been the restriction of the use of antimicrobial agents.[1129, 1130]

C. difficile is an anaerobic, gram-positive bacterium. Normally fastidious in its vegetative state, it is capable of sporulating when environmental conditions no longer support its continued growth. The capacity to form spores enables the organism to persist in the environment (e.g., in soil and on dry surfaces) for extended periods of time. Environmental contamination by this microorganism is well known, especially in places where fecal contamination may occur.[1131] The environment (especially housekeeping surfaces) rarely serves as a direct source of infection for patients.[1024, 1132–1136] However, direct exposure to contaminated patient-care items (e.g., rectal thermometers) and high-touch surfaces in patients' bathrooms (e.g., light switches) have been implicated as sources of infection.[1130, 1135, 1136, 1138]

Transfer of the pathogen to the patient via the hands of health-care workers is thought to be the most likely mechanism of exposure.[24, 1133, 1139] Standard isolation techniques intended to minimize enteric contamination of patients, health-care–workers' hands, patient-care items, and environmental surfaces have been published.[1140] Handwashing remains the most effective means of reducing hand contamination. Proper use of gloves is an ancillary measure that helps to further minimize transfer of these pathogens from one surface to another.

The degree to which the environment becomes contaminated with *C. difficile* spores is proportional to the number of patients with *C. difficile*-associated diarrhea,[24, 1132, 1135] although asymptomatic, colonized patients may also serve as a source of contamination. Few studies have examined the use of specific chemical germicides for the inactivation of *C. difficile* spores, and no well-controlled trials have been conducted to determine efficacy of surface disinfection and its impact on health-care associated diarrhea. Some investigators have evaluated the use of chlorine-containing chemicals (e.g., 1,000 ppm hypochlorite at recommended use-dilution, 5,000 ppm sodium hypochlorite [1:10 v/v dilution], 1:100 v/v dilutions of unbuffered hypochlorite, and phosphate-buffered hypochlorite [1,600 ppm]). One of the studies demonstrated that the number of contaminated environmental sites was reduced by half,[1135] whereas another two studies demonstrated declines in health-care associated *C. difficile* infections in a HSCT unit[1141] and in two geriatric medical units[1142] during a period of hypochlorite use. The presence of confounding factors, however, was acknowledged in one of these studies.[1142]

***C. difficile* Update [April 2019]**

Recommendations E.VI.G. and E.VI.H. were updated to reflect changes in Federal regulatory approvals: LIST K: EPA's Registered Antimicrobial Products Effective against Clostridium difficile Spores (https://www.epa.gov/pesticide-registration/list-k-epas-registered-antimicrobial-products-effective-against-clostridium).

The recommended approach to environmental infection control with respect to *C. difficile* is meticulous cleaning followed by disinfection using EPA-registered products specific for inactivating *C. difficile* spores as appropirate. Thus, combined use of appropriate hand hygiene, barrier precautions, and meticulous environmental cleaning, and use of an EPA-registered product that is appropriate for the level of risk, should effectively prevent spread of the organism. [LIST K: EPA's Registered Antimicrobial Products Effective against Clostridium difficile Spores (https://www.epa.gov/pesticide-registration/list-k-epas-registered-antimicrobial-products-effective-against-clostridium)].

c. Respiratory and Enteric Viruses in Pediatric-Care Settings

Although the viruses mentioned in this guideline are not unique to the pediatric-care setting in healthcare facilities, their prevalence in these areas, especially during the winter months, is substantial. Children

(particularly neonates) are more likely to develop infection and substantial clinical disease from these agents compared with adults and therefore are more likely to require supportive care during their illness.

Common respiratory viruses in pediatric-care areas include rhinoviruses, respiratory syncytial virus (RSV), adenoviruses, influenza viruses, and parainfluenza viruses. Transmission of these viruses occurs primarily via direct contact with small-particle aerosols or via hand contamination with respiratory secretions that are then transferred to the nose or eyes. Because transmission primarily requires close personal contact, contact precautions are appropriate to interrupt transmission.[6] Hand contamination can occur from direct contact with secretions or indirectly from touching high-touch environmental surfaces that have become contaminated with virus from large droplets. The indirect transfer of virus from one persion to other via hand contact with frequently-touched fomites was demonstrated in a study using a bacteriophage whose environmental stability approximated that of human viral pathogens (e.g., poliovirus and parvovirus).[1144] The impact of this mode of transmission with respect to human respiratory- and enteric viruses is dependent on the ability of these agents to survive on environmental surfaces. Infectious RSV has been recovered from skin, porous surfaces, and non-porous surfaces after 30 minutes, 1 hour, and 7 hours, respectively.[1145] Parainfluenza viruses are known to persist for up to 4 hours on porous surfaces and up to 10 hours on non-porous surfaces.[1146] Rhinoviruses can persist on porous surfaces and non-porous surfaces for approximately 1 and 3 hours respectively; study participants in a controlled environment became infected with rhinoviruses after first touching a surface with dried secretions and then touching their nasal or conjunctival mucosa.[1147] Although the efficiency of direct transmission of these viruses from surfaces in uncontrolled settings remains to be defined, these data underscore the basis for maintaining regular protocols for cleaning and disinfecting of high-touch surfaces.

The clinically important enteric viruses encountered in pediatric care settings include enteric adenovirus, astroviruses, caliciviruses, and rotavirus. Group A rotavirus is the most common cause of infectious diarrhea in infants and children. Transmission of this virus is primarily fecal-oral, however, the role of fecally contaminated surfaces and fomites in rotavirus transmission is unclear. During one epidemiologic investigation of enteric disease among children attending day care, rotavirus contamination was detected on 19% of inanimate objects in the center.[1148, 1149] In an outbreak in a pediatric unit, secondary cases of rotavirus infection clustered in areas where children with rotaviral diarrhea were located.[1150] Astroviruses cause gastroenteritis and diarrhea in newborns and young children and can persist on fecally contaminated surfaces for several months during periods of relatively low humidity.[1151, 1152] Outbreaks of small round-structured viruses (i.e., caliciviruses [Norwalk virus and Norwalk-like viruses]) can affect both patients and staff, with attack rates of ≥50%.[1153] Routes of person-to-person transmission include fecal-oral spread and aerosols generated from vomiting.[1154–1156] Fecal contamination of surfaces in care settings can spread large amounts of virus to the environment. Studies that have attempted to use low- and intermediate-level disinfectants to inactivate rotavirus suspended in feces have demonstrated a protective effect of high concentrations of organic matter.[1157, 1158] Intermediate-level disinfectants (e.g., alcoholic quaternary ammonium compounds, and chlorine solutions) can be effective in inactivating enteric viruses provided that a cleaning step to remove most of the organic matter precedes terminal disinfection.[1158] These findings underscore the need for proper cleaning and disinfecting procedures where contamination of environmental surfaces with body substances is likely. EPA-registered surface disinfectants with label claims for these viral agents should be used in these settings. Using disposable, protective barrier coverings may help to minimize the degree of surface contamination.[936]

d. Severe Acute Respiratory Syndrome (SARS) Virus

In November 2002 an atypical pneumonia of unknown etiology emerged in Asia and subsequently developed into an international outbreak of respiratory illness among persons in 29 countries during the

first six months of 2003. “Severe acute respiratory syndrome” (SARS) is a viral upper respiratory infection associated with a newly described coronavirus (SARS-associated Co-V [SARS-CoV]). SARS-CoV is an enveloped RNA virus. It is present in high titers in respiratory secretions, stool, and blood of infected persons. The modes of transmission determined from epidemiologic investigations were primarily forms of direct contact (i.e., large droplet aerosolization and person-to-person contact). Respiratory secretions were presumed to be the major source of virus in these situations; airborne transmission of virus has not been completely ruled out. Little is known about the impact of fecal-oral transmission and SARS.

The epidemiology of SARS-CoV infection is not completely understood, and therefore recommended infection control and prevention measures to contain the spread of SARS will evolve as new information becomes available.[1159] At present there is no indication that established strategies for cleaning (i.e., to remove the majority of bioburden) and disinfecting equipment and environmental surfaces need to be changed for the environmental infection control of SARS. In-patient rooms housing SARS patients should be cleaned and disinfected at least daily and at the time of patient transfer or discharge. More frequent cleaning and disinfection may be indicated for high-touch surfaces and following aerosol-producing procedures (e.g., intubation, bronchoscopy, and sputum production). While there are presently no disinfectant products registered by EPA specifically for inactivation of SARS-CoV, EPA-registered hospital disinfectants that are equivalent to low- and intermediate-level germicides may be used on pre-cleaned, hard, non-porous surfaces in accordance with manufacturer’s instructions for environmental surface disinfection. Monitoring adherence to guidelines established for cleaning and disinfection is an important component of environmental infection control to contain the spread of SARS.

e. Creutzfeldt-Jakob Disease (CJD) in Patient-Care Areas

Creutzfeldt-Jakob disease (CJD) is a rare, invariably fatal, transmissible spongiform encephalopathy (TSE) that occurs worldwide with an average annual incidence of 1 case per million population.[1160–1162] CJD is one of several TSEs affecting humans; other diseases in this group include kuru, fatal familial insomnia, and Gerstmann-Sträussler-Scheinker syndrome. A TSE that affects a younger population (compared to the age range of CJD cases) has been described primarily in the United Kingdom since 1996.[1163] This variant form of CJD (vCJD) is clinically and neuropathologically distinguishable from classic CJD; epidemiologic and laboratory evidence suggests a causal association for bovine spongiform encephalopathy (BSE [Mad Cow disease]) and vCJD.[1163–1166]

The agent associated with CJD is a prion, which is an abnormal isoform of a normal protein constituent of the central nervous system.[1167–1169] The mechanism by which the normal form of the protein is converted to the abnormal, disease-causing prion is unknown. The tertiary conformation of the abnormal prion protein appears to confer a heightened degree of resistance to conventional methods of sterilization and disinfection.[1170, 1171]

Although about 90% of CJD cases occur sporadically, a limited number of cases are the result of a direct exposure to prion-containing material (usually central nervous system tissue or pituitary hormones) acquired as a result of health care (iatrogenic cases). These cases have been linked to

a. pituitary hormone therapy [from human sources as opposed to hormones prepared through the use of recombinant technology],[1170–1174]
b. transplants of either dura mater or corneas,[1175–1181] and
c. neurosurgical instruments and depth electrodes.[1182–1185]

In the cases involving instruments and depth electrodes, conventional cleaning and terminal reprocessing methods of the day failed to fully inactivate the contaminating prions and are considered inadequate by today’s standards.

Prion inactivation studies involving whole tissues and tissue homogenates have been conducted to determine the parameters of physical and chemical methods of sterilization or disinfection necessary for complete inactivation;[1170, 1186–1191] however, the application of these findings to environmental infection control in health-care settings is problematic. No studies have evaluated the effectiveness of medical instrument reprocessing in inactivating prions. Despite a consensus that abnormal prions display some extreme measure of resistance to inactivation by either physical or chemical methods, scientists disagree about the exact conditions needed for sterilization. Inactivation studies utilizing whole tissues present extraordinary challenges to any sterilizing method.[1192] Additionally, the experimental designs of these studies preclude the evaluation of surface cleaning as a part of the total approach to pathogen inactivation.[951, 1192]

Some researchers have recommended the use of either a 1:2 v/v dilution of sodium hypochorite (approximately 20,000 ppm), full-strength sodium hypochlorite (50,000–60,000 ppm), or 1–2 N sodium hydroxide (NaOH) for the inactivation of prions on certain surfaces (e.g., those found in the pathology laboratory).[1170, 1188] Although these chemicals may be appropriate for the decontamination of laboratory, operating-room, or autopsy-room surfaces that come into contact with central nervous system tissue from a known or suspected patient, this approach is not indicated for routine or terminal cleaning of a room previously occupied by a CJD patient. Both chemicals pose hazards for the healthcare worker doing the decontamination. NaOH is caustic and should not make contact with the skin. Sodium hypochlorite solutions (i.e., chlorine bleach) can corrode metals (e.g., aluminum). MSDS information should be consulted when attempting to work with concentrated solutions of either chemical. Currently, no EPA-registered products have label claims for prion inactivation; therefore, this guidance is based on the best available evidence from the scientific literature.

Environmental infection-control strategies must based on the principles of the “chain of infection,” regardless of the disease of concern.[13] Although CJD is transmissible, it is not highly contagious. All iatrogenic cases of CJD have been linked to a direct exposure to prion-contaminated central nervous system tissue or pituitary hormones. The six documented iatrogenic cases associated with instruments and devices involved neurosurgical instruments and devices that introduced residual contamination directly to the recipient’s brain. No evidence suggests that vCJD has been transmitted iatrogenically or that either CJD or vCJD has been transmitted from environmental surfaces (e.g., housekeeping surfaces). Therefore, routine procedures are adequate for terminal cleaning and disinfection of a CJD patient’s room. Additionally, in epidemiologic studies involving highly transfused patients, blood was not identified as a source for prion transmission.[1193–1198] Routine procedures for containing, decontaminating, and disinfecting surfaces with blood spills should be adequate for proper infection control in these situations.[951, 1199]

Guidance for environmental infection control in ORs and autopsy areas has been published.[1197, 1199] Hospitals should develop risk-assessment procedures to identify patients with known or suspected CJD in efforts to implement prion-specific infection-control measures for the OR and for instrument reprocessing.[1200] This assessment also should be conducted for older patients undergoing non-lesionous neurosurgery when such procedures are being done for diagnosis. Disposable, impermeable coverings should be used during these autopsies and neurosurgeries to minimize surface contamination. Surfaces that have become contaminated with central nervous system tissue or cerebral spinal fluid should be cleaned and decontaminated by

a. removing most of the tissue or body substance with absorbent materials,
b. wetting the surface with a sodium hypochlorite solution containing ≥5,000 ppm or a 1 N NaOH solution, and
c. rinsing thoroughly.[951, 1197–1199, 1201]

The optimum duration of contact exposure in these instances is unclear. Some researchers recommend a 1-hour contact time on the basis of tissue-inactivation studies,[1197, 1198, 1201] whereas other reviewers of the subject draw no conclusions from this research.[1199] Factors to consider before cleaning a potentially contaminated surface are

a. the degree to which gross tissue/body substance contamination can be effectively removed and
b. the ease with which the surface can be cleaned.

F. Environmental Sampling

This portion of Part I addresses the basic principles and methods of sampling environmental surfaces and other environmental sources for microorganisms. The applied strategies of sampling with respect to environmental infection control have been discussed in the appropriate preceding subsections.

1. General Principles: Microbiologic Sampling of the Environment

Before 1970, U.S. hospitals conducted regularly scheduled culturing of the air and environmental surfaces (e.g., floors, walls, and table tops).[1202] By 1970, CDC and the American Hospital Association (AHA) were advocating the discontinuation of routine environmental culturing because rates of healthcare–associated infection had not been associated with levels of general microbial contamination of air or environmental surfaces, and because meaningful standards for permissible levels of microbial contamination of environmental surfaces or air did not exist.[1203–1205] During 1970–1975, 25% of U.S. hospitals reduced the extent of such routine environmental culturing — a trend that has continued.[1206, 1207]

Random, undirected sampling (referred to as "routine" in previous guidelines) differs from the current practice of targeted sampling for defined purposes.[2, 1204] Previous recommendations against routine sampling were not intended to discourage the use of sampling in which sample collection, culture, and interpretation are conducted in accordance with defined protocols.[2] In this guideline, targeted microbiologic sampling connotes a monitoring process that includes

a. a written, defined, multidisciplinary protocol for sample collection and culturing
b. analysis and interpretation of results using scientifically determined or anticipatory baseline values for comparison; and
c. expected actions based on the results obtained.

Infection control, in conjunction with laboratorians, should assess the health-care facility's capability to conduct sampling and determine when expert consultation and/or services are needed.

Microbiologic sampling of air, water, and inanimate surfaces (i.e., environmental sampling) is an expensive and time-consuming process that is complicated by many variables in protocol, analysis, and interpretation. It is therefore indicated for only four situations.[1208] The first is to support an investigation of an outbreak of disease or infections when environmental reservoirs or fomites are implicated epidemiologically in disease transmission.[161, 1209, 1210] It is important that such culturing be supported by epidemiologic data. Environmental sampling, as with all laboratory testing, should not be conducted if there is no plan for interpreting and acting on the results obtained.[11, 1211, 1212] Linking microorganisms from environmental samples with clinical isolates by molecular epidemiology is crucial whenever it is possible to do so.

The second situation for which environmental sampling may be warranted is in research. Well-designed and controlled experimental methods and approaches can provide new information about the spread of health-care associated diseases.[126, 129] A classic example is the study of environmental microbial contamination that compared health-care associated infection rates in an old hospital and a new facility before and shortly after occupancy.[947]

The third indication for sampling is to monitor a potentially hazardous environmental condition, confirm the presence of a hazardous chemical or biological agent, and validate the successful abatement of the hazard. This type of sampling can be used to:

a. detect bioaerosols released from the operation of health-care equipment (e.g., an ultrasonic cleaner) and determine the success of repairs in containing the hazard,[1213]
b. detect the release of an agent of bioterrorism in an indoor environmental setting and determine its successful removal or inactivation, and

c. sample for industrial hygiene or safety purposes (e.g., monitoring a “sick building”).

The fourth indication is for quality assurance to evaluate the effects of a change in infection-control practice or to ensure that equipment or systems perform according to specifications and expected outcomes. Any sampling for quality-assurance purposes must follow sound sampling protocols and address confounding factors through the use of properly selected controls. Results from a single environmental sample are difficult to interpret in the absence of a frame of reference or perspective. Evaluations of a change in infection-control practice are based on the assumption that the effect will be measured over a finite period, usually of short duration. Conducting quality-assurance sampling on an extended basis, especially in the absence of an adverse outcome, is usually unjustified. A possible exception might be the use of air sampling during major construction periods to qualitatively detect breaks in environmental infection-control measures. In one study, which began as part of an investigation of an outbreak of health-care associated aspergillosis, airborne concentrations of *Aspergillus* spores were measured in efforts to evaluate the effectiveness of sealing hospital doors and windows during a period of construction of a nearby building.[50] Other examples of sampling for quality-assurance purposes may include commissioning newly constructed space in special care areas (i.e., ORs and units for immunosuppressed patients) or assessing a change in housekeeping practice. However, the only types of routine environmental microbiologic sampling recommended as part of a quality-assurance program are

a. the biological monitoring of sterilization processes by using bacterial spores[1214] and
b. the monthly culturing of water used in hemodialysis applications and for the final dialysate use dilution.

Some experts also advocate periodic environmental sampling to evaluate the microbial/particulate quality for regular maintenance of the air handling system (e.g., filters) and to verify that the components of the system meet manufacturer’s specifications (A. Streifel, University of Minnesota, 2000). Certain equipment in health-care settings (e.g., biological safety cabinets) may also be monitored with air flow and particulate sampling to determine performance or as part of adherence to a certification program; results can then be compared with a predetermined standard of performance. These measurements, however, usually do not require microbiologic testing.

2. Air Sampling

Biological contaminants occur in the air as aerosols and may include bacteria, fungi, viruses, and pollens.[1215, 1216] Aerosols are characterized as solid or liquid particles suspended in air. Talking for 5 minutes and coughing each can produce 3,000 droplet nuclei; sneezing can generate approximately 40,000 droplets which then evaporate to particles in the size range of 0.5–12 μm.[137, 1217] Particles in a biological aerosol usually vary in size from <1 μm to ≥50 μm. These particles may consist of a single, unattached organism or may occur in the form of clumps composed of a number of bacteria. Clumps can also include dust and dried organic or inorganic material. Vegetative forms of bacterial cells and viruses may be present in the air in a lesser number than bacterial spores or fungal spores. Factors that determine the survival of microorganisms within a bioaerosol include

a. the suspending medium,
b. temperature,
c. relative humidity,
d. oxygen sensitivity, and
e. exposure to UV or electromagnetic radiation.[1215]

Many vegetative cells will not survive for lengthy periods of time in the air unless the protective cover (e.g., dried organic or inorganic matter).[1216] Pathogens that resist drying (e.g., *Staphylococcus* spp., *Streptococcus* spp., and fungal spores) can survive for long periods and can be carried considerable distances via air and still remain viable. They may also settle on surfaces and become airborne again as secondary aerosols during certain activities (e.g., sweeping and bed making).[1216, 1218]

Microbiologic air sampling is used as needed to determine the numbers and types of microorganisms, or particulates, in indoor air.[289] Air sampling for quality control is, however, problematic because of lack of uniform air-quality standards. Although airborne spores of *Aspergillus* spp. can pose a risk for

neutropenic patients, the critical number (i.e., action level) of these spores above which outbreaks of aspergillosis would be expected to occur has not been defined. Health-care professionals considering the use of air sampling should keep in mind that the results represent indoor air quality at singular points in time, and these may be affected by a variety of factors, including

a. indoor traffic,
b. visitors entering the facility,
c. temperature,
d. time of day or year,
e. relative humidity,
f. relative concentration of particles or organisms, and g) the performance of the air-handling system components.

To be meaningful, air-sampling results must be compared with those obtained from other defined areas, conditions, or time periods.

Several preliminary concerns must be addressed when designing a microbiologic air sampling strategy (Box 13). Because the amount of particulate material and bacteria retained in the respiratory system is largely dependent on the size of the inhaled particles, particle size should be determined when studying airborne microorganisms and their relation to respiratory infections. Particles >5 μm are efficiently trapped in the upper respiratory tract and are removed primarily by ciliary action.[1219] Particles ≤5 μm in diameter reach the lung, but the greatest retention in the alveoli is of particles 1–2 μm in diameter.[1220–1222]

Box 13. Preliminary concerns for conducting air sampling

- Consider the possible characteristics and conditions of the aerosol, including size range of particles, relative amount of inert material, concentration of microorganisms, and environmental factors.
- Determine the type of sampling instruments, sampling time, and duration of the sampling program.
- Determine the number of samples to be taken.
- Ensure that adequate equipment and supplies are available.
- Determine the method of assay that will ensure optimal recovery of microorganisms.
- Select a laboratory that will provide proper microbiologic support.
- Ensure that samples can be refrigerated if they cannot be assayed in the laboratory promptly.

Bacteria, fungi, and particulates in air can be identified and quantified with the same methods and equipment (Table 23). The basic methods include

a. impingement in liquids,
b. impaction on solid surfaces,
c. sedimentation,
d. filtration,
e. centrifugation,
f. electrostatic precipitation, and
g. thermal precipitation.[1218]

Of these, impingement in liquids, impaction on solid surfaces, and sedimentation (on settle plates) have been used for various air-sampling purposes in health-care settings.[289]

Several instruments are available for sampling airborne bacteria and fungi (Box 14). Some of the samplers are self-contained units requiring only a power supply and the appropriate collecting medium, but most require additional auxiliary equipment (e.g., a vacuum pump and an airflow measuring device [i.e., a flowmeter or anemometer]). Sedimentation or depositional methods use settle plates and therefore need no special instruments or equipment. Selection of an instrument for air sampling requires a clear understanding of the type of information desired and the particular determinations that must be made

(Box 14). Information may be needed regarding
a. one particular organism or all organisms that may be present in the air,
b. the concentration of viable particles or of viable organisms,
c. the change in concentration with time, and
d. the size distribution of the collected particles.

Before sampling begins, decisions should be made regarding whether the results are to be qualitative or quantitative. Comparing quantities of airborne microorganisms to those of outdoor air is also standard operating procedure. Infection-control professionals, hospital epidemiologists, industrial hygienists, and laboratory supervisors, as part of a multidisciplinary team, should discuss the potential need for microbial air sampling to determine if the capacity and expertise to conduct such sampling exists within the facility and when it is appropriate to enlist the services of an environmental microbiologist consultant.

Table 23. Air sampling methods and examples of equipment*

Method	Principle	Suitable for measuring:	Collection media or surface	Rate of collection (L/min.)	Auxilliary equipment needed+	Points to consider	Prototype samplers§
Impingement in liquids	Air drawn through a small jet and directed against a liquid surface	Viable organisms, and concentration over time. Example use: sampling water aerosols to *Legionella* spp.	Buffered gelatin, tryptose saline, peptone, nutrient broth	12.5	Yes	Antifoaming agent may be needed. Ambient temperature and humidity will influence length of collection time	Chemical Corps. All Glass Impinger (AGI)
Impaction on solid surfaces	Air drawn into the sampler; particles deposited on a dry surface	Viable particles; viable organisms (on non-nutrient surfaces, limited to organisms that resist drying and spores); size measurement, and concentration over time. Example use: sampling air for *Aspergillus* spp., fungal spores	Dry surface, coated surfaces, and agar	28 (sieve) 30–800 (slit)	Yes	Available as sieve impactors or slit impactors. Sieve impactors can be set up to measure particle size. Slit impactors have a rotating support stage for agar plates to allow for measurement of concentration over time.	Andersen Air Sampler (sieve impactor); TDL, Cassella MK-2 (slit impactors)
Sedimentation	Particles and micro-organisms settle onto surfaces via gravity	Viable particles. Example uses: sampling air for bacteria in the vicinity of and during a medical procedure; general measurements of microbial air quality.	Nutrient media (agars) on plates or slides	n/a	No	Simple and inexpensive; best suited for qualitative sampling; significant airborne fungal spores are too buoyant to settle efficiently for collection using this method.	Settle plates
Filtration	Air drawn through a filter unit; particles trapped; 0.2 µm pore size	Viable particles; viable organisms (on non-nutrient surfaces, limited to spores and organisms that resist drying);	Paper, cellulose, glass wool, gelatin foam, and membrane filters	1–50	Yes	Filter must be agitated first in rinse fluid to remove and disperse trapped micro- organisms; rinse fluid is	–

Method	Principle	Suitable for measuring:	Collection media or surface	Rate of collection (L/min.)	Auxilliary equipment needed+	Points to consider	Prototype samplers§
		concentration over time. Example use: air sampling for *Aspergillus* spp., fungal spores, and dust				assayed; used more for sampling dust and chemicals.	
Centrifugation	Aerosols subjected to centrifugal force; particles impacted onto a solid surface	Viable particles; viable organisms (on non-nutrient surfaces, limited to spores and organisms that resist drying); concentration over time. Example use: air sampling for *Aspergillus* spp., and fungal spores	Coated glass or plastic slides, and agar surfaces	40–50	Yes	Calibration is difficult and is done only by the factory; relative comparison of airborne contamination is its general use.	Biotest RCS Plus
Electrostatic precipitation	Air drawn over an electro-statically charged surface; particles become charged	Viable particles; viable organisms (on non-nutrient surfaces, limited to spores and organisms that resist drying); concentration over time	Solid collecting surfaces (glass, and agar)	85	Yes	High volume sampling rate, but equipment is complex and must be handled carefully; not practical for use in health- care settings.	–
Thermal precipitation	Air drawn over a thermal gradient; particles repelled from hot surfaces, settle on colder surfaces	Size measurements	Glass coverslip, and electron microscope grid	0.003–0.4	Yes	Determine particle size by direct observation; not frequently used because of complex adjustments and low sampling rates.	–

* Material in this table is compiled from references 289, 1218, 1223, and 1224.

\+ Most samplers require a flow meter or anemometer and a vacuum source as auxiliary equipment.

§ Trade names listed are for identification purposes only and are not intended as endorsements by the U.S. Public Health Service.

Box 14. Selecting an air sampling device*

The following factors must be considered when choosing an air sampling instrument:

- Viability and type of the organism to be sampled
- Compatibility with the selected method of analysis
- Sensitivity of particles to sampling
- Assumed concentrations and particle size
- Whether airborne clumps must be broken (i.e., total viable organism count vs. particle count)
- Volume of air to be sampled and length of time sampler is to be continuously operated
- Background contamination
- Ambient conditions
- Sampler collection efficiency
- Effort and skill required to operate sampler
- Availability and cost of sampler, plus back-up samplers in case of equipment malfunction
- Availability of auxiliary equipment and utilities (e.g., vacuum pumps, electricity, and water)

* Material in this box is compiled from reference 1218.

Liquid impinger and solid impactor samplers are the most practical for sampling bacteria, particles, and fungal spores, because they can sample large volumes of air in relatively short periods of time.[289] Solid impactor units are available as either "slit" or "sieve" designs. Slit impactors use a rotating disc as support for the collecting surface, which allows determinations of concentration over time. Sieve impactors commonly use stages with calibrated holes of different diameters. Some impactor-type samplers use centrifugal force to impact particles onto agar surfaces. The interior of either device must be made sterile to avoid inadvertent contamination from the sampler. Results obtained from either sampling device can be expressed as organisms or particles per unit volume of air (CFU/m^3).

Sampling for bacteria requires special attention, because bacteria may be present as individual organisms, as clumps, or mixed with or adhering to dust or covered with a protective coating of dried organic or inorganic substances. Reports of bacterial concentrations determined by air sampling therefore must indicate whether the results represent individual organisms or particles bearing multiple cells. Certain types of samplers (e.g., liquid impingers) will completely or partially disintegrate clumps and large particles; the sampling result will therefore reflect the total number of individual organisms present in the air.

The task of sizing a bioaerosol is simplified through the use of sieves or slit impactors because these samplers will separate the particles and microorganisms into size ranges as the sample is collected. These samplers must, however, be calibrated first by sampling aerosols under similar use conditions.[1225]

The use of settle plates (i.e., the sedimentation or depositional method) is not recommended when sampling air for fungal spores, because single spores can remain suspended in air indefinitely.[289] Settle plates have been used mainly to sample for particulates and bacteria either in research studies or during epidemiologic investigations.[161, 1226–1229] Results of sedimentation sampling are typically expressed as numbers of viable particles or viable bacteria per unit area per the duration of sampling time (i.e., CFU/area/time); this method can not quantify the volume of air sampled. Because the survival of microorganisms during air sampling is inversely proportional to the velocity at which the air is taken into the sampler,[1215] one advantage of using a settle plate is its reliance on gravity to bring organisms and particles into contact with its surface, thus enhancing the potential for optimal survival of collected organisms. This process, however, takes several hours to complete and may be impractical for some situations.

Air samplers are designed to meet differing measurement requirements. Some samplers are better suited for one form of measurement than others. No one type of sampler and assay procedure can be used to collect and enumerate 100% of airborne organisms. The sampler and/or sampling method chosen should, however, have an adequate sampling rate to collect a sufficient number of particles in a reasonable time period so that a representative sample of air is obtained for biological analysis. Newer analytical techniques for assaying air samples include PCR methods and enzyme-linked immunosorbent assays (ELISAs).

3. Water Sampling

A detailed discussion of the principles and practices of water sampling has been published.[945] Water sampling in health-care settings is used detect waterborne pathogens of clinical significance or to determine the quality of finished water in a facility's distribution system. Routine testing of the water in a health-care facility is usually not indicated, but sampling in support of outbreak investigations can help determine appropriate infection-control measures. Water-quality assessments in dialysis settings have been discussed in this guideline (see Water, Dialysis Water Quality and Dialysate, and Appendix C).

Health-care facilities that conduct water sampling should have their samples assayed in a laboratory that uses established methods and quality-assurance protocols. Water specimens are not "static specimens" at ambient temperature; potential changes in both numbers and types of microbial populations can occur during transport. Consequently, water samples should be sent to the testing laboratory cold (i.e., at approximately 39.2°F [4°C]) and testing should be done as soon as practical after collection (preferably within 24 hours).

Because most water sampling in health-care facilities involves the testing of finished water from the facility's distribution system, a reducing agent (i.e., sodium thiosulfate [Na2S2O3]) needs to be added to neutralize residual chlorine or other halogen in the collected sample. If the water contains elevated levels of heavy metals, then a chelating agent should be added to the specimen. The minimum volume of water to be collected should be sufficient to complete any and all assays indicated; 100 mL is considered a suitable minimum volume. Sterile collection equipment should always be used.

Sampling from a tap requires flushing of the water line before sample collection. If the tap is a mixing faucet, attachments (e.g., screens and aerators) must be removed, and hot and then cold water must be run through the tap before collecting the sample.[945] If the cleanliness of the tap is questionable, disinfection with 500–600 ppm sodium hypochlorite (1:100 v/v dilution of chlorine bleach) and flushing the tap should precede sample collection.

Microorganisms in finished or treated water often are physically damaged ("stressed") to the point that growth is limited when assayed under standard conditions. Such situations lead to false-negative readings and misleading assessments of water quality. Appropriate neutralization of halogens and chelation of heavy metals are crucial to the recovery of these organisms. The choice of recovery media and incubation conditions will also affect the assay. Incubation temperatures should be closer to the ambient temperature of the water rather than at 98.6°F (37°C), and recovery media should be formulated to provide appropriate concentrations of nutrients to support organisms exhibiting less than rigorous growth.[945] High-nutrient content media (e.g., blood agar and tryptic soy agar [TSA]) may actually inhibit the growth of these damaged organisms. Reduced nutrient media (e.g., diluted peptone and R2A) are preferable for recovery of these organisms.[945]

Use of aerobic, heterotrophic plate counts allows both a qualitative and quantitative measurement for water quality. If bacterial counts in water are expected to be high in number (e.g., during waterborne outbreak investigations), assaying small quantities using pour plates or spread plates is appropriate.[945] Membrane filtration is used when low-count specimens are expected and larger sampling volumes are

required (≥100 mL). The sample is filtered through the membrane, and the filter is applied directly face-up onto the surface of the agar plate and incubated.

Unlike the testing of potable water supplies for coliforms (which uses standardized test and specimen collection parameters and conditions), water sampling to support epidemiologic investigations of disease outbreaks may be subjected to modifications dictated by the circumstances present in the facility. Assay methods for waterborne pathogens may also not be standardized. Therefore, control or comparison samples should be included in the experimental design. Any departure from a standard method should be fully documented and should be considered when interpreting results and developing strategies. Assay methods specific for clinically significant waterborne pathogens (e.g., *Legionella* spp., *Aeromonas* spp., *Pseudomonas* spp., and *Acinetobacter* spp.) are more complicated and costly compared with both methods used to detect coliforms and other standard indicators of water quality.

4. Environmental Surface Sampling

Routine environmental-surface sampling (e.g., surveillance cultures) in health-care settings is neither cost-effective nor warranted.[951, 1225] When indicated, surface sampling should be conducted with multidisciplinary approval in adherence to carefully considered plans of action and policy (Box 15).

Box 15. Undertaking environmental-surface sampling*

The following factors should be considered before engaging in environmental-surface sampling:

- Background information from the literature and present activities (i.e., preliminary results from an epidemiologic investigation)
- Location of surfaces to be sampled
- Method of sample collection and the appropriate equipment for this task
- Number of replicate samples needed and which control or comparison samples are required
- Parameters of the sample assay method and whether the sampling will be qualitative, quantitative, or both
- An estimate of the maximum allowable microbial numbers or types on the surface(s) sampled (refer to the Spaulding classification for devices and surfaces)
- Some anticipation of a corrective action plan

* The material in this box is compiled from reference 1214.

Surface sampling is used currently for research, as part of an epidemiologic investigation, or as part of a comprehensive approach for specific quality assurance purposes. As a research tool, surface sampling has been used to determine

a. potential environmental reservoirs of pathogens,[564, 1230–1232]
b. survival of microorganisms on surfaces,[1232, 1233] and
c. the sources of the environmental contamination.[1023]

Some or all of these approaches can also be used during outbreak investigations.[1232] Discussion of surface sampling of medical devices and instruments is beyond the scope of this document and is deferred to future guidelines on sterilization and disinfection issues.

Meaningful results depend on the selection of appropriate sampling and assay techniques.[1214] The media, reagents, and equipment required for surface sampling are available from any well-equipped microbiology laboratory and laboratory supplier. For quantitative assessment of surface organisms, non-selective, nutrient-rich agar media and broth (e.g., TSA and brain-heart infusion broth [BHI] with or

without 5% sheep or rabbit blood supplement) are used for the recovery of aerobic bacteria. Broth media are used with membrane-filtration techniques. Further sample work-up may require the use of selective media for the isolation and enumeration of specific groups of microorganisms. Examples of selective media are MacConkey agar (MAC [selects for gram-negative bacteria]), Cetrimide agar (selects for *Pseudomonas aeruginosa*), or Sabouraud dextrose- and malt extract agars and broths (select for fungi). Qualitative determinations of organisms from surfaces require only the use of selective or non-selective broth media.

Effective sampling of surfaces requires moisture, either already present on the surface to be sampled or via moistened swabs, sponges, wipes, agar surfaces, or membrane filters.[1214, 1234–1236] Dilution fluids and rinse fluids include various buffers or general purpose broth media (Table 24). If disinfectant residuals are expected on surfaces being sampled, specific neutralizer chemicals should be used in both the growth media and the dilution or rinse fluids. Lists of the neutralizers, the target disinfectant active ingredients, and the use concentrations have been published.[1214, 1237] Alternatively, instead of adding neutralizing chemicals to existing culture media (or if the chemical nature of the disinfectant residuals is unknown), the use of either

a. commercially available media including a variety of specific and nonspecific neutralizers or
b. double-strength broth media will facilitate optimal recovery of microorganisms.

The inclusion of appropriate control specimens should be included to rule out both residual antimicrobial activity from surface disinfectants and potential toxicity caused by the presence of neutralizer chemicals carried over into the assay system.[1214]

Table 24. Examples of eluents and diluents for environmental-surface sampling* +

Solutions	Concentration in water
Ringer	1⁄4 strength
Peptone water	0.1%–1.0%
Buffered peptone water	0.067 M phosphate, 0.43% NaCl, 0.1% peptone
Phosphate-buffered saline	0.02 M phosphate, 0.9% NaCl
Sodium chloride (NaCl)	0.25%–0.9%
Calgon Ringer (This solution is used for dissolution of calcium alginate swabs.)	1⁄4 strength
Thiosulfate Ringer (This solution is used for neutralization of residual chlorine.)	1⁄4 strength
Water	n/a
Tryptic soy broth (TSB)	n/a
Brain-heart infusion broth (BHI) supplemented with 0.5% beef extract	n/a

* Material in this table is compiled from references 1214 and 1238.

\+ A surfactant (e.g., polysorbate [i.e., Tween® 80]) may be added to eluents and diluents. A concentration ranging from 0.01%–0.1% is generally used, depending on the specific application. Foaming may occur during use.

Several methods can be used for collecting environmental surface samples (Table 25). Specific step-bystep discussions of each of the methods have been published.[1214, 1239] For best results, all methods should incorporate aseptic techniques, sterile equipment, and sterile recovery media.

Table 25. Methods of environmental-surface sampling

Method	Suitable for appropriate surface(s)	Assay technique	Procedural notes	Points of interpretation	Available standards	References
Sample/rinse (Moistened swab/rinse)	Non-absorbent surfaces, corners, crevices, devices, and instruments	Dilutions; qualitative or quantitative assays	Assay multiple measures areas or devices with separate swabs	Report results per measured areas or if assaying an object, per the entire sample site	**YES**: food industry; **NO**: heath care	1214, 1239–1242
Sample/rinse (Moistened sponge/rinse)	Large areas and housekeeping surfaces (e.g., floors or walls)	Dilutions; qualitative or quantitative assays	Vigorously rub a sterile sponge over the surface	Report results per measured area	**YES**: food industry; **NO**: health care	1214, 1239–1242
Sample/rinse (Moistened wipe/rinse)	Large areas and housekeeping surfaces (e.g., countertops)	Dilutions; qualitative or quantitative assays	Use a sterile wipe	Report results per measured area	**YES**: food industry; **NO**: health care	1214, 1239–1242
Direct immersion	Small items capable of being immersed	Dilutions; qualitative or quantitative assays	Use membrane filtration if rinse volume is large and anticipated microbiological concentration is low	Report results per item	**NO**	1214
Containment	Interior surfaces of containers, tubes, or bottles	Dilutions; qualitative or quantitative assays	Use membrane filtration if rinse volume is large	Evaluate both the types and numbers of microorganisms	**YES**: food and industrial applications for containers prior to fill	1214
RODAC (Replicate Organism Direct Agar Contact)	Previously cleaned and sanitized flat, non-absorbent surfaces; not suitable for irregular surfaces	Direct assay	Overgrowth occurs if used on heavily contaminated surfaces; use neutralizers in the agar if surface disinfectant residuals are present	Provides direct, quantitative results; use a minimum of 15 plates per an average hospital room	**NO**	1214, 1237, 1239, 1243, 1244

Sample/rinse methods are frequently chosen because of their versatility. However, these sampling methods are the most prone to errors caused by manipulation of the swab, gauze pad, or sponge.[1238] Additionally, no microbiocidal or microbiostatic agents should be present in any of these items when used for sampling.[1238] Each of the rinse methods requires effective elution of microorganisms from the item used to sample the surface. Thorough mixing of the rinse fluids after elution (e.g., via manual or mechanical mixing using a vortex mixer, shaking with or without glass beads, and ultrasonic bath) will help to remove and suspend material from the sampling device and break up clumps of organisms for a more accurate count.[1238] In some instances, the item used to sample the surface (e.g., gauze pad and sponge) may be immersed in the rinse fluids in a sterile bag and subjected to stomaching.[1238] This technique, however, is suitable only for soft or absorbent items that will not puncture the bag during the elution process.

If sampling is conducted as part of an epidemiologic investigation of a disease outbreak, identification of isolates to species level is mandatory, and characterization beyond the species level is preferred.[1214] When interpreting the results of the sampling, the expected degree of microbial contamination associated with the various categories of surfaces in the Spaulding classification must be considered. Environmental surfaces should be visibly clean; recognized pathogens in numbers sufficient to result in secondary transfer to other animate or inanimate surfaces should be absent from the surface being sampled.[1214] Although the interpretation of a sample with positive microbial growth is self-evident, an environmental surface sample, especially that obtained from housekeeping surfaces, that shows no growth does not represent a "sterile" surface. Sensitivities of the sampling and assay methods (i.e., level of detection) must be taken into account when no-growth samples are encountered. Properly collected control samples will help rule out extraneous contamination of the surface sample.

G. Laundry and Bedding

1. General Information

Laundry in a health-care facility may include bed sheets and blankets, towels, personal clothing, patient apparel, uniforms, scrub suits, gowns, and drapes for surgical procedures.[1245] Although contaminated textiles and fabrics in health-care facilities can be a source of substantial numbers of pathogenic microorganisms, reports of health-care associated diseases linked to contaminated fabrics are so few in number that the overall risk of disease transmission during the laundry process likely is negligible. When the incidence of such events are evaluated in the context of the volume of items laundered in health-care settings (estimated to be 5 billion pounds annually in the United States),[1246] existing control measures (e.g., standard precautions) are effective in reducing the risk of disease transmission to patients and staff. Therefore, use of current control measures should be continued to minimize the contribution of contaminated laundry to the incidence of health-care associated infections. The control measures described in this section of the guideline are based on principles of hygiene, common sense, and consensus guidance; they pertain to laundry services utilized by health-care facilities, either inhouse or contract, rather than to laundry done in the home.

2. Epidemiology and General Aspects of Infection Control

Contaminated textiles and fabrics often contain high numbers of microorganisms from body substances, including blood, skin, stool, urine, vomitus, and other body tissues and fluids. When textiles are heavily contaminated with potentially infective body substances, they can contain bacterial loads of 10^6–10^8 CFU/100 cm^2 of fabric.[1247] Disease transmission attributed to health-care laundry has involved contaminated fabrics that were handled inappropriately (i.e., the shaking of soiled linens). Bacteria (*Salmonella* spp., *Bacillus cereus*), viruses (hepatitis B virus [HBV]), fungi (*Microsporum canis*), and ectoparasites (scabies) presumably have been transmitted from contaminated textiles and fabrics to workers via

a. direct contact or
b. aerosols of contaminated lint generated from sorting and handling contaminated textiles.[1248–1252]

In these events, however, investigations could not rule out the possibility that some of these reported infections were acquired from community sources. Through a combination of soil removal, pathogen removal, and pathogen inactivation, contaminated laundry can be rendered hygienically clean. Hygienically clean laundry carries negligible risk to health-care workers and patients, provided that the clean textiles, fabric, and clothing are not inadvertently contaminated before use.

OSHA defines contaminated laundry as "laundry which has been soiled with blood or other potentially infectious materials or may contain sharps."[967] The purpose of the laundry portion of the standard is to

protect the worker from exposure to potentially infectious materials during collection, handling, and sorting of contaminated textiles through the use of personal protective equipment, proper work practices, containment, labeling, hazard communication, and ergonomics.

Experts are divided regarding the practice of transporting clothes worn at the workplace to the healthcare worker's home for laundering. Although OSHA regulations prohibit home laundering of items that are considered personal protective apparel or equipment (e.g., laboratory coats),[967] experts disagree about whether this regulation extends to uniforms and scrub suits that are not contaminated with blood or other potentially infectious material. Health-care facility policies on this matter vary and may be inconsistent with recommendations of professional organizations.[1253, 1254] Uniforms without blood or body substance contamination presumably do not differ appreciably from street clothes in the degree and microbial nature of soilage. Home laundering would be expected to remove this level of soil adequately. However, if health-care facilities require the use of uniforms, they should either make provisions to launder them or provide information to the employee regarding infection control and cleaning guidelines for the item based on the tasks being performed at the facility. Health-care facilities should address the need to provide this service and should determine the frequency for laundering these items. In a recent study examining the microbial contamination of medical students' white coats, the students perceived the coats as "clean" as long as the garments were not visibly contaminated with body substances, even after wearing the coats for several weeks.[1255] The heaviest bacterial load was found on the sleeves and the pockets of these garments; the organisms most frequently isolated were *Staphylococcus aureus*, diphtheroids, and *Acinetobacter* spp.[1255] Presumably, the sleeves of the coat may make contact with a patient and potentially serve to transfer environmentally stable microorganisms among patients. In this study, however, surveillance was not conducted among patients to detect new infections or colonizations. The students did, however, report that they would likely replace their coats more frequently and regularly if clean coats were provided.[1255] Apart from this study, which documents the presence of pathogenic bacteria on health-care facility clothing, reports of infections attributed to either the contact with such apparel or with home laundering have been rare. [1256, 1257]

Laundry services for health-care facilities are provided either in-house (i.e., on-premise laundry [OPL]), co-operatives (i.e., those entities owned and operated by a group of facilities), or by off-site commercial laundries. In the latter, the textiles may be owned by the health-care facility, in which case the processor is paid for laundering only. Alternatively, the textiles may be owned by the processor who is paid for every piece laundered on a "rental" fee. The laundry facility in a health-care setting should be designed for efficiency in providing hygienically clean textiles, fabrics, and apparel for patients and staff. Guidelines for laundry construction and operation for health-care facilities, including nursing facilities, have been published.[120, 1258] The design and engineering standards for existing facilities are those cited in the AIA edition in effect during the time of the facility's construction.[120] A laundry facility is usually partitioned into two separate areas - a "dirty" area for receiving and handling the soiled laundry and a "clean" area for processing the washed items.[1259] To minimize the potential for recontaminating cleaned laundry with aerosolized contaminated lint, areas receiving contaminated textiles should be at negative air pressure relative to the clean areas.[1260–1262] Laundry areas should have handwashing facilities readily available to workers. Laundry workers should wear appropriate personal protective equipment (e.g., gloves and protective garments) while sorting soiled fabrics and textiles.[967] Laundry equipment should be used and maintained according to the manufacturer's instructions to prevent microbial contamination of the system.[1250, 1263] Damp textiles should not be left in machines overnight.[1250]

3. Collecting, Transporting, and Sorting Contaminated Textiles and Fabrics

The laundry process starts with the removal of used or contaminated textiles, fabrics, and/or clothing from the areas where such contamination occurred, including but not limited to patients' rooms, surgical/operating areas, and laboratories. Handling contaminated laundry with a minimum of agitation can help prevent the generation of potentially contaminated lint aerosols in patient-care areas.[967, 1259]

Sorting or rinsing contaminated laundry at the location where contamination occurred is prohibited by OSHA.[967] Contaminated textiles and fabrics are placed into bags or other appropriate containment in this location; these bags are then securely tied or otherwise closed to prevent leakage.[967] Single bags of sufficient tensile strength are adequate for containing laundry, but leak-resistant containment is needed if the laundry is wet and capable of soaking through a cloth bag.[1264] Bags containing contaminated laundry must be clearly identified with labels, color-coding, or other methods so that health-care workers handle these items safely, regardless of whether the laundry is transported within the facility or destined for transport to an off-site laundry service.[967]

Typically, contaminated laundry originating in isolation areas of the hospital is segregated and handled with special practices; however, few, if any, cases of health-care associated infection have been linked to this source.[1265] Single-blinded studies have demonstrated that laundry from isolation areas is no more heavily contaminated with microorganisms than laundry from elsewhere in the hospital.[1266] Therefore, adherence to standard precautions when handling contaminated laundry in isolation areas and minimizing agitation of the contaminated items are considered sufficient to prevent the dispersal of potentially infectious aerosols.[6]

Contaminated textiles and fabrics in bags can be transported by cart or chute.[1258, 1262] Laundry chutes require proper design, maintenance, and use, because the piston-like action of a laundry bag traveling in the chute can propel airborne microbial contaminants throughout the facility.[1267–1269] Laundry chutes should be maintained under negative air pressure to prevent the spread of microorganisms from floor to floor. Loose, contaminated pieces of laundry should not be tossed into chutes, and laundry bags should be closed or otherwise secured to prevent the contents from falling out into the chute.[1270] Health-care facilities should determine the point in the laundry process at which textiles and fabrics should be sorted. Sorting after washing minimizes the exposure of laundry workers to infective material in soiled fabrics, reduces airborne microbial contamination in the laundry area, and helps to prevent potential percutaneous injuries to personnel.[1271] Sorting laundry before washing protects both the machinery and fabrics from hard objects (e.g., needles, syringes, and patients' property) and reduces the potential for recontamination of clean textiles.[1272] Sorting laundry before washing also allows for customization of laundry formulas based on the mix of products in the system and types of soils encountered. Additionally, if work flow allows, increasing the amount of segregation by specific product types will usually yield the greatest amount of work efficiency during inspection, folding, and pack-making operations.[1253] Protective apparel for the workers and appropriate ventilation can minimize these exposures. [967, 1258–1260] Gloves used for the task of sorting laundry should be of sufficient thickness to minimize sharps injuries.[967] Employee safety personnel and industrial hygienists can help to determine the appropriate glove choice.

4. Parameters of the Laundry Process

Fabrics, textiles, and clothing used in health-care settings are disinfected during laundering and generally rendered free of vegetative pathogens (i.e., hygienically clean), but they are not sterile.[1273] Laundering cycles consist of flush, main wash, bleaching, rinsing, and souring.[1274] Cleaned wet textiles, fabrics, and clothing are then dried, pressed as needed, and prepared (e.g., folded and packaged) for distribution back to the facility. Clean linens provided by an off-site laundry must be packaged prior to transport to prevent inadvertent contamination from dust and dirt during loading, delivery, and unloading. Functional packaging of laundry can be achieved in several ways, including

a. placing clean linen in a hamper lined with a previously unused liner, which is then closed or covered
b. placing clean linen in a properly cleaned cart and covering the cart with disposable material or a properly cleaned reusable textile material that can be secured to the cart; and

c. wrapping individual bundles of clean textiles in plastic or other suitable material and sealing or taping the bundles.

The antimicrobial action of the laundering process results from a combination of mechanical, thermal, and chemical factors.[1271, 1275, 1276] Dilution and agitation in water remove substantial quantities of microorganisms. Soaps and detergents function to suspend soils and also exhibit some microbiocidal properties. Hot water provides an effective means of destroying microorganisms.[1277] A temperature of at least 160°F (71°C) for a minimum of 25 minutes is commonly recommended for hot-water washing.[2] Water of this temperature can be provided by steam jet or separate booster heater.[120] The use of chlorine bleach assures an extra margin of safety.[1278, 1279] A total available chlorine residual of 50–150 ppm is usually achieved during the bleach cycle.[1277] Chlorine bleach becomes activated at water temperatures of 135°F–145°F (57.2°C–62.7°C). The last of the series of rinse cycles is the addition of a mild acid (i.e., sour) to neutralize any alkalinity in the water supply, soap, or detergent. The rapid shift in pH from approximately 12 to 5 is an effective means to inactivate some microorganisms.[1247] Effective removal of residual alkali from fabrics is an important measure in reducing the risk for skin reactions among patients.

Chlorine bleach is an economical, broad-spectrum chemical germicide that enhances the effectiveness of the laundering process. Chlorine bleach is not, however, an appropriate laundry additive for all fabrics. Traditionally, bleach was not recommended for laundering flame-retardant fabrics, linens, and clothing because its use diminished the flame-retardant properties of the treated fabric.[1273] However, some modern-day flame retardant fabrics can now tolerate chlorine bleach. Flame-retardant fabrics, whether topically treated or inherently flame retardant, should be thoroughly rinsed during the rinse cycles, because detergent residues are capable of supporting combustion. Chlorine alternatives (e.g., activated oxygen-based laundry detergents) provide added benefits for fabric and color safety in addition to antimicrobial activity. Studies comparing the antimicrobial potencies of chlorine bleach and oxygen-based bleach are needed. Oxygen-based bleach and detergents used in health-care settings should be registered by EPA to ensure adequate disinfection of laundry. Health-care workers should note the cleaning instructions of textiles, fabrics, drapes, and clothing to identify special laundering requirements and appropriate hygienic cleaning options.[1278]

Although hot-water washing is an effective laundry disinfection method, the cost can be substantial. Laundries are typically the largest users of hot water in hospitals. They consume 50%–75% of the total hot water,[1280] representing an average of 10%–15% of the energy used by a hospital. Several studies have demonstrated that lower water temperatures of 71°F–77°F (22°C–25°C) can reduce microbial contamination when the cycling of the washer, the wash detergent, and the amount of laundry additive are carefully monitored and controlled.[1247, 1281–1285] Low-temperature laundry cycles rely heavily on the presence of chlorine- or oxygen-activated bleach to reduce the levels of microbial contamination. The selection of hot- or cold-water laundry cycles may be dictated by state health-care facility licensing standards or by other regulation. Regardless of whether hot or cold water is used for washing, the temperatures reached in drying and especially during ironing provide additional significant microbiocidal action.[1247] Dryer temperatures and cycle times are dictated by the materials in the fabrics. Man-made fibers (i.e., polyester and polyester blends) require shorter times and lower temperatures.

After washing, cleaned and dried textiles, fabrics, and clothing are pressed, folded, and packaged for transport, distribution, and storage by methods that ensure their cleanliness until use.[2] State regulations and/or accrediting standards may dictate the procedures for this activity. Clean/sterile and contaminated textiles should be transported from the laundry to the health-care facility in vehicles (e.g., trucks, vans, and carts) that allow for separation of clean/sterile and contaminated items. Clean/sterile textiles and contaminated textiles may be transported in the same vehicle, provided that the use of physical barriers and/or space separation can be verified to be effective in protecting the clean/sterile items from contamination. Clean, uncovered/unwrapped textiles stored in a clean location for short periods of time (e.g., uncovered and used within a few hours) have not been demonstrated to contribute to increased levels of health-care acquired infection. Such textiles can be stored in convenient places for use during the

provision of care, provided that the textiles can be maintained dry and free from soil and body-substance contamination.

In the absence of microbiologic standards for laundered textiles, no rationale exists for routine microbiologic sampling of cleaned health-care textiles and fabrics.[1286] Sampling may be used as part of an outbreak investigation if epidemiologic evidence suggests that textiles, fabrics, or clothing are a suspected vehicle for disease transmission. Sampling techniques include aseptically macerating the fabric into pieces and adding these to broth media or using contact plates (RODAC plates) for direct surface sampling.[1271, 1286] When evaluating the disinfecting properties of the laundering process specifically, placing pieces of fabric between two membrane filters may help to minimize the contribution of the physical removal of microorganisms.[1287]

Washing machines and dryers in residential-care settings are more likely to be consumer items rather than the commercial, heavy-duty, large volume units typically found in hospitals and other institutional health-care settings. Although all washing machines and dryers in health-care settings must be properly maintained for performance according to the manufacturer's instructions, questions have been raised about the need to disinfect washers and dryers in residential-care settings. Disinfection of the tubs and tumblers of these machines is unnecessary when proper laundry procedures are followed; these procedures involve

a. the physical removal of bulk solids (e.g., feces) before the wash/dry cycle and
b. proper use of temperature, detergent, and laundry additives.

Infection has not been linked to laundry procedures in residential-care facilities, even when consumer versions of detergents and laundry additives are used.

5. Special Laundry Situations

Some textile items (e.g., surgical drapes and reusable gowns) must be sterilized before use and therefore require steam autoclaving after laundering.[7] Although the American Academy of Pediatrics in previous guidelines recommended autoclaving for linens in neonatal intensive care units (NICUs), studies on the microbial quality of routinely cleaned NICU linen have not identified any increased risk for infection among the neonates receiving care.[1288] Consequently, hygienically clean linens are suitable for use in this setting.[997] The use of sterile linens in burn therapy units remains unresolved.

Coated or laminated fabrics are often used in the manufacture of PPE. When these items become contaminated with blood or other body substances, the manufacturer's instructions for decontamination and cleaning take into account the compatibility of the rubber backing with the chemical germicides or detergents used in the process. The directions for decontaminating these items should be followed as indicated; the item should be discarded when the backing develops surface cracks.

Dry cleaning, a cleaning process that utilizes organic solvents (e.g., perchloroethylene) for soil removal, is an alternative means of cleaning fabrics that might be damaged in conventional laundering and detergent washing. Several studies, however, have shown that dry cleaning alone is relatively ineffective in reducing the numbers of bacteria and viruses on contaminated linens;[1289, 1290] microbial populations are significantly reduced only when dry-cleaned articles are heat pressed. Dry cleaning should therefore not be considered a routine option for health-care facility laundry and should be reserved for those circumstances in which fabrics can not be safely cleaned with water and detergent.[1291]

6. Surgical Gowns, Drapes, and Disposable Fabrics

An issue of recent concern involves the use of disposable (i.e., single use) versus reusable (i.e., multiple use) surgical attire and fabrics in health-care settings.[1292] Regardless of the material used to manufacture gowns and drapes, these items must be resistant to liquid and microbial penetration.[7, 1293– 1297] Surgical gowns and drapes must be registered with FDA to demonstrate their safety and effectiveness. Repellency and pore size of the fabric contribute to gown performance, but performance capability can be influenced by the item's design and construction.[1298, 1299] Reinforced gowns (i.e., gowns with double-layered fabric) generally are more resistant to liquid strike-through.[1300, 1301] Reinforced gowns may, however, be less comfortable. Guidelines for selection and use of barrier materials for surgical gowns and drapes have been published.[1302] When selecting a barrier product, repellency level and type of barrier should be compatible for the exposure expected.[967] However, data are limited regarding the association between gown or drape characteristics and risk for surgical site infections.[7, 1303] Health-care facilities must ensure optimal protection of patients and health-care workers. Not all fabric items in health care lend themselves to single-use. Facilities exploring options for gowns and drapes should consider the expense of disposable items and the impact on the facility's waste-management costs once these items are discarded. Costs associated with the use of durable goods involve the fabric or textile items; staff expenses to collect, sort, clean, and package the laundry; and energy costs to operate the laundry if on-site or the costs to contract with an outside service.[1304, 1305]

7. Antimicrobial-Impregnated Articles and Consumer Items Bearing Antimicrobial Labeling

Manufacturers are increasingly incorporating antibacterial or antimicrobial chemicals into consumer and health-care items. Some consumer products bearing labels that indicate treatment with antimicrobial chemicals have included pens, cutting boards, toys, household cleaners, hand lotions, cat litter, soaps, cotton swabs, toothbrushes, and cosmetics. The "antibacterial" label on household cleaning products, in particular, gives consumers the impression that the products perform "better" than comparable products without this labeling, when in fact all household cleaners have antibacterial properties.

In the health-care setting, treated items may include children's pajamas, mattresses, and bed linens with label claims of antimicrobial properties. These claims require careful evaluation to determine whether they pertain to the use of antimicrobial chemicals as preservatives for the fabric or other components or whether they imply a health claim.[1306, 1307] No evidence is available to suggest that use of these products will make consumers and patients healthier or prevent disease. No data support the use of these items as part of a sound infection-control strategy, and therefore, the additional expense of replacing a facility's bedding and sheets with these treated products is unwarranted.

EPA has reaffirmed its position that manufacturers who make public health claims for articles containing antimicrobial chemicals must provide evidence to support those claims as part of the registration process.[1308] Current EPA regulations outlined in the Treated Articles Exemption of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) require manufacturers to register both the antimicrobial chemical used in or on the product and the finished product itself if a public health claim is maintained for the item. The exemption applies to the use of antimicrobial chemicals for the purpose of preserving the integrity of the product's raw material(s). The U.S. Federal Trade Commission (FTC) is evaluating manufacturer advertising of products with antimicrobial claims.[1309]

8. Standard Mattresses, Pillows, and Air-Fluidized Beds

Standard mattresses and pillows can become contaminated with body substances during patient care if the integrity of the covers of these items is compromised. The practice of sticking needles into the mattress

should be avoided. A mattress cover is generally a fitted, protective material, the purpose of which is to prevent the mattress from becoming contaminated with body fluids and substances. A linen sheet placed on the mattress is not considered a mattress cover. Patches for tears and holes in mattress covers do not provide an impermeable surface over the mattress. Mattress covers should be replaced when torn; the mattress should be replaced if it is visibly stained. Wet mattresses, in particular, can be a substantial environmental source of microorganisms. Infections and colonizations caused by *Acinetobacter* spp., MRSA, and *Pseudomonas aeruginosa* have been described, especially among burn patients.[1310–1315] In these reports, the removal of wet mattresses was an effective infection-control measure. Efforts were made to ensure that pads and covers were cleaned and disinfected between patients using disinfectant products compatible with mattress-cover materials to ensure that these covers remained impermeable to fluids.[1310–1314] Pillows and their covers should be easily cleanable, preferably in a hot water laundry cycle.[1315] These should be laundered between patients or if contaminated with body substances.

Air-fluidized beds are used for the care of patients immobilized for extended periods of time because of therapy or injury (e.g., pain, decubitus ulcers, and burns).[1316] These specialized beds consist of a base unit filled with microsphere beads fluidized by warm, dry air flowing upward from a diffuser located at the bottom of the unit. A porous, polyester filter sheet separates the patient from direct contact with the beads but allows body fluids to pass through to the beads. Moist beads aggregate into clumps which settle to the bottom where they are removed as part of routine bed maintenance.

Because the beads become contaminated with the patient's body substances, concerns have been raised about the potential for these beds to serve as an environmental source of pathogens. Certain pathogens (e.g., *Enterococcus* spp., *Serratia marcescens, Staphylococcus aureus*, and *Streptococcus fecalis*) have been recovered either from the microsphere beads or the polyester sheet after cleaning.[1317, 1318] Reports of cross-contamination of patients, however, are few.[1318] Nevertheless, routine maintenance and between-patient decontamination procedures can minimize potential risks to patients. Regular removal of bead clumps, coupled with the warm, dry air of the bed, can help to minimize bacterial growth in the unit.[1319–1321]

Beads are decontaminated between patients by high heat (113°F–194°F [45°C–90°C], depending on the manufacturer's specifications) for at least 1 hour; this procedure is particularly important for the inactivation of *Enterococcus* spp. which are relatively resistant to heat.[1322, 1323] The polyester filter sheet requires regular changing and thorough cleaning and disinfection, especially between patients.[1317, 1318, 1322, 1323]

Microbial contamination of the air space in the immediate vicinity of a properly maintained air-fluidized bed is similar to that found in air around conventional bedding, despite the air flow out of the base unit and around the patient.[1320, 1324, 1325] An operational air-fluidized bed can, however, interfere with proper pressure differentials, especially in negative-pressure rooms;[1326] the effect varies with the location of the bed relative to the room's configuration and supply and exhaust vent locations. Use of an air-fluidized bed in a negative-pressure room requires consultation with a facility engineer to determine appropriate placement of the bed.

H. Animals in Health-Care Facilities

1. General Information

Animals in health-care facilities traditionally have been limited to laboratories and research areas. However, their presence in patient-care areas is now more frequent, both in acute-care and long-term care settings, prompting consideration for the potential transmission of zoonotic pathogens from animals to humans in these settings. Although dogs and cats may be commonly encountered in health-care settings, other animals (e.g., fish, birds, non-human primates, rabbits, rodents, and reptiles) also can be present as research, resident, or service animals. These animals can serve as sources of zoonotic pathogens that could potentially infect patients and health-care workers (Table 26).[1327–1340] Animals potentially can serve as reservoirs for antibiotic-resistant microorganisms, which can be introduced to the health-care setting while the animal is present. VRE have been isolated from both farm animals and pets,[1341] and a cat in a geriatric care center was found to be colonized with MRSA.[1342]

* Material in this table is adapted from reference 1331 and used with permission of the publisher (Lippincott Williams and Wilkins).

§ Reptiles include lizards, snakes, and turtles. Rodents include hamsters, mice, and rats.

\+ Indicates that the pathogen associated with the infection has been isolated from animals and is considered to pose potential risk to humans.

Zoonoses can be transmitted from animals to humans either directly or indirectly via bites, scratches, aerosols, ectoparasites, accidental ingestion, or contact with contaminated soil, food, water, or unpasteurized milk.[1331, 1332, 1343–1345] Colonization and hand transferral of pathogens acquired from pets in health-care workers' homes represent potential sources and modes of transmission of zoonotic pathogens in health-care settings. An outbreak of infections caused by a yeast (*Malassezia pachydermatis*) among newborns was traced to transfer of the yeast from the hands of health-care workers with pet dogs at home.[1346] In addition, an outbreak of ringworm in a NICU caused by *Microsporum canis* was associated with a nurse and her cat,[1347] and an outbreak of *Rhodococcus (Gordona) bronchialis* sternal SSIs after coronary-artery bypass surgery was traced to a colonized nurse whose dogs were culture-positive for the organism.[1348] In the latter outbreak, whether the dogs were the sole source of the organism and whether other environmental reservoirs contributed to the outbreak are unknown. Nonetheless, limited data indicate that outbreaks of infectious disease have occurred as a result of contact with animals in areas housing immunocompetent patients. However, the low frequency of outbreaks may result from

a. the relatively limited presence of the animals in health-care facilities and
b. the immunocompetency of the patients involved in the encounters.

Formal scientific studies to evaluate potential risks of transmission of zoonoses in health-care settings outside of the laboratory are lacking.

2. Animal-Assisted Activities, Animal-Assisted Therapy, and Resident Animals

Animal-Assisted Activities (AAA) are those programs that enhance the patients' quality of life. These programs allow patients to visit animals in either a common, central location in the facility or in individual patient rooms. A group session with the animals enhances opportunities for ambulatory patients and facility residents to interact with caregivers, family members, and volunteers.[1349–1351] Alternatively, allowing the animals access to individual rooms provides the same opportunity to non-ambulatory patients and patients for whom privacy or dignity issues are a consideration. The decision to allow this access to patients' rooms should be made on a case-by-case basis, with the consultation and consent of the attending physician and nursing staff.

Animal-Assisted Therapy (AAT) is a goal-directed intervention that incorporates an animal into the treatment process provided by a credentialed therapist.[1330, 1331] The concept for AAT arose from the observation that some patients with pets at home recover from surgical and medical procedures more rapidly than patients without pets.[1352, 1353] Contact with animals is considered beneficial for enhancing wellness in certain patient populations (e.g., children, the elderly, and extended-care hospitalized patients).[1349, 1354–1357] However, evidence supporting this benefit is largely derived from anecdotal reports and observations of patient/animal interactions.[1357–1359] Guidelines for establishing AAT programs are available for facilities considering this option.[1360]

The incorporation of non-human primates into an AAA or AAT program is not encouraged because of concerns regarding potential disease transmission from and unpredictable behavior of these animals.[1361, 1362] Animals participating in either AAA or AAT sessions should be in good health and up-to-date with recommended immunizations and prophylactic medications (e.g., heartworm prevention) as determined by a licensed veterinarian based on local needs and recommendations. Regular re-evaluation of the animal's health and behavior status is essential.[1360] Animals should be routinely screened for enteric parasites and/or have evidence of a recently completed antihelminthic regimen.[1363] They should also be free of ectoparasites (e.g., fleas and ticks) and should have no sutures, open wounds, or obvious dermatologic lesions that could be associated with bacterial, fungal, or viral infections or parasitic infestations. Incorporating young animals (i.e., those aged <1 year) into these programs is not encouraged because of issues regarding unpredictable behavior and elimination control. Additionally, health of these animals at risk. Animals should be clean and well-groomed. The visits must be supervised by persons who know the animals and their behavior. Animal handlers should be trained in these activities and

receive site-specific orientation to ensure that they work efficiently with the staff in the specific health-care environment.[1360] Additionally, animal handlers should be in good health.[1360]

The most important infection-control measure to prevent potential disease transmission is strict enforcement of hand-hygiene measures (e.g., using either soap and water or an alcohol-based hand rub) for all patients, staff, and residents after handling the animals.[1355, 1364] Care should also be taken to avoid direct contact with animal urine or feces. Clean-up of these substances from environmental surfaces requires gloves and the use of leak-resistant plastic bags to discard absorbent material used in the process.[2] The area must be cleaned after visits according to standard cleaning procedures.

The American Academy of Allergy, Asthma, and Immunology estimates that dog or cat allergies occur in approximately 15% of the population.[1365] Minimizing contact with animal saliva, dander, and/or urine helps to mitigate allergic responses.[1365–1367] Some facilities may not allow animal visitation for patients with

a. underlying asthma,
b. known allergies to cat or dog hair,
c. respiratory allergies of unknown etiology, and
d. immunosuppressive disorders.

Hair shedding can be minimized by processes that remove dead hair (e.g., grooming) and that prevent the shedding of dead hair (e.g., therapy capes for dogs). Allergens can be minimized by bathing therapy animals within 24 hours of a visit.[1333, 1368]

Animal therapists and handlers must take precautions to prevent animal bites. Common pathogens associated with animal bites include *Capnocytophaga canimorsus, Pasteurella* spp., *Staphylococcus* spp., and *Streptococcus* spp. Selecting well-behaved and well-trained animals for these programs greatly decreases the incidence of bites. Rodents, exotic species, wild/domestic animals (i.e., wolf-dog hybrids), and wild animals whose behavior is unpredictable should be excluded from AAA or AAT programs. A well-trained animal handler should be able to recognize stress in the animal and to determine when to terminate a session to minimize risk. When an animal bites a person during AAA or AAT, the animal is to be permanently removed from the program. If a bite does occur, the wound must be cleansed immediately and monitored for subsequent infection. Most infections can be treated with antibiotics, and antibiotics often are prescribed prophylactically in these situations.

The health-care facility's infection-control staff should participate actively in planning for and coordinating AAA and AAT sessions. Many facilities do not offer AAA or AAT programs for severely immunocompromised patients (e.g., HSCT patients and patients on corticosteroid therapy).[1339] The question of whether family pets or companion animals can visit terminally-ill HSCT patients or other severely immunosuppressed patients is best handled on a case-by-case basis, although animals should not be brought into the HSCT unit or any other unit housing severely immunosuppressed patients. An in-depth discussion of this issue is presented elsewhere.[1366]

Immunocompromised patients who have been discharged from a health-care facility may be at higher risk for acquiring some pet-related zoonoses. Although guidelines have been developed to minimize the risk of disease transmission to HIV-infected patients,[8] these recommendations may be applicable for patients with other immunosuppressive disorders. In addition to handwashing or hand hygiene, these recommendations include avoiding contact with

a. animal feces and soiled litter box materials,
b. animals with diarrhea,
c. very young animals (i.e., dogs <6 months of age and cats <1 year of age), and
d. exotic animals and reptiles.[8]

Pets or companion animals with diarrhea should receive veterinary care to resolve their condition.

Many health-care facilities are adopting more home-like environments for residential-care or extended-stay patients in acute-care settings, and resident animals are one element of this approach.[1369] One

concept, the "Eden Alternative," incorporates children, plants, and animals (e.g., dogs, cats, fish, birds, rabbits, and rodents) into the daily care setting.[1370, 1371] The concept of working with resident animals has not been scientifically evaluated. Several issues beyond the benefits of therapy must be considered before embarking on such a program, including

a. whether the animals will come into direct contact with patients and/or be allowed to roam freely in the facility
b. how the staff will provide care for the animals;
c. the management of patients' or residents' allergies, asthma, and phobias;
d. precautionary measures to prevent bites and scratches; and
e. measures to properly manage the disposal of animal feces and urine, thereby preventing environmental contamination by zoonotic microorganisms (e.g., *Toxoplasma* spp., *Toxocara* spp., and *Ancylostoma* spp.).[1372, 1373]

Few data document a link between health-care acquired infection rates and frequency of cleaning fish tanks or rodent cages. Skin infections caused by *Mycobacterium marinum* have been described among persons who have fish aquariums at home.[1374, 1375] Nevertheless, immunocompromised patients should avoid direct contact with fish tanks and cages and the aerosols that these items produce. Further, fish tanks should be kept clean on a regular basis as determined by facility policy, and this task should be performed by gloved staff members who are not responsible for patient care. The use of the infection-control risk assessment can help determine whether a fish tank poses a risk for patient or resident safety and health in these situations. No evidence, however, links the incidence of health-care acquired infections among immunocompetent patients or residents with the presence of a properly cleaned and maintained fish tank, even in dining areas. As a general preventive measure, resident animal programs are advised to restrict animals from

a. food preparation kitchens,
b. laundries,
c. central sterile supply and any storage areas for clean supplies, and
d. medication preparation areas.

Resident-animal programs in acute-care facilities should not allow the animals into the isolation areas, protective environments, ORs, or any area where immunocompromised patients are housed. Patients and staff routinely should wash their hands or use waterless, alcohol-based hand-hygiene products after contact with animals.

3. Service Animals

Although this section provides an overview about service animals in health-care settings, it cannot address every situation or question that may arise (see Appendix E - Information Resources). A service animal is any animal individually trained to do work or perform tasks for the benefit of a person with a disability.[1366, 1376] A service animal is not considered a pet but rather an animal trained to provide assistance to a person because of a disability. Title III of the "Americans with Disabilities Act" (ADA) of 1990 mandates that persons with disabilities accompanied by service animals be allowed access with their service animals into places of public accommodation, including restaurants, public transportation, schools, and health-care facilities.[1366, 1376] In health-care facilities, a person with a disability requiring a service animal may be an employee, a visitor, or a patient.

An overview of the subject of service animals and their presence in health-care facilities has been published.[1366] No evidence suggests that animals pose a more significant risk of transmitting infection than people; therefore, service animals should not be excluded from such areas, unless an individual patient's situation or a particular animal poses greater risk that cannot be mitigated through reasonable measures. If health-care personnel, visitors, and patients are permitted to enter care areas (e.g., inpatient rooms, some ICUs, and public areas) without taking additional precautions to prevent transmission of infectious agents (e.g., donning gloves, gowns, or masks), a clean, healthy, well-behaved service animal should be allowed access with its handler.[1366] Similarly, if immunocompromised patients are able to

receive visitors without using protective garments or equipment, an exclusion of service animals from this area would not be justified.[1366]

Because health-care facilities are covered by the ADA or the Rehabilitation Act, a person with a disability may be accompanied by a service animal within the facility unless the animal's presence or behavior creates a fundamental alteration in the nature of a facility's services in a particular area or a direct threat to other persons in a particular area.[1366] A "direct threat" is defined as a significant risk to the health or safety of others that cannot be mitigated or eliminated by modifying policies, practices, or procedures.[1376] The determination that a service animal poses a direct threat in any particular healthcare setting must be based on an individualized assessment of the service animal, the patient, and the health-care situation. When evaluating risk in such situations, health-care personnel should consider the nature of the risk (including duration and severity); the probability that injury will occur; and whether reasonable modifications of policies, practices, or procedures will mitigate the risk (J. Wodatch, U.S. Department of Justice, 2000). The person with a disability should contribute to the risk-assessment process as part of a pre-procedure health-care provider/patient conference.

Excluding a service animal from an OR or similar special care areas (e.g., burn units, some ICUs, PE units, and any other area containing equipment critical for life support) is appropriate if these areas are considered to have "restricted access" with regards to the general public. General infection-control measures that dictate such limited access include

a. the area is required to meet environmental criteria to minimize the risk of disease transmission,
b. strict attention to hand hygiene and absence of dermatologic conditions, and
c. barrier protective measures [e.g., using gloves, wearing gowns and masks] are indicated for persons in the affected space.

No infection-control measures regarding the use of barrier precautions could be reasonably imposed on the service animal. Excluding a service animal that becomes threatening because of a perceived danger to its handler during treatment also is appropriate; however, exclusion of such an animal must be based on the actual behavior of the particular animal, not on speculation about how the animal might behave.

Another issue regarding service animals is whether to permit persons with disabilities to be accompanied by their service animals during all phases of their stay in the health-care facility. Healthcare personnel should discuss all aspects of anticipatory care with the patient who uses a service animal. Health-care personnel may not exclude a service animal because health-care staff may be able to perform the same services that the service animal does (e.g., retrieving dropped items and guiding an otherwise ambulatory person to the restroom). Similarly, health-care personnel can not exclude service animals because the health-care staff perceive a lack of need for the service animal during the person's stay in the health-care facility. A person with a disability is entitled to independent access (i.e., to be accompanied by a service animal unless the animal poses a direct threat or a fundamental alteration in the nature of services); "need" for the animal is not a valid factor in either analysis. For some forms of care (e.g., ambulation as physical therapy following total hip replacement or knee replacement), the service animal should not be used in place of a credentialed health-care worker who directly provides therapy. However, service animals need not be restricted from being in the presence of its handler during this time; in addition, rehabilitation and discharge planning should incorporate the patient's future use of the animal. The health-care personnel and the patient with a disability should discuss both the possible need for the service animal to be separated from its handler for a period of time during non-emergency care and an alternate plan of care for the service animal in the event the patient is unable or unwilling to provide that care. This plan might include family members taking the animal out of the facility several times a day for exercise and elimination, the animal staying with relatives, or boarding off-site. Care of the service animal, however, remains the obligation of the person with the disability, not the health-care staff.

Although animals potentially carry zoonotic pathogens transmissible to man, the risk is minimal with a healthy, clean, vaccinated, well-behaved, and well-trained service animal, the most common of which are dogs and cats. No reports have been published regarding infectious disease that affects humans originating in service dogs. Standard cleaning procedures are sufficient following occupation of an area

by a service animal.[1366] Clean-up of spills of animal urine, feces, or other body substances can be accomplished with blood/body substance procedures outlined in the Environmental Services section of this guideline. No special bathing procedures are required prior to a service animal accompanying its handler into a health-care facility.

Providing access to exotic animals (e.g., reptiles and non-human primates) that are used as service animals is problematic. Concerns about these animals are discussed in two published reviews.[1331, 1366] Because some of these animals exhibit high-risk behaviors that may increase the potential for zoonotic disease transmission (e.g., herpes B infection), providing health-care facility access to nonhuman primates used as service animals is discouraged, especially if these animals might come into contact with the general public.[1361, 1362] Health-care administrators should consult the Americans with Disabilities Act for guidance when developing policies about service animals in their facilities.[1366, 1376]

Requiring documentation for access of a service animal to an area generally accessible to the public would impose a burden on a person with a disability. When health-care workers are not certain that an animal is a service animal, they may ask the person who has the animal if it is a service animal required because of a disability; however, no certification or other documentation of service animal status can be required.[1377]

4. Animals as Patients in Human Health-Care Facilities

The potential for direct and indirect transmission of zoonoses must be considered when rooms and equipment in human health-care facilities are used for the medical or surgical treatment or diagnosis of animals.[1378] Inquiries should be made to veterinary medical professionals to determine an appropriate facility and equipment to care for an animal.

The central issue associated with providing medical or surgical care to animals in human health-care facilities is whether cross-contamination occurs between the animal patient and the human health-care workers and/or human patients. The fundamental principles of infection control and aseptic practice should differ only minimally, if at all, between veterinary medicine and human medicine. Health-care–associated infections can and have occurred in both patients and workers in veterinary medical facilities when lapses in infection-control procedures are evident.[1379–1384] Further, veterinary patients can be at risk for acquiring infection from veterinary health-care workers if proper precautions are not taken.[1385]

The issue of providing care to veterinary patients in human health-care facilities can be divided into the following three areas of infection-control concerns:

a. whether the room/area used for animal care can be made safe for human patients,
b. whether the medical/surgical instruments used on animals can be subsequently used on human patients, and
c. which disinfecting or sterilizing procedures need to be done for these purposes.

Studies addressing these concerns are lacking. However, with respect to disinfection or sterilization in veterinary settings, only minimal evidence suggests that zoonotic microbial pathogens are unusually resistant to inactivation by chemical or physical agents (with the exception of prions). Ample evidence supports the contrary observation (i.e., that pathogens from human- and animal sources are similar in their relative instrinsic resistance to inactivation).[1386–1391] Further, no evidence suggests that zoonotic pathogens behave differently from human pathogens with respect to ventilation. Despite this knowledge, an aesthetic and sociologic perception that animal care must remain separate from human care persists. Health-care facilities, however, are increasingly faced with requests from the veterinary medical community for access to human health-care facilities for reasons that are largely economical (e.g., costs of acquiring sophisticated diagnostic technology and complex medical instruments). If hospital guidelines allow treatment of animals, alternate veterinary resources (including veterinary hospitals, clinics, and universities) should be exhausted before using human health-care settings. Additionally, the hospital's public/media relations should be notified of the situation. The goal is to develop policies and procedures to proactively and positively discuss and disclose this activity to the general public.

An infection-control risk assessment (ICRA) must be undertaken to evaluate the circumstances specific to providing care to animals in a human health-care facility. Individual hospital policies and guidelines should be reviewed before any animal treatment is considered in such facilities. Animals treated in human health-care facilities should be under the direct care and supervision of a licensed veterinarian; they also should be free of known infectious diseases, ectoparasites, and other external contaminants (e.g., soil, urine, and feces). Measures should be taken to avoid treating animals with a known or suspected zoonotic disease in a human health-care setting (e.g., lambs being treated for Q fever).

If human health-care facilities must be used for animal treatment or diagnostics, the following general infection-control actions are suggested:

a. whenever possible, the use of ORs or other rooms used for invasive procedures should be avoided [e.g., cardiac catheterization labs and invasive nuclear medicine areas]
b. when all other space options are exhausted and use of the aforementioned rooms is unavoidable, the procedure should be scheduled late in the day as the last procedure for that particular area such that patients are not present in the department/unit/area;
c. environmental surfaces should be thoroughly cleaned and disinfected using procedures discussed in the Environmental Services portion of this guideline after the animal is removed from the care area;
d. sufficient time should be allowed for ACH to help prevent allergic reactions by human patients [Table B.1. in Appendix B];
e. only disposable equipment or equipment that can be thoroughly and easily cleaned, disinfected, or sterilized should be used;
f. when medical or surgical instruments, especially those invasive instruments that are difficult to clean [e.g., endoscopes], are used on animals, these instruments should be reserved for future use only on animals; and g) standard precautions should be followed.

5. Research Animals in Health-Care Facilities

The risk of acquiring a zoonotic infection from research animals has decreased in recent years because many small laboratory animals (e.g., mice, rats, and rabbits) come from quality stock and have defined microbiologic profiles.[1392] Larger animals (e.g., nonhuman primates) are still obtained frequently from the wild and may harbor pathogens transmissible to humans. Primates, in particular, benefit from vaccinations to protect their health during the research period provided the vaccination does not interfere with the study of the particular agent. Animals serving as models for human disease studies pose some risk for transmission of infection to laboratory or health-care workers from percutaneous or mucosal exposure. Exposures can occur either through

a. direct contact with an infected animal or its body substances and secretions or
b. indirect contact with infectious material on equipment, instruments, surfaces, or supplies.[1392]

Uncontained aerosols generated during laboratory procedures can also transmit infection.

Infection-control measures to prevent transmission of zoonotic infections from research animals are largely derived from the following basic laboratory safety principles:

a. purchasing pathogen-free animals,
b. quarantining incoming animals to detect any zoonotic pathogens,
c. treating infected animals or removing them from the facility,
d. vaccinating animal carriers and high-risk contacts if possible,
e. using specialized containment caging or facilities, and
f. using protective clothing and equipment [e.g., gloves, face shields, gowns, and masks].[1392]

An excellent resource for detailed discussion of these safety measures has been published.[1013]

The animal research unit within a health-care facility should be engineered to provide

a. adequate containment of animals and pathogens;
b. daily decontamination and transport of equipment and waste;

c. proper ventilation and air filtration, which prevents recirculation of the air in the unit to other areas of the facility; and
d. negative air pressure in the animal rooms relative to the corridors.

To ensure adequate security and containment, no through traffic to other areas of the health-care facility should flow through this unit; access should be restricted to animal-care staff, researchers, environmental services, maintenance, and security personnel.

Occupational health programs for animal-care staff, researchers, and maintenance staff should take into consideration the animals' natural pathogens and research pathogens. Components of such programs include
a. prophylactic vaccines,
b. TB skin testing when primates are used,
c. baseline serums, and
d. hearing and respiratory testing.

Work practices, PPE, and engineering controls specific for each of the four animal biosafety levels have been published.[1013, 1393] The facility's occupational or employee health clinic should be aware of the appropriate post-exposure procedures involving zoonoses and have available the appropriate post-exposure biologicals and medications.

Animal-research-area staff should also develop standard operating procedures for
a. daily animal husbandry [e.g., protection of the employee while facilitating animal welfare]
b. pathogen containment and decontamination;
c. management, cleaning, disinfecting and/or sterilizing equipment and instruments; and
d. employee training for laboratory safety and safety procedures specific to animal research worksites.[1013]

The federal Animal Welfare Act of 1966 and its amendments serve as the regulatory basis for ensuring animal welfare in research.[1394, 1395]

I. Regulated Medical Waste

1. Epidemiology

No epidemiologic evidence suggests that most of the solid- or liquid wastes from hospitals, other healthcare facilities, or clinical/research laboratories is any more infective than residential waste. Several studies have compared the microbial load and the diversity of microorganisms in residential wastes and wastes obtained from a variety of health-care settings.[1399–1402] Although hospital wastes had a greater number of different bacterial species compared with residential waste, wastes from residences were more heavily contaminated.[1397, 1398] Moreover, no epidemiologic evidence suggests that traditional waste-disposal practices of health-care facilities (whereby clinical and microbiological wastes were decontaminated on site before leaving the facility) have caused disease in either the health-care setting or the general community.[1400, 1401] This statement excludes, however, sharps injuries sustained during or immediately after the delivery of patient care before the sharp is "discarded." Therefore, identifying wastes for which handling and disposal precautions are indicated is largely a matter of judgment about the relative risk of disease transmission, because no reasonable standards on which to base these determinations have been developed. Aesthetic and emotional considerations (originating during the early years of the HIV epidemic) have, however, figured into the development of treatment and disposal policies, particularly for pathology and anatomy wastes and sharps.[1402–1405] Public concerns have resulted in the promulgation of federal, state, and local rules and regulations regarding medical waste management and disposal.[1406–1414]

2. Categories of Medical Waste

Precisely defining medical waste on the basis of quantity and type of etiologic agents present is virtually impossible. The most practical approach to medical waste management is to identify wastes that represent a sufficient potential risk of causing infection during handling and disposal and for which some precautions likely are prudent.[2] Health-care facility medical wastes targeted for handling and disposal precautions include microbiology laboratory waste (e.g., microbiologic cultures and stocks of microorganisms), pathology and anatomy waste, blood specimens from clinics and laboratories, blood products, and other body-fluid specimens.[2] Moreover, the risk of either injury or infection from certain sharp items (e.g., needles and scalpel blades) contaminated with blood also must be considered. Although any item that has had contact with blood, exudates, or secretions may be potentially infective, treating all such waste as infective is neither practical nor necessary. Federal, state, and local guidelines and regulations specify the categories of medical waste that are subject to regulation and outline the requirements associated with treatment and disposal. The categorization of these wastes has generated the term "regulated medical waste." This term emphasizes the role of regulation in defining the actual material and as an alternative to "infectious waste," given the lack of evidence of this type of waste's infectivity. State regulations also address the degree or amount of contamination (e.g., blood-soaked gauze) that defines the discarded item as a regulated medical waste. The EPA's *Manual for Infectious Waste Management* identifies and categorizes other specific types of waste generated in health-care facilities with research laboratories that also require handling precautions.[1406]

3. Management of Regulated Medical Waste in Health-Care Facilities

Medical wastes require careful disposal and containment before collection and consolidation for treatment. OSHA has dictated initial measures for discarding regulated medical-waste items. These measures are designed to protect the workers who generate medical wastes and who manage the wastes from point of generation to disposal.[967] A single, leak-resistant biohazard bag is usually adequate for containment of regulated medical wastes, provided the bag is sturdy and the waste can be discarded without contaminating the bag's exterior. The contamination or puncturing of the bag requires placement into a second biohazard bag. All bags should be securely closed for disposal. Puncture-resistant containers located at the point of use (e.g., sharps containers) are used as containment for discarded slides or tubes with small amounts of blood, scalpel blades, needles and syringes, and unused sterile sharps.[967] To prevent needlestick injuries, needles and other contaminated sharps should not be recapped, purposefully bent, or broken by hand. CDC has published general guidelines for handling sharps.[6, 1415] Health-care facilities may need additional precautions to prevent the production of aerosols during the handling of blood-contaminated items for certain rare diseases or conditions (e.g., Lassa fever and Ebola virus infection).[203]

Transporting and storing regulated medical wastes within the health-care facility prior to terminal treatment is often necessary. Both federal and state regulations address the safe transport and storage of on- and off-site regulated medical wastes.[1406–1408] Health-care facilities are instructed to dispose medical wastes regularly to avoid accumulation. Medical wastes requiring storage should be kept in labeled, leak-proof, puncture-resistant containers under conditions that minimize or prevent foul odors. The storage area should be well ventilated and be inaccessible to pests. Any facility that generates regulated medical wastes should have a regulated medical waste management plan to ensure health and environmental safety as per federal, state, and local regulations.

4. Treatment of Regulated Medical Waste

Regulated medical wastes are treated or decontaminated to reduce the microbial load in or on the waste and to render the by-products safe for further handling and disposal. From a microbiologic standpoint, waste need not be rendered "sterile" because the treated waste will not be deposited in a sterile site. In addition, waste need not be subjected to the same reprocessing standards as are surgical instruments. Historically, treatment methods involved steam-sterilization (i.e., autoclaving), incineration, or interment

(for anatomy wastes). Alternative treatment methods developed in recent years include chemical disinfection, grinding/shredding/disinfection methods, energy-based technologies (e.g., microwave or radiowave treatments), and disinfection/encapsulation methods.[1409] State medical waste regulations specify appropriate treatment methods for each category of regulated medical waste.

Of all the categories comprising regulated medical waste, microbiologic wastes (e.g., untreated cultures, stocks, and amplified microbial populations) pose the greatest potential for infectious disease transmission, and sharps pose the greatest risk for injuries. Untreated stocks and cultures of microorganisms are subsets of the clinical laboratory or microbiologic waste stream. If the microorganism must be grown and amplified in culture to high concentration to permit work with the specimen, this item should be considered for on-site decontamination, preferably within the laboratory unit. Historically, this was accomplished effectively by either autoclaving (steam sterilization) or incineration. If steam sterilization in the health-care facility is used for waste treatment, exposure of the waste for up to 90 minutes at 250°F (121°C) in a autoclave (depending on the size of the load and type container) may be necessary to ensure an adequate decontamination cycle.[1416–1418] After steam sterilization, the residue can be safely handled and discarded with all other nonhazardous solid waste in accordance with state solid-waste disposal regulations. On-site incineration is another treatment option for microbiologic, pathologic, and anatomic waste, provided the incinerator is engineered to burn these wastes completely and stay within EPA emissions standards.[1410] Improper incineration of waste with high moisture and low energy content (e.g., pathology waste) can lead to emission problems. State medical-waste regulatory programs identify acceptable methods for inactivating amplified stocks and cultures of microorganisms, some of which may employ technology rather than steam sterilization or incineration.

Concerns have been raised about the ability of modern health-care facilities to inactivate microbiologic wastes on-site, given that many of these institutions have decommissioned their laboratory autoclaves. Current laboratory guidelines for working with infectious microorganisms at biosafety level (BSL) 3 recommend that all laboratory waste be decontaminated before disposal by an approved method, preferably within the laboratory.[1013] These same guidelines recommend that all materials removed from a BSL 4 laboratory (unless they are biological materials that are to remain viable) are to be decontaminated before they leave the laboratory.[1013] Recent federal regulations for laboratories that handle certain biological agents known as “select agents” (i.e., those that have the potential to pose a severe threat to public health and safety) require these agents (and those obtained from a clinical specimen intended for diagnostic, reference, or verification purposes) to be destroyed on-site before disposal.[1412] Although recommendations for laboratory waste disposal from BSL 1 or 2 laboratories (e.g., most health-care clinical and diagnostic laboratories) allow for these materials to be decontaminated off-site before disposal, on-site decontamination by a known effective method is preferred to reduce the potential of exposure during the handling of infectious material.

A recent outbreak of TB among workers in a regional medical-waste treatment facility in the United States demonstrated the hazards associated with aerosolized microbiologic wastes.[1419, 1420] The facility received diagnostic cultures of *Mycobacterium tuberculosis* from several different health-care facilities before these cultures were chemically disinfected; this facility treated this waste with a grinding/shredding process that generated aerosols from the material. [1419, 1420] Several operational deficiencies facilitated the release of aerosols and exposed workers to airborne *M. tuberculosis*. Among the suggested control measures was that health-care facilities perform on-site decontamination of laboratory waste containing live cultures of microorganisms before release of the waste to a waste management company.[1419, 1420] This measure is supported by recommendations found in the CDC/NIH guideline for laboratory workers.[1013] This outbreak demonstrates the need to avoid the use of any medical-waste treatment method or technology that can aerosolize pathogens from live cultures and stocks (especially those of airborne microorganisms) unless aerosols can be effectively contained and workers can be equipped with proper PPE.[1419–1421] Safe laboratory practices, including those addressing waste management, have been published.[1013, 1422]

In an era when local, state, and federal health-care facilities and laboratories are developing bioterrorism response strategies and capabilities, the need to reinstate in-laboratory capacity to destroy cultures and stocks of microorganisms becomes a relevant issue.[1423] Recent federal regulations require health-care

facility laboratories to maintain the capability of destroying discarded cultures and stocks on-site if these laboratories isolate from a clinical specimen any microorganism or toxin identified as a "select agent" from a clinical specimen (Table 27).[1412, 1413] As an alternative, isolated cultures of select agents can be transferred to a facility registered to accept these agents in accordance with federal regulations.[1412] State medical waste regulations can, however, complicate or completely prevent this transfer if these cultures are determined to be medical waste, because most states regulate the inter-facility transfer of untreated medical wastes.

Table 27. Microorganisms and biologicals identified as select agents*+

Table 27 A. HHS Non-overlap select agents and toxins (42 CFR Part 73 §73.4)

Pathogen type	Select agents
Viruses	Crimean-Congo hemorrhagic fever virus; Ebola viruses; Cercopithecine herpesvirus 1 (herpes B virus); Lassa fever virus; Marburg virus; monkeypox virus; South American hemorrhagic fever viruses (Junin, Machupo, Sabia, Flexal, Guanarito); tick-borne encephalitis complex (flavi) viruses (Central European tick-borne encephalitis, Far Eastern tick-borne encephalitis [Russian spring and summer encephalitis, Kyasnaur Forest disease, Omsk hemorrhagic fever]); variola major virus (smallpox virus); and variola minor virus (alastrim) **Exclusions:** ¶ Vaccine strain of Junin virus (Candid. #1)
Bacteria	Rickettsia prowazekii, R. rickettsii, Yersinia pestis
Fungi	Coccidioides posadasii
Toxins	Abrin; conotoxins; diacetoxyscirpenol; ricin; saxitoxin; Shiga-like ribosome inactivating proteins; tetrodotoxin **Exclusions:** ¶ The following toxins (in purified form or in combinations of pure and impure forms) if the aggregate amount under the control of a principal investigator does not, at any time, exceed the amount specified: 100 mg of abrin; 100 mg of conotoxins; 1,000 mg of diacetoxyscirpenol; 100 mg of ricin; 100 mg of saxitoxin; 100 mg of Shiga-like ribosome inactivating proteins; or 100 mg of tetrodotoxin
Genetic elements, recombinant nucleic acids, and recombinant organisms¶	• Select agent viral nucleic acids (synthetic or naturally-derived, contiguous or fragmented, in host chromosomes or in expression vectors) that can encode infectious and/or replication competent forms of any of the select agent viruses; • Nucleic acids (synthetic or naturally-derived) that encode for the functional form(s) of any of the toxins listed in this table if the nucleic acids: a. are in a vector or host chromosome; b. can be expressed *in vivo* or *in vitro*; or c. are in a vector or host chromosome and can be expressed *in vivo* or *in vitro*; • Viruses, bacteria, fungi, and toxins listed in this table that have been genetically modified.

Table 27 B. High consequence livestock pathogens and toxins/select agents (overlap agents) (42 CFR Part 73 §73.5 and USDA regulation 9 CFR Part 121)

Pathogen type	Select agents
Viruses	Eastern equine encephalitis virus; Nipah and Hendra complex viruses; Rift Valley fever virus; Venezuelan equine encephalitis virus **Exclusions:** ¶ MP-12 vaccine strain of Rift Valley fever virus; TC-83 vaccine strain of Venezuelan equine encephalitis virus
Bacteria	Bacillus anthracis; Brucella abortus, B. melitensis, B. suis; Burkholderia mallei (formerly Pseudomonas mallei), B. pseudomallei (formerly P. pseudomallei); botulinum neurotoxin-producing species of Clostridium; Coxiella burnetii; Francisella tularensis
Fungi	Coccidioides immitis
Toxins	Botulinum neurotoxins; *Clostridium perfringens* epsilon toxin; Shigatoxin; staphylococcal enterotoxins; T-2 toxin **Exclusions:** ¶The following toxins (in purified form or in combinations of pure and impure forms) if the aggregate amount under the control of a principal investigator does not, at any time, exceed the amount specified: 0.5 mg of botulinum neurotoxins; 100 mg of *Clostridium perfringens* epsilon toxin; 100 mg of Shigatoxin; 5 mg of staphylococcal enterotoxins; or 1,000 mg of T-2 toxin

Pathogen type	Select agents
Genetic elements, recombinant nucleic acids, and recombinant organisms¶	• Select agent viral nuclei acids (synthetic or naturally derived, contiguous or fragmented, in host chromosomes or in expression vectors) thatcan encode infectious and/or replication competent forms of any of the select agent viruses; • Nucleic acids (synthetic or naturally derived) that encode for the functional form(s) of any of the toxins listed in this table if the nucleic acids: a. are in a vector or host chromosome; b. can be expressed *in vivo* or *in vitro*; or c. are in a vector or host chromosome and can be expressed *in vivo* or *in vitro*; • Viruses, bacteria, fungi, and toxins listed in this table that have been genetically modified

* Material in this table is compiled from references 1412, 1413, 1424. Reference 1424 also contains lists of select agents that include plant pathogens and pathogens affecting livestock.

\+ 42 CFR 73 §§73.4 and 73.5 do not include any select agent or toxin that is in its naturally-occurring environment, provided it has not been intentionally introduced, cultivated, collected, or otherwise extracted from its natural source. These sections also do not include non-viable select agent organisms or nonfunctional toxins. This list of select agents is current as of 3 October 2003 and is subject to change pending the final adoption of 42 CFR Part 73.

¶ These table entries are listed in reference 1412 and 1413, but were not included in reference 1424.

5. Discharging Blood, Fluids to Sanitary Sewers or Septic Tanks

The contents of all vessels that contain more than a few milliliters of blood remaining after laboratory procedures, suction fluids, or bulk blood can either be inactivated in accordance with state-approved treatment technologies or carefully poured down a utility sink drain or toilet.[1414] State regulations may dictate the maximum volume allowable for discharge of blood/body fluids to the sanitary sewer. No evidence indicates that bloodborne diseases have been transmitted from contact with raw or treated sewage. Many bloodborne pathogens, particularly bloodborne viruses, are not stable in the environment for long periods of time;[1425, 1426] therefore, the discharge of small quantities of blood and other body fluids to the sanitary sewer is considered a safe method of disposing of these waste materials.[1414] The following factors increase the likelihood that bloodborne pathogens will be inactivated in the disposal process:

a. dilution of the discharged materials with water
b. inactivation of pathogens resulting from exposure to cleaning chemicals, disinfectants, and other chemicals in raw sewage; and
c. effectiveness of sewage treatment in inactivating any residual bloodborne pathogens that reach the treatment facility.

Small amounts of blood and other body fluids should not affect the functioning of a municipal sewer system. However, large quantities of these fluids, with their high protein content, might interfere with the biological oxygen demand (BOD) of the system. Local municipal sewage treatment restrictions may dictate that an alternative method of bulk fluid disposal be selected. State regulations may dictate what quantity constitutes a small amount of blood or body fluids.

Although concerns have been raised about the discharge of blood and other body fluids to a septic tank system, no evidence suggests that septic tanks have transmitted bloodborne infections. A properly functioning septic system is adequate for inactivating bloodborne pathogens. System manufacturers' instructions specify what materials may be discharged to the septic tank without jeopardizing its proper operation.

6. Medical Waste and CJD

Concerns also have been raised about the need for special handling and treatment procedures for wastes generated during the care of patients with CJD or other transmissible spongiform encephalopathies (TSEs). Prions, the agents that cause TSEs, have significant resistance to inactivation by a variety of physical, chemical, or gaseous methods.[1427] No epidemiologic evidence, however, links acquisition of CJD with medical-waste disposal practices. Although handling neurologic tissue for pathologic examination and autopsy materials with care, using barrier precautions, and following specific procedures for the autopsy are prudent measures,[1197] employing extraordinary measures once the materials are

discarded is unnecessary. Regulated medical wastes generated during the care of the CJD patient can be managed using the same strategies as wastes generated during the care of other patients. After decontamination, these wastes may then be disposed in a sanitary landfill or discharged to the sanitary sewer, as appropriate.

Part II. Recommendations for Environmental Infection Control in Health-Care Facilities

A. Rationale for Recommendations

As in previous CDC guidelines, each recommendation is categorized on the basis of existing scientific data, theoretic rationale, applicability, and possible economic benefit. The recommendations are evidence-based wherever possible. However, certain recommendations are derived from empiric infection-control or engineering principles, theoretic rationale, or from experience gained from events that cannot be readily studied (e.g., floods).

The HICPAC system for categorizing recommendations has been modified to include a category for engineering standards and actions required by state or federal regulations. Guidelines and standards published by the American Institute of Architects (AIA), American Society of Heating, Refrigeration, and Air-Conditioning Engineers (ASHRAE), and the Association for the Advancement in Medical Instrumentation (AAMI) form the basis of certain recommendations. These standards reflect a consensus of expert opinions and extensive consultation with agencies of the U.S. Department of Health and Human Services. Compliance with these standards is usually voluntary. However, state and federal governments often adopt these standards as regulations. For example, the standards from AIA regarding construction and design of new or renovated health-care facilities, have been adopted by reference by >40 states. Certain recommendations have two category ratings (e.g., Categories IA and IC or Categories IB and IC), indicating the recommendation is evidence-based as well as a standard or regulation.

B. Rating Categories

Recommendations are rated according to the following categories:

- **Category IA.** Strongly recommended for implementation and strongly supported by well-designed experimental, clinical, or epidemiologic studies.
- **Category IB.** Strongly recommended for implementation and supported by certain experimental, clinical, or epidemiologic studies and a strong theoretical rationale.
- **Category IC.** Required by state or federal regulation, or representing an established association standard. (Note: Abbreviations for governing agencies and regulatory citations are listed, where appropriate. Recommendations from regulations adopted at state levels are also noted. Recommendations from AIA guidelines cite the appropriate sections of the standard).
- **Category II.** Suggested for implementation and supported by suggestive clinical or epidemiologic studies, or a theoretical rationale.
- **Unresolved Issue.** No recommendation is offered. No consensus or insufficient evidence exists regarding efficacy.

C. Recommendations—Air

C.I. Air-Handling Systems in Health-Care Facilities

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Use AIA guidelines as minimum standards where state or local regulations are not in place for design and construction of ventilation systems in new or renovated health-care facilities. Ensure that existing structures continue to meet the specifications in effect at the time of construction.[120] ***Category IC*** (AIA: 1.1.A, 5.4)

B. Monitor ventilation systems in accordance with engineers' and manufacturers' recommendations to ensure preventive engineering, optimal performance for removal of particulates, and elimination of excess moisture.[18, 35, 106, 120, 220, 222, 333, 336] ***Category IB, IC*** (AIA: 7.2, 7.31.D, 8.31.D, 9.31.D, 10.31.D, 11.31.D, EPA guidance)
   1. Ensure that heating, ventilation, air conditioning (HVAC) filters are properly installed and maintained to prevent air leakages and dust overloads.[17, 18, 106, 222] ***Category IB***
   2. Monitor areas with special ventilation requirements (e.g., AII or PE) for ACH, filtration, and pressure differentials.[21, 120, 249, 250, 273–275, 277, 333–344] ***Category IB, IC*** (AIA: 7.2.C7, 7.2.D6)
      - * Develop and implement a maintenance schedule for ACH, pressure differentials, and filtration efficiencies using facility-specific data as part of the multidisciplinary risk assessment. Take into account the age and reliability of the system.
      - * Document these parameters, especially the pressure differentials.
   3. Engineer humidity controls into the HVAC system and monitor the controls to ensure proper moisture removal.[120] ***Category IC*** (AIA: 7.31.D9)
      - * Locate duct humidifiers upstream from the final filters.
      - * Incorporate a water-removal mechanism into the system.
      - * Locate all duct takeoffs sufficiently down-stream from the humidifier so that moisture is completely absorbed.
   4. Incorporate steam humidifiers, if possible, to reduce potential for microbial proliferation within the system, and avoid use of cool mist humidifiers. ***Category II***
   5. Ensure that air intakes and exhaust outlets are located properly in construction of new facilities and renovation of existing facilities.[3, 120] ***Category IC*** (AIA: 7.31.D3, 8.31.D3, 9.31.D3, 10.31.D3, 11.31.D3)
      - * Locate exhaust outlets >25 ft. from air-intake systems.
      - * Locate outdoor air intakes ≥6 ft. above ground or ≥3 ft. above roof level.
      - * Locate exhaust outlets from contaminated areas above roof level to minimize recirculation of exhausted air.
   6. Maintain air intakes and inspect filters periodically to ensure proper operation.[3, 120, 249, 250, 273–275, 277] ***Category IC*** (AIA: 7.31.D8)
   7. Bag dust-filled filters immediately upon removal to prevent dispersion of dust and fungal spores during transport within the facility.[106, 221] ***Category IB***
      - * Seal or close the bag containing the discarded filter.
      - * Discard spent filters as regular solid waste, regardless of the area from which they were removed.[221]
   8. Remove bird roosts and nests near air intakes to prevent mites and fungal spores from entering the ventilation system.[3, 98, 119] ***Category IB***
   9. Prevent dust accumulation by cleaning air-duct grilles in accordance with facility-specific procedures and schedules when rooms are not occupied by patients.[21, 120, 249, 250, 273–275, 277] ***Category IC, II*** (AIA: 7.31.D10)
   10. Periodically measure output to monitor system function; clean ventilation ducts as part of routine HVAC maintenance to ensure optimum performance.[120, 263, 264] ***Category II*** (AIA: 7.31.D10)

C. Use portable, industrial-grade HEPA filter units capable of filtration rates in the range of 300–800 ft^3/min. to augment removal of respirable particles as needed.[219] ***Category II***

1. Select portable HEPA filters that can recirculate all or nearly all of the room air and provide the equivalent of ≥12 ACH.[4] ***Category II***
2. Portable HEPA filter units previously placed in construction zones can be used later in patient-care areas, provided all internal and external surfaces are cleaned, and the filter's performance verified by appropriate particle testing. ***Category II***
3. Situate portable HEPA units with the advice of facility engineers to ensure that all room air is filtered.[4] ***Category II***
4. Ensure that fresh-air requirements for the area are met.[214, 219] ***Category II***

D. Follow appropriate procedures for use of areas with through-the-wall ventilation units.[120] ***Category IC*** (AIA: 8.31.D1, 8.31.D8, 9.31.D23, 10.31.D18, 11.31.D15)
   1. Do not use such areas as PE rooms.[120] ***Category IC*** (AIA: 7.2.D3)
   2. Do not use a room with a through-the-wall ventilation unit as an AII room unless it can be demonstrated that all required AII engineering controls required are met.[4, 120] ***Category IC*** (AIA: 7.2.C3)

E. Conduct an infection-control risk assessment (ICRA) and provide an adequate number of AII and PE rooms (if required) or other areas to meet the needs of the patient population.[4, 6, 9, 18, 19, 69, 94, 120, 142, 331–334, 336–338] ***Category IA, IC*** (AIA: 7.2.C, 7.2.D)

F. When UVGI is used as a supplemental engineering control, install fixtures:
   - * on the wall near the ceiling or suspended from the ceiling as an upper air unit;
   - * in the air-return duct of an AII room; or
   - * in designated enclosed areas or booths for sputum induction.[4] ***Category II***

G. Seal windows in buildings with centralized HVAC systems and especially with PE areas.[35, 111, 120] ***Category IB, IC*** (AIA: 7.2.D3)

H. Keep emergency doors and exits from PE rooms closed except during an emergency; equip emergency doors and exits with alarms. ***Category II***

I. Develop a contingency plan for backup capacity in the event of a general power failure.[713] ***Category IC*** (Joint Commission on Accreditation of Healthcare Organizations [JCAHO]: Environment of Care [EC] 1.4)
   1. Emphasize restoration of proper air quality and ventilation conditions in AII rooms, PE rooms, operating rooms, emergency departments, and intensive care units.[120, 713] ***Category IC*** (AIA: 1.5.A1; JCAHO: EC 1.4)
   2. Deploy infection-control procedures to protect occupants until power and systems functions are restored.[6, 120, 713] ***Category IC*** (AIA: 5.1, 5.2; JCAHO: EC 1.4)

J. Do not shut down HVAC systems in patient-care areas except for maintenance, repair, testing of emergency backup capacity, or new construction.[120, 206] ***Category IB, IC*** (AIA: 5.1, 5.2.B, C)
   1. Coordinate HVAC system maintenance with infection-control staff to allow for relocation of immunocompromised patients if necessary.[120] ***Category IC*** (AIA: 5.1, 5.2)
   2. Provide backup emergency power and air-handling and pressurization systems to maintain filtration, constant ACH, and pressure differentials in PE rooms, AII rooms, operating rooms, and other critical-care areas.[9, 120, 278] ***Category IC*** (AIA: 1.5, 5.1, 5.2)
   3. For areas not served by installed emergency ventilation and backup systems, use portable units and monitor ventilation parameters and patients in those areas.[219] ***Category II***
   4. Coordinate system startups with infection-control staff to protect patients in PE rooms from bursts of fungal spores.[9, 35, 120, 278] ***Category IC*** (AIA: 5.1, 5.2) 120
   5. Allow sufficient time for ACH to clean the air once the system is operational (Appendix B, Table B.1).[4, 120] ***Category IC*** (AIA: 5.1, 5.2)

K. HVAC systems serving offices and administration areas may be shut down for energy conservation purposes, but the shutdown must not alter or adversely affect pressure differentials maintained in laboratories or critical-care areas with specific ventilation requirements (i.e., PE rooms, AII rooms, operating rooms). ***Category II***

L. Whenever possible, avoid inactivating or shutting down the entire HVAC system at one time, especially in acute-care facilities. ***Category II***

M. Whenever feasible, design and install fixed backup ventilation systems for new or renovated construction for PE rooms, AII rooms, operating rooms, and other critical care areas identified by ICRA.[120] ***Category IC*** (AIA: 1.5.A1)

C.II. Construction, Renovation, Remediation, Repair, and Demolition

⚠ **Edit [February 2017]:** These recommendations contain minor edits in order to clarify the meaning. The edits do not constitute any change to the intent of the recommendations.
* Indicates a change to the numbering system.
~ Indicates a text change.

A. Establish a multidisciplinary team that includes infection-control staff to coordinate demolition, construction, and renovation projects and consider proactive preventive measures at the inception; produce and maintain summary statements of the team's activities.[17, 19, 20, 97, 109, 120, 249, 250, 273–277] ***Category IB, IC*** (AIA: 5.1)

B. Educate both the construction team and the health-care staff in immunocompromised patient-care areas regarding the airborne infection risks associated with construction projects, dispersal of fungal spores during such activities, and methods to control the dissemination of fungal spores.[3, 249, 250, 273–277, 1428–1432] ***Category IB***

C. Incorporate mandatory adherence agreements for infection control into construction contracts, with penalties for noncompliance and mechanisms to ensure timely correction of problems.[3, 120, 249, 273–277] ***Category IC*** (AIA: 5.1)

D. Establish and maintain surveillance for airborne environmental disease (e.g., aspergillosis) as appropriate during construction, renovation, repair, and demolition activities to ensure the health and safety of immunocompromised patients.[3, 64, 65, 79] ***Category IB***
   1. Using active surveillance, monitor for airborne fungal infections in immunocompromised patients.[3, 9, 64, 65] ***Category IB***
   2. Periodically review the facility's microbiologic, histopathologic, and postmortem data to identify additional cases.[3, 9, 64, 65] ***Category IB***
   3. If cases of aspergillosis or other health-care associated airborne fungal infections occur, aggressively pursue the diagnosis with tissue biopsies and cultures as feasible.[3, 64, 65, 79, 249, 273–277] ***Category IB***

E. Implement infection-control measures relevant to construction, renovation, maintenance, demolition, and repair.[96, 97, 120, 276, 277] ***Category IB, IC*** (AIA: 5.1, 5.2)
   1. Before the project gets underway, perform an ICRA to define the scope of the project and the need for barrier measures.[96, 97, 120, 249, 273–277]
      - * Determine if immunocompromised patients may be at risk for exposure to fungal spores from dust generated during the project.[20, 109, 273–275, 277]
      - * Develop a contingency plan to prevent such exposures.[20, 109, 273–275, 277] ***Category IB, IC*** (AIA: 5.1)
   2. Implement infection-control measures for external demolition and construction activities.[50, 249, 273–277, 283]
      - * Determine if the facility can operate temporarily on recirculated air; if feasible, seal off adjacent air intakes.
      - * If this is not possible or practical, check the low-efficiency (roughing) filter banks frequently and replace as needed to avoid buildup of particulates.
      - * Seal windows and reduce wherever possible other sources of outside air intrusion (e.g., open doors in stairwells and corridors), especially in PE areas. ***Category IB***
   3. Avoid damaging the underground water distribution system (i.e., buried pipes) to prevent soil and dust contamination of the water.[120, 305] ***Category IB, IC*** (AIA: 5.1) 121
   4. Implement infection-control measures for internal construction activities.[20, 49, 97, 120, 249, 273–277]
      - * Construct barriers to prevent dust from construction areas from entering patient-care areas; ensure that barriers are impermeable to fungal spores and in compliance with local fire codes.[20, 49, 97, 120, 284, 312, 713, 1431]

- * Block and seal off return air vents if rigid barriers are used for containment.[120, 276, 277]
- * Implement dust control measures on surfaces and by diverting pedestrian traffic away from work zones.[20, 49, 97, 120]
- * Relocate patients whose rooms are adjacent to work zones, depending upon their immune status, the scope of the project, the potential for generation of dust or water aerosols, and the methods used to control these aerosols.[49, 120, 281] ***Category IB, IC*** (AIA: 5.1, 5.2)

5. Perform those engineering and work-site related infection-control measures as needed for internal construction, repairs, and renovations:[20, 49, 97, 109, 120, 312] ***Category IB, IC*** (AIA: 5.1, 5.2)
   a. Ensure proper operation of the air-handling system in the affected area after erection of barriers and before the room or area is set to negative pressure.[49, 69, 276, 278] ***Category IB***
   b. Create and maintain negative air pressure in work zones adjacent to patient-care areas and ensure that required engineering controls are maintained.[20, 49, 97, 109, 120, 132] ***~ Category IB***
   c. Monitor negative air flow inside rigid barriers.[120, 281] ***~ Category IC***
   d. Monitor barriers and ensure the integrity of the construction barriers; repair gaps or breaks in barrier joints.[120, 284, 307, 312] ***~ Category IC***
   e. Seal windows in work zones if practical; use window chutes for disposal of large pieces of debris as needed, but ensure that the negative pressure differential for the area is maintained.[20, 120, 273] ***~ Category IC***
   f. Direct pedestrian traffic from construction zones away from patient-care areas to minimize the dispersion of dust.[20, 49, 97, 109, 111, 120, 273–277] ***~ Category IB***
   g. Provide construction crews with
      - * designated entrances, corridors, and elevators whenever practical;
      - * essential services [e.g., toilet facilities], and convenience services [e.g., vending machines];
      - * protective clothing [e.g., coveralls, footgear, and headgear] for travel to patient-care areas; and
      - * a space or anteroom for changing clothing and storing equipment.[120, 249, 273–277] ***~ Category IB***
   h. Clean work zones and their entrances daily by
      - wet-wiping tools and tool carts before their removal from the work zone;
      - placing mats with tacky surfaces inside the entrance; and
      - covering debris and securing this covering before removing debris from the work zone.[120, 249, 273–277] ***~ Category IB***
   i. In patient-care areas, for major repairs that include removal of ceiling tiles and disruption of the space above the false ceiling, use plastic sheets or prefabricated plastic units to contain dust; use a negative pressure system within this enclosure to remove dust; and either pass air through an industrial grade, portable HEPA filter capable of filtration rates ranging from 300–800 ft^3/min., or exhaust air directly to the outside.[49, 276, 277, 281, 309] ***~ Category IB***
   j. Upon completion of the project, clean the work zone according to facility procedures, and install barrier curtains to contain dust and debris before removal of rigid barriers.[20, 97, 120, 249, 273–277] ***~ Category IB***
   k. Flush the water system to clear sediment from pipes to minimize waterborne microorganism proliferation.[120, 305] ***~ Category IB***
   l. Restore appropriate ACH, humidity, and pressure differential; clean or replace air filters; dispose of spent filters.[35, 106, 221, 278] ***~ Category IC***

F. Use airborne-particle sampling as a tool to evaluate barrier integrity.[35, 100] ***Category II***
G. Commission the HVAC system for newly constructed health-care facilities and renovated spaces before occupancy and use, with emphasis on ensuring proper ventilation for operating rooms, AII rooms, and PE areas.[100, 120, 288, 304] ***Category IC*** (AIA: 5.1; ASHRAE: 11996)
H. **No recommendation is offered** on routine microbiologic air sampling before, during, or after construction or before or during occupancy of areas housing immunocompromised patients.[17, 20, 49, 97, 109, 272, 1433] ***Unresolved issue***

I. If a case of health-care acquired aspergillosis or other opportunistic environmental airborne fungal disease occurs during or immediately after construction, implement appropriate follow-up measures.[20, 55, 62, 77, 94, 95] ***Category IB***
   1. Review pressure differential monitoring documentation to verify that pressure differentials in the construction zone and in PE rooms were appropriate for their settings.[94, 95, 120] ***Category IB, IC*** (AIA: 5.1)
   2. Implement corrective engineering measures to restore proper pressure differentials as needed.[94, 95, 120] ***Category IB, IC*** (AIA: 5.1)
   3. Conduct a prospective search for additional cases and intensify retrospective epidemiologic review of the hospital's medical and laboratory records.[3, 20, 62, 63, 104] ***Category IB***
   4. If there is no evidence of ongoing transmission, continue routine maintenance in the area to prevent health-care acquired fungal disease.[3, 55] ***Category IB***

J. If there is epidemiologic evidence of ongoing transmission of fungal disease, conduct an environmental assessment to determine and eliminate the source.[3, 96, 97, 109, 111, 115, 249, 273–277] ***Category IB***
   1. Collect environmental samples from potential sources of airborne fungal spores, preferably using a high-volume air sampler rather than settle plates.[3, 18, 44, 48, 49, 97, 106, 111, 112, 115, 249, 254, 273–277, 292, 312] ***Category IB***
   2. If either an environmental source of airborne fungi or an engineering problem with filtration or pressure differentials is identified, promptly perform corrective measures to eliminate the source and route of entry.[96, 97] ***Category IB***
   3. Use an EPA-registered anti-fungal biocide (e.g., copper-8-quinolinolate) for decontaminating structural materials.[50, 277, 312, 329] ***Category IB***
   4. If an environmental source of airborne fungi is not identified, review infection control measures, including engineering controls, to identify potential areas for correction or improvement.[73, 117] ***Category IB***
   5. If possible, perform molecular subtyping of *Aspergillus* spp. isolated from patients and the environment to establish strain identities.[252, 293–296] ***Category II***

K. If air-supply systems to high-risk areas (e.g., PE rooms) are not optimal, use portable, industrial-grade HEPA filters on a temporary basis until rooms with optimal air-handling systems become available.[3, 120, 273–277] ***Category II***

C.III. Infection-Control and Ventilation Requirements for PE Rooms

⚠ **Edit [February 2017]:** These recommendations contain minor edits in order to clarify the meaning. The edits do not constitute any change to the intent of the recommendations.
* Indicates a change to the numbering system.
~ Indicates a text change.

A. Minimize exposures of severely immunocompromised patients (e.g., solid organ transplant patients or allogeneic neutropenic patients) to activities that might cause aerosolization of fungal spores (e.g., vacuuming or disruption of ceiling tiles).[9, 20, 109, 272] ***Category IB***

B. Minimize the length of time that immunocompromised patients in PE are outside their rooms for diagnostic procedures and other activities.[9, 283] ***Category IB***

C. Provide respiratory protection for severely immunocompromised patients when they must leave PE for diagnostic studies and other activities; consult the most recent revision of CDC's *Guidelines for Prevention of Health-Care Associated Pneumonia* for information regarding the appropriate type of respiratory protection.[3, 9] ***Category II***

D. Incorporate ventilation engineering specifications and dust-controlling processes into the planning and construction of new PE units. ***Category IB, IC***
   1. Install central or point-of-use HEPA filters for supply (incoming) air.[3, 18, 20, 44, 99–104, 120, 254, 316–318, 1432, 1434] ***Category IB, IC*** (AIA: 5.1, 5.2, 7.2.D)
   2. Ensure that rooms are well sealed by
      - * properly constructing windows, doors, and intake and exhaust ports;
      - * maintaining ceilings that are smooth and free of fissures, open joints, and crevices;
      - * sealing walls above and below the ceiling, and

- * monitoring for leakage and making necessary repairs.[3, 111, 120, 317, 318] ***Category IB, IC*** (AIA: 7.2.D3)

3. Ventilate the room to maintain ≥12 ACH.[3, 9, 120, 241, 317, 318] ***Category IC*** (AIA: 7.2.D)
4. Locate air supply and exhaust grilles so that clean, filtered air enters from one side of the room, flows across the patient's bed, and exits from the opposite side of the room. [3, 120, 317, 318] ***Category IC*** (AIA: 7.31.D1)
5. Maintain positive room air pressure (≥2.5 Pa [0.01-inch water gauge]) in relation to the corridor.[3, 35, 120, 317, 318] ***Category IB, IC*** (AIA: Table 7.2)
6. Maintain airflow patterns and monitor these on a daily basis by using permanently installed visual means of detecting airflow in new or renovated construction, or using other visual methods (e.g., flutter strips, or smoke tubes) in existing PE units. Document the monitoring results.[120, 273] ***Category IC*** (AIA: 7.2.D6)
7. Install self-closing devices on all room exit doors in protective environments.[120] ***Category IC*** (AIA: 7.2.D4)

E. Do not use laminar air flow systems in newly constructed PE rooms.[316, 318] ***Category II***
F. Take measures to protect immunocompromised patients who would benefit from a PE room and who also have an airborne infectious disease (e.g., acute VZV infection or tuberculosis).
   1. Ensure that the patient's room is designed to maintain positive pressure. ~ ***Category IC***
   2. Use an anteroom to ensure appropriate air balance relationships and provide independent exhaust of contaminated air to the outside, or place a HEPA filter in the exhaust duct if the return air must be recirculated.[120, 317] ***Category IC*** (AIA: 7.2.D1, A7.2.D)
   3. If an anteroom is not available, place the patient in AII and use portable, industrial-grade HEPA filters to enhance filtration of spores in the room.[219] ***Category II***
G. Maintain backup ventilation equipment (e.g., portable units for fans or filters) for emergency provision of ventilation requirements for PE areas and take immediate steps to restore the fixed ventilation system function.[9, 120, 278] ***Category IC*** (AIA: 5.1)

C.IV. Infection-Control and Ventilation Requirements for All Rooms

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Incorporate certain specifications into the planning, and construction or renovation of AII units.[4, 107, 120, 317, 318] ***Category IB, IC***
   1. Maintain continuous negative air pressure (2.5 Pa [0.01-inch water gauge]) in relation to the air pressure in the corridor; monitor air pressure periodically, preferably daily, with audible manometers or smoke tubes at the door (for existing AII rooms) or with a permanently installed visual monitoring mechanism. Document the results of monitoring.[120, 317, 318] ***Category IB, IC*** (AIA: 7.2.C7, Table 7.2)
   2. Ensure that rooms are well-sealed by properly constructing windows, doors, and air-intake and exhaust ports; when monitoring indicates air leakage, locate the leak and make necessary repairs.[120, 317, 318] ***Category IB, IC*** (AIA: 7.2.C3)
   3. Install self-closing devices on all AII room exit doors.[120] ***Category IC*** (AIA: 7.2.C4)
   4. Provide ventilation to ensure ≥12 ACH for renovated rooms and new rooms, and ≥6 ACH for existing AII rooms.[4, 107, 120] ***Category IC*** (AIA: Table 7.2)
   5. Direct exhaust air to the outside, away from air-intake and populated areas. If this is not practical, air from the room can be recirculated after passing through a HEPA filter.[4, 120] ***Category IC*** (AIA: Table 7.2)

B. Where supplemental engineering controls for air cleaning are indicated from a risk assessment of the AII area, install UVGI units in the exhaust air ducts of the HVAC system to supplement HEPA filtration or install UVGI fixtures on or near the ceiling to irradiate upper room air.[4] ***Category II***
C. Implement environmental infection-control measures for persons with known or suspected airborne infectious diseases.
   1. Use AII rooms for patients with or suspected of having an airborne infection who also require cough-inducing procedures, or use an enclosed booth that is engineered to provide

- * ≥12 ACH;
- * air supply and exhaust rate sufficient to maintain a 2.5 Pa [0.01-inch water gauge] negative pressure difference with respect to all surrounding spaces with an exhaust rate of ≥50 ft^3/min.; and
- * air exhausted directly outside away from air intakes and traffic or exhausted after HEPA filtration prior to recirculation.[4, 120, 348–350] ***Category IB, IC*** (AIA: 7.15.E, 7.31.D23, 9.10, Table 7.2)

2. Although airborne spread of viral hemorrhagic fever (VHF) has not been documented in a health-care setting, prudence dictates placing a VHF patient in an AII room, preferably with an anteroom to reduce the risk of occupational exposure to aerosolized infectious material in blood, vomitus, liquid stool, and respiratory secretions present in large amounts during the end stage of a patient's illness.[202–204]
   - * If an anteroom is not available, use portable, industrial-grade HEPA filters in the patient's room to provide additional ACH equivalents for removing airborne particulates.
   - * Ensure that health-care workers wear face shields or goggles with appropriate respirators when entering the rooms of VHF patients with prominent cough, vomiting, diarrhea, or hemorrhage.[203] ***Category II***

   ⚠ **Ebola Virus Disease [August 2014]:** The recommendations in this guideline for Ebola has been superseded by these CDC documents:
   - Infection Prevention and Control Recommendations for Hospitalized Patients with Known or Suspected Ebola Virus Disease in U.S. Hospitals (https://www.cdc.gov/vhf/ebola/healthcare-us/hospitals/infection-control.html)
   - Interim Guidance for Environmental Infection Control in Hospitals for Ebola Virus (https://www.cdc.gov/vhf/ebola/healthcare-us/cleaning/hospitals.html)

   See CDC's Ebola Virus Disease website (https://www.cdc.gov/vhf/ebola/index.html) for current information on how Ebola virus is transmitted.

3. Place smallpox patients in negative pressure rooms at the onset of their illness, preferably using a room with an anteroom if available.[6] ***Category II***

D. **No recommendation is offered** regarding negative pressure or isolation rooms for patients with *Pneumocystis carinii* pneumonia.[126, 131, 132] ***Unresolved issue***

E. Maintain back-up ventilation equipment (e.g., portable units for fans or filters) for emergency provision of ventilation requirements for AII rooms and take immediate steps to restore the fixed ventilation system function.[4, 120, 278] ***Category IC*** (AIA: 5.1)

C.V. Infection-Control and Ventilation Requirements for Operating Rooms

A. Implement environmental infection-control and ventilation measures for operating rooms.
   1. Maintain positive-pressure ventilation with respect to corridors and adjacent areas.[7, 120, 356] ***Category IB, IC*** (AIA: Table 7.2)
   2. Maintain ≥15 ACH, of which ≥3 ACH should be fresh air.[120, 357, 358] ***Category IC*** (AIA: Table 7.2)
   3. Filter all recirculated and fresh air through the appropriate filters, providing 90% efficiency (dust-spot testing) at a minimum.[120, 362] ***Category IC*** (AIA: Table 7.3)
   4. In rooms not engineered for horizontal laminar airflow, introduce air at the ceiling and exhaust air near the floor.[120, 357, 359] ***Category IC*** (AIA: 7.31.D4)
   5. Do not use UV lights to prevent surgical-site infections.[356, 364–370] ***Category IB***
   6. Keep operating room doors closed except for the passage of equipment, personnel, and patients, and limit entry to essential personnel.[351, 352] ***Category IB***

B. Follow precautionary procedures for TB patients who also require emergency surgery.[4, 347, 371] ***Category IB, IC***
   1. Use an N95 respirator approved by the National Institute for Occupational Safety and Health (NIOSH) without exhalation valves in the operating room.[347, 372] ***Category IC*** (Occupational Safety and Health Administration [OSHA]; 29 Code of Federal Regulations [CFR] 1910.134,139)

2. Intubate the patient in either the AII room or the operating room; if intubating the patient in the operating room, do not allow the doors to open until 99% of the airborne contaminants are removed (Appendix B, Table B.1).[4, 358] ***Category IB***
3. When anesthetizing a patient with confirmed or suspected TB, place a bacterial filter between the anesthesia circuit and patient's airway to prevent contamination of anesthesia equipment or discharge of tubercle bacilli into the ambient air.[371, 373] ***Category IB***
4. Extubate and allow the patient to recover in an AII room.[4, 358] ***Category IB***
5. If the patient has to be extubated in the operating room, allow adequate time for ACH to clean 99% of airborne particles from the air (Appendix B, Table B.1) because extubation is a cough-producing procedure.[4, 358] ***Category IB***

C. Use portable, industrial-grade HEPA filters temporarily for supplemental air cleaning during intubation and extubation for infectious TB patients who require surgery.[4, 219, 358] ***Category II***
1. Position the units appropriately so that all room air passes through the filter; obtain engineering consultation to determine the appropriate placement of the unit.[4] ***Category II***
2. Switch the portable unit off during the surgical procedure. ***Category II***
3. Provide fresh air as per ventilation standards for operating rooms; portable units do not meet the requirements for the number of fresh ACH.[120, 215, 219] ***Category II***

D. If possible, schedule infectious TB patients as the last surgical cases of the day to maximize the time available for removal of airborne contamination. ***Category II***

E. **No recommendation is offered** for performing orthopedic implant operations in rooms supplied with laminar airflow.[362, 364] ***Unresolved issue***

F. Maintain backup ventilation equipment (e.g., portable units for fans or filters) for emergency provision of ventilation requirements for operating rooms, and take immediate steps to restore the fixed ventilation system function.[68, 120, 278,372] ***Category IB, IC*** (AIA: 5.1)

C.VI. Other Potential Infectious Aerosol Hazards in Health-Care Facilities

A. In settings where surgical lasers are used, wear appropriate personal protective equipment, including N95 or N100 respirators, to minimize exposure to laser plumes.[347, 378, 389] ***Category IC*** (OSHA; 29 CFR 1910.134,139)

B. Use central wall suction units with in-line filters to evacuate minimal laser plumes.[378, 382, 386, 389] ***Category II***

C. Use a mechanical smoke evacuation system with a high-efficiency filter to manage the generation of large amounts of laser plume, when ablating tissue infected with human papilloma virus (HPV) or performing procedures on a patient with extrapulmonary TB.[4, 382, 389– 392] ***Category II***

D. Recommendations—Water

D.I. Controlling the Spread of Waterborne Microoganisms

A. Practice hand hygiene to prevent the hand transfer of waterborne pathogens, and use barrier precautions (e.g., gloves) as defined by other guidelines.[6, 464, 577, 586, 592, 1364] ***Category IA***

B. Eliminate contaminated water or fluid environmental reservoirs (e.g., in equipment or solutions) wherever possible.[464, 465] ***Category IB***

C. Clean and disinfect sinks and wash basins on a regular basis by using an EPA-registered product as set by facility policies. ***Category II***

D. Evaluate for possible environmental sources (e.g., potable water) of specimen contamination when waterborne microorganisms (e.g., NTM) of unlikely clinical importance are isolated from clinical cultures (e.g., specimens collected aseptically from sterile sites or, if post-procedural, colonization occurs after use of tap water in patient care).[607, 610–612] ***Category IB***

E. Avoid placing decorative fountains and fish tanks in patient-care areas; ensure disinfection and fountain maintenance if decorative fountains are used in the public areas of the healthcare facility.[664] ***Category IB***

D.II. Routine Prevention of Waterborne Microbial Contamination Within the Distribution System

A. Maintain hot water temperature at the return at the highest temperature allowable by state regulations or codes, preferably ≥124°F (≥51°C), and maintain cold water temperature at <68°F (<20°C).[3, 661] ***Category IC*** (States; ASHRAE: 12:2000)
B. If the hot water temperature can be maintained at ≥124°F (≥51°C), explore engineering options (e.g., install preset thermostatic valves in point-of-use fixtures) to help minimize the risk of scalding.[661] ***Category II***
C. When state regulations or codes do not allow hot water temperatures above the range of 105°F–120°F (40.6°C–49°C) for hospitals or 95°F–110°F (35°C–43.3°C) for nursing care facilities or when buildings cannot be retrofitted for thermostatic mixing valves, follow either of these alternative preventive measures to minimize the growth of *Legionella* spp. in water systems. ***Category II***
    1. Periodically increase the hot water temperature to ≥150°F (≥66°C) at the point of use.[661] ***Category II***
    2. Alternatively, chlorinate the water and then flush it through the system.[661, 710, 711] ***Category II***
D. Maintain constant recirculation in hot-water distribution systems serving patient-care areas. [120] ***Category IC*** (AIA: 7.31.E.3)

D.III. Remediation Strategies for Distribution System Repair or Emergencies

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Whenever possible, disconnect the ice machine before planned water disruptions. ***Category II***
B. Prepare a contingency plan to estimate water demands for the entire facility in advance of significant water disruptions (i.e., those expected to result in extensive and heavy microbial or chemical contamination of the potable water), sewage intrusion, or flooding.[713, 719] ***Category IC*** (JCAHO: EC 1.4)
C. When a significant water disruption or an emergency occurs, adhere to any advisory to boil water issued by the municipal water utility.[642] ***Category IB, IC*** (Municipal order)
    1. Alert patients, families, staff, and visitors not to consume water from drinking fountains, ice, or drinks made from municipal tap water, while the advisory is in effect, unless the water has been disinfected (e.g., by bringing to a rolling boil for ≥1 minute).[642] ***Category IB, IC*** (Municipal order)
    2. After the advisory is lifted, run faucets and drinking fountains at full flow for ≥5 minutes, or use high-temperature water flushing or chlorination.[642, 661] ***Category IC, II*** (Municipal order; ASHRAE 12:2000)
D. Maintain a high level of surveillance for waterborne disease among patients after a boil water advisory is lifted. ***Category II***
E. Corrective decontamination of the hot water system might be necessary after a disruption in service or a cross-connection with sewer lines has occurred.
    1. Decontaminate the system when the fewest occupants are present in the building (e.g., nights or weekends).[3, 661] ***Category IC*** (ASHRAE: 12:2000)
    2. If using high-temperature decontamination, raise the hot-water temperature to 160°F– 170°F (71°C–77°C) and maintain that level while progressively flushing each outlet around the system for ≥5 minutes.[3, 661] ***Category IC*** (ASHRAE: 12:2000)
    3. If using chlorination, add enough chlorine, preferably overnight, to achieve a free chlorine residual of ≥2 mg/L (≥2 ppm) throughout the system.[661]
        - * Flush each outlet until chlorine odor is detected.
        - * Maintain the elevated chlorine concentration in the system for ≥2 hrs (but ≤24 hrs).
    4. Use a very thorough flushing of the water system instead of chlorination if a highly chlorine-resistant microorganism (e.g., *Cryptosporidium* spp.) is suspected as the water contaminant. ***Category II***
F. Flush and restart equipment and fixtures according to manufacturers' instructions. ***Category II***

G. Change the pretreatment filter and disinfect the dialysis water system with an EPA-registered product to prevent colonization of the reverse osmosis membrane and downstream microbial contamination.[721] ***Category II***
H. Run water softeners through a regeneration cycle to restore their capacity and function. ***Category II***
I. If the facility has a water-holding reservoir or water-storage tank, consult the facility engineer or local health department to determine whether this equipment needs to be drained, disinfected with an EPA-registered product, and refilled. ***Category II***
J. Implement facility management procedures to manage a sewage system failure or flooding (e.g., arranging with other health-care facilities for temporary transfer of patients or provision of services), and establish communications with the local municipal water utility and the local health department to ensure that advisories are received in a timely manner upon release.[713, 719] ***Category IC*** (JCAHO: EC 1.4; Municipal order)
K. Implement infection-control measures during sewage intrusion, flooding, or other water-related emergencies.
    1. Relocate patients and clean or sterilize supplies from affected areas. ***Category II***
    2. If hands are not visibly soiled or contaminated with proteinaceous material, include an alcohol-based hand rub in the hand hygiene process
        - * before performing invasive procedures;
        - * before and after each patient contact; and
        - * whenever hand hygiene is indicated.[1364] ***Category II***
    3. If hands are visibly soiled or contaminated with proteinaceous material, use soap and bottled water for handwashing.[1364] ***Category II***
    4. If the potable water system is not affected by flooding or sewage contamination, process surgical instruments for sterilization according to standard procedures. ***Category II***
    5. Contact the manufacturer of the automated endoscope reprocessor (AER) for specific instructions on the use of this equipment during a water advisory. ***Category II***
L. Remediate the facility after sewage intrusion, flooding, or other water-related emergencies.
    1. Close off affected areas during cleanup procedures. ***Category II***
    2. Ensure that the sewage system is fully functional before beginning remediation so contaminated solids and standing water can be removed. ***Category II***
    3. If hard-surface equipment, floors, and walls remain in good repair, ensure that these are dry within 72 hours; clean with detergent according to standard cleaning procedures. ***Category II***
    4. Clean wood furniture and materials (if still in good repair); allow them to dry thoroughly before restoring varnish or other surface coatings. ***Category II***
    5. Contain dust and debris during remediation and repair as outlined in air recommendations (Air: II G 4, 5). ***Category II***
M. Regardless of the original source of water damage (e.g., flooding versus water leaks from point-of-use fixtures or roofs), remove wet, absorbent structural items (e.g., carpeting, wallboard, and wallpaper) and cloth furnishings if they cannot be easily and thoroughly cleaned and dried within 72 hours (e.g., moisture content ≤20% as determined by moisture meter readings); replace with new materials as soon as the underlying structure is declared by the facility engineer to be thoroughly dry.[18, 266, 278, 1026] ***Category IB***

D.IV. Additional Engineering Measures as Indicated by Epidemiologic Investigation for Controlling Waterborne, Health-Care Associated Legionnaires Disease

A. When using a pulse or one-time decontamination method, superheat the water by flushing each outlet for ≥5 minutes with water at 160°F–170°F (71°C–77°C) or hyperchlorinate the system by flushing all outlets for ≥5 minutes with water containing ≥2 mg/L (≥2 ppm) free residual chlorine using a chlorine-based product registered by the EPA for water treatment (e.g., sodium hypochlorite [chlorine bleach]).[661, 711, 714, 724, 764, 766] ***Category IB*** (ASHRAE: 12:2000)
B. After a pulse treatment, maintain both the heated water temperature at the return and the cold water temperature as per the recommendation (Water: IIA) wherever practical and permitted by state

codes, or chlorinate heated water to achieve 1–2 mg/L (1–2 ppm) free residual chlorine at the tap using a chlorine-based product registered by the EPA for water treatment (e.g., sodium hypochlorite [bleach]).[26, 437, 661, 709, 726, 727] ***Category IC*** (States; ASHRAE: 12:2000)

C. Explore engineering or educational options (e.g., install preset thermostatic mixing valves in point-of-use fixtures or post warning signs at each outlet) to minimize the risk of scalding for patients, visitors, and staff. ***Category II***

D. **No recommendation is offered** for treating water in the facility's distribution system with chlorine dioxide, heavy-metal ions (e.g., copper or silver), monochloramine, ozone, or UV light.[728–746] ***Unresolved issue***

D.V. General Infection-Control Strategies for Preventing Legionnaires Disease

A. Conduct an infection-control risk assessment of the facility to determine if patients at risk or severely immunocompromised patients are present.[3, 431, 432] ***Category IB***

B. Implement general strategies for detecting and preventing Legionnaires disease in facilities that do not provide care for severely immunocompromised patients (i.e., facilities that do not have HSCT or solid organ transplant programs).[3, 431, 432] ***Category IB***
   1. Establish a surveillance process to detect health-care associated Legionnaires disease.[3, 431, 432] ***Category IB***
   2. Inform health-care personnel (e.g., infection control, physicians, patient-care staff, and engineering) regarding the potential for Legionnaires disease to occur and measures to prevent and control health-care associated legionellosis.[437, 759] ***Category IB***
   3. Establish mechanisms to provide clinicians with laboratory tests (e.g., culture, urine antigen, direct fluorescence assay [DFA], and serology) for the diagnosis of Legionnaires disease.[3, 431] ***Category IB***

C. Maintain a high index of suspicion for health-care associated Legionnaires disease, and perform laboratory diagnostic tests for legionellosis on suspected cases, especially in patients at risk who do not require a PE for care (e.g., patients receiving systemic steroids; patients aged ≥65 years; or patients with chronic underlying disease [e.g., diabetes mellitus, congestive heart failure, or chronic obstructive lung disease]).[3, 395, 417, 423–425, 432, 435, 437, 453] ***Category IA***

D. Periodically review the availability and clinicians' use of laboratory diagnostic tests for Legionnaires disease in the facility; if clinicians' use of the tests on patients with diagnosed or suspected pneumonia is limited, implement measures (e.g., an educational campaign) to enhance clinicians' use of the test(s).[453] ***Category IB***

E. If one case of laboratory-confirmed, health-care associated Legionnaires disease is identified, or if two or more cases of laboratory-suspected, health-care associated Legionnaires disease occur during a 6-month period, certain activities should be initiated.[405, 408, 431, 453, 739, 759] ***Category IB***
   1. Report the cases to the state and local health departments where required. ***Category IC*** (States)
   2. If the facility does not treat severely immunocompromised patients, conduct an epidemiologic investigation, including retrospective review of microbiologic, serologic, and postmortem data to look for previously unidentified cases of healthcare–associated Legionnaires disease, and begin intensive prospective surveillance for additional cases.[3, 405, 408, 431, 453, 739, 759] ***Category IB***
   3. If no evidence of continued health-care associated transmission exists, continue intensive prospective surveillance for ≥2 months after the initiation of surveillance.[3, 405, 408, 431, 453, 739, 759] ***Category IB***

F. If there is evidence of continued health-care associated transmission (i.e., an outbreak), conduct an environmental assessment to determine the source of *Legionella* spp.[403–410, 455] ***Category IB***
   1. Collect water samples from potential aerosolized water sources (Appendix C).[1209] ***Category IB***
   2. Save and subtype isolates of *Legionella* spp. obtained from patients and the environment.[403–410, 453, 763, 764] ***Category IB***
   3. If a source is identified, promptly institute water system decontamination measures per recommendations (see Water IV).[766, 767] ***Category IB***
   4. If *Legionella* spp. are detected in ≥1cultures (e.g., conducted at 2-week intervals during 3 months), reassess the control measures, modify them accordingly, and repeat the

decontamination procedures; consider intensive use of techniques used for initial decontamination, or a combination of superheating and hyperchlorination.[3, 767, 768] ***Category IB***

G. If an environmental source is not identified during a Legionnaires disease outbreak, continue surveillance for new cases for ≥2 months. Either defer decontamination pending identification of the source of *Legionella* spp., or proceed with decontamination of the hospital's water distribution system, with special attention to areas involved in the outbreak. ***Category II***

H. **No recommendation is offered** regarding routine culturing of water systems in health-care facilities that do not have patient-care areas (i.e., PE or transplant units) for persons at high risk for *Legionella* spp. infection. [26, 453, 707, 709, 714, 747, 753] ***Unresolved issue***

I. **No recommendation is offered** regarding the removal of faucet aerators in areas for immunocompetent patients. ***Unresolved issue***

J. Keep adequate records of all infection-control measures and environmental test results for potable water systems. ***Category II***

D.VI. Preventing Legionnaires Disease in Protective Environments and Transplant Units

A. When implementing strategies for preventing Legionnaires disease among severely immunosuppressed patients housed in facilities with HSCT or solid-organ transplant programs, incorporate these specific surveillance and epidemiologic measures in addition to the steps previously outlined (Water: V and Appendix C).
   1. Maintain a high index of suspicion for legionellosis in transplant patients even when environmental surveillance cultures do not yield legionellae.[430, 431] ***Category IB***
   2. If a case occurs in a severely immunocompromised patient, or if severely immunocompromised patients are present in high-risk areas of the hospital (e.g., PE or transplant units) and cases are identified elsewhere in the facility, conduct a combined epidemiologic and environmental investigation to determine the source of *Legionella* spp. [431, 767] ***Category IB***

B. Implement culture strategies and potable water and fixture treatment measures in addition to those previously outlined (Water: V). ***Category II***
   1. Depending on state regulations on potable water temperature in public buildings,[725] hospitals housing patients at risk for health-care associated legionellosis should either maintain heated water with a minimum return temperature of ≥124°F [≥51°C] and cold water at <68°F [<20°C]), or chlorinate heated water to achieve 1–2 mg/L (1–2 ppm) of free residual chlorine at the tap.[26, 441, 661, 709–711, 726, 727] ***Category II***
   2. Periodic culturing for legionellae in potable water samples from HSCT or solid-organ transplant units can be performed as part of a comprehensive strategy to prevent Legionnaires disease in these units.[9, 431, 710, 769] ***Category II***
   3. **No recommendation is offered** regarding the optimal methodology (i.e., frequency or number of sites) for environmental surveillance cultures in HSCT or solid organ transplant units. ***Unresolved issue***
   4. In areas with patients at risk, when *Legionella* spp. are not detectable in unit water, remove, clean, and disinfect shower heads and tap aerators monthly by using a chlorine-based, EPA-registered product. If an EPA-registered chlorine disinfectant is not available, use a chlorine bleach solution (500–615 ppm [1:100 v/v dilution]).[661, 745] ***Category II***

C. If *Legionella* spp. are determined to be present in the water of a transplant unit, implement certain measures until *Legionella* spp. are no longer detected by culture.
   1. Decontaminate the water supply as outlined previously (Water: IV).[3, 9, 661, 766, 767] ***Category IB***
   2. Do not use water from the faucets in patient-care rooms to avoid creating infectious aerosols.[9, 412] ***Category IB***
   3. Restrict severely immunocompromised patients from taking showers.[9, 412] ***Category IB***
   4. Use water that is not contaminated with *Legionella* spp. for HSCT patients' sponge baths.[9, 412] ***Category IB***
   5. Provide patients with sterile water for tooth brushing, drinking, and for flushing nasogastric tubing during legionellosis outbreaks.[9, 412] ***Category IB***

D. Do not use large-volume room air humidifiers that create aerosols (e.g., by Venturi principle, ultrasound, or spinning disk) unless they are subjected to high-level disinfection and filled only with sterile water.[3, 9, 402, 455] ***Category IB***

D.VII. Cooling Towers and Evaporative Condensers

A. When planning construction of new health-care facilities, locate cooling towers so that the drift is directed away from the air-intake system, and design the towers to minimize the volume of aerosol drift.[404, 661, 786] ***Category IC*** (ASHRAE: 12:2000) 131

B. Implement infection-control procedures for operational cooling towers.[404, 661, 784] ***Category IC*** (ASHRAE: 12:2000)
   1. Install drift eliminators.[404, 661, 784] ***Category IC*** (ASHRAE: 12:2000)
   2. Use an effective EPA-registered biocide on a regular basis.[661] ***Category IC*** (ASHRAE: 12:2000)
   3. Maintain towers according to manufacturers' recommendations, and keep detailed maintenance and infection control records, including environmental test results from legionellosis outbreak investigations.[661] ***Category IC*** (ASHRAE: 12:2000)

C. If cooling towers or evaporative condensers are implicated in health-care associated legionellosis, decontaminate the cooling-tower system.[404, 405, 786, 787] ***Category IB***

D.VIII. Dialysis Water Quality and Dialysate

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Adhere to current AAMI standards for quality assurance performance of devices and equipment used to treat, store, and distribute water in hemodialysis centers (both acute and maintenance [chronic] settings) and for the preparation of concentrates and dialysate.[31, 32, 666–668, 789, 791, 800, 807, 809, 1454, 1455] ***Category IA, IC*** (AAMI: ANSI/AAMI RD5:1992, ANSI/AAMI RD 47:1993)

B. **No recommendation is offered** regarding whether more stringent requirements for water quality should be imposed in hemofiltration and hemodiafiltration. ***Unresolved issue***

C. Conduct microbiological testing specific to water in dialysis settings.[789, 791, 792, 834, 835] ***Category IA, IC*** (AAMI: ANSI/AAMI RD 5: 1992, ANSI/AAMI RD 47: 1993, ANSI/AAMI RD 62:2001)
   1. Perform bacteriologic assays of water and dialysis fluids at least once a month and during outbreaks using standard quantitative methods.[792, 834, 835]
      - * Assay for heterotrophic, mesophilic bacteria (e.g., *Pseudomonas* spp).
      - * Do not use nutrient-rich media (e.g., blood agar or chocolate agar). ***Category IA, IC*** (AAMI: ANSI/AAMI RD 62:2001)
   2. In conjunction with microbiological testing, perform endotoxin testing on product water used to reprocess dialyzers for multiple use.[789, 791, 806, 811, 816, 829] ***Category IA, IC*** (AAMI: ANSI/AAMI RD 5:1992, ANSI/AAMI RD 47:1993)
   3. Ensure that water does not exceed the limits for microbial counts and endotoxin concentrations outlined in Table 18.[789, 791, 800] ***Category IA, IC*** (AAMI: ANSI/AAMI RD 5:1992, ANSI/AAMI RD 47:1993)

D. Disinfect water distribution systems in dialysis settings on a regular schedule. Monthly disinfection is recommended.[666–668, 792, 800] ***Category IA, IC*** (AAMI: ANSI/AAMI RD62:2001)

E. Whenever practical, design and engineer water systems in dialysis settings to avoid incorporating joints, dead-end pipes, and unused branches and taps that can harbor bacteria.[666–668, 792, 800] ***Category IA, IC*** (AAMI: ANSI/AAMI RD62:2001)

F. When storage tanks are used in dialysis systems, they should be routinely drained, disinfected with an EPA-registered product, and fitted with an ultrafilter or pyrogenic filter (membrane filter with a pore size sufficient to remove small particles and molecules ≥1 kilodalton) installed in the water line distal to the storage tank.[792] ***Category IC*** (AAMI: ANSI/AAMI RD62:2001)

D.IX. Ice Machines and Ice

A. Do not handle ice directly by hand, and wash hands before obtaining ice. ***Category II***

B. Use a smooth-surface ice scoop to dispense ice.[680, 863] ***Category II***
   1. Keep the ice scoop on a chain short enough the scoop cannot touch the floor, or keep the scoop on a clean, hard surface when not in use.[680, 863] ***Category II***
   2. Do not store the ice scoop in the ice bin. ***Category II***
C. Do not store pharmaceuticals or medical solutions on ice intended for consumption; use sterile ice to keep medical solutions cold, or use equipment specifically manufactured for this purpose.[600, 863] ***Category IB***
D. Machines that dispense ice are preferred to those that require ice to be removed from bins or chests with a scoop.[687, 869] ***Category II***
E. Limit access to ice-storage chests, and keep the container doors closed except when removing ice.[863] ***Category II***
F. Clean, disinfect, and maintain ice-storage chests on a regular basis. ***Category II***
   1. Follow the manufacturer's instructions for cleaning. ***Category II***
   2. Use an EPA-registered disinfectant suitable for use on ice machines, dispensers, or storage chests in accordance with label instructions. ***Category II***
   3. If instructions and EPA-registered disinfectants suitable for use on ice machines are not available, use a general cleaning/disinfecting regimen as outlined in Box 12.[863] ***Category II***
   4. Flush and clean the ice machines and dispensers if they have not been disconnected before anticipated lengthy water disruptions. ***Category II***
G. Install proper air gaps where the condensate lines meet the waste lines. ***Category II***
H. Conduct microbiologic sampling of ice, ice chests, and ice-making machines and dispensers where indicated during an epidemiologic investigation.[861–863] ***Category IB***

D.X. Hydrotherapy Tanks and Pools

A. Drain and clean hydrotherapy equipment (e.g., Hubbard tanks, tubs, whirlpools, whirlpool spas, or birthing tanks) after each patient's use, and disinfect equipment surfaces and components by using an EPA-registered product in accordance with the manufacturer's instructions. ***Category II***
B. In the absence of an EPA-registered product for water treatment, add sodium hypochlorite to the water: ***Category II***
   1. Maintain a 15-ppm chlorine residual in the water of small hydrotherapy tanks, Hubbard tanks, and tubs.[889] ***Category II***
   2. Maintain a 2–5 ppm chlorine residual in the water of whirlpools and whirlpool spas.[905] ***Category II***
   3. If the pH of the municipal water is in the basic range (e.g., when chloramine is used as the primary drinking water disinfectant in the community), consult the facility engineer regarding the possible need to adjust the pH of the water to a more acid level before disinfection, to enhance the biocidal activity of chlorine.[894] ***Category II***
C. Clean and disinfect hydrotherapy equipment after using tub liners. ***Category II***
D. Clean and disinfect inflatable tubs unless they are single-use equipment. ***Category II***
E. **No recommendation is offered** regarding the use of antiseptic chemicals (e.g., chloramine-T) in the water during hydrotherapy sessions. ***Unresolved issue***
F. Conduct a risk assessment of patients prior to their use of large hydrotherapy pools, deferring patients with draining wounds or fecal incontinence from pool use until their condition resolves. ***Category II***
G. For large hydrotherapy pools, use pH and chlorine residual levels appropriate for an indoor pool as provided by local and state health agencies. ***Category IC*** (States)
H. **No recommendation is offered** regarding the use in health care of whirlpools or spa equipment manufactured for home or recreational use. ***Unresolved issue***

D.XI. Miscellaneous Medical Equipment Connected to Water Systems

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Clean, disinfect, and maintain AER equipment according to the manufacturer's instructions and relevant scientific literature to prevent inadvertent contamination of endoscopes and bronchoscopes with waterborne microorganisms.[911–915] ***Category IB***
   1. To rinse disinfected endoscopes and bronchoscopes, use water of the highest quality practical for the system's engineering and design (e.g., sterile water or bacteriologically-filtered water [water filtered through 0.1–0.2-µm filters]).[912, 914, 915, 918] ***Category IB***
   2. Dry the internal channels of the reprocessed endoscope or bronchoscope using a proven method (e.g., 70% alcohol followed by forced-air treatment) to lessen the potential for the proliferation of waterborne microorganisms and to help prevent biofilm formation.[671, 921, 923, 925, 928] ***Category IB***

B. Use water that meets nationally recognized standards set by the EPA for drinking water (<500 CFU/mL for heterotrophic plate count) for routine dental treatment output water.[935, 936, 943, 944] ***Category IB, IC*** (EPA: 40 CFR 1 Part 141, Subpart G).

C. Take precautions to prevent waterborne contamination of dental unit water lines and instruments.
   1. After each patient, discharge water and air for a minimum of 20–30 seconds from any dental device connected to the dental water system that enters the patient's mouth (e.g., handpieces, ultrasonic scalers, and air/water syringe).[936, 937] ***Category II***
   2. Consult with dental water-line manufacturers to
      - * determine suitable methods and equipment to obtain the recommended water quality; and
      - * determine appropriate methods for monitoring the water to ensure quality is maintained.[936, 946] ***Category II***
   3. Consult with the dental unit manufacturer on the need for periodic maintenance of anti-retraction mechanisms.[937, 946] ***Category IB***

E. Recommendations—Environmental Services

E.I. Cleaning and Disinfecting Strategies for Environmental Surfaces in Patient-Care Areas

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Select EPA-registered disinfectants, if available, and use them in accordance with the manufacturer's instructions.[2, 974, 983] ***Category IB, IC*** (EPA: 7 United States Code [USC] § 136 et seq)

B. Do not use high-level disinfectants/liquid chemical sterilants for disinfection of either noncritical instrument/devices or any environmental surfaces; such use is counter to label instructions for these toxic chemicals.[951, 952, 961–964] ***Category IB, IC*** (FDA: 21 CFR 801.5, 807.87.e)

C. Follow manufacturers' instructions for cleaning and maintaining noncritical medical equipment. ***Category II***

D. In the absence of a manufacturer's cleaning instructions, follow certain procedures.
   1. Clean noncritical medical equipment surfaces with a detergent/disinfectant. This may be followed with an application of an EPA-registered hospital disinfectant with or without a tuberculocidal claim (depending on the nature of the surface and the degree of contamination), in accordance with disinfectant label instructions.[952] ***Category II***
   2. Do not use alcohol to disinfect large environmental surfaces.[951] ***Category II***
   3. Use barrier protective coverings as appropriate for noncritical equipment surfaces that are
      - * touched frequently with gloved hands during the delivery of patient care;
      - *likely to become contaminated with blood or body substances; or
      - *difficult to clean (e.g., computer keyboards).[936] ***Category II***

E. Keep housekeeping surfaces (e.g., floors, walls, and tabletops) visibly clean on a regular basis and clean up spills promptly.[954] ***Category II***
   1. Use a one-step process and an EPA-registered hospital disinfectant/detergent designed for general housekeeping purposes in patient-care areas when
      - * uncertainty exists as to the nature of the soil on these surfaces [e.g., blood or body fluid contamination versus routine dust or dirt]; or

- * uncertainty exists regarding the presence or absence of multi-drug resistant organisms on such surfaces.[952, 983, 986, 987] ***Category II***

2. Detergent and water are adequate for cleaning surfaces in nonpatient-care areas (e.g., administrative offices). ***Category II***
3. Clean and disinfect high-touch surfaces (e.g., doorknobs, bed rails, light switches, and surfaces in and around toilets in patients' rooms) on a more frequent schedule than minimal touch housekeeping surfaces. ***Category II***
4. Clean walls, blinds, and window curtains in patient-care areas when they are visibly dusty or soiled.[2, 971, 972, 982] ***Category II***

F. Do not perform disinfectant fogging in patient-care areas.[2, 976] ***Category IB***

Environmental Fogging [December 2009]. Clarification Statement: CDC and HICPAC have recommendations in the 2003 Guidelines for Environmental Infection Control in Health-Care Facilities that state that the CDC does not support disinfectant fogging.

These recommendations refer to the spraying or fogging of chemicals (e.g., formaldehyde, phenol-based agents, or quaternary ammonium compounds) as a way to decontaminate environmental surfaces or disinfect the air in patient rooms. The recommendation against fogging was based on studies in the 1970's that reported a lack of microbicidal efficacy (e.g., use of quaternary ammonium compounds in mist applications) but also adverse effects on healthcare workers and others in facilities where these methods were utilized. Furthermore, some of these chemicals are not EPA-registered for use in fogging-type applications.

These recommendations do not apply to newer technologies involving fogging for room decontamination (e.g., ozone mists, vaporized hydrogen peroxide) that have become available since the 2003 recommendations were made. These newer technologies were assessed by CDC and HICPAC in the 2011 Guideline for the Prevention and Control of Norovirus Gastroenteritis Outbreaks in Healthcare Settings, which makes the recommendation:

"More research is required to clarify the effectiveness and reliability of fogging, UV irradiation, and ozone mists to reduce norovirus environmental contamination. (No recommendation/ unresolved issue)"

The 2003 recommendations still apply; however, CDC does not yet make a recommendation regarding these newer technologies. This issue will be revisited as additional evidence becomes available.

G. Avoid large-surface cleaning methods that produce mists or aerosols or disperse dust in patient-care areas.[9, 20, 109, 272] ***Category IB***

H. Follow proper procedures for effective use of mops, cloths, and solutions. ***Category II***

1. Prepare cleaning solutions daily or as needed, and replace with fresh solution frequently according to facility policies and procedures.[986, 987] ***Category II***
2. Change the mop head at the beginning of the day and also as required by facility policy, or after cleaning up large spills of blood or other body substances. ***Category II***
3. Clean mops and cloths after use and allow to dry before reuse; or use single-use, disposable mop heads and cloths.[971, 988–990] ***Category II***

I. After the last surgical procedure of the day or night, wet vacuum or mop operating room floors with a single-use mop and an EPA-registered hospital disinfectant.[7] ***Category IB***

J. Do not use mats with tacky surfaces at the entrance to operating rooms or infection-control suites.[7] ***Category IB***

K. Use appropriate dusting methods for patient-care areas designated for immunocompromised patients (e.g., HSCT patients):[9, 94, 986] ***Category IB***

1. Wet-dust horizontal surfaces daily by moistening a cloth with a small amount of an EPA-registered hospital detergent/disinfectant.[9, 94, 986] ***Category IB***
2. Avoid dusting methods that disperse dust (e.g., feather-dusting).[94] ***Category IB***

L. Keep vacuums in good repair, and equip vacuums with HEPA filters for use in areas with patients at risk.[9, 94, 986, 994] ***Category IB***

M. Close the doors of immunocompromised patients' rooms when vacuuming, waxing, or buffing corridor floors to minimize exposure to airborne dust.[9, 94, 994] ***Category IB***

N. When performing low- or intermediate-level disinfection of environmental surfaces in nurseries and neonatal units, avoid unnecessary exposure of neonates to disinfectant residues on environmental surfaces by using EPA-registered disinfectants in accordance with manufacturers' instructions and safety advisories.[974, 995–997] ***Category IB, IC*** (EPA: 7 USC § 136 et seq.)
   1. Do not use phenolics or any other chemical germicide to disinfect bassinets or incubators during an infant's stay.[952, 995–997] ***Category IB***
   2. Rinse disinfectant-treated surfaces, especially those treated with phenolics, with water.[995–997] ***Category IB***

O. When using phenolic disinfectants in neonatal units, prepare solutions to correct concentrations in accordance with manufacturers' instructions, or use premixed formulations.[974, 995–997] ***Category IB, IC*** (EPA: 7 USC § 136 et seq.)

E.II. Cleaning Spills of Blood and Body Substances

A. Promptly clean and decontaminate spills of blood or other potentially infectious materials.[967, 998–1004] ***Category IB, IC*** (OSHA: 29 CFR 1910.1030 §d.4.ii.A)

B. Follow proper procedures for site decontamination of spills of blood or blood-containing body fluids.[967, 998–004] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.ii.A)
   1. Use protective gloves and other PPE appropriate for this task.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.3.i, ii) 135
   2. If the spill contains large amounts of blood or body fluids, clean the visible matter with disposable absorbent material, and discard the contaminated materials in appropriate, labeled containment.[967, 1002, 1003, 1010, 1012] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iii.B)
   3. Swab the area with a cloth or paper towels moderately wetted with disinfectant, and allow the surface to dry.[967, 1010] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.ii.A)

C. Use EPA-registered hospital disinfectants labeled tuberculocidal or registered germicides on the EPA Lists D and E (products with specific label claims for HIV or hepatitis B virus [HBV]) in accordance with label instructions to decontaminate spills of blood and other body fluids.[967, 1007, 1010] ***Category IC*** (OSHA 29 CFR 1910.1030 § d.4.ii.A memorandum 2/28/97; compliance document CPL 2-2.44D [11/99])

D. An EPA-registered sodium hypochlorite product is preferred, but if such products are not available, generic versions of sodium hypochlorite solutions (e.g., household chlorine bleach) may be used.
   1. Use a 1:100 dilution (500–615 ppm available chlorine) to decontaminate nonporous surfaces after cleaning a spill of either blood or body fluids in patient-care settings.[1010, 1011] ***Category II***
   2. If a spill involves large amounts of blood or body fluids, or if a blood or culture spill occurs in the laboratory, use a 1:10 dilution (5,000–6,150 ppm available chlorine) for the first application of germicide before cleaning.[954, 1010] ***Category II***

E.III. Carpeting and Cloth Furnishings

A. Vacuum carpeting in public areas of health-care facilities and in general patient-care areas regularly with well-maintained equipment designed to minimize dust dispersion.[986] **Category II**

B. Periodically perform a thorough, deep cleaning of carpeting as determined by facility policy by using a method that minimizes the production of aerosols and leaves little or no residue.[111] ***Category II***

C. Avoid use of carpeting in high-traffic zones in patient-care areas or where spills are likely (e.g., burn therapy units, operating rooms, laboratories, and intensive care units).[111, 1023, 1028] ***Category IB***

D. Follow proper procedures for managing spills on carpeting.
   1. Spot-clean blood or body substance spills promptly.[967, 1010, 1011, 1032] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.ii.A, interpretation)
   2. If a spill occurs on carpet tiles, replace any tiles contaminated by blood and body fluids or body substances.[1032] ***Category IC*** (OSHA 29 CFR 1910.1030 § d.4.ii interpretation)

E. Thoroughly dry wet carpeting to prevent the growth of fungi; replace carpeting that remains wet after 72 hours.[9, 1026] ***Category IB***
F. **No recommendation is offered** regarding the routine use of fungicidal or bactericidal treatments for carpeting in public areas of a health-care facility or in general patient-care areas. ***Unresolved issue***
G. Do not use carpeting in hallways and patient rooms in areas housing immunosuppressed patients (e.g., PE areas).[9, 111] ***Category IB***
H. Avoid the use of upholstered furniture and furnishings in high-risk patient-care areas and in areas with increased potential for body substance contamination (e.g., pediatrics units).[9] ***Category II***
I. **No recommendation is offered** regarding whether upholstered furniture and furnishings should be avoided in general patient-care areas. ***Unresolved issue***
J. Maintain upholstered furniture in good repair. ***Category II***
    1. Maintain the surface integrity of the upholstery by repairing tears and holes. ***Category II***
    2. If upholstered furniture in a patient's room requires cleaning to remove visible soil or body substance contamination, move that item to a maintenance area where it can be adequately cleaned with a process appropriate for the type of upholstery and the nature of the soil. ***Category II***

E.IV. Flowers and Plants in Patient-Care Areas

A. Flowers and potted plants need not be restricted from areas for immunocompetent patients.[515, 702, 1040, 1042] ***Category II***
B. Designate care and maintenance of flowers and potted plants to staff not directly involved with patient care.[702] ***Category II***
C. If plant or flower care by patient-care staff is unavoidable, instruct the staff to wear gloves when handling the plants and flowers and perform hand hygiene after glove removal.[702] ***Category II***
D. Do not allow fresh or dried flowers, or potted plants in patient-care areas for immunosuppressed patients.[9, 109, 515, 1046] ***Category II***

E.V. Pest Control

A. Develop pest-control strategies, with emphasis on kitchens, cafeterias, laundries, central sterile supply areas, operating rooms, loading docks, construction activities, and other areas prone to infestations.[1050, 1072, 1075] ***Category II***
B. Install screens on all windows that open to the outside; keep screens in good repair.[1072] ***Category IB***
C. Contract for routine pest control service by a credentialed pest-control specialist who will tailor the application to the needs of a health-care facility.[1075] ***Category II***
D. Place laboratory specimens (e.g., fixed sputum smears) in covered containers for overnight storage.[1065, 1066] ***Category II***

E.VI. Special Pathogens

A. Use appropriate hand hygiene, PPE (e.g., gloves), and isolation precautions during cleaning and disinfecting procedures.[5, 952, 1130, 1364] ***Category IB***
B. Use standard cleaning and disinfection protocols to control environmental contamination with antibiotic-resistant gram-positive cocci (e.g., methicillin-resistant *Staphylococcus aureus*, vancomycin intermediate-resistant *Staphylococcus aureus*, or vancomycin-resistant *Enterococcus* [VRE]).[5, 1116–1118] ***Category IB***
    1. Pay close attention to cleaning and disinfection of high-touch surfaces in patient-care areas (e.g., bed rails, carts, bedside commodes, bedrails, doorknobs, or faucet handles).[5, 1116–1118] ***Category IB***
    2. Ensure compliance by housekeeping staff with cleaning and disinfection procedures.[5, 1116–1118] ***Category IB***
    3. Use EPA-registered hospital disinfectants appropriate for the surface to be disinfected (e.g., either low- or intermediate-level disinfection) as specified by the manufacturers' instructions.[974, 1106–1110, 1118] ***Category IB, IC*** (EPA: 7 USC § 136 et seq.)
    4. When contact precautions are indicated for patient care, use disposable patient-care items (e.g., blood pressure cuffs) whenever possible to minimize cross-contamination with multiple-resistant microorganisms.[1102] ***Category IB***

5. Follow these same surface cleaning and disinfecting measures for managing the environment of VRSA patients.[1110, 1116–1118] ***Category II***

C. Environmental-surface culturing can be used to verify the efficacy of hospital policies and procedures before and after cleaning and disinfecting rooms that house patients with VRE.[5, 1084, 1087, 1088, 1092, 1096] ***Category II***
   1. Obtain prior approval from infection-control staff and the clinical laboratory before performing environmental surface culturing. ***Category II***
   2. Infection-control staff, with clinical laboratory consultation, must supervise all environmental culturing. ***Category II***

D. Thoroughly clean and disinfect environmental and medical equipment surfaces on a regular basis using EPA-registered disinfectants in accordance with manufacturers' instructions.[952, 974, 1130, 1143] ***Category IB, IC*** (EPA: 7 USC § 136 et seq.)

E. Advise families, visitors, and patients about the importance of hand hygiene to minimize the spread of body substance contamination (e.g., respiratory secretions or fecal matter) to surfaces.[952] ***Category II***

F. Do not use high-level disinfectants (i.e., liquid chemical sterilants) on environmental surfaces; such use is inconsistent with label instructions and because of the toxicity of the chemicals.[2, 951, 952, 964] ***Category IC*** (FDA: 21 CFR 801.5, 807.87.e)

C. difficile **Update [April 2019]**

Recommendations E.VI.G. and E.VI.H. were updated to reflect changes in Federal regulatory approvals: LIST K: EPA's Registered Antimicrobial Products Effective against Clostridium difficile Spores (https://www.epa.gov/pesticide-registration/list-k-epas-registered-antimicrobial-products-effective-against-clostridium).

G. Update: Use an EPA-registered product effective against *Clostridium difficile* spores for disinfection of environmental surfaces in rooms where *C. difficile* patients are treated. (New Categorization Scheme: **Recommendation**. See page 2) See LIST K: EPA's Registered Antimicrobial Products Effective against Clostridium difficile Spores (https://www.epa.gov/pesticide-registration/list-k-epas-registered-antimicrobial-products-effective-against-clostridium).

H. Update: This recommendation has been superseded by recommendation E.VI.G. **See** LIST K: EPA's Registered Antimicrobial Products Effective against Clostridium difficile Spores (https://www.epa.gov/pesticide-registration/list-k-epas-registered-antimicrobial-products-effective-against-clostridium).

I. Apply standard cleaning and disinfection procedures to control environmental contamination with respiratory and enteric viruses in pediatric-care units and care areas for immunocompromised patients.[986, 1158] ***Category IC*** (EPA: 7 USC § 136 et seq.)

J. Clean surfaces that have been contaminated with body substances; perform low- to intermediate-level disinfection on cleaned surfaces with an EPA-registered disinfectant in accordance with the manufacturer's instructions.[967, 974, 1158] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.ii.A; EPA: 7 USC § 136 et seq.)

K. Use disposable barrier coverings as appropriate to minimize surface contamination. ***Category II***

L. Develop and maintain cleaning and disinfection procedures to control environmental contamination with agents of Creutzfeldt-Jakob disease (CJD), for which no EPA-registered product exists. ***Category II***
   1. In the absence of contamination with central nervous system tissue, extraordinary measures (e.g., use of 2N sodium hydroxide [NaOH] or applying full-strength sodium hypochlorite) are not needed for routine cleaning or terminal disinfection of a room housing a confirmed or suspected CJD patient.[951, 1199] ***Category II***
   2. After removing gross tissue from the surface, use either 1N NaOH or a sodium hypochlorite solution containing approximately 10,000–20,000 ppm available chlorine (dilutions of 1:5 to 1:3 v/v, respectively, of U.S. household chlorine bleach; contact the manufacturers of commercially

available sodium hypochlorite products for advice) to decontaminate operating room or autopsy surfaces with central nervous system or cerebral spinal fluid contamination from a diagnosed or suspected CJD patient.[951, 1170, 1188, 1191, 1197–1199, 1201]

- * The contact time for the chemical used during this process should be 30 min–1 hour.[1191, 1197, 1201]
- * Blot up the chemical with absorbent material and rinse the treated surface thoroughly with water.
- * Discard the used, absorbent material into appropriate waste containment. ***Category II***

3. Use disposable, impervious covers to minimize body substance contamination to autopsy tables and surfaces.[1197, 1201] ***Category IB***

M. Use standard procedures for containment, cleaning, and decontamination of blood spills on surfaces as previously described (Environmental Services: II).[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 §d.4.ii.A)

1. Wear PPE appropriate for a surface decontamination and cleaning task.[967, 1199] ***Category IC*** (OSHA 29 CFR 1910.1030 §d.3.i, ii)
2. Discard used PPE by using routine disposal procedures or decontaminate reusable PPE as appropriate.[967, 1199] ***Category IC*** (OSHA 29 CFR 1910.1030 §d.3.viii)

F. Recommendations—Environmental Sampling

F.I. General Information

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Do not conduct random, undirected microbiologic sampling of air, water, and environmental surfaces in health-care facilities.[2, 1214] ***Category IB***

B. When indicated, conduct microbiologic sampling as part of an epidemiologic investigation or during assessment of hazardous environmental conditions to detect contamination and verify abatement of a hazard.[2, 1214] ***Category IB***

C. Limit microbiologic sampling for quality assurance purposes to

- * biological monitoring of sterilization processes;
- * monthly cultures of water and dialysate in hemodialysis units; and
- * short-term evaluation of the impact of infection-control measures or changes in infection-control protocols.[2, 1214] ***Category IB***

F.II. Air, Water, and Environmental-Surface Sampling

A. When conducting any form of environmental sampling, identify existing comparative standards and fully document departures from standard methods.[945, 1214, 1223, 1224, 1238] **Category II**

B. Select a high-volume air sampling device if anticipated levels of microbial airborne contamination are expected to be low.[290, 1218, 1223, 1224] ***Category II***

C. Do not use settle plates to quantify the concentration of airborne fungal spores.[290] ***Category II***

D. When sampling water, choose growth media and incubation conditions that will facilitate the recovery of waterborne organisms.[945] ***Category II***

E. When using a sample/rinse method for sampling an environmental surface, develop and document a procedure for manipulating the swab, gauze, or sponge in a reproducible manner so that results are comparable.[1238] ***Category II***

F. When environmental samples and patient specimens are available for comparison, perform the laboratory analysis on the recovered microorganisms down to the species level at a minimum and beyond the species level if possible.[1214] ***Category II***

G. Recommendations—Laundry and Bedding

G.I. Employer Responsibilities

A. Employers must launder workers' personal protective garments or uniforms that are contaminated with blood or other potentially infectious materials.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.3.iv)

G.II. Laundry Facilities and Equipment

A. Maintain the receiving area for contaminated textiles at negative pressure compared with the clean areas of the laundry in accordance with AIA construction standards in effect during the time of facility construction.[120, 1260–1262] ***Category IC*** (AIA: 7.23.B1, B2)
B. Ensure that laundry areas have handwashing facilities and products and appropriate PPE available for workers.[120, 967] ***Category IC*** (AIA: 7.23.D4; OSHA: 29 CFR 1910.1030 § d.2.iii)
C. Use and maintain laundry equipment according to manufacturers' instructions.[1250, 1263] ***Category II***
D. Do not leave damp textiles or fabrics in machines overnight.[1250] ***Category II***
E. Disinfection of washing and drying machines in residential care is not needed as long as gross soil is removed before washing and proper washing and drying procedures are used. ***Category II***

G.III. Routine Handling of Contaminated Laundry

A. Handle contaminated textiles and fabrics with minimum agitation to avoid contamination of air, surfaces, and persons.[6, 967, 1258, 1259] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iv)
B. Bag or otherwise contain contaminated textiles and fabrics at the point of use.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iv)
    1. Do not sort or prerinse contaminated textiles or fabrics in patient-care areas.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 §d.4.iv)
    2. Use leak-resistant containment for textiles and fabrics contaminated with blood or body substances.[967, 1258] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iv)
    3. Identify bags or containers for contaminated textiles with labels, color coding, or other alternative means of communication as appropriate.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iv)
C. Covers are not needed on contaminated textile hampers in patient-care areas. ***Category II***
D. If laundry chutes are used, ensure that they are properly designed, maintained, and used in a manner to minimize dispersion of aerosols from contaminated laundry.[1253, 1267–1270] ***Category IC*** (AAMI: ANSI/AAMI ST65:2000)
    1. Ensure that laundry bags are closed before tossing the filled bag into the chute. ***Category II***
    2. Do not place loose items in the chute. ***Category II***
E. Establish a facility policy to determine when textiles or fabrics should be sorted in the laundry facility (i.e., before or after washing).[1271, 1272] ***Category II***

G.IV. Laundry Process

A. If hot-water laundry cycles are used, wash with detergent in water ≥160°F (≥71°C) for ≥25 minutes.[2, 120] ***Category IC*** (AIA: 7.31.E3)
B. **No recommendation is offered** regarding a hot-water temperature setting and cycle duration for items laundered in residence-style health-care facilities. ***Unresolved issue***
C. Follow fabric-care instructions and special laundering requirements for items used in the facility.[1278] ***Category II***
D. Choose chemicals suitable for low-temperature washing at proper use concentration if low-temperature (<160°F [<71°C]) laundry cycles are used.[1247, 1281–1285] ***Category II***
E. Package, transport, and store clean textiles and fabrics by methods that will ensure their cleanliness and protect them from dust and soil during interfacility loading, transport, and unloading.[2] ***Category II***

G.V. Microbiologic Sampling of Textiles

A. Do not conduct routine microbiological sampling of clean textiles.[2, 1286] ***Category IB***
B. Use microbiological sampling during outbreak investigations if epidemiologic evidence suggests a role for health-care textiles and clothing in disease transmission.[1286] ***Category IB***

G.VI. Special Laundry Situations

A. Use sterilized textiles, surgical drapes, and gowns for situations requiring sterility in patient care.[7] ***Category IB***
B. Use hygienically clean textiles (i.e., laundered, but not sterilized) in neonatal intensive care units.[997, 1288] ***Category IB***
C. Follow manufacturers' recommendations for cleaning fabric products including those with coated or laminated surfaces. ***Category II***
D. Do not use dry cleaning for routine laundering in health-care facilities.[1289–1291] ***Category II***
E. Use caution when considering the use of antimicrobial mattresses, textiles, and clothing as replacements for standard bedding and other fabric items; EPA has not approved public health claims asserting protection against human pathogens for treated articles.[1306] ***Category II***
F. **No recommendation is offered** regarding using disposable fabrics and textiles versus durable goods. ***Unresolved issue***

G.VII. Mattresses and Pillows

A. Keep mattresses dry; discard them if they become and remain wet or stained, particularly in burn units.[1310–1315] ***Category IB***
B. Clean and disinfect mattress covers using EPA-registered disinfectants, if available, that are compatible with the cover materials to prevent the development of tears, cracks, or holes in the cover.[1310–1315] ***Category IB***
C. Maintain the integrity of mattress and pillow covers. ***Category II***
    1. Replace mattress and pillow covers if they become torn or otherwise in need of repair. ***Category II***
    2. Do not stick needles into the mattress through the cover. ***Category II***
D. Clean and disinfect moisture-resistant mattress covers between patients using an EPA-registered product, if available.[1310–1315] ***Category IB***
E. If using a mattress cover completely made of fabric, change these covers and launder between patients.[1310–1315] ***Category IB***
F. Launder pillow covers and washable pillows in the hot-water cycle between patients or when they become contaminated with body substances.[1315] ***Category IB***

G.VIII. Air-Fluidized Beds

A. Follow manufacturers' instructions for bed maintenance and decontamination. ***Category II***
B. Change the polyester filter sheet at least weekly or as indicated by the manufacturer.[1317, 1318, 1322, 1323] ***Category II***
C. Clean and disinfect the polyester filter sheet thoroughly, especially between patients, using an EPA-registered product, if available.[1317, 1318, 1322, 1323] ***Category IB***
D. Consult the facility engineer to determine the proper location of air-fluidized beds in negative-pressure rooms.[1326] ***Category II***

H. Recommendations—Animals in Health-Care Facilities

H.I. General Infection-Control Measures for Animal Encounters

A. Minimize contact with animal saliva, dander, urine, and feces.[1365–1367] ***Category II***
B. Practice hand hygiene after any animal contact.[2, 1364] ***Category IB***
    1. Wash hands with soap and water, especially if hands are visibly soiled.[1364] ***Category IB***
    2. Use either soap and water or alcohol-based hand rubs when hands are not visibly soiled.[1364] ***Category IB***

H.II. Animal-Assisted Activities, Animal-Assisted Therapy, and Resident Animal Programs

A. Avoid selection of nonhuman primates and reptiles in animal-assisted activities, animal- assisted therapy, or resident animal programs.[1360–1362] ***Category IB***
B. Enroll animals that are fully vaccinated for zoonotic diseases and that are healthy, clean, well-groomed, and negative for enteric parasites or otherwise have completed recent antihelminthic treatment under the regular care of a veterinarian.[1349, 1360] ***Category II***
C. Enroll animals that are trained with the assistance or under the direction of individuals who are experienced in this field.[1360] ***Category II***
D. Ensure that animals are handled by persons trained in providing activities or therapies safely, and who know the animals' health status and behavior traits.[1349, 1360] ***Category II***
E. Take prompt action when an incident of biting or scratching by an animal occurs during an animal-assisted activity or therapy.
    1. Remove the animal permanently from these programs.[1360] ***Category II***
    2. Report the incident promptly to appropriate authorities (e.g., infection-control staff, animal program coordinator, or local animal control).[1360] ***Category II***
    3. Promptly clean and treat scratches, bites, or other accidental breaks in the skin. ***Category II***
F. Perform an ICRA and work actively with the animal handler prior to conducting an animal-assisted activity or therapy to determine if the session should be held in a public area of the facility or in individual patient rooms. [1349, 1360] ***Category II***
G. Take precautions to mitigate allergic responses to animals. ***Category II***
    1. Minimize shedding of animal dander by bathing animals <24 hours before a visit.[1360] ***Category II***
    2. Groom animals to remove loose hair before a visit, or using a therapy animal cape.[1358] ***Category II***
H. Use routine cleaning protocols for housekeeping surfaces after therapy sessions. ***Category II***
I. Restrict resident animals, including fish in fish tanks, from access to or placement in patient-care areas, food preparation areas, dining areas, laundry, central sterile supply areas, sterile and clean supply storage areas, medication preparation areas, operating rooms, isolation areas, and PE areas. ***Category II***
J. Establish a facility policy for regular cleaning of fish tanks, rodent cages, bird cages, and any other animal dwellings and assign this cleaning task to a nonpatient-care staff member; avoid splashing tank water or contaminating environmental surfaces with animal bedding. ***Category II***

H.III. Protective Measures for Immunocompromised Patients

A. Advise patients to avoid contact with animal feces and body fluids such as saliva, urine, or solid litter box material.[8] ***Category II***
B. Promptly clean and treat scratches, bites, or other wounds that break the skin.[8] ***Category II***
C. Advise patients to avoid direct or indirect contact with reptiles.[1340] ***Category IB***
D. Conduct a case-by-case assessment to determine if animal-assisted activities or animal-assisted therapy programs are appropriate for immunocompromised patients.[1349] ***Category II***
E. **No recommendation is offered** regarding permitting pet visits to terminally ill immunosuppressed patients outside their PE units. ***Unresolved issue***

H.IV. Service Animals

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Avoid providing access to nonhuman primates and reptiles as service animals.[1340, 1362] ***Category IB***
B. Allow service animals access to the facility in accordance with the Americans with Disabilities Act of 1990, unless the presence of the animal creates a direct threat to other persons or a fundamental alteration in the nature of services.[1366, 1376] ***Category IC*** (U.S. Department of Justice: 28 CFR § 36.302)
C. When a decision must be made regarding a service animal's access to any particular area of the health-care facility, evaluate the service animal, the patient, and the health-care situation on a case-

by-case basis to determine whether significant risk of harm exists and whether reasonable modifications in policies and procedures will mitigate this risk.[1376] ***Category IC*** (Justice: 28 CFR § 36.208 and App.B)

D. If a patient must be separated from his or her service animal while in the health-care facility
   - * ascertain from the person what arrangements have been made for supervision or care of the animal during this period of separation; and
   - * make appropriate arrangements to address the patient's needs in the absence of the service animal. ***Category II***

H.V. Animals as Patients in Human Health-Care Facilities

A. Develop health-care facility policies to address the treatment of animals in human healthcare facilities.
   1. Use the multidisciplinary team approach to policy development, including public media relations in order to disclose and discuss these activities. ***Category II***
   2. Exhaust all veterinary facility, equipment, and instrument options before undertaking the procedure. ***Category II***
   3. Ensure that the care of the animal is supervised by a licensed veterinarian. ***Category II***

B. When animals are treated in human health-care facilities, avoid treating animals in operating rooms or other patient-care areas where invasive procedures are performed (e.g., cardiac catheterization laboratories, or invasive nuclear medicine areas). ***Category II***

C. Schedule the animal procedure for the last case of the day for the area, at a time when human patients are not scheduled to be in the vicinity. ***Category II***

D. Adhere strictly to standard precautions. ***Category II***

E. Clean and disinfect environmental surfaces thoroughly using an EPA-registered product in the room after the animal is removed. ***Category II***

F. Allow sufficient ACH to clean the air and help remove airborne dander, microorganisms, and allergens [Appendix B, Table B.1.]). ***Category II***

G. Clean and disinfect using EPA-registered products or sterilize equipment that has been in contact with animals, or use disposable equipment. ***Category II***

H. If reusable medical or surgical instruments are used in an animal procedure, restrict future use of these instruments to animals only. ***Category II***

H.VI. Research Animals in Health-Care Facilities

A. Use animals obtained from quality stock, or quarantine incoming animals to detect zoonotic diseases. ***Category II***

B. Treat sick animals or remove them from the facility. ***Category II***

C. Provide prophylactic vaccinations, as available, to animal handlers and contacts at high risk. ***Category II***

D. Ensure proper ventilation through appropriate facility design and location.[1395] ***Category IC*** (U.S. Department of Agriculture [USDA]: 7 USC 2131)
   1. Keep animal rooms at negative pressure relative to corridors.[1395] ***Category IC*** (USDA: 7 USC 2131)
   2. Prevent air in animal rooms from recirculating elsewhere in the health-care facility.[1395] ***Category IC*** (USDA: 7 USC 2131)

E. Keep doors to animal research rooms closed. ***Category II***

F. Restrict access to animal facilities to essential personnel. ***Category II***

G. Establish employee occupational health programs specific to the animal research facility, and coordinate management of postexposure procedures specific for zoonoses with occupational health clinics in the health-care facility.[1013, 1378] ***Category IC*** (U.S. Department of Health and Human Services [DHHS]: BMBL; OSHA: 29 CFR 1910.1030.132-139)

H. Document standard operating procedures for the unit.[1013] ***Category IC*** (DHHS: BMBL)

I. Conduct routine employee training on worker safety issues relevant to the animal research facility (e.g., working safely with animals and animal handling).[1013, 1393] ***Category IC*** (DHHS: BMBL; OSHA: 29 CFR 1910.1030.132-139)

J. Use precautions to prevent the development of animal-induced asthma in animal workers.[1013] ***Category IC*** (DHHS: BMBL)

I. Recommendations—Regulated Medical Waste

I.I. Categories of Regulated Medical Waste

⚠ **Edit [February 2017]:** An * indicates recommendations that were renumbered for clarity. The renumbering does not constitute change to the intent of the recommendations.

A. Designate the following as major categories of medical waste that require special handling and disposal precautions:
- * microbiology laboratory wastes [e.g., cultures and stocks of microorganisms];
- * bulk blood, blood products, blood, and bloody body fluid specimens;
- * pathology and anatomy waste; and
- * sharps [e.g., needles and scalpels].[2] ***Category II***

B. Consult federal, state, and local regulations to determine if other waste items are considered regulated medical wastes.[967, 1407, 1408] ***Category IC*** (States; Authorities having jurisdiction [AHJ]; OSHA: 29 CFR 1910.1030 §g.2.1; U.S. Department of Transportation [DOT]: 49 CFR 171-180; U.S. Postal Service: CO23.8)

I.II. Disposal Plan for Regulated Medical Wastes

A. Develop a plan for the collection, handling, predisposal treatment, and terminal disposal of regulated medical wastes.[967, 1409] ***Category IC*** (States; AHJ; OSHA: 29 CFR 1910.1030 §g.2.i;)

B. Designate a person or persons to be responsible for establishing, monitoring, reviewing, and administering the plan. ***Category II***

I.III. Handling, Transporting, and Storing Regulated Medical Wastes

A. Inform personnel involved in the handling and disposal of potentially infective waste of the possible health and safety hazards; ensure that they are trained in appropriate handling and disposal methods.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § g.2.i)

B. Manage the handling and disposal of regulated medical wastes generated in isolation areas by using the same methods as for regulated medical wastes from other patient-care areas.[2] ***Category II***

C. Use proper sharps disposal strategies.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iii.A)
1. Use a sharps container capable of maintaining its impermeability after waste treatment to avoid subsequent physical injuries during final disposal.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iii.A)
2. Place disposable syringes with needles, including sterile sharps that are being discarded, scalpel blades, and other sharp items into puncture-resistant containers located as close as practical to the point of use.[967] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.4.iii.A)
3. Do not bend, recap, or break used syringe needles before discarding them into a container.[6, 967, 1415] ***Category IC*** (OSHA: 29 CFR 1910.1030 § d.2.vii and § d.2.vii.A)

D. Store regulated medical wastes awaiting treatment in a properly ventilated area that is inaccessible to vertebrate pests; use waste containers that prevent the development of noxious odors. ***Category IC*** (States; AHJ)

E. If treatment options are not available at the site where the medical waste is generated, transport regulated medical wastes in closed, impervious containers to the on-site treatment location or to another facility for treatment as appropriate. ***Category IC*** (States; AHJ)

I.IV. Treatment and Disposal of Regulated Medical Wastes

A. Treat regulated medical wastes by using a method (e.g., steam sterilization, incineration, interment, or an alternative treatment technology) approved by the appropriate authority having jurisdiction (AHJ) (e.g., states, Indian Health Service [IHS], Veterans Affairs [VA]) before disposal in a sanitary landfill. ***Category IC*** (States, AHJ)

B. Follow precautions for treating microbiological wastes (e.g., amplified cultures and stocks of microorganisms).[1013] ***Category IC*** (DHHS: BMBL)
   1. Biosafety level 4 laboratories must inactivate microbiological wastes in the laboratory by using an approved inactivation method (e.g., autoclaving) before transport to and disposal in a sanitary landfill.[1013] ***Category IC*** (DHHS: BMBL)
   2. Biosafety level 3 laboratories must inactivate microbiological wastes in the laboratory by using an approved inactivation method (e.g., autoclaving) or incinerate them at the facility before transport to and disposal in a sanitary landfill.[1013] ***Category IC*** (DHHS: BMBL)

C. Biosafety levels 1 and 2 laboratories should develop strategies to inactivate amplified microbial cultures and stocks onsite by using an approved inactivation method (e.g., autoclaving) instead of packaging and shipping untreated wastes to an offsite facility for treatment and disposal.[1013, 1419–1421] ***Category II***

D. Laboratories that isolate select agents from clinical specimens must comply with federal regulations for the receipt, transfer, management, and appropriate disposal of these agents.[1412] ***Category IC*** (DHHS: 42 CFR 73 § 73.6)

E. Sanitary sewers may be used for the safe disposal of blood, suctioned fluids, ground tissues, excretions, and secretions, provided that local sewage discharge requirements are met and that the state has declared this to be an acceptable method of disposal.[1414] ***Category II***

I.V. Special Precautions for Wastes Generated During Care of Patients with Rare Diseases

A. When discarding items contaminated with blood and body fluids from VHF patients, contain these regulated medical wastes with minimal agitation during handling.[6, 203] ***Category II***

B. Manage properly contained wastes from areas providing care to VHF patients in accordance with recommendations for other isolation areas (Regulated Medical Waste: III B).[2, 6, 203] ***Category II***

C. Decontaminate bulk blood and body fluids from VHF patients using approved inactivation methods (e.g., autoclaving or chemical treatment) before disposal.[6, 203] ***Category IC, II*** (States; AHJ)

D. When discarding regulated medical waste generated during the routine (i.e., non-surgical) care of CJD patients, contain these wastes and decontaminate them using approved inactivation methods (e.g., autoclaving or incineration) appropriate for the medical waste category (e.g., blood, sharps, pathological waste).[2, 6, 948, 1199] ***Category IC, II*** (States; AHJ)

E. Incinerate medical wastes (e.g., central nervous system tissues or contaminated disposable materials) from brain autopsy or biopsy procedures of diagnosed or suspected CJD patients.[1197, 1201] ***Category IB***

Part IV. Appendices

Appendix A. Glossary of Terms

Acceptable indoor air quality: air in which there are no known contaminants at harmful concentrations as determined by knowledgeble authorities and with which a substantial majority (≥80%) of the people exposed do not express dissatisfaction.
ACGIH: American Conference of Governmental Industrial Hygienists.
Action level: the concentration of a contaminant at which steps should be taken to interrupt the trend toward higher, unacceptable levels.
Aerosol: particles of respirable size generated by both humans and environmental sources and that have the capability of remaining viable and airborne for extended periods in the indoor environment.
AIA: American Institute of Architects, a professional group responsible for publishing the *Guidelines for Design and Construction of Hospitals and Healthcare Facilities*, a consensus document for design and construction of health-care facilities endorsed by the U.S. Department of Health and Human Services, health-care professionals, and professional organizations.
Air changes per hour (ACH): the ratio of the volume of air flowing through a space in a certain period of time (the airflow rate) to the volume of that space (the room volume). This ratio is expressed as the number of air changes per hour (ACH).
Air mixing: the degree to which air supplied to a room mixes with the air already in the room, usually expressed as a mixing factor. This factor varies from 1 (for perfect mixing) to 10 (for poor mixing). It is used as a multiplier to determine the actual airflow required (i.e., the recommended ACH multiplied by the mixing factor equals the actual ACH required).
Airborne transmission: a means of spreading infection when airborne droplet nuclei (small particle residue of evaporated droplets ≤5 μm in size containing microorganisms that remain suspended in air for long periods of time) are inhaled by the susceptible host.
Air-cleaning system: a device or combination of devices applied to reduce the concentration of airborne contaminants (e.g., microorganisms, dusts, fumes, aerosols, other particulate matter, and gases).
Air conditioning: the process of treating air to meet the requirements of a conditioned space by controlling its temperature, humidity, cleanliness, and distribution.
Allogeneic: non-twin, non-self. The term refers to transplanted tissue from a donor closely matched to a recipient but not related to that person.
Ambient air: the air surrounding an object.
Anemometer: a flow meter which measures the wind force and velocity of air. An anemometer is often used as a means of determining the volume of air being drawn into an air sampler.
Anteroom: a small room leading from a corridor into an isolation room. This room can act as an airlock, preventing the escape of contaminants from the isolation room into the corridor.
ASHE: American Society for Healthcare Engineering, an association affiliated with the American Hospital Association.
ASHRAE: American Society of Heating, Refrigerating, and Air-Conditioning Engineers Inc.
Autologous self: The term refers to transplanted tissue whose source is the same as the recipient, or an identical twin.
Automated cycler: a machine used during peritoneal dialysis which pumps fluid into and out of the patient while he/she sleeps.
Biochemical oxygen demand (BOD): a measure of the amount of oxygen removed from aquatic environments by aerobic microorganisms for their metabolic requirements. Measurement of BOD is used to determine the level of organic pollution of a stream or lake. The greater the BOD, the greater the degree of water pollution. The term is also referred to as Biological Oxygen Demand (BOD).
Biological oxygen demand (BOD): an indirect measure of the concentration of biologically degradable material present in organic wastes (pertaining to water quality). It usually reflects the amount of oxygen consumed in five days by biological processes breaking down organic waste (BOD5).
Biosafety level: a combination of microbiological practices, laboratory facilities, and safety equipment determined to be sufficient to reduce or prevent occupational exposures of laboratory personnel to the

microbiological agents they work with. There are four biosafety levels based on the hazards associated with the various microbiological agents.
BOD5: the amount of dissolved oxygen consumed in five days by biological processes breaking down organic matter.
Bonneting: a floor cleaning method for either carpeted or hard surface floors that uses a circular motion of a large fibrous disc to lift and remove soil and dust from the surface.
Capped spur: a pipe leading from the water recirculating system to an outlet that has been closed off ("capped"). A capped spur cannot be flushed, and it might not be noticed unless the surrounding wall is removed.
CFU/m^3: colony forming units per cubic meter (of air).
Chlamydospores: thick-walled, typically spherical or ovoid resting spores asexually produced by certain types of fungi from cells of the somatic hyphae.
Chloramines: compounds containing nitrogen, hydrogen, and chlorine. These are formed by the reaction between hypochlorous acid (HOCl) and ammonia (NH3) and/or organic amines in water. The formation of chloramines in drinking water treatment extends the disinfecting power of chlorine. The term is also referred to as Combined Available Chlorine.
Cleaning: the removal of visible soil and organic contamination from a device or surface, using either the physical action of scrubbing with a surfactant or detergent and water, or an energy-based process (e.g., ultrasonic cleaners) with appropriate chemical agents.
Coagulation-flocculation: coagulation is the clumping of particles that results in the settling of impurities. It may be induced by coagulants (e.g., lime, alum, and iron salts). Flocculation in water and wastewater treatment is the agglomeration or clustering of colloidal and finely-divided suspended matter after coagulation by gentle stirring by either mechanical or hydraulic means, such that they can be separated from water or sewage.
Commissioning (a room): testing a system or device to ensure that it meets the pre-use specifications as indicated by the manufacturer or predetermined standard, or air sampling in a room to establish a preoccupancy baseline standard of microbial or particulate contamination. The term is also referred to as benchmarking at 77°F (25°C).
Completely packaged: functionally packaged, as for laundry.
Conidia: asexual spores of fungi borne externally.
Conidiophores: specialized hyphae that bear conidia in fungi.
Conditioned space: that part of a building that is heated or cooled, or both, for the comfort of the occupants.
Contaminant: an unwanted airborne constituent that may reduce the acceptibility of air.
Convection: the transfer of heat or other atmospheric properties within the atmosphere or in the airspace of an enclosure by the circulation of currents from one region to another, especially by such motion directed upward.
Cooling tower: a structure engineered to receive accumulated heat from ventilation systems and equipment and transfer this heat to water, which then releases the stored heat to the atmosphere through evaporative cooling.
Critical item (medical instrument): a medical instrument or device that contacts normally sterile areas of the body or enters the vascular system. There is a high risk of infection from such devices if they are microbiologically contaminated prior to use. These devices must be sterilized before use.
Dead legs: areas in the water system where water stagnates. A dead leg is a pipe or spur, leading from the water recirculating system to an outlet that is used infrequently, resulting in inadequate flow of water from the recirculating system to the outlet. This inadequate flow reduces the perfusion of heat or chlorine into this part of the water distribution system, thereby adversely affecting the disinfection of the water system in that area.
Deionization: removal of ions from water by exchange with other ions associated with fixed charges on a resin bed. Cations are usually removed and H^+ ions are exchanged; OH^- ions are exchanged for anions.
Detritis: particulate matter produced by or remaining after the wearing away or disintegration of a substance or tissue.
Dew point: the temperature at which a gas or vapor condenses to form a liquid; the point at which moisture begins to condense out of the air. At dew point, air is cooled to the point where it is at 100% relative humidity or saturation.

Dialysate: the aqueous electrolyte solution, usually containing dextrose, used to make a concentration gradient between the solution and blood in the hemodialyzer (dialyzer).
Dialyzer: a device that consists of two compartments (blood and dialysate) separated by a semipermeable membrane. A dialyzer is usually referred to as an artificial kidney.
Diffuser: the grille plate that disperses the air stream coming into the conditioned air space.
Direct transmission: involves direct body surface-to-body surface contact and physical transfer of microorganisms between a susceptible host and an infected/colonized person, or exposure to cloud of infectious particles within 3 feet of the source; the aerosolized particles are >5 μm in size.
Disability: as defined by the Americans with Disabilities Act, a disability is any physical or mental impairment that substantially limits one or more major life activities, including but not limited to walking, talking, seeing, breathing, hearing, or caring for oneself.
Disinfection: a generally less lethal process of microbial inactivation (compared to sterilization) that eliminates virtually all recognized pathogenic microorganisms but not necessarily all microbial forms (e.g., bacterial spores).
Drain pans: pans that collect water within the HVAC system and remove it from the system. Condensation results when air and steam come together.
Drift: circulating water lost from the cooling tower in the form as liquid droplets entrained in the exhaust air stream (i.e., exhaust aerosols from a cooling tower).
Drift eliminators: an assembly of baffles or labyrinth passages through which the air passes prior to its exit from the cooling tower. The purpose of a drift eliminator is to remove entrained water droplets from the exhaust air.
Droplets: particles of moisture, such as are generated when a person coughs or sneezes, or when water is converted to a fine mist by a device such as an aerator or shower head. These particles may contain infectious microorganisms. Intermediate in size between drops and droplet nuclei, these particles tend to quickly settle out from the air so that any risk of disease transmission is generally limited to persons in close proximity to the droplet source.
Droplet nuclei: sufficiently small particles (1–5 μm in diameter) that can remain airborne indefinitely and cause infection when a susceptible person is exposed at or beyond 3 feet of the source of these particles.
Dual duct system: an HVAC system that consists of parallel ducts that produce a cold air stream in one and a hot air stream in the other.
Dust: an air suspension of particles (aerosol) of any solid material, usually with particle sizes ≤100 μm in diameter.
Dust-spot test: a procedure that uses atmospheric air or a defined dust to measure a filter's ability to remove particles. A photometer is used to measure air samples on either side of the filter, and the difference is expressed as a percentage of particles removed.
Effective leakage area: the area through which air can enter or leave the room. This does not include supply, return, or exhaust ducts. The smaller the effective leakage area, the better isolated the room.
Endotoxin: the lipopolysaccharides of gram-negative bacteria, the toxic character of which resides in the lipid portion. Endotoxins generally produce pyrogenic reactions in persons exposed to these bacterial components.
Enveloped virus: a virus whose outer surface is derived from a membrane of the host cell (either nuclear or the cell's outer membrane) during the budding phase of the maturation process. This membrane-derived material contains lipid, a component that makes these viruses sensitive to the action of chemical germicides.
Evaporative condenser: a wet-type, heat-rejection unit that produces large volumes of aerosols during the process of removing heat from conditioned space air.
Exhaust air: air removed from a space and not reused therein.
Exposure: the condition of being subjected to something (e.g., infectious agents) that could have a harmful effect.
Fastidious: having complex nutritional requirements for growth, as in microorganisms.
Fill: that portion of a cooling tower which makes up its primary heat transfer surface. Fill is alternatively known as "packing."
Finished water: treated, or potable water.
Fixed room-air HEPA recirculation systems: nonmobile devices or systems that remove airborne contaminants by recirculating air through a HEPA filter. These may be built into the room and permanently

ducted or may be mounted to the wall or ceiling within the room. In either situation, they are fixed in place and are not easily movable.
Fomite: an inanimate object that may be contaminated with microorganisms and serves in their transmission.
Free and available chlorine: the term applied to the three forms of chlorine that may be found in solution (i.e., chlorine [Cl2], hypochlorite [OCl^-], and hypochlorous acid [HOCl]).
Germicide: a chemical that destroys microorganisms. Germicides may be used to inactivate microorganisms in or on living tissue (antiseptics) or on environmental surfaces (disinfectants).
Health-care associated: an outcome, usually an infection, that occurs in any health-care facility as a result of medical care. The term "health-care associated" replaces "nosocomial," the latter term being limited to adverse infectious outcomes occurring only in hospitals.
Hemodiafiltration: a form of renal replacement therapy in which waste solutes in the patient's blood are removed by both diffusion and convection through a high-flux membrane.
Hemodialysis: a treatment for renal replacement therapy in which waste solutes in the patient's blood are removed by diffusion and/or convection through the semipermeable membrane of an artificial kidney or dialyzer.
Hemofiltration: cleansing of waste products or other toxins from the blood by convection across a semipermeable, high-flux membrane where fluid balance is maintained by infusion of sterile, pyrogenfree substitution fluid pre- or post-hemodialyzer.
HEPA filter: High Efficiency Particulate Air filters capable of removing 99.97% of particles 0.3 μm in diameter and may assist in controlling the transmission of airborne disease agents. These filters may be used in ventilation systems to remove particles from the air or in personal respirators to filter air before it is inhaled by the person wearing the respirator. The use of HEPA filters in ventilation systems requires expertise in installation and maintenance. To test this type of filter, 0.3 μm particles of dioctylphthalate (DOP) are drawn through the filter. Efficiency is calculated by comparing the downstream and upstream particle counts. The optimal HEPA filter allows only three particles to pass through for every 10,000 particles that are fed to the filter.
Heterotrophic (heterotroph): that which requires some nutrient components from exogenous sources. Heterotrophic bacteria cannot synthesize all of their metabolites and therefore require certain nutrients from other sources.
High-efficiency filter: a filter with a particle-removal efficiency of 90%–95%.
High flux: a type of dialyzer or hemodialysis treatment in which large molecules (>8,000 daltons [e.g., β2 microglobulin]) are removed from blood.
High-level disinfection: a disinfection process that inactivates vegetative bacteria, mycobacteria, fungi, and viruses, but not necessarily high numbers of bacterial spores.
Housekeeping surfaces: environmental surfaces (e.g., floors, walls, ceilings, and tabletops) that are not involved in direct delivery of patient care in health-care facilities.
Hoyer lift: an apparatus that facilitates the repositioning of the non-ambulatory patient from bed to wheelchair or gurney and subsequently to therapy equipment (immersion tanks).
Hubbard tank: a tank used in hydrotherapy that may accomodate whole-body immersion (e.g., as may be indicated for burn therapy). Use of a Hubbard tank has been replaced largely by bedside post-lavage therapy for wound care management.
HVAC: Heating, Ventilation, Air Conditioning.
Iatrogenic: induced in a patient by a physician's activity, manner, or therapy. The term is used especially in reference to an infectious complication or other adverse outcome of medical treatment.
Impactor: an air-sampling device in which particles and microorganisms are directed onto a solid surface and retained there for assay.
Impingement: an air-sampling method during which particles and microorganisms are directed into a liquid and retained there for assay.
Indirect transmission: involves contact of a susceptible host with a contaminated intermediate object, usually inanimate (a fomite).
Induction unit: the terminal unit of an in-room ventilation system. Induction units take centrally conditioned air and further moderate its temperature. Induction units are not appropriate for areas with high exhaust requirements (e.g., research laboratories).

Intermediate-level disinfection: a disinfection process that inactivates vegetative bacteria, most fungi, mycobacteria, and most viruses (particularly the enveloped viruses), but does not inactivate bacterial spores.
Isoform: a possible configuration (tertiary structure) of a protein molecule. With respect to prion proteins, the molecules with large amounts of α-conformation are the normal isoform of that particular protein, whereas those prions with large amounts of β-sheet conformation are the proteins associated with the development of spongiform encephalopathy (e.g., Creutzfeldt-Jakob disease [CJD]).
Laminar flow: HEPA-filtered air that is blown into a room at a rate of 90 ± 10 feet/min in a unidirectional pattern with 100 ACH–400 ACH.
Large enveloped virus: viruses whose particle diameter is >50 nm and whose outer surface is covered by a lipid-containing structure derived from the membranes of the host cells. Examples of large enveloped viruses include influenza viruses, herpes simplex viruses, and poxviruses.
Laser plume: the transfer of electromagnetic energy into tissues which results in a release of particles, gases, and tissue debris.
Lipid-containing viruses: viruses whose particle contains lipid components. The term is generally synonymous with enveloped viruses whose outer surface is derived from host cell membranes. Lipid-containing viruses are sensitive to the inactivating effects of liquid chemical germicides.
Lithotriptors: instruments used for crushing caliculi (i.e., calcified stones, and sand) in the bladder or kidneys.
Low efficiency filter: the prefilter with a particle-removal efficiency of approximately 30% through which incoming air first passes. See also Prefilter.
Low-level disinfection: a disinfection process that will inactivate most vegetative bacteria, some fungi, and some viruses, but cannot be relied upon to inactivate resistant microorganisms (e.g., mycobacteria or bacterial spores).
Makeup air: outdoor air supplied to the ventilation system to replace exhaust air.
Makeup water: a cold water supply source for a cooling tower.
Manometer: a device that measures the pressure of liquids and gases. A manometer is used to verify air filter performance by measuring pressure differentials on either side of the filter.
Membrane filtration: an assay method suitable for recovery and enumeration of microorganisms from liquid samples. This method is used when sample volume is large and anticipated microbial contamination levels are low.
Mesophilic: that which favors a moderate temperature. For mesophilic bacteria, a temperature range of 68°F–131°F (20°C–55°C) is favorable for their growth and proliferation.
Mixing box: the site where the cold and hot air streams mix in the HVAC system, usually situated close to the air outlet for the room.
Mixing faucet: a faucet that mixes hot and cold water to produce water at a desired temperature.
MMAD: Mass Median Aerodynamic Diameter. This is the unit used by ACGIH to describe the size of particles when particulate air sampling is conducted.
Moniliaceous: hyaline or brightly colored. This is a laboratory term for the distinctive characteristics of certain opportunistic fungi in culture (e.g., *Aspergillus* spp. and *Fusarium* spp.).
Monochloramine: the result of the reaction between chlorine and ammonia that contains only one chlorine atom. Monochloramine is used by municipal water systems as a water treatment.
Natural ventilation: the movement of outdoor air into a space through intentionally provided openings (i.e., windows, doors, or nonpowered ventilators).
Negative pressure: air pressure differential between two adjacent airspaces such that air flow is directed into the room relative to the corridor ventilation (i.e., room air is prevented from flowing out of the room and into adjacent areas).
Neutropenia: a medical condition in which the patient's concentration of neutrophils is substantially less than that in the normal range. Severe neutropenia occurs when the concentration is <1,000 polymorphonuclear cells/μL for 2 weeks or <100 polymorphonuclear cells /mL for 1 week, particularly for hematopoietic stem cell transplant (HSCT) recipients.
Noncritical devices: medical devices or surfaces that come into contact with only intact skin. The risk of infection from use of these devices is low.

Non-enveloped virus: a virus whose particle is not covered by a structure derived from a membrane of the host cell. Non-enveloped viruses have little or no lipid compounds in their biochemical composition, a characteristic that is significant to their inherent resistance to the action of chemical germicides.
Nosocomial: an occurrence, usually an infection, that is acquired in a hospital as a result of medical care.
NTM: nontuberculous mycobacteria. These organisms are also known as atypical mycobacteria, or as "Mycobacteria other than tuberculosis" (MOTT). This descriptive term refers to any of the fast- or slow-growing *Mycobacterium* spp. found in primarily in natural or man-made waters, but it excludes *Mycobacterium tuberculosis* and its variants.
Nuisance dust: generally innocuous dust, not recognized as the direct cause of serious pathological conditions.
Oocysts: a cyst in which sporozoites are formed; a reproductive aspect of the life cycle of a number of parasitic agents (e.g., *Cryptosporidium* spp., and *Cyclospora* spp.).
Outdoor air: air taken from the external atmosphere and, therefore, not previously circulated through the ventilation system.
Parallel streamlines: a unidirectional airflow pattern achieved in a laminar flow setting, characterized by little or no mixing of air.
Particulate matter (particles): a state of matter in which solid or liquid substances exist in the form of aggregated molecules or particles. Airborne particulate matter is typically in the size range of 0.01–100 μm diameter.
Pasteurization: a disinfecting method for liquids during which the liquids are heated to 140°F (60°C) for a short time (≥30 mins.) to significantly reduce the numbers of pathogenic or spoilage microorganisms.
Plinth: a treatment table or a piece of equipment used to reposition the patient for treatment.
Portable room-air HEPA recirculation units: free-standing portable devices that remove airborne contaminants by recirculating air through a HEPA filter.
Positive pressure: air pressure differential between two adjacent air spaces such that air flow is directed from the room relative to the corridor ventilation (i.e., air from corridors and adjacent areas is prevented from entering the room).
Potable (drinking) water: water that is fit to drink. The microbiological quality of this water as defined by EPA microbiological standards from the Surface Water Treatment Rule:
a. *Giardia lamblia*: 99.9% killed/inactivated
b. viruses: 99.9% inactivated;
c. *Legionella* spp.: no limit, but if *Giardia* and viruses are inactivated, *Legionella* will also be controlled;
d. heterotrophic plate count [HPC]: ≤500 CFU/mL; and
e. >5% of water samples total coliform-positive in a month.
PPE: Personal Protective Equipment.
ppm: parts per million. The term is a measure of concentration in solution. Chlorine bleaches (undiluted) that are available in the U.S. (5.25%–6.15% sodium hypochlorite) contain approximately 50,000–61,500 parts per million of free and available chlorine.
Prefilter: the first filter for incoming fresh air in a HVAC system. This filter is approximately 30% efficient in removing particles from the air. See also Low-Efficiency Filter.
Prion: a class of agent associated with the transmission of diseases knowns as transmissible spongiform encephalopathies (TSEs). Prions are considered to consist of protein only, and the abnormal isoform of this protein is thought to be the agent that causes diseases such as Creutzfeldt-Jakob disease (CJD), kuru, scrapie, bovine spongiform encephalopathy (BSE), and the human version of BSE which is variant CJD (vCJD).
Product water: water produced by a water treatment system or individual component of that system.
Protective environment: a special care area, usually in a hospital, designed to prevent transmission of opportunistic airborne pathogens to severely immunosuppressed patients.
Pseudoepidemic (pseudo-outbreak): a cluster of positive microbiologic cultures in the absence of clinical disease. A pseudoepidemic usually results from contamination of the laboratory apparatus and process used to recover microorganisms.
Pyrogenic: an endotoxin burden such that a patient would receive ≥5 endotoxin units (EU) per kilogram of body weight per hour, thereby causing a febrile response. In dialysis this usually refers to water or dialysate having endotoxin concentrations of ≥5 EU/mL.

Rank order: a strategy for assessing overall indoor air quality and filter performance by comparing airborne particle counts from lowest to highest (i.e., from the best filtered air spaces to those with the least filtration).
RAPD: a method of genotyping microorganisms by randomly amplified polymorphic DNA. This is one version of the polymerase chain reaction method.
Recirculated air: air removed from the conditioned space and intended for reuse as supply air.
Relative humidity: the ratio of the amount of water vapor in the atmosphere to the amount necessary for saturation at the same temperature. Relative humidity is expressed in terms of percent and measures the percentage of saturation. At 100% relative humidity, the air is saturated. The relative humidity decreases when the temperature is increased without changing the amount of moisture in the air.
Reprocessing (of medical instruments): the procedures or steps taken to make a medical instrument safe for use on the next patient. Reprocessing encompasses both cleaning and the final or terminal step (i.e., sterilization or disinfection) which is determined by the intended use of the instrument according to the Spaulding classification.
Residuals: the presence and concentration of a chemical in media (e.g., water) or on a surface after the chemical has been added.
Reservoir: a nonclinical source of infection.
Respirable particles: those particles that penetrate into and are deposited in the nonciliated portion of the lung. Particles >10 μm in diameter are not respirable.
Return air: air removed from a space to be then recirculated.
Reverse osmosis (RO): an advanced method of water or wastewater treatment that relies on a semipermeable membrane to separate waters from pollutants. An external force is used to reverse the normal osmotic process resulting in the solvent moving from a solution of higher concentration to one of lower concentration.
Riser: water piping that connects the circulating water supply line, from the level of the base of the tower or supply header, to the tower's distribution system.
RODAC: Replicate Organism Direct Agar Contact. This term refers to a nutrient agar plate whose convex agar surface is directly pressed onto an environmental surface for the purpose of microbiologic sampling of that surface.
Room-air HEPA recirculation systems and units: devices (either fixed or portable) that remove airborne contaminants by recirculating air through a HEPA filter.
Routine sampling: environmental sampling conducted without a specific, intended purpose and with no action plan dependent on the results obtained.
Sanitizer: an agent that reduces microbial contamination to safe levels as judged by public health standards or requirements.
Saprophytic: a naturally-occurring microbial contaminant.
Sedimentation: the act or process of depositing sediment from suspension in water. The term also refers to the process whereby solids settle out of wastewater by gravity during treatment.
Semicritical devices: medical devices that come into contact with mucous membranes or non-intact skin.
Service animal: any animal individually trained to do work or perform tasks for the benefit of a person with a disability.
Shedding: the generation and dispersion of particles and spores by sources within the patient area, through activities such as patient movement and airflow over surfaces.
Single-pass ventilation: ventilation in which 100% of the air supplied to an area is exhausted to the outside.
Small, non-enveloped viruses: viruses whose particle diameter is <50 nm and whose outer surface is the protein of the particle itself and not that of host cell membrane components. Examples of small, non-enveloped viruses are polioviruses and hepatitis A virus.
Spaulding Classification: the categorization of inanimate medical device surfaces in the medical environment as proposed in 1972 by Dr. Earle Spaulding. Surfaces are divided into three general categories, based on the theoretical risk of infection if the surfaces are contaminated at time of use. The categories are "critical," "semicritical," and "noncritical."
Specific humidity: the mass of water vapor per unit mass of moist air. It is expressed as grains of water per pound of dry air, or pounds of water per pound of dry air. The specific humidity changes as moisture is added or removed. However, temperature changes do not change the specific humidity unless the air is cooled below the dew point.

Splatter: visible drops of liquid or body fluid that are expelled forcibly into the air and settle out quickly, as distinguished from particles of an aerosol which remain airborne indefinitely.
Steady state: the usual state of an area.
Sterilization: the use of a physical or chemical procedure to destroy all microbial life, including large numbers of highly-resistant bacterial endospores.
Stop valve: a valve that regulates the flow of fluid through a pipe. The term may also refer to a faucet.
Substitution fluid: fluid that is used for fluid management of patients receiving hemodiafiltration. This fluid can be prepared on-line at the machine through a series of ultrafilters or with the use of sterile peritoneal dialysis fluid.
Supply air: air that is delivered to the conditioned space and used for ventilation, heating, cooling, humidification, or dehumidification.
Tensile strength: the resistance of a material to a force tending to tear it apart, measured as the maximum tension the material can withstand without tearing.
Therapy animal: an animal (usually a personal pet) that, with their owners or handlers, provide supervised, goal-directed intervention to clients in hospitals, nursing homes, special-population schools, and other treatment sites.
Thermophilic: capable of growing in environments warmer than body temperature.
Thermotolerant: capable of withstanding high temperature conditions.
TLV®: an exposure level under which most people can work consistently for 8 hours a day, day after day, without adverse effects. The term is used by the ACGIH to designate degree of exposure to contaminants. TLV® can be expressed as approximate milligrams of particulate per cubic meter of air (mg/m^3). TLVs® are listed as either an 8-hour TWA (time weighted average) or a 15-minute STEL (short term exposure limit).
TLV-TWA: Threshold Limit Value-Time Weighted Average. The term refers to the time-weighted average concentration for a normal 8-hour workday and a 40-hour workweek to which nearly all workers may be exposed repeatedly, day after day, without adverse effects. The TLV-TWA for "particulates (insoluble) not otherwise classified" (PNOC) - (sometimes referred to as nuisance dust) - are those particulates containing no asbestos and <1% crystalline silica. A TLV-TWA of 10 mg/m^3 for inhalable particulates and a TLV-TWA of 3 mg/m^3 for respirable particulates (particulates ≤5 m in aerodynamic diameter) have been established.
Total suspended particulate matter: the mass of particles suspended in a unit of volume of air when collected by a high-volume air sampler.
Transient: a change in the condition of the steady state that takes a very short time compared with the steady state. Opening a door, and shaking bed linens are examples of transient activities.
TWA: average exposure for an individual over a given working period, as determined by sampling at given times during the period. TWA is usually presented as the average concentration over an 8-hour workday for a 40-hour workweek.
Ultraclean air: air in laminar flow ventilation that has also passed through a bank of HEPA filters.
Ultrafilter: a membrane filter with a pore size in the range of 0.001–0.05 μm, the performance of which is usually rated in terms of a nominal molecular weight cut-off (defined as the smallest molecular weight species for which the filter membrance has more than 90% rejection).
Ultrafiltered dialysate: the process by which dialysate is passed through a filter having a molecular weight cut-off of approximately 1 kilodalton for the purpose of removing bacteria and endotoxin from the bath.
Ultraviolet germicidal irradiation (UVGI): the use of ultraviolet radiation to kill or inactivate microorganisms.
Ultraviolet germicidal irradiation lamps: lamps that kill or inactivate microorganisms by emitting ultraviolet germicidal radiation, predominantly at a wavelength of 254 nm. UVGI lamps can be used in ceiling or wall fixtures or within air ducts of ventilation systems.
Vapor pressure: the pressure exerted by free molecules at the surface of a solid or liquid. Vapor pressure is a function of temperature, increasing as the temperature rises.
Vegetative bacteria: bacteria that are actively growing and metabolizing, as opposed to a bacterial state of quiescence that is achieved when certain bacteria (gram-positive bacilli) convert to spores when the environment can no longer support active growth.
Vehicle: any object, person, surface, fomite, or media that may carry and transfer infectious microorganisms from one site to another.

Ventilation: the process of supplying and removing air by natural or mechanical means to and from any space. Such air may or may not be conditioned.
Ventilation air: that portion of the supply air consisting of outdoor air plus any recirculated air that has been treated for the purpose of maintaining acceptable indoor air quality.
Ventilation, dilution: an engineering control technique to dilute and remove airborne contaminants by the flow of air into and out of an area. Air that contains droplet nuclei is removed and replaced by contaminant-free air. If the flow is sufficient, droplet nuclei become dispersed, and their concentration in the air is diminished.
Ventilation, local exhaust: ventilation used to capture and removed airborne contaminants by enclosing the contaminant source (the patient) or by placing an exhaust hood close to the contaminant source.
v/v: volume to volume. This term is an expression of concentration of a percentage solution when the principle component is added as a liquid to the diluent.
w/v: weight to volume. This term is an expression of concentration of a percentage solution when the principle component is added as a solid to the diluent.
Weight-arrestance: a measure of filter efficiency, used primarily when describing the performance of low- and medium-efficiency filters. The measurement of weight-arrestance is performed by feeding a standardized synthetic dust to the filter and weighing the fraction of the dust removed.

Appendix B. Air

1. Airborne Contaminant Removal

Table B.1. Air changes/hour (ACH) and time required for airborne-contaminant removal by efficiency *

ACH § ¶	Time (mins.) required for removal: 99% efficiency	Time (mins.) required for removal: 99.9% efficiency
2	138	207
4	69	104
6+	46	69
8	35	52
10+	28	41
12+	23	35
15+	18	28
20	14	21
50	6	8

* This table is revised from Table S3-1 in reference 4 and has been adapted from the formula for the rate of purging airborne contaminants presented in reference 1435.
\+ Denotes frequently cited ACH for patient-care areas.
§ Values were derived from the formula:

$$t_2 - t_1 = \frac{-\ln\left(C_2/C_1\right)}{\left(Q/V\right)} \times 60$$

where
t1 = initial timepoint in minutes
t2 = final timepoint in minutes
C1 = initial concentration of contaminant
C2 = final concentration of contaminant
C2 / C1 = 1 – (removal efficiency / 100)
Q = air flow rate in cubic feet/hour
V = room volume in cubic feet
Q / V = ACH

¶ Values apply to an empty room with no aerosol-generating source. With a person present and generating aerosol, this table would not apply. Other equations are available that include a constant generating source. However, certain diseases (e.g., infectious tuberculosis) are not likely to be aerosolized at a constant rate. The times given assume perfect mixing of the air within the space (i.e., mixing factor = 1). However, perfect mixing usually does not occur. Removal times will be longer in rooms or areas with imperfect mixing or air stagnation.[213] Caution should be exercised in using this table in such situations. For booths or other local ventilation enclosures, manufacturers' instructions should be consulted.

2. Air Sampling for Aerosols Containing Legionellae

Air sampling is an insensitive means of detecting *Legionella pneumophila,* and is of limited practical value in environmental sampling for this pathogen. In certain instances, however, it can be used to

a. demonstrate the presence of legionellae in aerosol droplets associated with suspected bacterial reservoirs
b. define the role of certain devices [e.g., showers, faucets, decorative fountains, or evaporate condensers] in disease transmission; and
c. quantitate and determine the size of the droplets containing legionellae.[1436] Stringent controls and calibration are necessary when sampling is used to determine particle size and numbers of viable bacteria.[1437] Samplers should be placed in locations where human exposure to aerosols is anticipated, and investigators should wear a NIOSH-approved respirator (e.g., N95 respirator) if sampling involves exposure to potentially infectious aerosols.

Methods used to sample air for legionellae include impingement in liquid, impaction on solid medium, and sedimentation using settle plates.[1436] The Chemical Corps.-type all-glass impingers (AGI) with the stem 30 mm from the bottom of the flask have been used successfully to sample for legionellae.[1436] Because of the velocity at which air samples are collected, clumps tend to become fragmented, leading to a more accurate count of bacteria present in the air. The disadvantages of this method are

a. the velocity of collection tends to destroy some vegetative cells
b. the method does not differentiate particle sizes; and
c. AGIs are easily broken in the field.

Yeast extract broth (0.25%) is the recommended liquid medium for AGI sampling of legionellae;[1437] standard methods for water samples can be used to culture these samples.

Andersen samplers are viable particle samplers in which particles pass through jet orifices of decreasing size in cascade fashion until they impact on an agar surface.[1218] The agar plates are then removed and incubated. The stage distribution of the legionellae should indicate the extent to which the bacteria would have penetrated the respiratory system. The advantages of this sampling method are

a. the equipment is more durable during use
b. the sampler can cetermine the number and size of droplets containing legionellae;
c. the agar plates can be placed directly in an incubator with no further manipulations; and
d. both selective and nonselective BCYE agar can be used. If the samples must be shipped to a laboratory, they should be packed and shipped without refrigeration as soon as possible.

3. Calculation of Air Sampling Results

Assuming that each colony on the agar plate is the growth from a single bacteria-carrying particle, the contamination of the air being sampled is determined from the number of colonies counted. The airborne microorganisms may be reported in terms of the number per cubic foot of air sampled. The following formulas can be applied to convert colony counts to organisms per cubic foot of air sampled.[1218]

For solid agar impactor samplers:

$C / (R\ H\ P) = N$ where N = number of organisms collected per cubic foot of air sampled
C = total plate count
R = airflow rate in cubic feet per minute
P = duration of sampling period in minutes

For liquid impingers:

$(C\ H\ V) / (Q\ H\ P\ H\ R) = N$ where C = total number of colonies from all aliquots plated
V = final volume in mL of collecting media
Q = total number of mL plated
P, R, and N are defined as above

4. Ventilation Specifications for Health-Care Facilities

The following tables from the AIA *Guidelines for Design and Construction of Hospitals and Health-Care Facilities, 2001* are reprinted with permission of the American Institute of Architects and the publisher (The Facilities Guidelines Institute).[120]

Note: This table is Table 7.2 in the AIA guidelines, 2001 edition. Superscripts used in this table refer to notes following the table.

Table B.2. Ventilation requirements for areas affecting patient care in hospitals and outpatient facilities[1]

Area designation	Air movement relationship to adjacent area[2]	Minimum air changes of outdoor air per hour[3]	Minimum total air change per hour [4,5]	All air exhausted directly to outdoors[6]	Recirculated by means of room units[7]	Relative humidity[8] (%)	Design temperature[9] (degrees F [C])
Surgery and critical care

Janitor’s closet	In	–	10	Yes	No	–	–

Notes:

1. The ventilation rates in this table cover ventilation for comfort, as well as for asepsis and odor control in areas of acute care hospitals that directly affect patient care and are determined based on health-care facilities being predominantly “No Smoking” facilities. Where smoking may be allowed, ventilation rates will need adjustment. Areas where specific ventilation rates are not given in the table shall be ventilated in accordance with ASHRAE Standard 62, *Ventilation for Acceptable Indoor Air Quality*, and ASHRAE *Handbook - HVAC Applications*. Specialized patient care areas, including organ transplant units, burn units, specialty procedure rooms, etc., shall have additional ventilation provisions for air quality control as may be appropriate. OSHA standards and/or NIOSH criteria require special ventilation requirements for employee health and safety within health-care facilities.
2. Design of the ventilation system shall provide air movement which is generally from clean to less clean areas. If any form of variable air volume or load shedding system is used for energy conservation, it must not compromise the corridor-to-room pressure balancing relationships or the minimum air changes required by the table.
3. To satisfy exhaust needs, replacement air from the outside is necessary. Table B2 does not attempt to describe specific amounts of outside air to be supplied to individual spaces except for certain areas such as those listed. Distribution of the outside air, added to the system to balance required exhaust, shall be as required by good engineering practice. Minimum outside air quantities shall remain constant while the system is in operation.
4. Number of air changes may be reduced when the room is unoccupied if provisions are made to ensure that the number of air changes indicated is reestablished any time the space is being utilized. Adjustments shall include provisions so that the direction of air movement shall remain the same when the number of air changes is reduced. Areas not indicated as having continuous directional control may have ventilation systems shut down when space is unoccupied and ventilation is not otherwise needed, if the maximum infiltration or exfiltration permitted in Note 2 is not exceeded and if adjacent pressure balancing relationships are not compromised. Air quantity calculations must account for filter loading such that the indicated air change rates are provided up until the time of filter change-out.
5. Air change requirements indicated are minimum values. Higher values should be used when required to maintain indicated room conditions (temperature and jumidity), based on the cooling load of the space (lights, equipment, people, exterior walls and windows, etc.).
6. Air from areas with contamination and/or odor problems shall be exhausted to the outside and not recirculated to other areas. Note that individual circumstances may require special consideration for air exhaust to the outside, (e.g., in intensive care units in which patients with pulmonary infection are treated) and rooms for burn patients.
7. Recirculating room HVAC units refer to those local units that are used primarily for heating and cooling of air, and not disinfection of air. Because of cleaning difficulty and potential for buildup of contamination, recirculating room units shall not be used in areas marked “No.” However, for airborne infection control, air may be recirculated within individual isolation rooms if HEPA filters are used. Isolation and intensive care unit rooms may be ventilated by reheat induction units in which only the primary air supplied from a central system passes through the reheat unit. Gravity-type heating or cooling units such as radiators or convectors shall not be used in operating rooms and other special care areas. See this table’s Appendix I for a description of recirculation units to be used in isolation rooms (A7).
8. The ranges listed are the minimum and maximum limits where control is specifically needed. The maximum and minimum limits are not intended to be independent of a space’s associated temperature. The humidity is expected to be at the higher end of the range when the temperature is also at the higher end, and vice versa.
9. Where temperature ranges are indicated, the systems shall be capable of maintaining the rooms at any point within the range during normal operation. A single figure indicates a heating or cooling capacity of at least the indicated temperature. This is usually applicable when patients may be undressed

and require a warmer environment. Nothing in these guidelines shall be construed as precluding the use of temperatures lower than those noted when the patients' comfort and medical conditions make lower temperatures desirable. Unoccupied areas such as storage rooms shall have temperatures appropriate for the function intended.

10. National Institute for Occupational Safety and Health (NIOSH) criteria documents regarding “Occupational Exposure to Waste Anesthetic Gases and Vapors,” and “Control of Occupational Exposure to Nitrous Oxide” indicate a need for both local exhaust (scavenging) systems and general ventilation of the areas in which the respective gases are utilized.
11. Differential pressure shall be a minimum of 0.01" water gauge (2.5 Pa). If alarms are installed, allowances shall be made to prevent nuisance alarms of monitoring devices.
12. Some surgeons may require room temperatures which are outside of the indicated range. All operating room design conditions shall be developed in consultation with surgeons, anesthesiologists, and nursing staff.
13. The term “trauma room” as used here is the operating room space in the emergency department or other trauma reception area that is used for emergency surgery. The “first aid room” and/or “emergency room” used for initial treatment of accident victims may be ventilated as noted for the “treatment room.” Treatment rooms used for bronchoscopy shall be treated as Bronchoscopy rooms. Treatment rooms used for cryosurgery procedures with nitrous oxide shall contain provisions for exhausting waste gases.
14. In a ventilation system that recirculates air, HEPA filters can be used in lieu of exhausting the air from these spaces to the outside. In this application, the return air shall be passed through the HEPA filters before it is introduced into any other spaces.
15. If it is not practical to exhaust the air from the airborne infection isolation room to the outside, the air may be returned through HEPA filters to the air-handling system exclusively serving the isolation room.
16. Total air changes per room for patient rooms, labor/delivery/recovery rooms, and labor/delivery/recovery/postpartum rooms may be reduced to 4 when supplemental heating and/or cooling systems (radiant heating and cooling, baseboard heating, etc.) are used.
17. The protective environment airflow design specifications protect the patient from common environmental airborne infectious microbes (i.e., *Aspergillus* spores). These special ventilation areas shall be designed to provide directed airflow from the cleanest patient care area to less clean areas. These rooms shall be protected with HEPA filters at 99.97 percent efficiency for a 0.3 μm sized particle in the supply airstream. These interrupting filters protect patient rooms from maintenance-derived release of environmental microbes from the ventilation system components. Recirculation HEPA filters can be used to increase the equivalent room air exchanges. Constant volume airflow is required for consistent ventilation for the protected environment. If the facility determines that airborne infection isolation is necessary for protective environment patients, an anteroom should be provided. Rooms with reversible airflow provisions for the purpose of switching between protective environment and airborne infection isolation functions are not acceptable.
18. The infectious disease isolation room described in these guidelines is to be used for isolating the airborne spread of infectious diseases, such as measles, varicella, or tuberculosis. The design of airborne infection isolation (AII) rooms should include the provision for normal patient care during periods not requiring isolation precautions. Supplemental recirculating devices may be used in the patient room to increase the equivalent room air exchanges; however, such recirculating devices do not provide the outside air requirements. Air may be recirculated within individual isolation rooms if HEPA filters are used. Rooms with reversible airflow provisions for the purpose of switching between protective environment and AII functions are not acceptable.
19. When required, appropriate hoods and exhaust devices for the removal of noxious gases or chemical vapors shall be provided (see Section 7.31.D14 and 7.31.D15 in the AIA guideline [reference 120] and NFPA 99).

20. Food preparation centers shall have ventilation systems whose air supply mechanisms are interfaced appropriately with exhaust hood controls or relief vents so that exfiltration or infiltration to or from exit corridors does not compromise the exit corridor restrictions of NFPA 90A, the pressure requirements of NFPA 96, or the maximum defined in the table. The number of air changes may be reduced or varied to any extent required for odor control when the space is not in use. See Section 7.31.D1.p in the AIA guideline (reference 120).

Appendix I:

A7. Recirculating devices with HEPA filters may have potential uses in existing facilities as interim, supplemental environmental controls to meet requirements for the control of airborne infectious agents. Limitations in design must be recognized. The design of either portable or fixed systems should prevent stagnation and short circuiting of airflow. The supply and exhaust locations should direct clean air to areas where health-care workers are likely to work, across the infectious source, and then to the exhaust, so that the healthcare worker is not in position between the infectious source and the exhaust location. The design of such systems should also allow for easy access for scheduled preventative maintenance and cleaning.

A11. The verification of airflow direction can include a simple visual method such as smoke trail, ball-in-tube, or flutterstrip. These devices will require a minimum differential air pressure to indicate airflow direction.

Note: This table is Table 8.1 in the AIA guidelines, 2001 edition. Superscripts used in this table refer to notes following the table.

Table B.3. Pressure relationships and ventilation of certain areas of nursing facilities[1]

Area designation	Air movement relationship to adjacent area[2]	Minimum air changes of outdoor air per hour[3]	Minimum total air change per hour [4]	All air exhausted directly to outdoors[5]	Recirculated by means of room units[6]	Relative humidity[7] (%)	Design temperature[8] (degrees F [C])

Notes:

1. The ventilation rates in this table cover ventilation for comfort, as well as for asepsis and odor control in areas of nursing facilities that directly affect resident care and are determined based on nursing facilities being predominantly “No Smoking” facilities. Where smoking may be allowed, ventilation rates will need adjustment. Areas where specific ventilation rates are not given in the table shall be ventilated in accordance with ASHRAE Standard 62, *Ventilation for Acceptable Indoor Air Quality,* and ASHRAE *Handbook - HVAC Applications.* OSHA standards and/or NIOSH criteria require special ventilation requirements for employee health and safety within nursing facilities.
2. Design of the ventilation system shall, insofar as possible, provide that air movement is from clean to less clean areas. However, continuous compliance may be impractical with full utilization of some forms of variable air volume and load shedding systems that may be used for energy conservation. Areas that do require positive and continuous control are noted with “Out” or “In” to indicate the required direction of air movement in relation to the space named. Rate of air movement may, of course, be varied as needed within the limits required for positive control. Where indication of air movement direction is enclosed in parentheses, continuous directional control is required only when the specialized equipment or device is in use or where room use may otherwise compromise the intent of movement from clean to less clean. Air movement for rooms with dashes and nonpatient areas may vary as necessary to satisfy the requirements of those spaces. Additional adjustments may be needed when space is unused or unoccupied and air systems are deenergized or reduced.

3. To satisfy exhaust needs, replacement air from outside is necessary. Table B.3 does not attempt to describe specific amounts of outside air to be supplied to individual spaces except for certain areas such as those listed. Distribution of the outside air, added to the system to balance required exhaust, shall be as required by good engineering practice.
4. Number of air changes may be reduced when the room is unoccupied if provisions are made to ensure that the number of air changes indicated is reestablished any time the space is being utilized. Adjustments shall include provisions so that the direction of air movement shall remain the same when the number of air changes is reduced. Areas not indicated as having continuous directional control may have ventilation systems shut down when space is unoccupied and ventilation is not otherwise needed.
5. Air from areas with contamination and/or odor problems shall be exhausted to the outside and not recirculated to other areas. Note that individual circumstances may require special consideration for air exhaust to outside.
6. Because of cleaning difficulty and potential for buildup of contamination, recirculating room units shall not be used in areas marked “No.” Isolation rooms may be ventilated by reheat induction units in which only the primary air supplied from a central system passes through the reheat unit. Gravity-type heating or cooling units such as radiators or convectors shall not be used in special care areas.
7. The ranges listed are the minimum and maximum limits where control is specifically needed. See A8.31.D in the AIA guideline (reference 120) for additional information.
8. Where temperature ranges are indicated, the systems shall be capable of maintaining the rooms at any point within the range. A single figure indicates a heating or cooling capacity of at least the indicated temperature. This is usually applicable where residents may be undressed and require a warmer environment. Nothing in these guidelines shall be construed as precluding the use of temperatures lower than those noted when the residents’ comfort and medical conditions make lower temperatures desirable. Unoccupied areas such as storage rooms shall have temperatures appropriate for the function intended.
9. See A8.31.D1 in the AIA guideline (reference 120).
10. Food preparation facilities shall have ventilation systems whose air supply mechanisms are interfaced appropriately with exhaust hood controls or relief vents so that exfiltration or infiltration to or from exit corridors does not compromise the exit corridor restrictions of NFPA 90A, the pressure requirements of NFPA 96, or the maximum defined in the table. The number of air changes may be reduced or varied to any extent required for odor control when the space is not in use.

Table B.4. Filter efficiencies for central ventilation and air conditioning systems in general hospitals*

Area designation	Number of filter beds	Filter bed no.1 (%)*	Filter bed no. 2 (%)*
All areas for inpatient care, treatment, and diagnosis, and those areas providing direct service or clean supplies, such as sterile and clean processing, etc.	2	30	90
Protective environment room	2	30	99.97
Laboratories	1	80	n/a
Administrative, bulk storage, soiled holding areas, food preparation areas, and laundries	1	30	n/a

Note: This table is Table 7.3 in the AIA guidelines, 2001 edition.

* Additional roughing or prefilters should be considered to reduce maintenance required for filters with efficiency higher than 75%. The filtration efficiency ratings are based on average dust sopt efficiency per ASHRAE 52.1–1992.

Table B.5. Filter efficiencies for central ventilation and air conditioning systems in outpatient facilities*

Area designation	Number of filter beds	Filter bed no.1 (%)*	Filter bed No. 2 (%)*
All areas for patient care, treatment, and/or diagnosis, and those areas providing direct service or clean supplies such as sterile and clean processing, etc.	2	30	90
Laboratories	1	80	n/a
Administrative, bulk storage, soiled holding areas, food preparation areas, and laundries	1	30	n/a

Note: This table is Table 9.1 in the AIA guidelines, 2001 edition.

* Additional roughing or prefilters should be considered to reduce maintenance required for main filters. The filtration efficiency ratings are based on dust spot efficiency per ASHRAE 52.1–1992.

\+ These requirements do not apply to small primary (e.g., neighborhood) outpatient facilities or outpatient facilities that do not perform invasive applications or procedures.

Table B.6. Filter efficiencies for central ventilation and air conditioning systems in nursing facilities

Area designation	Minimum number of filter beds	Filter bed no.1 (%)*	Filter bed No. 2 (%)*
All areas for inpatient care, treatment, and/or diagnosis, and those areas providing direct service or clean supplies	2	30	80
Administrative, bulk storage, soiled holding, laundries, and food preparation areas	1	30	n/a

Appendix C. Water

1. Biofilms

Microorganisms have a tendency to associate with and stick to surfaces. These adherent organisms can initiate and develop biofilms, which are comprised of cells embedded in a matrix of extracellularly produced polymers and associated abiotic particles.[1438] It is inevitable that biofilms will form in most water systems. In the health-care facility environment, biofilms may be found in the potable water supply piping, hot water tanks, air conditioning cooling towers, or in sinks, sink traps, aerators, or shower heads. Biofilms, especially in water systems, are not present as a continuous slime or film, but are more often scanty and heterogeneous in nature.[1439] Biofilms may form under stagnant as well as flowing conditions, so storage tanks, in addition to water system piping, may be vulnerable to the development of biofilm, especially if water temperatures are low enough to allow the growth of thermophilic bacteria (e.g., *Legionella* spp.). Favorable conditions for biofilm formation are present if these structures and equipment are not cleaned for extended periods of time.[1440]

Algae, protozoa, and fungi may be present in biofilms, but the predominant microorganisms of water system biofilms are gram-negative bacteria. Although most of these organisms will not normally pose a problem for healthy individuals, certain biofilm bacteria (e.g., *Pseudomonas aeruginosa, Klebsiella* spp., *Pantoea agglomerans*, and *Enterobacter cloacae*) all may be agents for opportunistic infections for immunocompromised individuals.[1441, 1442] These biofilm organisms may easily contaminate indwelling medical devices or intravenous (IV) fluids, and they could be transferred on the hands of health-care workers.[1441–1444]

Biofilms may potentially provide an environment for the survival of pathogenic organisms, such as *Legionella pneumophila* and *E. coli* O157:H7. Although the association of biofilms and medical devices provides a plausible explanation for a variety of health-care associated infections, it is not clear how the presence of biofilms in the water system may influence the rates of health-care– associated waterborne infection.

Organisms within biofilms behave quite differently than their planktonic (i.e., free floating) counterparts. Research has shown that biofilm-associated organisms are more resistant to antibiotics and disinfectants than are planktonic organisms, either because the cells are protected by the polymer matrix, or because they are physiologically different.[1445–1450] Nevertheless, municipal water utilities attempt to maintain a chlorine residual in the distribution system to discourage microbiological growth. Though chlorine in its various forms is a proven disinfectant, it has been shown to be less effective against biofilm bacteria.[1448] Higher levels of chlorine for longer contact times are necessary to eliminate biofilms.

Routine sampling of health-care facility water systems for biofilms is not warranted. If an epidemiologic investigation points to the water supply system as a possible source of infection, then water sampling for biofilm organisms should be considered so that prevention and control strategies can be developed. An established biofilm is is difficult to remove totally in existing piping. Strategies to remediate biofilms in a water system would include flushing the system piping, hot water tank, dead legs, and those areas of the facility's water system subject to low or intermittent flow. The benefits of this treatment would include

a. elimination of corrosion deposits and sludge from the bottom of hot water tanks,
b. removal of biofilms from shower heads and sink aerators, and
c. circulation of fresh water containing elevated chlorine residuals into the health-care facility water system.

The general strategy for evaluating water system biofilm depends on a comparision of the bacteriological quality of the incoming municipal water and that of water sampled from within facility's distribution system. Heterotrophic plate counts and coliform counts, both of which are routinely run by the municipal water utility, will at least provide in indication of the potential for biofilm formation. Heterotrophic plate count levels in potable water should be <500 CFU/mL. These levels may increase on occasion, but counts consistently >500 CFU/mL would indicate a general decrease in water quality. A direct correlation between heterotrophic plate count and biofilm levels has been demonstrated.[1450] Therefore, an increase in

heterotrophic plate count would suggest a greater rate and extent of biofilm formation in a health-care facility water system. The water supplied to the facility should also contain <1 coliform bacteria/100 mL. Coliform bacteria are organisms whose presence in the distribution system could indicate fecal contamination. It has been shown that coliform bacteria can colonize biofilms within drinking water systems. Intermittant contamination of a water system with these organisms could lead to colonization of the system.

Water samples can be collected from throughout the health-care facility system, including both hot and cold water sources; samples should be cultured by standard methods.[945] If heterotrophic plate counts in samples from the facility water system are higher than those from samples collected at the point of water entry to the building, it can be concluded that the facility water quality has diminished. If biofilms are detected in the facility water system and determined by an epidemiologic and environmental investigation to be a reservoir for health-care associated pathogens, the municipal water supplier could be contacted with a request to provide higher chlorine residuals in the distribution system, or the health-care facility could consider installing a supplemental chlorination system.

Sample collection sites for biofilm in health-care facilities include
a. hot water tanks
b. shower heads; and
c. faucet aerators, especially in immunocompromised patient-care areas.

Swabs should be placed into tubes containing phosphate buffered water, pH 7.2 or phosphate buffered saline, shipped to the laboratory under refrigeration and processed within 24 hrs. of collection. Samples are suspended by vortexing with sterile glass beads and plated onto a nonselective medium (e.g., Plate Count Agar or R2A medium) and selective media (e.g., media for *Legionella* spp. isolation) after serial dilution. If the plate counts are elevated above levels in the water (i.e. comparing the plate count per square centimeter of swabbed surface to the plate count per milliliter of water), then biofilm formation can be suspected. In the case of an outbreak, it would be advisable to isolate organisms from these plates to determine whether the suspect organisms are present in the biofilm or water samples and compare them to the organisms isolated from patient specimens.

2. Water and Dialysate Sampling Strategies in Dialysis

In order to detect the low, total viable heterotrophic plate counts outlined by the current AAMI standards for water and dialysate in dialysis settings, it is necessary to use standard quantitative culture techniques with appropriate sensitivity levels.[792, 832, 833] The membrane filter technique is particularly suited for this application because it permits large volumes of water to be assayed.[792, 834] Since the membrane filter technique may not be readily available in clinical laboratories, the spread plate assay can be used as an alternative.[834] If the spread plate assay is used, however, the standard prohibits the use of a calibrated loop when applying sample to the plate.[792] The prohibition is based on the low sensitivity of the calibrated loop. A standard calibrated loop transfers 0.001 mL of sample to the culture medium, so that the minimum sensitivity of the assay is 1,000 CFU/mL. This level of sensitivity is unacceptable when the maximum allowable limit for microorganisms is 200 CFU/mL. Therefore, when the spread plate method is used, a pipette must be used to place 0.1–0.5 mL of water on the culture medium.

The current AAMI standard specifically prohibits the use of nutrient-rich media (e.g., blood agar, and chocolate agar) in dialysis water and dialysate assays because these culture media are too rich for growth of the naturally occurring organisms found in water.[792] Debate continues within AAMI, however, as to the most appropriate culture medium and incubation conditions to be used. The original clinical observations on which the microbiological requirements of this standard were based used Standard Methods Agar (SMA), a medium containing relatively few nutrients.[666] The use of tryptic soy agar (TSA), a general purpose medium for isolating and cultivating microorganisms was recommended in later versions of the standard because it was thought to be more appropriate for culturing bicarbonate-containing dialysate.[788, 789, 835] Moreover, culturing systems based on TSA are readily available from commercial sources. Several studies, however, have shown

that the use of nutrient-poor media, such as R2A, results in an increased recovery of bacteria from water.[1451, 1452] The original standard also specified incubation for 48 hours at 95°F–98.6°F (35°C–37°C) before enumeration of bacterial colonies. Extending the culturing time up to 168 hours, or 7 days and using incubation temperatures of 73.4°F– 82.4°F (23°C–28°C) have also been shown to increase the recovery of bacteria.[1451, 1452] Other investigators, however, have not found such clear cut differences between culturing techniques.[835, 1453] After considerable discussion, the AAMI Committee has not reached a consensus regarding changes in the assay technique, and the use of TSA or its equivalent for 48 hours at 95°F–98.6°F (35°C–37°C) remains the recommended method. It should be recognized, however, that these culturing conditions may underestimate the bacterial burden in the water and fail to identify the presence of some organisms. Specifically, the recommended method may not detect the presence of various NTM that have been associated with several outbreaks of infection in dialysis units.[31, 32] In these instances, however, the high numbers of mycobacteria in the water were related to the total heterotrophic plate counts, each of which was significantly greater than that allowable by the AAMI standard. Additionally, the recommended method will not detect fungi and yeast, which have been shown to contaminate water used for hemodialysis applications.[1454] Biofilm on the surface of the pipes may hide viable bacterial colonies, even though no viable colonies are detected in the water using sensitive culturing techniques.[1455] Many disinfection processes remove biofilm poorly, and a rapid increase in the level of bacteria in the water following disinfection may indicate significant biofilm formation. Therefore, although the results of microbiological surveillance obtained using the test methods outlined above may be useful in guiding disinfection schedules and in demonstrating compliance with AAMI standards, they should not be taken as an indication of the absolute microbiological purity of the water.[792]

Endotoxin can be tested by one of two types of assays
a. a kinetic test method [e.g., colorimetric or turbidimetric] or
b. a gel-clot assay.

Endotoxin units are assayed by the *Limulus* Amebocyte Lysate (LAL) method. Because endotoxins differ in their activity on a mass basis, their activity is referred to a standard *Escherichia coli* endotoxin. The current standard (EC-6) is prepared from *E. coli* O113:H10. The relationship between mass of endotoxin and its activity varies with both the lot of LAL and the lot of control standard endotoxin used. Since standards for endotoxin were harmonized in 1983 with the introduction of EC-5, the relationship between mass and activity of endotoxin has been approximately 5–10 EU/ng. Studies to harmonize standards have led to the measurement of endotoxin units (EU) where 5 EU is equivalent to 1 ng *E. coli* O55:B5 endotoxin.[1456]

In summary, water used to prepare dialysate and to reprocess hemodialyzers should not contain a total microbial count >200 CFU/mL as determined by assay on TSA agar for 48 hrs. at 96.8°F (36°C), and ≤2 endotoxin units (EU) per mL. The dialysate at the end of a dialysis treatment should not contain >2,000 CFU/mL.[31, 32, 668, 789, 792]

3. Water Sampling Strategies and Culture Techniques for Detecting Legionellae

Legionella spp. are ubiquitous and can be isolated from 20%–40% of freshwater environments, including man-made water systems.[1457, 1458] In health-care facilities, where legionellae in potable water rarely result in disease among immunocompromised patients, courses of remedial action are unclear.

Scheduled microbiologic monitoring for legionellae remains controversial because the presence of legionellae is not necessarily evidence of a potential for causing disease.[1459] CDC recommends aggressive disinfection measures for cleaning and maintaining devices known to transmit legionellae, but does not recommend regularly scheduled microbiologic assays for the bacteria.[396] However, scheduled monitoring of potable water within a hospital might be considered in certain settings where persons are highly susceptible to illness and mortality from *Legionella* infection (e.g., hematopoietic stem cell transplantation units and solid organ transplant units).[9] Also, after an outbreak of legionellosis, health officials agree monitoring is necessary to identify the source and to evaluate the efficacy of biocides or other prevention measures.

Examination of water samples is the most efficient microbiologic method for identifying sources of legionellae and is an integral part of an epidemiologic investigation into health-care associated Legionnaires

disease. Because of the diversity of plumbing and HVAC systems in health-care facilities, the number and types of sites to be tested must be determined before collection of water samples. One environmental sampling protocol that addresses sampling site selection in hospitals might serve as a prototype for sampling in other institutions.[1209] Any water source that might be aerosolized should be considered a potential source for transmission of legionellae. The bacteria are rarely found in municipal water supplies and tend to colonize plumbing systems and point-of-use devices. To colonize, legionellae usually require a temperature range of 77°F–108°F (25°C–42.2°C) and are most commonly located in hot water systems.[1460] Legionellae do not survive drying. Therefore, air-conditioning equipment condensate, which frequently evaporates, is not a likely source.[1461]

Water samples and swabs from point-of-use devices or system surfaces should be collected when sampling for legionellae (Box C.1).[1437] Swabs of system surfaces allow sampling of biofilms, which frequently contain legionellae. When culturing faucet aerators and shower heads, swabs of surface areas should be collected first; water samples are collected after aerators or shower heads are removed from their pipes. Collection and culture techniques are outlined (Box C.2). Swabs can be streaked directly onto buffered charcoal yeast extract agar (BCYE) plates if the pates are available at the collection site. If the swabs and water samples must be transported back to a laboratory for processing, immersing individual swabs in sample water minimizes drying during transit. Place swabs and water samples in insulated coolers to protect specimens from temperature extremes.

Box C.1. Potential sampling sites for *Legionella* spp. in health-care facilities*

- **Potable water systems**
  incoming water main, water softener unit, holding tanks, cisterns, water heater tanks (at the inflows and outflows)
- **Potable water outlets, especially those in or near patient rooms**
  faucets or taps, showers
- **Cooling towers and evaporative condensers**
  makeup water (e.g., added to replace water lost because of evaporation, drift, or leakage), basin (i.e., area under the tower for collection of cooled water), sump (i.e., section of basin from which cooled water returns to heat source), heat sources (e.g., chillers)
- **Humidfiers (e.g., nebullizers)**
  bubblers for oxygen, water used for respiratory therapy equipment
- **Other sources**
  decorative fountains, irrigation equipment, fire sprinkler system (if recently used), whirlpools, spas

* Material in this box is adapted from reference 1209.

Box C.2. Procedures for collecting and processing environmental specimens for *Legionella* spp.*

1. Collect water (1-liter samples, if possible) in sterile, screw-top bottles.
2. Collect culture swabs of internal surfaces of faucets, aerators, and shower heads in a sterile, screw-top container (e.g., 50 mL plastic centrifuge tube). Submerge each swab in 5–10 mL of sample water taken from the same device from which the sample was obtained.
3. Transport samples and process in a laboratory proficient at culturing water specimens for *Legionella* spp. as soon as possible after collection. (Samples may be transported at room temperature but must be protected from temperature extremes. Samples not processed within 24 hours of collection should be refrigerated.)
4. Test samples for the presence of *Legionella* spp. by using semiselective culture media using procedures specific to the cultivation and detection of *Legionella* spp.
   - Detection of *Legionella* spp. antigen by the direct fluorescent antibody technique is not suitable for environmental samples.
   - Use of polymerase chain reaction for identification of *Legionella* spp. is not recommended until more data regading the sensitivity and specificity of this procedure are available.

* Material in this table is compiled from references1209, 1437, 1462–1465.

4. Procedure for Cleaning Cooling Towers and Related Equipment

I. Perform these steps prior to chemical disinfection and mechanical cleaning.

A. Provide protective equipment to workers who perform the disinfection, to prevent their exposure to chemicals used for disinfection and aerosolized water containing *Legionella* spp. Protective equipment may include full-length protective clothing, boots, gloves, goggles, and a full- or half-face mask that combines a HEPA filter and chemical cartridges to protect against airborne chlorine levels of up to 10 mg/L.

B. Shut off cooling tower.
   1. Shut off the heat source, if possible.
   2. Shut off fans, if present, on the cooling tower/evaporative condenser (CT/EC).
   3. Shut off the system blowdown (i.e., purge) valve.
   4. Shut off the automated blowdown controller, if present, and set the system controller to manual.
   5. Keep make-up water valves open.
   6. Close building air-intake vents within at least 30 meters of the CT/EC until after the cleaning procedure is complete.
   7. Continue operating pumps for water circulation through the CT/EC.

II. Perform these chemical disinfection procedures.

A. Add fast-release, chlorine-containing disinfectant in pellet, granular, or liquid form, and follow safety instructions on the product label. Use EPA-registered products, if available. Examples of disinfectants include sodium hypochlorite (NaOCl) or calcium hypochlorite (Ca[OCl]2), calculated to achieve initial free residual chlorine (FRC) of 50 mg/L: either
   a. 3.0 lbs [1.4 kg] industrial grade NaOCl [12%–15% available Cl] per 1,000 gallons of CT/EC water
   b. 10.5 lbs
   c. [4.8 kg] domestic grade NaOCl [3%–5% available Cl] per 1,000 gallons of CT/EC water; or
   d. 0.6 lb [0.3 kg] Ca[OCl]2 per 1,000 gallons of CT/EC water. If significant biodeposits are present, additional chlorine may be required. If the volume of water in the CT/EC is unknown, it can be estimated (in gallons) by multiplying either the recirculation rate in gallons per minute by 10 or the refrigeration capacity in tons by 30. Other appropriate compounds may be suggested by a water-treatment specialist.

B. Record the type and quality of all chemicals used for disinfection, the exact time the chemicals were added to the system, and the time and results of FRC and pH measurements.

C. Add dispersant simultaneously with or within 15 minutes of adding disinfectant. The dispersant is best added by first dissolving it in water and adding the solution to a turbulent zone in the water system. Automatic-dishwasher compounds are examples of low- or nonfoaming, silicate-based dispersants. Dispersants are added at 10–25 lbs (4.5–11.25 kg) per 1,000 gallons of CT/EC water.

D. After adding disinfectant and dispersant, continue circulating the water through the system. Monitor the FRC by using an FRC-measuring device with the DPD method (e.g., a swimming-pool test kit), and measure the pH with a pH meter every 15 minutes for 2 hours. Add chlorine as needed to maintain the FRC at ≥10 mg/L. Because the biocidal effect of chlorine is reduced at a higher pH, adjust the pH to 7.5–8.0. The pH may be lowered by using any acid (e.g., nuriatic acid or sulfuric acid used for maintenance of swimming pools) that is compatible with the treatment chemicals.

E. Two hours after adding disinfectant and dispersant or after the FRC level is stable at ≥10 mg/L, monitor at 2-hour intervals and maintain the FRC at ≥10 mg/L for 24 hours.

F. After the FRC level has been maintained at ≥10 mg/L for 24 hours, drain the system. CT/EC water may be drained safely into the sanitary sewer. Municipal water and sewerage authorities should be contacted regarding local regulations. If a sanitary sewer is not available, consult local or state authorities (e.g., a department of natural resources or environmental protection) regarding disposal of water. If necessary, the drain-off may be dechlorinated by dissipation or chemical neutralization with sodium bisulfite.

G. Refill the system with water and repeat the procedure outline in steps 2–7 in I-B above.

III. Perform mechanical cleaning.

A. After water from the second chemical disinfection has been drained, shut down the CT/EC.
B. Inspect all water-contact areas for sediment, sludge, and scale. Using brushes and/or a low-pressure water hose, thoroughly clean all CT/EC water-contact areas, including the basin, sump, fill, spray nozzles, and fittings. Replace components as needed.
C. If possible, clean CT/EC water-contact areas within the chillers.

IV. Perform these procedures after mechanical cleaning.

A. Fill the system with water and add chlorine to achieve an FRC level of 10 mg/L.
B. Circulate the water for 1 hour, then open the blowdown valve and flush the entire system until the water is free of turbidity.
C. Drain the system.
D. Open any air-intake vents that were closed before cleaning.
E. Fill the system with water. The CT/EC may be put back into service using an effective water-treatment program.

5. Maintenance Procedures Used to Decrease Survival and Multiplications of *Legionella* spp. in Potable-Water Distribution Systems

Wherever allowable by state code, provide water at ≥124°F (≥51°C) at all points in the heated water system, including the taps. This requires that water in calorifiers (e.g., water heaters) be maintained at ≥140°F (≥60°C). In the United Kingdom, where maintenance of water temperatures at ≥122°F (≥50°C) in hospitals has been mandated, installation of blending or mixing valves at or near taps to reduce the water temperature to ≤109.4°F (≤63°C) has been recommended in certain settings to reduce the risk for scald injury to patients, visitors, and health care workers.[726] However, *Legionella* spp. can multiply even in short segments of pipe containing water at this temperature. Increasing the flow rate from the hot-water-circulation system may help lessen the likelihood of water stagnation and cooling.[711, 1465] Insulation of plumbing to ensure delivery of cold (<68°F [<20°C]) water to water heaters (and to cold-water outlets) may diminish the opportunity for bacterial multiplication.[456] Both dead legs and capped spurs within the plumbing system provide areas of stagnation and cooling to <122°F (<50°C) regardless of the circulating water temperature; these segments may need to be removed to prevent colonization.[704] Rubber fittings within plumbing systems have been associated with persistent colonization, and replacement of these fittings may be required for *Legionella* spp. eradication.[1467]

Continuous chlorination to maintain concentrations of free residual chlorine at 1–2 mg/L (1–2 ppm) at the tap is an alternative option for treatment. This requires the placement of flow-adjusted, continuous injectors of chlorine throughout the water distribution system. Adverse effects of continuous chlorination can include accelerated corrosion of plumbing (resulting in system leaks) and production of potentially carcinogenic trihalomethanes. However, when levels of free residual chlorine are below 3 mg/L (3 ppm), trihalomethane levels are kept below the maximum safety level recommended by the EPA.[727, 1468, 1469 228]

Appendix F. Areas of Future Research

Air

- Standardize the methodology and interpretation of microbiologic air sampling (e.g., determine action levels or minimum infectious dose for aspergillosis, and evaluate the significance of airborne bacteria and fungi in the surgical field and the impact on postoperative SSI).
- Develop new molecular typing methods to better define the epidemiology of health-care associated outbreaks of aspergillosis and to associate isolates recovered from both clinical and environmental sources.
- Develop new methods for the diagnosis of aspergillosis that can lead reliably to early recognition of infection.
- Assess the value of laminar flow technology for surgeries other than for joint replacement surgery.
- Determine if particulate sampling can be routinely performed in lieu of microbiologic sampling for purposes such as determining air quality of clean environments (e.g., operating rooms, HSCT units).

Water

- Evaluate new methods of water treatment, both in the facility and at the water utility (e.g., ozone, chlorine dioxide, copper/silver/monochloramine) and perform cost-benefit analyses of treatment in preventing health-care associated legionellosis.
- Evaluate the role of biofilms in overall water quality and determine the impact of water treatments for the control of biofilm in distribution systems.
- Determine if the use of ultrapure fluids in dialysis is feasible and warranted, and determine the action level for the final bath.
- Develop quality assurance protocols and validated methods for sampling filtered rinse water used with AERs and determine acceptable microbiologic quality of AER rinse water.

Environmental Services

- Evaluate the innate resistance of microorganisms to the action of chemical germicides, and determine what, if any, linkage there may be between antibiotic resistance and resistance to disinfectants.

Laundry and Bedding

- Evaluate the microbial inactivation capabilities of new laundry detergents, bleach substitutes, other laundry additives, and new laundry technologies.

Animals in Health-Care Facilities

- Conduct surveillance to monitor incidence of infections among patients in facilities that use animal programs, and conduct investigations to determine new infection control strategies to prevent these infections.
- Evaluate the epidemiologic impact of performing procedures on animals (e.g., surgery or imaging) in human health-care facilities.

Regulated Medical Waste

- Determine the efficiency of current medical waste treatment technologies to inactivate emerging pathogens that may be present in medical waste (e.g., SARS-coV).
- Explore options to enable health-care facilities to reinstate the capacity to inactivate microbiological cultures and stocks on-site.

Subject: RE: question

IPCT were not involved in the decision to reduce air changes and were not involved in the design of ventilation systems so its difficult to comment on the rationale retrospectively.
From what I've learned from Glasgow I speculate that there may have been a perception that the air changes per hour stated in the SHTM was mainly to manage room temperature. If the room temperature was being regulated by another system (in QEUH this is done with "chill beams" but fortunately none of these are installed in RHCYP) then there may have been a perception that the number of air changes could be dropped if it wasn't appreciated that the air changes per hour are fundamental to dilution and removal of airborne pathogens too.
Likewise, opening windows to assist with air changes in areas such as critical care where patients are immobile and partially clothed and unable to regulate temperature themselves or communicate that they are cold is not appropriate as it risks hypothermia when outside air temperature may be low. Additionally unpredictable direction of air flow from an open window (much like a fan) in non critical care areas can blow aerosolised organisms in unpredictable directions that result in transmission between patients and facilitate or perpetuate outbreaks (e.g. norovirus).

Subject: question

You'll be aware we are being sent lots of questions to answer but one important one to get an answer for today is:

Q: why did you think that moving from 6 to 4 air changes/hour was acceptable? [their wording not mine]
A: [please could you give a clinical answer- I think this was related to the pressure- and the clinical need for balanced or negative rather than positive]

Also can we be clear about 6 or 6 in mixed mode- this seems to vary across conversations?

Infection Prevention & Control

13/01/2021 15:00

Situation

Hospital: RHCYP Ward: Dental outpatients

30/12/2020 - Water staining and damp identified on the wall between dental surgery rooms 1 and 2. Investigation identified significant damage to the wall.
13/01/2021 Investigation to wall between dental 2 and 3 has also identified extensive mould.

Background

The new RHCYP is in the process of being commissioned, Outpatients (including dental) were in the 1st phases for opening.
The dental department and surgeries deal with various groups of patients including those who are immunocompromised and at high risk of infection.

Assessment

- 30/12/2020 damp identified
- Surgeries 1 and 2 closed for investigation
- Scribe document completed for the initial investigation work
- Investigation discovered extensive water damage in the wall between the two surgeries.
- 13/01/2021 Investigation to wall between surgery 2 and 3, identified extensive mould.
- Discussion re issue. Rooms to be put out of use.
- Patients listed 13/01/2021 pm must have a risk assessment completed to review the risk of proceeding with the appointment.

Recommendation

I recommend that the following be undertaken within the given timescales:

- Rooms closed for use (exception todays patients if risk assessed) Patients re allocated appointments 14/01/2021
- Associate Director for IPC to inform Executive medical director and Executive Director, Nursing, Midwifery, AHP's
- PAG to be held 13/01/2021 16:00
- Request to Bouygues for the scope and extent of current investigation and current findings to date. (13/01/2021)
- Plan to be decided to move forward (13/1/2021)

NES Infection Prevention and Control Education Team

Healthcare Built Environment

☆ Add to favourites

Resources to support the workforce in gaining knowledge and skills to prevent and control potential risks posed by healthcare facilities and promote a culture of life-long learning, continuous improvement and improved patient safety.

Welcome

The resources on this site have been co-produced by NHS Education for Scotland and NHS Scotland Assure, established to be an internationally recognised national centre for reducing risks in the healthcare built environment and ensuring healthcare facilities are safe, fit for purpose, cost effective and capable of delivering sustainable services over the long term. In this context, risks refer to those commonly associated with service systems, that is, the provision of water and drainage, air ventilation, electricity, fire prevention and medical gases, with infection prevention and control as a consideration for each.

They are intended to:

- support learning and development for this diverse multi-agency and multi professional staff group including clinical, estates and facilities staff
- support the workforce in gaining the knowledge and skills to prevent and control the potential risks posed by healthcare facilities and promote a culture of life-long learning, continuous improvement and improved patient safety

The Healthcare built environment learning zone contains the following resources :

- **Learning and development strategy**
- **Knowledge and skills framework**
- **Senior leadership development**
- **Healthcare Built Environment Educational Resources**
- **Related resources and links**
- **NES IPC Education Team Newsletter - January 24**
- **Winter Prepardness 2023_24**

Meet the team

Meet the Infection Prevention and Control Education Team members responsible for the healthcare built environment portfolio of work:

Guidelines for Preventing Opportunistic Infections Among Hematopoietic Ster Cell Transplant Recipients

Recommendations of CDC, the Infectious Disease Society of America, and the American Society of Blood and Marrow Transplantation

Please note: *An erratum has been published for this article. To view the erratum, please click here.*

Abbreviations Used in This Publication

ANC	absolute neutrophil count
BAL	bronchoalveolar lavage
CDA	chlorodeoxyadenosine
CJD	Creutzfeldt-Jakob disease
CMV	cytomegalovirus
CRV	community-acquired respiratory virus
DNA	deoxyribonucleic acid
EBV	Epstein-Barr virus
EPA	Environmental Protection Agency
FDA	Food and Drug Administration
G-CSF	granulocyte colony-stimulating factor (filgastrim)
GM-CSF	granulocyte-macrophage colony-stimulating factor (sargramostim)
GVHD	graft-versus-host disease
HCW	health-care worker
HEPA filter	high-efficiency (>90%) particulate air filter
Hib	*Haemophilus influenzae* type b
HIV	human immunodeficiency virus
HLA	human lymphocyte antigen
HSCT	hematopoietic stem cell transplant; for this report, includes all blood- and marrow-derived hematopoietic stem cell transplants
HSV	herpes simplex virus
HTLV	human T-lymphotropic virus
IgA	immunoglobulin A
IgG	immunoglobulin G
IgM	immunoglobulin M
IVIG	intravenous immunoglobulin
LAF	laminar air flow
LD	Legionnaires' disease
LRI	lower respiratory infection
MIC	minimum inhibitory concentration
MRSA	methicillin-resistant *Staphylococcus aureus*
nvCJD	new variant Creutzfeldt-Jakob disease
OI	opportunistic infection
PCP	*Pneumocystis carinii* pneumonia
PCR	polymerase chain reaction
PZA/RIF	pyrazinamide/rifampin
RNA	ribonucleic acid
RSV	respiratory syncytial virus
TB	*Mycobacteria tuberculosis*
TMP-SMZ	trimethoprim-sulfamethasaxole
TST	tuberculin skin test
UCB	umbilical cord blood
URI	upper respiratory infection
VRE	vancomycin-resistant *Enterococcus*
VZIG	varicella-zoster immunoglobulin
VZV	varicella-zoster virus

Summary

CDC, the Infectious Disease Society of America, and the American Society of Blood and Marrow Transplantation have cosponsored these guidelines for preventing opportunistic infections (OIs) among hematopoietic stem cell transplant (HSCT) recipients. The guidelines were drafted with the assistance of a working group of expe in infectious diseases, transplantation, and public health. For the purposes of this report, HSCT is defined as any transplantation of blood- or marrow-derived hematopoietic stem cells, regardless of transplant type (i.e., allogeneic or autologous) or cell source (i.e., bone marrow, peripheral blood, or placental or umbilical co blood). Such OIs as bacterial, viral, fungal, protozoal, and helminth infections occur with increased frequency or severity among HSCT recipients. These evidence-bas guidelines contain information regarding preventing OIs, hospital infection control, strategies for safe living after transplantation, vaccinations, and hematopoietic ste cell safety. The disease-specific sections address preventing exposure and disease for pediatric and adult and autologous and allogeneic HSCT recipients. The goal of these guidelines is twofold: to summarize current data and provide evidence-based recommendations regarding preventing OIs among HSCT patients. The guidelines were developed for use by HSCT recipients, their household and close contacts, transplant and infectious diseases physicians, HSCT center personnel, and public heal professionals. For all recommendations, prevention strategies are rated by the strength of the recommendation and the quality of the evidence supporting the recommendation. Adhering to these guidelines should reduce the number and severity of OIs among HSCT recipients.

INTRODUCTION

In 1992, the Institute of Medicine (*1*) recommended that CDC lead a global effort to detect and control emerging infectious agents. In response, CDC published a plan that outlined national disease prevention priorities, including the development of guidelines for preventing opportunistic infections (OIs) among immunosuppressed persons. During 1995, CDC published guidelines for preventing OIs among persons infected with human immunodeficiency virus (HIV) and revised those guidelines during 1997 and 1999 (*3--5*). Because of the success of those guidelines, CDC sought to determine the need for expanding OI prevention activities to other immunosuppressed populations. An informal survey of hematology, oncology, and infectious disease specialists at transplant centers and a working group formed by CDC determined that guidelines were needed to help prevent OIs among hematopoietic stem cell transplant (HSCT)* recipients.

The working group defined OIs as infections that occur with increased frequency or severity among HSCT recipients, and they drafted evidence-based recommendatio for preventing exposure to and disease caused by bacterial, fungal, viral, protozoal, or helminthic pathogens. During March 1997, the working group presented the first draft of these guidelines at a meeting of representatives from public and private health organizations. After review by that group and other experts, these guidelines wer revised and made available during September 1999 for a 45-day public comment period after notification in the *Federal Register*. Public comments were added when feasible, and the report was approved by CDC, the Infectious Disease Society of America, and the American Society of Blood and Marrow Transplantation. The pediat content of these guidelines has been endorsed also by the American Academy of Pediatrics. The hematopoietic stem cell safety section was endorsed by the Internation Society of Hematotherapy and Graft Engineering.

The first recommendations presented in this report are followed by recommendations for hospital infection control, strategies for safe living, vaccinations, and hematopoietic stem cell safety. Unless otherwise noted, these recommendations address allogeneic and autologous and pediatric and adult HSCT recipients. Additional these recommendations are intended for use by the recipients, their household and other close contacts, transplant and infectious diseases specialists, HSCT center personnel, and public health professionals.

Using These Guidelines

For all recommendations, prevention strategies are rated by the strength of the recommendation (Table 1) and the quality of the evidence (Table 2) supporting the recommendation. The principles of this rating system were developed by the Infectious Disease Society of America and the U.S. Public Health Service for use in the guidelines for preventing OIs among HIV-infected persons (*3--6*). This rating system allows assessments of recommendations to which adherence is critical.

BACKGROUND

HSCT is the infusion of hematopoietic stem cells from a donor into a patient who has received chemotherapy, which is usually marrow-ablative. Increasingly, HSCT h been used to treat neoplastic diseases, hematologic disorders, immunodeficiency syndromes, congenital enzyme deficiencies, and autoimmune disorders (e.g., systemic lupus erythematosus or multiple sclerosis) (*7--10*). Moreover, HSCT has become standard treatment for selected conditions (*7,11,12*). Data from the International Bone Marrow Transplant Registry and the Autologous Blood and Marrow Transplant Registry indicate that approximately 20,000 HSCTs were performed in North America during 1998 (Statistical Center of the International Bone Marrow Transplant Registry and Autologous Blood and Marrow Transplant Registry, unpublished data, 1998)

HSCTs are classified as either allogeneic or autologous on the basis of the source of the transplanted hematopoietic progenitor cells. Cells used in allogeneic HSCTs ar harvested from a donor other than the transplant recipient. Such transplants are the most effective treatment for persons with severe aplastic anemia (*13*) and offer the only curative therapy for persons with chronic myelogenous leukemia (*12*). Allogeneic donors might be a blood relative or an unrelated donor. Allogeneic transplants a usually most successful when the donor is a human lymphocyte antigen (HLA)-identical twin or matched sibling. However, for allogeneic candidates who lack such a donor, registry organizations (e.g., the National Marrow Donor Program) maintain computerized databases that store information regarding HLA type from millions of volunteer donors (*14--16*). Another source of stem cells for allogeneic candidates without an HLA-matched sibling is a mismatched family member (*17,18*). However, persons who receive allogeneic grafts from donors who are not HLA-matched siblings are at a substantially greater risk for graft-versus-host disease (GVHD) (*19*). Th persons are also at increased risk for suboptimal graft function and delayed immune system recovery (*19*). To reduce GVHD among allogeneic HSCTs, techniques hav been developed to remove T-lymphocytes, the principal effectors of GVHD, from the donor graft. Although the recipients of T-lymphocyte--depleted marrow grafts generally have lower rates of GVHD, they also have greater rates of graft rejection, cytomegalovirus (CMV) infection, invasive fungal infection, and Epstein-Barr viru (EBV)-associated posttransplant lymphoproliferative disease (*20*).

The patient's own cells are used in an autologous HSCT. Similar to autologous transplants are syngeneic transplants, among whom the HLA-identical twin serves as th donor. Autologous HSCTs are preferred for patients who require high-level or marrow-ablative chemotherapy to eradicate an underlying malignancy but have healthy,

undiseased bone marrows. Autologous HSCTs are also preferred when the immunologic antitumor effect of an allograft is not beneficial. Autologous HSCTs are used most frequently to treat breast cancer, non-Hodgkin's lymphoma, and Hodgkin's disease (*21*). Neither autologous nor syngeneic HSCTs confer a risk for chronic GVHI

Recently, medical centers have begun to harvest hematopoietic stem cells from placental or umbilical cord blood (UCB) immediately after birth. These harvested cells used primarily for allogeneic transplants among children. Early results demonstrate that greater degrees of histoincompatibility between donor and recipient might be tolerated without graft rejection or GVHD when UCB hematopoietic cells are used (*22--24*). However, immune system function after UCB transplants has not been we studied.

HSCT is also evolving rapidly in other areas. For example, hematopoietic stem cells harvested from the patient's peripheral blood after treatment with hematopoietic colony-stimulating factors (e.g., granulocyte colony-stimulating factor [G-CSF or filgastrim] or granulocyte-macrophage colony-stimulating factor [GM-CSF or sargramostim]) are being used increasingly among autologous recipients (*25*) and are under investigation for use among allogeneic HSCT. Peripheral blood has largely replaced bone marrow as a source of stem cells for autologous recipients. A benefit of harvesting such cells from the donor's peripheral blood instead of bone marrow i that it eliminates the need for general anesthesia associated with bone marrow aspiration.

GVHD is a condition in which the donated cells recognize the recipient's cells as nonself and attack them. Although the use of intravenous immunoglobulin (IVIG) in t routine management of allogeneic patients was common in the past as a means of producing immune modulation among patients with GVHD, this practice has decline because of cost factors (*26*) and because of the development of other strategies for GVHD prophylaxis (*27*). For example, use of cyclosporine GVHD prophylaxis has become commonplace since its introduction during the early 1980s. Most frequently, cyclosporine or tacrolimus (FK506) is administered in combination with other immunosuppressive agents (e.g., methotrexate or corticosteroids) (*27*). Although cyclosporine is effective in preventing GVHD, its use entails greater hazards for infectious complications and relapse of the underlying neoplastic disease for which the transplant was performed.

Although survival rates for certain autologous recipients have improved (*28,29*), infection remains a leading cause of death among allogeneic transplants and is a majo cause of morbidity among autologous HSCTs (*29*). Researchers from the National Marrow Donor Program reported that, of 462 persons receiving unrelated allogeneic HSCTs during December 1987--November 1990, a total of 66% had died by 1991 (*15*). Among primary and secondary causes of death, the most common cause was infection, which occurred among 37% of 307 patients (*15*).**

Despite high morbidity and mortality after HSCT, recipients who survive long-term are likely to enjoy good health. A survey of 798 persons who had received an HSC before 1985 and who had survived for >5 years after HSCT, determined that 93% were in good health and that 89% had returned to work or school full time (*30*). In another survey of 125 adults who had survived a mean of 10 years after HSCT, 88% responded that the benefits of transplantation outweighed the side effects (*31*).

Immune System Recovery After HSCT

During the first year after an HSCT, recipients typically follow a predictable pattern of immune system deficiency and recovery, which begins with the chemotherapy c radiation therapy (i.e., the conditioning regimen) administered just before the HSCT to treat the underlying disease. Unfortunately, this conditioning regimen also destroys normal hematopoiesis for neutrophils, monocytes, and macrophages and damages mucosal progenitor cells, causing a temporary loss of mucosal barrier integrity. The gastrointestinal tract, which normally contains bacteria, commensal fungi, and other bacteria-carrying sources (e.g., skin or mucosa) becomes a reservoir potential pathogens. Virtually all HSCT recipients rapidly lose all T- and B-lymphocytes after conditioning, losing immune memory accumulated through a lifetime of exposure to infectious agents, environmental antigens, and vaccines. Because transfer of donor immunity to HSCT recipients is variable and influenced by the timing c antigen exposure among donor and recipient, passively acquired donor immunity cannot be relied upon to provide long-term immunity against infectious diseases amo HSCT recipients.

During the first month after HSCT, the major host-defense deficits include impaired phagocytosis and damaged mucocutaneous barriers. Additionally, indwelling intravenous catheters are frequently placed and left in situ for weeks to administer parenteral medications, blood products, and nutritional supplements. These catheters serve as another portal of entry for opportunistic pathogens from organisms colonizing the skin (e.g., coagulase-negative *Staphylococci*, *Staphylococcus aureus*, *Candida* species, and *Enterococci*) (*32,33*).

Engraftment for adults and children is defined as the point at which a patient can maintain a sustained absolute neutrophil count (ANC) of >500/mm^3 and sustained platelet count of ≥20,000, lasting ≥3 consecutive days without transfusions. Among unrelated allogeneic recipients, engraftment occurs at a median of 22 days after HSCT (range: 6--84 days) (*15*). In the absence of corticosteroid use, engraftment is associated with the restoration of effective phagocytic function, which results in a decreased risk for bacterial and fungal infections. However, all HSCT recipients and particularly allogeneic recipients, experience an immune system dysfunction for months after engraftment. For example, although allogeneic recipients might have normal total lymphocyte counts within ≥2 months after HSCT, they have abnormal CD4/CD8 T-cell ratios, reflecting their decreased CD4 and increased CD8 T-cell counts (*27*). They might also have immunoglobulin G $(IgG)_2$, IgG_4, and immunoglobulin A (IgA) deficiencies for months after HSCT and have difficulty switching from immunoglobulin M (IgM) to IgG production after antigen exposure (3 Immune system recovery might be delayed further by CMV infection (*34*).

During the first ≥2 months after HSCT, recipients might experience acute GVHD that manifests as skin, gastrointestinal, and liver injury, and is graded on a scale of I-- (*32,35,36*). Although autologous or syngeneic recipients might occasionally experience a mild, self-limited illness that is acute GVHD-like (*19,37*), GVHD occurs primarily among allogeneic recipients, particularly those receiving matched, unrelated donor transplants. GVHD is a substantial risk factor for infection among HSCT recipients because it is associated with a delayed immunologic recovery and prolonged immunodeficiency (*19*). Additionally, the immunosuppressive agents used for GVHD prophylaxis and treatment might make the HSCT recipient more vulnerable to opportunistic viral and fungal pathogens (*38*).

Certain patients, particularly adult allogeneic recipients, might also experience chronic GVHD, which is graded as either limited or extensive chronic GVHD (*19,39*). Chronic GVHD appears similar to autoimmune, connective-tissue disorders (e.g., scleroderma or systemic lupus erythematosus) (*40*) and is associated with cellular an humoral immunodeficiencies, including macrophage deficiency, impaired neutrophil chemotaxis (*41*), poor response to vaccination (*42--44*), and severe mucositis (*19* Risk factors for chronic GVHD include increasing age, allogeneic HSCT (particularly those among whom the donor is unrelated or a non-HLA identical family membe (*40*), and a history of acute GVHD (*24,45*). Chronic GVHD was first described as occurring >100 days after HSCT but can occur 40 days after HSCT (*19*). Although allogeneic recipients with chronic GVHD have normal or high total serum immunoglobulin levels (*41*), they experience long-lasting IgA, IgG, and IgG subclass deficiencies (*41,46,47*) and poor opsonization and impaired reticuloendothelial function. Consequently, they are at even greater risk for infections (*32,39*), particularly life-threatening bacterial infections from encapsulated organisms (e.g., *Stre. pneumoniae*, *Ha. influenzae*, or *Ne. meningitidis*). After chronic GVHD resolves, which might take years, cell-mediated and humoral immunity function are gradually restored.

Opportunistic Pathogens After HSCT

HSCT recipients experience certain infections at different times posttransplant, reflecting the predominant host-defense defect(s) (Figure). Immune system recovery fo HSCT recipients takes place in three phases beginning at day 0, the day of transplant. Phase I is the preengraftment phase (<30 days after HSCT); phase II, the postengraftment phase (30--100 days after HSCT); and phase III, the late phase (>100 days after HSCT). Prevention strategies should be based on these three phases a the following information:

- **Phase I, preengraftment.** During the first month posttransplant, HSCT recipients have two critical risk factors for infection --- prolonged neutropenia and break in the mucocutaneous barrier resulting from the HSCT preparative regimens and frequent vascular access required for patient care. Consequently, oral, gastro-intestinal, and skin flora are sources of infection. Prevalent pathogens include *Candida* species, and as neutropenia continues, *Aspergillus* species. Additionally, herpes simplex virus (HSV) reactivation can occur during this phase. During preengraftment, the risks for infection are the same for autologous or allogeneic patients, and OIs can appear as febrile neutropenia. Although a recipient's first fever during preengraftment is probably caused by a bacterial pathogen, rarely is a organism or site of infection identified. Instead, such infections are usually treated preemptively or empirically (*48*) until the neutropenia resolves (*49*). Growth factors can be administered during phase I to decrease neutropenia duration and complications (e.g., febrile neutropenia) (*50*).
- **Phase II, postengraftment.** Phase II is dominated by impaired cell-mediated immunity for allogeneic or autologous recipients. Scope and impact of this defect f allogeneic recipients are determined by the extent of GVHD and its immunosuppressive therapy. After engraftment, the herpes viruses, particularly CMV, are

critical pathogens. At 30--100 days after HSCT, CMV causes pneumonia, hepatitis, and colitis and potentiates superinfection with opportunistic pathogens, particularly among patients with active GVHD. Other dominant pathogens during this phase include *Pneumocystis carinii* and *Aspergillus* species.

- **Phase III, late phase.** During phase III, autologous recipients usually have more rapid recovery of immune system function and, therefore, a lower risk for OIs than do allogeneic recipients. Because of cell-mediated and humoral immunity defects and impaired reticuloendothelial system function, allogeneic patients with chronic GVHD and recipients of alternate donor allogeneic transplants are at risk for certain infections during this phase. Alternate donors include matched unrelated, UCB, or mismatched family-related donors. These patients are at risk for infections that include CMV, varicella-zoster virus (VZV), EBV-related posttransplant lymphoproliferative disease, community-acquired respiratory viruses (CRV), and infections with encapsulated bacteria (e.g., *Ha. influenzae* and *S. pneumoniae*). Risk for these infections is approximately proportional to the severity of the patient's GVHD during phases II and III. Patients receiving mismatche allogeneic transplants have a higher attack rate and severity of GVHD and, therefore, a higher risk for OIs during phases II and III than do patients receiving matched allogeneic HSCTs. In contrast, patients undergoing autologous transplantation are primarily at risk for infection during phase I.

Preventing infections among HSCT recipients is preferable to treating infections. How ever, despite recent technologic advances, more research is needed to optimize health outcomes for HSCT recipients. Efforts to improve immune system reconstitution, particularly among allogeneic transplant recipients, and to prevent or resolve t immune dysregulation resulting from donor-recipient histoincompatibility and GVHD remain substantial challenges for preventing recurrent, persistent, or progressive infections among HSCT patients.

BACTERIAL INFECTIONS

General Recommendations

Preventing Exposure

Because bacteria are carried on the hands, health-care workers (HCWs) and others in contact with HSCT recipients should routinely follow appropriate hand-washing practices to avoid exposing recipients to bacterial pathogens (AIII).

Preventing Disease

Preventing Early Disease (0--100 Days After HSCT). Routine gut decontamination is not recommended for HSCT candidates (51--53) (DIII). Because of limited data no recommendations can be made regarding the routine use of antibiotics for bacterial prophylaxis among afebrile, asymptomatic neutropenic recipients. Although studies have reported that using prophylactic antibiotics might reduce bacteremia rates after HSCT (51), infection-related fatality rates are not reduced (52). If physicia choose to use prophylactic antibiotics among asymptomatic, afebrile, neutropenic recipients, they should routinely review hospital and HSCT center antibiotic-susceptibility profiles, particularly when using a single antibiotic for antibacterial prophylaxis (BIII). The emergence of fluoquinolone-resistant coagulase-negative *Staphylococci* and *Es. coli* (51,52), vancomycin-intermediate *Sta. aureus* and vancomycin-resistant *Enterococcus* (VRE) are increasing concerns (54). Vancomycin should not be used as an agent for routine bacterial prophylaxis (DIII). Growth factors (e.g., GM-CSF and G-CSF) shorten the duration of neutropenia after HSCT (55) however, no data were found that indicate whether growth factors effectively reduce the attack rate of invasive bacterial disease.

Physicians should not routinely administer IVIG products to HSCT recipients for bacterial infection prophylaxis (DII), although IVIG has been recommended for use i producing immune system modulation for GVHD prevention. Researchers have recommended routine IVIG*** use to prevent bacterial infections among the approximately 20%--25% of HSCT recipients with unrelated marrow grafts who experience severe hypogamma-globulinemia (e.g., IgG < 400 mg/dl) within the first 1 days after transplant (CIII). For example, recipients who are hypogammaglobulinemic might receive prophylactic IVIG to prevent bacterial sinopulmonary infections (e.g., from *Stre. pneumoniae*) (*8*) (CIII). For hypogammaglobulinemic allogeneic recipients, physicians can use a higher and more frequent dose of IVIG than is standa for non-HSCT recipients because the IVIG half-life among HSCT recipients (generally 1--10 days) is much shorter than the half-life among healthy adults (generally 1 -23 days) (*56--58*). Additionally, infections might accelerate IgG catabolism; therefore, the IVIG dose for a hypogammaglobulinemic recipient should be individualized to maintain trough serum IgG concentrations >400--500 mg/dl (*58*) (BII). Consequently, physicians should monitor trough serum IgG concentrations among these patients approximately every 2 weeks and adjust IVIG doses as needed (BIII) (Appendix).

Preventing Late Disease (>100 Days After HSCT). Antibiotic prophylaxis is recommended for preventing infection with encapsulated organisms (e.g., *Stre. pneumoni Ha. influenzae*, or *Ne. meningitidis*) among allogeneic recipients with chronic GVHD for as long as active chronic GVHD treatment is administered (*59*) (BIII). Antibiotic selection should be guided by local antibiotic resistance patterns. In the absence of severe demonstrable hypogammaglobulinemia (e.g., IgG levels < 400 mg/dl, which might be associated with recurrent sinopulmonary infections), routine monthly IVIG administration to HSCT recipients >90 days after HSCT is not recommended (*60*) (DI) as a means of preventing bacterial infections.

Other Disease Prevention Recommendations. Routine use of IVIG among autologous recipients is not recommended (*61*) (DII). Recommendations for preventing bacterial infections are the same among pediatric or adult HSCT recipients.

Recommendations Regarding *Stre. pneumoniae*

Preventing Exposure

Appropriate care precautions should be taken with hospitalized patients infected with *Stre. pneumoniae* (*62,63*) (BIII) to prevent exposure among HSCT recipients.

Preventing Disease

Information regarding the currently available 23-valent pneumococcal polysaccharide vaccine indicates limited immunogenicity among HSCT recipients. However, because of its potential benefit to certain patients, it should be administered to HSCT recipients at 12 and 24 months after HSCT (*64--66*) (BIII). No data were found regarding safety and immunogenicity of the 7-valent conjugate pneumococcal vaccine among HSCT recipients; therefore, no recommendation regarding use of this vaccine can be made.

Antibiotic prophylaxis is recommended for preventing infection with encapsulated organisms (e.g., *Stre. pneumoniae*, *Ha. influenzae*, and *Ne. meningitidis*) among allogeneic recipients with chronic GVHD for as long as active chronic GVHD treatment is administered (*59*) (BIII). Trimethoprim-sulfamethasaxole (TMP-SMZ) administered for *Pneumocystis carinii* pneumonia (PCP) prophylaxis will also provide protection against pneumococcal infections. However, no data were found to support using TMP-SMZ prophylaxis among HSCT recipients solely for the purpose of preventing *Stre. pneumoniae* disease. Certain strains of *Stre. pneumoniae* are resistant to TMP-SMZ and penicillin. Recommendations for preventing pneumococcal infections are the same for allogeneic or autologous recipients.

As with adults, pediatric HSCT recipients aged ≥2 years should be administered the current 23-valent pneumococcal polysaccharide vaccine because the vaccine can b effective (BIII). However, this vaccine should not be administered to children aged <2 years because it is not effective among that age population (DI). No data were found regarding safety and immunogenicity of the 7-valent conjugate pneumococcal vaccine among pediatric HSCT recipients; therefore, no recommendation regardir use of this vaccine can be made.

Recommendations Regarding *Streptococci viridans*

Preventing Exposure

Because *Streptococci viridans* colonize the oropharynx and gut, no effective method of preventing exposure is known.

Preventing Disease

Chemotherapy-induced oral mucositis is a potential source of *Streptococci viridans* bacteremia. Consequently, before conditioning starts, dental consults should be obtained for all HSCT candidates to assess their state of oral health and to perform any needed dental procedures to decrease the risk for oral infections after transplant (*67*) (AIII).

Generally, HSCT physicians should not use prophylactic antibiotics to prevent *Streptococci viridans* infections (DIII). No data were found that demonstrate efficacy of prophylactic antibiotics for this infection. Furthermore, such use might select antibiotic-resistant bacteria, and in fact, penicillin- and vancomycin-resistant strains of *Streptococci viridans* have been reported (*68*). However, when *Streptococci viridans* infections among HSCT recipients are virulent and associated with overwhelming sepsis and shock in an institution, prophylaxis might be evaluated (CIII). Decisions regarding the use of *Streptococci viridans* prophylaxis should be made only after consultation with the hospital epidemiologists or infection-control practitioners who monitor rates of nosocomial bacteremia and bacterial susceptibility (BIII).

HSCT physicians should be familiar with current antibiotic susceptibilities for patient isolates from their HSCT centers, including *Streptococci viridans* (BIII). Physici should maintain a high index of suspicion for this infection among HSCT recipients with symptomatic mucositis because early diagnosis and aggressive therapy are currently the only potential means of preventing shock when severely neutropenic HSCT recipients experience *Streptococci viridans* bacteremia (*69*).

Recommendations Regarding *Ha. influenzae* type b

Preventing Exposure

Adults with *Ha. influenzae* type b (Hib) pneumonia require standard precautions (*62*) to prevent exposing the HSCT recipient to Hib. Adults and children who are in contact with the HSCT recipient and who have known or suspected invasive Hib disease, including meningitis, bacteremia, or epiglottitis, should be placed in droplet precautions until 24 hours after they begin appropriate antibiotic therapy, after which they can be switched to standard precautions. Household contacts exposed to persons with Hib disease and who also have contact with HSCT recipients should be administered rifampin prophylaxis according to published recommendations (*70,71*); prophylaxis for household contacts of a patient with Hib disease are necessary if all contacts aged <4 years are not fully vaccinated (BIII) (Appendix). This recommendation is critical because the risk for invasive Hib disease among unvaccinated household contacts aged <4 years is increased, and rifampin can be effective eliminating Hib carriage and preventing invasive Hib disease (*72--74*). Pediatric household contacts should be up-to-date with Hib vaccinations to prevent possible Hit exposure to the HSCT recipient (AII).

Preventing Disease

Although no data regarding vaccine efficacy among HSCT recipients were found, Hib conjugate vaccine should be administered to HSCT recipients at 12, 14, and 24 months after HSCT (BII). This vaccine is recommended because the majority of HSCT recipients have low levels of Hib capsular polysaccharide antibodies ≥4 months after HSCT (*75*), and allogeneic recipients with chronic GVHD are at increased risk for infection from encapsulated organisms (e.g., Hib) (*76,77*). HSCT recipients wh are exposed to persons with Hib disease should be offered rifampin prophylaxis according to published recommendations (*70*) (BIII) (Appendix).

Antibiotic prophylaxis is recommended for preventing infection with encapsulated organisms (e.g., *Stre. pneumoniae*, *Ha. influenzae*, or *Ne. meningitidis*) among allogeneic recipients with chronic GVHD for as long as active chronic GVHD treatment is administered (*59*) (BIII). Antibiotic selection should be guided by local antibiotic-resistance patterns. Recommendations for preventing Hib infections are the same for allogeneic or autologous recipients. Recommendations for preventing H disease are the same for pediatric or adult HSCT recipients, except that any child infected with Hib pneumonia requires standard precautions with droplet precautions added for the first 24 hours after beginning appropriate antibiotic therapy (*62,70*) (BIII). Appropriate pediatric doses should be administered for Hib conjugate vaccine and for rifampin prophylaxis (*71*) (Appendix).

VIRAL INFECTIONS

Recommendations Regarding Cytomegalovirus

Preventing Exposure

HSCT candidates should be tested for the presence of serum anti-CMV IgG antibodies before transplantation to determine their risk for primary CMV infection and reactivation after HSCT (AIII). Only Food and Drug Administration (FDA) licensed or approved tests should be used. HSCT recipients and candidates should avoid sharing cups, glasses, and eating utensils with others, including family members, to decrease the risk for CMV exposure (BIII).

Sexually active patients who are not in long-term monogamous relationships should always use latex condoms during sexual contact to reduce their risk for exposure t CMV and other sexually transmitted pathogens (AII). However, even long-time monogamous pairs can be discordant for CMV infections. Therefore, during periods of immuno-compromise, sexually active HSCT recipients in monogamous relationships should ask partners to be tested for serum CMV IgG antibody, and discordant couples should use latex condoms during sexual contact to reduce the risk for exposure to this sexually transmitted OI (CIII).

After handling or changing diapers or after wiping oral and nasal secretions, HSCT candidates and recipients should practice regular hand washing to reduce the risk fo CMV exposure (AII). CMV-seronegative recipients of allogeneic stem cell transplants from CMV-seronegative donors (i.e., R-negative or D-negative) should receive only leukocyte-reduced or CMV-seronegative red cells or leukocyte-reduced platelets (<1 x 10^6 leukocytes/unit) to prevent transfusion-associated CMV infection (*78*) (AI). However, insufficient data were found to recommend use of leukocyte-reduced or CMV-seronega tive red cells and platelets among CMV-seronegative recipients who have CMV-seropositive donors (i.e., R-negative or D-positive).

All HCWs should wear gloves when handling blood products or other potentially contaminated biologic materials (AII) to prevent transmission of CMV to HSCT recipients. HSCT patients who are known to excrete CMV should be placed under standard precautions (*62*) for the duration of CMV excretion to avoid possible transmission to CMV-seronegative HSCT recipients and candidates (AIII). Physicians are cautioned that CMV excretion can be episodic or prolonged.

Preventing Disease and Disease Recurrence

HSCT recipients at risk for CMV disease after HSCT (i.e., all CMV-seropositive HSCT recipients, and all CMV-seronegative recipients with a CMV-seropositive donc should be placed on a CMV disease prevention program from the time of engraftment until 100 days after HSCT (i.e., phase II) (AI). Physicians should use either prophylaxis or preemptive treatment with ganciclovir for allogeneic recipients (AI). In selecting a CMV disease prevention strategy, physicians should assess the risks and benefits of each strategy, the needs and condition of the patient, and the hospital's virology laboratory support capability.

Prophylaxis strategy against early CMV (i.e., <100 days after HSCT) for allogeneic recipients involves administering ganciclovir prophylaxis to all allogeneic recipien at risk throughout phase II (i.e., from engraftment to 100 days after HSCT). The induction course is usually started at engraftment (AI), although physicians can add a brief prophylactic course during HSCT preconditioning (CIII) (Appendix).

Preemptive strategy against early CMV (i.e., <100 days after HSCT) for allogeneic recipients is preferred over prophylaxis for CMV-seronegative HSCT recipients of seropositive donor cells (i.e., D-positive or R-negative) because of the low attack rate of active CMV infection if screened or filtered blood product support is used (BI Preemptive strategy restricts ganciclovir use for those patients who have evidence of CMV infection after HSCT. It requires the use of sensitive and specific laboratory tests to rapidly diagnose CMV infection after HSCT and to enable immediate administration of ganciclovir after CMV infection has been detected. Allogeneic recipien at risk should be screened ≥1 times/week from 10 days to 100 days after HSCT (i.e., phase II) for the presence of CMV viremia or antigenemia (AIII).

HSCT physicians should select one of two diagnostic tests to determine the need for preemptive treatment. Currently, the detection of CMV pp65 antigen in leukocytes (antigenemia) (*79,80*) is preferred for screening for preemptive treatment because it is more rapid and sensitive than culture and has good positive predictive value (*79- -81*). Direct detection of CMV-DNA (deoxyribonucleic acid) by polymerase chain reaction (PCR) (*82*) is very sensitive but has a low positive predictive value (*79*).

Although CMV-DNA PCR is less sensitive than whole blood or leukocyte PCR, plasma CMV-DNA PCR is useful during neutropenia, when the number of leukocytes/slide is too low to allow CMV pp65 antigenemia testing.

Virus culture of urine, saliva, blood, or bronchoalveolar washings by rapid shell-vial culture (*83*) or routine culture (*84,85*) can be used; however, viral culture techniqu are less sensitive than CMV-DNA PCR or CMV pp65 antigenemia tests. Also, rapid shell-viral cultures require ≥48 hours and routine viral cultures can require weeks obtain final results. Thus, viral culture techniques are less satisfactory than PCR or antigenemia tests. HSCT centers without access to PCR or antigenemia tests should use prophylaxis rather than preemptive therapy for CMV disease prevention (*86*) (BII). Physicians do use other diagnostic tests (e.g., hybrid capture CMV-DNA assay, Version 2.0 [*87*] or CMV pp67 viral RNA [ribonucleic acid] detection) (*88*); however, limited data were found regarding use among HSCT recipients, and therefore, nc recommendation for use can be made.

Allogeneic recipients ≤100 days after HSCT (i.e., during phase II) should begin preemptive treatment with ganciclovir if CMV viremia or any antigenemia is detected if the recipient has ≥2 consecutively positive CMV-DNA PCR tests (BIII). After preemptive treatment has been started, maintenance ganciclovir is usually continued until 100 days after HSCT or for a minimum of 3 weeks, whichever is longer (AI) (Appendix). Antigen or PCR tests should be negative when ganciclovir is stopped. Studies report that a shorter course of ganciclovir (e.g., for 3 weeks or until negative PCR or antigenemia occurs) (*89--91*) might provide adequate CMV prevention wi less toxicity, but routine weekly screening by pp65 antigen or PCR test is necessary after stopping ganciclovir because CMV reactivation can occur (BIII).

Presently, only the intravenous formulation of ganciclovir has been approved for use in CMV prophylactic or preemptive strategies (BIII). No recommendation for ora ganciclovir use among HSCT recipients can be made because clinical trials evaluating its efficacy are still in progress. One group has used ganciclovir and foscarnet or alternate days for CMV prevention (*92*), but no recommendation can be made regarding this strategy because of limited data. Patients who are ganciclovir-intolerant should be administered foscarnet instead (*93*) (BII) (Appendix). HSCT recipients receiving ganciclovir should have ANCs checked ≥2 times/week (BIII). Researchers report managing ganciclovir-associated neutropenia by adding G-CSF (*94*) or temporarily stopping ganciclovir for ≥2 days if the patient's ANC is <1,000 (CIII). Ganciclovir can be restarted when the patient's ANC is ≥1,000 for 2 consecutive days. Alternatively, researchers report substituting foscarnet for ganciclovir if a) the HSCT recipient is still CMV viremic or antigenemic or b) the ANC remains <1,000 for >5 days after ganciclovir has been stopped (CIII) (Appendix). Because neutropenia accompanying ganciclovir administration is usually brief, such patients do not require antifungal or antibacterial prophylaxis (DIII).

Currently, no benefit has been reported from routinely administering ganciclovir prophylaxis to all HSCT recipients at >100 days after HSCT (i.e., during phase III). However, persons with high risk for late CMV disease should be routinely screened biweekly for evidence of CMV reactivation as long as substantial immunocompromise persists (BIII). Risk factors for late CMV disease include allogeneic HSCT accompanied by chronic GVHD, steroid use, low CD4 counts, delay i high avidity anti-CMV antibody, and recipients of matched unrelated or T-cell--depleted HSCTs who are at high risk (*95--99*). If CMV is still detectable by routine screening ≥100 days after HSCT, ganciclovir should be continued until CMV is no longer detectable (AI). If low-grade CMV antigenemia (<5 positive cells/slide) is detected on routine screening, the antigenemia test should be repeated in 3 days (BIII). If CMV antigenemia indicates ≥5 cells/slide, PCR is positive, or the shell-vial culture detects CMV viremia, a 3-week course of preemptive ganciclovir treatment should be administered (BIII) (Appendix). Ganciclovir should also be started if the patient has had ≥2 consecutively positive viremia or PCR tests (e.g., in a person receiving steroids for GVHD or who received ganciclovir or foscarnet at <100 days afl HSCT). Current investigational strategies for preventing late CMV disease include the use of targeted prophylaxis with antiviral drugs and cellular immunotherapy for those with deficient or absent CMV-specific immune system function.

If viremia persists after 4 weeks of ganciclovir preemptive therapy or if the level of antigenemia continues to rise after 3 weeks of therapy, ganciclovir-resistant CMV should be suspected. If CMV viremia recurs during continuous treatment with ganciclovir, researchers report restarting ganciclovir induction (*100*) or stopping ganciclovir and starting foscarnet (CIII). Limited data were found regarding the use of foscarnet among HSCT recipients for either CMV prophylaxis or preemptive therapy (*92,93*).

Infusion of donor-derived CMV-specific clones of CD8+ T-cells into the transplant recipient is being evaluated under FDA Investigational New Drug authorization; therefore, no recommendation can be made. Although, in a substantial cooperative study, high-dose acyclovir has had certain efficacy for preventing CMV disease (*10* its utility is limited in a setting where more potent anti-CMV agents (e.g., ganciclovir) are used (*102*). Acyclovir is not effective in preventing CMV disease after autologous HSCT (*103*) and is, therefore, not recommended for CMV preemptive therapy (DII). Consequently, valacyclovir, although under study for use among HSC recipients, is presumed to be less effective than ganciclovir against CMV and is currently not recommended for CMV disease prevention (DII).

Although HSCT physicians continue to use IVIG for immune system modulation, IVIG is not recommended for CMV disease prophylaxis among HSCT recipients (D Cidofovir, a nucleoside analog, is approved by FDA for the treatment of AIDS-associated CMV retinitis. The drug's major disadvantage is nephrotoxicity. Cidofovir is currently in FDA phase 1 trial for use among HSCT recipients; therefore, recommendations for its use cannot be made.

Use of CMV-negative or leukocyte-reduced blood products is not routinely required for all autologous recipients because most have a substantially lower risk for CMV disease. However, CMV-negative or leukocyte-reduced blood products can be used for CMV-seronegative autologous recipients (CIII). Researchers report that CMV-seropositive autologous recipients be evaluated for preemptive therapy if they have underlying hematologic malignancies (e.g., lymphoma or leukemia), are receiving intense conditioning regimens or graft manipulation, or have recently received fludarabine or 2-chlorodeoxyadenosine (CDA) (CIII). This subpopulation of autologous recipients should be monitored weekly from time of engraftment until 60 days after HSCT for CMV reactivation, preferably with quantitative CMV pp65 antigen (*80*) quantitative PCR (BII).

Autologous recipients at high risk who experience CMV antigenemia (i.e., blood levels of ≥5 positive cells/slide) should receive 3 weeks of preemptive treatment with ganciclovir or foscarnet (*80*), but CD34+-selected patients should be treated at any level of antigenemia (BII) (Appendix). Prophylactic approach to CMV disease prevention is not appropriate for CMV-seropositive autologous recipients. Indications for the use of CMV prophylaxis or preemptive treatment are the same for childre or adults.

Recommendations Regarding EBV

Preventing Exposure

All transplant candidates, particularly those who are EBV-seronegative, should be advised of behaviors that could decrease the likelihood of EBV exposure (AII). For example, HSCT recipients and candidates should follow safe hygiene practices (e.g., frequent hand washing [AIII] and avoiding the sharing of cups, glasses, and eating utensils with others) (*104*) (BIII), and they should avoid contact with potentially infected respiratory secretions and saliva (*104*) (AII).

Preventing Disease

Infusion of donor-derived, EBV-specific cytotoxic T-lymphocytes has demonstrated promise in the prophylaxis of EBV-lymphoma among recipients of T-cell--depleted unrelated or mismatched allogeneic recipients (*105,106*). However, insufficient data were found to recommend its use. Prophylaxis or preemptive therapy with acyclov is not recommended because of lack of efficacy (*107,108*) (DII).

Recommendations Regarding HSV

Preventing Exposure

HSCT candidates should be tested for serum anti-HSV IgG before transplant (AIII); however, type-specific anti-HSV IgG serology testing is not necessary. Only FDA licensed or -approved tests should be used. All HSCT candidates, particularly those who are HSV-seronegative, should be informed of the importance of avoiding HSV infection while immunocompromised and should be advised of behaviors that will decrease the likelihood of HSV exposure (AII). HSCT recipients and candidates should avoid sharing cups, glasses, and eating utensils with others (BIII). Sexually active patients who are not in a long-term monogamous relationship should always latex condoms during sexual contact to reduce the risk for exposure to HSV as well as other sexually transmitted pathogens (AII). However, even long-time monogam pairs can be discordant for HSV infections. Therefore, during periods of immunocompromise, sexually active HSCT recipients in such relationships should ask partner

to be tested for serum HSV IgG antibody. If the partners are discordant, they should consider using latex condoms during sexual contact to reduce the risk for exposure this sexually transmitted OI (CIII). Any person with disseminated, primary, or severe mucocutaneous HSV disease should be placed under contact precautions for the duration of the illness (*62*) (AI) to prevent transmission of HSV to HSCT recipients.

Preventing Disease and Disease Recurrence

Acyclovir. Acyclovir prophylaxis should be offered to all HSV-seropositive allogeneic recipients to prevent HSV reactivation during the early posttransplant period (*10 -113*) (AI). Standard approach is to begin acyclovir prophylaxis at the start of the conditioning therapy and continue until engraftment occurs or until mucositis resolve whichever is longer, or approximately 30 days after HSCT (BIII) (Appendix). Without supportive data from controlled studies, routine use of antiviral prophylaxis for >30 days after HSCT to prevent HSV is not recommended (DIII). Routine acyclovir prophylaxis is not indicated for HSV-seronegative HSCT recipients, even if the donors are HSV-seropositive (DIII). Researchers have proposed administration of ganciclovir prophylaxis alone (*86*) to HSCT recipients who required simultaneous prophylaxis for CMV and HSV after HSCT (CIII) because ganciclovir has in vitro activity against CMV and HSV 1 and 2 (*114*), although ganciclovir has not been approved for use against HSV.

Valacyclovir. Researchers have reported valacyclovir use for preventing HSV among HSCT recipients (CIII); however, preliminary data demonstrate that very high do of valacyclovir (8 g/day) were associated with thrombotic thrombocytopenic purpura/hemolytic uremic syndrome among HSCT recipients (*115*). Controlled trial data among HSCT recipients are limited (*115*), and the FDA has not approved valacyclovir for use among recipients. Physicians wishing to use valacyclovir among recipier with renal impairment should exercise caution and decrease doses as needed (BIII) (Appendix).

Foscarnet. Because of its substantial renal and infusion-related toxicity, foscarnet is not recommended for routine HSV prophylaxis among HSCT recipients (DIII).

Famciclovir. Presently, data regarding safety and efficacy of famciclovir among HSCT recipients are limited; therefore, no recommendations for HSV prophylaxis wit famciclovir can be made.

Other Recommendations

HSV prophylaxis lasting >30 days after HSCT might be considered for persons with frequent recurrent HSV (CIII) (Appendix). Acyclovir can be used during phase I f administration to HSV-seropositive autologous recipients who are likely to experience substantial mucositis from the conditioning regimen (CIII). Antiviral prophylaxi doses should be modified for use among children (Appendix), but no published data were found regarding valacyclovir safety and efficacy among children.

Recommendations Regarding VZV

Preventing Exposure

HSCT candidates should be tested for the presence of serum anti-VZV IgG antibodies (AIII). However, these tests are not 100% reliable, particularly among severely immunosuppressed patients. Researchers recommend that a past history of varicella accompanied by a positive titer is more likely to indicate the presence of immunity VZV than a low positive titer alone. All HSCT candidates and recipients, particularly those who are VZV-seronegative, should be informed of the potential seriousness VZV disease among immunocompromised persons and advised of strategies to decrease their risk for VZV exposure (*116--122*) (AII).

Although researchers report that the majority of VZV disease after HSCT is caused by reactivation of endogenous VZV, HSCT candidates and recipients who are VZV seronegative, or VZV-seropositive and immunocompromised, should avoid exposure to persons with active VZV infections (*123*) (AII). HCWs, family members, household contacts, and visitors who are healthy and do not have a reported history of varicella infection or who are VZV-seronegative should receive VZV vaccinatio before being allowed to visit or have direct contact with an HSCT recipient (AIII). Ideally, VZV-susceptible family members, household contacts, and potential visitors immunocompromised HSCT recipients should be vaccinated as soon as the decision is made to perform HSCT. The vaccination dose or doses should be completed ≥4 weeks before the conditioning regimen begins or ≥6 weeks (42 days) before the HSCT is performed (BIII).

HSCT recipients and candidates undergoing conditioning therapy should avoid contact with any VZV vaccine recipient who experiences a rash after vaccination (BIII) When this rash occurs, it usually appears 14--21 days after VZV vaccination (median: 22 days; range: 5--35 days) (personal communication from Robert G. Sharrar, M.D., Merck & Co., Inc.). However, to date, no serious disease has been reported among immuno-compromised patients from transmission of VZV vaccine virus, and the VZV vaccine strain is susceptible to acyclovir.

All HSCT recipients with VZV disease should be placed under airborne and contact precautions (*62*) (AII) to prevent transmission to other HSCT recipients. Contact precautions should be continued until all skin lesions are crusted. Airborne precautions should be instituted 10 days after exposure to VZV and continued until 21 days after last exposure or 28 days postexposure if the patient received varicella-zoster immunoglobulin (VZIG)**** (*62*) (AI) because a person infected with VZV can be infectious before the rash appears.

Preventing Disease

VZIG. VZV-seronegative HSCT recipients should be administered VZIG as soon as possible but ideally within 96 hours after close or household contact with a person having either chickenpox or shingles if the HSCT recipient is not immunocompetent (i.e., allogeneic patient <24 months after HSCT, ≥24 months after HSCT and on immunosuppressive therapy, or having chronic GVHD) (AII). Researchers report VZIG administration for VZV exposure as described for HSCT recipients who were VZV-seropositive before HSCT (CIII).

Because of the high morbidity of VZV-associated disease among severely immunocompromised HSCT recipients and until further data are published, HSCT physician should administer VZIG to all VZV-seronegative HSCT recipients or candidates undergoing conditioning therapy who are exposed to a VZV vaccinee having a varicel like rash (BIII). Researchers also report VZIG administration for this situation for VZV-seropositive HSCT recipients and candidates undergoing conditioning therapy (CIII). These recommendations are made because the vaccinee might be unknowingly incubating wild-type varicella, particularly during the first 14 days after varicella vaccination, and because vaccine-strain VZV has been rarely transmitted by VZV vaccinees with vesicular rashes postvaccination (*121*).

If VZV-seronegative HSCT recipients or candidates undergoing conditioning therapy are closely exposed to varicella >3 weeks after receiving VZIG, they should be administered another dose of VZIG (*120*) (BIII). Researchers also recommend VZIG administration for this condition for VZV-seropositive HSCT recipients and candidates undergoing conditioning therapy (CIII).

Antiviral Drugs. Any HSCT recipient or candidate undergoing conditioning therapy who experiences a VZV-like rash (particularly after exposure to a person with wil type varicella or shingles) should receive preemptive intravenous acyclovir until ≥2 days after all lesions have crusted (BIII) (Appendix). Any HSCT recipient or candidate undergoing conditioning therapy who experiences a VZV-like rash after exposure to a VZV vaccinee with a rash should be administered intravenous acyclov preemptively to prevent severe, disseminated VZV disease (BII). Acyclovir should be administered until 2 days after all lesions have crusted.

Long-term acyclovir prophylaxis to prevent recurrent VZV infection (e.g., during the first 6 months after HSCT) is not routinely recommended (*124--126*) (DIII); however, this therapy could be considered for use among HSCT recipients with severe, long-term immunodeficiency (CIII). When acyclovir resistance occurs among patients, HSCT physicians should use foscarnet for preemptive treatment of VZV disease (*127*) (BIII). Researchers report valacyclovir use for preventing HSV among HSCT recipients (CIII). However, preliminary data demonstrate that very high doses of valacyclovir (8 g/day) were associated with thrombotic thrombocytopenic purpura/hemolytic uremic syndrome among HSCT recipients (*115*). Controlled trial data regarding HSCT recipients are limited (*115*), and the FDA has not approved valacyclovir for use among HSCT recipients. Physicians wishing to use valacyclovir among HSCT recipients with renal impairment should exercise caution and decrea doses as needed (BIII) (Appendix). No data were found demonstrating safety and efficacy of preemptive treatment of famciclovir against herpes zoster among HSCT recipients. Consequently, no recommendation for its use can be made.

Live-Attenuated VZV Vaccine. VZV vaccine use is contraindicated among HSCT recipients <24 months after HSCT (*128*) (EIII). Use of VZV vaccine among HSCT recipients is restricted to research protocols for recipients ≥24 months after HSCT who are presumed immunocompetent. Further research is needed to determine the safety, immunogenicity, and efficacy of VZV vaccine among HSCT recipients.

Other Recommendations

An inactivated VZV vaccine has been used investigationally among HSCT recipients (*129*); however, more studies are needed before a recommendation regarding its u can be made. Recommendations for VZV prevention are the same for allogeneic or autologous recipients. Recommendations for preventing VZV disease among pedia or adult HSCT recipients are the same, except that appropriate dose adjustments for VZIG should be made for pediatric HSCT recipients (AIII) (Appendix).

Recommendations Regarding CRV Infections: Influenza, Respiratory Syncytial Virus, Parainfluenza Virus, and Adenovirus

Preventing Exposure

Preventing CRV exposure is critical in preventing CRV disease (*130,131*). To prevent nosocomial CRV transmission, HSCT recipients and their HCWs should always follow HSCT infection control guidelines (AIII). To minimize the risk for CRV transmission, HCWs and visitors with upper respiratory infection (URI) symptoms sho be restricted from contact with HSCT recipients and HSCT candidates undergoing conditioning therapy (AIII). At a minimum, active clinical surveillance for CRV disease should be conducted on all hospitalized HSCT recipients and candidates undergoing conditioning therapy; this clinical surveillance should include daily screen for signs and symptoms of CRV (e.g., URI or lower respiratory infection [LRI]) (AIII). Viral cultures of asymptomatic HSCT candidates are unlikely to be useful. HSC recipients with URI or LRI symptoms should be placed under contact precautions to avoid transmitting infection to other HSCT candi dates and recipients, HCWs, and visitors until the etiology of illness is identified (*62*) (BIII). Optimal isolation precautions should be modified as needed after the etiology is identified (AIII). HSCT recipients and candidates, their family members and visitors, and all HCWs should be informed regarding CRV infection control measures and the potential severity of CRV infections among HSCT recipients (*130--140*) (BIII). Physicians have routinely conducted culture-based CRV surveillance among HSCT recipients; however, the cost effectiveness of this approach has not been evaluated.

Influenza vaccination of family members and close or household contacts is strongly recommended during each influenza season (i.e., October--May) starting the seas before HSCT and continuing ≥24 months after HSCT (*141*) (AI) to prevent influenza exposure among the recipients or candidates. All family members and close or household contacts of HSCT recipients who remain immunocompromised ≥24 months after HSCT should continue to be vaccinated annually as long as the HSCT recipient's immuno-compromise persists (*141*) (AI). Seasonal influenza vaccination is strongly recommended for all HCWs of HSCT recipients (*142,143*) (AI).

If HCWs, family members, or other close contacts of HSCT recipients receive influenza vaccination during an influenza A outbreak, they should receive amantadine o rimantadine chemoprophylaxis for 2 weeks after influenza vaccination (BI) while the vaccinee experiences an immunologic response to the vaccine. Such a strategy is likely to prevent transmission of influenza A to HCWs and other close contacts of HSCT recipients, which could prevent influenza A transmission to HSCT recipients themselves. However, if a nosocomial outbreak occurs with an influenza A strain that is not contained in the available influenza vaccine, all healthy family members, close and household contacts, and HCWs of HSCT recipients and candidates should be administered influenza A chemoprophylaxis with amantadine or rimantadine un the end of the outbreak (*141*) (BIII).

In 1999, two neuroaminidase inhibitors (zanamivir and oseltamivir) were approved for treatment of influenza, but are not currently approved for prophylaxis. To date, experience is limited regarding use of zanamivir or oseltamivir in the treatment or prophylaxis of influenza among HSCT settings. However, HCWs, family members, other close contacts can be offered a neuroaminidase inhibitor (e.g., zanamivir or oseltamivir) using the same strategies outlined previously, if a) rimantadine or amantadine cannot be tolerated, b) the outbreak strain of influenza A is amantadine or rimantadine-resistant, or c) the outbreak strain is influenza B (*144--147*) (BI). Zanamivir can be administered to persons aged ≥12 years, and oseltamivir can be administered to persons aged ≥18 years. Patients with influenza should be placed unc droplet and standard precautions (AIII) to prevent transmission of influenza to HSCT recipients. HCWs with influenza should be excused from patient care until they a no longer infectious (AIII).

Preventing Disease

HSCT physicians should determine the etiology of a URI in an HSCT recipient or candidate undergoing conditioning therapy, if possible, because respiratory syncytial virus (RSV), influenza, parainfluenza, and adenovirus URIs can progress to more serious LRI, and certain CRVs can be treated (BIII). Appropriate diagnostic samples include nasopharyngeal washes, swabs or aspirates, throat swabs, and bronchoalveolar lavage (BAL) fluid. HSCT candidates with URI symptoms at the time conditioning therapy is scheduled to start should postpone their conditioning regimen until the URIs resolve, if possible, because certain URIs might progress to LRI during immunosuppression (*131,133,137,138*) (BIII).

Recommendations Regarding Influenza. Life-long seasonal influenza vaccination is recommended for all HSCT candidates and recipients, beginning during the influenza season before HSCT and resuming ≥6 months after HSCT (*142*) (BIII). Influenza vaccinations administered to HSCT recipients <6 months after HSCT are unlikely to be beneficial and are not recommended (*142*) (DII). HSCT recipients <6 months after HSCT should receive chemoprophylaxis with amantadine or rimantadine during community or nosocomial influenza A outbreaks (BIII). These drugs are not effective against influenza B. Additionally, antiviral-resistant strains of influenza can emerge during treatment with amantadine or rimantadine and transmission of resistant strains can occur (*148,149*). During such outbreaks, HSCT recipie 6--24 months after HSCT, or >24 months after HSCT and still substantially immunocompromised (i.e., receiving immunosuppressive therapy, have had a relapse of the underlying disease, or have GVHD) and who have not yet received a current influenza vaccination, should be vaccinated against influenza immediately (BIII). Additionally, to allow sufficient time for the patient to experience an immunologic response to influenza vaccine, chemoprophylaxis with amantadine or rimantadine ca be used for these HSCT recipients for 2 weeks after vaccination during a nosocomial or community influenza A outbreak (CIII). Influenza A chemoprophylaxis with amantadine or rimantadine has been recommended for all influenza A-exposed HSCT recipients <24 months after HSCT or ≥24 months after HSCT and substantially immunocompromised regardless of vaccination history, because of their likely suboptimal immunologic response to influenza vaccine (*142,143*). However, no recommendation regarding such chemoprophylaxis can be made because of lack of data.

To prevent severe disease, early preemptive therapy with amantadine or rimantadine has been reported for HSCT recipients with unexplained acute URI or LRI symptoms during a community or nosocomial outbreak of influenza A (*141*). However, the effectiveness in preventing influenza-related complications and the safety o this strategy have not been evaluated among HSCT recipients. Therefore, data are insufficient to make a recommendation.

Neuroaminidase inhibitors (zanimivir and oseltamivir), intravenous and aerosol ribavirin, and combination drug therapy (e.g., rimantadine or amantadine with ribavirir or interferon) (*143,150--153*) have been proposed for investigational, preemptive treatment to prevent severe influenza disease among HSCT recipients. However, because of lack of data, no recommendation for use of these strategies among HSCT recipients can be made.

Recommendations Regarding RSV. Respiratory secretions of any hospitalized HSCT candidate or recipient who experiences signs or symptoms of CRV infection sho be tested promptly by viral culture and rapid diagnostic tests for RSV (BIII). If two diagnostic samples taken ≥2 days apart do not identify a respiratory pathogen despi persistence of respiratory symptoms, BAL and further testing are advised (BIII). This testing is critical because of the high morbidity and case fatality of RSV disease among HSCT recipients (*154,155*). HSCT recipients, particularly those who are preengraftment and at highest risk for severe RSV pneumonia, should have their illnes diagnosed early (i.e., during RSV URI), and their illness should be treated aggressively to prevent fatal RSV disease (BIII).

Although a definitive, uniformly effective preemptive therapy for RSV infection among HSCT recipients has not been identified, certain strategies have been proposed including use of aerosolized ribavirin (*155,156*), RSV antibodies (i.e., passive immunization with high RSV-titered IVIG or RSV immunoglobulin) in combination wit aerosolized ribavirin (*137,157*), and RSV monoclonal antibody (*158*). Clinical trials are currently underway to evaluate the efficacy of these strategies. No recommendation regarding the optimal method for RSV prevention and preemptive therapy can be made because of limited data. Further, current data do not support u of intravenous ribavirin for preemptive therapy for RSV pneumonia among HSCT recipients (*60*) (DIII), and no commercially licensed vaccines against RSV are currently available.

Recommendations Regarding Parainfluenza Virus and Adenovirus. Immuno-prophylaxis, chemoprophylaxis, and preemptive treatment for parainfluenza virus and adenovirus infections among HSCT recipients have been proposed (*159,160*). However, no recommendation can be made in these guidelines because of insufficient da No commercially licensed vaccines against parainfluenza or adenovirus are currently available.

Other Disease Prevention Recommendations

The recommendations for preventing CRV infections and their recurrence are the same for allogeneic or autologous recipients. Generally, these recommendations appl to children or adults (*161--164*), but with appropriate adjustments in antiviral drug and influenza vaccine doses for children (Appendix).

For pediatric HSCT recipients and candidates aged >6 months, annual seasonal influenza vaccination is recommended HSCT (BIII). Children aged <9 years who are receiving influenza vaccination for the first time require two doses administered ≥1 months apart (AI). Healthy children who receive influenza vaccination for the first time might not generate protective antibodies until 2 weeks after receipt of the second dose of influenza vaccine. Therefore, during an influenza A outbreak, pediatric recipients aged <9 years, ≥6 months after HSCT, and receiving their first influenza vaccination, should be administered ≥6 weeks of influenza A chemoprophylaxis aft the first dose of influenza vaccine (*141*) (BIII) (Appendix). Amantadine and rimantadine are not FDA-approved for children aged <1 year (*141,161*) (DIII).

To prevent RSV disease, researchers report substituting RSV-IVIG for IVIG during RSV season (i.e., November--April) for pediatric recipients (i.e., children aged <18 years) who receive routine IVIG therapy (*164*) (i.e., those with hypogammaglobulinemia) (CIII) (Appendix). Other researchers report that pediatric recipients with RS can be considered for preemptive therapy (e.g., during URI or early LRI) with aerosolized ribavirin (CIII), although this therapy remains controversial (*164*) (Appendi Droplet and contact precautions for the duration of illness are required for pediatric recipients for the duration of adenovirus (*62*) (AIII).

FUNGAL INFECTIONS

General Recommendations

Preventing Exposure

Limited data were found that demonstrate to what extent preventing fungal exposures is effective in preventing infection and disease. However, HSCT recipients and candidates undergoing conditioning therapy have been advised to avoid contact with certain areas and substances, including foods, that might increase a patient's risk f fungal exposures (CII). Specific precautions have included avoiding areas of high dust exposure (e.g., excavation sites, areas of building construction or renovation, chicken coops, and caves), occupations involving soil, and foods that contain molds (e.g., blue cheese).

Preventing Disease

Growth factors (e.g., GM-CSF and G-CSF) shorten the duration of neutropenia after HSCT (*165*); however, no data were found that indicate which growth factors effectively reduce the attack rate of invasive fungal disease. Therefore, no recommendation for use of growth factors solely for prophylaxis against invasive fungal disease can be made.

Topical antifungal drugs, which are applied to the skin or mucosa (e.g., nystatin or clotrimazole), might reduce fungal colonization in the area of application. However, these agents have not been proven to prevent generation of locally invasive or disseminated yeast infections (e.g., candidiasis) or mold infections (e.g., aspergillosis) a are not recommended for their prophylaxis (DII). Performing fungal surveillance cultures is not indicated for asymptomatic HSCT recipients (*166,167*) (DII), but cultu should be obtained from symptomatic HSCT recipients (BIII).

Recommendations Regarding Yeast Infections

Preventing Exposure

Invasive candidiasis is usually caused by dissemination of endogenous *Candida* species that have colonized a patient's gastrointestinal tract (*168*). Consequently, meth of preventing exogenous yeast exposure usually do not prevent invasive yeast infections after HSCT. However, because *Candida* species can be carried on the hands, HCWs and others in contact with HSCT recipients should follow appropriate hand-washing practices to safeguard patients from exposure (AIII).

Preventing Disease

Allogeneic recipients should be administered fluconazole prophylaxis to prevent invasive disease with fluconazole-susceptible *Candida* species during neutropenia, particularly among centers where *Can. albicans* is the predominant cause of invasive fungal disease preengraftment (AI) (Appendix). Because candidiasis occurs durin phase I (*169*), fluconazole (400 mg/day by mouth or intravenously) should be administered (*169,170*) from the day of HSCT until engraftment (AII). However, fluconazole is not effective against certain *Candida* species, including *Can. krusei* (*171*) and *Can. glabrata* and is, therefore, not recommended for their prevention (DI Further studies are needed to determine the optimal duration of fluconazole prophylaxis. Preliminary studies have reported that low-dose fluconazole prophylaxis (100 -200 mg/day by mouth) among neutropenic patients has variable efficacy in preventing candidiasis (*172*). Therefore, this therapy is not recommended for HSCT recipients (DII). Oral, nonabsorbable antifungal drugs, including oral amphotericin B (500 mg suspension every 6 hours), nystatin, and clotrimazole troches, might reduce superficial colonization and control local mucosal candidiasis, but have not been demonstrated to reduce invasive candidiasis (CIII).

Other Recommendations

HSCT candidates with candidemia or invasive candidiasis can safely receive transplants (*173*) if a) their infection was diagnosed early and treated immediately and aggressively with amphotericin B or alternatively with appropriate doses of fluconazole if the organism is susceptible; and b) evidence of disease control is reported (e by serial computed tomography scans) before the transplant (BIII). Such patients should continue receiving therapeutic doses of an appropriate antifungal drug throughout phase I (BII) and until a careful review of clinical, laboratory, and serial computed tomography scans verifies resolution of candidiasis (BII).

Because autologous recipients generally have an overall lower risk for invasive fungal infection than allogeneic recipients, certain autologous recipients do not require routine antiyeast prophylaxis (DIII). However, researchers recommend administering antiyeast prophylaxis to a subpopulation of autologous recipients with underlying hematologic malignancies (e.g., lymphoma or leukemia) and who have or will have prolonged neutropenia and mucosal damage from intense conditioning regimens o graft manipulation, or have received fludarabine or 2-CDA recently (BIII). Recommendations regarding preventing invasive yeast infections among pediatric or adult HSCT recipients are the same, except that appropriate dose adjustments for prophylactic drugs should be made for pediatric recipients (Appendix).

Recommendations Regarding Mold Infections

Preventing Exposure

Nosocomial mold infections among HSCT recipients result primarily from respiratory exposure to and direct contact with fungal spores (*174*). Ongoing hospital construction and renovation have been associated with an increased risk for nosocomial mold infection, particularly aspergillosis, among severely immunocompromise patients (*175--177*). Therefore, whenever possible, HSCT recipients who remain immunocompromised should avoid hospital construction or renovation areas (AIII). When constructing new HSCT centers or renovating old ones, hospital planners should ensure that rooms for HSCT patients have an adequate capacity to minimize fungal spore counts through use of

- high-efficiency (>90%) particulate air (HEPA) filtration (*140,178,179*) (BIII);
- directed room airflow (i.e., positive air pressure in patient rooms in relation to corridor air pressure) so that air from patient rooms flows into the corridor (*180*) (BIII);

- correctly sealed rooms, including correctly sealed windows and electrical outlets (*140*) (BIII);
- high rates of room air exchange (i.e., >12 air changes/hour) (*140,178*) (BIII); and
- barriers between patient care and renovation or construction areas (e.g., sealed plastic) that prevent dust from entering patient care areas and that are
- impermeable to *Aspergillus* species (*175,179*) (BIII).

Additionally, HSCT centers should be cleaned with care, particularly after hospital renovation or construction, to avoid exposing HSCT recipients and candidates to m spores (*174,176*) (BIII).

Preventing Disease

No regimen has been reported to be clearly effective or superior in preventing aspergillosis, and therefore, no recommendation can be made. Further studies are needed determine the optimal strategy for aspergillosis prevention. Moderate-dose (0.5 mg/kg/day) amphotericin B (*181--184*), low-dose (0.1--0.25 mg/kg/day) amphotericin (*185--187*), intranasal amphotericin B spray (*188*), lipid formulations of amphotericin B (*182,189*), and aerosolized amphotericin B (*190*) have been administered for aspergillosis prophylaxis, but data are limited regarding the safety and efficacy of these formulations among HSCT recipients. Additionally, itraconazole capsules are n recommended for fungal prophylaxis among HSCT recipients (*191*) (DII) for three reasons. First, itraconazole capsules are poorly absorbed gastrointestinally, particularly among patients who are fasting (*192*) or receiving cytotoxic agents (*193*). Second, persons taking itraconazole capsules do not achieve steady-state serum levels for 2 weeks (*188,194*), and when achieved, these levels are lower than the average *Aspergillus* species minimum inhibitory concentration (MIC) among HSCT recipients (*195*). Third, itraconazole has adverse interactions with other drugs (e.g., antiepileptics, rifampin, oral hypoglycemics, protease inhibitors, vinca alkaloids, cyclosporine, methylprednisolone, and warfarin-like anticoagulants) (*196*). Trials assessing the efficacy of the recently licensed cyclodextrin oral solution and intravenous formulations of itraconazole in preventing invasive fungal disease among HSCT recipients are in progress; however, no recommendations regarding its use for *Aspergillus* species infection prophylaxis can be made. For HSCT recipients whose respiratory specimens are culture positive for *Aspergillus* species, acute invasiv aspergillosis should be diagnosed presumptively (*197*) and treated preemptively and aggressively (e.g., with intravenous amphotericin) (AIII).

The risk for aspergillosis recurrence has been high among allogeneic recipients with preexisting invasive aspergillosis. Previously, allogeneic HSCTs were avoided among persons with uncontrolled, proven aspergillosis. However, HSCT center personnel have recently reported successful allogeneic or autologous HSCT among a limited number of persons who have had successfully treated, prior invasive pulmonary aspergillosis (*198--200*). Because of limited data, no recommendations regardi strategies for preventing aspergillosis recurrence can be made.

PROTOZOAL AND HELMINTHIC INFECTIONS

Recommendations Regarding PCP

Preventing Exposure

Although a possible cause of PCP is reactivation of latent infection among immunocompromised persons, cases of person-to-person transmission of PCP have been reported (*201--206*). Generally, standard precautions should be used for patients with PCP (*62*) (BIII), but researchers have reported patients with PCP being isolated (*201,204*) and contact precautions being used if evidence existed of person-to-person transmission in the institution (CIII). This subject remains controversial, and until further data are published, HSCT recipients should avoid exposure to persons with PCP (*62*) (CIII).

Preventing Disease and Disease Recurrence

Physicians should prescribe PCP prophylaxis for allogeneic recipients throughout all periods of immunocompromise (*207*) after engraftment. Prophylaxis should be administered from engraftment until 6 months after HSCT (AII) for all patients, and >6 months after HSCT for the duration of immunosuppression for those who a) ar receiving immunosuppressive therapy (e.g. prednisone or cyclosporine) (AI), or b) have chronic GVHD (BII). However, PCP prophylaxis can be initiated before engraftment if engraftment is delayed (CIII). Researchers report an additional 1- to 2-week course of PCP prophylaxis before HSCT (i.e., day --14 to day --2) (CIII).

Preferred PCP prophylaxis is TMP-SMZ (AII); however, if TMP-SMZ is administered before engraftment, the associated myelosuppression could delay engraftment, a patients might experience sensitivity to the drug. Every effort should be made to keep such patients on the drug, including assessment of desensitization therapy, althou data regarding this technique among HSCT recipients are limited. For patients who cannot tolerate TMP-SMZ, physicians can choose to use alternative PCP prophylax regimens (e.g., dapsone) (*208*) (BIII). Use of aerosolized pentamidine (*209*) is associated with the lowest PCP prevention rates and should only be used if other agents cannot be tolerated. Atovaquone is a possible alternative drug for PCP prophylaxis among dapsone-intolerant persons with HIV infection (*210*); however, no recommendation regarding use of atovaquone among HSCT recipients can be made because of lack of data. Although data are limited, concomitant use of leucovorin (folinic acid) and TMP-SMZ is not recommended (*211,212*) (DIII). A patient's history of PCP should not be regarded as a contraindication to HSCT (*213*) (DIII).

Recurrent PCP among HSCT recipients is rare; however, patients with continued immunosuppression should remain on PCP prophylaxis until their immunosuppressio is resolved (AI). The regimen recommended for preventing toxoplasmosis recurrence among HSCT recipients (i.e., TMP-SMZ) will also prevent PCP recurrence.

Other Recommendations

PCP prophylaxis should be considered for autologous recipients who have underlying hematologic malignancies (i.e., lymphoma or leukemia), are receiving intense conditioning regimens or graft manipulation, or have recently received fludarabine or 2-CDA (*207,214*) (BIII). PCP prophylaxis should be administered ≥6 months aft HSCT if substantial immunosuppression or immunosuppressive therapy (e.g., steroids) persists (CIII). Use of PCP prophylaxis among other autologous recipients is controversial (CIII). Generally, indications for PCP prophylaxis are the same among children or adults, but pediatric doses should be used (Appendix).

Recommendations Regarding *Toxoplasma gondii*

Preventing Exposure

All HSCT recipients should be provided information regarding strategies to reduce their risk for *Toxoplasma* species exposure. Researchers report that potential donors for allogeneic HSCT be tested for *To. gondii* antibodies (*215,216*) by using FDA-licensed or -approved screening tests that include IgG antibody testing because *To. gondii* has been reported to be transmitted by leukocyte transfusion (*217*) and HSCT (*218,219*) (CIII).

Preventing Disease and Disease Recurrence

Because most toxoplasmosis among HSCT recipients is caused by disease reactivation, researchers report that candidates for allogeneic HSCT can be tested for IgG antibody to determine whether they are at risk for disease reactivation after HSCT (*215,216,218*) (CIII). However, the value of such testing is controversial because a limited number of patients who were seronegative for *To. gondii* pretransplant experienced the infection posttransplant (*220*). If testing is performed, only FDA-license or -approved screening tests should be used.

Researchers recommend toxoplasmosis prophylaxis for seropositive allogeneic recipients with active GVHD or a prior history of toxoplasmic chorioretinitis (*221,222*) but data demonstrating efficacy are limited (CIII). The optimal prophylactic regimen for toxoplasmosis among HSCT recipients has not been determined, but a propos drug is TMP-SMZ (BII), although allogeneic recipients have experienced break-through clinical disease despite TMP-SMZ prophylaxis (*218*). For patients who are TMP-SMZ--intolerant, a combination of clindamycin, pyramethamine, and leucovorin can be substituted for *To. gondii* prophylaxis (Appendix). After therapy for toxoplasmosis, HSCT recipients should continue receiving suppressive doses of TMP-SMZ or an alternate regimen for the duration of their immunosuppression (BIII) (Appendix).

Other Recommendations

Recipients of autologous transplants are at negligible risk for toxoplasmosis reactivation (*218*). No prophylaxis or screening for toxoplasmosis infection is recommend for such patients (DIII). Indications for toxoplasmosis prophylaxis are the same among children or adults, but pediatric doses should be used among children (Appendi

Recommendations Regarding *Strongyloides stercoralis*

Preventing Exposure

Allogeneic recipients should avoid contact with outhouses and cutaneous exposure to soil or other surfaces that might be contaminated with human feces (*223*) (AIII). Allogeneic recipients who work in settings (e.g., hospitals or institutions) where they could be exposed to fecal matter should wear gloves when working with patients in areas with potential fecal contamination (AIII).

Preventing Disease and Disease Recurrence

Travel and residence histories should be obtained for all patients before HSCT to determine any exposures to high-risk areas (e.g., such moist temperate areas as the tropics, subtropics, or the southeastern United States and Europe) (*223*) (BIII). HSCT candidates who have unexplained peripheral eosinophilia or who have resided in traveled to areas endemic for strongyloidiasis, even during the distant past, should be screened for asymptomatic strongyloidiasis before HSCT (BIII). Serologic testing with an enzyme-linked immunosorbent assay is the preferred screening method and has a sensitivity and specificity of >90% (*223,224*) (BIII). FDA-licensed or - approved screening tests should be used. Although stool examinations for strongyloidiasis are specific, the sensitivity obtained from ≥3 stool examinations is 60%--70 the sensitivity obtained from concentrated stool exams is, at best, 80% (*223*). A total of ≥3 stool examinations should be performed if serologic tests are unavailable or strongyloidiasis is clinically suspected in a seronegative patient (BIII).

HSCT candidates whose screening tests before HSCT are positive for *Strongyloides* species, and those with an unexplained eosinophilia and a travel or residence histo indicative of exposure to *Strongyloides stercoralis* should be empirically treated before transplantation (*225,226*), preferably with ivermectin (BIII), even if seronegativ or stool-negative (Appendix).

To prevent recurrence among HSCT candidates with parasitologically confirmed strongyloidiasis, cure after therapy should be verified with ≥3 consecutive negative st examinations before proceeding with HSCT (AIII). Data are insufficient to recommend a drug prophylaxis regimen after HSCT to prevent recurrence of strongyloidias HSCT recipients who had strongyloidiasis before or after HSCT should be monitored carefully for signs and symptoms of recurrent infection for 6 months after treatm (BIII).

Other Recommendations

Hyperinfection strongyloidiasis has not been reported after autologous HSCT; however, the same screening precautions should be used among autologous recipients (BIII). Indications for empiric treatment for strongyloidiasis before HSCT are the same among children or adults except for children weighing <15 kg, for whom the preferred drug is thiabendazole (BIII) (Appendix).

Recommendations Regarding *Trypanosoma cruzi*

Preventing Exposure

HSCT physicians should be aware that *Trypanosoma cruzi*, the etiologic agent of Chagas' disease, can be transmitted congenitally, through blood transfusion (*227*), an possibly through HSCT. Additionally, treatment for persons infected with *Tr. cruzi* is not always effective, even during the acute stage of infection (*227*). Therefore, potential donors who were born, received a blood transfusion, or ever lived for ≥6 months in a Chagas' disease endemic area (e.g., parts of South and Central America and Mexico) should be screened serologically for anti-*Tr. cruzi* serum IgG antibody (*228*) (BIII). Persons who lived <6 months in a Chagas'-endemic area but who had high-risk living conditions (e.g., having had extensive exposure to the Chagas' disease vector --- the reduviid bug --- or having lived in dwellings with mud walls, unmilled logs and sticks, or a thatched roof) should also be screened for evidence of *Tr. cruzi* infection (BIII). Because Chagas' disease can be transmitted congenitally, researchers report that any person with extensive multigenerational maternal family histories of cardiac disease (e.g., cardiomegaly and arrhythmias) should be screene serologically for serum IgG anti-*Tr. cruzi* antibodies (*227*) (CIII). To decrease the risk for misdiagnosis by false-positive or false-negative serologic tests, *Tr. cruzi* screening should consist of ≥2 conventional serologic tests (e.g., enzyme immunoassay, indirect hemagglutination, indirect fluorescent antibody) or ≥1 conventional serologic tests, followed by a confirmatory serologic test (e.g., radioimmunoprecipitation assay) (*229*) (BIII). Persons with active Chagas' disease should not serve as HSCT donors (DIII). Researchers also recommend deferral of HSCT donation for a past history of Chagas' disease (CIII).

Preventing Disease

HSCT candidates who are at risk for being infected with *Tr. cruzi* should be screened for serum IgG anti-*Tr. cruzi* antibody (*228*) (BIII). *Tr. cruzi* seropositivity is not a contraindication to HSCT (*228,230*). However, if an acute illness occurs in a *Tr. cruzi*-seropositive HSCT recipient, particularly during neutropenia, *Tr. cruzi* reactivati should be included in the differential diagnosis (*230*) (BIII). Researchers have proposed use of beznidazole or nifurtimox for preemptive therapy or prophylaxis of recurrent *Tr. cruzi* among seropositive HSCT recipients (*230,231*), but insufficient data were found to make a recommendation.*****

Other Recommendations

Recommendations are the same for autologous or allogeneic recipients. However, recurrence of Chagas' disease is probably less likely to occur among autologous recipients because of the shorter duration of immunosuppression. Recommendations are the same among children or adults.

HOSPITAL INFECTION CONTROL

Room Ventilation

HSCT center personnel should follow published guidelines for hospital room design and ventilation (*140,180*) (BIII). HSCT centers should also prevent birds from gaining access to hospital air-intake ducts (*140,174*) (AII). All allogeneic recipients should be placed in rooms with >12 air exchanges/hour (*232,233*) and point-of-use HEPA filters that are capable of removing particles ≥0.3 µm in diameter (*140,178,180,233*) (AIII). Correct filtration is critical in HSCT centers with ongoing construct and renovation (*179*). When portable HEPA filters are used as adjuncts to the primary ventilation system, they must be placed centrally in patient rooms so that space is available around all surfaces to allow free air circulation (BIII). The need for environmental HEPA filtration for autologous recipients has not been established. Howev HEPA-filtered rooms should be evaluated for autologous recipients if they experience prolonged neutropenia, a substantial risk factor for nosocomial aspergillosis (CII

A laminar air flow (LAF) room contains filtered air that moves in parallel, unidirectional flow --- the air enters the room from one wall and exits the room on the oppos wall (*232*). Although LAF has been demonstrated to protect patients from infection during aspergillosis outbreaks related to hospital construction (*234,235*), the value routine LAF room use for all HSCT recipients is doubtful because substantial overall survival benefit has not been reported (*236*). During 1983, LAF rooms were preferred for allogeneic recipients with aplastic anemia and HLA-identical sibling donors because use of regular rooms was associated with a mortality rate that was approximately four times higher than for those recipients treated in LAF rooms (*237*). However, the survival of aplastic anemia HSCT recipients during the late 1990s exceeds that reported during the early 1980s, and no studies have been done to determine whether HSCT recipients with aplastic anemia still have an improved surviva rate when treated in an LAF room. Therefore, HSCT centers need not construct LAF rooms for each HSCT recipient. Use of LAF rooms, if available, is optional (CII).

Hospital rooms should have directed airflow so that air intake occurs at one side of the room and air exhaust occurs at the opposite side (*140*) (BIII). Each hospital roo should also be well-sealed (e.g, around windows and electrical outlets) (*140*) (BIII). To provide consistent positive pressure in the recipient's room, HSCT centers shou maintain consistent pressure differentials between the patient's room and the hallway or anteroom at >2.5 Pa (i.e., 0.01 inches by water gauge) (*232,233*) (BIII). Generally, hospital rooms for HSCT recipients should have positive room air pressure when compared with any adjoining hallways, toilets, and anterooms, if present.

Anterooms should have positive air pressure compared with hallways (*180*). An exception is the HSCT recipient with an active disease that has airborne transmission (e.g., pulmonary or laryngeal *Mycobacteria tuberculosis* [TB] or measles). These HSCT patients should be placed in negative isolation rooms (*62*) (BIII), and a room with an anteroom is recommended for such patients (*180*) (BIII).

Whenever possible, HSCT centers should have self-closing doors to maintain constant pressure differentials among the HSCT recipients' room and anterooms, if available, and hallways (*233*) (BIII). To enable the nursing staff to observe the HSCT recipient even when the doors are closed, windows can be installed in either the door or the wall of the HSCT recipient's room (*233*) (CIII).

HSCT centers should provide backup emergency power and redundant air-handling and pressurization systems to maintain a constant number of air exchanges and roo pressurization in the center when the central ventilation system is shut off for maintenance and repair (*238*) (BIII). Additionally, infection control personnel should wor with maintenance personnel to develop protocols to protect HSCT centers at all times from bursts of mold spores that might occur when air-handling systems are restarted after routine maintenance shut-downs (BIII).

Construction, Renovation, and Building Cleaning

Construction and Renovation

Hospital construction and renovation have been associated with an increased risk for nosocomial fungal infection, particularly aspergillosis, among severely immuno-compromised patients (*175,176*). Therefore, persons responsible for HSCT center construction or renovation should consult published recommendations regarding environmental controls during construction (*239,240*) (AIII).

Whenever possible, HSCT recipients, HCWs, and visitors should avoid construction or renovation areas (*240*) (AIII). Also, equipment and supplies used by HSCT recipients or their HCWs should not be exposed to construction or renovation areas (*240*). When planning for construction or renovation, the HSCT center should inclu plans for intensified aspergillosis-control measures (AIII). Construction and renovation infection control planning committees should include engineers, architects, housekeeping staff, infection control personnel, the director of the HSCT center, the administration, and safety officers (*241*) (BIII).

When constructing new HSCT centers, planners should ensure that patient rooms will have adequate capacity to minimize fungal spore counts by following room ventilation recommendations. During outdoor construction and demolition, the intake air should be sealed (BIII), if possible; if not, filters should be checked frequently Additionally, to protect HSCT patient care areas during fire drills and emergencies, weather stripping should be placed around stairwell doors, or alternatively, the stairwell air should be filtered to the level of safety of the adjacent hospital air (BIII). False ceilings should be avoided whenever possible (*174*) (BII). If use of false ceilings cannot be avoided, the area above false ceilings should be vacuumed routinely to minimize dust and, therefore, fungal exposure to patients (*174*) (BIII).

During hospital construction or renovation, hospitals should construct rigid, dust-proof barriers with airtight seals (*242*) between patient care and construction or renovation areas to prevent dust from entering patient care areas; these barriers (i.e., sealed drywall) should be impermeable to *Aspergillus* species (*140,175,176,179,2* (BIII). If impervious barriers cannot be created around the construction or renovation area, patients should be moved from the area until renovation or construction is complete and the area has been cleaned appropriately (*176*) (BIII). HSCT centers should direct pedestrian traffic occurring near construction or renovation areas away from patient care areas to limit the opening and closing of doors or other barriers that might cause dust dispersion, entry of contaminated air, or tracking of dust into patient areas (*140*), particularly those in the HSCT center (*176*) (BIII). If possible, specific corridors, entrances, and exits should be dedicated to construction use only (*240*). An elevator to which patients do not have access also should be dedicated to construction use only (*240*). Construction workers, whose clothing might be contaminated with *Aspergillus* species spores, should use the construction elevator and avoid contact with patients, patient care areas, other elevators, and nonconstruction areas (BIII).

Hospital construction or renovation areas should have negative air pressure relative to that in adjacent patient care areas, if no contraindications exist for such pressure differential (*140,176,179,240,242*) (BIII). Ideally, air from the construction or renovation areas should be exhausted to the outside of the hospital (*176*) (BIII) or if recirculated, it should be HEPA-filtered first (BIII).

Researchers have proposed that HSCT recipients wear the N95 respirator to prevent mold exposure during transportation near hospital construction or renovation areas (CIII) because the N95 respirators are regarded as effective against any aerosol. However, to be maximally effective, N95 respirators must be fit-tested and all users m be trained. With correct personnel fit-testing and training, N95 respirators reliably reduce aerosol exposure by 90%. Without fit-testing and training, aerosol exposure would be reduced but not necessarily by 90% (*243*). For patients who cannot use or tolerate an N95 respirator, researchers have proposed using the powered air purifyi respirator (*244,245*), which can be used by patients in wheelchairs. Limitations of the powered air purifying respirator include its cost and that it is not appropriate for young children and infants. General limitations of using respirators are that no commercially available respi rator, including N95, has been tested specifically for its efficacy in reducing exposure to *Aspergillus* species in hospital construction or renovation areas, and no studies have been done that assess the usefulness and acceptability of using respirators among HSCT recipients. Standard surgical masks provide negligible protection against mold spores and are not recommended for this indication (DIII).

Newly constructed or renovated areas should be cleaned before patients are allowed to enter them (*140,176*) (AIII). Decontamination of fungal-contaminated areas tha cannot be extracted and replaced should be done using copper-8-quinolate (*179*) (BIII). Also, areas above false ceilings located under or adjacent to construction areas should be vacuumed (*174*) (BIII). Additionally, the ventilation, direction of airflow, and room pressurization should be tested and correctly adjusted before patients are allowed to enter (BIII).

Cleaning

HSCT centers should be cleaned ≥1 times/day with special attention to dust control (BIII). Exhaust vents, window sills, and all horizontal surfaces should be cleaned w cloths and mop heads that have been premoistened with an FDA- or Environmental Protection Agency (EPA)-registered hospital disinfectant (BIII). Thorough cleaning during and after any construction activity, including minor renovation projects, is critical (BIII).

HSCT center personnel should prohibit exposures of patients to such activities as vacuuming or other floor or carpet vacuuming that could cause aerosolization of fung spores (e.g., *Aspergillus* species) (*140*) (AIII). Accordingly, doors to patient rooms should be closed when vacuuming HSCT center corridors. All vacuum cleaners use in the HSCT center should be fitted with HEPA filters. An FDA- or EPA-registered disinfectant (*246,247*) should be used daily for environmental disinfection and whe wet vacuuming is performed in the HSCT center (BIII). If an HSCT center provides care for infants, phenolic disinfectants can be used to clean the floors only if the compound is diluted according to the product label; but phenolic compounds should not be used to clean basinets or incubators (*246*) (DIII).

Water leaks should be cleaned up and repaired as soon as possible but within 72 hours to prevent mold proliferation in floor and wall coverings, ceiling tiles, and cabinetry in and around all HSCT patients care areas (BIII). If cleanup and repair are delayed ≥72 hours after the water leak, the involved materials should be assumed contain fungi and handled accordingly. Use of a moisture meter to detect water penetration of walls should be used whenever possible to guide decision-making (*238*) (BIII). For example, if the wall does not have <20% moisture content ≥72 hours after water penetration, it should be removed (BIII). Design and selection of furnishing should focus on creating and maintaining a dust-free environment. Flooring and finishes (i.e., wall coverings, window shades, and countertops) used in HSCT centers should be scrubbable, nonporous, easily disinfected, and they should collect minimal dust (BIII).

Isolation and Barrier Precautions

HSCT center personnel should follow published guidelines for hospital isolation practices, including CDC guidelines for preventing nosocomial infections (*62,140,248* (AIII). However, the efficacy of specific isolation and barrier precautions in preventing noso-comial infections among HSCT recipients has not been evaluated.

HSCT recipients should be placed in private (i.e., single-patient) rooms (BIII). If contact with body fluids is anticipated, standard precautions should be followed (AIII These precautions include hand washing and wearing appropriate gloves, surgical masks or eye and face protection, and gowns during procedures and activities that ar likely to generate splashes or sprays of blood, body fluids, secretions or excretions, or cause soiling of clothing (*62*). When indicated, HSCT recipients should also be

placed on airborne, droplet, or contact precautions in addition to standard precautions (*62*) (AIII). Careful observation of isolation precautions is critical in preventing transmission of infectious agents among HSCT recipients, HCWs, visitors, and other HSCT recipients. Physicians are cautioned that HSCT recipients might have a prolonged or episodic excretion of organisms (e.g., CMV).

Researchers have proposed that HSCT recipients wear surgical mask and gloves when exiting their hospital rooms before engraftment (CIII). All HSCT recipients who are immunocompromised (phases I--III of immune system recovery) and candidates undergoing conditioning therapy should minimize the time spent in crowded areas the hospital (e.g., waiting areas and elevators) (BIII) to minimize potential exposure to persons with CRV infections.

Hand Hygiene

Hand washing is the single-most critical and effective procedure for preventing nosocomial infection (*62*). All persons, but particularly HCWs, should wash their hands before entering and after leaving the rooms of HSCT recipients and candidates undergoing conditioning therapy (*62,249*) or before and after any direct contact with patients regardless of whether they were soiled from the patient, environment, or objects (AI). HSCT recipients should be encouraged to practice safe hand hygiene (e.g., washing hands before eating, after using the toilet, and before and after touching a wound) (BIII). Hand washing should be done with an antimicrobial soap and water (AIII); alternatively, use of hygienic hand rubs is another acceptable means of maintaining hand hygiene (*250,251*). If gloves are worn, HCWs should put them on in the patient's room after hand washing and then discard them in the same patient's room before washing hands again after exiting the room. When worn, gloves should always be changed between patients or when soiled before touching a clean area (e.g., change gloves after touching the perineum and before going to a "clean" area) (AIII). Appropriate gloves should be used by all persons when handling potentially contaminated biological materials (AII). Items worn on the hands and fingers (e.g., rings or artificial nails [*248,252*]) and adhesive bandage strips, can create a nidus for pathogenic organisms that is difficult to clean. Thus, HCWs should avoid wearing such items whenever possible (BII).

Equipment

All HSCT center personnel should sterilize or disinfect and maintain equipment and devices using only EPA-registered compounds as directed by established guidelines (*140,180,246,247,253--256*) (AIII). HSCT center personnel should monitor opened and unopened wound-dressing supplies (e.g., adhesive bandages [*257,258*] and surgical and elastic adhesive tape [*259*]) to detect mold contamination and prevent subsequent cutaneous transmission to patients (BII).

Monitoring should consist of discarding all bandages and wound dressings that are out of date, have damaged packaging, or are visually contaminated by construction debris or moisture (BIII). When arm boards are used to provide support for intravenous lines, only sterile dressing materials should be used (*260*), and arm boards should be changed frequently (e.g., daily) (BIII). Additionally, unsterile tongue depressors inserted into a piece of foam tubing should not be used as splints for intravenous and arterial catheter sites because these have been associated with an outbreak of fatal invasive nosocomial *Rhizopus microsporus* among preterm (i.e., very low-birth--weight) infants (*261*) (DII). HSCT centers should not install carpeting in hallways outside (DII) or in patient rooms (DIII) because contaminated carpeting has been associated with outbreaks of aspergillosis among HSCT recipients (*262,263*).

Plants, Play Areas, and Toys

Although to date, exposure to plants and flowers has not been conclusively reported to cause fungal infections among HSCT recipients, most researchers strongly recommend that plants and dried or fresh flowers should not be allowed in the rooms of hospitalized HSCT candidates undergoing conditioning therapy and HSCT recipients (phases I--III of immune system recovery) because *Aspergillus* species have been isolated from the soil of potted ornamental plants (e.g., cacti), the surface of dried flower arrangements, and fresh flowers (*140,174,178,264*) (BIII).

Play areas for pediatric HSCT recipients and candidates undergoing conditioning therapy should be cleaned and disinfected ≥1 times/week and as needed (BIII). Only toys, games, and videos that can be kept clean and disinfected should be allowed in the HSCT center (BIII). HSCT centers should follow published recommendations for washing and disinfecting toys (*265*) (BIII). All HSCT center toys, games, and videos should be routinely and thoroughly washed or wiped down when brought into the HSCT center and thereafter ≥1 times/week and as needed by using a nontoxic FDA- or EPA-registered disinfectant (*246,247,265*) followed by a water rinse (BIII). Cloth or plush toys should be washed in a hot cycle of a washing machine or dry-cleaned ≥1 times/week and as needed (BIII). Alternatively, machine washing in a cold cycle is acceptable if laundry chemicals for cold water washing are used in proper concentration (*265*). Hard plastic toys should be scrubbed with warm soapy water using a brush to clean crevices, rinsed in clean water, immersed in a mild bleach solution, which should be made fresh daily, for 10--20 minutes, rinsed again, and allowed to air dry (*246*). Alternatively, hard plastic toys can be washed in a dishwasher or hot cycle of a washing machine (BIII). Broviac dolls****** should be disassembled upon completion of play and washed with a nontoxic FDA- or EPA-registered disinfectant (*246,247*), rinsed with tap water, and allowed to air dry before other children are allowed to play with them (BIII). Toys that cannot be washed, disinfected, or dry-cleaned after use should be avoided (BIII). Infants, toddlers, and children who put toys in their mouths should not share toys (*265*) (DIII). For children in isolation, researchers recommend the following:

- Disposable play items should be offered whenever possible (BIII).
- Before returning a washable toy used in an isolation room to the pediatric play room for use by another child, it should be cleaned again as previously described (BIII).
- When a child is taken out of isolation, toys, games, and videos used during the period of isolation and that might serve as fomites for infection should be thoroughly disinfected with a nontoxic FDA- or EPA-registered disinfectant (*246,247,265*) (BIII). After use in isolation rooms, cloth or plush toys should be placed in a plastic bag and separated from unused toys. All cloth or plush toys used in isolation rooms should be washed in a washing machine or dry-cleaned before being used in a nonisolation room (BIII). Toys that cannot be disinfected or dry-cleaned after use in an isolation room should be discarded (BIII).

Water-retaining bath toys have been associated with an outbreak of *Pseudomonas aeruginosa* in a pediatric oncology ward (*266*); therefore, these toys should not be used by immunocompromised HSCT recipients and candidates (DII). Occupational and physical therapy items should be cleaned and disinfected as previously described (BIII). Soil-based materials (e.g., clay or potting soil) should be avoided (BIII).

HCWs

HSCT center personnel should have a written comprehensive policy regarding their immunizations and vaccinations, and that policy should meet current CDC, Advisory Committee on Immunization Practices, and Healthcare Infection Control Practices Advisory Committee recommendations (*267*) (BIII). Immunizations are needed to prevent transmission of vaccine-preventable diseases to HSCT recipients and candidates undergoing conditioning therapy. All HCWs with diseases transmissible by airborne, droplet, and direct contact (e.g., VZV, infectious gastroenteritis, HSV lesions of lips or fingers, and URIs) should be restricted from patient contact and temporarily reassigned to other duties (AI). HSCT center personnel should follow published recommendations regarding the duration of work restrictions for HCWs with infectious diseases (*268,269*) (BIII). HSCT center HCWs with bloodborne viruses (e.g., HIV or hepatitis B or C viruses) should not be restricted from patient contact (DIII) as long as they do not perform procedures that pose a high risk for injury that could result in patient exposure to the HCW's blood or body fluids. Work exclusion policies should be designed to encourage HCWs to report their illnesses or exposures (AII).

HSCT Center Visitors

Hospitals should have written policies for screening HSCT center visitors, particularly children, for potentially infectious conditions. Such screening should be performed by clinically trained HCWs (BII). Visitors who might have communicable infectious diseases (e.g., URIs, flu-like illnesses, recent exposure to communicable diseases, active shingles rash whether covered or not, a VZV-like rash within 6 weeks of receiving a live-attenuated VZV vaccine, or a history of receiving an oral polio vaccine within the previous 3--6 weeks) should not be allowed in the HSCT center or allowed to have direct contact with HSCT recipients or candidates undergoing conditioning therapy (AII). No absolute minimum age requirement for HSCT center visitors exists; however, all visitors must be able to understand and follow appropriate hand washing and isolation precautions (AIII). The number of HSCT center visitors at any one time should be restricted to a number that permits the nursing staff to perform appropriate screening for contagious diseases and adequate instruction and supervision of hand washing, glove and mask use, and biosafety precautions (BIII).

Patient Skin and Oral Care

To optimize skin care, HSCT recipients should take daily showers or baths during and after transplantation (BIII), using a mild soap (BIII). Skin care during neutropen should also include daily inspection of skin sites likely to be portals of infection (e.g., the perineum and intravascular access sites) (BIII). HSCT recipients and candida undergoing conditioning therapy should maintain good perineal hygiene to minimize loss of skin integrity and risk for infection (BIII). To facilitate this precaution, HSCT center personnel should develop protocols for patient perineal care, including recommendations for gentle but thorough perineal cleaning after each bowel movement and thorough drying of the perineum after each urination (BIII). Females should always wipe the perineum from front to back after using the toilet to prevei fecal contamination of the urethra and urinary tract infections (AIII). Moreover, to prevent vaginal irritation, menstruating immunocompromised HSCT recipients shou not use tampons (DIII) to avoid the risk for cervical and vaginal abrasions. Additionally, the use of rectal thermometers, enemas, suppositories, and rectal exams are contraindicated among HSCT recipients to avoid skin or mucosal breakdown (DIII).

All HSCT candidates and their caregivers should be educated regarding the importance of maintaining good oral and dental hygiene for at least the first year after HSC to reduce the risk for oral and dental infections (AIII). For example, HSCT candidates should be informed that establishment of the best possible periodontal health before HSCT is a substantial step in avoiding short- and long-term oral infections and that maintenance of safe oral hygiene after HSCT can minimize the severity of infections and facilitate healing of mucositis, particularly before engraftment (BIII).

All HSCT candidates should receive a dental evaluation and relevant treatment before conditioning therapy begins (*270,271*) (AIII). Likely sources of dental infection should be vigorously eliminated (*271*) (AIII). For example, teeth with moderate to severe caries should be restored; ill-fitting dental prostheses should be repaired; and teeth compromised by moderate to severe periodontal disease should be extracted (*271*). Ideally, 10--14 days should elapse between the completion of tissue-invasive oral procedures and onset of conditioning therapy to allow for adequate healing and monitoring for postsurgical complications (AIII).

HSCT recipients with mucositis and HSCT candidates undergoing conditioning therapy should maintain safe oral hygiene by performing oral rinses 4--6 times/day wit sterile water, normal saline, or sodium bicarbonate solutions (*270*) (AIII). HSCT recipients and candidates should brush their teeth ≥2 times/day with a soft regular toothbrush (*270*) (BIII). If the recipient cannot tolerate these brushings, use of an ultrasoft toothbrush or toothette (i.e., foam swab on a stick), can be used (CIII), but physicians should be aware that using the latter products are less desirable than using soft regular or ultrasoft toothbrushes because the toothettes remove less dental debris (*270*). Using toothpaste is optional, depending on the recipient's tolerance (*270*) (CIII). HSCT recipients and candidates undergoing conditioning therapy who ar skilled at dental flossing should floss daily if this can be done without trauma (BIII). Routine dental supervision is advised to monitor and guide the patient's maintenar of oral and dental hygiene (BIII). To decrease the risk for mechanical trauma and infection of oral mucosa, fixed orthodontic appliances and space maintainers should r be worn from the start of conditioning therapy until preengraftment mucositis resolves, and these devices should not be worn during any subsequent periods of mucosi (*270*) (DIII). Dental and transplant teams and the patient's community dentist should coordinate removal of these appliances and long-term rehabilitation of any oral lesions (BIII). However, patients who normally wear removable dental prostheses might be able to wear them during conditioning therapy before HSCT and during mucositis after HSCT, depending on the degree of tissue integrity at the denture-bearing sites and the ability of the patient to maintain denture hygiene on a daily basis (CIII).

Preventing Bacterial Intravascular Catheter-Related Infections

HSCT center personnel are advised to implement published guidelines for preventing intravascular device-related infections (*33*) (AIII). Contact with tap water at the central venous catheter site should be avoided (BIII). For long-term central venous access among children, HSCT physicians can use a totally implantable device amor children aged <4 years if the anticipated duration of vascular access is >30 days (CII). However, such a device among children aged <4 years is not generally used as tl actual HSCT infusion site because a) problems with skin fragility contraindicate repeated punctures over the port site and b) the port device might have an insufficient number of lumens for optimal patient management immediately after HSCT.

To prevent bloodstream infections associated with needleless intravenous access devices, HSCT recipients should a) cover and protect the catheter tip or end cap durin bathing or showering to protect it from tap water contamination, b) change the device in accordance with manufacturers' recommendations, if available, and c) have a caregiver perform intravenous infusions whenever possible (*272,273*) (BII). Also, HSCT recipients and their caregivers should be educated regarding proper care of needleless intravenous access devices (*272*) (BII). No recommendation regarding the use of antibiotic-impregnated central venous catheters among HSCT recipients ca be made because of lack of data.

Control of Specific Nosocomial Infections

Recommendations Regarding* Legionella *Species

HSCT physicians should always include Legionnaires' disease (LD) in the differential diagnosis of pneumonia among HSCT recipients (*140*) (AIII). Appropriate tests confirm LD include a) culturing sputum, BAL, and tissue specimens; b) testing BAL specimens for *Legionellae* by direct fluorescent antibody; and c) testing for *Legionella pneumophila* serogroup 1 antigen in urine. The incubation period for LD is usually 2--10 days; thus, laboratory-confirmed legionellosis that occurs in a pati who has been hospitalized continuously for ≥10 days before the onset of illness is regarded as a definite case of nosocomial LD, and a laboratory-confirmed infection t occurs 2--9 days after hospital admission is a possible case of nosocomial LD (*140*). When a case of laboratory-confirmed nosocomial LD (*274,275*) is identified in a person who was in the inpatient HSCT center during all or part of the 2--10 days before illness onset, or if two or more cases of laboratory-confirmed LD occur among patients who had visited an outpatient HSCT center, hospital personnel should

- report the case(s) to the local or state health department if the disease is reportable in that state or if assistance is needed (*140*) (AIII); and
- in consultation with the hospital infection control team, conduct a thorough epidemiologic and environmental investigation to determine the likely environmenta source(s) of *Legionella* species (e.g., showers, tap water faucets, cooling towers, and hot water tanks) (*274,276*) (AI).

The source of *Legionella* infection should be identified and decontaminated or removed (AIII). Extensive hospital investigations of an isolated case of possible nosocomial LD might not be indicated if the patient has had limited contact with the inpatient center during most of the incubation period (CIII). Because HSCT recipients are at much higher risk for disease and death from legionellosis compared with other hospitalized persons (*274*), periodic routine culturing for *Legionellae* ir water samples from the center's potable water supply could be regarded as part of an overall strategy for preventing LD in HSCT centers (CIII). However, the optimal methodology (i.e., frequency or number of sites) for environmental surveillance cultures in HSCT centers has not been determined, and the cost-effectiveness of this strategy has not been evaluated. Because HSCT recipients are at high risk for LD and no data were found to determine a safe concentration of *Legionellae* organisms ir potable water, the goal, if environmental surveillance for *Legionellae* is undertaken, should be to maintain water systems with no detectable organisms (AIII). Physicia should suspect legionellosis among HSCT recipients with nosocomial pneumonia even when environmental surveillance cultures do not yield *Legionellae* (AIII). If *Legionella* species are detected in the water supplying an HSCT center, the following should be done until *Legionella* species are no longer detected by culture:

- The water supply should be decontaminated (*140*) (AII).
- HSCT recipients should be given sponge baths with water that is not contami-nated with *Legionella* species (e.g., not with the HSCT center's *Legionella* species-contaminated potable water system) (BIII).
- Patients should not take showers in LD-contaminated water (DIII).
- Water from faucets containing LD-contaminated water should not be used in patient rooms or the HSCT center and outpatient clinic to avoid creating infectious aerosols (CIII).
- HSCT recipients should be given sterile water instead of tap water for drinking, brushing teeth, or flushing nasogastric tubes during Legionellosis outbreaks (BII

HSCT center personnel should use only sterile water (i.e., not distilled unsterile water) for rinsing nebulization devices and other semicritical respiratory-care equipmei after cleaning or disinfecting and for filling reservoirs of nebulization devices (*140*) (BII). HSCT centers should not use large-volume room air humidifiers that create aerosols (e.g., by Venturi principle, ultrasound, or spinning disk) and, thus, are actually nebulizers (*140*) (DI) unless these humidifier or nebulizers are sterilized or subjected to daily high-level disinfection and filled with sterile water only (*140*) (CIII).

When a new hospital with an HSCT center is constructed, the cooling towers should be placed so that the tower drift is directed away from the hospital's air-intake system, and the cooling towers should be designed so that the volume of aerosol drift is minimized (*140*) (BII). For operational hospital cooling towers, hospitals shoul

- install drift eliminators,
- regularly use an effective biocide,
- maintain cooling towers according to the manufacturer's recommendations, and
- keep adequate maintenance records (*140*) (BII).

HSCT physicians are encouraged to consult published recommendations regarding preventing nosocomial Legionellosis (*140,277*) (BIII). No data were found to determine whether drinking tap water poses a risk for *Legionella* exposure among HSCT recipients in the absence of an outbreak.

***Recommendations Regarding Methicillin-Resistant* Sta. aureus**

HSCT center HCWs should follow basic infection control practices (e.g., hand washing between patients and use of barrier precautions, including wearing gloves whenever entering the methicillin-resistant *Sta. aureus* [MRSA] infected or colonized patient's room); these practices are essential for MRSA control (*62*) (AII). If MR is a substantial problem in the HSCT center and evidence exists of ongoing MRSA transmission, MRSA infected or colonized patients should be treated as a cohort (e. cared for exclusively by a limited number of HCWs) (BIII). HSCT transplant recipients with recurrent *Sta. aureus* infections should undergo extensive evaluation for persistent colonization, including cultures of nares, groin, axilla, and ostomy sites (e.g., tracheostomy or gastrointestinal tube) (BIII). For patients with recurrent MRSA infection, elimination of the carrier state should be attempted by applying a 2% mupirocin calcium ointment to the nares (BIII), although this strategy has been only marginally effective in certain institutions (*278*) (Appendix). High-level mupirocin-resistant MRSA has been reported in Europe, the Middle East, and South America (*279--283*) but is uncommon in the United States. As with any antibiotic, incorrect or overuse of mupirocin can result in mupirocin-resistant *Staphylococci*; therefore, mupirocin use should be reserved for infection control strategies only (*279,280*). For patients who fail mupirocin, physicians have used bacitracin, TMP-SMZ, or rifampin administered with another antibiotic, but no standardized protocol using these drugs for this indication has been evaluated and no recommendations can be ma because of lack of data. Selection of a systemic antibiotic should be guided by susceptibility patterns.

Intravascular cannulas or other implantable devices that are infected or colonized with MRSA should be removed (AIII). Patients with MRSA should be placed under contact precautions until all antibiotics are discontinued and until three consecutive cultures, taken ≥1 weeks apart, are negative (*62*) (BIII). Screening cultures for MR include the anterior nares, any body site previously positive for MRSA, and any wounds or surgical sites.

Recommendations Regarding* Staphylococcus *Species with Reduced Susceptibility to Vancomycin

All HSCT centers should have sufficient laboratory capability to identify all *Staphylococci* isolates and their susceptibility patterns to antibiotics, including vancomycin (*284,285*) (AIII). Additionally, all HSCT center personnel should conduct routine surveillance for the emergence of *Staphylococcus* species strains with reduced susceptibility to vancomycin (*285,286*) (AIII). Reduced susceptibility should be considered for all *Sta. aureus* strains that have a vancomycin MIC of ≥4 µg/mL and al coagulase-negative *Staphylococci* that have a vancomycin MIC of ≥8 µg/mL. If repeat testing of the organism in pure culture confirms the genus, species, and elevated vancomycin MICs, the following steps should be taken (*287*):

- The laboratory should immediately contact hospital infection control personnel, the patient's clinical center, and the patient's attending physician, as well as the local or state health department, and CDC's Hospital Infections Program Help Desk ([404] 639-6106 or [800] 893-0485) (*284,285,287,288*) (AIII).
- The HSCT center's infection control personnel, in collaboration with appropriate authorities (i.e., state and local health departments and CDC) should promptly initiate an epidemiologic and laboratory investigation (*287,288*) (AIII) and follow published guidelines for the control of such species (*285,287,288*) (BIII).
- Medical and nursing staff should
  - institute contact precautions (e.g., wearing of gown and gloves, using antibacterial soap for hand washing, and wearing masks when contamination of the HCW with secretions is likely) as recommended for multidrug-resistant organisms (*62,284,287*);
  - minimize the number of persons with access to colonized or infected patients (*287*); and
  - treat as a cohort colonized or infected patients (e.g., care for them exclusively with a limited number of HCWs) (*286,287*) (AIII).
- If a patient in an HSCT center is colonized or infected with *Staphylococci* that have reduced susceptibility to vancomycin, the infection control personnel should follow published guidelines for the control of such species (*285,287,288*) (BIII).

Avoiding overuse and misuse of antibiotics will decrease the emergence of *Staphylococcus* species with reduced susceptibility to vancomycin (*286,287*). There-fore, medical and ancillary staff members who are responsible for monitoring antimicrobial use patterns in the facility should routinely review vancomycin-use patterns (*284,285,287*) (AIII). Additionally, HSCT center personnel should institute prudent use of all antibiotics, particularly vancomycin, to prevent the emergence of *Staphylococcus* with reduced susceptibility to vancomycin (*284,285,287--289*) (AII). Intravascular cannulas or other implantable devices that are infected or colonized with *Staphylococcus* species strains with reduced susceptibility to vancomycin should be removed (AIII).

Recommendations Regarding VRE

Use of intravenous vancomycin is associated with VRE emergence. Vancomycin and all other antibiotics, particularly antianaerobic agents (e.g., metronidazole and thi generation cephalosporins) must be used judiciously (*284,290--292*) (AII). Oral van-comycin use can be limited by treating recurrences of *Cl. difficile* diarrhea with or metronidazole instead of vancomycin (BIII). Physicians have placed patients with a history of VRE or VRE colonization into continuous isolation during clinic visits a hospitalizations; however, this practice is controversial because certain non-HSCT recipients might clear VRE from their stools. No recommendation regarding use of continuous isolation among HSCT recipients can be made because of lack of data. To control VRE exposure, strict adherence to the following standard infection contro measures is necessary (*292*) (AI):

- Wash hands with antibacterial soap before entering and after leaving HSCT recipients' rooms, particularly those who have VRE colonization or infection; alternatively, wash hands with a waterless antiseptic agent (e.g., an alcohol-based rinse or gel) (*250*).
- Whenever possible, treat as a cohort patients who are known to be colonized or infected with VRE (*290*).
- Disinfect patient rooms and equipment (*291,293*), including surfaces of the hospital ward environment (e.g., floors, walls, bed frames, doors, bathroom surfaces) with an FDA- or EPA-registered disinfectant (*246,247*). A nontoxic disinfectant should be used for pediatric areas (BIII).
- Place patients with VRE under contact precautions until all antibiotics are discontinued (CIII) and repeated cultures are negative (*62*) (BIII). HCWs should alway wear gloves when in the VRE patient or carrier's room and discard gloves in the patient's room before exiting.

No evidence exists that treating VRE carriers is beneficial; therefore, chronic antibiotic treatment of carriers is not recommended (DIII). HSCT recipients and candidat should be screened for VRE colonization at the time of interfacility transfer to allow for immediate institution of appropriate infection control practices and to minimiz transmission of VRE between and within facilities (*294*) (BII). However, the role of outpatient surveillance in VRE control is unknown; such surveillance is costly and should not be undertaken in nonoutbreak settings (DIII). A history of having resolved VRE bacteremia or being a VRE carrier are not contraindications to HSCT (BIII)

***Recommendations Regarding* Cl. difficile**

HSCT physicians should follow published recommendations for preventing and controlling *Cl. difficile* disease, including minimizing the duration of antibiotic therapy and number of antibiotics used for any indication (*295,296*) (AIII). All patients with *Cl. difficile* disease should be placed under contact precautions for the duration of illness (*62*) (AII). All HCWs who anticipate contact with a *Cl. difficile*-infected patient or the patient's environment or possessions should put on gloves before entering the patient's room (*62,295--298*) and before handling the patient's secretions and excretions (AI). During *Cl. difficile* outbreaks, HSCT center personnel should restrict use of antibiotics (e.g., clindamycin) (*299*) (BII). To prevent transmission of *Cl. difficile* to patients during nosocomial *Cl. difficile* outbreaks, HSCT center HCWs shou a) use disposable rectal thermometers or tympanic thermometers; b) disinfect gastrointestinal endoscopes with 2% glutaraldehyde immersion for 10 minutes or use an equivalent disinfectant strategy (*255,256*); and c) perform surface sterilization of the hospital ward environment (e.g., floors, walls, bed frames, doors, bathroom surfac with an FDA- or EPA-registered sterilant (e.g., phosphate-buffered sodium hypochlorite solution [1,660 ppm available chloride]; unbuffered hypochlorite solution [50

ppm available chloride]; 0.04% formaldehyde and 0.03% glutaraldehyde [*255,295,300*]; or ethylene oxide [*247,296*]) (BII). Additionally, physicians should treat patien with *Cl. difficile* disease with antibiotics as recommended in published reports (*62,295*) (BII).

Certain researchers also recommend antibiotic treatment of *Cl. difficile* carriers (*301*). However, other researchers have reported that treatment of asymptomatic *Cl. difficile* carriers with metronidazole is not effective and that treatment with vancomycin is only effective temporarily (i.e., <2 months after treatment) (*302*). Consequently, no recommendation regarding treatment of asymptomatic *Cl. difficile* carriers can be made. Similarly, although symptomatic *Cl. difficile* disease recurrence or relapse occurs among 7%--20% of patients (*295*), data are insufficient to make a recommendation for preventing multiple *Cl. difficile* relapses.

The following practices are not recommended for *Cl. difficile* control:

- routine stool surveillance cultures for *Cl. difficile* for asymptomatic patients or HCWs, even during outbreaks (DIII);
- culturing HCWs' hands for *Cl. difficile* (DIII); or
- treating patients presumptively for *Cl. difficile* disease pending toxin results (DIII), unless the patient is very sick with a compatible syndrome or the hospital has high prevalence of *Cl. difficile* (CIII).

Prophylactic use of lyophilized *Saccharomyces boulardii* to reduce diarrhea among antibiotic recipients is not recommended because this therapy is not associated with substantial reduction in diarrhea associated with *Cl. difficile* disease (*303*) and has been associated with *Saccharomyces boulardii* fungemia (*304*) (DII).

Recommendations Regarding CRV Infections

Physicians should institute appropriate precautions and infection control measures for preventing nosocomial pneumonia among hospitalized HSCT recipients and candidates undergoing conditioning therapy, particularly during community or nosocomial CRV outbreaks (*140*) (AIII). Patients with URI or LRI symptoms should be placed under a) contact precautions for most viral respiratory infections including varicella; b) droplet precautions for influenza or adenovirus; or c) airborne precautio for measles or varicella to avoid transmitting infection to other HSCT candidates and recipients as well as to HCWs and visitors (BIII). Identifying HSCT recipients wi RSV infection and placing them under contact precautions immediately (AIII) to prevent nosocomial transmission is critical. When suctioning the respiratory tract of patients with URI or LRI symptoms, HCWs should wear gowns, surgical masks, and eye protection to avoid contamination from the patient's respiratory secretions. Al protective clothing (e.g., gown, gloves, surgical mask, and eye protection) should be put on when entering a patient's room and discarded in the same room before exiting; protective clothing should always be changed between patient rooms (*140*) (AIII). When caring for an HSCT recipient or candidate undergoing conditioning therapy with URI or LRI, HCWs and visitors should change gloves and wash hands a) after contact with a patient; b) after handling respiratory secretions or objects contaminated with secretions from one patient and before contact with another patient, object, or environmental surface; and c) between contacts with a contaminated body site and the respiratory tract of or respiratory device used on the same patient (*140*) (AII). This practice is critical because most respiratory infections are usually transmitted by contact, particularly by hand to nose and eye. Therefore just wearing a mask, without appropriate hand washing, glove-wearing, or use of eye protection insufficient to prevent transmission of CRV infections.

Researchers have proposed that HSCT recipients or candidates undergoing conditioning therapy be placed under contact precautions during nosocomial outbreaks (*131* (CIII). Even when no nosocomial or community outbreak of CRV infections exists, all persons who enter the HSCT center should be screened daily for URI symptoms including visitors and HCWs (BIII). Researchers also describe systems where HCWs provide daily verification (e.g., using sign-in sheets) that they are free of URI symptoms before being allowed to provide HSCT patient care. HCWs and visitors with URI symptoms should be restricted from contact with HSCT recipients and candidates undergoing conditioning therapy to minimize the risk for CRV transmission (*131*) (AIII). All HCWs with URI symptoms should be restricted from patient contact and reassigned to nonpatient care duties until the HCW's symptoms resolve (BIII). Visitors with URI symptoms should be asked to defer their visit to the HSCT center (*131*) until their URI symptoms resolve (BIII).

Respiratory secretions of any hospitalized HSCT candidate or recipient with signs or symptoms of CRV infection should be tested promptly by viral culture and rapid diagnostic tests for CRV (BIII). Appropriate samples include nasopharyngeal washes, swabs, aspirates, throat swabs, and BAL fluid. This practice is critical because preemptive treatment of certain CRVs (e.g., influenza and RSV) (*133*) might prevent severe disease and death among HSCT recipients. Viral shedding among HSCT recipients with CRV infection has been reported to last ≤4 months for influenza (*143*), ≤2 years for adenovirus (*305,306*), and ≤22 days for RSV (*136*); however, RSV viral shedding has been reported to last 112 days in a child with severe combined immunodeficiency (*307*). Therefore, to prevent nosocomial transmission of CRV (*13* HSCT center HCWs should recognize that prolonged CRV shedding can occur when determining the duration of appropriate precautions for CRV-infected HSCT recipients or candidates undergoing conditioning therapy (CIII). HSCT centers should use serial testing by using cultures from nasopharyngeal swabs, throat swabs or aspirates, or rapid antigen tests to help determine whether patients have stopped shedding influenza virus (BIII). Researchers have proposed that HSCT physicians conduct routine CRV surveillance among HSCT recipients to detect outbreaks and implement infection control measures as early as possible (CIII). During RSV seaso HSCT recipients and candidates with signs or symptoms should be tested for RSV infection (i.e., the presence of RSV antigen in respiratory secretions tested by enzym linked immunosorbent assay and viral culture) starting with admission to the HSCT center. All patients who are RSV-antigen positive should be treated as a cohort dur nosocomial RSV outbreaks because this practice reduces nosocomial RSV transmission (*130,131*) (BII). Symptomatic HCWs should be excluded from patient contact until symptoms resolve. HCWs and visitors with infectious conjunctivitis should be restricted from direct patient contact until the drainage resolves (i.e., usually, 5--7 days for adenovirus) and the ophthalmology consultant concurs that the infection and inflammation have resolved (*268*) (AII) to avoid possible transmission of adenovirus to HSCT recipients.

Preventing CRV exposure among HSCT recipients after hospital discharge is more challenging because of high CRV prevalence. Preventive measures should be individualized in accordance with the immunologic status and tolerance of the patient. In outpatient waiting rooms, patients with CRV infections should be separated to the extent possible from other patients (BIII).

Recommendations Regarding TB

HSCT candidates should be screened for TB by careful medical history and chart review to ascertain any history of prior TB exposure (AIII) because immunocompromised persons have higher risk for progression from latent TB infection to active disease (*244*). Also, physicians can administer a tuberculin skin test (TST) using the Mantoux method with five tuberculin units of purified protein derivative (CIII); but because of a patient's immunocompromise, this test might not be reliable. If a TST is administered, either the Tubersol® or Aplisol® formulation of purified protein derivative can be used (*244,308*). Persons with a recently positive TS or a history of a positive TST and no prior preventive therapy should be administered a chest radiograph and evaluated for active TB (*309*) (AI). For immunocompromised persons, a positive TST is defined as ≥5 mm of induration (*309,310*) because of their decreased ability to mount a delayed hypersensitivity response (CIII). Because immunosuppressive therapy decreases the sensitivity of the TST, HSCT physicians should not rely solely on the TST to determine whether latent TB infection is present and whether preventive therapy should be administered to HSCT recipients or candidates (DIII). Instead, a full 9-month course of isonicotinic acid hydrazide preventive therapy should be administered to immunocompromised HSCT recipients or candidates who have been substantially exposed to someone with active, infectious (i.e., sputum-smear positive) pulmonary or laryngeal TB, regardless of the HSCT recipient's or candidate's TST status (*309*) (BIII). A f 9-month course of isonicotinic acid hydrazide preventive therapy should also be administered to HSCT recipients or candidates with a positive TST who were not previously treated and have no evidence of active TB disease (*309*) (AIII) (Appendix). Routine anergy screening might not be reliable among HSCT recipients and candidates undergoing conditioning therapy and, therefore, is not recommended (DIII). An HSCT should not be canceled or delayed because of a positive TST (DIII).

Use of a 2-month course of a daily pyrazinamide/rifampin (PZA/RIF) regimen has been recommended as an alternate preventive therapy for persons with TB (*309*). However, limited data were found regarding safety and efficacy of this regimen among non-HIV--infected persons. Furthermore, rifampin has substantial drug interactions with certain medications, including cyclosporine, tacrolimus (FK506), corticosteroids, fluconazole, and pain medications. Therefore, routine use of the 2-month PZA/RIF prophylactic regimen among HSCT recipients is not recommended (DIII). However, this regimen can be used for HSCT candidates who are not at risk for serious rifampin drug interactions and whose HSCT is not scheduled until ≥2 weeks after completion of the 2-month PZA/RIF course (CIII). This delay will dimini the possibility of adverse effects of rifampin on drugs used for routine HSCT OI prophylaxis (e.g., fluconazole) (*311*). An HSCT candidate or recipient who has been exposed to an active case of extrapulmonary, and therefore, noninfectious TB does not require preventive therapy (DIII).

HSCT center personnel should follow guidelines regarding the control of TB in health-care facilities (*244,245*), including instituting airborne precautions and negative pressure rooms for patients with suspected or confirmed pulmonary or laryngeal TB (*62,244*) (AII). HCWs should wear N95 respirators, even in isolation rooms, to

protect themselves from possible TB transmission from patients with active pulmonary or laryngeal TB, particularly during cough-inducing procedures (*62,244,245,31* (AIII). To be maximally effective, respirators (e.g., N95) must be fit-tested, and all respirator users must be trained to use them correctly (*243*) (AIII). Unless they become soiled or damaged, changing N95 respirators between patient rooms is not necessary (DIII). Bacillus of Calmette and Guérin vaccination is contraindicated among HSCT candidates and recipients because it might cause disseminated or fatal disease among immunocompromised persons (*313,314*) (EII). No role has been identified for chronic suppressive therapy or follow-up surveillance cultures among HSCT recipients who have a history of successfully treated TB (DIII).

Infection Control Surveillance

HSCT center personnel are advised to follow standard guidelines for surveillance of antimicrobial use and nosocomial pathogens and their susceptibility patterns (*315*) (BIII). HSCT center personnel should not perform routine fungal or bacterial cultures of asymptomatic HSCT recipients (*166,167*) (DII). In the absence of epidemiolo clusters of infections, HSCT center personnel should not perform routine periodic bacterial surveillance cultures of the HSCT center environment or of equipment or devices used for respiratory therapy, pulmonary-function testing, or delivery of inhalation anesthesia (*140*) (DIII). Researchers recommend that hospitals perform routi sampling of air, ceiling tiles, ventilation ducts, and filters to test for molds, particularly when construction or renovation occurs near or around the rooms of immunocompromised patients (*167,174*) or when clinical surveillance demonstrates a possible increase in mold (i.e., aspergillosis) cases (CIII). Strategies that might decrease fungal spores in the ventilation system include eliminating access of birds (i.e., primarily pigeons) to air-intake systems, removing bird droppings from the air intake ducts, and eliminating moss from the hospital roof (*174*). Furthermore, in the absence of a nosocomial fungal outbreak, HSCT centers need not perform routine fungal cultures of devices and dust in the rooms of HSCT recipients and candidates undergoing conditioning therapy (DIII). HSCT center personnel should routinely perform surveillance for the number of aspergillosis cases occurring among HSCT recipients, particularly during hospital construction or renovation (BIII). A two-fold greater increase in the attack rate of aspergillosis during any 6-month period indicates that the HSCT center environment should be evaluated for breaks in infection control techniques and procedures and that the ventilation system should be investigated carefully (*174*) (BIII).

STRATEGIES FOR SAFE LIVING AFTER HSCT -- PREVENTING EXPOSURE AND DISEASE

Avoiding Environmental Exposures

HSCT recipients and candidates undergoing conditioning therapy, particularly allogeneic recipients, and parents of pediatric HSCT recipients and candidates should be educated regarding strategies to avoid environmental exposures to opportunistic pathogens (AIII).

Preventing Infections Transmitted by Direct Contact

HSCT recipients and candidates should wash their hands thoroughly (i.e., with soap and water) and often. For example, hands should be washed

- before eating or preparing food;
- after changing diapers;
- after gardening or touching plants or dirt;
- after touching pets or animals;
- after touching secretions or excretions or items that might have had contact with human or animal stool (e.g., clothing, bedding, toilets, or bedpans);
- after going outdoors; and
- before and after touching wounds (*249*) (AIII).

Conscientious hand washing is critical during the first 6 months after HSCT and during other periods of substantial immunosuppression (e.g., GVHD, systemic steroid use, or relapse of the underlying disease for which the transplant was performed) (AIII). Pediatric HSCT recipients and candidates should be supervised by adults duri hand washing to ensure thorough cleaning (*316*) (BIII). Hand washing should be performed with an antimicrobial soap and water (AIII); alternatively, use of hygienic hand rubs is an acceptable means of maintaining hand hygiene (*250,251*). HSCT recipients who visit or live on farms should follow published recommendations for preventing cryptosporidiosis (*5,316,317--319*) (BIII).

Preventing Respiratory Infections

To prevent respiratory infections after hospital discharge, HSCT recipients should observe the following precautions:

- Frequent and thorough hand washing is critical (BIII), but HSCT recipients should also avoid touching their mucus membranes, unless they have washed their hands first, to avoid inoculating themselves with CRV.
- HSCT recipients should avoid close contact with persons with respiratory illnesses (BIII). When close contact is unavoidable, those persons with respiratory illnesses should be encouraged to wash their hands frequently and to wear surgical masks or, at a minimum, smother their sneezes and coughs in disposable tissu Alternatively, the HSCT recipient can wear a surgical mask (CIII).
- HSCT recipients should avoid crowded areas (e.g., shopping malls or public elevators) where close contact with persons with respiratory illnesses is likely (BIII)
- HSCT candidates or recipients should be advised that certain activities and occupations (e.g., work in health-care settings, prisons, jails, or homeless shelters) ca increase their risk for TB exposure (BIII). In deciding whether a patient should continue activities in these settings, physicians should evaluate the patient's speci duties, the precautions used to prevent TB exposure in the workplace, and the prevalence of TB in the community. The decision to continue or terminate such activities should be made jointly between patient and physician (BIII). HSCT recipients should avoid exposure to persons with active tuberculosis, particularly during the first 6 months after HSCT and during other periods of substantial immunosuppression (e.g., GVHD, systemic steroid use, or relapse of the underlying disease for which the transplant was performed) (BIII).

Researchers report that allogeneic recipients should avoid construction or excavation sites or other dust-laden environments for the first 6 months after HSCT and duri other periods of substantial immunosuppression (e.g., GVHD, systemic steroid use, or relapse of the underlying disease for which the transplant was performed) to avo exposures to molds (CIII). Researchers also report that outpatient HSCT recipients should be advised of travel routes to the HSCT center that will avoid or minimize exposure to construction sites (CIII).

Coccidioidomycosis is uncommon after allogeneic HSCT; however, researchers report that HSCT recipients traveling to or residing in coccidioidomycosis-endemic ar (e.g., the American southwest, Mexico, and Central and South America) should avoid or minimize exposure to disturbed soil, including construction or excavation site areas with recent earthquakes, farms, or other rural areas (CIII). Histoplasmosis (*Histoplasma capsulatum*) after allogeneic HSCT is also rare; however, researchers re that HSCT recipients in histoplasmosis-endemic areas should avoid exposure to chicken coops and other bird-roosting sites and caves for the first 6 months after HSC and during periods of substantial immunosuppression (e.g., GVHD, systemic steroid use, or relapse of the underlying disease for which the transplant was performed) (CIII).

Smoking tobacco and exposure to environmental tobacco smoke are risk factors for bacterial and CRV infections among healthy adults and children (*320--325*); consequently, logic dictates that physicians advise HSCT recipients not to smoke and to avoid exposure to environmental tobacco smoke (CIII). However, no data wer found that specifically assess whether smoking or environmental smoke exposure are risk factors for OIs among HSCT recipients. Researchers have reported that marijuana smoking might be associated with generation of invasive pulmonary aspergillosis among immunocompromised persons, including HSCT recipients (*326--329*). Therefore, HSCT recipients should refrain from smoking marijuana to avoid *Aspergillus*species exposure (*326,330--334*) (BIII).

Preventing Infections Transmitted Through Direct Contact and Respiratory Transmission

Researchers have proposed that immunocompromised HSCT recipients and candidates who are undergoing conditioning therapy avoid gardening or direct contact wit soil, plants, or their aerosols to reduce exposure to potential pathogens (e.g., *To. gondii*, *Hi. capsulatum*, *Cryptococcus neoformans*, *Nocardia* species, and *Aspergillus* species) (CIII). HSCT recipients, particularly allogeneic recipients, could wear gloves while gardening or touching plants or soil (*335*) (CIII), and they should avoid

creating plant or soil aerosols (BIII). Additionally, they should always wash their hands afterwards (*335*) and care for skin abrasions or cuts sustained during soil or pla contact (AIII).

Persons whose occupations involve animal contact (e.g., veterinarians, pet store employees, farmers, or slaughterhouse workers) could be at increased risk for toxoplasmosis and other zoonotic diseases. Although data are insufficient to justify a general recommendation against HSCT recipients working in such settings, these exposures should be avoided during the first 6 months after HSCT and during other periods of substantial immunosuppression (e.g., GVHD, systemic steroid use, or relapse of the underlying disease for which the transplant was performed) (BIII).

Safe Sex

Sexually active HSCT recipients should avoid sexual practices that could result in oral exposure to feces (*5,316*) (AIII). Sexually active patients who are not in long-te monogamous relationships should always use latex condoms during sexual contact to reduce their risk for exposure to CMV, HSV, HIV, hepatitis B and C, and other sexually transmitted pathogens (AII). However, even long-time monogamous partners can be discordant for these infections. Therefore, during periods of immunocompromise, sexually active HSCT recipients in such relationships should consider using latex condoms during sexual contact to reduce the risk for exposure these sexually transmitted infections (CIII).

Pet Safety

Preventing Pet-Transmitted Zoonotic Infections

HSCT physicians should advise recipients and candidates undergoing conditioning therapy of the potential infection risks posed by pet ownership; however, they shoul not routinely advise HSCT recipients to part with their pets, with limited exceptions. Generally, immunocompromised HSCT recipients and candidates undergoing conditioning therapy should minimize direct contact with animals (*336,337*), particularly those animals that are ill (e.g., with diarrhea) (*335*) (BIII). Immunocompromised persons who choose to own pets should be more vigilant regarding maintenance of their pet's health than immunocompetent pet owners (BIII). This recommendation means seeking veterinary care for their pet early in the pet's illness to minimize the possible transmission of the pet's illness to the owner (*335*) (BIII). Feeding pets only high-quality commercial pet foods reduces the possibility of illness caused by spoiled or contaminated foods, thus reducing the possibility of transmitting illness from the pet to the HSCT recipient. If eggs, poultry, or meat products are given to the pet as supplements, they should be well-cooked. Any dairy products given to pets should be pasteurized (*335*) (BIII). Pets should be prevented from drinking toilet bowl water and from having access to garbage; pets should not scavenge, hunt, or eat other animals' feces (*335*) (BIII).

If HSCT recipients have contact with pets or animals, they should wash their hands after handling them (particularly before eating) and after cleaning cages; HSCT recipients should avoid contact with animal feces to reduce the risk for toxoplasmosis, cryptosporidiosis, salmonellosis, and campylobacteriosis (*335*) (BIII). Adults should supervise hand washing of pediatric HSCT recipients (BIII). Immunocompromised HSCT recipients and candidates should not clean pet litter boxes or cages or dispose of animal waste (DIII). If this cannot be avoided, patients should wear disposable gloves during such activities and wash their hands thoroughly afterwards (BIII). Immunocompromised HSCT recipients and candidates should avoid adopting ill or juvenile pets (e.g., aged <6 months for cats) (*335*) and any stray animals (*5,316*) (BIII). Any pet that experiences diarrhea should be checked by a veterinarian for infection with *Cryptosporidium* (*5,316*), *Giardia* species (*335*), *Salmonella*, a *Campylobacter* (*5,335,337*) (BIII).

Immunocompromised HSCT recipients and candidates should not have contact with reptiles (e.g., snakes, lizards, turtles, or iguanas) (DII) to reduce their risk for acquiring salmonellosis (*335,338--341*). Additionally, patients should be informed that salmonellosis can occur from fomite contact alone (*342*). Therefore, HSCT recipients and candidates should avoid contact with a reptile, its food, or anything that it has touched, and if such contact occurs, recipients and candidates should wash their hands thoroughly afterwards (AIII). Immunocompromised HSCT recipients and candidates should avoid contact with ducklings and chicks because of the risk for acquiring *Salmonella* or *Campylobacter* species infections (*338,343*) (BIII). Immunocompromised HSCT recipients and candidates should avoid contact with exotic pe (e.g., nonhuman primates) (BIII). Bird cage linings should be cleaned regularly (e.g., daily) (*337*). All persons, but particularly immunocompromised HSCT candidates and recipients, should wear gloves whenever handling items contaminated with bird droppings (*337*) (BIII) because droppings can be a source of *Cryptococcus neoformans*, *Mycobacterium avium*, or *Hi. capsulatum*. However, routine screening of healthy birds for these diseases is not recommended (*335*) (DIII). To minimize potential exposure to *Mycobacterium marinum*, immunocompromised HSCT recipients and candidates should not clean fish tanks (DIII). If this task cannot be avoided patients should wear disposable gloves during such activities and wash their hands thoroughly afterwards (*335,337*) (BIII).

Preventing Toxoplasmosis

The majority of toxoplasmosis cases in the United States is acquired through eating undercooked meat (*335,337*). However, all HSCT recipients and candidates, particularly those who are *To. gondii* seronegative, should be informed of the risks for contracting toxoplasmosis from cat feces (BIII), but need not be advised to give away their cats (DII). For households with cats, litter boxes should not be placed in kitchens, dining rooms, or other areas where food preparation and eating occur (*33* Additionally, litter boxes should be cleaned daily by someone other than the HSCT recipient during the first 6 months after HSCT and during periods of substantial immunosuppression (e.g., GVHD, steroid use, or relapse of the underlying disease for which the transplant was performed) to reduce the risk for transmitting toxoplasmosis to the HSCT recipient (BIII). Daily litter box changes will minimize the risk for fecal transmission of *To. gondii* oocysts, because fecal oocysts require ≥ days of incubation to become infectious. If HSCT recipients perform this task during the first 6 months after HSCT and during subsequent periods of substantial immunocompromise (e.g., during GVHD, systemic steroid use, or relapse of the underlying neoplastic disease for which the transplant was performed), they should we disposable gloves (*335*). Gloves should be discarded after a single use (BIII). Soiled, dried litter should be disposed of carefully to prevent aerosolizing the *To. gondii* oocysts (BIII). Cat feces (but not litter) can be flushed down the toilet (BIII). Also, persons who clean cat litter, particularly HSCT recipients, should wash their hands thoroughly with soap and water afterwards to reduce their risk for acquiring toxoplasmosis (BIII).

HSCT recipients and candidates with cats should keep their cats inside (BIII) and should not adopt or handle stray cats (DIII). Cats should be fed only canned or dried commercial food or well-cooked table food, not raw or undercooked meats, to eliminate the possibility of causing an illness that could be transmitted from the cat to th HSCT recipient (BIII). Pet cats of HSCT recipients do not need to be tested for toxo-plasmosis (EII). Playground sandboxes should be kept covered when not in use to prevent cats from soiling them (BIII). HSCT recipients and candidates undergoing conditioning therapy should avoid drinking raw goat's milk to decrease the risk for acquiring toxoplasmosis (BIII).

Water and Other Beverage Safety

Although limited data were found regarding the risks for and epidemiology of *Cryptosporidium* disease among HSCT recipients, HSCT recipients are prudent to avoid possible exposures to *Cryptosporidium* (BIII) because it has been reported to cause severe, chronic diarrhea, malnutrition, and death among other immunocompromise persons (*5,318,319*). HSCT recipients should avoid walking, wading, swimming, or playing in recreational water (e.g., ponds or lakes) that is likely to be contaminated with *Cryptosporidium*, *Es. coli* O157:H7 (*344--346*), sewage, or animal or human waste (BII). HSCT recipients should also avoid swallowing such water (e.g., while swimming) (*5,344,346*) as well as any water taken directly from rivers and lakes (*5,316*) (AIII).

HSCT recipients should not use well water from private wells or from public wells in communities with limited populations (DIII) because tests for microbial contamination are performed too infrequently (e.g., in certain locations, tests are performed ≤1 times/month) to detect sporadic bacterial contamination. However, drinking well water from municipal wells serving highly populated areas is regarded as safe from bacterial contamination because the water is tested ≥2 times/day for bacterial contamination. If HSCT recipients consume tap water, they should routinely monitor mass media (e.g., radio, television, or newspapers) in their area to immediately implement any boil-water advisories that might be issued for immunocompromised persons by state or local governments (BIII). A boil-water advisory means that all tap water should be boiled for ≥1 minutes before it is consumed. Tap water might not be completely free of *Cryptosporidium*. To eliminate the risk for *Cryptosporidium* exposure from tap water, HSCT recipients can boil tap water for ≥1 minutes before consuming it (e.g., drinking or brushing teeth) (*5*) (CIII). Alternately, they can use certain types of water filters (*316*) or a home distiller (*317*) to reduce their risk for *Cryptosporidium* (*5*) and other waterborne pathogens (CIII If a home water filter******* is used, it should be capable of removing particles ≥1 µm in diameter, or filter by reverse osmosis. However, the majority of these filters are not capable of removing smaller microbes (e.g., bacteria or viruses), and therefore, should only be used on properly treated municipal water. Further, the majority o

these devices would not be appropriate for use on an unchlorinated private well to control viral or bacterial pathogens. Bottled water can be consumed if it has been processed to remove *Cryptosporidium* by one of three processes --- reverse osmosis, distillation, or 1-µm particulate absolute filtration. To confirm that a specific bottl water has undergone one of these processes, HSCT recipients should contact the bottler directly.******** Patients can take other precautions in the absence of boil-wa advisories to further reduce their risk for cryptosporidiosis. These extra precautions include avoiding fountain beverages and ice made from tap water at restaurants, ba and theaters (*5*), fruit drinks made from frozen concentrate mixed with tap water, and iced tea or coffee made with tap water (*317*). Drinks that are likely to be *Cryptosporidium* safe for HSCT recipients include nationally distributed brands of bottled or canned carbonated soft drinks and beers (*5*); commercially packaged noncarbonated drinks that contain fruit juice; fruit juices that do not require refrigeration until after opening (e.g., those that are stored unrefrigerated on grocery shelve (*5*); canned or bottled soda, seltzer or fruit drinks; steaming hot (≥175 F) tea or coffee (*317*); juices labeled as pasteurized; and nationally distributed brands of frozen fruit juice concentrate that are reconstituted with water from a safe source (*5*). HSCT recipients should not drink unpasteurized milk or fruit or vegetable juices (e.g., apple cider or orange juice) to avoid infection with *Brucella* species, *Es. coli* O157:H7, *Salmonella* species, *Cryptosporidium*, and others (*319,347--351*) (DII).

Food Safety

HSCT candidates and household or family members who prepare food for them after HSCT should review food safety practices that are appropriate for all persons (*35* (AIII), and food preparers should be educated regarding additional food safety practices appropriate for HSCT recipients. This review and education should be done before the conditioning regimen (i.e., chemotherapy and radiation) begins (BIII). Adherence to these guidelines will decrease the risk for foodborne disease among HS recipients.

Food Safety Practices Appropriate for All Persons

Raw poultry, meats, fish, and seafood should be handled on separate surfaces (e.g., cutting board or counter top) from other food items. Food preparers should always u separate cutting boards (i.e., one for poultry and other meats and one for vegetables and remaining cutting or carving tasks) (AIII), or the board(s) should be washed wi warm water and soap between cutting different food items (AIII). To prevent foodborne illnesses caused by *Campylobacter jejuni* and *Salmonella enteritidis*, which ca cause severe and invasive infections among immunocompromised persons (*353,354*), uncooked meats should not come in contact with other foods (BIII).

After preparing raw poultry, meats, fish, and seafood and before preparing other foods, food handlers should wash their hands thoroughly in warm, soapy water. Any cutting boards, counters, knives, and other utensils used should be washed thoroughly in warm, soapy water also (AIII). Food preparers should keep shelves, counter tops, refrigerators, freezers, utensils, sponges, towels, and other kitchen items clean (AIII). All fresh produce should be washed thoroughly under running water before serving (*355*) (AIII). Persons preparing food should follow published U.S. Department of Agriculture recommendations regarding safe food thawing (*356*) (BIII).

Persons cooking food for HSCT recipients should follow established guidelines for monitoring internal cooking temperatures for meats (*357*) (AII). The only method f determining whether the meat has been adequately cooked is to measure its internal temperature with a thermometer because the color of the meat after cooking does n reliably reflect the internal temperature. Different kinds of meat should be cooked to varying internal temperatures, all ≥150 F (AII). Specifically, the U.S. Department Agriculture recommends that poultry be cooked to an internal temperature of 180 F; other meats and egg-containing casseroles and souffles should be cooked to an internal tem perature of ≥160 F. Cold foods should be stored at <40 F; hot foods should be kept at >140 F (BIII). Food preparers should

- wash their hands before and after handling leftovers (AIII);
- use clean utensils and food-preparation surfaces (AIII);
- divide leftovers into small units and store in shallow containers for quick cooling (AII);
- refrigerate leftovers within 2 hours of cooking (AII).
- discard leftovers that were kept at room temperature for >2 hours (AIII);
- reheat leftovers or heat partially cooked foods to ≥165 F throughout before serving (AII);
- bring leftover soups, sauces, and gravies to a rolling boil before serving (AIII); and
- follow published guidelines for cold storage of food (*352*) (AII).

Additional Food Safety Practices Appropriate for HSCT Recipients

HSCT recipients' diets should be restricted to decrease the risk for exposure to foodborne infections from bacteria, yeasts, molds, viruses, and parasites (BIII). Currentl a low microbial diet is recommended for HSCT recipients (*358,359*) (BIII). This diet should be continued for 3 months after HSCT for autologous recipients. Allogene recipients should remain on the diet until all immunosuppressive drugs (e.g., cyclosporine, steroids, and tacrolimus) are discontinued. However, the HSCT physician should have final responsibility for determining when the diet can be discontinued safely. Only one study has reported that dietary changes (e.g., consuming yogurt) ha decreased the risk for mycotic infections (e.g., candidal vaginitis) (*360*) (Table 3). HSCT recipients should not eat any raw or undercooked meat, including beef, poultr pork, lamb, venison or other wild game, or combination dishes containing raw or undercooked meats or sweetbreads from these animals (e.g., sausages or casseroles) (AII). Also, HSCT recipients should not consume raw or undercooked eggs or foods that might contain them (e.g., certain preparations of hollandaise sauce, Caesar an other salad dressings, homemade mayonnaise, and homemade eggnog) because of the risk for infection with *Salmonella enteritidis* (*354*) (AII). HSCT recipients shoul not consume raw or undercooked seafood (e.g., oysters or clams) to prevent exposure to *Vibrio* species, viral gastroenteritis, and *Cryptosporidium parvum* (*361--364*) (AII).

HSCT recipients and candidates should only consume meat that is welldone when they or their caretakers do not have direct control over food preparation (e.g., when eating in a restaurant) (AI). To date, no evidence exists in the United States that eating food at a fast food restaurant is riskier than eating at a conventional sit-down restaurant. Generally, HSCT candidates undergoing conditioning therapy and HSCT recipients with neutropenia (i.e., ANC < 1,000/ml^3), GVHD, or immunosuppressi should avoid exposures to naturopathic medicines that might contain molds (*365*) (DIII). HSCT recipients wishing to take naturopathic medications are advised to use them only as prescribed by a licensed naturopathic physician working in consultation with the recipient's transplant and infectious disease physicians (CIII).

Travel Safety

Travel to developing countries can pose substantial risks for exposure to opportunistic pathogens for HSCT recipients, particularly allogeneic recipients chronically immunosuppressed. HSCT recipients should not plan travel to developing countries without consulting their physicians (AIII), and travel should not occur until the period of severe immunosuppression has resolved. Generally, allogeneic recipients should not plan travel to developing countries for 6--12 months after HSCT, particularly if GVHD has occurred. Autologous recipients can travel to developing countries 3--6 months after HSCT if their physicians agree.

HSCT recipients should be informed regarding strategies to minimize the risk for acquiring foodborne and waterborne infections while traveling. They should obtain updated, detailed health information for international travelers from health organizations (*366,367*) (AIII). Generally, while traveling in developing countries, HSCT recipients should avoid consuming the following (BIII):

- raw fruits and vegetables,
- tap water or any potentially untreated or contaminated water,
- ice made from tap water or any potentially contaminated water,
- unpasteurized milk or any unpasteurized dairy products,
- fresh fruit juices,
- food and drinks from street vendors, and
- raw or undercooked eggs.

Steaming hot foods, fruits peeled by oneself, bottled and canned processed drinks, and hot coffee or tea are probably safe (*367,368*). Travelers should plan for treating their drinking water while in developing countries. If bottled water is not available, boiling is the best method of making water safe. However, if boiling water is not feasible, the traveler should carry supplies for disinfecting water (e.g., commercially available iodine disinfection tablets or a portable water filter) (*366,368*).

Antimicrobial prophylaxis for traveler's diarrhea is not recommended routinely for HSCT recipients traveling to developing countries (DIII) because traveler's diarrhea not known to be more frequent or more severe among immunocompromised hosts. However, HSCT physicians who wish to provide prophylaxis to HSCT recipients w are traveling can prescribe a fluoroquinolone (e.g., ciprofloxacin hydrochloride) or TMP-SMZ (CIII), although resistance to TMP-SMZ is now common and resistance fluoroquinolones is increasing in tropical areas (Appendix). Researchers recommend using bismuth subsalicylate to prevent traveler's diarrhea among adults (*366*). However, no data were found regarding safety and efficacy among HSCT recipients, and salicylates are not recommended for use among persons aged <18 years becau salicylates are associated with Reye's syndrome (*369*).

HSCT recipients' immunization status should be assessed and their vaccinations updated as needed before travel (*366*). Influenza chemoprophylaxis with rimantadine c amantadine can be used for immunocompromised HSCT recipients who are traveling outside the continental United States and who could be exposed to influenza A (CIII).

HSCT RECIPIENT VACCINATIONS

Antibody titers to vaccine-preventable diseases (e.g., tetanus, polio, measles, mumps, rubella, and encapsulated organisms) decline during the 1--4 years after allogene or autologous HSCT (*66,370--373*) if the recipient is not revaccinated. Clinical relevance of decreased antibodies to vaccine-preventable diseases among HSCT recipie is not immediately apparent because a limited number of cases of vaccine-preventable diseases are reported among U.S. recipients. However, vaccine-preventable diseases still pose risks to the U.S. population. Additionally, evidence exists that certain vaccine-preventable diseases (e.g., encapsulated organisms) can pose increasec risk for HSCT recipients (*66*); therefore, HSCT recipients should be routinely revaccinated after HSCT so that they can experience immunity to the same vaccine-preventable diseases as others (Table 4).

HSCT center personnel have developed vaccination schedules for HSCT recipients (*374*). One study determined that HSCT center personnel used 3--11 different vaccination schedules per vaccine (*374*); consequently, the study authors requested national guidelines for doses and timing of vaccines after HSCT to eliminate confusion among HSCT center personnel regarding how to vaccinate their patients. To address this need, an interim vaccination schedule for HSCT recipients was drafted in collaboration with partner organizations, including CDC's Advisory Committee on Immunization Practices. The purpose of the vaccination schedule in these guidelines is to provide guidance for HSCT centers (Table 4). Although limited data were found regarding safety and immunogenicity (e.g., serologic studies of antibo titers after vaccination) among HSCT recipients, no data were found regarding vaccine efficacy among HSCT recipients (e.g., which determine whether vaccinated HSCT recipients have decreased attack rates of disease compared with unvaccinated HSCT recipients). Because certain HSCT recipients have faster immune system recovery after HSCT than others, researchers have proposed that different vaccination schedules be recommended for recipients of different types of HSCT. However, date, data are too limited to do so. Therefore, the same vaccination schedule is recommended for all HSCT recipients (e.g., allogeneic, autologous, and bone marrow, peripheral, or UCB grafts) until additional data are published. In the tables, vaccines have only been recommended for use among HSCT recipients if evidence exists o safety and immunogenicity for those recipients. Vaccination of family members, household contacts, and HCWs are also recommended to minimize exposure of vaccir preventable diseases among HSCT recipients (Tables 5--8).

HEMATOPOIETIC STEM CELL SAFETY

With allogeneic HSCT, the life of the recipient might depend on the timely selection of an acceptable HLA-matched donor. Only a limited number of HLA-matched donors might be identified; hence, the transplant physician often has to accept a higher risk for transmission of an infectious agent through HSCT than would be permitted for routine blood transfusion. This section provides strategies for the HSCT physician to minimize transmission of infectious diseases, whenever possible, fr donors to recipients.********* ********** Whether to select a donor who is at risk for or who has an infectious disease transmissible by HSCT, should be determine on a case-by-case basis (AIII) and is the final responsibility of the HSCT physician (AIII). If the only possible donor is at risk for or known to be infected with a bloodborne pathogen and the patient is likely to succumb rapidly from his or her disease if an HSCT is not received, the physician must carefully weigh the risks and benefits of using potentially infected donor cells. No person should be denied a potentially life-saving HSCT procedure solely on the basis of the risk for an infectious disease. However, HSCT physicians should avoid transplanting any infected or infectious donor hematopoietic stem cell product unless no other stem cell product can obtained and the risk for death from not undergoing transplantation is deemed to be greater than the risk for morbidity or death from the infection that could potentially be transmitted (DII). If such a product is selected for use, it should be done on a case-by-case basis (*375*) and the following should be noted in the recipient's chart:

- knowledge and authorization of the recipient's HSCT physician regarding the potential for transmission of an infectious agent during HSCT, and
- advance informed consent from the recipient or recipient's legal guardian acknowledging the possible transmission of an infectious agent during the transplantati (AIII).

Subsequently, the HSCT physician should include the infectious agent in the differential diagnosis of any illness that the HSCT recipient experiences so that the infecti if transmitted, can be diagnosed early and treated preemptively, if possible. Infectious products (except those in which CMV seropositivity is the only evidence of infectiousness) should be labeled as being a biohazard or as untested for biohazards, as applicable. Tissue intended for autologous use should be labeled "For Autologo Use Only --- Use Only for (Patient's Name)."

Preventing Transmission of Infections from HSCT Donors to Recipients

All prospective HSCT donors should be evaluated through a physical history and examination to determine their general state of health and whether they pose a risk fo transmitting infectious diseases to the recipient (*376*). To detect transmissible infections, all HSCT donor collection site personnel should follow up-to-date published guidelines and standards for donor screening (e.g., medical history), physical exam, and serologic testing (*377--383*) (AIII). Initial donor screening and physical exam should be performed ≤8 weeks before the planned donation (BIII). Donor serologic testing should be done ≤30 days before donation to detect potentially transmissible infections (BII); additionally, researchers recommend that donors be retested ≤7 days before collection. If testing is done >7 days before donation, donor screening sho be repeated to ensure that no new risk behaviors have occurred during the interval between the original screening and the time of donation (BIII). This practice is critic because if new behavioral risk factors have occurred, the potential donor might need to be deferred. Screening and testing should be done on all allogeneic or syngenei donors (AIII). Screening and testing of autologous donors is recommended to ensure the safety of laboratory personnel and to prevent cross contamination (BIII). If autologous donors are not tested, their autologous units should be specially labeled and handled as if potentially infected (BIII). For donors screened in the United Stat FDA-licensed or -approved tests should be used in accordance with the manufacturers' instructions (AIII), and the donor samples should be tested in laboratories certif by the Clinical Laboratory Improvement Amendments of 1988 (AIII).

All HSCT donors should be in good general health (*376*) (BIII). Acute or chronic illness in the prospective donor should be investigated to determine the etiology. Generally, persons who are ill should not be HSCT donors (DIII). A flu-like illness in a prospective donor at the time of evaluation or between the time of evaluation a donation should prompt evaluation of and serologic testing for infections that might pose a risk to the recipient (e.g., EBV, CMV, *To. gondii*) (BIII). Persons with a positive serum EBV-viral capsid antigen IgM but negative serum EBV-viral capsid antigen IgG should not serve as donors for allogeneic T-cell--depleted HSCT, particularly for unrelated or mismatched transplants, until their serum EBV-viral capsid antigen IgG becomes positive (DIII). Persons with acute toxoplasmosis should not donate until the acute illness has resolved (DII); however, physicians should be aware that persons who are asymptomatically seropositive for *To. gondii* might transmit this infection through HSCT (*218*).

Prospective donors with symptoms of active TB should be evaluated for that disease (*383*) (BIII). Prospective donors with active TB should not donate (EIII) until the is well-controlled (e.g., no longer contagious as determined by the donor's primary physician) after appropriate medical therapy. However, no known risk exists from transplanting marrow from an untreated, tuberculin-positive donor who has no evidence of active disease. Screening potential donors for TB with Mantoux skin tests (DIII) is not necessary. Prospective HSCT donors who reside in or have traveled to areas endemic for rickettsia or other tickborne pathogens and who are suspected of having an acute tickborne infection should be temporarily deferred as donors until infection with these pathogens is excluded (DIII). Relevant pathogens include *Rickettsia rickettsii*, *Babesia microti* and other *Babesia* species, *Coxiella burnetii*, and the Colorado tick fever virus, which are the etiologic agents of Rocky Mountain spotted fever, babesiosis, Q fever, and Colorado tick fever, respectively; these pathogens have been reported to be transmitted by blood transfusion (*384--388*). Researchers recommend deferral for a past history of Q fever or babesiosis because these infections can be chronic and the babesiosis parasite might persist despite

appropriate therapy (*389*) (CIII). Additionally, researchers have recommended deferring persons with acute human ehrlichiosis (e.g., human active human granulocytic ehrlichiosis [*390*], human monocytic ehrlichiosis, as well as any infections from *Ehrlichia ewingii*) from HSCT donation (CIII).

The medical history of the prospective HSCT donor should include the following:

- History of vaccinations (*377*) during the 4 weeks before donation (AII). If the potential donor is unsure of vaccinations received, his or her records should be reviewed. HSCT donation should be deferred for 4 weeks after the donor receives any live-attenuated vaccine (e.g., rubeola [measles], mumps, rubella [German measles], oral polio, varicella, yellow fever, and oral typhoid vaccines) (EIII). This deferral will avoid the possibility of infusing a live infectious agent into an HSCT recipient. HSCT donation need not be deferred for persons who have recently received toxoid or killed (i.e., inactivated), recombinant viral, bacterial, or rickettsial vaccines as long as the donor is asymptomatic and afebrile (*389*) (BIII). Such vaccines include tetanus toxoid, diphtheria toxoid, hepatitis A and B, cholera, influenza (i.e., killed intramuscular vaccine), meningococcal, paratyphoid, pertussis, plague, polio (i.e., inactivated polio vaccine), rabies, typhoid (i.e., inactivated intramuscular vaccine), or typhus vaccines (*389*).
- Travel history (BIII) to determine whether the donor has ever resided in or traveled to countries with endemic diseases that might be transmitted through HSCT (e.g., malaria). Permanent residents of nonendemic countries who have traveled to an area that CDC regards as endemic for malaria can be accepted as HSCT donors if 1 year has elapsed since the donor's departure from the endemic area and if the donor has been free of malaria symptoms, regardless of whether he or sl received antimalarial chemoprophylaxis. Because cases of HSCT-transmitted malaria have been reported (*391,392*), persons who have had malaria and received appropriate treatment should be deferred from HSCT donation for 3 years after becoming asymptomatic. Immigrants, refugees, citizens, or residents for ≥5 years endemic countries can be accepted as HSCT donors if 3 years have elapsed since they departed the malarious area and if they have been free of malaria symptom
- History of Chagas' disease and leishmaniasis. Persons with active Chagas' disease or leishmaniasis should not serve as HSCT donors (DIII) because these disease can be transmitted by transfusion (*227,229,231,393--395*). Researchers also recommend deferral of HSCT donation if a past history exists of either of these diseases because the parasite can persist despite therapy (*227--229,231, 389,393--395*) (CIII).
- History of any deferral from plasma or blood donation. The reason for such a deferral (*376*) and whether it was based on a reported infectious disease or behavio or other risk factor should be investigated (BIII).
- History of viral hepatitis. A person with a history of viral hepatitis after his or her eleventh birthday should be excluded from HSCT donation (BIII).
- History of blood product transfusion, solid organ transplantation, or transplantation of tissue within the last 12 months (BIII). Such persons should be excluded from HSCT donation (DIII). Xenotransplant product recipients and their close contacts should be indefinitely deferred from donating any blood products, includi hematopoietic stem cells, whole blood, or other blood components including plasma, leukocytes, and tissues (*396*) (AIII). Close contacts to be deferred from donations include persons who have engaged repeatedly in activities that could result in an intimate exchange of body fluids with a xenotransplantation product recipient. Such close contacts could include sexual partners, household members who share razors or toothbrushes, and HCWs or laboratory personnel with repeated percutaneous, mucosal, or other direct exposures.
- History of risk factors for classic Creutzfeldt-Jakob disease (CJD), including any blood relative with Creutzfeldt-Jakob disease, receipt of a human pituitary-derived growth hormone or receipt of a corneal or dura mater graft (*383,397--399*) (BIII). Potential HSCT donors should also be screened for new variant Creutzfeldt-Jakob Disease (nvCJD) risk factors, including a history of cumulative travel or residence in the United Kingdom for ≥6 months during 1980--1996 o receipt of injectable bovine insulin since 1980, unless the product was not manufactured since 1980 from cattle in the United Kingdom (*398*) (BIII). The clinical latency period for iatrogenic, classic CJD can be >30 years (*398*), and transmission of classic CJD by blood products is highly unlikely (*398*). Although no classi or nvCJD has ever been reported among HSCT recipients, persons with a history of classic or nvCJD risk factors should be excluded from donation for unrelated HSCT (DIII) if a choice exists between two otherwise equally suitable donors. The risk for transmitting classic or nvCJD from an HSCT donor to a recipient is unknown, but researchers believe that persons with nvCJD risk factors could be at higher risk for transmitting nvCJD to HSCT recipients than persons with class CJD risk factors.
- Past medical history that indicates the donor has clinical evidence of or is at high risk for acquiring a bloodborne infection (e.g., HIV-1 or -2, human T-lymphotropic virus [HTLV]-I or -II, hepatitis C, or hepatitis B) (*381,383*), including
  - men who have had sex with another man during the preceding 5 years (*381,383*) (BIII);
  - persons who report nonmedical intravenous, intramuscular, or subcutaneous injection of drugs during the preceding 5 years (*381*) (BIII);
  - persons with hemophilia or related clotting disorders who have received human-derived clotting factor concentrates (*381*) (BIII);
  - persons who have engaged in sex in exchange for money or drugs during the preceding 5 years (*381*) (BIII);
  - persons who have had sex during the preceding 12 months with any person described previously (*381*) or with a person known or suspected to have HIV (*381*) or hepatitis B infections (BIII);
  - persons who have been exposed during the preceding 12 months to known or suspected HIV, hepatitis B- or C-infected blood through percutaneous inoculation or through contact with an open wound, nonintact skin, or mucous membrane (*381*) (BIII);
  - inmates of correctional systems (*379--381*) and persons who have been incarcerated for >72 consecutive hours during the previous 12 months (BIII);
  - persons who have had or have been treated for syphilis or gonorrhea during the preceding 12 months (*376,379,380*) (BIII); and
  - persons who within 12 months have undergone tattooing, acupuncture, ear or body piercing (*380,400,401*) in which shared instruments are known to have been used (BIII) or other nonsterile conditions existed.

Persons reporting any of these past medical histories should be excluded from donation (DIII).

The following serologic tests should be performed for each prospective donor:

- HIV-1 antigen, anti-HIV-1 and -2, anti-HTLV-I and -II, hepatitis B surface antigen, total antihepatitis B core antigen, antihepatitis C, anti-CMV, and a serologic t for syphilis (*376,379,380,383*) (AIII). Potential donors who have repeatedly reactive screening tests for HIV-1 antigen, anti-HIV-1 or -2, anti-HTLV-I or -II, antihepatitis C, hepatitis B surface antigen, or antihepatitis B core antigen should be excluded as HSCT donors (*381*) (EII). Persons who refuse infectious disease testing should also be excluded as HSCT donors (*381*) (EIII).
- Investigational nucleic acid tests to detect hepatitis C virus RNA and HIV RNA are currently being used in the United States to screen blood donors and could be used for screening HSCT donors. If nucleic acid tests are approved by FDA, these tests should be incorporated into routine screening regimens for HSCT donors When nucleic acid testing is done for HIV and hepatitis C investigationally, a positive result should exclude the potential donor.

All infectious disease testing and results should be reported to the HSCT physician before the candidate's conditioning regimen begins (*381*) (AIII). Bone marrow shou be collected using sterile technique in a medically acceptable setting and according to standard operating procedures (AIII).

HSCT transplant center personnel should keep accurate records of all HSCT received and the disposition of each sample obtained (*381*). These tracking records must b separate from patients' medical records (e.g., in a log book) so that this information is easily obtainable. Recorded information should include the donor identification number, name of procurement of distribution center supplying the HSCT, recipient-identifying information, name of recipient's physician, and dates of a) receipt by the HSCT center and b) either transplantation to the recipient or further distribution (*381*) (AIII). All centers for donation, transplantation, or collection of hematopoietic st cells should keep records of donor screening and testing, and HSCT harvesting, processing, testing, cryopreservation, storage, and infusion or disposal of each aliquot donated hematopoietic progenitor cells for ≥10 years after the date of implantation, transplantation, infusion, or transfer of the product (*378*) (AIII). However, if that da is not known, records should be retained ≥10 years after the product's distribution, disposition, or expiration, whichever is latest.

Pediatric Donors

Children aged >18 months who are born to mothers with or at risk for HIV infection, who have not been breast-fed during the past 12 months, and whose HIV antibod tests, physical examination, and medical records do not indicate evidence of HIV infection can be accepted as donors (*381*) (BIII). Children aged <18 months who are born to mothers with or at risk for HIV infection and who have not been breast-fed by an HIV-infected woman during the past 12 months can be accepted as donors on if HIV infection has been excluded according to established criteria (*402*) (BIII). Children who have been breast-fed by an HIV-infected woman during the past 12 months should be excluded as stem cell donors regardless of HIV infection status (AIII). The mother and, if possible, the father of all pediatric stem-cell donors who ar at risk for perinatal transmission of HIV and other bloodborne infections, should be interviewed by a health-care professional competent to elicit information regarding risk factors for possible bloodborne infection in the potential pediatric donor (AIII). Children who meet any of the adult donor exclusion criteria should not become HSCT donors (*381*) (EIII).

Preventing Infection from Extraneous Contamination of Donated Units

Personnel of donation, collection, or transplantation centers, cell-processing laboratories, and courier services should follow current standards for detecting and preventing extrinsic bacterial and fungal contamination of collected stem cell units at the collection site, during processing and transportation, and at the transplant cen (*376*) (AIII). Quality improvement programs and procedure manuals of collection centers, cell-processing laboratories, and transplant programs should include strategi for preventing transplant-associated infections. For example, collection centers should use aseptic techniques when collecting marrow, peripheral blood, and UCB hematopoietic stem cells (*376,378*) (AIII). Whenever possible, closed systems should be used for pooling hematopoietic stem cells during a collection procedure (BIII) because higher rates of microbial contamination seen in marrow harvests versus blood stem cell collections can be caused by use of open collecting systems (*375,403,404*). The highest risk for extraneous microbial contamination of hematopoietic stem cells occurs during extensive manipulation and processing in the laboratory (*404,405*). Potential sources include unprotected hands and laboratory equipment and freezers (*406*), particularly the liquid phases of liquid nitrogen freezer (*407*). Therefore, stem cell processing should be performed according to current standards (*378*) using approved manufacturing practices (AIII). Hematopoietic stem c units thawed in a water bath should be enclosed in a second bag (i.e., double-bagged technique) to prevent contamination of the ports or caps from unsterile bath water (*407*) (BIII). Additionally, water baths should be cleaned routinely (BIII) and certain researchers have proposed that the bath contain sterile water (*407*) (CIII). Researchers also report sterilizing liquid nitrogen freezers before initial use for hematopoietic stem cell storage (*407*) until fungal and bacterial cultures are negative (CIII).

Cell-processing laboratory personnel should implement programs to detect extrinsic bacterial or fungal contamination of collected stem cell units, ideally before transplantation (AIII). Although repeated cultures are costly (*408*), donated hematopoietic stem cells should be cultured for aerobic bacteria and fungi $\geq$1 times during initial processing and freezing (BIII). Researchers also have proposed adding anaerobic bacterial cultures and culturing twice, once at the end of processing, and once after thawing just before use (*407*) (CIII). If bacterial culture results are positive, antibiotic-susceptibility tests should be performed (BIII). Results of cultures and antibiotic-susceptibility tests should be provided to the transplant physician before release of a cryopreserved marrow or blood stem cell unit, and as soon as feasible fo transplants infused before completion of culture incubation (BIII).

Collection center, cell-processing laboratory, and transplant program personnel should maintain active surveillance of infections among persons who have received hematopoietic stem cells from those facilities to collect data regarding the number of infections after HSCT that might have been caused by exogenous contamination donor stem cells (BIII) because this type of infection has been reported (*405*).

In Utero or Fetal HSCT

No national standards exist for in utero or fetal HSCT, and the overall risks for transmitting infections to a fetus through HSCT (*409,410*) have not been determined. However, in addition to precautions appropriate for adult recipients, physicians performing in utero or fetal HSCT are advised to evaluate potential donors for evidence active infectious diseases that could cause serious congenital infections (e.g., rubella, varicella, CMV, syphilis, or *To. gondii*) in the fetus (CIII).

* For this report, HSCT is defined as any transplantation of blood- or marrow-derived hematopoietic stem cells, regardless of transplant type (e.g., allogeneic or autologous) or cell source (e.g., bone marrow, peripheral blood, or placental/umbilical cord blood). In addition, HSCT recipients are presumed immunocompetent at ≥24 months after HSCT if they are not on immunosuppressive therapy ar do not have graft-versus-host disease (GVHD), a condition that occurs when the transplanted cells recognize that the recipient's cells are not the same cells and attack them.

** Presently, no updated data have been published.

*** Since November 1997, the United States has had a shortage of intravenous immunoglobulin (IVIG) (**Source:** CDC. Availability of immune globulin intravenous for treatment of immune deficient patients---United States, 1997--1998. MMWR 1999:48[8];159--162). Physicians who have difficulty obtaining IVIG should contact the following sources:

- American Red Cross Customer Service Center, (800) 261-5772;
- Alpha Therapeutic Corporation, (800) 421-0008;
- Baxter Healthcare Corporation, (847) 940-5955;
- Bayer Pharmaceutical Division, (800) 288-8370;
- Aventis Behring Customer Support, (800) 683-1288;
- Novartis Pharmaceuticals Corporation, (973) 781-8300, or the IVIG Emergency Hotline, (888) 234-2520; or
- Immune Deficiency Foundation, (800) 296-4433.

Physicians who are unable to obtain IVIG for a licensed indication from one of these sources should contact the Product Shortage Officer at the Food and Drug Administration's Center for Biologics Evaluation and Research, Office of Compliance, (301) 827-6220, for assistance.

**** VZIG is distributed by FFF Enterprises, Inc., under contract with the American Red Cross, except in Massachusetts where it is distributed by the Massachusetts Public Health Biologic Laboratori (now a unit of the University of Massachusetts) (*19)* . FFF Enterprises, Inc., can be contacted at

FFF Enterprises, Inc.
41093 County Center Drive
Temecula, CA 92591
Phone: (800) 522-4448

***** For additional information regarding the epidemiology of Chagas' disease, contact CDC/National Center for Infectious Diseases/Division of Parasitic Diseases, (770) 488-7760.

****** Broviac dolls are used to demonstrate medical procedures (e.g., insertion of catheters) to children to lessen their fears.

******* For a list of filters certified under NSF Standard 053 for cyst (i.e., *Cryptosporidium* removal, contact the NSF International consumer line at (800) 673-8010 or <http://www.nsf.org/notice/crypto.html>.

******** The International Bottled Water Association can be contacted at (703) 683-5213 from 9 a.m. to 5 p.m. EST or anytime at their Internet site (<http://www.bottledwater.org>) to obtain contact information regarding water bottlers.

********* The U.S. Public Health Service is reexamining the current donor deferral recommendations regarding risk behaviors for donors of organs, cells, tissues, xenotransplantation, and reproductiv cells and tissue, including semen, and revisions to these guidelines could become necessary as the research evolves.

********** Guidelines for screening UCB donors and their mothers are evolving and will not be addressed in this document.

Table 1

TABLE 1. Evidence-based rating system used to determine strength of recommendations

Category	Definition	Recommendation
A	Strong evidence for efficacy and substantial clinical benefit	Strongly recommended
B	Strong or moderate evidence for efficacy, but only limited clinical benefit	Generally recommended
C	Insufficient evidence for efficacy; or efficacy does not outweigh possible adverse consequences (e.g., drug toxicity or interactions) or cost of chemoprophylaxis or alternative approaches	Optional
D	Moderate evidence against efficacy or for adverse outcome	Generally not recommended
E	Strong evidence against efficacy or of adverse outcome	Never recommended

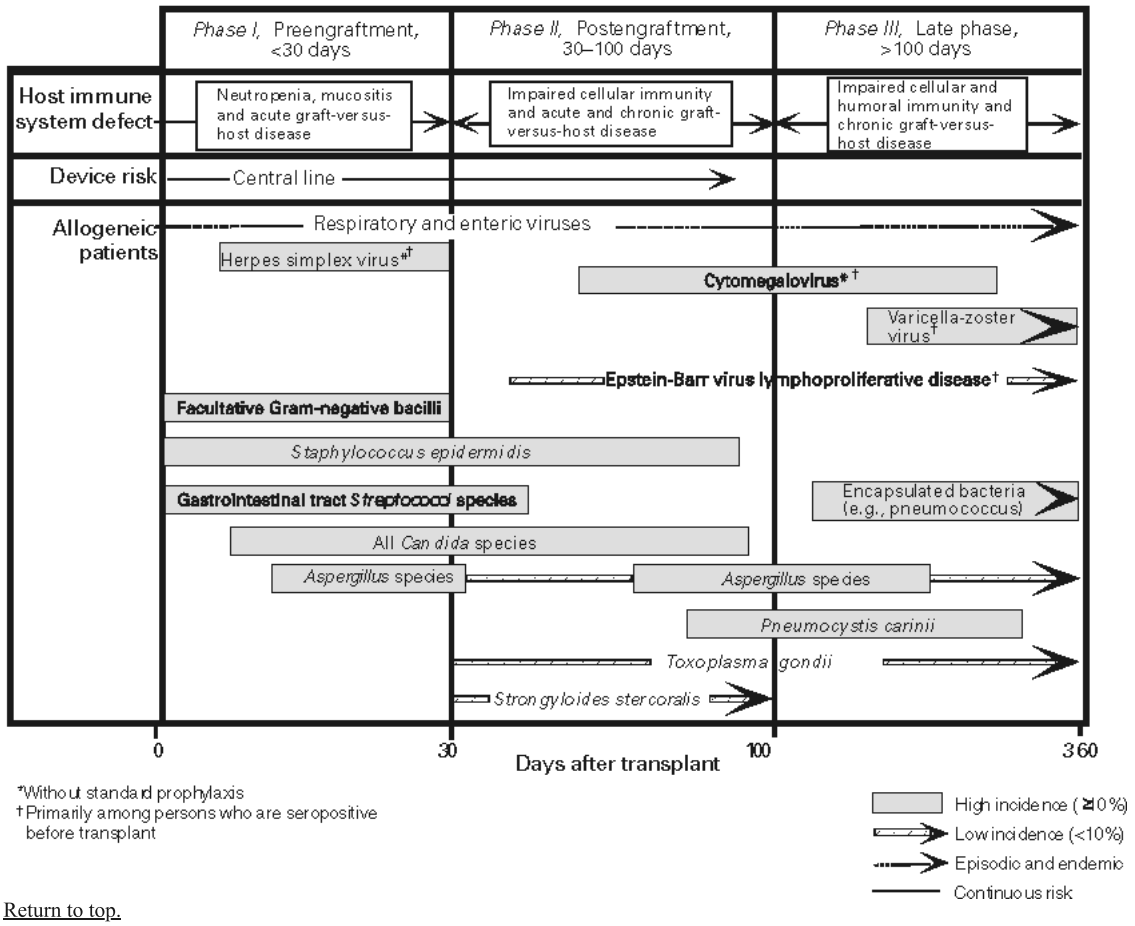
Return to top.

Figure

FIGURE. Phases of opportunistic infections among allogeneic HSCT recipients



Return to top.

Table 2

TABLE 2. Evidence-based rating system used to determine quality of evidence supporting recommendation

Category	Definition
I	Evidence from at least one well-executed randomized, controlled trial
II	Evidence from at least one well-designed clinical trial without randomization; cohort or case-controlled analytic studies (preferably from more than one center); multiple time-series studies; or dramatic results from uncontrolled experiments
III	Evidence from opinions of respected authorities based on clinical experience, descriptive studies, or reports of expert committees

Source: Adapted from CDC. 1999 USPHS/IDSA guidelines for the prevention of opportunistic infections in persons infected with human immunodeficiency virus. MMWR 1999;48(RR-10):1–66.

Table 3

TABLE 3. Foods that pose a high risk for hematopoietic stem cell transplant (HSCT) recipients and safer substitutions

Foods That Pose a High Risk	Safer Substitutions
Raw and undercooked eggs* and foods containing them (e.g., french toast, omelettes, salad dressings, egg nog, and puddings)	Pasteurized or hard boiled eggs
Unpasteurized dairy products (e.g., milk, cheese, cream, butter, and yogurt)	Pasteurized dairy products
Fresh-squeezed, unpasteurized fruit and vegetable juices	Pasteurized juices
Unpasteurized cheeses or cheeses containing molds	Pasteurized cheeses
Undercooked or raw poultry, meats, fish, and seafood	Cooked poultry, well-done meats, cooked fish, and seafood
Vegetable sprouts (e.g., alfalfa, bean, and other seed sprouts)†	Should be avoided
Raw fruits with a rough texture (e.g., raspberries)§	Should be avoided
Smooth raw fruits	Should be washed under running water, peeled, or cooked
Unwashed raw vegetables¶	Should be washed under running water, peeled, or cooked
Undercooked or raw tofu	Cooked tofu (i.e., cut into 1-inch cubes and boiled for 5 minutes in water or broth before eating or using in recipes)
Raw or unpasteurized honey	Should be avoided
Deli meats, hot dogs, and processed meats**	Should be avoided unless further cooked
Raw, uncooked grain products	Cooked grain products including bread, cooked, and ready-to-eat cold cereal, pretzels, popcorn, potato chips, corn chips, tortilla chips, cooked pasta, and rice
Maté tea††	Should be avoided
All moldy and outdated food products	Should be avoided
Unpasteurized beer (e.g., home-brewed and certain microbrewery beer)	Pasteurized beer (i.e., retail bottled or canned, or draft beer that has been pasteurized after fermentation)
Raw, uncooked brewers yeast	Should be avoided; HSCT recipients should avoid any contact with raw yeast (e.g., they should not make bread products themselves)
Unroasted raw nuts	Cooked nuts
Roasted nuts in the shell	Canned or bottled roasted nuts or nuts in baked products

Table 4

TABLE 4. Recommended vaccinations for hematopoietic stem cell transplant* (HSCT) recipients, including both allogeneic and autologous recipients

For these guidelines, HSCT recipients are presumed immunocompetent at ≥24months after HSCT if they are not on immunosuppressive therapy and do not have graft-versus-host disease (GVHD).

Vaccine or toxoid	Time after HSCT: 12 months	14 months	24 months	Rating
Inactivated vaccine or toxoid				
Diphtheria, tetanus, pertussis				
Children aged <7 years*	Diphtheria toxoid-tetanus toxoid-pertussis vaccine (DTP) or diphtheria toxoid-tetanus toxoid (DT)†	DTP or DT	DTP or DT	BIII
Children aged 7 years§	Tetanus-diphtheria toxoid (Td)	Td	Td	BII
Haemophilus influenzae type b (Hib) conjugate¶	Hib conjugate	Hib conjugate	Hib conjugate	BII
Hepatitis (HepB)**	HepB	HepB	HepB	BIII
23-valent pneumococcal polysaccharide (PPV23)††	PPV23	—	PPV23	BIII
Hepatitis A§§	Routine administration not indicated			Not rated because of limited data
Influenza¶¶	Lifelong, seasonal administration, beginning before HSCT and resuming at ≥6 months after HSCT			BII
Meningococcal***	Routine administration not indicated			Not rated because of limited data
Inactivated polio (IPV)†††	IPV	IPV	IPV	BII
Rabies§§§	Routine administration not indicated			Not rated because of limited data
Lyme disease	Routine administration not indicated; limited data regarding safety, efficacy, or immunogenicity among HSCT recipients			Not rated because of limited data
Live-attenuated vaccine				
Measles-mumps-rubella (MMR)¶¶¶ **** ††††	—	—	MMR	BIII
Varicella vaccine §§§§	Contraindicated for HSCT recipients			EIII
Rotavirus vaccine	Not recommended for any person in the United States¶¶¶¶			EII

TABLE 4. (*Continued*) Recommended vaccinations for hematopoietic stem cell transplant* (HSCT) recipients, including both allogeneic and autologous recipients

* Studies report that an HSCT recipient can be primed if the donor has had primary vaccination series. Studies also report that a recipient's antibody titer bef HSCT might affect the titer 1 year after HSCT (**Source**: Lum LG. Kinetics of immune reconstitution after human marrow transplantation. Blood 1987;69[2]:369–8 No data were found regarding safety and immunogenicity of pertussis vaccination among HSCT recipients.

† DT should be used whenever a contraindication exists to pertussis vaccination.

§ HSCT recipients should be revaccinated with tetanus-diphtheria toxoids every 10 years, as routinely recommended for all adolescents and adults (**Sources**: C Diphtheria, tetanus, and pertussis: recommendations of vaccine use and other prevention measures; recommendations of the Advisory Committee on Immuni tion Practices [ACIP]. MMWR 1991;40[No.RR-10]:1–28; and CDC. Use of vaccines and immunoglobulin in persons with altered immunocompetence: recomm dations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1993;42[No.RR-4]:1–18).

¶ Hib conjugate vaccine is recommended for HSCT recipients of any age (**Sources**: CDC. Recommendations for use of *Haemophilus* b conjugate vaccines an combined diphtheria, tetanus, pertussis, and *Haemophilus* b vaccine: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MM 1993;42[No. RR-13]:1–15; and CDC. Use of vaccines and immunoglobulin in persons with altered immunocompetence: recommendations of the Advis Committee on Immunization Practices [ACIP]. MMWR 1993;42[No.RR-4]:1–18).

** Hepatitis B vaccination is recommended for all susceptible persons aged ≤18 years and for adults who have risk factors for hepatitis B virus infection (**Sourc** CDC. Hepatitis B virus: a comprehensive strategy for eliminating transmission in the United States through universal childhood vaccination; recommendatio of the Immunization Practices Advisory Committee [ACIP]. MMWR 1991;40[No.RR-13]:1–25; and CDC. Notice to readers: update; recommendations to prev hepatitis B virus transmission—United States. MMWR 1995;44[30]:574–5). ACIP hepatitis B vaccination recommendations indicate that high doses (40 µg/do are recommended for adult dialysis patients and other immunocompromised adults (**Source**: CDC. Notice to readers: update; recommendations to prev hepatitis B virus transmission—United States. MMWR 1995;44[30]:574–5). No data were found regarding immunocompromised children and their response higher doses of vaccine. Postvaccination testing for antibody to hepatitis B surface antigen is recommended 1–2 months after the third vaccine dose to ens protection among immunocompromised persons (**Source**: CDC. Notice to readers: update; recommendations to prevent hepatitis B virus transmission—Uni States. MMWR 1995;44[30]:574–5). Persons who do not respond to the primary vaccine series should complete a second 3-dose series.

†† The 23-valent pneumococcal polysaccharide vaccine might not be protective against pneumococcal infection among HSCT recipients. The second dose of vacc is not a booster dose, but provides a second chance for immunologic response among persons who failed to respond to the first dose (**Source**: Guinan EC, Molr DC, Antin JH, et al. Polysaccharide conjugate vaccine responses in bone marrow transplant patients. Transplant 1994;57[5]:677–84). Adjunctive antibio prophylaxis against encapsulated organisms, including pneumococcal disease, is recommended for allogeneic recipients with chronic GVHD (**Source**: Bortin M Horowitz MM, Gale RP, et al. Changing trends in allogeneic bone marrow transplantation for leukemia in the 1980s. JAMA 1992; 268[5]:607–12). No data were fou regarding safety and immunogenicity of the 7-valent conjugate pneumococcal vaccine among HSCT recipients; therefore, no recommendation regarding use of t vaccine can be made.

§§ No data were found regarding immunogenicity, safety, and efficacy of hepatitis A vaccine among HSCT recipients. Researchers report that hepatitis A vaccinat can be used for investigational use among HSCT recipients aged ≥24 months at ≥12 months after HSCT and who are at increased risk for hepatitis A or its adve consequences (e.g., persons with chronic liver disease, including chronic GVHD, and children living in areas with consistently elevated hepatitis A inciden (**Source**: CDC. Prevention of hepatitis A through active or passive immunization: recommendations of the Advisory Committee on Immunization Practices [AC MMWR 1999;48[No.RR-12]:1–37).

¶¶ Children aged <9 years receiving influenza vaccination for the first time require two doses. Children aged ≤12 years should receive only split-virus influe vaccine. Persons aged >12 years can receive whole- or split-virus vaccine. ACIP's and the American Academy of Pediatrics' dosing schedule should be us (**Sources**: American Academy of Pediatrics. Influenza. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Gro Village, IL: American Academy of Pediatrics, 2000:351–9; and CDC. Prevention and control of influenza: recommendations of the Advisory Committee Immunization Practices [ACIP]. MMWR 2000;49[No.RR-3]:1–38). For optimal influenza prevention, both vaccination and influenza chemoprophylaxis should used among HSCT recipients.

*** Administration of meningococcal vaccine should be evaluated for HSCT recipients who live in endemic areas or areas experiencing outbreaks (**Source**: C Control and prevention of meningococcal disease and control and prevention of serogroup C meningococcal disease: evaluation and management of suspec outbreaks. MMWR 1997;46[No.RR-5]:1–21). However, meningococcal vaccine immunogenicity and efficacy among HSCT recipients have not been studied.

††† Inactivated polio virus vaccine is immunogenic among HSCT recipients, although no data were found regarding efficacy and more data are needed regard optimal methods and timing of immunization (**Sources**: Henning KJ, White MH, Sepkowitz KA, Armstrong D. National survey of immunization practices follow allogeneic bone marrow transplantation. JAMA 1997;277[14]:1148–51; and CDC. Poliomyelitis prevention in the United States: introduction of a sequen vaccination schedule of inactivated poliovirus vaccine followed by oral poliovirus vaccine; recommendations of the Advisory Committee on Immunizat Practices [ACIP]. MMWR 1997;46[No.RR-3]:1–25).

TABLE 4. (*Continued*) Recommended vaccinations for hematopoietic stem cell transplant* (HSCT) recipients, including both allogeneic and autologous recipients

§§§ Clinicians can administer preexposure rabies vaccine to HSCT recipients with potential occupational exposures to rabies (**Source**: CDC. Human rab prevention—United States, 1999: recommendations of the Advisory Committee on Immunization Practices [ACIP] MMWR 1999;48[No.RR-1]:1–21; and publis erratum, MMWR 1999;48[1]:16). However, the safety and immunogenicity of rabies vaccination among HSCT recipients has not been studied. Preexposure rab vaccination should probably be delayed until 12–24 months after HSCT. Administration of rabies vaccine with human rabies immunoglobulin postexposure recan administered anytime after HSCT as indicated. Existing ACIP and American Academy of Pediatrics guidelines for postexposure human rabies immunoglobulina vaccine administration should be followed, which include administering 5 doses of rabies vaccine administered on days 0, 3, 7, 14, and 28 postexposure (**Sourc** American Academy of Pediatrics. Rabies. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, American Academy of Pediatrics;2000:475–82; and CDC. Human rabies prevention—United States, 1999: recommendations of the Advisory Committee Immunization Practices [ACIP] MMWR 1999;48[No.RR-1]:1–21; publish ederratum, MMWR 1999;48[1]:16).

¶¶¶ The first dose of measles-mumps-rubella vaccine should be administered ≥24 months after HSCT if the HSCT recipient is presumed immunocompetent. The secc measles-mumps-rubella dose is recommended 6–12 months later (BIII); however, the benefit of a second dose among HSCT recipients has not been evaluat During outbreaks, the second dose can be administered 4 weeks after the first dose (**Source**: CDC. Use of vaccines and immunoglobulin in persons with alte immunocompetence: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1993;42[No.RR-4]:1–18).

**** The half-life of intravenous immunoglobulin is decreased among HSCT recipients, but its effect on vaccine immunogenicity has not been evaluated. ACIP's and American Academy of Pediatrics' recommendations regarding intervals between administration of immunoglobulin preparations for various indications a vaccines containing live measles virus should be used (**Sources**: American Academy of Pediatrics. Measles. In: Pickering LK, ed. 2000 red book: report of Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics, 2000:385–96; CDC. Measles, mumps, and rubella—vaccine and strategies for elimination of measles, rubella, and congenital rubella syndrome and control of mumps: recommendations of the Advisory Committee Immunization Practices [ACIP]. MMWR 1998;47[No. RR-8]:1–48; and CDC. General recommendations on immunization: recommendations of the Advis Committee on Immunization Practices [ACIP]. MMWR 1994;43[No.RR-1]:1–38).

†††† Use of live vaccines (e.g., measles-mumps-rubella) is indicated only among immunocompetent persons and is contraindicated for recipients after HSCT who not presumed immunocompetent (**Sources**: CDC. Prevention of varicella: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MM 1996;45[No.RR-11]:1–36; and CDC. General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices [AC MMWR 1994;43[No.RR-1]:1–38). Further research is needed to determine the safety, immunogenicity, and efficacy of varicella vaccine among HSCT recipier

§§§§ To protect HSCT recipients from varicella exposure, all varicella-susceptible health-care workers, family members, and close contacts of the recipient should vaccinated against varicella (**Source**: American Academy of Pediatrics. Varicella-zoster infections. In: Pickering LK, ed. 2000 red book: report of the commit on Infectious diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics;2000:624–38).

¶¶¶¶ **Source**: CDC. Withdrawal of rotavirus vaccine recommendation. MMWR 1999;48[43]:1007.

Additional Notes: All indicated nonlive vaccines should be administered to HSCT recipients regardless of HSCT type or presence of GVHD. Live-attenuated vaccines, (e.g., measles-mumps-rubella, varicella, Bacillus Calmette-Guérin, yellow fever, and oral typhoid vaccines) should not be administered to any HSCT recipient with active GVHD or immunosuppression (**Source**: CDC. Role of BCG [Bacillus of Calmette and Guérin] vaccine in the prevention and control of tuberculosis in the United States: a joint statement by the Advisory Council for the Elimination of Tuberculosis and the Advisory Committee on Immunization Practices. MMWR 1996;45[No.RR-4]:1–18). To date, no adverse events have been reported (e.g., exacerbation of GVHD) among vaccinated HSCT recipients. However, data regarding immunization among HSCT recipients are limited and further studies are needed to evaluate safety, efficacy, and immunogenicity of th proposed HSCT immunization schedule. Use of combination vaccines is encouraged (**Source**: CDC. Combination vaccines for childhood immunization: recomme dations of the Advisory Committee on Immunization Practices [ACIP], the American Academy of Pediatrics [AAP], and the American Academy of Family Physicia [AAFP]. MMWR 1999;48[No. RR-5]:1–15). No contraindications to simultaneous administration of any vaccines exist, except cholera and yellow fever. Adverse events after vaccination should be reported promptly to the Vaccine Adverse Event Reporting System (VAERS), P.O. Box 1100, Rockville, MD 20849-1100. Forms and information can be obtained from VAERS ([800] 822-7967). If the HSCT recipient has lapsed immunizations after HSCT (i.e., has missed one or more vaccine doses), the immunization schedule does not have to be restarted. Instead, the missing vaccine dose should be administered as soon as possible or during the next scheduled clinic appointment.

Return to top.

Table 5

Table 5. Vaccinations for family close contacts, and health-care workers (HCWs) of hematopoietic stem cell transplantation (HSCT) recipients*

Vaccine	Recommendations for use	Rating
Hepatitis A†	Routine vaccination is recommended for persons at increased risk for hepatitis A or its adverse consequences (e.g., persons with chronic liver disease or persons traveling to hepatitis A-endemic countries) and for children aged ≥24 months living in areas with consistently elevated hepatitis A incidence.†	BII
Influenza§¶	Household contacts — Vaccination is strongly recommended during each influenza season (i.e., October–May) beginning in the season before the transplant and continuing to ≥24 months after HSCT. All household contacts of immunocompromised HSCT recipients should be vaccinated annually as long as these conditions persist.	AI
	HCWs and home caregivers — Annual vaccination is strongly recommended during each influenza season.	AI
Polio**	Vaccination is not routinely recommended for adults but should be administered when polio vaccination is indicated according to published Advisory Committee on Immunization Practices guidelines; when polio vaccine is administered, inactivated polio vaccine should be used.	AI
Measles-mumps-rubella††	Vaccination is recommended for all persons who are aged ≥12 months and who are not pregnant or immunocompromised.	AI
Rotavirus§§	Contraindicated because intussusception has been reported among infants during the first 1–2 weeks after rotavirus vaccination with substantially increased frequency.	EII
Varicella¶¶	Vaccination should be administered to all susceptible HCWs, household contacts, and family members who are aged ≥12 months and who are not pregnant or immunocompromised. When varicella vaccination is administered to persons aged ≥13 years, 2 doses are required, administered 4–8 weeks apart.	AIII

* This vaccination schedule refers only to vaccine-preventable diseases that are spread person-to-person.

† **Source**: CDC. Prevention of hepatitis A through active or passive immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1999;48(No. RR-12):1–37.

§ Children aged <9 years receiving influenza vaccination for the first time require 2 doses. Children aged ≤12 years should receive only split-virus influenza vaccine. Persons aged >12 years can receive whole- or split-virus vaccine (**Sources**: CDC. Prevention and control of influenza: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 2000;49[No. RR-3]:1–38; and CDC. Immunization of health care workers: recommendations of the Advisory Committee on Immunization Practices [ACIP] and the Hospital Infection Control Practices Advisory Committee. MMWR 1997;46[No. RR-18]:1–42).

¶ If HCWs, family members, or other close contacts of HSCT recipients receive influenza vaccination during an influenza A outbreak, they should also receive amantadine or rimantadine chemoprophylaxis for 2 weeks after the influenza vaccination (BI) while the vaccinee develops an immunologic response to the vaccine. However, if a nosocomial outbreak occurs with an influenza A strain that is not contained in the available influenza vaccine, HCWs, family members, and other close contacts of HSCT recipients and candidates should be administered influenza A chemoprophylaxis with amantadine or rimantadine until the end of the outbreak (**Source**: CDC. Prevention and control of influenza: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 2000;49[No. RR-3]:1–38) (BIII). HCWs, family members, or other close contacts can be offered a neuraminidase inhibitor (e.g., zanamivir or oseltamivir) using the same strategies outlined previously, if one or more of the following exists: a) rimantadine or amantadine cannot be tolerated; b) the outbreak strain of influenza A is amantadine- or rimantadine-resistant; or c) the outbreak strain is influenza B (**Sources**: Monto AS, Robinson DP, Herlocher ML, Hinson JM Jr, Elliott MJ, Crisp A. Zanamivir in the prevention of influenza among healthy adults: a randomized controlled trial. JAMA 1999;282[1]:31–5; Hayden FG, Atmar RL, Schilling M, et al. Use of the selective oral neuraminidase inhibitor oseltamivir to prevent influenza. New Engl J Med 1999;341[18]:1336–43; Hayden FG, Gubareva L, Klein T, et al. Inhaled zanamivir for preventing transmission of influenza in families [Abstract LB-2]. In: Final program, abstracts and exhibits addendum, 38th Interscience Conference on Antimicrobial Agents and Chemotherapy. Washington, DC: American Society for Microbiology, 1991:1; and CDC. Neuraminidase inhibitors for treatment of influenza A and B infections. MMWR 1999;48[No. RR-14]:1–10) (BI). Zanamivir can be administered to persons aged ≥12 years, and oseltamivir can be administered to persons aged ≥18 years.

** **Caution**: Vaccine-strain polio virus in oral polio vaccine can be transmitted person-to-person; therefore, oral polio vaccine administration is contraindicated among household contacts of immunocompromised persons. If oral polio vaccine is inadvertently administered to a household contact of an HSCT recipient, ACIP's and the American Academy of Pediatrics' recommendations should be followed to minimize close contact with the immunocompromised person for 4–6 weeks after vaccination (**Sources**: American Academy of Pediatrics. Poliovirus infections. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics, 2000:465–70; CDC. Immunization of health care workers: recommendations of the Advisory Committee on Immunization Practices (ACIP) and the Hospital Infection Control

Table 5. (*Continued*) Vaccinations for family close contacts, and health-care workers (HCWs) of hematopoietic stem cell transplantation (HSCT) recipients*

Practices Advisory Committee. MMWR 1997;46[No. RR-18]:1–42; and CDC. Poliomyelitis prevention in the United States: introduction of a sequential vaccination schedule of inactivated poliovirus vaccine followed by oral poliovirus vaccine; recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1997;46[No. RR-3]:1–25). Although vaccine-associated paralytic poliomyelitis has not been reported among HSCT recipients after exposure to household contacts inadvertently vaccinated with oral polio vaccine, inactivated polio vaccine should be used among family members, close contacts, and HCWs to avoid person-to-person transmission of vaccine-strain poliovirus (**Source**: CDC. Poliomyelitis prevention in the United States: introduction of a sequential vaccination schedule of inactivated poliovirus vaccine followed by oral poliovirus vaccine; recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1997;46[No. RR-3]:1–25).

†† No evidence exists that live-attenuated vaccine-strain viruses in measles-mumps-rubella vaccine have ever been transmitted from person-to-person, except rubella vaccine virus from a nursing mother to her infant (**Source**: CDC. Measles, mumps, and rubella—vaccine use and strategies for elimination of measles, rubella, and congenital rubella syndrome and control of mumps: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1998;47[No. RR-8]:1–48).

** HCWs, family members, close contacts and visitors who do not have a documented history of varicella-zoster infection or who are seronegative should receive this vaccination before being allowed to visit or have direct contact with an HSCT recipient (AIII). Ideally, varicella-zoster–susceptible HCWs, family members, household contacts, and potential visitors of immunocompromised HSCT recipients should be vaccinated as soon as the decision to perform an HSCT is made. The vaccination dose or doses should be completed ≥4 weeks before the conditioning regimen begins or ≥6 weeks (42 days) before contact with the HSCT recipient is planned (BIII). If a varicella vaccinee develops a postvaccination rash within 42 days of vaccination, the vaccinee should avoid contact with HSCT recipients until all rash lesions are crusted or the rash has resolved (**Sources**: CDC. Prevention of varicella: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1996;45[No. RR-11]:1–36; and CDC. Immunization of health care workers: recommendations of the Advisory Committee on Immunization Practices [ACIP] and the Hospital Infection Control Practices Advisory Committee. MMWR 1997;46[No. RR-18]:1–42).

Return to top.

Table 6

TABLE 6. Vaccinations for hematopoietic stem cell transplant (HSCT) recipients traveling to areas endemic for selected vaccine-preventable diseases

Vaccine	Recommendations for use	Rating
Bacillus of Calmette and Guérin (live-attenuated vaccine)	Use of live-attenuated vaccine is contraindicated among HSCT recipients at <24 months after HSCT and among all persons who are immunocompromised.* No data were found regarding use among HSCT recipients.	EIII
Cholera	Vaccination is not indicated. No data were found regarding safety and immunogenicity among HSCT recipients.†	DIII
Hepatitis A	No data were found regarding immunogenicity, safety, or efficacy of hepatitis A vaccine among HSCT recipients; therefore, intramuscular immunoglobulin use is preferred for hepatitis A prophylaxis among HSCT recipients. However, administration of intramuscular immunoglobulin does not replace avoidance behaviors (e.g., careful selection of food and water).§ Researchers recommend that hepatitis A vaccination be evaluated for investigational use among HSCT recipients aged ≥24 months; however, no recommendation can be made because of limited data.	Not rated because of limited data
Japanese B encephalitis	No data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.¶	Not rated because of limited data
Lyme disease	No data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.	Not rated because of limited data
Meningococcal vaccine	Vaccine should be administered to HSCT recipients traveling to endemic areas or to areas experiencing outbreaks.** However, meningococcal vaccine immunogenicity and efficacy have not been studied among HSCT recipients.	Not rated because of limited data
Plague	No data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.††	Not rated because of limited data
Polio (inactivated polio vaccine only)	Booster dose can be administered as indicated.§§	CIII
Rabies	Researchers recommend that administration of a preexposure series be evaluated for persons at ≥12 months after HSCT if they anticipate travel to endemic areas.¶¶ However, no data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.	Not rated because of limited data
Typhoid, oral (live-attenuated vaccine)	Use of oral typhoid vaccine (live-attenuated strain) is contraindicated among HSCT recipients at <24 months after HSCT and among those who are immunocompromised.*** No data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.	EIII
Typhoid (intramuscular)	No data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.	Not rated because of limited data
Yellow fever (live-attenuated vaccine)	Use of live-attenuated vaccine is contraindicated among HSCT recipients at <24 months after HSCT and among all immunocompromised persons.††† No data were found regarding safety, immunogenicity, or efficacy among HSCT recipients.	EIII

Table 7

TABLE 7. Use of passive immunization for hematopoietic stem cell transplant (HSCT) recipients exposed to vaccine-preventable diseases

Preparation	Recommendations for Use	Rating
Cytomegalovirus immunoglobulin	Not recommended for prophylaxis among HSCT recipients because of its lack of efficacy.*	DI
Hepatitis B immunoglobulin	Immunocompromised persons who have percutaneous or permucosal exposure to hepatitis B virus should receive 2 doses administered 1 month apart. For immunocompetent persons, the need for postexposure prophylaxis depends on the vaccination history and antibody to hepatitis B surface antigen response status of the exposed person.†	CIII
Human rabies immunoglobulin	Should be administered with rabies vaccine at anytime after HSCT as indicated for postexposure rabies prophylaxis. Existing Advisory Committee on Immunization Practices guidelines for postexposure should be followed, with 5 doses of rabies vaccine administered on days 0, 3, 7, 14, and 28 postexposure.§	CIII
Respiratory syncytial virus immunoglobulin¶	Because of high rates of case fatality from respiratory syncytial virus pneumonia among HSCT recipients, HSCT physicians can administer HSCT recipients with upper or lower respiratory infection preemptive therapy with a high titer of neutralizing antibodies to prevent severe disease and death until controlled trials can be performed.**	CIII
Respiratory syncytial virus monoclonal antibody	Physicians can use respiratory syncytial virus monoclonal antibody†† investigationally as preemptive therapy (Appendix).	Not rated because of limited data
Tetanus immunoglobulin	Postexposure vaccination should be administered with or without tetanus immunoglobulin as indicated for tetanus exposure§§ that occurs anytime after HSCT.	CIII
Varicella-zoster immunoglobulin¶¶	Ideally, should be administered to HSCT recipients ≤96 hours after close contact with a person with varicella or shingles if the HSCT recipient is at a) <24 months after HSCT or b) ≥24 months after HSCT and still immunocompromised. Administration can extend the varicella incubation period from 10–21 days to 10–28 days. If the HSCT recipient experiences a varicella-zoster virus-like rash after contact with or exposure to a person with varicella or herpes zoster, antiviral drug therapy should be administered until ≥2 days after all lesions have crusted.***	AII
Intramuscular immunoglobulin	Should be administered to hepatitis A-susceptible HSCT recipients who anticipate hepatitis A exposure, (e.g., during travel to endemic areas) and for postexposure prophylaxis as indicated.††† Should also be administered after measles exposure among HSCT recipients who were not vaccinated against measles after HSCT.§§§	BIII
Intravenous immunoglobulin¶¶¶	Can be administered to HSCT recipients with severe hypogammaglobulinemia (immunoglobulin G <400 mg/dl) ≤100 days after HSCT to prevent bacterial infections**** (Appendix).	CIII

Human rabies prevention—United States, 1999: recommendations of the Advisory Committee on Immunization Practices (ACIP) MMWR 1999;48(No. RR-1):1–21; published erratum, MMWR 1999;48(1):16.

TABLE 7. (*Continued*) Use of passive immunization for hematopoietic stem cell transplant (HSCT) recipients exposed to vaccine-preventable diseases

¶ Researchers recommend substituting respiratory syncytial virus immunoglobulin for intravenous immunoglobulin for HSCT recipients on replacement intravenous immunoglobulin therapy during respiratory syncytial virus season (i.e., November–April) (**Source**: American Academy of Pediatrics. Respiratory syncytial virus. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2000:483–7) (CIII). However, no data were found demonstrating safety and efficacy of respiratory syncytial virus immunoglobulin use among HSCT recipients.

§§ **Source**: CDC. Diphtheria, tetanus, and pertussis: recommendations of vaccine use and other prevention measures; recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1991;40(No. RR-10):1–28.

¶¶ If intravenous immunoglobulin replacement therapy (>250 mg/kg) has been administered <2 weeks before varicella or zoster rash exposure, varicella-zoster immunoglobulin administration is probably not required. Varicella-zoster immunoglobulin is distributed by the American Red Cross, except in Massachusetts, where it is distributed by the Massachusetts Public Health Biologic Laboratories (now a unit of the University of Massachusetts) (**Source**: CDC. Prevention of varicella: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 1996;45[No. RR-11]:1–36).

*** **Source**: CDC. Prevention of varicella: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1996;45(No. RR-11):1–36.

††† **Source**: CDC. Prevention of hepatitis A through active or passive immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1999;48(No. RR-12):1–37.

§§§ **Sources**: CDC. Measles, mumps, and rubella—vaccine use and strategies for elimination of measles, rubella, and congenital rubella syndrome and control of mumps: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 1998;47(No. RR-8):1–48; and Eibl MM, Wedgwood RJ. Intravenous immunoglobulin: a review. Immunodeficiency Reviews 1989;1:1–42.

¶¶¶ When administered, serum immunoglobulin G levels should be monitored regularly (e.g., every 2 weeks).

**** **Sources**: Antman KH, Rowlings PA, Vaughn WP, et al. High-dose chemotherapy with autologous hematopoietic stem cell support for breast cancer in North America. J Clin Oncol 1997;15(5):1870–9; and Wolff SN, Fay JW, Herzig RH, et al. High-dose weekly intravenous immunoglobulin to prevent infections in patients undergoing autologous bone marrow transplantation or severe myelosuppressive therapy. Ann Intern Med 1993;118(12):937–42.

Additional Notes : Intravenous immunoglobulin can be obtained from the American Red Cross Blood Services, although shortages occasionally occur. Physicians who have difficulty obtaining urgently needed intravenous immunoglobulin and other immunoglobulin products are advised to contact any of the following:

- American Red Cross Customer Service Center, (800) 261-5772;
- Alpha Therapeutic Corporation, (800) 421-0008;
- Baxter Healthcare Corporation, (847) 940-5955;
- Bayer Pharmaceutical Division, (800) 288-8370;
- Aventis Behring Customer Support, (800) 683-1288;
- Novartis Pharmaceuticals Corporation, (973) 781-8300, or the Intravenous Immunoglobulin Emergency Hotline, (888) 234-2520; or
- Immune Deficiency Foundation, (800) 296-4433.

Physicians who are unable to obtain intravenous immunoglobulin for a licensed indication from one of these sources should contact the Product Shortage Officer at the Food and Drug Administration's Center for Biologics Evaluation and Research, Office of Compliance, (301) 827-6220, for assistance. Patients with immunoglobulin E anti-immunoglobulin A antibodies are at high risk for experiencing anaphylaxis from immunoglobulin administration (**Source**: Burks AW, Sampson HA, Buckley RH. Anaphylactic reactions after gamma globulin administration in patients with hypogammaglobulinemia. New Engl J Med 1986;314[9]:560–4). Therefore, persons with immunoglobulin A deficiency should not be administered standard immunoglobulin preparations (DIII; BIII). However, researchers report that use of immunoglobulin A-depleted immunoglobulin preparations can be used with caution in these persons (**Sources**: Burks AW, Sampson HA, Buckley RH. Anaphylactic reactions after gamma globulin administration in patients with hypogammaglobulinemia. New Engl J Med 1986;314[9]:560–4; Siberry GK, Iannone R, eds. Harriet Lane handbook: a manual for pediatric house officers. 15th ed.; St. Louis, MO: Mosby, Inc., 2000:339;739; and Stiehm ER. Human intravenous immunoglobulin in primary and secondary antibody deficiencies [Review]. Pediatr Infect Dis J 1997;16[7]:696–707).

Appendix

Appendix

Dosing Charts for Preventing Opportunistic Infections Among Hematopoietic Stem Cell Transplant Recipients

I. Preventive regimens for adult or adolescent hematopoietic stem cell transplant (HSCT) recipients

Pathogen: Cytomegalovirus

Indication	First choice	Alternatives
Universal prophylaxis for cytomegalovirus disease among all allogeneic adult or adolescent HSCT recipients at risk throughout phase II (i.e., from engraftment to day 100 after HSCT)	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 5–7 days, followed by 5–6 mg/kg intravenously daily for 5 days/week from engraftment until day 100 after HSCT (AI)	Foscarnet, 60 mg/kg intravenously every 12 hours for 7 days, followed by 90–120 mg/kg intravenously daily until day 100 after HSCT (CIII)
Or preemptive cytomegalovirus treatment administered <100 days after HSCT to all allogeneic adult or adolescent HSCT recipients at risk: Start ganciclovir when the patient experiences any level of cytomegalovirus antigenemia or viremia or has ≥2 consecutively positive cytomegalovirus-DNA polymerase chain reaction tests	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 7–14 days, followed by 5 mg/kg/day for 5 days/week until day 100 after HSCT or for a minimum of 3 weeks, whichever is longer (AI); or administer ganciclovir for a total of 3–6 weeks; antigen or polymerase chain reaction tests should be negative when ganciclovir is stopped; reinstitute ganciclovir if subsequent weekly cytomegalovirus antigenemia screening tests become positive (BI)	
Preemptive treatment for cytomegalovirus seropositive autologous adult or adolescent HSCT recipients at <100 days after HSCT: Start ganciclovir when antigenemia is ≥5 cells/slide, but CD34+-selected patients should be treated at any level of antigenemia*	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 7 days, followed by 5 mg/kg/day intravenously for 5 days/week for 2 weeks (BII)	
Preemptive treatment of allogeneic adult or adolescent HSCT recipients >100 days after HSCT: Start ganciclovir when a) antigenemia is ≥5 cells/slide or b) the patient has had ≥2 consecutively positive viremia or polymerase chain reaction tests (e.g., in a person receiving steroids for graft-versus-host disease or who received ganciclovir or foscarnet at <100 days after HSCT)	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 7 days, followed by 5 mg/kg/day intravenously for 5 days/week for 2 weeks (BIII)	

* **Source**: Holmberg LA, Boeckh M, Hooper H, et al. Increased incidence of cytomegalovirus disease after autologous CD34-selected peripheral blood stem cell transplantation [Clinical observations, interventions, and therapeutic trials]. Blood 1999;94(12):4029–35.

Notes: Patients who do not tolerate standard doses of ganciclovir should be administered foscarnet. Ganciclovir and foscarnet doses should be modified for renal impairment. Prehydration is required for foscarnet administration.

Pathogen: Herpes simplex virus

Indication	First choice	Alternatives
Prevention of herpes simplex virus reactivation among seropositive adult or adolescent HSCT recipients: Start acyclovir at the beginning of conditioning therapy and continue until engraftment or until mucositis resolves (i.e., approximately 30 days after HSCT for allogeneic HSCT recipients)	Acyclovir, 200 mg by mouth 3 times/day or 250 mg/m^2/dose infused over 1 hour intravenously every 12 hours (BIII)	Valacyclovir, 500 mg by mouth daily (CIII)

Note: For patients requiring prophylaxis for cytomegalovirus and herpes simplex virus after engraftment, ganciclovir alone provides effective prophylaxis for both pathogens.

Pathogen: Varicella-zoster virus

Indication	First choice	Alternatives
Prevention of varicella-zoster virus disease after exposure among adult or adolescent HSCT recipients who are at <24 months after HSCT or who are at ≥24 months after HSCT and on immunosuppressive therapy or have chronic graft-versus-host disease: Ideally, administer prophylaxis within 96 hours (preferably, within 48 hours) after close contact with a person who has chickenpox or shingles	Varicella-zoster immunoglobulin, 5 vials (1.25 ml each or 625 units total) intramuscularly (AII)	None

Pathogen: Influenza

Indication	First choice	Alternatives
Prevention of influenza A or B among adult or adolescent HSCT recipients	Lifelong annual seasonal (i.e., October–May) influenza vaccination starting before HSCT and restarting 6 months after HSCT (BIII); whole- or split-virus influenza vaccine, 0.5 ml/dose intramuscularly	None
Prophylaxis and preemptive treatment among all HSCT recipients during community and nosocomial outbreaks of influenza A	Rimantadine, 100 mg by mouth 2 times/day (CIII)	Amantadine, 100 mg by mouth 2 times/day (CIII)

Notes: Rimantadine dose should be reduced for patients with impaired renal function or for severely impaired hepatic function. Amantadine dose should be reduced for renal impairment.

Pathogen: Bacterial infections, general prophylaxis

Indication	First choice	Alternatives
Prevention of bacterial infections among allogeneic adult or adolescent HSCT recipients with severe hypogammaglobulinemia (i.e., serum immunoglobulin G level < 400 mg/dl) at <100 days after HSCT	Intravenous immunoglobulin, 500 mg/kg/week (CIII)	None

Notes: Patients with immunoglobulin E anti-immunoglobulin A antibodies are at high risk for experiencing anaphylaxis from immunoglobulin administration (**Source**: Burks AW, Sampson HA, Buckley RH. Anaphylactic reactions after gamma globulin administration in patients with hypogammaglobulinemia. New Engl J Med 1986;314[9]:560–4). Therefore, persons with immunoglobulin A deficiency should not receive standard immunoglobulin products (**Source**: Siberry GK, Iannone R, eds. Harriet Lane handbook: a manual for pediatric house officers. 15th ed.; St. Louis, MO: Mosby, Inc., 2000:339;739) (DIII). However, researchers have reported that use of immunoglobulin A-depleted immunoglobulin preparations can be used with caution among these persons (**Sources**: Burks AW, Sampson HA, Buckley RH. Anaphylactic reactions after gamma globulin administration in patients with hypogammaglobulinemia. New Engl J Med 1986;314[9]:560–4; Stiehm ER. Human intravenous immunoglobulin in primary and secondary antibody deficiencies [Review]. Pediatr Infect Dis J 1997;16[7]:696–707; and American Academy of Pediatrics. Passive immunization. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics;2000:41–53). Researchers also propose checking serum immunoglobulin G levels every 2 weeks among patients receiving intravenous immunoglobulin replacement therapy.

Pathogen: *Streptococcus pneumoniae*

Indication	First choice	Alternatives
Prevention of pneumococcal disease among adult or adolescent HSCT recipients	23-valent pneumococcal polysaccharide vaccine at 12 and 24 months after HSCT (BIII)	None

Note: Penicillin-resistant *Streptococcus pneumoniae* is increasing in the United States.

Pathogen: *Haemophilus influenzae* type b

Indication	First choice	Alternatives
Prevention of invasive *Haemophilus influenzae* type b (Hib) disease among adult or adolescent HSCT recipients	Hib conjugate vaccine administered at 12, 14, and 24 months after HSCT (BII)	None
Generally, HSCT recipients who are household contacts of a person with Hib disease should be administered rifampin prophylaxis* (BIII); however, prophylaxis is not needed for adult or adolescent HSCT recipients who are household contacts of a person with Hib disease if all household contacts aged <4 years are fully vaccinated	Rifampin 600 mg by mouth daily for 4 days (BIII)	

* **Source**: American Academy of Pediatrics. *Haemophilus influenzae* infections. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics;2000:262–72.

Pathogen: Methicillin-resistant *Staphylococcus aureus*

Indication	First choice	Alternatives
Elimination of methicillin-resistant *Staphylococcus aureus* carrier state among adults or adolescents to prevent this disease among chronic carriers	Mupirocin calcium ointment 2%; use a cotton-tipped applicator or equivalent to apply to nares 2 times/day for 5 days or to wounds daily for 2 weeks	None

Pathogen: *Candida* species

Indication	First choice	Alternatives
Prophylaxis for disease from fluconazole-susceptible *Candida* species among a) allogeneic adult or adolescent HSCT recipients or b) autologous adult or adolescent HSCT recipients with lymphoma or leukemia and who have or will have prolonged neutropenia and mucosal damage from intense conditioning regimens or graft manipulation or who have recently received fludarabine or 2-chlorodeoxyadenosine: Administer prophylaxis from the day of transplantation (i.e., day 0) until engraftment (i.e., approximately 30 days after HSCT) or until 7 days after the absolute neutrophil count > 1,000 cells/mm³	Fluconazole, 400 mg by mouth or intravenously daily (AI)	None

Pathogen: *Pneumocystis carinii*

Indication	First choice	Alternatives
Prophylaxis for *Pneumocystis carinii* pneumonia among a) all allogeneic adult or adolescent HSCT recipients or b) autologous adult or adolescent HSCT recipients with underlying hematologic malignancies (e.g., lymphoma or leukemia) or for those receiving intense conditioning regimens or graft manipulation or for those who have recently received fludarabine or 2-chlorodeoxyadenosine:* Administer prophylaxis from time of engraftment for ≥6 months after HSCT; continue >6 months after HSCT for the duration of immunosuppression for all persons who a) are receiving immunosuppressive therapy (e.g., prednisone or cyclosporine) or who b) have chronic graft-versus-host disease	Trimethoprim-sulfamethoxazole, 1 double-strength tablet by mouth daily or 1 single-strength tablet by mouth daily or 1 double-strength tablet by mouth 3 times/week (AII); researchers also recommend administering prophylaxis for 1–2 weeks before HSCT (i.e., day –14 to –2) (CIII)	Dapsone, 50 mg by mouth 2 times/day or 100 mg by mouth daily (BIII) or pentamidine, 300 mg every 3–4 weeks by Respirgard II™ nebulizer (CIII)

* **Source**: Tuan IZ, Dennison D, Weisdorf DJ. *Pneumocystis carinii* pneumonitis after bone marrow transplantation. Bone Marrow Transplant 1992;10(3):267–72.

Note : Patients who are receiving sulfadiazine-pyrimethamine for toxoplasmosis therapy are protected against *Pneumocystis carinii* and do not need additional prophylaxis.

Pathogen: *Toxoplasma gondii*

Indication	First choice	Alternatives
Prophylaxis of *Toxoplasma gondii* disease among seropositive allogeneic adult or adolescent HSCT recipients: Start after engraftment and administer as long as patients remain on immunosuppressive therapy (i.e., generally, until 6 months after HSCT)	Trimethoprim-sulfamethoxazole, 1 double-strength tablet by mouth daily or 1 single-strength tablet by mouth daily or 1 double-strength table by mouth 3 times/week (AII)	For those persons who are intolerant of trimethoprim-sulfamethoxazole, the following drugs can be substituted: Clindamycin, 300–450 mg by mouth every 6–8 hours; plus pyrimethamine, 25–75 mg by mouth daily; plus leucovorin, 10–25 mg by mouth 4 times/day (CIII)

Note: Among allogeneic HSCT recipients, clinical toxoplasmosis has occurred despite the use of trimethoprim-sulfamethoxazole for *Pneumocystis carinii* prophylaxis (**Source**: Slavin MA, Meyers JD, Remington JS, Hackman RC. *Toxoplasma gondii* infection in marrow transplant recipients: a 20 year experience. Bone Marrow Transplant 1994;13[5]:549–57).

Pathogen: *Strongyloides* species

Indication	First choice	Alternatives
Prevention of strongyloidiasis hyperinfection among adult or adolescent HSCT candidates whose HSCT screening tests are positive for *Strongyloides* species or who have an unexplained eosinophilia and a travel or residence history suggestive of exposure to *Strongyloides stercoralis*: Administer prophylaxis before HSCT	Ivermectin, 200 µg/kg by mouth daily for 2 consecutive days* (BIII); 1 tablet = 6 mg; doses administered as follows: Body weight (kg) — Oral dose <15 — Not recommended ≥15–24 — ½ tablet 25–35 — 1 tablet 36–50 — 1½ tablets 51–65 — 2 tablets 66–79 — 2½ tablets ≥80 — 200 µg/kg	Albendazole, 400 mg by mouth daily for 3 days or thiabendazole, 25 mg/kg by mouth 2 times/day for 2 days (BIII); maximum dose, 3 g/24 hours

***Sources**: Liu LX, Weller PF. Strongyloidiasis and other intestinal nematode infections [Review]. Infect Dis Clin North Am 1993;7(3):655–82; and Naquira C, Jimenez G, Guerra JG, et al. Ivermectin for human strongyloidiasis and other intestinal helminths. Am J Trop Med Hyg 1989;40:304–9.

Notes: Among immunocompromised patients, multiple courses at 2-week intervals might be required; however, cure might not be achievable. Safety and efficacy of ivermectin has not been established during pregnancy. Albendazole and thiabendazole are contraindicated during pregnancy.

Pathogen: Traveler's diarrhea

Indication	First choice	Alternatives
Prophylaxis among adult or adolescent HSCT recipients who are immunocompromised and who plan to travel in developing countries	Ciprofloxacin, 500 mg by mouth daily for the duration of stay in developing countries (BIII) or bismuth subsalicylate, 2 oz by mouth 4 times/day or 2 tablets by mouth 4 times/day; can be administered for ≤3 weeks to prevent travelers' diarrhea in adults aged >18 years only	Trimethoprim-sulfamethoxazole, 1 double-strength tablet by mouth daily for the duration of stay in developing country (CIII)

Notes: Use of aspirin-containing products including bismuth subsalicylate is contraindicated in persons aged <18 years unless prescribed by a physician because these products have been associated with Reye's syndrome (**Source**: Belay E, Bresee JS, Holman RC, Khan AS, Shahriari A, Schonberger LB. Reye's syndrome in the United States from 1981 through 1997. New Engl J Med 1999;340[18]:1377–82). Ciprofloxacin, norfloxacin, and ofloxacin are not approved for use among children aged <18 years.

Pathogen: *Mycobacteria tuberculosis*

Indication	First choice	Alternatives
Prevention of *Mycobacteria tuberculosis* among a) highly immunocompromised adult or adolescent HSCT recipients or candidates who have been substantially exposed to someone with active, infectious (e.g., sputum smear positive) pulmonary or laryngeal tuberculosis, regardless of the HSCT recipient's or candidate's tuberculin skin test status, or b) adult or adolescent HSCT recipients or candidates with a positive tuberculin skin test and who were not previously treated and have no evidence of active tuberculosis disease	Isoniazid, 5 mg/kg/day by mouth or intramuscularly for 9 months (i.e., for ≥270 doses);* maximum dose, 300 mg/day, and pyridoxine (vitamin B_6), 25–50 mg by mouth daily for 9 months; administer to nutritionally deficient HSCT recipients and candidates while on isoniazid preventive therapy to reduce the occurrence of isoniazid-induced neuropathy* (BIII)	None

***Source**: CDC. Prevention and treatment of tuberculosis among patients infected with human immunodeficiency virus: principles of therapy and revised recommendations. MMWR 1998;47(No. RR-20):1–58.

Notes: A twice-weekly schedule of isoniazid and pyridoxine can be administered (CIII). The twice-weekly isoniazid dose is 15 mg/kg by mouth or intramuscularly (maximum dose, 900 mg). The twice-weekly pyridoxine dose is 50–100 mg by mouth. A 2-month pyrazinamide/rifampin preventive therapy regimen can be used for HSCT candidates who are not at risk for serious rifampin drug interactions and whose HSCT is not scheduled until ≥2 weeks after the 2-month course is completed (**Sources**: CDC. Notice to readers: use of short-course tuberculosis preventive therapy regimens in HIV-seronegative persons. MMWR 1998;47[42]:911–2; and CDC. Prevention and treatment of tuberculosis among patients infected with human immunodeficiency virus: principles of therapy and revised recommendations. MMWR 1998;47[No. RR-20]:1–58) (CIII). The usual pyrazinamide dose is 15–30 mg/kg/day by mouth or 50–70 mg/kg/dose by mouth 2 times/week (maximum daily pyrazinamide dose, 2.0 gm; maximum twice-weekly dose, 3.5 gm). Rifampin dose is 10 mg/kg/day by mouth or intravenously or 10 mg/kg/dose administered 2 times/week by mouth or intravenously (maximum rifampin dose, 600 mg). Routine use of a 2-month pyrazinamide/rifampin preventive therapy regimen is not recommended after HSCT because of the risk for serious rifampin drug interactions (DIII). Persons who have been exposed to rifampin- and isoniazid-resistant tuberculosis should be placed on preventive therapy regimens that involve ≥2 antituberculosis drugs to which the infecting strain is susceptible, and a tuberculosis specialist should be consulted (**Source**: CDC. Prevention and treatment of tuberculosis among patients infected with human immunodeficiency virus: principles of therapy and revised recommendations. MMWR 1998;47[No. RR-20]:1–58) (BIII). A tuberculosis specialist should also be consulted for patients who are intolerant to isoniazid (AIII). All intermittent dosing strategies should be administered as directly observed therapy (AIII).

II. Preventive regimens for pediatric hematopoietic stem cell transplant (HSCT) recipients

Pathogen: Cytomegalovirus

Indication	First choice	Alternatives
Universal prophylaxis for cytomegalovirus disease among all allogeneic pediatric HSCT recipients at risk throughout phase II (i.e., from engraftment to day 100 after HSCT)	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 5–7 days, followed by 5 mg/kg/dose intravenously daily for 5 days/week from engraftment until day 100 after HSCT (AI)	Foscarnet, 60 mg/kg intravenously every 12 hours for 14 days, followed by 90–120 mg/kg/day until day 100 after HSCT (CIII)
Or preemptive cytomegalovirus treatment administered <100 days after HSCT to all allogeneic pediatric HSCT recipients at risk: Start ganciclovir when the patient experiences any level of cytomegalovirus antigenemia or viremia or has ≥2 consecutively positive cytomegalovirus-DNA polymerase chain reaction tests	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 7–14 days, followed by 5 mg/kg/day for 5 days/week until day 100 after HSCT or for a minimum of 3 weeks, whichever is longer (AI); or administer ganciclovir for a total of 3–6 weeks; antigen or polymerase chain reaction tests should be negative when ganciclovir is stopped; reinstitute ganciclovir if subsequent weekly cytomegalovirus antigenemia screening tests become positive (BI)	
Preemptive treatment for cytomegalovirus seropositive autologous pediatric HSCT recipients at <100 days after HSCT: Start ganciclovir when antigenemia is ≥5 cells/slide, but CD34+-selected patients should be treated at any level of antigenemia*	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 7 days, followed by 5 mg/kg/day intravenously for 5 days/week for 2 weeks (BII)	
Preemptive treatment of allogeneic pediatric HSCT recipients >100 days after HSCT: Start ganciclovir when a) antigenemia is ≥5 cells/slide or b) the patient has had ≥2 consecutively positive viremia or polymerase chain reaction tests (e.g., in a person receiving steroids for graft-versus-host disease or who received ganciclovir or foscarnet at <100 days after HSCT)	Ganciclovir, 5 mg/kg/dose intravenously every 12 hours for 7 days, followed by 5 mg/kg/day intravenously for 5 days/week for 2 weeks (BIII)	

* **Source**: Holmberg LA, Boeckh M, Hooper H, et al. Increased incidence of cytomegalovirus disease after autologous CD34-selected peripheral blood stem cell transplantation [Clinical observations, interventions, and therapeutic trials]. Blood 1999;94(12):4029–35.

Notes: Patients who do not tolerate standard doses of ganciclovir should be administered foscarnet. Ganciclovir and foscarnet doses should be modified for renal impairment. Prehydration is required for foscarnet administration.

Pathogen: Herpes simplex virus

Indication	First choice	Alternatives
Prevention of herpes simplex virus reactivation among seropositive pediatric HSCT recipients: Start acyclovir at the beginning of conditioning therapy and continue until engraftment or until mucositis resolves (i.e., approximately 30 days after HSCT for allogeneic HSCT recipients)	Acyclovir, 250 mg/m²/dose intravenously every 8 hours (BIII) or 125 mg/m²/dose intravenously every 6 hours (CIII)	Acyclovir 600–1,000 mg/24 hours by mouth, divided in 3–5 doses/day

Note: For patients requiring prophylaxis for cytomegalovirus and herpes simplex virus after engraftment, ganciclovir alone provides effective prophylaxis for both pathogens. Valacyclovir is not approved for use among children.

Pathogen: Varicella-zoster virus

Indication	First choice	Alternatives
Prevention of varicella-zoster virus disease after exposure among pediatric HSCT recipients who are at <24 months after HSCT or who are at ≥24 months after HSCT and on immunosuppressive therapy or have chronic graft-versus-host disease: Ideally, administer prophylaxis within 96 hours (preferably, within 48 hours) after close contact with a person who has chickenpox or shingles	Varicella-zoster immunoglobulin, 125 units (1.25 ml)/10 kg (22 lbs) of body weight administered intramuscularly; maximum dose, 625 units or 5 vials (AII); doses administered as follows:	Limited data demonstrate that a 1-week course of high-dose acyclovir might prevent varicella

Body weight (kg)	Dose	Number of vials
0–10	125 units	1
10.1–20	250 units	2
20.1–30	375 units	3
30.1–40	500 units	4
>40 kg	625 units	5

Pathogen: Influenza

Indication	First choice	Alternatives
Prevention of influenza A and B among pediatric HSCT recipients	Lifelong annual seasonal (i.e., October–May) influenza vaccination before HSCT and resuming 6 months after HSCT (BIII); doses administered as follows: Age / Number of doses / Type of influenza vaccine 6–35 mo / 0.25 ml / Split-virus* 3–8 years / 0.5 ml / Split-virus* 9–12 years / 0.5 ml / Split-virus >12 years / 0.5 ml / Whole- or split-virus	None
Prophylaxis and preemptive treatment of influenza A among pediatric HSCT recipients during nosocomial or community influenza A outbreaks	Rimantadine, for children aged 1–9 years, 5 mg/kg/day once daily or divided in 2 doses (CIII); maximum daily dose, 150 mg; for children aged ≥10 years (weight, <40 kg), 5 mg/kg/day by mouth, divided in 2 doses; for children aged ≥10 years (weight, ≥40kg), 100 mg by mouth 2 times/day	Amantadine, for children aged 1–9 years, 5 mg/kg/day; maximum daily dose, 150 mg; for children aged ≥10 years (weight, <40 kg), 5 mg/kg/day by mouth, divided in 2 doses; for children aged ≥10 years (weight, ≥40kg), 100 mg by mouth 2 times/day; maximum daily dose, 200 mg

* Children aged <9 years receiving influenza vaccination for the first time require 2 doses of vaccine spaced ≥1 months apart.

Notes: Neither rimantadine nor amantadine are Federal Drug Administration-approved for children aged <1 year. Rimantadine and amantadine doses should be reduced for patients with impaired renal function.

Pathogen: Respiratory syncytial virus

Indication	First choice	Alternatives
Prophylaxis for respiratory syncytial virus (RSV) lower respiratory infection among hypogammaglobulinemic pediatric HSCT recipients	RSV intravenous immunoglobulin can be administered in place of intravenous immunoglobulin during RSV season (i.e., November–April in the United States) for pediatric HSCT recipients who are on routine intravenous immunoglobulin therapy* (e.g., those with hypogammaglobulinemia) (CIII); usual RSV intravenous immunoglobulin dose is 750 mg/kg/month or a 1-mg/1-mg dosing substitution of RSV intravenous immunoglobulin for intravenous immunoglobulin can be used for patients who normally require high intravenous immunoglobulin doses to maintain serum immunoglobulin G >400 mg/dl; can administer more frequently than monthly as needed to keep serum immunoglobulin G >400 mg/dl	None
Preemptive treatment of RSV upper respiratory infection or early lower respiratory infection among pediatric HSCT recipients	Aerosolized ribavirin,* 6 g/300 ml sterile water to make a concentration of 20 mg/ml; administer 18 hours/day for 10 days in a tent (CIII); for HSCT recipients with lower respiratory infections who cannot tolerate a tent or who have RSV upper respiratory infection, administer ribavirin as 2 g for 2 hours every 8 hours by face mask for 10 days; use small particle aerosol generator model SPAG-2	

***Source**: American Academy of Pediatrics. Respiratory syncytial virus. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Disease. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2000: 483–7.

Notes: RSV intravenous immunoglobulin is contraindicated among patients with immunoglobulin A deficiency or who might have allergic reactions or anaphylaxis when receiving blood products containing immunoglobulin A (DIII) RSV monoclonal antibody is under investigational use among HSCT recipients for treatment with ribavirin but not for prophylaxis.

Pathogen: Bacterial infections, general prophylaxis

Indication	First choice	Alternatives
Prevention of bacterial infections among allogeneic pediatric HSCT recipients with severe hypogammaglobulinemia (i.e., serum immunoglobulin G level < 400 mg/dl) at <100 days after HSCT	Intravenous immunoglobulin 400 mg/kg/month; increase dose or frequency as needed to keep serum immunoglobulin G levels > 400 mg/dl (CIII)	None

Notes: Patients with immunoglobulin E anti-immunoglobulin A antibodies are at high risk for experiencing anaphylaxis from immunoglobulin administration (**Source**: Burks AW, Sampson HA, Buckley RH. Anaphylactic reactions after gamma globulin administration in patients with hypogammaglobulinemia. New Engl J Med 1986;314[9]:560–4). Therefore, persons with immunoglobulin A deficiency should not receive standard immunoglobulin products (**Source**: Siberry GK, Iannone R, eds. Harriet Lane handbook: a manual for pediatric house officers. 15th ed.; St. Louis, MO: Mosby, Inc., 2000:339;739) (DIII). However, researchers report that use of immunoglobulin A-depleted immunoglobulin preparations can be used with caution in these persons (**Sources**: Burks AW, Sampson HA, Buckley RH. Anaphylactic reactions after gamma globulin administration in patients with hypogammaglobulinemia. New Engl J Med 1986;314[9]:560–4; Siberry GK, Iannone R, eds. Harriet Lane handbook: a manual for pediatric house officers. 15th ed.; St. Louis, MO: Mosby, Inc., 2000:339;739; Stiehm ER. Human intravenous immunoglobulin in primary and secondary antibody deficiencies [Review]. Pediatr Infect Dis J 1997;16[7]:696–707; American Academy of Pediatrics. Passive immunization. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics;2000:41–53). Researchers also propose checking serum immunoglobulin G levels every 2 weeks for patients receiving intravenous immunoglobulin replacement therapy.

Pathogen: *Streptococcus pneumoniae*

Indication	First choice	Alternatives
Prevention of pneumococcal disease among pediatric HSCT recipients	23-valent pneumococcal polysaccharide vaccine at 12 and 24 months after HSCT (BIII)	None

Notes : The 23-valent pneumococcal polysaccharide vaccine should not be administered to children aged <2 years because of lack of efficacy (DI). Penicillin-resistant *Streptococcus pneumoniae* is increasing in the United States.

Pathogen: *Haemophilus influenzae* type b

Indication	First choice	Alternatives
Prevention of invasive *Haemophilus influenzae* type b (Hib) disease among pediatric HSCT recipients	Hib conjugate vaccine administered at 12, 14, and 24 months after HSCT (BII)	None
Generally, pediatric HSCT recipients who are household contacts of a person with Hib disease should be administered rifampin prophylaxis* (BIII); however, prophylaxis is not needed for pediatric HSCT recipients who are household contacts of a person with Hib disease if all household contacts aged <4 years are fully vaccinated	Rifampin, administered as follows: Age — Dose 0–1 mo — 10 mg/kg by mouth daily for 4 days >1 mo — 20 mg/kg by mouth daily for 4 days Maximum dose, 600 mg/day (BIII)	None

* **Source**: American Academy of Pediatrics. *Haemophilus influenzae* infections. In: Pickering LK, ed. 2000 red book: report of the Committee on Infectious Diseases. 25th ed. Elk Grove Village, IL: American Academy of Pediatrics;2000:262–72.

Pathogen: Methicillin-resistant *Staphylococcus aureus*

Indication	First choice	Alternatives
Elimination of methicillin-resistant *Staphylococcus aureus* carrier state among pediatric patients to prevent this disease among chronic carriers	Mupirocin calcium ointment 2%; use a cotton-tipped applicator or equivalent to apply to nares 2 times/day for 5 days or to wounds daily for 2 weeks*	Bacitracin is regarded safe for use among children, and the dose is the same as for mupirocin; however, no standardized protocol has been evaluated

* Safety of mupirocin calcium ointment 2% use among children aged <12 years has not be established.

Pathogen: *Candida* species

Indication	First choice	Alternatives
Prophylaxis for disease from fluconazole-susceptible *Candida* species among a) allogeneic pediatric HSCT recipients or b) autologous pediatric HSCT recipients with lymphoma or leukemia and who have or will have prolonged neutropenia and mucosal damage from intense conditioning regimens or graft manipulation or who have recently received fludarabine or 2-chlorodeoxyadenosine: Administer prophylaxis from the day of transplantation (i.e., day 0) until engraftment (i.e., approximately 30 days after HSCT) or until 7 days after the absolute neutrophil count > 1,000 cells/mm^3	Fluconazole, for children aged 6 months–13 years, administer 3–6 mg/kg/day by mouth or intravenously (AI); maximum dose, 600 mg/day; for children aged >13 years, administer 400 mg by mouth or intravenously daily (AI)	None

Pathogen: *Pneumocystis carinii*

Indication	First choice	Alternatives
Prophylaxis for *Pneumocystis carinii* pneumonia among a) all allogeneic pediatric HSCT recipients or b) autologous pediatric HSCT recipients with underlying hematologic malignancies (e.g., lymphoma or leukemia) or for those receiving intense conditioning regimens or graft manipulation or for those who have recently received fludarabine or 2-chlorodeoxyadenosine:* Administer prophylaxis from time of engraftment for ≥6 months after HSCT; continue >6 months after HSCT for the duration of immunosuppression for all persons who a) are receiving immunosuppressive therapy (e.g., prednisone or cyclosporine) or who b) have chronic graft-versus-host disease	Trimethoprim-sulfamethoxazole, 150 mg trimethoprim/750 mg sulfamethoxazole/m²/day by mouth in 2 divided doses 3 times/week on consecutive days (AII); or a single dose by mouth 3 times/week on consecutive days; or by mouth in 2 divided doses daily for 7 days; or by mouth in 2 divided doses 3 times/week on alternate days; researchers also report administering prophylaxis for 1–2 weeks before HSCT (i.e., day –14 to –2) (CIII)	Dapsone, for HSCT recipients aged ≥1 months, 2 mg/kg (maximum dose, 100 mg) by mouth daily (BIII); or intravenous pentamidine, 4 mg/kg every 2–4 weeks; or aerosolized pentamidine, for HSCT recipients aged ≤5 years, 9 mg/kg/dose; or for HSCT recipients aged >5 years, 300 mg; should be administered every month by Respirgard II™ nebulizer (CIII)

* **Source**: Tuan IZ, Dennison D, Weisdorf DJ. *Pneumocystis carinii* pneumonitis after bone marrow transplantation. Bone Marrow Transplant 1992;10(3):267–72.

Notes: Trimethoprim-sulfamethoxazole is not recommended for patients aged <2 months because of risk for kernicterus. Patients who are receiving sulfadiazine-pyrimethamine for toxoplasmosis therapy are protected against *Pneumocystis carinii* and do not need additional prophylaxis.

Pathogen: *Toxoplasma gondii*

Indication	First choice	Alternatives
Prophylaxis of *Toxoplasma gondii* disease among seropositive allogeneic pediatric HSCT recipients: Start after engraftment and administer as long as patients remain on immunosuppressive therapy (i.e., generally, until 6 months after HSCT)	Trimethoprim-sulfamethoxazole, 150 mg trimethoprim/750 mg sulfamethoxazole/m²/day by mouth in 2 divided doses 3 times/week on consecutive days (AII); or a single dose by mouth 3 times/week on consecutive days; or by mouth in 2 divided doses daily for 7 days; or by mouth in 2 divided doses 3 times/weekly on alternate days	For those persons who are intolerant of trimethoprim-sulfamethoxazole, the following drugs can be substituted: Clindamycin, 20–30 mg/kg/day by mouth, divided in 4 divided doses daily; plus pyrimethamine, 1 mg/kg by mouth daily; plus leucovorin, 5 mg by mouth every 3 days (CIII)

Note: Trimethoprim-sulfamethoxazole is not recommended for patients aged <2 months because of risk for kernicterus. Among allogeneic HSCT recipients, clinical toxoplasmosis has occurred despite the use of trimethoprim-sulfamethoxazole for *Pneumocystis carinii* prophylaxis (**Source**: Slavin MA, Meyers JD, Remington JS, Hackman RC. *Toxoplasma gondii* infection in marrow transplant recipients: a 20 year experience. Bone Marrow Transplant 1994;13[5]:549–57).

Pathogen: *Strongyloides* species

Indication	First choice	Alternatives
Prevention of strongyloidiasis hyperinfection among pediatric HSCT candidates whose HSCT screening tests are positive for *Strongyloides* species or who have an unexplained eosinophilia and a travel or residence history suggestive of exposure to *Strongyloides stercoralis*: Administer prophylaxis before HSCT	Ivermectin, 200 µg/kg by mouth daily for 2 consecutive days* (BIII); 1 tablet = 6 mg; doses administered as follows: Body weight (kg) — Oral dose <15 — Not recommended ≥15–24 — ½ tablet 25–35 — 1 tablet 36–50 — 1½ tablets 51–65 — 2 tablets 66–79 — 2½ tablets ≥80 — 200 µg/kg	Thiabendazole, 25 mg/kg 2 times daily for 2 days; maximum dose, 3 g/24 hours

* **Sources**: Liu LX, Weller PF. Strongyloidiasis and other intestinal nematode infections [Review]. Infect Dis Clin North Am 1993;7(3):655–82; and Naquira C, Jimenez G, Guerra JG, et al. Ivermectin for human strongyloidiasis and other intestinal helminths. Am J Trop Med Hyg 1989;40:304–9.

Notes: Ivermectin safety among children weighing <15 kg has not been established. Among immunocompromised patients, multiple courses of ivermectin at 2-week intervals might be required; however, cure might not be achievable. Safety and efficacy of ivermectin has not been established during pregnancy. Thiabendazole is contraindicated during pregnancy.

Pathogen: Traveler's diarrhea

Indication	First choice	Alternatives
Prophylaxis among pediatric HSCT recipients who are immunocompromised and who plan to travel in developing countries	Trimethoprim-sulfamethoxazole, 150 mg trimethoprim/750 mg sulfamethoxazole/m²/day by mouth, divided in 2 doses 3 times/week on consecutive days (CIII); can be administered for duration of stay in developing country	Trimethoprim-sulfamethoxazole, single dose by mouth 3 times/week on consecutive days

Notes: Use of aspirin-containing products including bismuth subsalicylate is contraindicated in persons aged <18 years unless prescribed by a physician because these products have been associated with Reye's syndrome (**Source**: Belay E, Bresee JS, Holman RC, Khan AS, Shahriari A, Schonberger LB. Reye's syndrome in the United States from 1981 through 1997. New Engl J Med 1999;340[18]:1377–82). Trimethoprim-sulfamethoxazole is not recommended for patients aged <2 months because of risk for kernicterus. Resistance to trimethoprim-sulfamethoxazole is common in tropical areas. Usual doses of trimethoprim-sulfamethoxazole for *Pneumocystis carinii* pneumonia prophylaxis should provide limited protection against traveler's diarrhea.

Pathogen: *Mycobacteriatuberculosis*

Indication	First choice	Alternatives
Prevention of *Mycobacteria tuberculosis* among a) highly immunocompromised pediatric HSCT recipients or candidates who have been exposed to someone with active, infectious (e.g., sputum smear positive) pulmonary or laryngeal tuberculosis, regardless of the HSCT recipient's or candidate's tuberculin skin test status, or b) pediatric HSCT recipients or candidates with a positive tuberculin skin test and who were not previously treated and have no evidence of active tuberculosis disease	Isoniazid, 10–20 mg/kg/day by mouth or intramuscularly for 9 months (i.e., for ≥270 doses);* maximum dose, 300 mg/day, and pyridoxine (vitamin B_6), 1–2 mg/kg/day by mouth daily for 9 months; dose required might vary by age and condition;† administer to nutritionally deficient HSCT recipients and candidates while on isoniazid preventive therapy to reduce the occurrence of isoniazid-induced neuropathy* (BIII)	None

Elk Grove Village, IL: American Academy of Pediatrics;2000:593–613; CDC. Prevention and treatment of tuberculosis among patients infected with human immunodeficiency virus: principles of therapy and revised recommendations. MMWR 1998;47(No. RR-20):1–58; and CDC. Notice to readers: use of short-course tuberculosis preventive therapy regimens in HIV-seronegative persons. MMWR 1998;47(42):911–2.

† **Source**: Siberry GK, Iannone R, eds. Harriet Lane handbook: a manual for pediatric house officers. 15th ed.; St. Louis, MO: Mosby, Inc., 2000:834–5.

Notes: A twice-weekly schedule of isoniazid and pyridoxine can be administered (CIII). The twice-weekly isoniazid dose is 20–40 mg/kg by mouth or intramuscularly (maximum dose, 900 mg). A 2-month pyrazinamide/rifampin preventive therapy regimen can be used for HSCT candidates who are not at risk for serious rifampin drug interactions and whose HSCT is not scheduled until ≥2 weeks after the 2-month course is completed. Rifampin dose is 10–20 mg/kg/day by mouth or intravenously or 10–20 mk/kg/dose by mouth or intravenously, administered 2 times/week (maximum pyrazinamide dose, 3.5 g; maximum rifampin dose, 600 mg) (**Sources**: CDC. Notice to readers: use of short-course tuberculosis preventive therapy regimens in HIV-seronegative persons. MMWR 1998;47[42]:911–2; and CDC. Prevention and treatment of tuberculosis among patients infected with human immunodeficiency virus: principles of therapy and revised recommendations. MMWR 1998;47[No. RR-20]:1–58.) (CIII). The usual pyrazinamide dose is 15–30 mg/kg/day by mouth or 50–70 mg/kg/dose by mouth 2 times/week (maximum) (maximum daily pyrazinamide dose, 2 g). Routine use of a 2-month pyrazinamide/rifampin preventive therapy regimen is not recommended after HSCT because of the risk for serious rifampin drug interactions (DIII). Persons who have been exposed to rifampin- and isoniazid-resistant tuberculosis should be placed on preventive therapy regimens that involve ≥2 antituberculosis drugs to which the infecting strain is susceptible (**Source**: CDC. Prevention and treatment of tuberculosis among patients infected with human immunodeficiency virus: principles of therapy and revised recommendations. MMWR 1998;47[No. RR-20]:1–58), and a tuberculosis specialist should be consulted (BIII). A tuberculosis specialist should also be consulted for patients who are intolerant to isoniazid (AIII). All intermittent dosing strategies should be administered as directly observed therapy (AIII).

Dear Ashley
The parents of children will continue to attend their children to the neuro Operating Thr and leave from the anaesthetic room. The whole of the theatre area is a clean area and that is why the Thr staff can return to the area in the scrubs and clogs they left the area in as long as they adhere to the dress and uniform policy

Good Afternoon Janette

Please could you update our position on the door between MRI and theatres is DCN theatres clean area.

Hope this makes sense.

Subject: RE: Urgent--advice required

Dear All,

I have spoken with Lindsay Guthrie the Lead IPCN for NHS Lothian. I have explained to her the route of travel for paediatric in patients to Thr and to the Neuro Thr on a Wednesday, and she agrees that the procedures currently in place at RHSC with parents coming into the anaesthetic room or recovery room in their own clothing and shoes can continue. However if they are going into or go into The operating Thr they must change into Thr attire including clogs/Thr foot wear.

For ward staff escorting patients, who need that extra nursing support, to the inter-operative MRI room until they are in the MRI room there is no need for ward staff to change into SCRUBS and Thr attire. If the Ward staff go into the Operating Thr they must change into Thr attire .

For Out Patients who come to the area for MRI scan the plan to have these people change into gowns etc at the changing room near reception is the acceptable procedure. If the person walks to the area in their shoes the Radiology staff will address this with regards to being MRI compliant. The frequency of cleaning in that area will address any issues on the floor.

As the radiology staff wear scrubs in the Operative MRI and Thr area they are to comply with the Uniform/dress code attached.

Regards
Janette

Subject: Urgent--advice required

Dear All,
I need to meet and discuss issues that have cropped up with regards to accessing the inter operative MRI Scanner at the new RHSC/DCN in the Thr areas.

I have the afternoon of Fri this week available and would like to discuss with you the flow of Out patients walking through the Thr corridors and parents accessing the Neuro Thr area from RHSC

I also attach the most recent Uniform Policy and ask if there are any infection control concerns re Thr attire.

Regards
Janette

Hi Janette,

That's just it, it doesn't. There is some dubiety over a couple of things:

1. Can a 4 bed bay be described as a general ward.
2. If so what is the pressure relationship to the corridor as there is just a dash in the box in the table you attach.

I am looking for infection controls' take on a scenario such as if 4 patients with infection status unknown are in the room what way do you want the air to go – To the room from the corridor or to the corridor from the room?

Regards

Ronnie

Subject: RE: Macerator overflow

Hi Janette,

Thanks for that, I'll await your update and let Colin Grindlay know after..

On another matter, ventilation pressure regime to 4 bed bays – in your opinion should it be same as single bedrooms i.e. balanced or slightly negative to corridor (keeps any infection in the room) or is it presumed that patients in multi bed bays are not infected and pressure regime does not matter?

Regards

Ronnie

Dear Ronnie,

I am looking into the question you asked with regards to over flow outlet and allowing the over flow to drain to the floor.
As yet I have not found information to support this and I have spoken to tech people at Haig who would not do that either. I have a couple of more enquiries to make this morning but will have an answer for you by 2pm,
Regards
Janette

SBAR- Draft Risk Assessment regarding Impact of Design Ventilation on managing HAI risk in RHCYP clinical areas (not including Critical Care)

1. Situation:

NHS Lothian are required by the National Oversight Group "*to consider its clinical service model in light of the ventilation arrangements in place for general wards and other non critical areas (incorporating literature review and design information not yet available)*".

This relates to the project design provided which aims to deliver the 6 air changes required by SHTM 03-01 Part A to shared bed spaces and single room accommodation through mechanical supply for 4 air changes and 2 air changes through natural ventilation (although investigation is underway to establish if this is deliverable through window opening as had been designed).

Independent verification (by IOM) of the ventilation system has highlighted some areas where the ventilation performance requires further review and adjustment to ensure this performs in line with the design specification outlined above. This includes shared bed spaces and single room accommodation. NHS Lothian have been asked to demonstrate through risk assessment, that the Board is assured that the provision of 4 air changes per hour on mechanical supply, rather than 6 air changes per hour on mechanical supply does not compromise patient safety by introducing either an increased risk of transmission of infection or acquisition of healthcare associated infection.

2. Background:

SHTM 03-01 part A (appendix 1) and SHPN 04 Supplement 1: Isolation facilities in acute settings define the air change rates, filter requirements, mode of delivery and pressure differentials required for hospital ventilation systems. The ventilation system at RHCYP DCN was designed to deliver the following ventilation

	SHTM 03-01 requirement	Design specification	Current performance	
General ward (shared bed spaces)	6 air changes per hour (Ach/hr) – mix of supply and natural	4 air changes per hour supply	Awaiting clarification from IOM	
Single en-suite rooms	6 air changes per hour - mix of supply, extract and natural ventilation Balanced or negative pressure	4 air changes per hour supply Balanced or negative pressure	Awaiting clarification from IOM	
Isolation rooms (Positive pressure ventilated lobby-PPVL)	10 air changes per hour Lobby at 10 Pascals positive pressure	10 air changes per hour Lobby at 10 Pascals positive pressure	Awaiting clarification from IOM	
Treatment Room	10 air changes per hour		Awaiting clarification from	

	Positive pressure		IOM	

The ventilation design and performance for some shared bed spaces and single rooms does not conform to SHTM 03-01 part A, in terms of supply ventilation[Independent verification (by IOM) of the ventilation system has highlighted some areas where the ventilation performance requires further review and adjustment to ensure this performs in line with the design specification .

Lochranza ward (Haematology Oncology) does not have HEPA filters in the air supply ventilation to the single rooms which is indicated for rooms where neutropenic patients would be managed. The grade of air filter fitted in the supply air for these rooms (F9) is of a higher standard than the filters advocated for general ward areas or single rooms in SHTM 03-01 Part A Appendix 1 (G4 filter). As such the supply air in the single rooms of Lochranza is of a "cleaner" quality than a general ward but is not of a High Efficiency Particulate Air (HEPA) standard and this benefit would be immediately removed by opening a window to outside air as windows in the single rooms will open. The supply air ventilation in the 5 PPVL isolation rooms does pass through HEPA filters in the room lobbies., The 5 PPVL rooms do perform to the parameters set in SHTM 03-01 for rooms where all neutropenic patients can be safely placed. Windows in the PPVL isolation rooms do not open.

All shared and single rooms which do not have an opening window are provided with 6 air changes per hour (achieved through mechanical supply and extract).

Assessment :

3.1 A review of all clinical departments was undertaken by the clinical leads from the project team (Janice Mackenzie, Dorothy Hanley, Fiona Halcrow); lead infection prevention and control nurse (Lindsay Guthrie) and lead infection control doctor & consultant microbiologist (Dr Donald Inverarity). This was shared with key clinical colleagues in paediatrics and neurosciences for comment and input prior to submission to the NHS Lothian Executive Steering Group: Royal Hospital for Children and Young People and Department of Clinical Neurosciences for approval.

3.2 In view of planned revision of ventilation systems in Critical Care & Neonatal Unit to meet conformance with SHTM 03-01, it was agreed that these locations did not require to be part of this review, and will not be considered further in this paper.

3.3 A summary table of all wards, bed configuration and clinical service types which informed this risk assessment is provided in appendix 1. This outlines the risk profile of patients being cared for in each area based on the clinical speciality, known patient risk factors and type of treatment or interventions provided. It also identifies anticipated HAI/IPC risks associated with each clinical area.

3.4 The highest risk patient groups are defined as:

- Any haematology/oncology patient
- Any neutropenic patient
- Any other immunocompromised patient (related to underlying disease process or treatment induced)
- Any patient with Cystic Fibrosis
- Any patient with a complex wound dressing or burn treated in the Plastics Dressing Treatment Area

- Any patient with a known infection alert (known colonisation or history of infection with alert organism)
- Any patient presenting with a suspected or confirmed infection transmitted by contact, droplet or airborne transmission

This categorisation of patient risk is in line with the definitions provided in Scottish Health Facilities Note 30 Part B: HAI Scribe Implementation strategy and assessment process; Health Protection Scotland interim guidance for routine sampling of Pseudomonas in augmented care areas (2018); and HPS National Infection Prevention and Control Manual.

3.5 Paediatric renal dialysis is not provided at RHCYP. Any child or young person requiring this is referred to QEUH in Glasgow.

3.6 Paediatric organ transplantation is not provided at RHCYP. Surgery and subsequent hospital follow up is generally provided at QEUH. Rarely, a transplant recipient may be admitted for treatment in the medical ward (Dalhousie ward). These patients would be considered immunocompromised and managed in line with the NHS Lothian Prioritisation of Isolation Guidance (attached as Appendix 2).

3.7 Within Lochranza ward (Haematology/Oncology), although the five PPVL isolation rooms provide 10 Air Changes/hour and 10 Pascals positive pressure from lobby to corridor, none of the single rooms available meet the specification for 'Neutropenic patient ward' defined in SHTM 03-01 Appendix 1 (also 10 Air Changes plus 10 Pascals positive pressure). Based on current occupancy, it is estimated that there may be 5-10 neutropaenic patients being cared for in RHSC on any given day. Although it is acknowledged that not all chemotherapy regimens result in the same intensity of immunosuppression and neutropenia, within the new facility, there may be a shortfall in the number of rooms which meet the SHTM 03-01 standard for safe placement of all neutropenic patients.

3.8 Appropriate patient placement and management is considered against the HPS National Infection Prevention and Control Manual (Appendix 11) and NHS Lothian Prioritisation of Isolation Guidelines. The latter was developed by the IPCT in Lothian to assist clinical teams to risk assess and provide safe, effective patient care where demand for isolation or single room accommodation is exceeded by demand. Paediatric and Neuroscience teams have previously been directed to use this document which is applicable for placement of both paediatric and adult patients.

3.9 The review group agreed that the wards with the highest perceived overall risk of demand for isolation exceeding capacity (and thereby potential risk of onward transmission of infection) are: Castle Mey ward (Paediatric acute receiving unit); Dalhousie ward (Medical in-patients); Lochranza ward (Haematology/Oncology)

3.10 Ventilation in healthcare premises is designed to achieve a number of objectives including management of temperature and humidity, removal of odour (particularly required in wards with cancer patients receiving chemotherapy), provide a clean air path directing flow from 'clean' to 'dirty' and dilution of airborne contaminants. These latter two points are of most significance from infection prevention & control perspective.

3.11 The burden of seasonal respiratory viruses is recognised as a risk, particularly for RHCYP. This risk is however mitigated via the provision of a significantly increased availability of en-suite single room accommodation with doors. HPS National Manual Appendix 11 advocates that

patients are cared for in such rooms. The risk of droplet transmission is greatest within 3 feet/1 metre of the patient. The primary protection therefore offered by en-suite single rooms is physical separation greater than 1 metre and containment of infectious patients by means of a closed door. The impact on transmission risk of a reduced air exchange rate from 6 to 4 air changes per hour in each shared bed space is unknown.

3.12 A review of all alert organism reports for the current wards at RHSC and DCN demonstrates that the Paediatric Acute Receiving Unit (Castle Mey) is likely to experience the highest burden of patients with presentations due to respiratory viral infections, loose stool or diarrhoeal illness and will have both the highest turn over of patients and the highest demand on isolation and single rooms.

3.13 The risk of transmission of infection is also mitigated by application of other aspects of transmission based precautions i.e. enhanced cleaning with chlorine 1000ppm av chlorine, use of dedicated or single use equipment, use of appropriate facial or respiratory protection The application of standard infection prevention and control measures such as personal protective equipment used optimally, optimal hand hygiene and access to alcohol based hand rub across all clinical areas will also mitigate some risk of transmission of infection.

3.14 HFS have also asked that NHS Lothian risk assess and define the actions required if one or more air handling unit fails resulting in the loss of isolation room supply ventilation, noting that between 1 and 5 isolation rooms are provided off single air handling units in the new building. Taking cognisance of the above assessment, in the absence of an infectious disease of high consequence, and providing all other standard and transmission based precautions required by HPS NIPCM are in place, the risk of infection to patients, staff or visitors is likely to be low as SICPs would remain in use and physical isolation in a single room with doors would be maintained. Additionally an air flow from room to toilet air extract would likely continue even if supply air ventilation failed rendering the rooms at slight negative pressure or balanced pressure to the corridor with doors shut.

3.15 Depending on the nature and duration of the AHU failure, and in line with NHS Lothian Prioritisation of Isolation Guidance, a clinical risk assessment would be required in conjunction with the IPCT to determine any further actions required on a case by case basis. This would take account of: the patient's overall clinical condition, the ward type, the infection risk and mode of transmission, the risk profile of adjacent patients and isolation room capacity unaffected by the outage. Additional mitigating actions specific to infectious diseases of high consequence (such as MERS or Multi Drug Resistant TB) would also be required in the event of supply ventilation failure.

3. Recommendations

4.1 Staff at RHCYP and DCN should refer to and implement the NHS Lothian Prioritisation of Isolation Guidelines to ensure that all patients with a suspected or known infection risk, or who are vulnerable to opportunistic infections, are placed appropriately within all clinical care environments.

4.2 All NHS Lothian staff should continue to implement standard and transmission based precautions in line with national policy. This includes, but is not limited to, ensuring that patients with known or suspected infections are cared for in single or isolation room accommodation and the door to the room remains closed.

4.3 All children, young people or adults cared for in RHCYP DCN who are receiving chemotherapy, radiotherapy or who are considered to be immunosuppressed should be prioritised for single room or isolation room accommodation where possible.

4.4 In line with national policy, co-horting of children with confirmed respiratory viral illness should be considered where this is clinically appropriate and demand for single room isolation has been exceeded. Strict application of standard and transmission based precautions is required for the duration of this

4.5 A separate review and assessment of patient accommodation and patient risk in Lochranza ward is required to inform any further adjustment to the ventilation system required prior to migration of paediatric services.

Health Building Note 04-02
Critical care units

Preface

About Health Building Notes

Health Building Notes give "best practice" guidance on the design and planning of new healthcare buildings and on the adaptation/extension of existing facilities.

They provide information to support the briefing and design processes for individual projects in the NHS building programme.

The Health Building Note suite

Healthcare delivery is constantly changing, and so too are the boundaries between primary, secondary and tertiary care. The focus now is on delivering healthcare closer to people's homes.

The Health Building Note framework (shown below) is based on the patient's experience across the spectrum of care from home to healthcare setting and back, using the national service frameworks (NSFs) as a model.

Health Building Note structure

The Health Building Notes have been organised into a suite of 17 core subjects.

Care-group-based Health Building Notes provide information about a specific care group or pathway but cross-refer to Health Building Notes on **generic (clinical) activities** or **support systems** as appropriate.

Core subjects are subdivided into specific topics and classified by a two-digit suffix (-01, -02 etc), and may be further subdivided into Supplements A, B etc.

All Health Building Notes are supported by the overarching Health Building Note 00 in which the key areas of design and building are dealt with.

Example

The Health Building Note on accommodation for adult in-patients is represented as follows:

> "Health Building Note 04-01: Adult in-patient facilities"

The supplement to Health Building Note 04-01 on isolation facilities is represented as follows:

> "Health Building Note 04-01: Supplement 1 – Isolation facilities for infectious patients in acute settings"

Health Building Note number and series title	Type of Health Building Note
Health Building Note 00 – Core elements	Support-system-based
Health Building Note 01 – Cardiac care	Care-group-based
Health Building Note 02 – Cancer care	Care-group-based
Health Building Note 03 – Mental health	Care-group-based
Health Building Note 04 – In-patient care	Generic-activity-based
Health Building Note 05 – Older people	Care-group-based
Health Building Note 06 – Diagnostics	Generic-activity-based
Health Building Note 07 – Renal care	Care-group-based
Health Building Note 08 – Long-term conditions/long-stay care	Care-group-based
Health Building Note 09 – Children, young people and maternity services	Care-group-based
Health Building Note 10 – Surgery	Generic-activity-based
Health Building Note 11 – Community care	Generic-activity-based
Health Building Note 12 – Out-patient care	Generic-activity-based
Health Building Note 13 – Decontamination	Support-system-based
Health Building Note 14 – Medicines management	Support-system-based
Health Building Note 15 – Emergency care	Care-group-based
Health Building Note 16 – Pathology	Support-system-based

Other resources in the DH Estates and Facilities knowledge series

Health Technical Memoranda

Health Technical Memoranda give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare (for example medical gas pipeline systems, and ventilation systems).

They are applicable to new and existing sites, and are for use at various stages during the inception, design, construction, refurbishment and maintenance of a building.

All Health Building Notes should be read in conjunction with the relevant parts of the Health Technical Memorandum series.

Activity DataBase (ADB)

The Activity DataBase (ADB) data and software assists project teams with the briefing and design of the healthcare environment. Data is based on guidance given in the Health Building Notes, Health Technical Memoranda and Health Technical Memorandum Building Component series.

1. Room data sheets provide an activity-based approach to building design and include data on personnel, planning relationships, environmental considerations, design character, space requirements and graphical layouts.
2. Schedules of equipment/components are included for each room, which may be grouped into ergonomically arranged assemblies.
3. Schedules of equipment can also be obtained at department and project level.
4. Fully loaded drawings may be produced from the database.
5. Reference data is supplied with ADB that may be adapted and modified to suit the users' project-specific needs.

Note

The sequence of numbering within each subject area does not necessarily indicate the order in which the Health Building Notes were or will be published/printed. However, the overall structure/number format will be maintained as described.

Executive summary

This Health Building Note provides guidance on critical care units that admit patients whose dependency levels are classified as level 2 or 3 (see 'Comprehensive Critical Care', DH 2000, for definitions of levels of critical care). However, it does not distinguish between the different requirements for level 2 and 3 patients.

It excludes facilities for the high-security isolation of patients, dedicated centres for burns patients and areas within the hospital where level 2 or 3 patients are managed on a time-limited basis.

Contents

1 Policy context

1.1 'Comprehensive Critical Care' (DH, 2000) was a pivotal publication. It introduced the concept of "critical care without walls"; identifying for the first time that a patient's clinical needs and not their location of care determined the required level and type of organ support. Patients thereafter have been described according to their required level of organ support (see levels of care on the Intensive Care Society website).

1.2 In addition 'Comprehensive Critical Care' highlighted the need for early recognition of deteriorating health and appropriate comprehensive transfer arrangements for patients to wards after recovery from critical illness. These concepts and guidance on operational service delivery such as the role of critical care networks were reinforced in 'Quality Critical Care – Beyond Comprehensive Critical Care' (DH, 2005).

1.3 NICE has subsequently issued guidance on 'Acutely ill patients in hospital' (Clinical guidelines CG50, July 2007) and 'Rehabilitation after critical illness' (Clinical guidelines CG83, 2009). Accompanying CG50, 75 acute care competencies have been detailed in 'Competencies for recognising and responding to acutely ill patients in hospital' (DH, 2009). Such guidance has led to the development of critical care outreach services.

1.4 The operational changes that have followed the release of 'Comprehensive Critical Care' have been significant. Critical care networks have developed, many of which are delivered now as managed clinical networks. The provision of mutual and collective planning of services is essential for service resilience. This means that critical care units across a conurbation will work together to meet needs.

1.5 The building blocks for commissioning of critical care services are now in place. A new dataset, Critical Care Minimum Dataset, was mandated from April 2006; annual reference cost submission followed and from 1 April 2011 a new model for commissioning of critical care services has been used. This model uses the mandated dataset and derivation of seven healthcare resources groups for critical care as the currency, but uses local tariffs ('Payment by Results Guidance for 2011–12', DH).

Mixed-sex accommodation in critical care units

1.6 Patient acuity determines the need for access to critical care, and although every effort is made to group members of the same sex together, this is frequently not possible. Nevertheless, it is imperative that the highest standards of privacy and dignity are maintained at all times.

1.7 For guidance on the justification for mixed sex accommodation in critical care units see PL/CNO/2010/3 – 'Eliminating Mixed Sex Accommodation'.

2 Service context

2.1 The Department of Health collects data on the number of critical care beds twice a year. For details see 'Census on number of critical care beds in England'.

3 Scope of guidance

3.1 This Health Building Note describes spaces that are unique to a critical care unit. It also describes any variations to common hospital spaces and clarifies requirements for these spaces, where necessary.

3.2 For a full list of space requirements see the following example schedules of accommodation for an 8-bed, 16-bed and 32-bed critical care unit. The example schedules provide a basis for sizing facilities at initial planning stages but exact requirements should be determined locally based on the number and case mix of patients, hospital policy for the provision of supplies and waste disposal, and the layout of the unit. Links to guidance on common spaces are provided from the schedules.

Example schedules of accommodation for critical care units								
Version 1, published 15.09.11								
				Cost guide allowances:	**Circulation and communication**	**Engineering**		
				Public	35%	23%		
				Clinical	35%	35%		
				Staff	35%	21%		
Example 1: 8-bed critical care unit								
	Room name/function	**Unit area allowance**	**Quantity**	**Net internal area**	**Circulation and communication allowance**	**Engineering allowance**	**Gross internal area**	**Notes**
Public spaces								
	Entrance: visitors		1					
	Entrance: patients, staff and supplies		1					Separate entrance for staff and supplies is an option.
J0232	Reception desk (size based on number of places)	5.5	1	5.5	1.9	1.3	8.7	1-place reception for small/medium sized units; 2-place reception for large units (>30 beds).
J1155/J1414	Waiting area: 10 places	22.5	1	22.5	7.9	5.2	35.6	Includes children's play area and 10% wheelchair places. 1 place per bed with minimum of 10.
P0711	Mini kitchen	5.0	1	5.0	1.8	1.2	7.9	1 per unit.
	WC: independent wheelchair	4.5	1	4.5	1.6	1.0	7.1	1 per small/medium sized unit; 2 per large unit (>30 beds).
Clinical spaces								
T0214-03	Staff communication base: 2 places	13.0	1	13.0	4.6	4.6	22.1	2 places per 8 beds.
B1603	Isolation room: critical care	26.0	4	104.0	36.4	36.4	176.8	Planning and design manual specifies 20% singles (subject to case mix); in an 8-bed unit with a standard 4-bed bay arrangement 50% singles may be provided.
G0510	Gowning lobby	6.0	4	24.0	8.4	8.4	40.8	
B1610	4-bed bay: critical care	143.0	1	143.0	50.1	50.1	243.1	
M0727	Interview room: 7 places	12.0	1	12.0	4.2	4.2	20.4	1 per 10 beds.
V1635	Shower room: assisted	8.0	1	8.0	2.8	2.8	13.6	Nominal allowance. Requirement subject to case mix of unit.
Clinical support spaces								
T0535	Clean utility room	16.0	1	16.0	5.6	5.6	27.2	1 per 12 beds.
G0605	Ice-making machine bay	1.5	1	1.5	0.5	0.5	2.6	1 per unit.
L1308	Near patient testing room	8.0	1	8.0	2.8	2.8	13.6	1 per 16 beds.
Y0331	Dirty utility room for bedpan processing	12.0	1	12.0	4.2	4.2	20.4	1 per 16 beds.
P0627	Pantry/refreshment room	12.0	1	12.0	4.2	4.2	20.4	1 per unit.
W0540/1450/ 1590/1594	Storage: bulky consumables, medical gas cylinders, linen and furniture	4.0	8	32.0	11.2	11.2	54.4	4 m^2 allowance per bed. Based on a review of a number of reference sites.
W1584-06	Store: clinical equipment	24.0	1	24.0	8.4	8.4	40.8	1 for small/medium sized units; 2 for large units (>30 beds).
Y0335	Decontamination room: clinical equipment	16.0	1	16.0	5.6	5.6	27.2	1 per unit. Located adjacent to clinical equipment store.
G0171	Parking bay: imaging equipment	6.0	1	6.0	2.1	2.1	10.2	1 per small/medium sized unit; 2 per large unit (>30 beds).
G0180-01	Parking bay: resuscitation trolley	2.0	1	2.0	0.7	0.7	3.4	1 per 8 beds.
Y0642	Disposal hold: 1700 litres	8.0	1	8.0	2.8	2.8	13.6	Minimum 1500 litres per 8 beds
Y1510	Cleaners' room	8.0	1	8.0	2.8	2.8	13.6	1 for small/medium sized units; 2 for large units (>30 beds).
Staff spaces								
M0251	Office: 1-person	8.0	3	24.0	8.4	5.0	37.4	For clinical director, lead nurse and tutor.
M0278-01/M0281/ M0410/M0731	Admin area: shared use (size based on number of workstations)	6.6	5	33.0	11.6	6.9	51.5	For consultants and outreach staff.
M0727	Meeting room: 7 places	16.0	1	16.0	5.6	3.4	25.0	
H1304-01	Seminar room: 8 places	17.0	1	17.0	6.0	3.6	26.5	May be sized up and shared with other departments.
D0434-01	Rest room with mini kitchen (size based on number of seats)	1.9	8	15.2	5.3	3.2	23.7	
V0554-03/V0667-01/ V0725/V1321	Changing area: staff (size based on number of lockers)	1.4	35	49.0	17.2	10.3	76.4	Includes uniform exchange area, showers and a number of individual changing rooms. Based on 32 staff who need a locker (allowing for shift changeover), plus a 10% contingency to allow for male/female split (suggested apportionment 2/3 female to 1/3 male).
V0725	Changing room: semi-ambulant	2.0	1	2.0	0.7	0.4	3.1	Additional individual changing room to allow for male and female segregation.
V1321	Shower room: ambulant	2.5	1	2.5	0.9	0.5	3.9	Additional shower room to allow for male and female segregation.
V1010	WC: ambulant	2.0	4	8.0	2.8	1.7	12.5	Serving up to 50 staff, with additional WC to allow for gender segregation.
Total allowance				**653.7**	**228.8**	**201.0**	**1083.5**	
Optional accommodation								
W0652	Blood refrigerator bay	2.0	1	2.0				Only required if blood storage not available nearby.
L1804-03	Service room: clinical equipment	12.0	1	12.0				Only required if biomedical engineering workshop not available nearby.
G0171-02	Parking bay: mobile image intensifier	2.0	1	2.0				
P0808	Vending machine	3.0	1	3.0				In lieu of visitors' mini kitchen.
D1120	Sitting room: 7 places	12.0	1	12.0				For visitors.
D1312	Relatives' overnight stay	17.0	1	17.0				For visitors. Requirement based on case mix of patients.
V1323	Shower room: semi-ambulant: standing use	5.0	2	10.0				For visitors. Requirement based on case mix of patients.

V1323	Shower room: semi-ambulant: standing use	5.0	2	10.0				For visitors. Requirement based on case mix of patients.

4 Whole unit planning and design considerations

Departmental relationships

4.1 A critical care unit should be centrally located within an acute hospital development. It should be adjacent to and/or have easy access to (and be easily accessible from) imaging facilities and operating theatres. The emergency department should be adjacent and/or have easy access to the critical care unit.

4.2 The critical care unit requires close links to the main hospital pharmacy and microbiology laboratory; where a pneumatic tube system is used to transport specimens and computers are used for transmitting test results and placing prescription orders, physical proximity is less important.

Bed spaces

4.3 Each bed space should include the following:

- an electric bed capable of attaining chair and Trendelenberg positions, and fitted with a pressure-relieving mattress;
- a high-backed chair with foot elevation and tilting facility for the patient;
- a ceiling-mounted twin-armed pendant to accommodate a range of equipment and for the provision of medical gases and electrical and data connectivity;
- a clinical wash-hand basin;

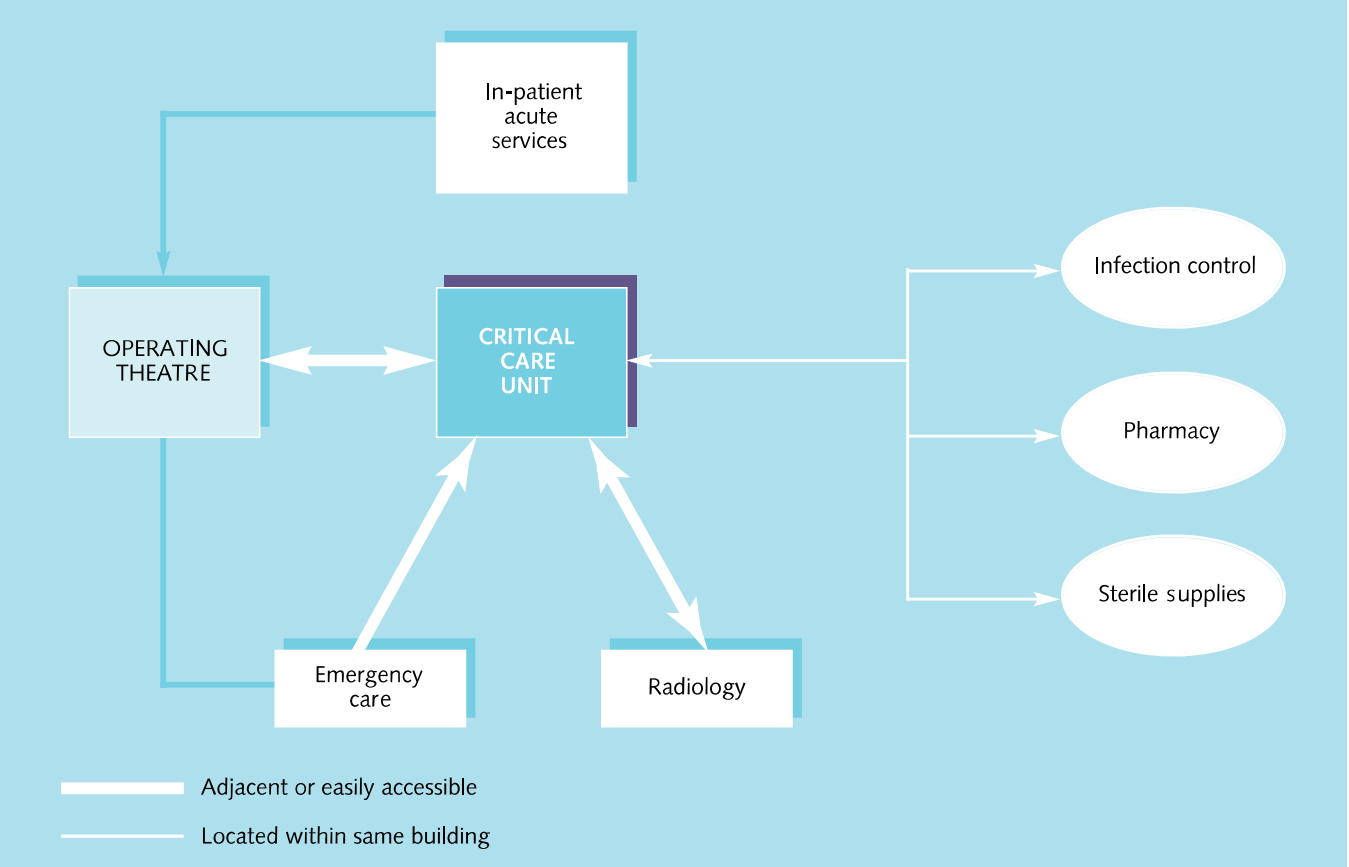

Figure 1 Departmental relationships for a critical care unit

- enclosed storage for a small quantity of consumables;
- drugs storage (wall-mounted drugs cabinet or within the patient's bedside locker);
- a ceiling-mounted hoist for lifting patients.

4.4 Storage of patients' clothes and personal effects should be dealt with in accordance with whole-hospital policy. They should not normally be kept at the bedside; however, some personal items such as family photographs can help the patient's orientation and provide emotional support.

4.5 The following outlets should be located on the pendant:

- at least 28 unswitched single socket-outlets;
- up to four data outlets, one of which should be networked to the hospital's patient record system;
- 3–4 oxygen outlets;
- two 4-bar air outlets;
- one 7-bar air outlet (where surgical equipment is used), clearly labelled with the appropriate warning;
- 2–4 medical vacuum outlets;
- anaesthetic gas scavenging points, if anaesthetic inhalation gases and/ or inhalation antibiotics are used;
- patient/staff and staff emergency call systems, including a separate switch for crash call;
- telephone outlet for internal and external calls;
- TV outlet.

4.6 The following equipment should be located on the pendant:

- computer with flat-screen monitor;
- multi-parameter patient monitoring equipment;
- 3–6 infusion pumps;
- 4–10 syringe pumps;
- blood warmer;
- feeding pump;
- ventilation and humidification equipment.

4.7 Ceiling-mounted rather than floor-mounted pendants are recommended since they avoid the need to trail cables across the floor, thereby providing better access to the patient and improved safety for staff and visitors. They are also easier to keep clean. Powered ceiling-mounted pendants enable staff of all heights to operate them easily. Care should be taken in the positioning of the pendants to ensure convenient access by staff.

4.8 The pendant should be connected to an isolated power supply and provide an uninterruptable power supply (UPS) to an agreed number of electrical outlets. IPS and UPS sockets should be colour-coded to differentiate them from one another. Additional switched and shuttered sockets, connected to ring circuits, may be provided at the bedhead for portable non-medical equipment.

4.9 The temperature within bed spaces is usually controlled by the ventilation system rather than radiators. Facilities for temperature and humidity adjustment should be provided, to parameters agreed with clinical representatives on the project team. Children should only be placed in bed spaces that provide local temperature control (due to the need to elevate the room temperature for this patient group).

4.10 The ventilation system should include mechanical cooling and provide for a range of temperatures that can be adjusted by staff, taking particular care to establish and accommodate the unusually high heat gains that may be anticipated from medical equipment. The position of ventilation grilles should minimise the risk of patients experiencing discomfort through down drafts.

4.11 The following equipment may be required at the bedside on an intermittent or continuous basis:

- mobile X-ray machine;
- haemodialysis machine;
- haemofiltration machine;
- peritoneal dialysis machine;
- EEG machines;
- electrocardiography machines;
- echocardiography machines;
- transoesophageal echocardiography machines;
- invasive cardiac output monitoring devices;
- ultrasound machines;
- gamma cameras;
- endoscopes (fibre-optic light source);

- defibrillators;
- non-invasive respiratory equipment (continuous positive airway pressure (CPAP)/bi-level positive airway pressure (BIPAP)): this may be mounted on the pendant;
- vacuum dressings.

4.12 A wall-mounted renal dialysis panel with water supply and drainage may be provided at some bed spaces to facilitate haemodialysis. Alternatively, it may be more economical to supply potable water to small water treatment units at the bed space. The specification for the water quality should be agreed with the project team.

4.13 A clock with an elapsed time control should be clearly visible from each bed space.

4.14 The bed space should be a minimum of 25.5 m^2 in order to accommodate the above equipment/ furniture. This will also allow:

- staff access to the patient from all sides of the bed;
- staff to manoeuvre the patient, themselves and equipment safely;
- five members of staff to attend to the patient in an emergency situation;
- two visitors to sit at the bedside.

4.15 All bed spaces should be capable of providing visual privacy and reasonable auditory privacy, when required. All bed spaces should have natural daylight with outside views wherever possible. Artificial lighting should be dimmable and of sufficient strength to enable surgical interventions and response to life-threatening situations at the bedside. Lighting may be provided as part of the pendant system.

4.16 Glass walls (in the case of single-bed rooms) or partitions (in the case of multi-bed areas), which can be obscured for privacy when appropriate, aid observation of patients.

4.17 A ceiling height of 3 m in bed areas is recommended in order to accommodate pendants and ceiling-mounted hoists. The position of overhead equipment requires careful consideration. The construction of the ceiling should take account of weight-bearing requirements.

5 Public spaces

Entrances

5.1 Patients and visitors should not share the same entrance, to ensure that visitors do not observe patients coming in and out of the critical care unit. Deceased patients should be transported using the patients' entrance. Staff may share an entrance with either visitors or patients. However, a dedicated entrance for visitors may provide them with a calmer, less busy environment. Supplies should be delivered via the same entrance used by staff.

5.2 The entrance for visitors requires an intercom-controlled entry system or similar linked to the reception desk and staff communication base(s). CCTV should also be considered, with monitors at the reception desk and staff communication base(s) to assist with identification of visitors out-of-hours.

5.3 Where access control measures are in place, close-proximity cards rather than swipe cards or keypads should be used, as they are easier to clean and offer better infection control.

Reception desk

5.4 The entry system for the visitors' entrance, CCTV monitor, if provided, and a telephone for internal and external calls should be located here. The reception desk should have natural surveillance of the visitors' entrance and/or point of entry to clinical areas.

Visitors' waiting area and associated facilities

5.5 On arrival, visitors will be admitted immediately to the appropriate clinical area or asked to wait in the waiting area. There should be a door between the waiting area and clinical areas, controlled by staff, to prevent visitors wandering into clinical areas. Beverage-making facilities and WCs should be available nearby. The waiting area may include a TV. A separate visitors' sitting room may be of value for those spending long periods of time within the vicinity of the critical care unit.

Visitors' overnight accommodation

5.6 Overnight accommodation for visitors may be provided within the hospital, or the hospital may have an arrangement with a nearby hotel. Where children are being treated, overnight accommodation for parents should be provided. Enlarged single bedrooms provide the option of adding an extra bed for parents to stay overnight.

6 Clinical spaces

Staff communication base(s)

6.1 Ideally, staff at the base(s) should be able to see all multi-bed spaces under their control and the entry point to clinical areas. Control of the visitors' entry system will be transferred from the reception desk to the communication base(s) at night.

6.2 Alarms to signify the failure of medical gas and power outlets within the bed spaces should be located here. Central consoles for multi-parameter patient monitoring equipment should also be located here.

6.3 A telephone for internal and external calls will be required. Task lighting should be provided for use at night to prevent disturbing patients. Each base should be partially enclosed to control noise transfer.

Isolation rooms

6.4 Single-bed rooms with lobbies are required for the isolation of patients to control the spread of infection or for the protection of immuno-suppressed patients.

6.5 Single-bed rooms should be rectangular, not L-shaped, with an entrance wide enough to allow bulky equipment to pass easily – at least a door and a half wide. Care should be taken to ensure that the door opening is sufficient to allow the passage of the bed and equipment.

6.6 The ventilation system should be designed to provide simultaneous source and protective isolation. A balanced supply and extract ventilation to each isolation room and gowning lobby is, therefore, proposed. The lobby, which functions as

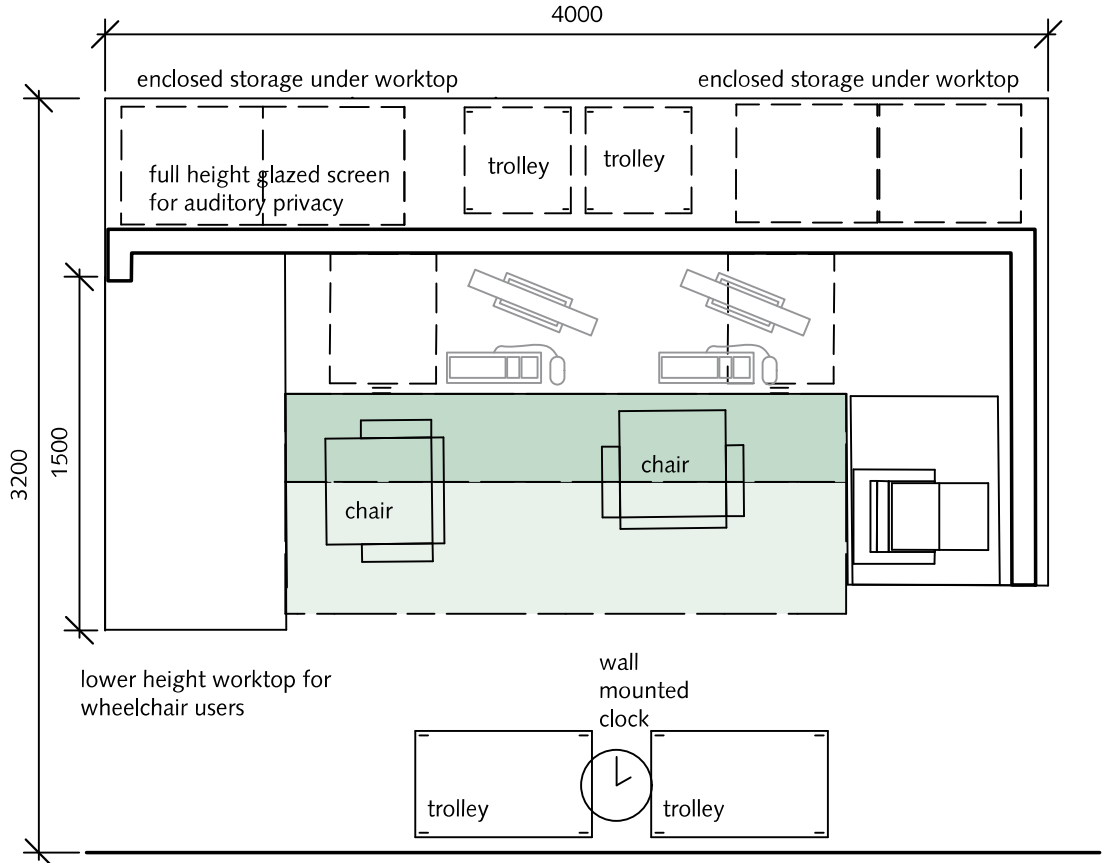

Figure 2 Critical care 2-place staff communication base

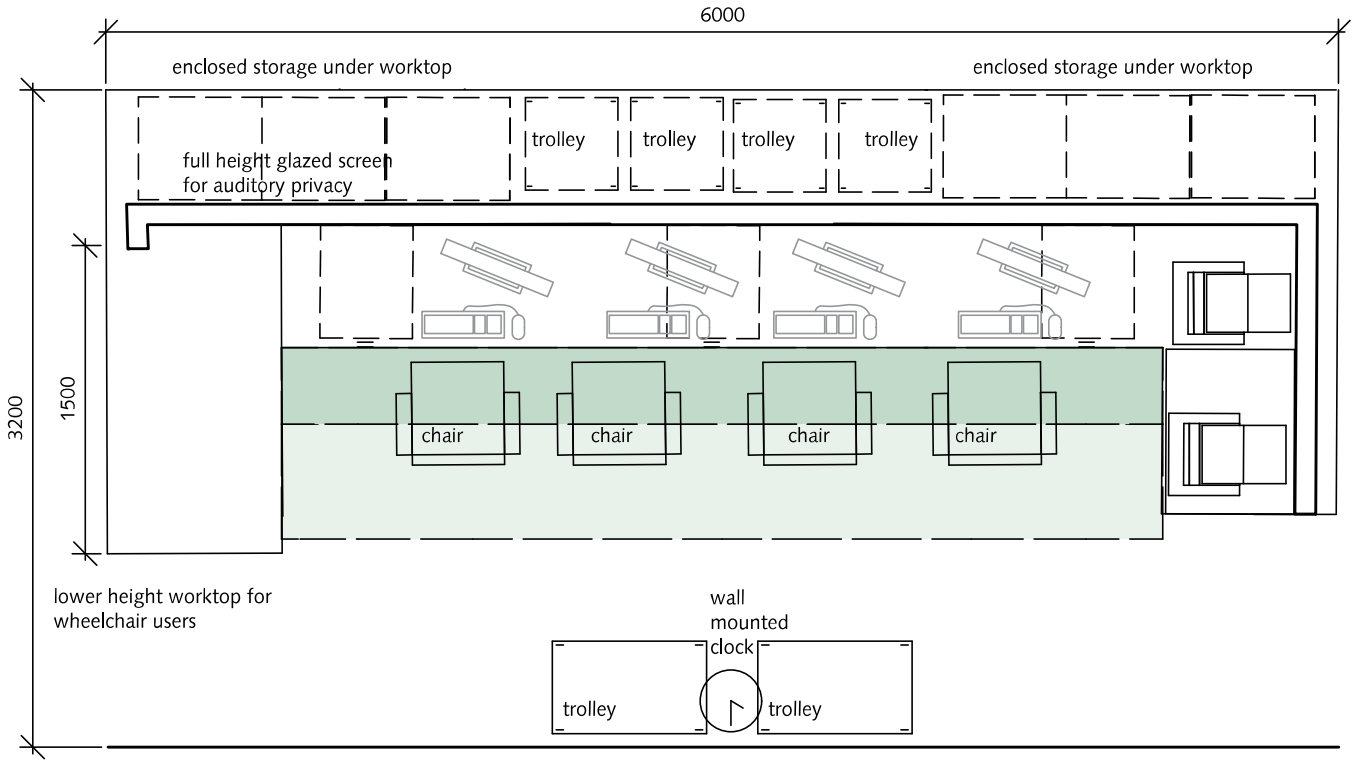

Figure 3 Critical care 4-place staff communication base

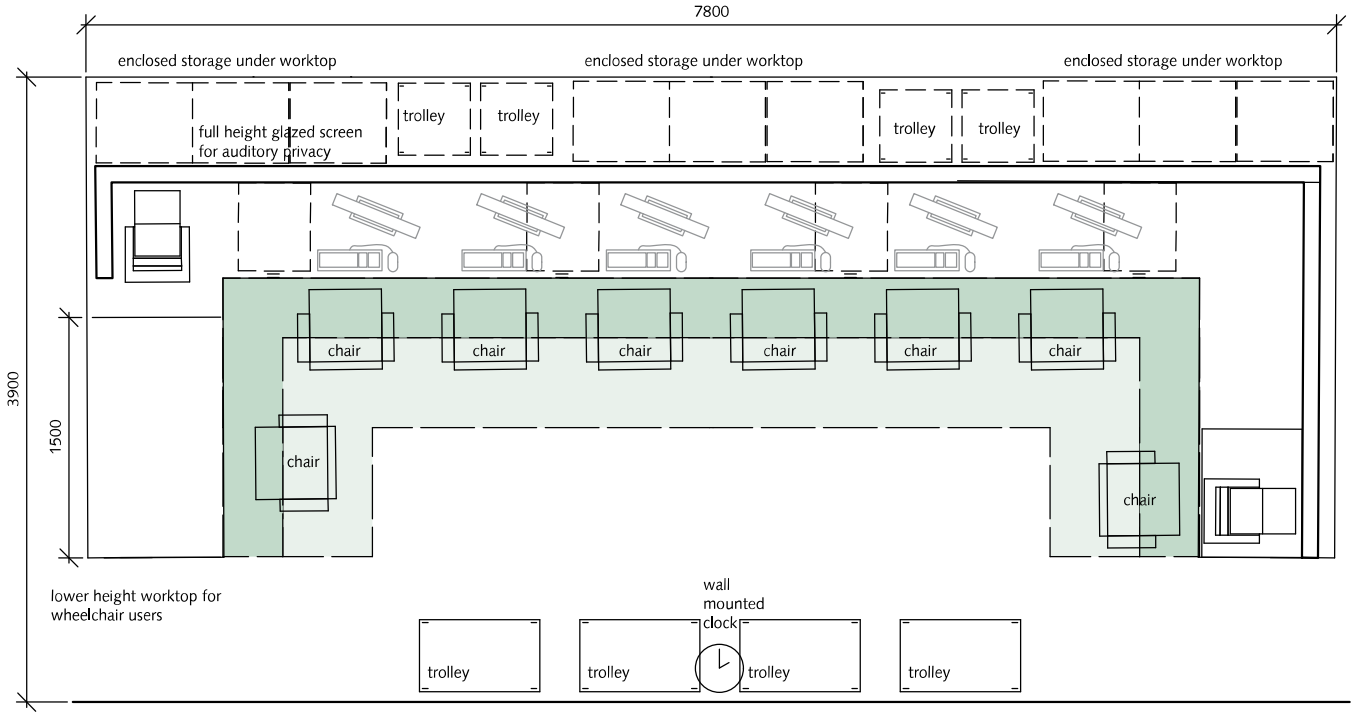

Figure 4 Critical care 8-place staff communication base

an airlock, requires a relatively high and balanced supply and extract air change rate to be effective against airborne organisms moving between circulation areas and isolation rooms.

6.7 Ceilings and windows should be sealed. Doors should be tight-fitting, with seals to minimise air transfer.

6.8 Isolation rooms should have local temperature controls that are accessible to nursing staff and may require humidity within the range 40–60% Rh, depending on the specialty.

6.9 The precise number of isolation rooms will depend on the case mix of the critical care unit. For example, units that routinely admit neutropenic haematology patients may require up to 50% of their beds to be provided as isolation rooms with lobbies. No unit should, however, have less than 20% of their beds as isolation rooms.

Multi-bed areas

6.10 A 2.5 m-wide unobstructed circulation space should be provided at the foot of each bed space. It is imperative to maintain the required bed separation for infection control reasons and to aid positioning of equipment.

6.11 The temperature in the multi-bed areas should be centrally controlled.

6.12 Requirements for scrub troughs should be determined locally based on patient case mix.

6.13 Project teams should select a curtain system that meets the following criteria:

- when the curtains are pulled around the bed space, there should be 100% visual privacy;
- it should be possible to pull the curtains back completely against the wall;

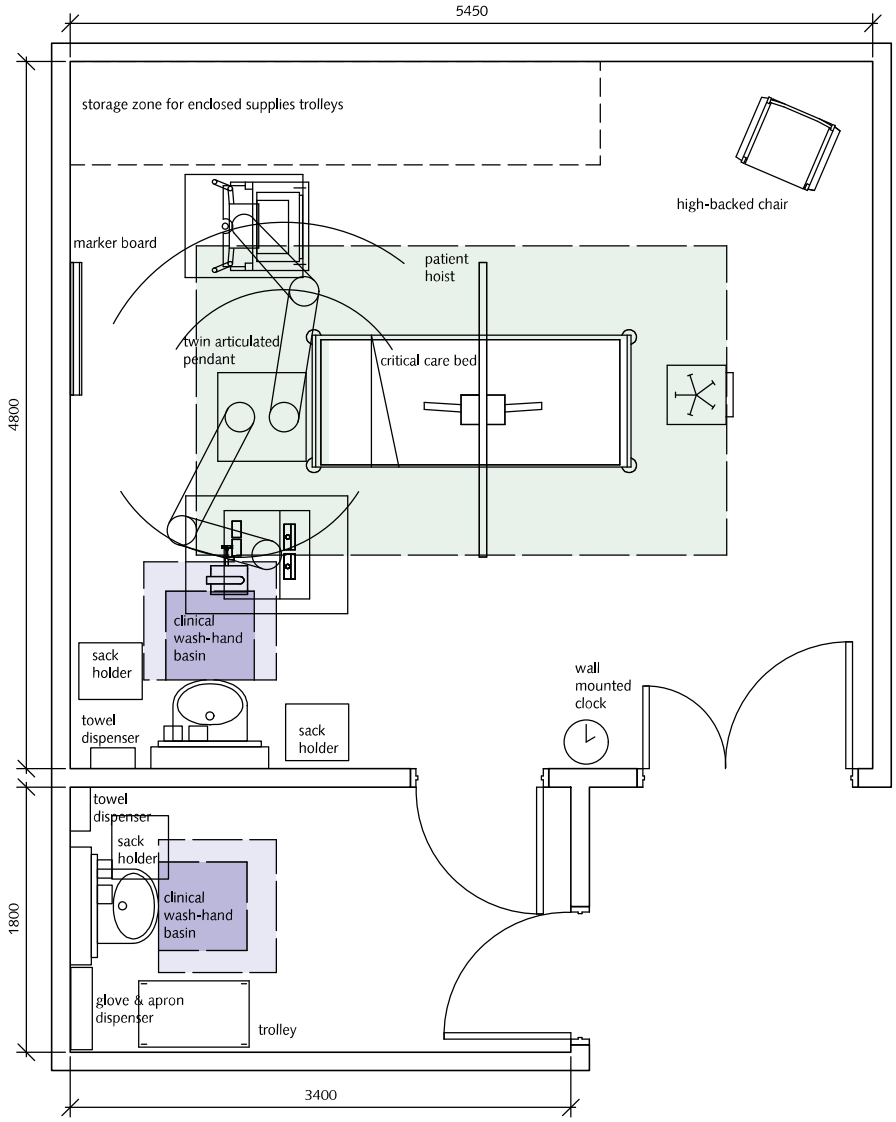

Figure 5 Critical care isolation room and lobby

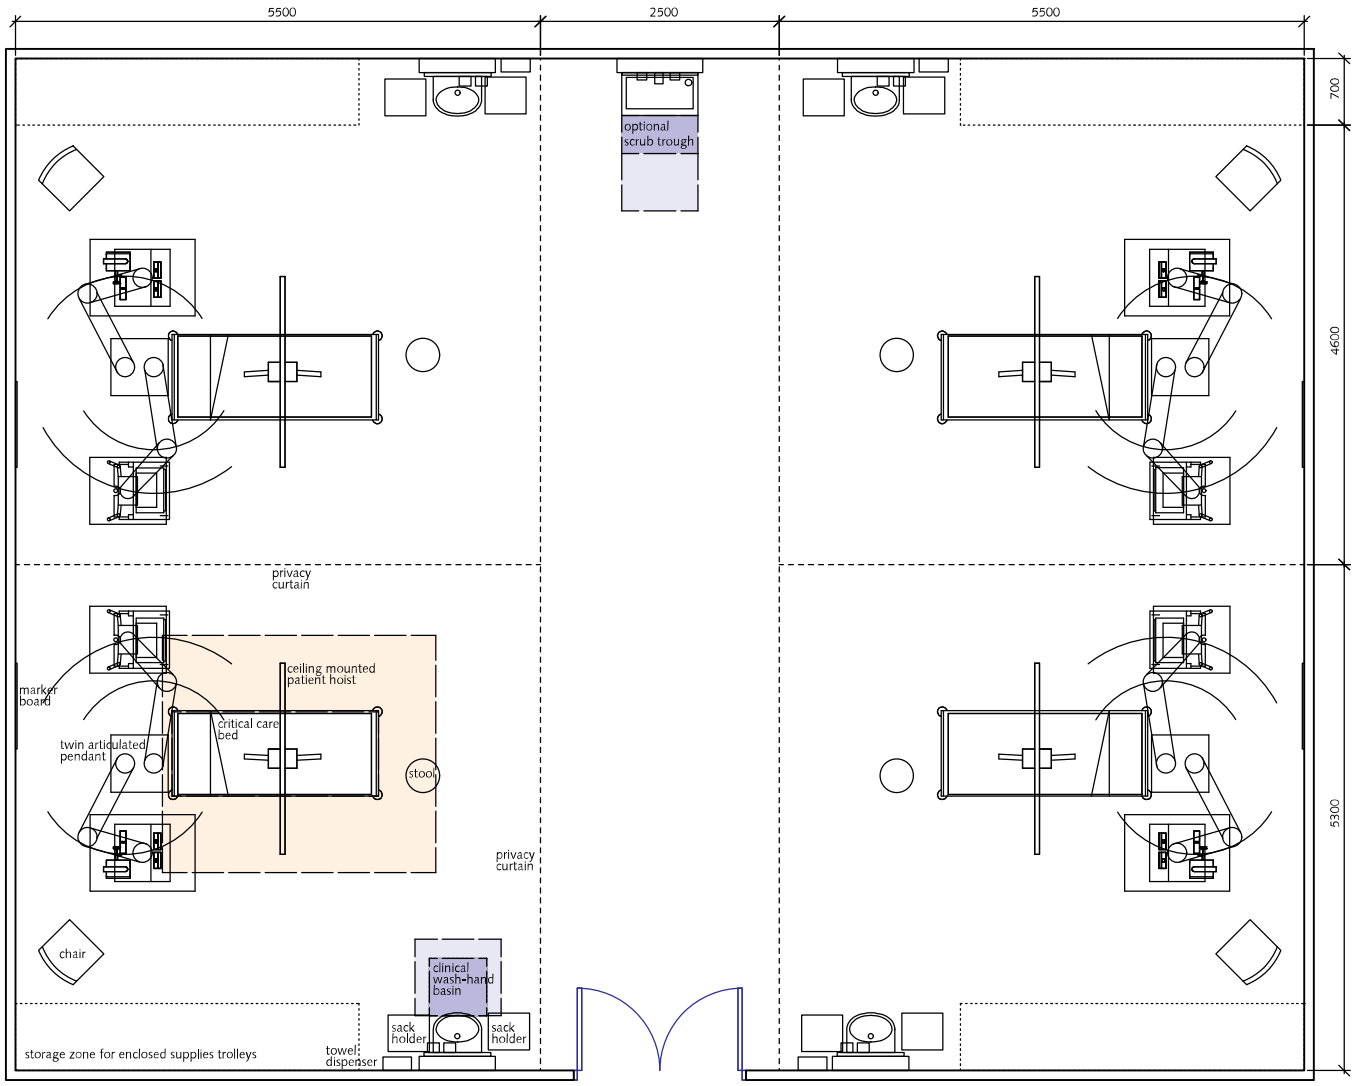

Figure 6 Critical care 4-bed bay

- the density of the curtains should reduce the level of general noise transmitted and also improve the level of auditory privacy in the bed-space;
- the curtains should be easily movable and disposable.

Interview rooms

6.14 Interview rooms should be provided within the vicinity of the bed spaces to enable staff to speak to visitors in privacy. The rooms should be in a quiet location.

7 Clinical support spaces

Ice-making machine bay

7.1 An industrial ice-making machine should be provided to facilitate hypothermic interventions. It should be located in a designated bay.

Storage for bulky consumables, medical gas cylinders, linen and furniture

7.2 The example schedules include a combined storage allowance for bulky consumables, medical gas cylinders, linen and furniture. However, these four categories of item should be stored separately. (It is assumed that non-bulky sterile supplies and consumables are held in the clean utility rooms.)

7.3 The project team should ensure that the provision of standby medical gases reflects the emergency procedures and contingency plans for the unit. The medical gas cylinder store(s) should be easily accessible from clinical areas and enclosed in fire-resisting construction.

7.4 The furniture store(s) will need to accommodate bulky equipment, including mattresses, when not in use, chairs, bariatric equipment and cots.

Clinical equipment store(s)

7.5 A dedicated area should be provided for the storage and charging of transfer equipment (transport trolley, monitors, syringes, ventilators, suction pumps). Dedicated ventilation may be required to remove gases and heat from chargers. An area for hanging endoscopes and transoesophageal echocardiography probes is also required. The clinical equipment store(s) should be within easy access of the bed areas.

Clinical equipment decontamination room

7.6 Clinical equipment should be cleaned following use prior to transfer to the clinical equipment store(s) or, if the equipment requires maintenance, to the equipment servicing room. A clinical equipment decontamination room should be provided for this purpose. This room should be adjacent to the clinical equipment store(s).

Imaging equipment bay

7.7 An open bay should be provided close to the clinical equipment store(s) for the storage of imaging equipment and protective lead aprons. A socket-outlet should be provided for charging equipment.

7.8 Lead aprons should be stored vertically to maintain their protective capability. Suitable wall brackets attached to a load-bearing wall, or mobile stands, are required for this purpose. The bay should also accommodate a mobile X-ray machine, a minimum of one ultrasound machine, and a transoesophageal echocardiography machine. A larger bay is required if mobile image intensifiers are used.

7.9 Regulations pertaining to the use of ionising radiation, such as IR(ME)R 2000 and IRR99, must be complied with.

Resuscitation trolley bays

7.10 It is essential that adequate provision is made for siting resuscitation trolleys within the critical care unit. The precise equipment positioned on these trolleys should be determined locally.

Blood refrigerator bay (optional)

7.11 A blood refrigerator will only be required if a blood store is not available nearby. If provided, the fridge should be located in a designated bay and should be networked to the central system to permit traceability of blood. The use of blood refrigerators is governed by national and local blood transfusion service regulations.

Clinical equipment service room (optional)

7.12 Facilities are required for equipment servicing as defined in equipment manufacturers' user manuals, supplemented by any formally agreed local instructions. A dedicated room should be provided in the critical care unit for this purpose if an existing biomedical engineering workshop is not located nearby. When provided as part of the critical care unit, this room should be adjacent to the clinical equipment decontamination room.

8 Staff spaces

1-person offices

8.1 The clinical director, lead nurse and Faculty of Intensive Care Medicine tutor require dedicated 1-person offices.

Admin areas

8.2 The following staff may require access to a workstation, but these may be provided in an open-plan office environment:

- clinical staff (doctors, nurses, allied health professions);
- outreach staff;
- audit clerk;
- technician;
- secretarial staff;
- IM&T staff;
- organ donation staff;
- research staff.

8.3 Workstations for clinical staff should provide quick and easy access to the patient bed areas in case of an emergency.

Seminar room

8.4 Access to a seminar room within the vicinity of the critical care unit must be provided. An intercom system should be installed between the seminar room and the clinical areas to recall staff in an emergency. The seminar room may double up as a skills laboratory, for example for training in resuscitation, using mannikins, defibrillators, and simulated body parts for venepuncture or suture practice.

Rest rooms

8.5 Staff rest rooms should be located far enough away from patient bed areas for staff to withdraw, but also close enough for them to return quickly to the patient bed areas in case of an emergency. Rest rooms require call systems to recall staff to the clinical areas in case of an emergency.

Changing areas

8.6 Space is required within the changing areas for the storage and disposal of scrub suits and footwear.

Hi Donald,

Can you go to the main site security office at the site cabins and I will pick you up from there. I believe Lindsay is coming as well so have copied her in.

I will pick you up from security at 12:00 and bring you to our office where you can get PPE

Regards

Ronnie

Hi Ronnie,
I can make Tuesday 11th at midday. I'm waiting to hear which of the other microbiologists with engineering aspects of infection control training can be free at that time and once I know I'll forward you their names. I'll be at RIE that morning anyway so no need for a parking space.
Thanks
Donald

Hi Donald,

I have availability as follows;

Fri 7/12 Before 11:00
Mon 10/12 After 10:00
Tue 11/12 12:00 – 15:00
Wed 12/12/18 No availibility
Thu 13/12 09:00 – 13:00

If you let me know which of these suits best and who will be coming and I will arrange the necessary access. If you are travelling by car I can also arrange a parking space for you

Regards

Hi Ronnie,
Thanks for your e-mail. Given how crucial it is to get this right, I think it would be best if we could meet and physically see what is being proposed in the building as well as on paper.
Janette has retired so I am copying in colleagues from infection control who would need to be aware of this development.
Can you suggest some days/times when viewing might be possible?
Thanks
Donald

Subject: Isolation Room Heater Batteries
Importance: High

Hi Donald,

As you are probably aware the issues surrounding the location of heater batteries in the isolation room lobbies is still rumbling on. We have now had an updated proposal from Multiplex and their designers that I feel moves us closer to an acceptable solution, however I do not want to commit to it without seeking your input/approval.

The proposal can be summarised as follows:

1. Blank off pipework to existing heater batteries above lobby ceiling and drain down. Blanking off to occur at tee off point from main pipe runs. Infrastructure to be left in place for future use.
2. Install ceiling mounted radiant panel with sensor in extract ductwork and adjustable controller external to room.

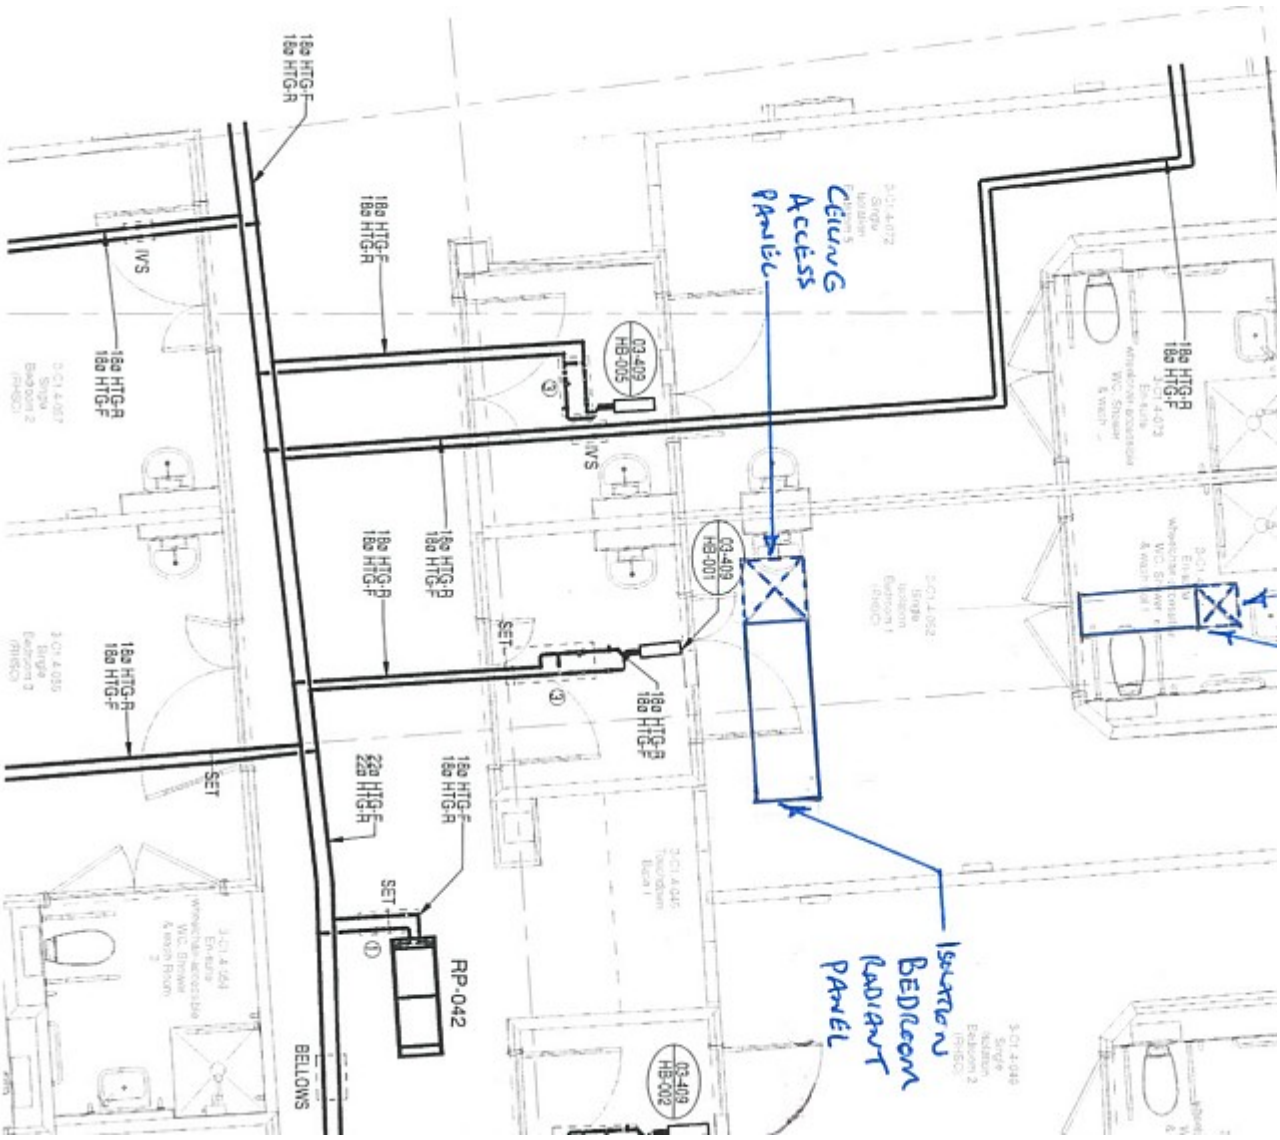
Advantages:

- Panel is fixed flat to ceiling and sealed
- Gives a secondary source of heat that can be adjusted by staff to patients needs
- No drip tray required
- Requires no regular maintenance and any ad hoc repairs can be programmed around room availability.

Disadvantages:

- Additional pipework above isolation room ceiling (already has water services for en suites and WHB running there)
- Another airtight ceiling hatch may be required

For further information please see example of proposed layout of ceiling mounted radiant panel.



Can you please have a look at this and provide any comments and if required we can meet and view an isolation room.

Regards

Ronnie

ISSUES RELATING TO LOCATION OF HEATER BATTERIES

1. Introduction

Due to the specific needs of certain patient groups and spaces there is a requirement to provide higher or lower temperatures than those provided within general areas of the relevant department. In order to meet this requirement water filled batteries are installed local to the space. The relevant guidance covering the location of these batteries is SHTM 03-01, specifically the following clauses:

'4.71 Where possible, wet-trimmer heater-batteries should be located in plant areas.'

'4.72 Where it is necessary to locate heater-batteries in false ceilings etc, consideration should be given to the use of electric heaters. If this is not practicable, drip-trays should be installed under both the battery and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. In any event, to facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.'

2. Background to Issue

Due to space constraints limiting the available space in corridor voids for ductwork several batteries have been installed above both critical and clinical spaces. Of particular concern is the heater batteries located above all Isolation room lobbies as any work required on these immediately puts the associated isolation room out of use. Uncontrolled leaks from these may also penetrate the sealed ceiling and introduce pathogens into the airstream supplying the patient space. Small leaks can be mitigated by providing drip trays, ideally connected to drain to prevent ponding of stagnant water, and fitted with monitored leak detection. This solution does not eliminate the need for maintenance personnel to access the above ceiling space which will again put the room out of use.

Other concerning locations are above rooms such as CT, X-Ray, Fluoroscopy, Dental and MRI Tech rooms.

3. Engagement

Correspondence with infection control (Donald Inverarity & Janette Rae) has identified serious concerns about the Isolation rooms battery location to the extent that it is unacceptable to them for it to remain there.

Discussion has also taken place with Mike Conroy regarding the radiology related locations which cover the majority of the remaining issues.

Concerns have been fed back to Multiplex and site reviews have been undertaken.

4. **Options for Resolution**

Multiplex have provided drawings showing the location of all heater batteries which fall into 3 categories:

- Batteries they propose to relocate to non clinical/critical locations
- Batteries where drip tray, leak detection and drainage will be provided in current location
- Batteries where it will be both difficult to move and difficult to connect a drip tray to drain – these to be risk assessed with NHSL

The first option would be the preferred solution and Multiplex had indicated on the drawings their intent to move all isolation room batteries to the corridor. The drawings were returned with comments and Multiplex were to advise whether they could be addressed.

5. **Current Position**

Despite earlier commitments Multiplex have withdrawn their proposal to relocate isolation room batteries citing 'interjection' of the independent tester which implies they have sought and received his approval for their position. NHSL have re stated their view that this is unacceptable in these locations. Further dialogue is still required to confirm solutions for the other locations.

Discussions with the independent tester have clarified his input which can be summarised as, providing the risk of leaving it in its current location is no greater than relocating it to the corridor then it should be possible to leave it there. NHSL provided evidence as to why the risk was greater in the current location focusing on the need to move a patient from the room any time a leak occurred or maintenance was required. The reasoning behind the corridor being the better proposal was stated by NHSL as that in the event of a leak or maintenance it would be possible to isolate the heater battery without disrupting the air flow to the isolation room and repair or maintenance could be scheduled for a time when it was possible to turn off ventilation to the room.

A compromise to this was discussed with the Independent Tester whereby the isolation valves for the battery would be located in the corridor along with the ability to safely drain the battery and associated pipework. This would still present a problem in the event of a major leak with the possibility that water and pathogens may penetrate the ceiling and contaminate the airstream, however it is worth noting that this could occur with several other wet services already above the ceiling. This idea is worth investigating further.

It is important to acknowledge that there are locations where it will be extremely difficult, very costly, and significantly time consuming to alter ductwork and services to facilitate the relocation of the heater battery. This does not alter the fact that they are installed in non compliant locations however, with the exception of the isolation rooms issue, this can hopefully be addressed by undertaking suitable risk assessment and deploying mitigation.

6. **Summary & Recommendations**
    - NHSL find the location of heater batteries above the Isolation Room Lobbies to be unacceptable
    - NHSL to consider possibility of locating isolation valves and drain points in corridor but leaving battery above lobby ceiling.
    - Multiplex to make every effort to provide drip tray, drainage, & leak detection to all locations
    - NHSL will participate in a risk assessment process to determine mitigation actions for other clinical locations
    - NHSL to update residual risk register once agreed solutions are identified

Inverarity, Donald

This looks better.

However I am slightly concerned about the blanking off of the pipework.

We would need to be happy that this will not create a nidus for biofilm formation.

Can we see any time the infrastructure would be used in future?

Would it be better to strip out the redundant pipework and heater batteries?

Ewan

Dear All,
I'm forwarding this to you for your views as you are already aware of some of the concerns we have had about the design of these rooms. I've replied to Ronnie and asked if we can see what is being proposed in the building as well as on paper before giving a reply.
It looks like the only time I can be free to view will be Tuesday next week (11th) at midday. I had hoped that we could delay things until Pota was back but that doesn't look feasible.
If any of you are at RIE at that time or can be free to join me I would value having a second opinion/perspective from another microbiologist(s) familiar with the issues.
Many thanks
Donald

4 air changes per hour is less than the minimum for any clinical area (general wards are supposed to be 6 air changes per hour). Single room WC are 3 but thats the only area where SHTM 03-01 would advise less than 6. Interestingly a SCBU is only 6 air changes per hour so it might be able to aim for the standard of a SCBU?

Health Facilities Scotland

Subject: RE: HAI SCRIBE RHCYP Risks and Mitigations

If paediatric patients are moving from RHSC to the new site to Little France on 9th July there will need to be functioning ventilation in isolation rooms and functioning operating theatres (perhaps more immediately crucial for patient safety than isolation room ventilation) by the 9th July so although Thu 4th July is the date of the new Ventilation Steering group (which will never have met before this date), I'd be very uncomfortable not seeing the theatre/isolation room ventilation validation reports well before that date as it leaves virtually no time to fix anything significant that is uncovered in the independent validation process before patients are transferred and likely to need access to these (fully functioning) facilities.

Hi Alex

I would expect to see the documentation for **Risk 2** made available to the Water Safety Group on June 20th, and **Risk 1** ventilation information to be made available to the Ventilation Steering Group on 4th July.

I would suggest those are the 2 most pressing issues that we would seek assurance on, and in the absence of the information requested I'm not sure that the IPCT can give a realistic assessment of clinical risk.

The remaining issues are seeking information to inform an understanding of ongoing risk (such as mould development associated with previous leaks).

Regards
Lindsay

Thanks for sharing Lindsay.

What I got have a sense of, is what is the magnitude of these actions that remain to be complete in terms of risk to pts and in turn opening safely?

I didn't see any timelines. I'm assuming they have to be completed (do they?) before we move pts in?

Where: MacKinlay Room RHCYP

<< File: Updated Directions to Site 150398.pdf >>
Dear Jennifer,

I've booked the MacKinlay room for you.

Please go to the "Turnstiles" (shown on map) where the Security team will let you in and then go to the RHCYP Entrance (shown on map) where the Main Reception is. Please sign in at the reception desk.

I'd be grateful if you could send me a list of people attending the meeting so that we can add them to the visitors list to allow them through the security turnstiles.

Many thanks.

With kind regards,

Subject: QEUH building related HAI issues prom GG&C ICD perspective
Importance: High

Dear All,
Please see the reply I received this morning from my equivalent, Dr Teresa Inkster, in NHS GG&C based at QEUH and issues there she has had to deal with from an HAI risk which we need to be aware of. She is happy for this information to be shared with NHS Lothian.

Hi Donald

SHTM 0301 allows for thermal wheel technology provided they are fitted with a purge sector. However thermal wheels come with the risk of dirty extract air mixing with clean supply

In our paediatric haem-onc ward (non BMT patients) we experienced a significant number of outbreaks over a 2 year period. These proved difficult to control despite aggressive IC measures.

As part of the investigation we asked for an external review of the ventilation system. What we found was air changes of < 3 (due to chilled beams), rooms at slightly negative pressure to corridor, thermal wheel technology and ductwork configuration issues.

All of this combined was felt to be a factor in these outbreaks as mixing of dirty and clean air was occurring. HPS were asked to investigate and the conclusion of their report was that our outbreaks were not due to practice or IC issues but to the environment. Difficult to prove that retrospectively but it makes sense

Therefore, I would suggest that thermal wheel technology in a high risk area is reviewed, if you have it. I also would recommend getting detailed info regarding the ventilation spec in your haem onc ward - as I mentioned it was non BMT patients affected

I have listed below for you issues that have been identified as a risk in our new build since opening , I hope this helps

-Dialysis points - leaks and mould in walls due to untightened connection points and in one case faulty plumbing with backflow from a sluice area

- Water system - contaminated at outset and no control measures implemented

- Water coolers - poor maintenance and dead legs in the system, were positive for Gram negs in water incident

- dishwashers on wards - not fitted correctly and grew fungus including Exophiala in CF patients , we removed them

- Taps - taps in high risk units with flow straighteners , these were not maintained and were heavily contaminated with Gram negatives. We have replaced with a Marwick tap with copper bioguard

- Patient bathrooms in haem onc and CF- poor fittings, non water resistant gyproc, unsealed areas - significant problems with mould

- poor sink design with splash risk - we have replaced haem onc sinks with the new armitage shank shark fin model

- Drains - use of an aluminium sphigot which was heavily corroded and laden with black slime - retrograde biofilm creep into sink, resulted in Gram negative bacteraemias in haem onc patients

- Vents - makes sure you have a regular cleaning schedule , we had issues with dust dropping into rooms

- Air con units - not recommended for high risk areas. Again maintenance an issue and we grew Aspergillus from them

Multi Bed – Ventilation Amendment Proposal to Achieve Room Balance
WW-SZ-XX-DC-XXX-010

Proposed Solution to Rooms Identified as Being of Concern

Room Reference Location	Ventilation Layout Drawing Number	Room Number	Room Description	Proposed Solution	Severity of Works			Ductwork Fabricated
					Local	Medium	Major	Yes/No
A	WW-Z4-00-PL-524-001K	G-A2-054	Multi Bed (4) Room Occupancy 10 People	Retain the supply ventilation at 4ac/hr and the en-suite ventilation at 10ac/hr. Ducts servicing en-suite & toilets to be retained at their original sizes. Introduce new general extract ductwork and grille into the room to provide 4ac/hr overall. THE ARTICLES OF AGREEMENT

THIS AGREEMENT is made on the 24th day of February 2020.

BETWEEN

Imtech Engineering Services Central Limited ("the Contractor")
(Company registration No. *00443522*)

whose address is G&H House, Hooton Street, Carlton Road, Nottingham, NG3 5GL
and

HOARE LEA LLP ("the Consultant"). (Company registration No. OC407254)

whose address is 155 Aztec West, Almondsbury, Bristol, England, BS32 4UB

THE PARTICULARS OF AGREEMENT

IHS Lothian Limited (Company registration No. SC493676) ("the Main Contractor")

is proposing to appoint or has appointed the Contractor as a specialist sub-contractor to execute work under a design/build Sub-Contract in relation to

Commence with designs using reasonable endeavours to proceed in accordance with the indicative programme provided by the Main Contractor.This shall be inclusive of such necessary works, surveys or investigations at the Site as may be required in order to prepare such detailed Designs in respect of the Ventilation Works("**Advance Design Works").** Whilst the Consultant shall commence with the whole of the Advanced Design Works, this Appointment is limited to commencing such works and not undertaking scope in excess of the maximum value of £150,000.00 which shall be superseded following the conclusion of the Contractor's appointment for the main works. ("the Works")

at

the Royal Hospital for Sick Children, Child, and Adolescent Mental Health Service and the Department of Clinical Neurosciences adjoining the Royal Infirmary of Edinburgh, Little France, Edinburgh ("the Project")

The Contractor has decided to appoint the Consultant to provide professional services described in Appendix 2 for the Project and the Consultant has agreed to accept the appointment on the terms and conditions set out within this Agreement.

1. DEFINITIONS AND INTERPRETATION

1.1 Definitions

This Agreement contains the following defined terms:

"Appendices"	the Appendices to the Agreement, as completed by the parties.
"Brief"	means the Brief describing the Contractor's requirements for the Works to the Project referred to in Appendix 1.
"Design Documents"	means all drawings, plans, bill of quantities, specifications, designs, calculations and other documents including electronically generated data prepared by or on behalf of the Consultant in relation to the Project.(as detailed in Appendix 4)
"Project"	means the Project described in Appendix 1.
"Services"	means the Services to be provided by the Consultant under this Agreement, including the Services listed in Appendix 2.
"Sub- Contract"	the Contract entered into between the Contractor and the Main Contractor.
"Works"	the Works to be carried out by the Contractor under the Sub-Contract for the Main Contractor.

1.2 The attached Appendices 1,2,3,4,5 & 6 form part of this Agreement

1.3 The clause headings in this Agreement are for convenience only and do not affect its interpretation.

1.4 Words importing the singular meaning include where the context so allows the plural meaning and vice versa.

1.5 Words of one gender include both genders and words denoting natural persons include firms and companies and all are to be construed interchangeably in that manner.

2.0 APPOINTMENT

The Contractor appoints the Consultant and the Consultant agrees to act as Building Services Drawing Package Provider to include, but not limited to the following based upon the terms and conditions of this Agreement.

The works consist as follows:

1. Identify co-ordination issues in the contract issue design in all areas of the building and to communicate those areas for the project team to review. This includes capturing Fulcro co-ordination items previously highlighted to the design teams.

2. Generate with the engineering team an agreed materials matrix & 'Golden rules' to enable family/database creation, this is utilised for accurate modelling & data output.

3. Carry out building spatial co-ordination, validation & Generate clash detection reports.

4. Confirm spatial fit of plant & Equipment

5. To identify and highlight risk areas in regards to: Coordination, Completeness & Tolerances. These items are to be raised in the form of agreed mark-up sheets which require to include;

- Plans
- Elevations
- Sections
- 3D Screen grabs/shots
- Grid Locations
- Architecture
- Structure
- MEP

6. Produce all co-ordinated installation drawings to construction standards for scoped services (See Appendix 4) based upon the designer's information. This includes the provision for the following;
- Fully coordinated Services Drawings including interfacing & co-ordinating with CDP drawings.
- Single Services Drawings High & low Level
- All Scoped Services Systems Schematics
- Details & Sections Drawings
- BWIC Drawings
- Record Drawings
- Trade Interface Drawings
- Conversion of all co-ordinated 3D modelling data to 2D

7. Produce weekly reports in an agreed format confirming areas that require additional design input from the consultant teams.

8. Attend weekly / fortnightly co-ordination workshops to discuss reporting output

9. Work with the engineering team to prepare pre drawing checklists to ensure all equipment and materials are 'approved' to be included within drawn areas prior to commencement of any fabrication & construction drawings.

10. Issue CADMEP models weekly to the CDE (Common Data Environment) in line with the Imtech collaborate working protocol complete with report containing model completion percentages.

11. Issue all drawings to the CDE in line with the Imtech collaborate working protocol in Formats as listed below;

    - DWG's
    - PDF's
    - NWD's

12. Revise drawings based on design team comments

13. Ensure any matters identified under items 1 to 12 above undertaken by the Consultant are in strict accordance with the requirements of the Works identified by the Main Contractor.

3.0 COMMENCEMENT & TERM

The Consultant's Appointment shall be considered as having commenced from the date stated in this Agreement or if earlier, from the time when the Consultant commenced the provision of the Services set out in this Agreement. The appointment will continue until the completion of the Services or until it terminated by either party in accordance with this Agreement. However, the liability of the Consultant under this Agreement shall continue until 12 years from the date that practical completion is certified under the Sub-Contact for the project, except with respect to claims which have been notified before that date.

4.0 SCOPE OF SERVICES & DUTIES OF CONSULTANT

4.1 The Consultant shall as and when required carry out the Services listed in Appendix 2.

4.2 In performing the Services, the Consultant shall exercise the degree of reasonable skill, care and diligence to be expected of an appropriately qualified and competent Professional Consultant experienced in carrying out Services of the type defined in this Agreement for projects of a similar scope purpose and size as the Project. Notwithstanding any other provision in this Agreement, the Consultant's duty, in the performance of the scope of Services and obligations derived from third party agreements and other documents in or connected with this Agreement, shall be limited to the exercise of reasonable skill and care only and nothing in or connected with this Agreement shall imply or import any form of fitness for purpose or any guarantee of life expectancy.

4.2 The Consultant shall comply with any reasonable directions given by the Contractor or is duly authorised representative and shall designate a Consultant's Representative who shall be deemed to have full authority to give and receive Notices.

4.3 In the exercise of its duties, the Consultant shall

4.4.1 Provide all information reasonably required by the Contractor, promptly and in good time so as not to delay or disrupt the progress of the Project or as detailed in Appendix 2.

4.4.2 Provide the Contractor with regular reports on progress and on matters of interest and, in particular, the Consultant will promptly bring to the attention of the Contractor any matters which might affect the programme or cost of the project.

4.4.3 Coordinate its Services with those to be provided by other Consultants and any Contractors appointed by the Contractor and, to the extent required by this Agreement, monitor and report on the activities of other Consultants and Contractors.

4.4.4 Comply with all relevant legislation and statutory requirements including, but not limited to the latest CDM (Construction, Design and Management) Regulations and Joint Fire Code.

4.4.5 Not specify or authorise for use in this project any materials that are generally known to be deleterious to health and safety or to the durability of works in the particular circumstances in which they are to be used or which otherwise are not in accordance with relevant British Standards, Codes of Practice and Euro Codes.

4.4.6 Ensure that key personnel of the Consultant identified in this Agreement will not be removed or replaced without first notifying the Contractor and obtain its consent, not to be unreasonably withheld.

4.4.7 Not without the further approval of the Contractor, alter the Consultant's design to any material extent once the design has been approved by the Contractor.

5.0 FEES AND PAYMENT

5.1 The Contractor shall pay the Consultant the fees for the Services in accordance with the Terms of this Agreement and as set out in Appendix 3.

5.2 Unless otherwise stated in Appendix 3, payments due to the Consultant under this Agreement shall become due for payment 15 days after the monthly interim application 'Applied To Date' in the attached schedule (the payment due date"). The Consultant's applications for payment must state the sum that the Consultant considers to be due as at the payment due date and the basis upon which that sum is calculated.

5.3 The final date for payments ("the final payment due date") shall be 20 days from the date upon which the payment became due.

5.4 The Contractor shall, as per the dates detailed in the Payment Schedule (refer to Appendix 3) give a "Pay Notice" specifying the sum that the Contractor considers to be due or to have been due at the payment due date and the basis on which that sum is calculated. This sum, subject to any Pay Less notice issued by the Contractor under clause 5.5, shall be the sum payable to the Consultant on or before the final date for payment. If a Pay notice is not given by the Contractor, the amount of the payment due to the Consultant shall be, subject to any Pay Less notice given by the Contractor under clause 5.5, the sum stated in the Consultant's application for payment or invoice submitted in accordance with clause 5.2.

5.5 If the Contractor intends to pay less than the amount in the Pay notice or the sum stated in the Consultant's application for payment or invoice submitted in accordance with clause 5.2, whichever shall apply under clause 5.4, then not later than 2 days before the final payment due date of any payment, the Contractor may give written notice (a "Pay Less notice") to the Consultant which shall specify the sum the Contractor considers to be due or to have been due at the final payment due date and the basis on which the sum has been calculated. The amount to be paid to the Consultant shall not be less than the sum stated as due in the Pay Less notice.

5.6 No payment will be made until a~~n original~~ copy of this Agreement, is signed and initialled where required by the Consultant and provided to the Contractor.

6.0 ADDITIONAL SERVICES

6.1 If the Contractor requests any Services that, in the opinion of the Consultant, are not expressly or by implication covered in Appendix 2, the Consultant must immediately inform the Contractor if it intends to claim any extra fee for those services. The notice must be accompanied by an initial estimate of the likely cost and of any impact on the programme for the Project.

6.2 Once the Contractor has considered the Consultant's notice and received any further information it requires, the Contractor within a reasonable time will inform the Consultant in writing whether it agrees to the value of the said additional works. Under no circumstances must any additional services be carried out without written authority from the Contractor.

6.3 In the event that a formal instruction is issued to the Consultant, the Consultant must immediately act upon this instruction and notify the Contractor of any costs as outlined in clauses 6.1 and 6.2.

7.0 COPYRIGHT LICENCE

7.1 The Consultant hereby grants to the Contractor an irrevocable royalty-free non-exclusive licence to use, copy and reproduce all and any of the Design Documents for any purpose whatsoever connected with the Project including but without limitation the execution, completion, operation, maintenance, letting, management, sale,

advertisement, alteration, reinstatement and repair of the Project. The Consultant shall not be liable for any such use by the Contractor of the Design Documents for any purpose other than that for which the same were prepared and provided by the Consultant.

7.2 The licence referred to in clause 7.1 carries the right to grant sub-licences, shall be transferable to third parties and shall continue in force notwithstanding any termination of the Agreement and/or the Consultant's employment under the Agreement.

7.3 The Consultant warrants that the use of the Design Documents for the purpose of the Project and/or pursuant to the licence granted pursuant to clause 7.1 shall not infringe the rights of any third party.

8.0 PUBLIC LIABILITY AND PROFESSIONAL INDEMNITY INSURANCES

8.1 The Consultant shall maintain public liability in the sum of £10M any one claim and professional indemnity insurance in the sum of £10M any one claim and unlimited in the period of insurance but subject to separate aggregate limits of indemnity for all claims notified within the period of insurance relating to pollution/contamination, cladding, fire safety and asbestos (The limit of liability in respect of asbestos related claims is GBP 5,000,000 in the aggregate) and for the length of time sufficient to cover the Consultant's liabilities under this Agreement. This insurance shall be arranged with reputable insurers and maintained for so long as the Consultant has any liability to the Contractor under this Agreement. The Consultant will whenever reasonably requested produce to the Contractor suitable evidence of the terms of its policy and of the payment of the premiums.

8.2 If professional indemnity insurance ceases to be available in the market at commercial terms or rates of premium the Consultant must notify the Contractor without delay. The parties will then discuss and attempt to agree how best to protect their respective positions in the absence of such insurance.

9.0 ASSIGNMENT & SUBCONTRACTING

9.1 The Contractor may assign its interest in this Agreement with the consent of the Consultant, which shall not be unreasonably withheld or delayed.

9.2 The Consultant shall not without the written consent of the Contractor assign or transfer any of its rights or obligations under this Agreement to any third party.

9.3 If the Consultant wishes to sublet any of the Services it must first obtain the written consent of the Contractor. Subletting shall not in any way relieve the Consultant of any of its obligations under this Agreement and the Consultant will be fully liable to the Contractor for the work of any sub-consultant.

10.0 TERMINATION

10.1 This Agreement may be terminated by notice:

10.1.1 By the Contractor if the Consultant commits a material breach of this Agreement and (in the case of a breach capable of remedy) fails to take steps to remedy the breach within 7 days of being requested to do so in writing;

10.1.2 By either party (the Consultant must give the Contractor 7 days-notice of this occurrence) if the other is unable to pay its debts when they fall due or an application for an administrator is presented to the court or a receiver or manager or trustee in bankruptcy is appointed or a resolution passed for its winding up.

10.1.3 By the Contractor giving 7 days-notice if it decides not to proceed with the Project at any time;

10.1.4 By either party if the Contractor suspends the performance of the Services for more than 180 days.

10.2 Except where termination is due to the breach of contract or insolvency of the Consultant, the Contractor shall upon termination pay only reasonable costs incurred, valued on a fair and reasonable basis, due up to the date of termination incurred by the Consultant which are directly attributable to termination.

10.3 In the case of termination by the Contractor on account of the Consultant's breach of contract or insolvency, the Contractor may withhold payment of any and all outstanding fees and expenses until it has ascertained and set off or recovered from the Consultant any additional costs which it incurs as a direct result of the termination of this Agreement.

10.4 ~~The Contractor shall be entitled to set off against any sums (including retention) otherwise due to the Consultant under this Agreement, the amount of any damages, cost, losses and expenses incurred by the Contractor or which the Contractor in good faith estimates it is likely to incur as a result of any breach of this Agreement by the Consultant and/or the amount of any damages, cost, losses and expenses incurred by the Contractor or which the Contractor in good faith estimates it is likely to incur as a result of any breach by the Consultant of any contracts or other agreements entered into between the parties~~.

11.0 SUSPENSION

11.1 The Contractor may suspend the performance of any of the Services by giving reasonable notice to the Consultant.

11.2 If suspension of the Services continues for more than 180 days either party may give notice to terminate this Agreement.

11.3 Upon suspension by the Contractor the Consultant shall be paid only reasonable costs incurred, valued on a fair and reasonable basis, due up to the date of suspension.

12.0 CONFIDENTIALITY

12.1 The Consultant agrees that during the term of this appointment, and for a period of two years after its termination for whatever reason, it will not disclose to any party other than in the normal course of its duties under this Agreement any information concerning the Project or any other information of a confidential nature which may come into its possession as a result of this appointment unless expressly authorised in writing by the Contractor.

12.2 The Consultant must obtain the written consent of the Contractor before it issues any press release or publishes or permits the publication of any information concerning the Project.

13.0 NOTICES

13.1 Any notice under this Agreement must be given in writing. A notice will be treated as being properly given if it is delivered by hand or sent by registered post to the address of the recipient shown in this Agreement or any new address of which notice has been given under this clause.

13.2 Notice delivered by hand shall be treated as delivered at the time of delivery, unless this occurs outside the normal working hours of the recipient in which case delivery shall be treated as occurring on the next working day. Notice sent by registered post shall be treated as delivered after two working days.

14.0 RESOLUTION OF DISPUTES

14.1 Without prejudice to either parties' right to refer any dispute to Adjudication at any time, if any dispute or difference arises in connection with this Appointment, directors or other senior representatives of the parties with authority to settle the dispute will, within 7 days of a written request from one party to the other, meet in a good faith effort to resolve the dispute.

14.2 If the dispute is not resolved at that meeting, the parties may attempt to settle it by mediation in accordance with the CEDR Model Mediation Procedure. Unless otherwise agreed between the parties, the mediator will be nominated by CEDR. To initiate the mediation a party must give notice in writing ('ADR notice') to the other party to the dispute requesting mediation.

14.3 The dispute may be referred to adjudication at any time. Neither party shall take any steps in any proceedings relating to any dispute unless and until an adjudicator has delivered his decision on the dispute to the parties in accordance with this clause.

14.4 Clause 14.3 shall be subject to any rule of law to the contrary, shall not prejudice any of the parties' rights where the adjudicator lacks jurisdiction and shall not prevent either party issuing a claim for but shall prevent any further steps being taken.

14.5 The adjudicator shall be nominated at the request of the referring party by the Royal Institution of Chartered Surveyors

14.6 The procedure for the adjudication will be that set out in the Scheme for Construction Contracts.

14.7 If a dispute arising under this Agreement concerns matters arising in a dispute between the Contractor and another consultant or contractor appointed in connected with the project, the Contractor shall be entitled to require either that the dispute be referred to the adjudicator who has been appointed in relation to that other dispute or that the adjudicator appointed under this Agreement shall also be appointed as adjudicator in relation to that other dispute.

14.8 This Agreement shall be subject to English law and entirely without prejudice to clause 14.3. any dispute, if not resolved by agreement or by adjudication will be finally resolved by the English Courts.

15.0 GOVERNING LAW

This Agreement shall be governed by English Law.

16.0 PREVIOUS AGREEMENT

The provisions of this Agreement supersede the provisions of all or any previous agreements or understandings between the parties in relation to the subject matter of this Agreement.

17.0 RIGHTS OF THIRD PARTIES

Subject to clause 9, a person who is not a party to this Agreement shall not have any rights under or in connection with it by virtue of the Contracts (Rights of Third Parties) Act 1999.

18.0 PARTNERSHIP

Save where the Consultant is an LLP, where the Consultant is a partnership, each of the partners from time to time shall be jointly and severally liable for all obligations of the Consultant under this Deed.

19.0 WARRANTIES

The Consultant has agreed and has made due allowance within his fee for providing a reasonable quantity of collateral warranties for the benefit of reasonably agreed third parties, on reasonable terms, which are required to be procured from the Consultant by the Contractor under the Sub-Contract.

20.0 PI INSURANCE

Not Used

21.0 LIMITATION

Notwithstanding anything to the contrary in this Agreement, and without prejudice to any provision in this Agreement whereby liability is excluded or limited to a lesser amount, the total liability of the Consultant under or in connection with; this Agreement, whether in contract or in tort, in negligence (other than for personal injury, death, fraud and/or fraudulent misrepresentation),indemnity or for breach of statutory duty or otherwise shall not exceed the sum of £10,000,000 (Ten million pounds).

The Consultant shall have no asbestos related duties or obligations.

The Consultant shall not be held responsible or liable for any delay, breach or failure to complete an obligation under or in connection with this agreement caused by either the Employer or any party with whom the Consultant has no contractual relations.

IN WITNESS of which this Agreement was executed on the date specified above.

APPENDIX 1

The Brief provided by the Contractor

1. ~~The Brief is attached to this Agreement (See completed BSRIA 'A Design Framework for Building Services 2nd Edition ref **{Brief ref}**.. dated . **{Brief Date}**../or Appendix 1 – Allocation of Responsibilities)~~

Or

2. ~~The Brief is described in the formal Tender Enquiry dated **{Enquiry Date}**., the brief as set out under Section 2 of this agreement, **{ list another reference documents}**.and any other numbered documents forming part of this agreement (See attached list)~~

Or In accordance with enclosed *IHSL Agreement Exert* (15 pages)

APPENDIX 2

Services to be provided

Services

1. ~~The Services are attached to this Agreement (See completed BSRIA 'A Design Framework for Building Services 2nd Edition ref **{Services ref}**.. dated .**{Services Date}**../or Appendix 2 – Extent of Services – MEP systems)~~

Or

2. ~~The Brief is described in the formal Tender Enquiry dated **{Enquiry Date}**., the brief as set out section 2 of this agreement, , the current BSRIA 'A Design Framework for Building Services 2nd Edition', **{list another reference documents}** and any other numbered documents forming part of this agreement (See attached list)~~

Or

3. The Services are as follows:
   As per Appendix 1 to this agreement

APPENDIX 3

The Schedule of Consultant's Fees

Fees for the Services shall be as follows:

1. ~~The payment of fees for Services is to be on a lump sum basis, the fee shall be a lump sum of~~

   ~~£{Fee} - ({Fee in Words})~~

   ~~Payable via monthly application (As per Appendix K of the enquiry – see attached)~~

Or

2 The payment of fees for the Services is to be time-based, the following attached rates shall apply (Expenses incurred in performing the Services are included in the rate):

The payment fee for Services shall be capped at a maximum aggregate value of £150,000.00 (*one hundred and fifty thousand pounds*).

Grade	Hourly rate
Partner	£140
Director	£110
Associate Director	£100
Senior Associate	£95
Associate	£85
Principal Engineer	£82
Senior Engineer	£65
Engineer	£55
Graduate	£45
Administration	£40

Payable by monthly instalments from the effective date of the Agreement

APPENDIX 4

Drawing List

1. ~~The Drawing List for the Services are attached to this Agreement~~

~~Or~~

~~2. The Drawing List for the Services are described in a separate document referenced~~

Or

3. The Consultants shall identify the list of drawings that are to be produced for the Project. Attached Appendix 5 to be populated and returned back to the client.

   Drawing list should be accompanied by a drawing programme indicating release dates of each drawing.

APPENDIX 5

Programme for the Services

3. ~~The Preferred Suppliers for the Services are listed as follows~~:

RHSC AND DCN

NOTE FOR NHS LOTHIAN FOLLOWING WORKSHOP 20 AND 21 FEBRUARY 2018

Representatives of NHSL, IHSL and MXP attended a two day workshop 20 and 21 February 2018. As well as seeking to engender positive communication between the contracting parties and other relevant stakeholders, the purpose of the workshop was to establish "**what**" the final design and construction of the building will be. That necessarily needs to be ascertained before any proper discussion could take place about "**when**" (the programme) and "**how much**" (whether there was any commercial deal to be struck in relation to the associated costs).

We understand that the outcome of the two day workshop can be summarised as follows:-

1. A potential accommodation in relation to all Project Co Changes has been identified with the exception of the ventilation and possibly the HV issues regarding the ring distribution;

2. A potential accommodation in relation to all Board Changes has been identified;

3. A way forward in relation to the other non-compliances has been identified.

In other words, with the exception of the ventilation an agreed way forward (subject to all parties following the action plans agreed at the workshop) in relation to what is being built has been achieved.

All of the discussions proceeded on the basis that this was an "all or nothing" deal. Discussions necessarily need to proceed on that basis because all parties are compromising and are only prepared to do so if there is a commercially palatable deal in the round.

Another helpful product of the workshop is that it allows NHSL to assess the strength of the parties' respective positions. To date, communication from IHSL and their supply chain has been exceptionally poor. This improved somewhat during the workshops and NHSL now has a better understanding of their position.[i] We can use that to assess where the potential vulnerabilities may be for the NHSL.

Based on the information currently available to us we have prepared the following table which summarises the various risks, the current status of those risks, the strengths and weaknesses of NHSL's position and potential solutions / options available to NHSL in light of the information currently available to us.

In the Appendix we have included some additional narrative to explain:-

1. Our current understanding of IHSL's (or MXP's) position in relation to personal bar; and

2. Our initial views on the opinion now received from MXP's senior counsel in relation to ventilation.

MacRoberts LLP
28 February 2018

Table of comments on relative strengths and weaknesses of NHSL's position

Issue/Risk	Background/Status	Strengths of NHSL's position	Weaknesses of NHSL's position	Overview and potential solutions/options available to NHSL to mitigate risks
Ventilation	Decision pending on DRP	• Independent expert evidence supportive of NHSL's position. • Relevant facts as we understand them supportive of NHSL approach. • MPX's Senior Counsel Opinion appears to be based on incomplete information.	• DRP is Costly and time consuming. • Significant programme implications. • Dispute needs to be crystallised with IHSL as IHSL is currently "sitting on the fence" but NHSL can do this within a short period invoking the clause 13 procedure.	NHSL has the option to rely upon the IT or pursue DRP. If NHSL chooses to pursue DRP NHSL has more control over the process and can seek to mitigate the delays to the programme. However, this will be a costly and time consuming process with a litigation risk. That risk, time and cost is prevented if NHSL relies upon the IT, but there is no guarantee that the IT will not change his position. Even if he does not IHSL may pursue DRP in any event. **Recommendation**: To be reviewed on receipt of Senior Counsel's opinion, but our current view is that the **advantages of DRP outweigh the risks**. Based on the information currently available we consider it **more likely than not that NHSL will be successful at DRP**.
Project Co Changes	There are significant non-conformances with the Works which IHSL has proposed NHSL should accept as Project Co Changes.	• Project Co Change procedure is not designed to relieve IHSL from complying with its contractual obligations. • Non-conformant Works should be rectified so as to be conforming. • Good bargaining tool as no obligation on NHSL to accept Project Co Changes although NHSL has obligation to	• IHSL personal bar argument – NHSL has apparently agreed that it will 'accept' certain aspects of the Works which do not meet the Board's Construction Requirements (or Project Co Proposals)	NHSL is in a **strong position** on IHSL Changes. Personal Bar arguments can be countered with the "no waiver" provisions in the Project Agreement unless IHSL is able to point to actual agreement by NHSL to accept the IHSL Change. To date we have received no substantive evidence of this. **Recommendation**: Consider accepting IHSL Changes only as part of negotiated resolution.

Issue/Risk	Background/Status	Strengths of NHSL's position	Weaknesses of NHSL's position	Overview and potential solutions/options available to NHSL to mitigate risks
		consider in good faith taking account of all relevant issues (see paragraph 3 of Section 5 of Schedule Part 16). • Savings should be shared on a 50% / 50% basis. • No EOT risk - any time associated with this should be IHSL's risk.		
Board Changes	NHSL has sought certain changes to the Works. NHSL had been assured by IHSL at meetings that there was no programme impact in relation to the Board Changes. Where there are additional direct costs to the Board as a result of these works, those direct costs have generally been agreed.	• IHSL has given NHSL assurances that Board Changes would not result in the time for completion being extended. Accordingly, personal bar arguments may work against IHSL here. • IHSL has not followed contractual process, i.e. have not included any Extension of Time ("EOT") claim in their Estimate of the cost of the Change and therefore no contractual basis to seek EOT (this would be consistent with and tend to support NHSL's position that assurances were given that there was no impact on programme).	• IHSL argues entitlement to EOT for changes to the Work scope • NHSL at risk for direct cost of change not programme implications (on basis that IHSL has not followed the contractual process to entitle IHSL to an EOT).	The full extent of the alleged Board Changes is not known to us, but assuming there have been a lot of changes, NHSL could consider whether there is a negotiated position to be achieved where NHSL gives some time and money for some Board Changes, despite the previous assurances and apparent failures of IHSL to follow the contractual procedures. This potentially could be achieved by moving out the concession period but not making any further capital contribution for the Works. The downsides of doing this for NHSL are:- • reduces financial impact on IHSL and supply chain with no financial upside/or sharing of financial upside to NHSL; • NHSL to consider whether there are other costs of continuing to run the existing Sick Kids facility longer than anticipated that will not otherwise be recoverable.

Issue/Risk	Background/Status	Strengths of NHSL's position	Weaknesses of NHSL's position	Overview and potential solutions/options available to NHSL to mitigate risks
				To fully assess the potential risk to NHSL it would be necessary to consider all of the relevant correspondence in connection with each Board Change, but it will be difficult for IHSL to successfully argue it is entitled to an EOT where the contractual process has not been followed by IHSL. Accordingly, we consider NHSL will be in a **strong position** on this issue. **Recommendation**: Consider additional time / money as part of negotiated resolution.
RDD Status C – ongoing design of incomplete works	A significant amount of design (and Works) have still to be completed and not all designs (in particular) have been submitted for review in accordance with the Review Procedure in Schedule Part 8.	• NHSL entitled to review RDD under the Review Procedure and entitled to insist on amendments until matters are Level A or B status • Where IHSL carries out work which is not approved by NHSL under the Review procedure then IHSL does so at risk (clause 12.6). • IT has indicated he will not sign off completion until all RDD is approved at Level A or B.	• IHSL arguing there has been personal bar by NHSL • IHSL is in control of production of design information and there could be further non compliances NHSL does not know about	NHSL is in a **strong position** because it has no obligation to accept IHSL Changes (unless they comply with the BCRs and PCPs) and this can be used as a potential bargaining tool. The IT is supportive of NHSL's position. Personal Bar is not a concern unless NHSL has as a matter of fact agreed matters with IHSL and is bound by such agreement. **Recommendation**: Continue to review design in line with contractual timeframes and spot-check as built position. Consider accepting IHSL design Changes only as part of negotiated resolution.
SA1 (Additional Interface works)	The original SA1 issued by NHSL in December 2016 for the carrying out	• CCTV is at IHSL risk because IHSL is	• NHSL seeking to procure the Toucan	NHSL has secured all rights required from Consort.

Issue/Risk	Background/Status	Strengths of NHSL's position	Weaknesses of NHSL's position	Overview and potential solutions/options available to NHSL to mitigate risks
	of the CCTV Works, Hard Landscaping Works, Toucan Crossing Works, Street Lighting Works and additional rights to remain on Car Park E has been replaced by a Project Co Change issued by IHSL in December 2017 requesting access to install and maintain the CCTV Works only. No discussion at Workshop.	obliged to install this prior to completion of RHSC/DCN. • Car Park E is subject to a Project Co Change.	Crossing Works and Landscaping Works with an alternative contractor as they need to be carried out at some point for amenity and long term safety reasons.	NHSL does not need to carry out the landscaping works through IHSL nor MXP. The works will be secured through an alternative contractor. This means NHSL is in a **strong position** as regards IHSL's Project Co Change because IHSL has more need to secure the rights to carry out CCTV works. Without those rights IHSL ought not to get PC certification from the IT. **Recommendation**: NHSL should seek confirmation from the IT on his position re. signing off the facility with the absence of these works. Consider alternative ways to do landscaping works or factor into negotiated resolution.
SA2 (Boundary Adjustment)	NHSL wants to change boundaries of the RHSC/DCN and Consort RIE sites to reflect a more pragmatic responsibility for hard FM activities. Not discussed at the Workshop.	• It is not essential to change the boundaries and if IHSL is not cooperative then the boundaries as between the two hospitals can remain as per current arrangements.	• SA2 (Boundary Adjustment) if agreed this will result in Board Service Change and NHSL would have to bear cost consequences of extending IHSL's services – post completion of the RHSC/DCN - to the extended RHSC/DCN site.	Although this would be a Board Change (with resulting increased costs to IHSL Services) it should also result in costs savings for reduced FM Services from Consort at the RIE. NHSL is in a **strong position** as the boundary change is not essential more a "nice to have". All parties can continue operating within the current contractual arrangements. **Recommendation**: Unless this becomes essential to NHSL, we suggest it is parked.

Appendix

1. Personal Bar

It is understood that MXP (and possibly IHSL) is seeking to argue that NHSL has adopted a positive approach to Changes and is now barred from reneging on that. This is an argument based upon the Scots law doctrine of personal bar. The requirements of personal bar can be summarised as follows:-

- where A has by his words or conduct justified B in believing that a certain state of facts exists; and
- B has acted upon such belief to his prejudice;
- A is not permitted to affirm against B that a different state of facts existed at the same time.

Particular emphasis is placed upon the word "justified:" it is an objective test. To found a plea of personal bar, the representation must be such that the reasonable man would regard it as intended to be believed and relied upon. If it conveys to the reasonable man that it was seriously intended, and that the person to whom it was made was being invited to believe it and act upon it, it matters not that the party making the representation may not in fact have intended that it be relied upon.

The representation as to a state of facts may include the fact of a position adopted by a party in relation to its rights. In other words, if IHSL could point to NHSL making a representation that NHSL did not intend to enforce its rights in relation to a particular issue then that would amount to a fact that, provided the other criteria set out above are met, could found a plea of personal bar.

However, personal bar arguments are always uncertain and insecure bases for the remedies sought. They are fact sensitive and every set of circumstances would need to be judged on its own merits.

Furthermore, there are specific provisions in the Project Agreement which prevent IHSL from pursuing a personal bar argument. Reference is made in particular to clause 8.5 and clause 65 of the Project Agreement.

Before we can give a definitive view on the prospects of IHSL successfully pursuing a personal bar argument we would need to analyse the relevant facts and circumstances relative to each particular issue. Broadly, whilst this is a possible avenue that IHSL could seek to exploit, it is a high hurdle. At this stage, we would classify the risk to NHSL of IHSL being able to successfully maintain a personal bar argument as low.

2. Ventilation

We have now received the opinion Multiplex have obtained from Senior Counsel. His position can be summarised as follows:-

- The Environmental Matrix ("EM") is the key document which sets out the requirements for ventilation design for the bedrooms. It takes precedence over the ADB sheets and Room Data Sheets. Note 1 of the EM is relied upon to support that position.
- The Environmental Matrix received Level B approval on 15 April 2016. That version had no comment about the ventilation to the four bedded rooms.
- The design was finalised between May and September 2016 and IHSL was thereafter committed to build in accordance with that approved design.
- There is no conflict within the BCRs such that clause 2.5 is engaged because CEL 19 (2010) and SHTM 03-01 allow departure from the ADB Sheets and this was approved per the Environmental Matrix. Good Industry Practice does not require balanced / negative pressure (reliance is placed upon DSSR's opinion in this regard).

Based on the information available to us, this appears to be a misrepresentation of the position. There was a relevant comment on the EM Rev 5 in relation to the four bedded room ventilation as follows:-

"Detailed proposal awaited on bedroom ventilation to achieve balanced/negative pressure to corridor".

The initial response from IHSL is noted as “The single bedrooms have had their ensuite extract increased to achieve a balance within the room, this has been noted within the matrix.”

The “feedback” from NHSL is “Note 26 and ventilation type have not been altered.” The “Reconciliation” is “Refer to matrix.”

The reference to “bedrooms” is not beyond doubt and the “reconciliation” on the table may suggest the issue has been resolved. Nonetheless, the other contemporaneous correspondence does lend support to NHSL’s position.

The correspondence Mr Ellis relies upon to support MXP’s position does not fully corroborate their approach and ignores the other correspondence. In any event, even if Multiplex’s position is correct, we understand that the ventilation has not been designed or constructed with “positive to en suite” pressure.

Accordingly, we consider that Senior Counsel’s opinion may be based upon incomplete / inaccurate information as to the relevant facts. We await an opinion from Gerry Moynihan QC on behalf of NHSL.

[i] This note deals with matters at PA level only. A different analysis may be appropriate in a question between IHSL and MXP, but that is not immediately relevant to NHSL given that its contract is with IHSL. For the most part it is understood that the arrangements are back to back in any event.

CONFIDENTIAL - RHSC + DCN
Board preparation for the RHSC + DCN Principals Meeting on 20 and 21 Feb 18.
DRAFT REV 0E - 16 Feb 18

	Issue Description	Category of issue	Current status	Board opinion on Impact to Project Co (timing, cost, duration)	Board opinion on Project Co Position	Board Position	Possible Board Compromise	Impact of Compromise on the Board	Category (TBC)
	Issues on non-exhaustive list of potential non-compliances schedule on 13th February by Facilitators with Parties								
1	Lighting in fire-fighting stairwells	Risk to life of all occupants of the building.	MPX confirmed current installation is compliant, Board disagree.	Minor - electrical works Likely cost 8 staircases @ approx. £15k	Negotiable	Issue is non-negotiable Timing is negotiable	The requirement is definite, however possible compromise on timing (post PC pre- occupation).	Possible impact on Boards commissioning programming, with potential to extend the commissioning period. Completion Certificate would be awarded by the Independent Tester with non-complaint firefighting stairwells.	
2	Non-fire rated IPS / UPS cabling	Risk to patients in critical clinical areas, theatres etc locations.	MPX working on a revised design, detail of revised design is essential.	Major - electrical works Scale of works depends on the proposed solution, at least several weeks work @ approx. £200k to £300k	Negotiable	Non-negotiable	None	NA	
3	No earth bonding in certain required areas	Risk to all patients.	MPX working on a revised installation, sample room agreed, and circa 25% of rooms have been amended so far.	Minor - electrical works which is currently being carried out in full by Multiplex.	Negotiable	Non-negotiable	None	NA	
4	Bedroom ventilation pressure regime and air change rate rooms for neutropenic patients	Haematology and Oncology patients.	MPX have installed a non-compliant system, however the Board will be able to operationally manage around the issue.	Major - if the Board alter position on operational workaround.	Non-negotiable	Negotiable	The Board accept a Project Co Change.	Reduced operational flexibility. But manageable.	
5	25% spare capacity	Cost - future developments.	A nonspecific Derogation was agreed at FC, however details of any proposal for a reduction in 25% was to be agreed through the Review Procedure. Evidence on site that 25% spare capacity has not been provided. MPX has provided high level response in Feb 18, no previous consultation with the Board.	Critical - Extremely difficult to fix	Negotiable	Negotiable	Financial rebate to the Board	High cost of future flexibility	

6	HV distribution	Patient safety risk - life critical - potential complete loss of power to the Facility.	MPX working on a revised design.	Major - electrical works	Now appears negotiable as MPX progressing the design in the background.	Non-negotiable	None	NA	
7	4 bed ventilation	Patient safety risk - inability to cohort. Risk of infection	MPX confirmed current installation is compliant, Board disagree. MPX challenging Independent Tester interpretation of the contract, Noting the IT has since repeated his agreement with the Boards interpretation. ?	Major - mechanical works High cost and several months work.	Negotiable as Compromise design was prepared in Feb 17, however not progressed.	Negotiable, however must be completed before handover.	The Board accept a Project Co Change for a reduced air change rate, but achieve negative / balanced pressure. There are 20 rooms involved in total however on a risk analysis there are 13 for which sorting the problem is desirable, and 7 in which it is essential.	Less dilution of airborne containments and odours in the room. Reduced operational flexibility and reduced flexibility for change of ward use in the future.	
8	Bedhead trunking earth bonding points **[with IPS sockets]**	Patient safety risk.	Bedhead trunking has insufficient earth bonding points, MPX to investigate.	Minor - electrical works	Negotiable	Non-negotiable	None	NA	
9	Lack of non IPS sockets in **[critical care, radiology, ED resus, transitional care and theatres]** / Currently the IPS sockets are supplying the non-medical equipment	Patient safety risk	MPX confirmed current installation is as submitted through RDD and compliant, Board disagree.	Medium - electrical works Every area that has blue sockets - large volume of work.	Negotiable	Non-negotiable	None	NA	
10	Drainage above IPS room / above IPS panels **[refer also to item 23 below, appears to be a duplicate – CLARITY REQUIRED ON THE ISSUE]**	Risk to critical equipment which in turn is a life safety risk.	MPX has submitted a Project Co Change 055, however there is currently insufficient information for the Board to consider the Project Co Change.	Major - plumbing works Re-routing of pipework out with the rooms. Quantity currently unknown due to lack of detail in the Project Co Change.	Negotiable	Issue is Non-negotiable; however, the solution is negotiable. All subject to understanding the detail of the Change.	The Board accept the Project Co Change for Fusion welded pipes, however this cannot be done until the detail of the Change has been clarified.	Residual risk of a leakage from the pipes, and the Board may have to pay for replacement of the Equipment.	
11	Protection of electrical cables	Risk to life of all occupants of the building. Risk of fire.	MPX confirmed current installation is compliant. The Board have concerns from site visits the cables have been undersized, and require the calculations to undertake their duty of care. MPX have refused to disclose the calculations.	Depending on the outcome of the calculations - Possible Major - electrical works	Depends on the calculations - Negotiable	Depends on the calculations - Non-negotiable	Depends on the calculations – None – there would be no compromise available if the calculations were incorrect.	NA	
12	Lack of tamper proof flush fitted sockets in CAMHS **[and other anti-ligature rooms]**	Risk to life of patients and staff.	MPX have installed a non-compliant tamper proof flush fitted sockets. Raised by the Board	Minor - electrical works	Negotiable	Negotiable, but strong Board position.	1) The requirement is definite, however possible compromise on timing,	1) The timing compromise would have a minor impact	

			through the Room Reviews. Currently unclear on MPX position.				2) A further compromise is the Board could undertake the works as a Derogated Low Value Change.	on the Boards commissioning period. 2) The Derogated Low Value Change compromise would result in a small cost to the Board if conceded.	
13	Single bedroom ventilation air changes	Patient Comfort.	MPX have installed a non-compliant system, Board awaits a Project Co Change.	Major - if the Board does not accept the Project Co Change.	Non-negotiable	Negotiable	The Board accepts a Project Co Change for a reduced air change rate, but achieve negative / balanced pressure.	Reduced patient comfort.	
14	Smoke clearance in fire-fighting stairwells	Risk to life of all occupants of the building.	MPX working on a revised design.	Medium - mechanical works	Negotiable	Non-negotiable	None	NA	
	Issues out-with records/schedules discussed on 13th February by Facilitators with Parties								
15	Access hatches in theatre suites	Infection Control and potential loss of activity in clinical areas.	MPX working on a revised design that includes reducing the number of hatches, and changing the type of hatch to a sealed hatch.	Medium - fit out works	Negotiable	Negotiable	The Board accepts a Project Co Change that would allow Project Co to retain some sealed hatches in clinical areas where services can't be moved.	The downtime from hatches is less than pulling down ceilings. The downtime is related to the services needing to remain above clinical areas so relate to the BCR clause re services in clinical areas. infection control objections.	
	Issues on the "variation" schedule/record discussed on 13th February by Facilitators with Parties								
16	Helipad height reduction	Project Co Change – non-compliance with the Boards Construction Requirements	MPX has installed a non-compliant design and is seeking a Project Co Change to relieve them of their contractual obligations.	Critical - helipad would have to be rebuilt	Non- Negotiable	Negotiable	The Board accepts the Project Co Change	No new known risk.	
17	Link building (change in level)	Project Co Change – non-compliance with the Boards Construction Requirements	MPX has installed a non-compliant design and is seeking a Project Co Change to relieve them of their contractual obligations.	Critical - Whole Facility would have to be re-built	Non- Negotiable	Negotiable	The Board accepts the Project Co Change	Subject to site inspection –slightly uneven floor	
18	Movement joints **[in clinical areas]**	Project Co Change – non-compliance with the Boards Construction Requirements	MPX has installed a non-compliant design and is seeking a Project Co Change to relieve them of their contractual obligations.	Critical - Whole Facility would have to be re-built, or internal layouts re-designed.	Non-Negotiable	Negotiable	The Board accepts the Project Co Change	Reduction in room sizes, increased cleaning, and increased maintenance.	

19	Node rooms basement	Project Co Change – non-compliance with the Boards Construction Requirements	MPX has installed a non-compliant design and is seeking a Project Co Change to relieve them of their contractual obligations.	Critical - additional rooms would have to be found.	Non-Negotiable	Negotiable	The Board accepts the Project Co Change	Increased risk of water damage	
20	Car Park - E	Project Co Change – non-compliance with the Completion Criteria.	MPX is requesting a delayed handback of Car Park E through a Project Co Change to relieve them of their contractual obligations.	Major - delayed Completion, or lack of office and welfare Facilities.	Negotiable relative to the extent of car park available to the Board.	Negotiable relative to the extent of car park available to the Board.	The Board accepts the Project Co Change The Board require the use of all car park E spaces, and requires Project Co retain off site car parking.	Impact on Boards ability to commission the Facility. Restricted commissioning parking. Completion Certificate would be awarded by the Independent Tester with non-complaint Car Park E.	
21	4 bed lifts	Project Co Change – non-compliance with the Project Co Proposals.	MPX has installed a non-compliant design and is seeking a Project Co Change to relieve them of their contractual obligations.	Critical - lift shaft would have to be excavated to the basement.	Non- Negotiable	Negotiable	The Board accepts the Project Co Change	Minimal operational efficiency impact.	
22	FCU waterless traps	Project Co Change – non-compliance with the Project Co Proposals.	MPX has installed a non-compliant design and is seeking a Project Co Change to relieve them of their contractual obligations.	Medium - plumbing works.	Non-Negotiable relative to installation (already installed). Negotiable relative to price.	Negotiable	The Board accepts the Project Co Change and a small rebate.	None	
23	Node rooms / exclusion & critical areas - high level drainage **[refer also to item 10 above, appears to be a duplicate CLARITY REQUIRED ON THE ISSUE]**	Project Co Change – Non-compliance with the BCR's. Risk to critical equipment which in turn is a life safety risk.	MPX have submitted Project Co Change 055, however there is currently insufficient information for the Board to consider the Project Co Change.	Major - plumbing works Re-routing of pipework out with the rooms. Quantity currently unknown due to lack of detail in the Project Co Change.	Negotiable	Issue is Non-negotiable; however, solution is negotiable. All subject to understanding the detail of the Change and the areas impacted.	The Board accept the Project Co Change for Fusion welded pipes, however this cannot be done until the detail of the Change has been clarified.	Residual risk of a leakage from the pipes, and Board may have to pay for replacement of the Equipment.	
24	Ambulatory canopy	Board Change – commercial	The Board has submitted a Board Change for the removal of a canopy, however the cost of not installing the canopy has not been agreed.	Major - MPX potentially do not have the legal rights to install.	Negotiable relative to price. Non-negotiable relative to construction, due to legal issues.	Negotiable	The Board accept a reduced credit.	Board valuation £300k Project Co valuation £60k Accepting Project Co Valuation would cost the Board - £240k	
25	MRI room alteration	TBC	More information required		TBC

RHSC – DCN Edinburgh
Air Movement Report For Single Bedrooms (Draft)

Wallace Whittle

1.0 Introduction

We have been asked to review the air movement within the single bedrooms under various ventilation scenarios.

1. Windows and trickle vents closed, no natural ventilation, mechanical ventilation only provided to the bedrooms.

2. Windows and window trickle vents open, natural and mechanical ventilation provided to the bedrooms.

3. Some of the windows and window trickle vents open and some closed, mixture of natural and mechanical ventilation to the bedrooms.

2.0 Interpretation of SHTM 03 Ventilation for Healthcare Premises

A single room within Appendix 1 : Table A1 : Recommended air-change rates is given under the ventilation column as supply/extract/natural, with 6 ac/hr and room pressure as zero or negative. The single room WC from the table is 3 ac/hr and room pressure is negative.

Current bedroom ventilation design is supply into the room at 4 ac/hr with opening windows and trickle vents to provide natural ventilation, this gives a balanced room pressure as long as the window is open.

The single bedroom WC extract has been enhanced to 10 ac/hr and the room pressure is negative.

3.0 Ventilation Scenario's

Scenario 1

1. Bedroom is positively pressurised by supply air.
2. En-suite is negative pressure to the bedroom.
3. Excess bedroom air flows to the corridor via doors.
4. Corridor is provided with extract ventilation, pressure is balanced.

Scenario 2

1. Bedroom has balanced pressure.
2. En-suite is negative pressure to the bedroom.
3. Excess bedroom air flows out the open windows and trickle vents.
4. Corridor is provided with extract ventilation, pressure is negative to surrounding bedrooms and other rooms.

RHSC – DCN Edinburgh
Air Movement Report For Single Bedrooms (Draft)

Wallace Whittle

Scenario 3

1. Bedrooms with open windows have balanced pressure and bedrooms with closed windows are positively pressurised by supply air.
2. En-suite is negative pressure to the bedroom.
3. Excess bedroom air flows out the open windows or through the bedroom doors if the windows are closed.
4. Corridor is provided with extract ventilation, pressure is negative to surrounding bedrooms.

Refer to Appendix 1 for the Air Flow and Resultant Room Pressure drawings.

The original reference design as detailed within the Environmental Matrix is as follows:-

Bedroom - Supply 4Ac/Hr & Room Pressure Positive.
WC – Extract 10Ac/Hr & Room Pressure Negative.

4.0 Conclusion

Reviewing the three air flow and resultant room pressure scenario drawings G1547/(57)SK01-SK03:

When the windows and trickle vents are utilised for natural ventilation the bedroom pressure is balanced and the corridor becomes negative.

If some of the windows and trickle vents are closed, these bedrooms will become positive and the bedrooms with open windows again will be balanced, where the corridor is negative.

Should all the bedroom windows and trickle vents be closed, the bedroom pressure is positive and the corridor shall be balanced as the corridor extract rate will match the supply air coming from the bedrooms via their doors.

The window trickle vents should be left open when the rooms are occupied, this will ensure that the bedroom pressure is balanced.

By utilising the proposed mixed mode ventilation proposal for the bedrooms, ie. opening windows and trickle vents with the supply air reduced from 6Ac/Hr to 4Ac/Hr direct into the bedroom, this will provide the most energy efficient solution for the space.

We believe that we have complied with the reference design concept as detailed within the original Environmental Matrix.

Index

1.0 Introduction

This study has been prepared by Jonathan McMillan for Hulley Sim, a sustainable building design and simulation division within Hulley & Kirkwood Ltd. The purpose of this study is to:

- Determine peak annual internal temperature profiles for typical single ward room accommodation, within the proposed Royal Hospital for Sick Children & Department of Clinical Neuro-Sciences Building, through dynamic thermal simulation for the Reference Design Stage envisaged solution of providing ward rooms with mechanical ventilation and comfort cooled fresh air.

- To verify that mechanically ventilated and comfort cooled ward rooms have summertime peak temperatures which do not exceed the NHSL maximum internal temperature of 25°C.

- To demonstrate that with natural ventilation only ward rooms could potentially experience significant hours of internal temperatures above 25oC and up to 28°C and in many cases more than 50 hours above 28°C referred to in SHTM 03-01 guidance.

Executive Summary

- The profiles in Simulations 1 & 2 show that the internal temperatures in ward rooms can be maintained at comfortable levels with 4 ACH (air changes per hour) of cooled fresh air supply mechanical ventilation and could be controlled in summertime between 22°C and 25°C maximum.

- The results for Simulation 3 demonstrate that during peak summertime conditions, the ward rooms internal temperatures are predicted to rise above 28°C with natural ventilation only in almost all rooms simulated. Further interrogation shows significant hours between 25oC and 28oC experienced, representing a period extending across summer months.

1.1 Dynamic Thermal Modelling

Dynamic thermal modeling (DTM) has been utilized to establish building thermal profiles. The RHSC / DCN Building, as per the final 1:200 Reference Design Stage architectural layouts was simulated with respect to varying time dependant internal and external conditions affecting heat gains, bulk air flow movement & solar gain. The accuracy of the model, and hence the validity of any proposals, are governed by the assumptions made, and the resolution of the model's geometry. The model's geometry was accurately drawn from 1:200 departmental layouts supplied by the Architect, Nightingale Associates. Assumptions on the occupancies and internal heat gains were based on typical values for specific operational area usage. The input data, including the local weather data, is processed by thermodynamic algorithms in order to predict the environmental conditions experienced in each of the operational areas. The latest version of IES Virtual Environment modelling software has been used (IES version 6.4). The details of which are given in Table 1.1.

Calculation Engine:	Apache
Calculation Engine (version):	V6.4
Interface to Calculation Engine:	IES Virtual Environment

Table 1.1. Calculation Tool Details

1.2 Simulation Progression

In order to understand the effect of multiple system variables and possible system control options the following simulations were performed;

- **Simulation 1** – Ward rooms served by mechanical fresh air supply, rated to 4 ACH (Air Changes per Hour), cooled to control zone temperatures to 25°C or less. Windows in simulated spaces are closed continually.

- **Simulation 2** - Ward rooms served by mechanical fresh air supply, rated to 4 ACH (Air Changes per Hour), cooled to control zone temperatures to 25°C or less.

  In addition to mechanically supplied fresh air, each simulated zone is subject to natural ventilation through a 100mm restricted window opening of dimensions typically 1.3m by 1.6m wide providing 0.416m^2 of free ventilation opening area. Natural ventilation is simulated through the dynamic bulk airflow programme Macro Flow. Bulk airflow movement is driven by the following factors:

  - Window opening area specific to each simulated space and opening configuration.
  - External dry bulb temperature, derived from local historic weather data
  - External barometric pressure, derived from local historic weather data

- **Simulation 3** – No mechanical cooled fresh air supply ventilation. Natural ventilation is simulated as per Simulation 2.

  It should be noted that Simulation 3 is provided as a means of comparison, to illustrate the conditions which would occur if mechanical ventilation with cooling were not provided, which NHSL would not find acceptable given experiences in the adjacent ERI for ward rooms reliant on natural ventilation alone, hence the briefed maximum internal temperature of 25°C

It should be noted that The Reference Design Envisaged Solution does not rely on natural ventilation alone in any way to maintain internal temperatures within comfort levels and provides a robust level of control of internal temperatures and therefore thermal comfort by employing cooled mechanical fresh air supply ventilation which could operate in conjunction with supplementary natural ventilation as well as without it.

2.0 Simulation Component Properties

2.1 Building Fabric and Window Design

The following building fabric U-Values have been incorporated into the dynamic thermal simulation model. Solar glass has been specified for regions of the façade predicted to be exposed to high levels of solar gain through direct sunlight exposure. Glazing in all other areas has been defined as a clear Low-E glass. The material properties for the simulation model have been defined as follows;

	U-Value W/m^{2}K
External Wall	0.21
Floor	0.20
Roof	0.20
Fire Doors	1.7
Windows	1.7

Glass Construction Typical	
Outer Layer	8mm Clear Float Glass
Cavity	16mm Air Cavity
Inner Layer	8mm Clear Float Glass
Low-E glass material Properties - Typical	
U-value	2.0
g-value	61%
Light Transmission	75%
Solar glass material Properties - Typical	
U-value	1.9
g-value	40%
Light Transmission	66%

It should be noted that for the purposes of this study, in the absence of both an evolved prescriptive glazing strategy and elevation details, glazing has been set to meet the minimum guidelines set out in HTM 55 regarding window size, location and opening restrictions. For the purposes of this simulation all opening windows have been set such that opening area is equivalent to that achieved if a 100mm restrictor were fitted to a top hung window measuring 1.3m by 1.6 m, providing a minimum natural ventilation free area of 0.416m^2.

Cold bridging details

IES Virtual Environment incorporates cold bridging details by using specific ψ values, measured W/(m.K), for the relevant building element junctions.

	Junctions involving metal cladding	Junctions not involving metal cladding
Type of Junction	ψ (W/(m.K))	ψ (W/(m.K))
Roof-Wall	0.6	0.12
Wall-Ground Floor	1.15	0.16
Wall-Wall Corner	0.25	0.09
Wall – Floor (not ground)	0.07	0.07
Lintel above window	1.27	0.3
Sill below window	1.27	0.04
Jamb at window/door	1.27	0.05

2.2 Building Air Tightness

The infiltration rate was set to represent an air permeability of 7.5$m^3/h/m^2$ at 50Pa. This is a minimum backstop within the Section 6 Compliance model.

2.3 Internal Conditions & Associated Heat Gains

The various operational zones were subject to internal gains determined from National Calculation Method (NCM) templates and operational schedules. NCM templates were used to describe the daily activities and associated gains for the following room types.

- Bedroom
- Patient Accommodation Day
- Multi-bed Wards

For the National Calculation Method (NCM) templates detailed above, the following gains are taken into account;

Occupancy sensible	99.6	**w/m^2** with 12.5 **m^2** per person
Occupancy latent	40.04	**w/m^2** with 12.5 **m^2** per person
Lighting	6.5	**w/m^2**
Activity specific equipment	5.0	**w/m^2**
Miscellaneous small power	5.0	**w/m^2**

Each of the above gains are controlled by daily schedules for various operational usage.

Occupancy gains have been controlled by daily schedules which increase the number of occupants to three during anticipated visiting hours.

In addition to the typical NCM gains detailed for each zone, the amount of passive solar gain is calculated using our solar analysis package VE Suncast. Suncast uses detailed solar axis and azimuth tables to determine the angle and intensity of incident solar radiation on each exposed surface. Refer to section 2.4 for details of the tables used.

2.4 External Conditions

Each scenario was simulated with respect to statistically predicted weather data and the local solar path, determined by the location and orientation of the site. Details of the solar path and annual ambient thermal profile can be seen in sections 2.4.1 & 2.4.2 respectively.

2.4.1 Solar Axis and Azimuth

The following data is embedded within IES and is used to determine the magnitude of solar gain experienced due to direct sunlight exposure.

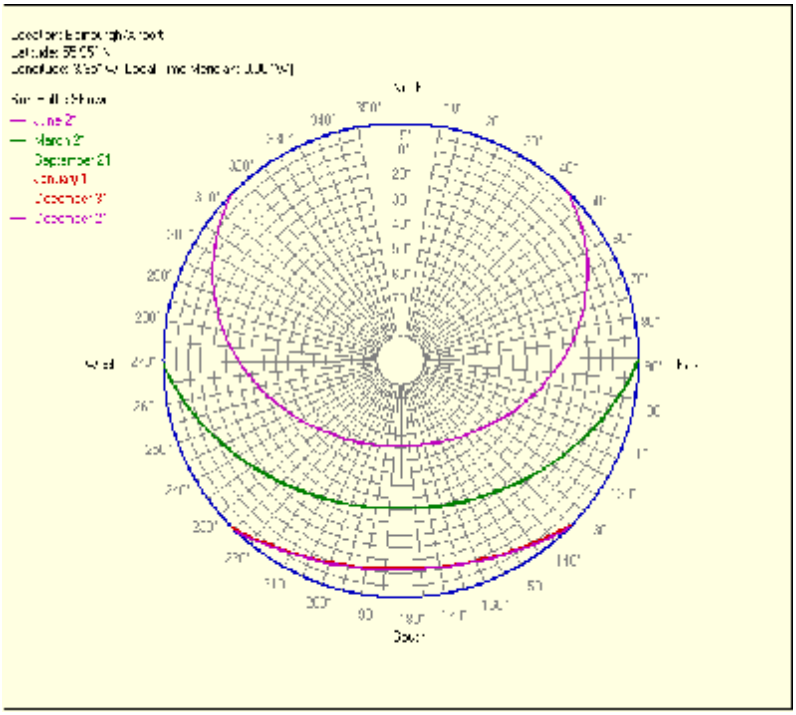

Figure 2.4.1 Solar Path Data

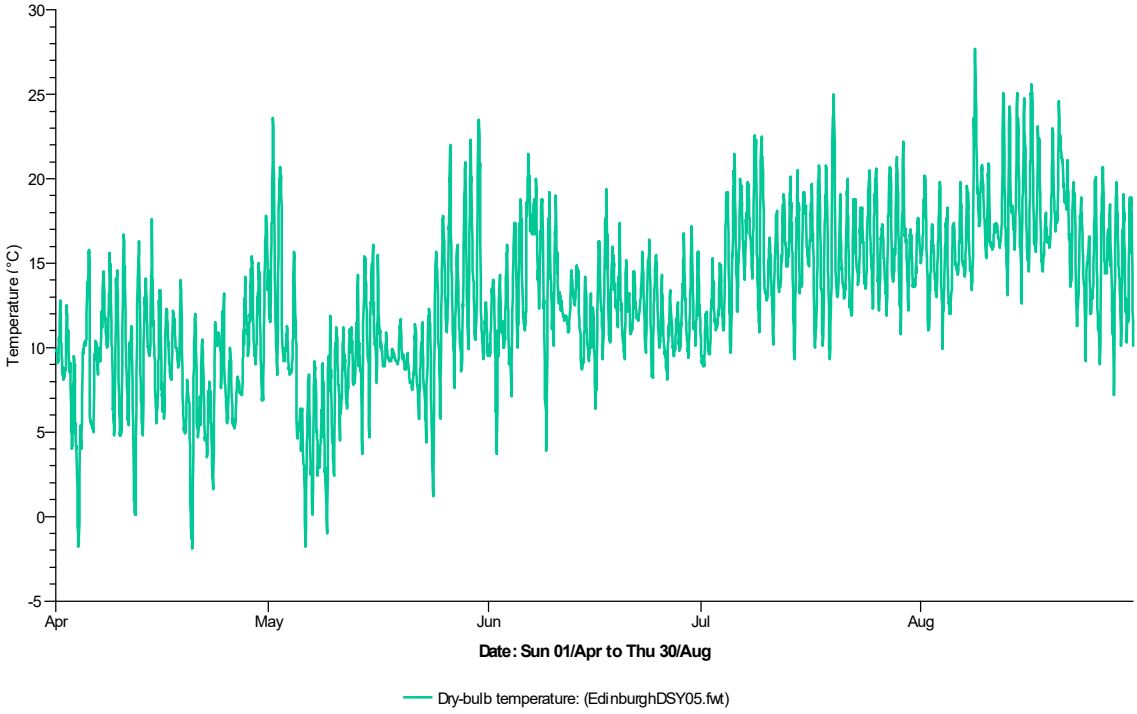
2.4.2 Ambient External Dry Bulb Temperature

The Design Summer Year (DSY) weather file for Edinburgh has been used. The Design Summer Year consists of an actual 1-year sequence of hourly data, selected from the 20-year data sets to represent a year with a hot summer



2.5 Space Conditioning Systems

Thermal templates have been created to reflect the space heating and ventilation systems present in the Royal Hospital for Sick Children & Department of Clinical Neuro-Sciences Reference Design Stage building envisaged solution.

Ward ventilation systems incorporated can be described as follows;

- LTHW radiant panels with local TRV temperature control with tempered and comfort cooled fresh air supply and dirty extract ventilation via adjacent en-suites through central mechanical AHU plant and central dirty extract plant.

- Summertime fresh air supply can be cooled to 16 degrees Celsius to maintain an ambient air temperature of 22 degrees Celsius, if necessary, in ward areas. Natural ventilation can be utilised as desired in addition to cooled fresh air supply. However in operational reality, management procedures would ensure an appropriate use of opening windows should ambient temperatures be greater than internal temperatures to conserve energy.

2.6 Building Geometry

A geometrically accurate representation of the proposed Royal Hospital for Sick Children & Department of Clinical Neuro-Sciences Reference Design Stage envisaged building was constructed from final 1:200 Reference Design Stage architectural layouts using the Model IT package within the IES Virtual Environment. This can be seen in figures 2.6.1 to 2.6.3 below.

As this study concerns the thermal comfort of ward rooms throughout the building, with the aim of verifying that mechanically ventilated and cooled ward rooms have summertime peak temperatures which provides for robust levels of thermal comfort whereby internal temperatures of 25°C or less can be provided throughout summertime months.

A selection of rooms has been chosen to represent the likely worst case combination of;

- Exposure to solar gain
- Density of occupation
- Provision of mechanically supplied cooled air.

As such critical care and high dependency type ward rooms which receive air change rates in the region of 10ACH, have not been analysed in this study.
Room types that have been analysed are illustrated in figure 2.6.5 below.

2.6.1 Analysed Rooms

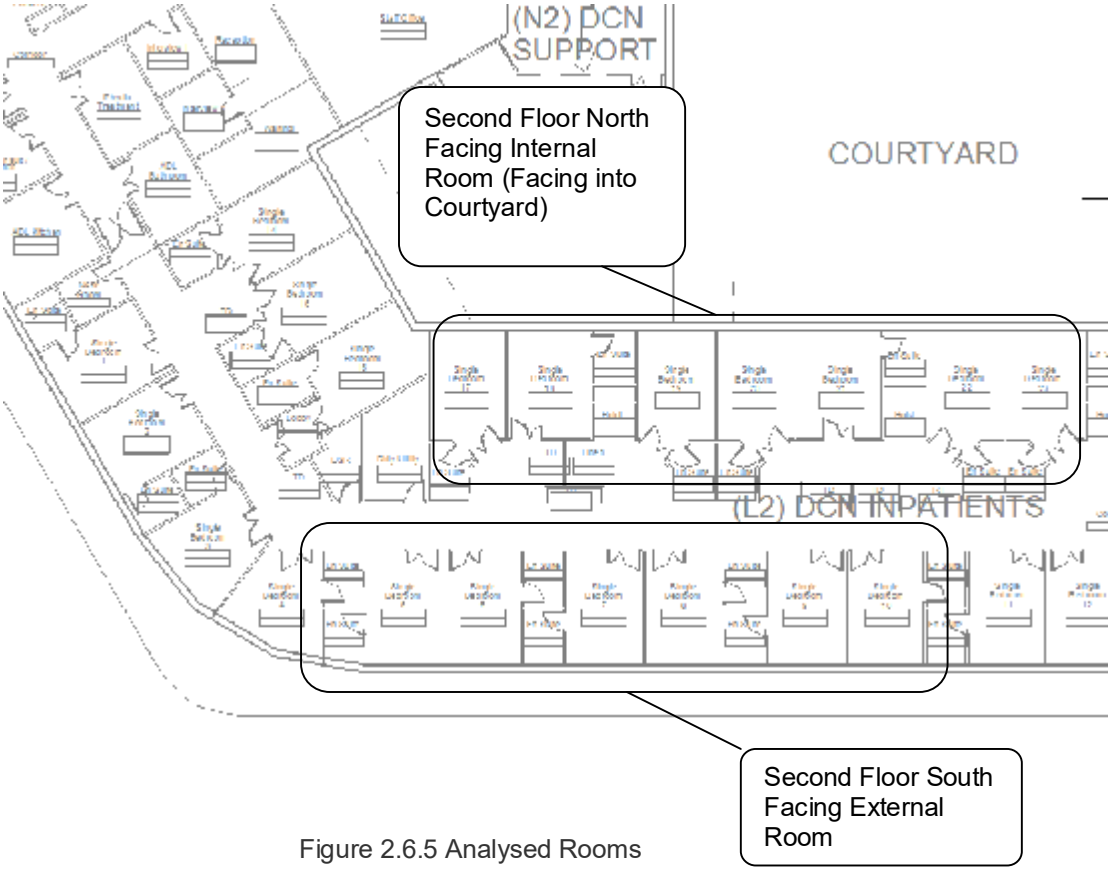

Figure 2.6.5 Analysed Rooms

3.0 Thermal Profile Results

Sections 3.1 – 3.2 present graphical results for room temperature (Dry Resultant Temperature) for both the whole summer period and for the day on which the peak temperature was recorded. For peak day graphs the following system variables are presented in order to place peak temperatures in context;

- Room Temperature profile (Dry Resultant Temperature).
- External Dry bulb temperature profile, derived from local historical weather data.
- Solar gain profile, derived from "Suncast" solar shading calculations and from the intrinsic material properties of building glazing systems.
- Internal room gains in kW, comprising occupancy, lighting, equipment and external conduction.

Note that due to the dynamic nature of the thermal simulation and the multiple variables which drive the simulation, peak temperatures for individual rooms will often occur on different days.

Simulation Summary Results

The following tables, Table 3.0.1 – 3.0.6, detailed overleaf provide an overview of "Hours Above" given temperature bands for each Simulation which are detailed below for ease of reference.

- **Simulation 1** – Ward rooms served by mechanical fresh air supply, rated to 4 ACH (Air Changes per Hour), cooled to control zone temperatures to 25^{o}C or less. Windows in simulated spaces are closed continually.

- **Simulation 2** - Ward rooms served by mechanical fresh air supply, rated to 4 ACH (Air Changes per Hour), cooled to control zone temperatures to 25^{o}C or less.

In addition to mechanically supplied fresh air, each simulated zone is subject to natural ventilation through a 100mm restricted window opening of dimensions typically 1.3m by 1.6m wide providing 0.416m^2 of free ventilation opening area. Natural ventilation is simulated through the dynamic bulk airflow programme Macro Flow. Bulk airflow movement is driven by the following factors:

- Window opening area specific to each simulated space and opening configuration.
- External dry bulb temperature, derived from local historic weather data
- External barometric pressure, derived from local historic weather data

- **Simulation 3** – No mechanical cooled fresh air supply ventilation. Natural ventilation is simulated as per Simulation 2.

4.0 Conclusions

- The thermal profiles observed in Simulations 1 & 2 show that the internal temperatures in ward rooms can be maintained at comfortable levels with mechanical ventilation and cooling available, and could be controlled throughout summertime providing a robust level thermal comfort as illustrated in the Summary Results Table in Section 3.0.

- The results for Simulation 3 demonstrate that during peak summertime conditions, the ward rooms internal temperatures experience significant hours between 22oC and 28oC representing compromised thermal comfort levels for much of the summer months. NHSL would not find this level of performance acceptable given experiences within the ERI for ward rooms reliant on Natural Ventilation alone.

- It should be noted that the envisaged approach is not intended to be prescriptive and that alternative approaches where put forward beyond the Reference Design could also be valid provided the conditions of planning are not compromised and can be complied with and that level of thermal comfort achieved satisfies the clients brief and expectations.

5.0 Concluding Remarks

The simulation results given in this report are based on the output of a complex, dynamic Energy model, which takes account of the following design criteria:

- Architect's drawings
- Weather data
- Simulation Software
- Internal Conditions
- Construction materials
- Space Conditioning system efficiency

Any output from the model is only as accurate as the input of the variables associated with the above criteria.

It is essential that all parties understand and accept the various criteria, as these 'drive' the performance of the building.

MEETING NOTE

Meeting Title: RHSC + DCN Programme Board

Date/ Time: 15 May 2017, 13:00 – 14:00

Location: MacKinlay Meeting Room, RHSC & DCN Site Office, Little France

Attendees:

Jim Crombie	Chief Officer + Project Owner (Chair)
Lynsey Cullen	Senior Communications Officer
Brian Currie	Project Director
Eddie Doyle	Associate Medical Director, Women's + Children's Services
Alison Mitchell	Non – Executive Director
Fiona Mitchell	Director, Women's + Children's Services
Jackie Sansbury	Head of Commissioning
Sorrel Cosens	Project Manager
Cathy Richards	Clinical Lead, CAMHs
Martin Egan	Director of e-Health
George Curley	Director of Operations – Facilities
Janice Mackenzie	Clinical Project Director
Lynda Cowie	Chief Nurse, RHSC

Apologies:

Lynn Allan	Project Accountant
Mike Conroy	Radiology Sector Manager
Fiona Halcrow	Project Manager
David Hood	General Manager, WGH
Susan Goldsmith	Director of Finance
Jenny McKinnon	Partnership Representative
Angela Timoney	Director of Pharmacy
Carol Harris	Head of Communications
Alison Hynd	Head of Physiotherapy, RIE & WGH
Carol Potter	Director of Finance – NHS Fife; SEAT Representative
Donna Stevenson	Associate Director, Scottish Futures Trust
Chris Stirling	Site Director, WGH
Aris Tyrothoulakis	Pan Lothian Service Director – DATCC
Catherine Young	Business Manager, Scheduled Care
Michael Pearson	General Manager, Surgical Services, RIE
Iain Graham	Director of Capital Planning + Projects
Gwyneth Bruce	Head Occupational Therapist - CAMHS
Andrew Bone	Assistant Head of Finance
Gillian Cunningham	General Manager, RIE
Mairi McCrae	Physiotherapy Manager

Re-provision of RHSC + DCN at Little France

PROUD HISTORIES | NEW CHAPTERS

NHS Lothian

Item ***Action***

1. Introductions/ Apologies

Apologies were noted as above.

2. Previous Action Notes from March

The action note of the previous meeting was accepted as a true and accurate record.

SA6A (rights to undertake construction works to face of RIE) is moving forward now and with lenders. Given the delay, the actual works will not be undertaken as per programme and may be pushed back to post Handover. SA6B (alteration of boundary) is being progressed with Consort ready to go to the lenders in June 17

3. Project Dashboard

Brian Currie spoke to the project dashboard.

The RAG dials remain in the same range as the previous meeting with the exception of the "programme" dial which is moving into the red zone.

At a recent Board to Board meeting IHSL announced that they will deliver by 12 October although they still remain unwilling to discuss in any meaningful way the potential delay to the programme. This date is becoming increasingly doubtful given that Multiplex has unofficially reported a four week delay and IHSL reported a 1 week delay. The impact of the four week slippage is being considered by JS & JMcK which would see clinical moves to be done at either, before Easter or both before and following on from Easter. A weekly progress report with metrics to measure progress was previously requested from IHSL but nothing has materialised as yet.

Key documents and deliverables are significantly behind and IHSL are reluctant to commit to any specific timeline details. Brian will be attending the next Board to Board meeting in early June where there will be further discussions on the programme and will endeavour to get a clearer picture of where the indicators are at. In regards to completion, formal notice to the Independent Tester is required three months prior to date of proposed completion and this is currently programmed for 12 July.

Room Reviews still remain behind schedule. Apart from readiness of rooms, many quality issues are emerging. JMacK gave examples of poor quality and inconsistency of finishes being recorded. Damage to rooms possibly caused by contractors returning to rooms to rectify changes has been identified as the cause. A pattern of the same issues within all rooms being reviewed is now emerging. Other ongoing problems being picked up are damage to doors, a poor standard of decoration/finishing quality and also power regularly being unavailable. It was agreed that this is clearly not acceptable and that NHS Lothian now requires definite reassurance around consistency of work. These problems may relate to the change process which is very cumbersome and has proved extremely challenging for IHSL/MPX's supply chain, most noticeably the performance and attitude of Mercury Engineering. Drawings which have been updated or changed via the RDD or change process are not being implemented and this is now resulting in clear mistakes with incorrect fixtures and fittings being installed. JC suggested this would need to be raised as a formal agenda item at the next Board to Board Meeting.

BC / JS

BC / JC

BC noted that the office will relocate at the end of June to directly across the road, in top left corner of currently car park E.

The Board noted the Dashboard update.

4. Construction Progress Update *(verbal)*

Brian Currie provided the Board with a verbal update on construction progress as covered above.

5. Change Management Report

BC spoke to the Change Management Report.

Since the last meeting only a small amount of movement in forecast costs has occurred with a slight increase of £100k which relates to:-

- Room Naming
- ED Signage
- IOMRI Partitions
- FM Storage

JC requested a financial update with confirmation of the project revenue and budget for the next meeting.

Brian indicated that negotiations continue on Compensation Events with the Constractor on the Off Site Flood Works.

Brian also advised that any changes from now would require be delivered post handover.

6. Risk Management Update

Brian Currie spoke to the risk management extract.

Same 6 risks continually stand as previously agreed. JC asked that these risks be added as an agenda item for June's meeting to allow full discussion of each.
Delay to the programme has the potential to cause direct impact on the finance equipment delivery and eventually the commissioning process

7. Commissioning Update

Jackie Sansbury spoke to Commissioning Update
NHSL Commissioning Plan remains incomplete as no Building Commissioning Programme has been received from IHSL.
Workforce numbers are almost all agreed with one outstanding issue which is related to paediatric Orthopaedics who currently attend RIE. FM updated on joint discussions between orthopaedics and Paediatrics to agree a way forward. The proposals will be brought back to the programme board at a later date.

Andrew Bone is due to write out to each of the departments with finalised agreed establishments.

8. Joint Commissioning Plan

Jackie Sansbury spoke to the Joint Commissioning Plan

The Joint Commissioning Plan is a Contractual requirement which NHSL have delivered on time. The contents of the plan covers interface issues between NHSL, Multiplex, IHSL and Bouygues and so it does not reflect majority of NHS activities.

An Open Day planned for the first Saturday in February 2018. This Open Day is for partner agencies such as Scottish Government and not for NHSL staff. Staff will be covered during their familiarisation process.

Work is currently taking place within Communications around a Scoping Campaign which relates to the countdown of the opening. Discussions around this will be ongoing at tomorrow's Communication Meeting.
A few key lessons will be learned from Glasgow. Lindsey mentioned the need to have a "Good News" press release following on from the move and this is included in the planning. Glasgow found that they had released all their good news before the moves and this allowed the press to focus on bad news arising from the commissioning process.
It was agreed that follow up filming after settling in period would be a better option than live filming at the time of the move.

9. RHSC Service Update

Fiona Mitchell spoke to the RHSC Service update
A key issue was the need for more staff within the department of Haematology and Oncology services particularly around day care services. This has become evident following a recent audit which demonstrated changes to drug regimes. A paper has been sent to CMT and the SMT on this.
The one stop dispensing has been delayed and a recovery plan is currently being implemented. The Head of Pharmacy is focusing on the plan and does not envisage any high risk to the implementation.

9. DCN Service Update

Jackie Sansbury spoke to the DCN Service update

Two key issues were identified. The recent appointment of a joint Clinical Nurse Manager/commissioning post which recognises the importance of operational responsibility for the resign work. This will be as a one year post. Secondly there has been a focus on pathways with a significant amount of work surrounding the pain pathways clinic and. Interoperative MRI Scanning ongoing.

10. CAMHS Service Update

Cathy Richards spoke to the CAMHS Service Update

Work continues to resolve the Out Of Hours Service and policies. A paper will be brought to the next meeting.

Re-provision of RHSC + DCN at Little France

11. Any Other Business

George Curley highlighted that there is a potential risk arising from programme delay as on a recent visit to the current RHSC at Sciennes Road by Fire Scotland it became clear that they were no longer comfortable to defer remedial work. George to advise cost and implementation date of these works at next Programme Board.

NHS Lothian

RHSC + DCN - Little France |Programme Board Report|24th July 2017

RHSC + DCN – Little France Progress July 2017

Executive Summary

	Progress	Blockage	Clarification	Next
Time	BioQ Signage granted Planning Permission. SA6a signing soon (rights to undertake works outside boundary). Exit Strategy for Off Site Flood Works agreed.	IHSL continue to advise 12th Oct Completion – see attached paper.	Impact on equipment deliveries, staff recruitment, migration of services. Outcome of DRP and compliance implementation.	
Cost £	SPEN Compensation Event agreed on Off Site Flood Works (see Finance Paper).	No agreement of measurement of Change where scope reduced.	IHSL supply chain attitude to costing changes continues to be problematic.	No assurance from IHSL that all changes will be implemented prior to completion.
Quality	Pharmacy Aseptic Suite to be handed over 28 July as planned. Temp suite to vacate 11 Sept. Staff visits all positive. FM recruitment very good response.	Room Reviews -quality variable. Witness + Testing sporadic. No progress with SA1. Major compliance issues (HV, Ventilation, MRI). H+S issues (vehicle / pedestrian segregation) remain at RIE – NHSL and Consort in dialogue.	Major Non Compliances – HV Resilience, 4 Bed Room Ventilation, MRI most onerous reqs). Slow progress by IHSL on completion paperwork for Ind Tester – Derogations, Completion Criteria etc. IHSL to confirm all mitigation measures in place – temp road crossing at QMRI.	Move to DRP whilst continuing to explore options to realise Board's reqs. (HV, Ventilation, MRI). SFT highlighted areas and themes of Quality Control from Cole Report and Grenfell. Detailed response for next meeting. RIE Car Parking Strategy to be agreed and implemented.

Commissioning

- Further development of the detail of the commissioning period continues. This includes mapping who will be in the building during the 14 week commissioning period, by company/organisation, what they are doing and exactly where in the building.
- Workshops are being planned to cover key handover issues such as the detail of the Bouygues and NHS Lothian early access period to support occupancy including cleaning of the space, delivery and installation of equipment, staff training and familiarisation etc during what is essentially still the construction period and the site is under the control of Multiplex as Lead Contractor.
- Work is progressing on the staff familiarisation programme clarifying the details of the content and the input required by others. This will be supplemented by the super user training and dates for the initial sessions are now available and being diarised. The training includes the NHS FM staff and the Bouygues staff and members of the project team.
- A meeting has also taken place with the NHS Lothian Fire Safety Team to discuss their input to the commissioning process. The key requirements include fire evacuation training which is needed for all staff from their new wards/departments as well as daily updates to the fire evacuation plans to take account of the numerous turnkey activities taking place. This is likely to be a major commitment for this team over the 4 month commissioning period.
- Meetings are taking place with the support services such as Medical Physics, Pharmacy, Medical Gas Testing Team and the Radiation Protection Advisors to detail and schedule their input.
- Meetings are ongoing with the Recruitment Team to support the recruitment of staff, starting with FM before moving onto the clinical teams. There is a dedicated RHSC and DCN campaign web page to assist with recruitment and content for this site is being prepared outlining Edinburgh and the Lothians as a good place to work. This content will be supplemented by interviews and photos of different staff members and some overview of the clinical excellence in some of these departments.
- The fourth meeting of the catering short life working group has taken place and a paper is being prepared with a proposal for the way forward for non-patient catering. This will have funding implications.

Equipment

- Detailed meetings continue with the imaging turnkey companies and Multiplex to finalise the details around the installation of this equipment. The demarcation reports prepared with Multiplex are being finalised and draft programmes for these works are nearing completion.
- Maintenance contract requirements for each new item of equipment if being assessed as the items are procured ad this information is being shared with Finance to support the development of the additional capital charges.
- Work on finalising specifications for group 3 equipment is ongoing although to date very few of these items have been ordered. In general terms only items which will initially go into service in the existing sites are being ordered at this time.

Design

- Continues to still be a small number of significant design issues to be resolved and these are now part of high level discussions with IHSL, NHSL and the Independent Tester.
- Another programme for Room Reviews has been issued, most of the dates have changed, with reviews now programmed until the end of September. The programme still takes no account yet of the need to re-review rooms and to mitigate against this we have now put in a Reserve Team for every day in August and September, which does have significant resource implications for the Project Team . The quality of the work continues to be variable and the Board is making a large number of 'observations'. In the zones reviewed recently there are still a number of rooms not reviewed as there is no power or the room has not been completed.
- There is still a substantial amount of RDD information being issued for review and sign-off. There continues to be a steady stream of RFIs in relation to a number of design and fixture & fittings that we are responding to.
- Design workshops continue in relation to Internal Wayfinding & Signage and Intra-operative MRI. Key suiting for every door with a key in the building has now been done and issued back to Multiplex.
- TCT are visiting again this month for a 2nd site visit to view progress and address any issues with the construction in these areas. A design meeting has been held with ECHC to progress the design of their shop.
- Design of NHSL Cafe and Grab & Go is almost finalised.
- The last site visit for users will be on the 4th August as these cannot continue to be supported due to the intensive room review programme and many departments can now not be visited as they have been locked down.

Commercial & Legal

- SA6a – expected to be concluded with Consort w/c 17/07/17
- SA6b – continues to be progressed with Project Co and Consort
- SA1 – NHSL could not accept IHSL indemnities

Programme

- IHSL have advised NHSL and the Independent Tester of anticipated actual completion date of 12 October 2017.

NHS Lothian

RHSC + DCN - Little France |Programme Board Report|24th July 2017

Stakeholder Management and Communication

- A funding application that was submitted to the ECHC for the development of a dedicated children's services website was unsuccessful. Feedback has not been provided.
- The construction break through into the RIE took place. Media activity may take place in August 2017.
- Countdown digital screens are in place. These screens will display project updates, patient information regarding the move and any related messages in four locations (RHSC, DCN and CAMHS)
- Recruitment campaign support is ongoing.

RIE Health, Safety & Logistics

Health & Safety

- Pedestrian safety remains a concern in the RIE Campus with long standing issues still to be resolved in key business areas. Risk of incident remains very high.
- Good pro-activity between contractors on campus at SWH&S meetings with low numbers of incidents being reported to the group.
- Access to with Service Yard B has control element on vehicle and pedestrian access. Continues to working well.
- Hospital Square works have progressed well. Good work on H&S aspects by Multiplex and Crummock.
- Real concerns on pending flood gate works on "blue light" route to ED.
- Real concerns on newly opened "temporary crossing" for new access to RHCYP for construction team. High volumes of people on crossing, sight lines are not good, new awareness signage requested and additional management by Multiplex required. Blue light traffic could be delayed to PCI if this is not better managed on a daily basis!

Logistics

- Large vehicle numbers on site remains high but are well managed and raising few concerns.
- Gate 4a activities going well since gate switch with no reported issues to date on PCI blue light route or bus services.
- Contractor Traffic Management Plans working well respecting blue light routes and NHSL core requirements.
- Positive initiatives in place from Multiplex on the management of large delivery vehicles!
- Hospital Square works are causing a few issues with vehicle management in the PCI / Day Case area. QMRI Bus Stop closed for safety reasons. Taxi Rank returned to outside of Anne Rowling and is being monitored closely on a daily basis.
- Concerns about perimeter road construction and surface break up. Enabling works defects are underway with BBCSUK carrying out remedial works in numerous areas on the perimeter road. We are awaiting a programme for the Bus Hub major remedial works from Consort and we have concerns already from Lothian Buses.

RIE Clinical Enabling

Pharmacy (Aseptic Suites, Store and Reception Areas)

- The pharmacy construction project will completed on 28th July 2017.
- The new aseptic will open the first week of September 2017.

Medical Photography

- The first phase of this project will start in October 2017 as a variation to the Acute Medical Unit Project.

eHealth, Health Records and Telecommunications

eHealth

- Node room fit out has commenced and currently running to schedule.
- Desktop equipment is almost finalised with 863 for transfer and 322 to be bought new.
- Ongoing review of printers with a concern that the printer estate will increase considerably.
- Specifications and discussions with suppliers for equipment in meeting rooms is underway. Focusing on specialist AV equipment such as interactive boards and video conferencing to support MDTs, management meetings etc.
- Trak build underway with clinic templates being gradually submitted with DCN build well underway. RHSC are in the process of compiling their clinic templates with Trak team needing visibility of these very soon.

Health Records

- Health Records continue to work towards their move with a view that the libraries will move in January 2018.
- Workload in Reception areas in relation to Outpatients in the Children and Young Persons is causing some concern in terms of the activity that will have to managed by the two reception areas manned by Health Records. Discussion to commence with the services to move this forward.

Telecommunications

- Procurement for telecommunication provision is a concern if the framework is not in place timely for the commissioning period. Alternative provision is available for the early access areas in Sept but these would go on a different number range.
- Telephone numbers for new build should be available by end of July for publishing in patient leaflets etc.
- Initial discussions with Multitone have started and full site survey to be scheduled. Potential for costs to be significant with a concern that the Multitone contract comes to an end at the end of the year.
- Initial approach to new provider for pagers, Pageone has been made with a survey to be scheduled.

Art & Therapeutic Design

- http://www.beyondwalls.blog/ has been launched to showcase the art and therapeutic design programme and contributors.
- ATD project costs still in discussion: patient entertainment system.
- Change instruction are complete for: courtyards, interview rooms, sanctuary and bereavement suites; CAMHS department, sitting rooms, drop-in centre, play and dining rooms, the Pod, adolescent spaces, sky ceiling projections in treatment rooms, interactive rehabilitation, Snoezelen room, programmable (gallery) spaces and archive cabinets in public corridors. Broadly these came in on or near to budget and the funders have responded positively to the proposal to use some of the recovered VAT on their donations to deliver the full design intention.
- Terms for the donation and running of the Ronald McDonald House are with legal advisers.
- Terms for the occupation and running of the Radio Lollipop studio have been concluded and signed.

Contract Management (RHSC+DCN / RIE)

• Continuing discussions with IHSL in terms of Facilities Management and Contract Management aspects.

• Continuation of contract monitoring programming, planning and procedures for the operational phase. A strong focus has developed towards the planned handover and the requisite information required to achieve the Completion Criteria.

• Draft Proforma's, procedures and reports from IHSL are being submitted for the Board to review. These documents detail how IHSL intend to operate and what information they will impart during the operational phase. These are being reviewed by the Facilities Management team and reported back to IHSL through both informal joint meetings and through Aconex as a formal mechanism.

• Continuation and progress of developing tools to administer and integrate contract management into the contract i.e. The Contract Administration Manual and the Contract Management Plan.

• Liaison Committee nr 07 took place on06 June 2017 to discuss ongoing matters. Following this meeting there was a scheduled meeting with NSS HFS and SFT. This allowed a focus on the Project Agreement generally and how the contract will operate in the operational phase which will take place in the future. The next meeting is scheduled to take place on 01/08/17. Terms of Reference, Agenda' and Notes have been issued.

• SFT ran a Payment Mechanism Workshop on 14 July 2017 with NHS and IHSL. This was refresh on the contractual mechanism within the Project Agreement. This allowed a factual insight into the way the contract will operate in practice and draft scenarios took place to allow calculation of payment deductions for poor performance.

• Review of RIE operational aspects including information provisions e.g. Programmed Maintenance (Life-Cycle), Building User Guide and review of existing RIE Project Agreements.

• The Travel Planning and Active Travel aspects continue at pace following the recent appointment of Sweco (Grontmij) through the Scotland Excel Framework. There has been much activity with the completion of Travel Plan surveys to all sites affected by the project. The collection of raw data will inform the Travel Plan, which is one of many Planning Condition for this project. Following topographical surveys and assessments there is a now a draft Active Travel Report for the Cameron Toll to the Edinburgh bioQuarter which assesses the relative merits of a physical transport intervention and how this may be achieved. Traffic Surveys counts commenced mid-May. Meetings continue in regard to transportation planning with NHSL, UoE, Scottish Enterprise, Edinburgh Council and Sweco (Grontmij). Further meetings have now been scheduled to progress matters. Discussions ongoing with the Bioquarter Partners i.e. Scottish Enterprise/Edinburgh Bioquarter, The City of Edinburgh Council and UoE to ensure a collaborative approach.

• Regular scheduled Interface meetings are continuing to take place between NHSL and IHSL together with Consort and Engie. Coordination is taking place with RIE Logistics and the remainder of the aspects of the key enabling works to ensure suitable and appropriate levels of planning are taking place.

• A shadow helpdesk has been in operation for circa 36 months to monitor progress by Engie in terms of Helpdesk operation. Sustained effort is required to promote service improvement within this area. Meetings are taking place with Consort/ Engie to assist and at a senior level.

• RIE contract documentation is being sourced and filed in an appropriate format / layout. A document and correspondence register has now been established to register contractual correspondence.

Facilities Management

Soft FM

- Short life working group reviewing options for non patient catering service concluded, paper to be updated and submitted to the programme board. Catering outlets received and reviewed through RDD.
- Recruitment programme in place; FM Open Day well attended; internal interviews for Security/Helipad Officer and Logistics Supervisor commenced with external interviews arranged for 14 July; training programme in place; Prince's Trust programme arranged for next FM Academy; Domestic and Portering posts advertised internally with external dates being released by the end of July.
- Interface meeting held with Consort / Engie, with workshops agreed, initial focus is Security
- FM workshop held to agree procedures for joint working in basement and service yard
- Commodity groups and equipment specification progressing
- Joint operational procedures with clinical and FM services progressing

Hard FM

- In house Hard FM structure and budget nearly concluded
- Witnessing & Testing ongoing albeit less than expected to date
- Review of Bouygues documents ongoing
- NHSL/Bouygues joint procedures ongoing

Decommissioning

- De-cluttering ongoing
- Decommissioning monthly meetings ongoing

PROGRAMME BOARD – 24/7/17

Risk Management Update

Recommendation/ action required:

The Programme Board is asked to

Author:	**Director:**
Callum Gordon Commissioning Manager RHSC and DCN Re-provision	Brian Currie Project Director RHSC and DCN reprovison

NHS LOTHIAN

RHSC & DCN Programme Board
24th July 2017

Brian Currie

RISK MANAGEMENT UPDATE

1 Purpose of the Report

1.1 The Chair of the Programme Board requested additional information regarding progress being made on the top 6 high risks on the RHSC/DCN Project Risk Register. The purpose of this report is to update the board on progress concerning those risks.

Any member wishing additional information should contact the Lead in advance of the meeting.

2 Recommendations

2.1 The Programme Board is asked to confirm they are assured that risks are being managed and progressed.

3 Discussion of Key Issues

3.1 At the November 2015 Programme Board, The Project Director reported that to address concerns raised during an internal audit of risk management practice in the project, the register had been transferred to Datix and is maintained, revised and updated with risk owners and handlers. The register is a standing item on the programme board agenda.

3.2 During regular review, risks are added, revised and closed. Because of the architecture of Datix and the organisational structure in Finance, the Project sub-Risk Registers (e.g. Equipment, Commissioning and Facilities) are retained in the Lothian Report format in Excel. Risks are sometimes raised onto the Project Register or closed from the Datix Register and downgraded to the sub registers. The Project Risk register and the closed risk reports are standing Programme Board Agenda items.

4 Key Risks

4.1 The High Risks on the Register:

4.1.1 3934 Affordability of FM Services

Portering Domestic, Security and Materials Management establishments are now resolved. Non patient catering and Contract management are outstanding. A paper is in preparation proposing a funded pilot for non-patient catering opening out of hours to test viability of services.

4.1.2 4141 Staff Parking

Remains high risk. Application for parking permits and subsequent review and allocation is planned for September 2017.

4.1.3 4145 Availability of PICU Nurses

Remains high risk. is cited as: *"Availability of specialist staff - PICU nurses"*. While there has been some recent success in recruitment, there are a number of vacancies outstanding.

4.1.4 3857 Performance Project Co.

NHSL's disappointment in relation to various aspects of the project (Construction Programme, Commissioning, Rooms Reviews, Change Process, Completion Criteria, Derogations and Non Compliances) was captured in a letter to Wallace Weir, PCo Representative from the Board's Representative dated 24th May, 2017.

A reply was forthcoming dated 30th June, 2017 to which the Board replied on the 13th July, 2017. The topics have been discussed at every Board to Board meeting in recent months and assurances have been given by IHSL that the actual anticipated completion date of 12th October, 2017 will be achieved and that all deliverables will be in place to facilitate this.

The Board's project team, inconjunction with technical advisers, are not convinced of this and a proposal to move back the migration of services is being tabled at the next Programme Board for their consideration.

The ability of IHSL to manage their supply chain remains a cause for concern and hence high risk.

4.1.5 4027 Impact of concurrent capital projects on RHSC & DCN Reprovision: e Health

Remains high risk. At this time the eHealth work streams are being progressed and resources managed accordingly to deliver tasks for all the work streams: Infrastructure; ICT Equipment; Telecoms; Health Records and System Administration. There are overarching concerns that any further changes to the schedule will have an impact on resources and conflict with many other projects which includes new builds such as REH; Roodlands and many healthcare centres across NHS Lothian and at the same time all eHealth teams will be delivering business as usual.

The fit out of the node and server rooms, commenced on the 5th June and complete 31st August 2017 with there being a concern that the eHealth work streams would have to consolidate if there are any further delays. This won't only impact the delivery of infrastructure but the delivery of all other elements of eHealth including; procuring and deployment of equipment to the site; updating and delivery of the changes to systems such as Trak (REH and RHSC & DCN demands of System Admin Resources). At this time resources are being managed effectively and is being monitored on an ongoing basis.

4.1.6 4139 Patient Catering DCN

This risk has been downgraded. It is cited as: *"Change of service from plated to bulk catering which requires meals to be plated at ward level. This is not currently a ward staff activity. Plating and portion control is not a current ward activity and this is time intensive."*

The Reprovision Risk register is revised with the following additions to the entry: "Other clinical areas manage this within existing establishments (but in lower acuity). Work ongoing for solution" It is on the DCN and Facilities Commissioning agendas and a Short Life Working Group including Facilities and Nursing being arranged.

4.1.7 4186 Neurointerventional Service Unavailability over DCN Transfer

Is high risk cited as: *"Potential inability of Glasgow Neuroscience Service to cover service during DCN transfer."* The risk was opened subsequent to last programme board and is a standing item for discussion and resolution in a number of fora including RHSC & DCN Commissioning Group. The current DCN WGH equipment due to transfer has significant downtime associated with intermittent faults. A range of solutions are under consideration.

5 Risk Register

5.1 The Project Risk register and the closed risk reports are standing Programme Board Agenda items.

6 Involving People

6.1 The Project Risk Register is on Datix. All Project Members and key operational stakeholders have access to the register. Every 2 months register is updated on Datix, extracted to excel, held on shared folders and discussed in a range of meetings.

7 Resource Implications

7.1 There are currently no resource implications.

Brian Currie
Project Director

[redacted]

Compromises Schedule

The following list details some of the items the Board has had to / is currently considering compromising during the Construction Phase of the project. The impact of the compromise has been split into the following categories:

1. Financial
2. Operational

Item	Title	Reason for Compromise	Technical Solution	Description of Compromise	Impact	Consulted	Status
1	Ventilation in Single Bedrooms	Project Co's design is not in line with SHTM guidance in relation to air changes. Currently the only extract is via the ensuite, meaning this is 'dirty extract' which can't be used for heat recovery.	Single bedrooms have reduced air supply rates to maintain correct pressure regime. There is not solution proposed to provide heat recovery from the bedrooms.	Less air supply to the bedroom than recommended by SHTM and increased extract through en-suite which will affect running cost of the Facility. No ability to recover heat from en-suite dirty extract.	Operational	Ronnie Henderson Dorothy Hanley Janice Mackenzie Fiona Halcrow Janette Richards Pota Kalima Haem/onc Clinical Team	Under Review
2	Neutropenic Patients	As per SHTM and Clinical Specs, the rooms for neutropenic patients should be designed as isolation rooms (+10 positive pressure). However, there are 10 single rooms which Project Co have designed to balanced pressure.	No Solution proposed	NHS took a decision to operationally manage the department rather than asking Project Co to change the design.	Operational	Ronnie Henderson Dorothy Hanley Janice Mackenzie Fiona Halcrow Janette Richards Pota Kalima Haem/onc Clinical Team	Under Review
3	Drainage Exclusion Zone	Project Co were unable to divert drainage from certain exclusion zones requested within the BCRs.	1. Some drainage stacks still appear in the rooms. The stacks were boxed out and diverted to adjoining corridor. 2. Some redesign has taken place to divert drainage pipes which has included in some shower trays being fitted in ensuites. 3. Some rooms needed to be redesigned to accommodate drainage requirements. Note some drainage still appears in MRI rooms which has to be removed.	The Board have had to accept the following: 1. Boxed out drainage stacks - Additional pipework (bends, joints etc) potentially create weak points of the pipework where leakage may occur. More onerous maintenence regime required. 2. Shower trays in some ensuites require a different cleaning and maintenence regime. 3. Accepted changes in the layout of a small number of rooms making the layout different from some type of rooms within other department/s. 4. There are some less critical rooms where the drainage could not be re-designed.	Operational	Ronnie Henderson Janice Mackenzie Fiona Halcrow Dorothy Hanley CAMHS Lead	Ongoing review as issues arise
4	Theatre Canopy	Project Co did not provide remote air handling within the design for the canopy leading to an increase in the size of the canopies from what was reviewed by the Board during PQ reviews.	No Solution proposed	Increased size of canopy in two of the RHSC theatres has resulted in a change of location of surgeon pendants meaning they are further from operating table, impacting on how theatre teams will work. The Board have also had to compromise the location of the anaesthetic pendants in other theatres and the separate monitor arms in RHSC theatres.	Operational	Patrick Macaulay Ashley Hall Fiona Halcrow All signed off by the Clinicians	Agreed
5	CAMHs intensive nursing suite external area	Project Co's Courtyard design drawings did not illustrate the covered section of the courtyard.	Project Co are currently looking at alternative screens to maximise light coming into the space and extending the size of the courtyard to allow some space that is not covered. The bricks will also be painted. There is no solution for removing the cover.	The intensive nursing suite external area in CAMHS is (unexpectedly) covered, and therefore unsuitable for use by patients without redesign as there is no part of the courtyard open to sky – The Board and Project Co have now reached a compromise and are awaiting an updated drawing and spec to confirm Project Co have proposed a solution to resolve the issue.	Operational	Janice Mackenzie Sorrel Cosens	Under Review
6	No Lift to basement in Core 3	Project Co did not construct lift core 3 to accommodate a lift access to the basement.	There is no alternative solution.	The Board had to accept the lift within core 3 will not serve the basement, however, this compromises the FM routes as it requires DCN beds to be brought down the RHSC lifts or the FM lift and reduces contingencies.	Operational	Brian Corrie Jackie Sansbury Jane Campbell	Project Co Change still to be issued

7	Removal of WC (G-Q1-068)	Project Co are having to increase the size of one of the switch cupboards.	MPX request to relocate one of the switch cupboards in the radiology department to WC (G-Q1-068) to support the increase in size of switch cupboard (G-Q1-156) and the resuscitation trolley	To optimise patient safety and operational functionality the Board have agreed for the WC (G-Q1-068) to be removed to accommodate the resuscitation trolley (G-Q1-064). There will be a new arrangement for both the resuscitation and linen bay (G-Q1-063)	Operational	Janice Mackenzie Fiona Halcrow Dorothy Hanley Mike Conroy Radiology Representatives	Project Co Change still to be issued
8	Location of MRI Chillers	Project Co's original design had chillers located outside the red line boundary without legal rights to do so.	The chillers have been relocated to the roof above Department C2.	The pipe run has increased making it more expensive to install and replace and harder to maintain. It will also have an effect on the operation of the chillers by adding extra strain on the system due to the pipework's length, also requiring an additional resilience chiller. After extensive discussion on access, maintenance and replacement the solution has been proposed that includes the use of lifts.	Financial and Operational	Jackie Sansbury Dougie Coull Mike Conroy	Under Review
9	Gauss Lines in IOMRI	Project Co did not consider the Gauss lines in the original design of the room and are currently not contained within the IOMRI room	1. The lobby between MRI and OT had to be created to ensure: - the extend of gauss lines do not protrude to operating theatre. - suitable access for maintenance for faraday cage door. 2. Some sockets in the anaesthetic room need to be relocated as they are within the fringe field. The room will have to be re-designed, however, the implications of this are still being discussed.	1. The Board will have to change procedures within the area below and above the MRI to 'controlled access'. BYES will need to implement a procedure for this to ensure safety of their staff. 2. It reduces the size of the theatre adjacent to the MRI machine. 3. Currently unknown if the area and room redesign will work.	Operational	Jackie Sansbury Dougie Coull Mike Conroy	Under Review
10	Removal of Sprinklers	Project Co have removed the sprinklers from the Pod and Atrium to allow the proposed ATD design within the Pod to be accommodated.	Project Co's solution is to minimise the allowable fire load in the POD/Atrium area to 2.5MW.	Maximum allowable fire load strategy implemented in the POD restricting the future usage of the public space. Therefore, the Board are compromised in terms of flexible use of the space due to restrictions on the fire load including limitations on the type and size of Christmas tree.	Operational	Clive Armstrong Billie Hamilton Jim Gardner	Under Review
11	Movement Joint	Through lack of coordination between the Architects and Structural Designers, Project Co has designed the movement joint through the key exclusion zones identified in the BCR's.	Project Co are currently working on solutions including moving internal partitions so the joint falls within the partition wall and installing special seals within the clinical areas.	The maintenance and lifecycle implications are still to be confirmed with the Board but it is likely to be more onerous. Therefore, the affected rooms will likely be unavailable more often and will require more intensive cleaning regime	Financial Operational	Brian Currie Jackie Sansbury Janice Mackenzie Fiona Halcrow Stuart Davidson Jane Campbell Janette Richards Dorothy Hanley	Project Co Change still to be issued
12	New Facility constructed at different level to the existing RIE.	Project Co used incorrect levels when constructing the facility. As a result there is a difference in level between the link building and the existing RIE.	There are 4 locations within the link building and 1 within the RIE there are steps within the floor slab and screed is having to be built up to form slopes to account for the change in level	Not best practise to have slopes within hospital corridors. Potentially more difficult to move trollies around in this area.	Operational	Brian Currie Janice Mackenzie Fiona Halcrow Jane Campbell Jackie Sansbury	Project Co Change Under Review
13	Trolley Area in the Lift lobby in Energy Centre Ground floor	The size of the trolley area was reduced by Project Co, only allowing for 5 trollies (instead of 6)	There is no solution.	The Board need to change operational procedures to account for fewer trollies which will lead to inefficiencies.	Operational	Jane Campbell Stuart Davidson Jackie Sansbury	Agreed
14	Waste Area in Service Yard	Project Co has designed the area in the service yard to a small to allow the full facility to use standard clinical bins because of storage space in the service yard	No solution to reduction in size.	The Board have had to change their operational policy for bins that are now smaller, will need emptied more frequently and will need to dip smaller bins into larger. This meant that the Board needed to buy both a bin tipper and bin washer	Operational and Financial	Jane Campbell Stuart Davidson Jackie Sansbury	Agreed
15	Turning circle in Service Yard	Due to the size of the service yard and the additional requirement for a bin washer and tipper, delivery lorries do not have a full turning circle to change direction and must reverse to accommodate delivery unloading.	Delivery vehicles will need to perform reverse manoeuvre with use of a reversing assistant and timed delivery slots.	Designed solution not available, service yard to be tightly managed with software for timed deliveries to be procured and reversing assistants trained and available.	Operational	Jackie Sansbury Jane Campbell Stuart Davidson	Agreed

16	Basement Transformer Replacement	Project Co have located Transformers in the basement which makes it difficult for them to be moved as they can't be taken out via the lifts due to size and weight restrictions.	Project Co's solution includes opening a hole in the concrete slab in the lift lobby	This closes the area in the ground floor and basement area in the energy centre. Therefore the Board will not be able to use this area while the replacement in undertaken. This time period is still to be confirmed. There is no alternative so all deliveries and some FM operations will stop during this period. This has not yet been covered by the access and maintenance strategy.	Operational	Stuart Davidson	Agreed
17	Height reduction in basement areas/service yard	The height within the service yard was meant to be no less then 2400mm, however, there are areas within the service yard and basement Project Co have constructed with a reduced height of 2100mm.	There is no alternative solution.	There will be a negative affect on the atmosphere within the enclosed area of the service yard with a much more enclosed space. There is also restrictions with the movement and handling within the basement.	Operational	Ronnie Henderson Jane Campbell	Under Review
18	Vents in Courtyards	Following FC, Project Co introduced vents in some of the courtyards	Project Co are enhancing the landscaping within the affected courtyards	The Board have reduced useable space within the courtyards.	Operational	Sorrel Cosens Janice Mackenzie	Agreed
19	Odours from helipad entering RIE and RHSC clinical areas including theatres.	Project Co had not assessed the effect of helicopter emission during the design of the helipad. Project Co then revised the design and lowered the helipad which may have worsened the situation.	Project Co are still to propose a solution to manage the emissions.	unknown until Project Co confirm their solution.	Operational	Brian Currie Jackie Sansbury Janice Mackenzie Fiona Halcrow Stuart Davidson	Project Co Change still to be issued
20	Foul Pump at Kitchen Door in the basement	Project Co's foul drainage design in the basement locates the pump within the corridor outside the kitchen area. This has the potential to create a uncomfortable odours in an area where food is being prepared and a frequent thoroughfare to those using the basement.	There is no solution proposed by Project Co but design must be HAI scribe compliant.	Maintenance of the pump will close off this section of the corridor and affect FM activities. On a more general note staff will potentially have to work in an uncomfortable odour that again effects the overall atmosphere of the basement working environment.	Operational	Stuart Davidson Jane Campbell	Agreed
21	no concealed grid for ceilings	Project Co changed the ceiling grid and tile specification and installation of same without consultation with Board after original specification has been reviewed as RDD.	In all areas of suspended ceiling with the exception of the kitchen, revised spec with exposed grid and Bio guard Acoustic tiles is being installed.	Board presented with a fait accompli when rooms presented for review. The compromise is an aesthetic issue.	-	Janice Mackenzie Fiona Halcrow	Awaiting Project Co Change
22	Lift Size too small for Anglo installation and Replacement	The lifts within the facility are too small to allow installation and replacement of Anglo Equipment	An access door has been constructed in the 1st floor of link building and anglo will need craned/raised into position from a platform.	This procedure will cost more and will introduce restriction in the area.	Financial	Stuart Davidson Jackie Sansbury	Agreed
23	Attenuation system under car parks	Project Co have not provided disabled parking signs at the end of each individual disable space as required in the British Standards	No solution as Project Co advise that the attenuation system under the car park stops foundations being constructed at the parking bays and the reference does not meet British Standards.	Against best practice and not consistent across Campus site.	Operational	Jackie Sansbury Stuart Davidson Steven Alderson	Agreed
24	Access to fire dampers	Project Co has located fire dampers in a position obstructed by services making them difficult to access.	Project Co are re-designing access to fire dampers	Due to the location of some fire dampers the access will take considerable amount of time to re-set following annual drop tests or in the event of actual alarm.	Operational	Ronnie Henderson	Project Co Change Under Review
25	Parents Beds	Project Co's original parent bed design did note allow enough circulation space to get to the patient or on the other side of the bed to clean and make up the bed	The bed has been made smaller	The Parent bed may be too small for some parents and therefore they may not be able to sleep comfortably beside their child.	Operational	Janice Mackenzie Fiona Halcrow Dorothy Hanley Jackie Sansbury Jane Campbell RHSC Nursing Team Reps	Agreed
26	LTHW Change	Project Co amended the route of LTHW pipework with no cost savings offered.	The LTHW being constructed in the link tunnel between energy centre and basement.	There is a drop in ceiling and a change in the light position that again has a negative affect on the atmosphere in the basement	Operational	Stuart Davidson	Project Co Change Under Review
27	No parent shower for parents in the 4 bedded rooms	Project Co's original design did not provide any parent showers on the ward for parents in the 4 bedded rooms because NHS policy doesn't allow parents to use the children's showers	The Board issued a Board Change to transform one of the Grab and Go's into a Parent's shower room.	This has cost additional money to provide	Financial	Janice Mackenzie Fiona Halcrow Dorothy Hanley Jane Campbell	Agreed

28	Inconsistencies between Design and Construction	The Board are finding a lot of instances where items have been constructed / fitted in the wrong space. For example 1. BMS control (BMS999) and Cleaner sockets (OUT0056) are not where they are illustrated on the drawings. 2. Cupboard in the wrong place in Sphere 3. In Sphere an observation window was higher than designed.	In order to minimise impact or reworks the Board take a view at the time the issue is raised whether the mistake needs to be corrected by Project Co.	The Board considered that some mistakes could be accommodated with some having no impact and others needing slight changes to operational procedures.	Operational	Janice Mackenzie Fiona Halcrow Dorothy Hanley	Under Review
29	Entrance Matting	Project Co did not provide entrance matting at all doors to external areas however, it is not possible to change the floor slab to incorporate recessed floor mats in all areas.	Project Co have provided several different details including: 1. Fixed but raised matting 2. Locating recessed mats outside 3. Board supplying some mats as group 3 that can be removed when not needed.	The Board are having to provide some mats as group 3.	Operational and Financial	Jackie Sansbury Jane Campbell Stuart Davidson	Agreed
30	Temperature Control Valves	Project Co have not provided electronically actuated valves to individual radiant panels that allows BMS control of temperature.	Thermostats are located in each room that allow slight changes to localised room temperature	The Board could not incorporate temperature control into enhancements to the patient bedside environment	-	Ronnie Henderson Janice Mackenzie Fiona Halcrow Sorrel Cosens

NHS LOTHIAN
Royal Hospital for Sick Children & Department of Clinical Neurosciences
Programme Board

24 July 2017

SUMMARY FINANCIAL POSITION AT 12 JULY 2017

1. Purpose

1.1 The purpose of this report is to provide the programme board with a summary of the forecast capital expenditure in relation to the re-provision of the current Royal Hospital for Sick Children and Department of Clinical Neurosciences, at Little France.

2 Recommendations

2.1 The Programme Board members are asked to:

- Note the projected overspend position.
- Note the risk that the project may not deliver a break even position against allocated budget.

3 Overall Forecast

3.1 As previously reported to the board, it is currently anticipated that there will be an overspend against the approved non-NPD Capital budget. Table 1, shown below, outlines the current forecast against approved budget at FBC, as well as illustrating movements in the forecast position from the last reported position at the March 2017 meeting of the board.

	Approved Budget at FBC	Forecast as at March 2017	Current Forecast	Variance from FBC	Variance from March 2017 Forecast
	£k	£k	£k	£k	£k
Reference Design	2,541	2,541	2,541	0	0
Petrol Station Site	550	702	702	(152)	0
Enabling & Town planning	22,174	22,691	22,691	(517)	0
Offsite Flood	4,298	6,294	6,999	(2,701)	(705)
Clinical Enabling	13,641	10,948	10,799	2,842	149
Equipment	36,880	35,095	35,095	1,785	0
Change / SA's	0	2,804	3,968	(3,968)	(1,164)
Total	**80,083**	**81,075**	**82,794**	**(2,711)**	**(1,719)**

Table 1 –Overall Non- NPD Capital Forecast

3.2 It should be noted that the above figures are inclusive of £2.427m of contingency funding, of which £2.277m sits within equipment budgets, and £0.150m is allocated to change costs.

3.3 Discussion of the material movements from the last reported position is contained below.

4 Enabling & Town Planning:

4.1 Although there is no projected movement from the March 2017 forecast, it is important to note that the costs included in the current forecast assume that costs incurred in respect of variation management for both NHSL and Consort are to end in October 2017, and that traffic management costs will continue to be incurred until the facility is fully operational in March 2017. Any slippage to these dates would incur further unfunded cost.

5 Offsite Flood

5.1 Table 3, shown below, outlines the movements in forecast expenditure in relation to the ongoing off-site flood prevention works.

Offsite Flood	Contractor Appointment	March 2017 Forecast	July 2017 Forecast	Variance from Original	Variance from March Forecast
	£k	£k	£k	£k	£k
Tendered Works	2,497	2,497	2,497	0	0
VAT on works	499	499	499	0	0
Approved CE's	0	415	1,878	(1,878)	(1,463)
Anticipated CE's	0	1,200	315	(315)	885
VAT on CE's	0	323	439	(439)	(116)
Sub Total - Total Works Cost	**2,997**	**4,935**	**5,629**	**(2,632)**	**(694)**
NHSL TA Fees / Design	690	1,128	1,133	(443)	(5)
NHSL Legal	87	83	83	4	0
Surveys	179	22	24	155	(2)
Enabling	110	128	131	(21)	(3)
Contingency	200	0	0	200	0
Total Forecast / Variance	**4,263**	**6,294**	**6,999**	**(2,736)**	**(703)**

Table 3 –Forecast Off-Site Flood Capital Spend

5.2 As has been described to the board previously, the nature of the NEC3 Type C contract means that NHSL is exposed to costs for compensation events (CE's). To date, a number of CE's have occurred, leading to

significant additional cost to the board and subsequent delays in project completion. The value of CE costs agreed to date is £1.878m, with a further forecast cost of £0.315m included for CE payments not yet agreed.

5.3 The above figures assume completion of off-site flood works in October 2017, if these dates were to slip there would be further cost to the board in respect of ongoing technical and project management fees.

5.4 VAT on the main works is irrecoverable, and therefore contributes towards the project overspend as costs increase.

6 Clinical Enabling

6.1. Projected clinical enabling costs have reduced from the March 2017 forecast, predominantly due to reductions on anticipated spend within the Pharmacy (£0.142m reduction), and Renal and Critical Care (£0.007m reduction) projects.

7 Equipment

7.1 Overall budget allocated to equipment costs remains at £35.095m, with projected expenditure on new build equipment projected to be £29.124m; a reduction from the prior forecast. The procurement process for the purchase of that equipment continues to progress, with 62% of the total by value committed as at July 2017. As the procurement process nears conclusion a greater degree of certainty in terms of the final equipment spend will be achieved.

7.2 Contingency budgets currently equal £2.277m, representing an increase from the position in March due to the aforementioned reduction in projected new build equipment and a reduction in clinical enabling equipment spend within Critical Care and Pharmacy. However there remains an element of risk around future purchase prices and, as such, any further transfer of this contingency to fund overspends in other project areas would require risk assessment.

Equipment Forecast	March 2017 Forecast	July 2017 Forecast	Variance
	£k	£k	£k
New Build / NPD Equipment	29,733	29,124	609
Contingency	1,500	2,277	(777)
MRI St Johns	1,200	1,200	0
Clinical Enabling	2,662	2,494	168
Total	**35,095**	**35,095**	**0**

Table 4 –Forecast Equipment Spend

7. Change

7.1. Change costs resulting from change instructions by the board are funded through a combination of NHSL capital funding and donations from charitable bodies. The below table outlines change costs attributable to NHSL which are currently included in the project change tracker, versus the March 2017 forecast, with estimated amounts included for SA legal fees based on prior experience.

Change Costs	March 2017 Forecast	July 2017 Forecast	Variance
	£k	£k	£k
Main works	1,931	3,094	(1,163)
NHS QS & Legal Fees	204	204	0
Consort Legal Fees	120	120	0
IHSL Fees	300	300	0
Compensation for late handover	100	100	0
Legal Fee Contingency	150	150	0
Total	**2,805**	**3,968**	**-1,163**

Table 5 –Forecast Change Capital Spend

7.2. As is shown above, there has been a significant increase in projected change costs due to change instructions issued by the board. The below table summarises the key changes which have contributed to the above increase.

Change	March 2017 Cost	July 2017 Cost	Variance
	£k	£k	£k
Chiller Pipework	256	328	(72)
Vending Storage	31	64	(33)
Emergency Department Sign	10	32	(22)
Courtyards	215	145	(70)
Room Naming	20	94	(74)
Landscaping Outside Blue Line Boundary	0	600	(600)
Number Plate Recognition	10	66	(56)
First Fix Equipment	0	40	(40)
External Lighting	0	19	(19)
IOMRI	0	51	(51)
Bio Quarter Street furniture	0	108	(108)
Miscellaneous Low Value	0	19	(19)
Total	542	1,566	(1,163)

PROGRAMME BOARD

24 JULY 2014

MRI PROVISION FOR THE NEW RHSC/DCN BUILDING

Recommendation/ action required:

The Programme Board is asked to approve the disposal/Selling of MRI and CT at both RHSC and DCN

Author:	**Director:**
Mike Conroy Radiology Manager DATCC	Brian Currie Project Director RHSC and DCN Reprovision

NHS LOTHIAN

Programme Board Meeting 24th July 2017

Brian Currie, Project Director

MRI PROVISION FOR THE NEW RHSC/DCN BUILDING

1 Purpose of the Report

1.1 The purpose of this report is to recommend that the Board approves the disposal/Selling of MRI and CT at both RHSC and DCN

Any member wishing additional information should contact the Executive Lead in advance of the meeting.

2 Recommendations

The Board is recommended to:

2.1 Approve the proposed changes as noted below.

3 Discussion of Key Issues

3.1 Currently there is 1 CT and 1 MRI on the RHSC site and 2 MRI (DCN and Main radiology department) and 2 CT (DCN and Main radiology department) on WGH site. Once the DCN has relocated, an additional CT has been commissioned for the WGH main Radiology department to ensure the 2000 In-Patients remaining on the WGH have capacity to be imaged and the current workload on mobile CT van can be absorbed back into funded NHS capacity. The MRI workload associated with DCN, which includes sessions on the main radiology scanner, will transfer to the little France site and the remaining In-patient workload will be absorbed into the remaining single MRI scanner in the main radiology Department. The data supporting this strategy was ratified by the external Capita report in 2015.

3.2 Post relocation of DCN and RHSC will leave 1 MRI and 1 CT available for disposal/selling/utilising on each site. The RHSC site will be closed and it is assumed that the equipment will be removed and sold to the most cost effective bidder as the equipment is out with its recommended replacement cycle (12years old)

3.3 Within DCN there are various options to consider, it is expected that the CT scanner will be sold/disposed as a new service is being commissioned in the main radiology department. The options around MRI are to be discussed further in this paper.

3.4 The University of Edinburgh have a MRI scanner housed within DCN that provides capacity for NHS Stroke and in-patients at a cost of £76K pa, the university wish to retain this facility as long as possible due to long term research projects..

3.5 The Current market value at this moment in time (April 17) for the equipment being replaced is:

- RHSC
  - MRI £300K - £100K
  - CT £125K - £15K
- DCN
  - MRI £200K - £150K
  - CT £100K – 40K

All these prices will decrease over the next 12 months as the equipment ages.

3.6 Option Appraisal – DCN MRI

- Option 1 - Sell/Dispose DCN MRI
  - Advantages
    - Releases capital
  - Disadvantages
    - No NHS contingency on WGH site if MRI fails.
    - Loss of potential capacity as the equipment will have 18 months asset life left once DCN relocates which could be utilised.

- Option 2 - Retain MRI and staff accordingly
  - Advantages
    - Provides Contingency for MRI on WGH site, if main department scanner fails.
    - Provides additional capacity as and when required
    - Ensures equipment on site is maximised for its full asset life.
  - Disadvantages
    - Doesn't release capital
    - Increased revenue costs (Circa £900K for staff and maintenance)
    - The longevity of the MRI in DCN is related to the potential need to vacate the space to make way for the cancer centre project.

- Option 3 - Retain MRI and use for backup only
  - Advantages
    - Provides Contingency for MRI on WGH site, if main department scanner fails.
    - Ensures equipment on Site is maximised for its full asset life.
  - Disadvantages
    - Doesn't release capital
    - Increased revenue costs (Circa £100K, does not include staff)

        - The longevity of the MRI in DCN is related to the potential need to vacate the space to make way for the cancer centre project.

- Option 4 – Utilise University MRI for Backup and sell/dispose existing scanners.
    - Advantages
        - Releases capital
        - Provides Contingency for MRI on WGH site, if main department scanner fails.
        - University currently provides back up for DCN MRI on a routine basis for stroke MRI.

    - Disadvantages
        - The longevity of the MRI in DCN is related to the potential need to vacate the space to make way for the cancer centre project.
        - Equipment will have 18 months asset life left once DCN relocates

3.7 The preferred option is Number 4 as it is the most cost affective option in the short to medium term. The University of Edinburgh have confirmed they would see this as a favourable option for themselves.

4 Key Risks

4.1 If activity changes on the WGH site due to new techniques requiring MRI scanning such as Multiparametric imaging of the prostate, activity could increase to the point that another MRI scanner on the WGH site will be needed in the next few years rather than in the next 5 years.

4.2 The decision on when the cancer centre project is commissioned affects all potential options, as the DCN building will need to be closed which in turn would decommission the UoE MRI and the NHS DCN MRI (if we kept it going). If Radiology required more capacity at this point on the WGH site, options would be to resort to expensive private sector mobile MR capacity or purchase a new MRI.

5 Risk Register

5.1 None to note

6 Resource Implications

6.1 If the Equipment is sold, at today's prices an opportunity exits to make £725K which also includes the removal from the building. With all options there will be a

revenue tail from funding an additional MRI that is fully staffed to paying the university for ad hoc support in terms of downtime.

Mike Conroy
Radiology Manager

NHS Lothian

RHSC & DCN – LITTLE FRANCE
PROGRAMME BOARD – 24/07/17

STATE OF READINESS

Recommendation/ action required:

The Programme Board is asked to note the current position in terms of the state of readiness in respect of the Contract Management related Completion Criteria.

Author:	**Director:**
Stuart Davidson Contracts Manager RHSC and DCN Reprovision	Brian Currie Project Director RHSC and DCN Reprovision

NHS LOTHIAN

Programme Board Meeting
24/07/17

Project Director

STATE OF READINESS

1 Purpose of the Report

1.1 The purpose of this report is to recommend that the Board note the current position in terms of the state of readiness in respect of the Contract Management related Completion Criteria.

Any member wishing additional information should contact the Executive Lead in advance of the meeting.

2 Recommendations

The Board is recommended to:

2.1 Note the contractual deliverables by IHS Lothian under the terms of the Project Agreement and the ramifications of not providing the requisite information timeously and in the required format.

3 Discussion of Key Issues

3.1 The Project Agreement places a requirement on IHS Lothian (IHSL) to produce and agree documentation and handover information with NHS Lothian at least three months before the issue of a Certificate of Practical Completion (Actual Completion). Information includes how IHSL will work and how they will work with the Board in jointly interfacing with hospital activities. Appendix 1 details the background to the Project Agreement and how the Board can be satisfied in terms of Performance requirements and monitoring.

3.2 Project Co (IHSL) is responsible for reporting any Availability and Performance Failures. The Board needs to have mechanisms in place to be able to verify the completeness and the accuracy of reporting which should include any failures recorded within the monthly performance reports. These are contained within the Contract Management Plan and Contracts Administration Manual.

3.3 Without the documentation and qualitative information imparted by Project Co this will affect the Boards operational phase and also the Boards post-completion activities. It will affect Project Co Service Providers ability to safely manage the facility and it will prohibit the Board from duly exercising its obligations under the

Construction (Design and Management) Regulations 2015 to provide information on the safe use and operation of the building.

3.4 The extent of engagement beyond what is anticipated as reasonable may incur additional costs and resources to ensure what is expected is attained.

4 Key Risks

4.1 The timing and qualitative aspects of the contractual deliverables are at risk. If the information is absent then Project Co will ultimately fail to meet a performance criteria under the Payment Mechanism and financial penalties will result during the operational phase.

4.2 If the requisite information is not prepared timeously this will have an effect on the Boards operational activities. Information includes how IHSL will work and how they will work with the Board in jointly interfacing with hospital activities.

It will also hinder the progression of post-completion activities as we would not be able to impart Health & Safety Information to contractors engaged by the Board – a legislative requirement under the Construction (Design and Management) Regulations 2015.

4.3 There is also a risk that the pressure to complete on the agreed date may render some documentation / information absent or poorly drafted.

5 Risk Register

5.1 There is a risk arising directly from the delay of the requisite information and the qualitative aspects absent arising from review.

6 Resource Implications

6.1 There are resource implications related to handover and commissioning activities and these are being factored into forward planning for the targeted end date. Should the targeted end date not be achieved there may be additional costs incurred.

Stuart Davidson
Contracts Manager
17/07/17
[redacted]

List of Appendices

Appendix 1: Contract operation summary

Appendix 1

Part 6 and Schedule Part 12 of the Project Agreement contains the Service Requirements which establishes facilities management (Hard FM) requirements to be achieved by Project Co, through their services subcontractor, after completion.

Service Commencement

Project Co has to satisfy to the Independent Tester to support their completion notification that the following matters have been addressed:

· Mobilisation Plan

· Project Co's Staff

· Helpdesk

· Project Co Plans (as below)

· Facilities Handover (including Government's Soft Landings as below)

The required Project Co Plans are identified as below.

· Interface Protocol

· Service Delivery Plan

· Trust Services Training Plan

· Mobilisation Plan

· Communications Plan

· Contingency Plan

· Health & Safety Plan

· Fire Safety Management Plan

· Building User Guide

· Quality Management Plan

· Environmental Management Plan

· Five Year Maintenance Plan

· Schedule of Programmed Maintenance

· Lifecycle Profile

· Lifecycle Schedule

· Energy, Utilities & Water Management Plan

· Energy Efficiency Plan

The Government Soft Landings relates to a recent initiative by the Government "to be used to bridge the gap between expectation and reality by engaging users and operators to review and comment upon the design, construction, commissioning and handover proposals."

Within 18 months from services commencement Project Co will achieve accreditation in their management systems in respect of Health & Safety, Quality Management and Environmental Management Systems. These accreditations shall be maintained throughout the tenure of the contract.

Helpdesk Services

Project Co will provide a Helpdesk service 24 hours per day, 365(6) days a year in respect of the Services.

Maintenance

Project Co will be responsible for providing maintenance, service contracts, repairs, replacements & preventative regimes to all elements of the Facilities, grounds, structure, fabric, mechanical and electrical services, as well as fixtures, fittings signage and specialist installations and equipment.

Replacement of Lifecycle Assets

Project Co will carry out the renewal and replacement of Lifecycle Assets in order to maintain the Facilities in accordance with the Agreement, to meet Availability requirements/Services Quality Standards and in accordance with the Lifecycle Schedule.

Unprogrammed Maintenance

All elements of the Facilities will comply with the Service Standards, Schedule Part 6 (Construction Matters), the Handback Requirements and the requirements of manufacturers' original and subsequently amended specifications, guidelines and warranties. Where Faults occur in the Facilities, Project Co will Respond and Make

Safe and Rectify such Faults within the Maintenance Service Respond and Make Safe Times and Rectification Times.

Equipment

To the extent that Project Co is required to maintain Equipment, it will be responsible for supplying, administering and distributing Equipment evaluation records required by the NHS.

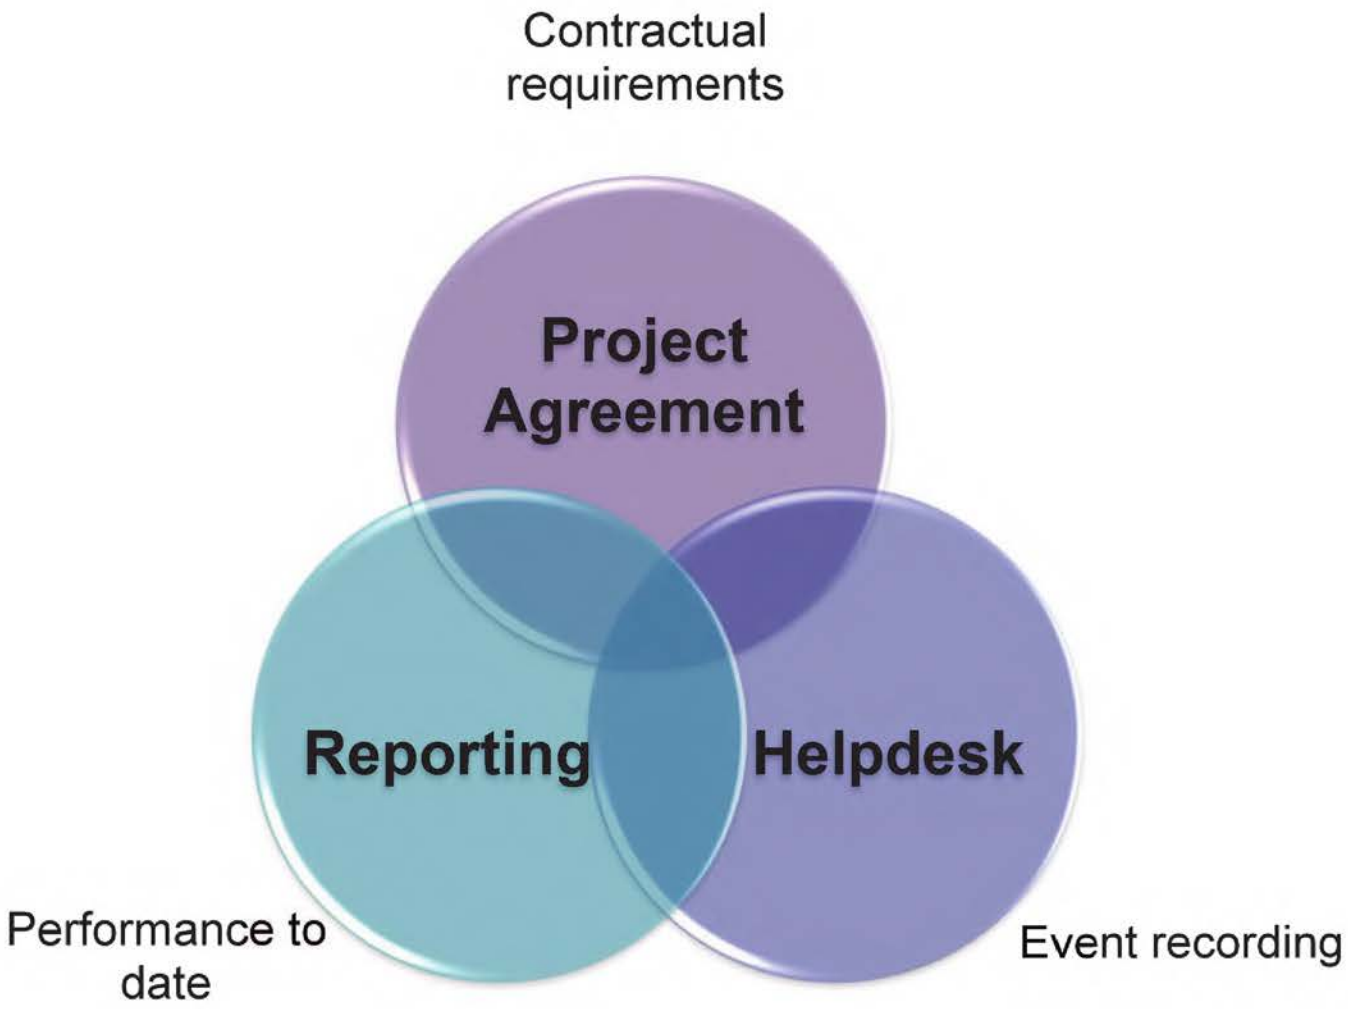
Energy & Utilities Management

Project Co will ensure the efficient, effective, safe and timely supply of energy, utilities and controls (electricity, gas and water, etc.) across all areas of the Site in order to ensure continued operation of the Facilities, 24 hours per day, 365(6) days per year for the duration of the Agreement.

In order to derive maximum benefit from this Project Agreement Project Co (IHSL) are required to deliver against circa 70 Performance Standards throughout the Project Term. They will regularly report against this criteria and deliver monthly and annualised reports stating such.

Where performance on the ground is negative and impacting on our services we have the mechanism through the Project Agreement to levy financial deductions. This is a means to incentivise performance levels. This is done via the Payment Mechanism (Paymech).

Performance Management Linkages



The payment mechanism lies at the heart of the NPD contract. The primary purpose of the payment mechanism is to incentivise Project Co (IHSL) to provide the services to the required standards.

If these standards are not met Project Co (IHSL) will incur financial deductions, if they are met Project Co (IHSL) receives full payment.

The NPD Contract details the deductions which should be applied in the event of Availability and/or Performance Failures occurring. These deductions are integral to

the value for money for the public sector and must be enforced in accordance with the terms of the contract.

Project Co (IHSL) is responsible for reporting any Availability and Performance Failures. The Board needs to have mechanisms in place to be able to verify the completeness and the accuracy of reporting which should include any failures recorded within the monthly performance reports.

Deductions from Monthly Service Payments and Service Failure Points (SFPs)

If at any time during the Operational Term an Unavailability Event or a Performance Failure shall occur the Board shall subject to criteria be entitled to make Deductions from the relevant Monthly Service Payment in respect of that Unavailability Event or Performance Failure. The maximum aggregate of all Deductions that the Board can make from a Monthly Service Payment shall be the Adjusted Service Payment.

Events

Reported through the Helpdesk - an incident or state of affairs:-

(a) not meeting the Service Requirements; or

(b) not satisfying the Availability Conditions

Logged on the Helpdesk and remains an Event unless fails Rectification Time

Performance Failures (PF)

An incident not meeting the Service Requirements; which has not been rectified within the relevant Rectification Time, if applicable

If not rectified within Rectification Period then Additional Period(s) run and further PFs can accrue.

If no Rectification Time then there is an immediate Performance Failure (PF) and if not remedied within Remedial Periods further PFs accrue will still apply.

Availability Condition

To remain Available, each area must continue to meet all of the Availability requirements:

- Accessibility Condition
- Safety Condition
- Use Condition and
- Prescribed Health Function Condition or, as appropriate,
- the Prescribed Operational Function Condition
- Use Parameters and relevance of Room Data sheets

The area does not need to be unusable or unused - continued use impacts on the amount of deductions

There is an Annual review of weightings.

Rectification Time

The Rectification Time is stated in the Service Requirements

In some cases there is none and hence immediate deduction applies.

The period commences

Logged Event Time (notification to helpdesk) is extended if the Board denies access to the area and in so doing prevents Rectification of that Event

When it goes wrong - consequences

Warning Notices issued by the Board

Increased monitoring by the Board at Project Co' cost

Exercise of remedial rights

Replacement of a non performing Sub Contractor

Project Co (IHSL) Event of Default (which can lead to termination)

The Helpdesk

It is vital to ensure that our staff understand how and when to report problems which are affecting them and in the delivery of patient care. There will either be contact made with our own in-house Estates & Facilities Helpdesk or the Project Co (IHSL) Helpdesk. To that end we are producing and influencing documentation to cater for all aspects and to communicate this. This will largely cater for reactive issues.

For planned and programmed maintenance works we have requested annualised and five-yearly look ahead programmes to ensure adequate planning and co-ordination can take place to absolutely minimise inconvenience to building users.

The Building User Guide

We are assisting in producing a Building User Guide which will cater from the outset as a one-stop guide to all you need to know about the operation of the building and its services. From the Family Hotel, ward level, Common Facilities all the information need to operate the facility safely and efficiently. This will be targeted at different levels dependent upon the audience.

This sits amongst a suite of documentation produced by Project Co (IHSL) together with jointly produced processes to ensure a robust level of co-ordination and co-operation takes place.

NHS Lothian

RHSC/DCN Edinburgh HV issues

19th Jun 2016

Health Facilities Scotland

1. Introduction

1.1. Health Facilities Scotland (HFS), were contacted my NHS Lothian (NHSL) via a telephone call on Tuesday 13th June 2016 to request a review of the High Voltage installation at The Royal Hospital for Sick Children (RHSC) in Edinburgh.

1.2. The initial request was backed up by email on 14th June 2016 which also provided some written context and schematics. The schematics provided are

- HV Schematic at Financial Close WW-XX-XX-SC-530-01_01-1
- HV Schematic revision F WW-XX-XX-SC-530-01-6 rev F
- Basement access 7 maintenance drawing (no drawing number)
- HV Cable routes (no drawing number)
- Energy Centre General Arrangement HLM-Z5-SL-PL-220-001_F

1.3. The questions asked by NHSL are as follows:-

- Does the installed fire wall separation of the substations comply with guidance and does the current arrangement constitute four separate substations?
- Does the route of the HV cables comply with SHTM 06 to provide critical care resilience?
- Does the HV solution provide a high degree of resilience if there is a loss of site wide HV supplies and in particular if there is a failure to substation 2A and 2B?
- Does the proposed solution adequately allow for partial or total shut down of the HV network in the event of a fire or some other emergency?
- Is the ventilation system appropriate for the substations?
- Should the LV and HV sections of the substation be segregated?
- What is Health Facilities Scotland's interpretation of the ventilation pressure requirements for four bed wards?

1.4. The questions posed in 1.3 will be considered and responded to in section 2.

2. Questions and responses

2.1. <u>Does the installed fire wall separation of the substations comply with guidance and does the current arrangement constitute four separate substations?</u>

- Can you confirm that the substations and surrounding plant rooms are defined as a "place of special fire risk" as per current Appendix A of Scottish Building Standards Non-Domestic Technical Handbook (NDTH)?
- The following are extracts from NDTH:-

2.1.8 Places of special fire risk

a place of special fire risk should be enclosed by compartment walls with a medium fire resistance duration. [note: for hospitals medium is 1hour fire resistant]

2.9.3 Travel Distance *see Table 2.11 Recommended travel distance (m)*

Within plant rooms or within roof top plant rooms: 1 Direction = 18m, >1 Direction = 45m

Within a place of special fire risk: 1 Direction = 9m, >1 Direction = 18m

2.9.10 Escape from inner room

Occupants within an inner room could become trapped where there is an outbreak of fire in the adjoining access room. Therefore, escape should only be by way of one other room, and the inner room should:

not be used as sleeping accommodation

have an escape route that does not pass through more than one access room

the access room should be fitted with a suitable automatic fire detection and alarm system to warn the occupants of the inner room of an out break of fire

the access room should not be a place of special fire risk.

2.9.16 However if the door is an emergency door or a door serving a place of special fire risk, the side-hung door should open in the direction of escape regardless of occupancy levels.

2.9.26 Due to a very high fire risk, with potential for rapid fire growth, a place of special fire risk should only be accessed from a protected zone by way of a protected lobby. This is to give additional protection to the protected route of escape.

2.14.9 Venting of heat and smoke from basements

Smoke outlets should ....

where they serve a place of special fire risk, they are separate from smoke outlets from other areas, and

Annex 2B: ***Additional guidance for hospitals***

Fire hazard departments

The departments in list A below should:

never be directly below, nor directly adjoin, the operating theatres, intensive therapy units or special care baby units, and

be provided with a fire suppression system (as in clause 2.1.2) where they are directly below, or directly adjoin, any other hospital department to which patients have access.

LIST A

boiler house

central stores

commercial enterprises

flammable stores

laundry

main electrical switchgear

main kitchens

refuse collection and incineration

works department.

A door from a hospital street to an adjoining compartment should:

be located so that an alternative independent means of escape from each compartment is available, and

not be located in the same sub-compartment as a door to a protected zone containing a stairway or lift.

Annex 2B.6 ...

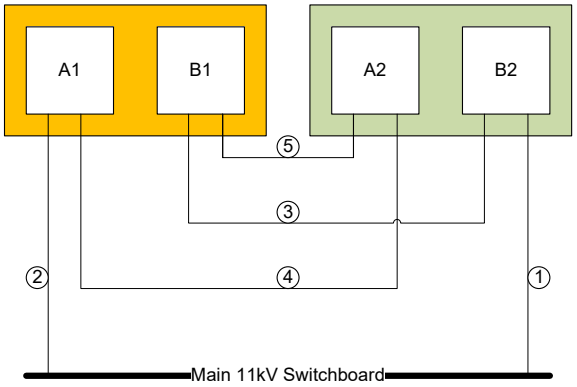
Different fire-fighting facilities should not be provided throughout the varying storey heights of a building. Once the topmost storey height of a building has been established, the intention is that fire-fighting facilities recommended at that height should be applied throughout the escape stair. Similarly, where a building contains a basement, the recommendations become more demanding the greater the depth.

Table 2.18 Facilities on escape stairs in hospitals with hospital streets:

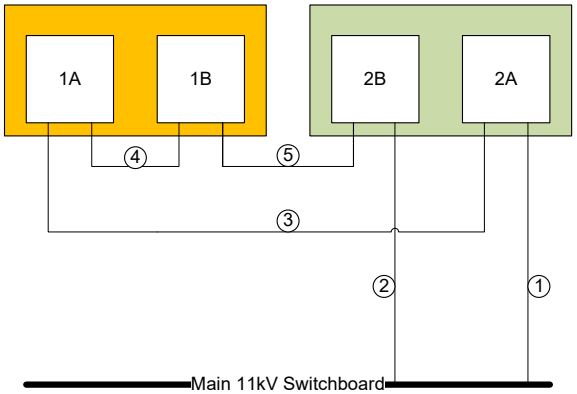
Basements at a depth <10m: fire-fighting stair (see clause 2.14.3); ventilation to stair (see clause 2.14.6); unvented fire-fighting lobby (see clause 2.14.5); dry fire main (outlet located at every departmental entrance).

2.2. Does the route of the HV cables comply with SHTM 06 to provide critical care resilience? Does the HV solution provide a high degree of resilience if there is a loss of site wide HV supplies and in particular if there is a failure to substation 2A and 2B? Does the proposed solution adequately allow for partial or total shut down of the HV network in the event of a fire or some other emergency? (Note: these questions considered together).

- Simplified schematics of the HV cabling and substation solutions are as follows:-



Financial close simplified schematic



Construction simplified schematic

- There is a material change between the financial close schematic (WW-XX-XX-SC-530-01_01-1) and the current construction schematic (WW-XX-XX-SC-530-01-6 revision F) with respect to the HV feeder cables.
- WW-XX-XX-SC-530-01-6 now shows the main feeder cables from the HV switchboard going to substations 2A and 2B. If both substations are lost (in say a fire event) there would be no HV circuit to Substations 1A and 1B.
- The financial close schematic shows the high voltage ring split between Substations A1 and B2. It is not clear from the schematics why this change has taken place.
- It is our opinion that the arrangement shown in WW-XX-XX-SC-530-01-6 is not as resilient as the solution shown in WW-XX-XX-SC-530-01_01-1. Further it is not clear how the solution shown in WW-XX-XX-SC-530-06 meets the various requirements for resilience with SHTM 06-01 (i.e. 4.37, 4.39, 4.40, 6.3 etc). Has a distribution risk assessment been carried out by the designers and clinical colleagues on the various electrical supplies to category 1 to 5 areas?
- It is noted that the Distribution network operator's (DNO's) HV switchgear and cables are close coupled to the main HV switchboard in the energy centre. Has a risk assessment been carried out for this arrangement and what is the fire strategy for this area?

2.3. Is the ventilation system appropriate for the substations?

- We are unable to comment on the ventilation rates to the substations as this is out with the scope of this report.
- The extract fans are shown in the substation. This means that they will not be able to be maintained without an authorised person for high voltage AP (HV), a permit to work and limitation of access permit. This may cause operation issues and SHTM 03-01 Part A 4.17 notes "Care should be taken during installation to ensure that electrical and mechanical services are not installed in positions that will reduce or impede access."
- Whist the extract fans are shown as duty and standby, there is no note on the resilience of the supply system. Further if these units (supply and extract) are fed via a single cable, this may be a cause for concern from a resilience perspective.

2.4. Should the LV and HV sections of the substation be segregated?

- SHTM 06-01 7.19 notes that "The access to any HV substation, including the HV side of a transformer, should be arranged so as to prevent unauthorised access (see Scottish Health Technical Memorandum 06-03)." It is not clear from the drawings how segregation from the HV and LV sections of the substations are achieved. Section 7 of SHTM 06-01 notes that "For the purpose of this guidance, HV substations are deemed to be the total area of the HV switchgear and transformer enclosure."
- SHTM 06-01 part A 9.41 notes advises that "Care should be taken to ensure that only HV Authorised Persons (AP (HV)) have access to the HV equipment."
- Section 3 of SHTM 06-03 outlines the Management policy for HV installations and this should be cross referenced to the installation to address any gaps.
- In addition SHTM 06-01 part A 7.18 requires that internal substations should have "a minimum of two sets of door openings connecting directly to a safe haven, on opposite sides, to provide suitable escape routes. Additional door openings will be required to ensure that the maximum travel distance to a safe haven is no greater than 9m." It is not clear that this is met given the potential layout of plant and equipment in the various rooms.
- The access strategy for plant and equipment is not clear from the drawings provided. How is a major item of plant, such as a transformer, intended to be replaced?
- Has the use of fire suppressions systems been considered and risk assessed for the substations (SHTM 06-03 7.25 et al).
- What clinical services are provided above each of these substations, the fire separation between the sub station and these areas and what is the resilience plan if there is a failure in these areas?

2.5. What is Health Facilities Scotland's interpretation of the ventilation pressure requirements for four bed wards?

- SHTM 03-01 Part A, Appendix 1, Table A indicates the air change rates and pressure regime for clinical areas within healthcare premises. There is no four bed ward noted

in Table A, however it would not be unreasonable to treat this area as one would a single bed ward with respect to ventilation as the measures for infection control would be the same. Therefore the room should be neutral or slightly negative with respect to the corridor.

- SHTM 03-01 Part A clause 1.35 et al details the Management Action with Clause 1.37 highlighting the need to seek guidance from Clinical colleagues.
- SHTM 03-01 Part A clause 1.39 et al details the Design and validation process. Table 2 highlights the model to be followed and item 2 outlines some the design questions to be asked and resolved.

3. Guidance reference

3.1. The following guidance documents have been used as reference documentation (al parts)

- SHTM 00
- SHTM 03-01
- SHTM 06-01
- SHTM 06-02
- SHTM 06-03
- SHTM 85
- Scottish Building Standards Non-Domestic Technical Handook

Susan

Thanks for passing on further correspondence from Alex and Donald Inverarity.

I respond to various points contained in numerous recent emails as follows:

1 Infection Control involvement in the project

I reiterate my email of 12/03/19 at 8.06 and 12/03/19 at 10.09 with further clarification in yellow:

On further reading of the chain of emails from Lindsay Guthrie to Alex can we just advise that Sarah Jane Sutherland, Lead HAI Scribe Advisor, and IPCN Emma Collett last visited the project on Monday 28th January, 2019 at 9.15am.

The purpose of this visit was to reassure Sarah Jane that Janette (recently retired HAI Scribe advisor) was fully involved in the room review process and in anticipation of an imminent completion or handover of the facility. Janette was provided with the timetable for our first and second round of reviews and she chose which ones she wanted to attend. To ensure a consistent approach was taken to the reviews a checklist of what to look at was developed, which was discussed with Janette. The project team have been consistently checking that previous observations made by them have been addressed and to identify any further observations that have occurred since the 2nd room reviews though to completion.

A further meeting on 27th February with one of the project's Commissioning Managers also took place to review previous documentation signed off by Janette Richards.
However, it is accepted that given the uncertainty of the actual completion date, to almost the day before it occurred, ICPT were not involved in the actual day of completion. It is worth emphasising that patients will not occupy the facility until 9th July, 2019. It is our intention to carry out a pre handover check when all construction activity by IHSL/MPX completes in June.

We can confirm that the Board's Infection Control have been involved from the early stages in the project including competitive dialogue, evaluation of some parts of the submission; actively

contributing with the clinical teams to the clinical area design development and approval process reviewing relevant specifications for items such as sanitary ware, flooring, vent coverings etc.

We have been fortunate in that there has always been a nominated IPCN for Reprovision and they have been an integral part of the process participating in key meetings and, if they could not be present at meetings, taking the opportunity to comment on meeting outputs where required and following up on issues in consultation with project and other clinical staff.

Throughout each of the stages of the project they have provided expert advice on elements such as isolation room design and functionality, room ventilation design, and HAI Scribe.

They have also joined project team personnel in reviewing the rooms for adherence to design brief, quality of finish and functionality, (including ease of cleaning and compliance with SHTM ~~and HEI guidance~~) and advised us on aspects of the building that they felt HEI inspectorate may consider during any future inspections.

2 Water Quality

Before updating you on the current water quality status on site we are at a loss to understand Donald's comment that "there was no further communication". The email attached to Donald's email is clearly a response (text in red) from our Hard FM Commissioning Manager. Indeed, we have still to receive a response to our request from Donald on whether the presence of Psedomonas species is an indicator of future risk of Pseudomonas Aeuriginosa

Current update is that all test results from latest full batch of sampling have come back clear for Legionella. Pseudomonas positives were found in 2 of 14 samples with elevated TVC counts, this from a total sample of 115. Further disinfection has taken place and the 14 elevated TVC locations will be re-sampled with results due by 20/03/19, until such times as these come back clear MPX are continuing with their responsibilities for water safety management. Further sampling will be carried out by Bouygues in the next 2 weeks once the current batch are all confirmed as clear and in addition there will be a further round of sampling at a time to be agreed prior to full operation. In the intervening period between the last two sampling exercises, Bouygues will implement a robust water management system involving flushing of little used outlets as per the positive obligation in the settlement agreement. It will be for the NHSL water safety management group to decide if this is enough reassurance as it complies with SHTM 04-01.

3 Ventilation to Isolation Rooms

All windows to isolation rooms and their lobbies are fixed pane windows (they do not open) except lobby 1-B1-033 which has been reported as a defect. I suspect Donald viewed room 1-B1-068 where works to correct an earlier identified defect were incomplete, this has now been resolved.

4 Theatre Ventilation Validation

Theatre ventilation commissioning, include cascade and UCV validation took place between October 2018 and February 2019 and all certificates and reports have been examined and verified by Arcadis as Independent Tester. These are available on the project data storage system 'Zutec'. These have however been rendered void by the agreed post completion works to enhance fire safety across the site and will be fully re tested and validated which will be witnessed by NHSL and the Independent Tester once these works are complete. In the meantime the information on the system can be reviewed by ICD and IPC at any time to ensure they meet their requirements. MPX will carry out air sampling on completion of their builders clean and prior to NHSL equipping the area. It is assumed IPC will wish to repeat this prior to theatres becoming fully operational.

5 Sub optimal Air Exchange Rates in clinical areas

During the review of the environmental matrix it was identified that air exchange rates within the single and 4 bedded rooms did not meet the recommendations of SHTM 03-01. Risk assessments were carried out and discussed with infection control staff (sample attached). A workable solution has been implemented which includes mixed mode ventilation where natural ventilation provides the difference between 4 and 6 ac/hr.

6 Consequences of water damage event

The project's Clinical Director and a Commissioning Manager toured the Facility on 5th July, 2019 with Janette Richards, Dr Pota Kalima and MPX and the remedial and reinstatement process proposed by IHSL/MPX was accepted in addressing the departments that were affected by the water damage. Donald's recommendation, in his email of 25/07/2018 to the project's Clinical Director that a building survey using a moisture meter to assess dryness of walls should be undertaken at the appropriate time will be undertaken. We assume the outcome of such a survey would suffice in providing the reassurance being sought by Fiona. To the best of our knowledge, and we believe also the Independent Tester's, all materials and systems damaged by water have been replaced.

We hope this clarifies the communications with Infection Control to date but needless to say we would welcome a walk round by Donald and members of the IPCT at any time as suggested by Alex.

Regards

Brian

All

I caught up with Donald after the DCN IMT. He said he would send me this email and I have his permission to forward on. For transparency I have copied Donald in.

The content gives me some cause for concern. Jim and Tracey can we take the opportunity to discuss this with Donald tomorrow afternoon. I know Jim you and I are meeting others at 4 but I think if we can take 5 mins just for a quick discussion that would be helpful.

In the meantime happy to take thoughts but one action we I am going to instruct is that Donald and members of the IPCT do a walk around of the whole building with the appropriate personnel.

Donald asks for sight of reports as set out below, Jim/Susan can we make these available as well.

Alex

From: Inverarity, Donald
Sent: 13 March 2019 15:37
To: McMahon, Alex
Subject: RE: Infection control + Ventilation Issues from Sunday Herald Article on Glasgow QEH- RHCYP
Sensitivity: Confidential

Dear Alex,
Following our discussion after the DCN IMT today, I'd like to raise a further issue that relates to water quality and ventilation in the new hospital site.
Please see the (confidential) e-mail dialogue attached which was sent to me by the commissioning team in the week before the building was handed over to NHS Lothian. It was highlighted that there were concerns about Pseudomonas aeruginosa and more concerningly Legionella in the water. Despite replying expressing concern particularly over the finding of Legionella, there was no further communication with me about the issue. I don't know where in the building this was found and I don't know what corrective action is/has been taken. Consequently it is not possible to risk assess whether there is a clinical risk to immunocompromised patients when they occupy the building without knowing if there are water issues in the clinical areas where such patients will be managed. Even if they have been addressed and corrected by the time patients are admitted later in the year, they would still count as higher risk areas that would deserve more scrutiny to ensure the level of Legionella remains low and would present a persisting clinical risk if in a clinical area.
I also mentioned to you the paediatric isolation rooms which are designed as positive pressure ultraclean rooms with HEPA filtered air and yet the windows open to the outside unfiltered Edinburgh air defeating the purpose of the room. I don't know if any corrective action has taken place regarding this design flaw which was identified by Lindsay, Ewan Olsen and myself when we were invited to review the design of the room and its ventilation pre handover.
Although given assurances that pre hand over there would be validation performed on all theatre ventilation, as ICD I've never seen any of these validation reports and neither have any of my consultant microbiologist colleagues albeit we were given a tour of the ventilation system and theatres as they were being built.
All the best
Donald

Subject: RE: Infection control + Ventilation Issues from Sunday Herald Article on Glasgow QEH- RHCYP

Brian

Alex sent on your email I am unsure what HEI guidance you are referring to. Healthcare Environment Inspectorate do not have standards for buildings. I can confirm any reviews, recommendations IPC made would be in alignment with the SHTM guidance by HFS for building works. I agree we did have involvement and a dedicate person i.e. our HAI SCRIBE lead involved. However as per communications with Alex IPC were not involved in handover as per SCRIBE guidance recommendations

I cannot reliably say if all our recommendations were accepted. I am aware as a result of the cancelled FOI there was discussion re air exchanges rates perhaps being suboptimal in clinical areas and we don't know what the outcome of that report was. The HAI SCRIBE documents or minutes of your project meetings should be able to confirm.

Another example IPCT can only assume the building engineer who accepted the building on behalf of NHS Lothian saw evidence of theatre validation See p114-124 of SHTM 03-01. IPC to the best of my knowledge have not seen a validation report (section 8.64-8.65 of SHTM 03-01). The validation/commissioning report should be a clearly understood document that outlines that the theatre is working optimally, not just engineering data, which allows us to have confidence in the efficiency of theatre ventilation and would go some way to provide the board with a level of assurance.

In addition not have we seen what evidence was provided to give NHS Lothian assurance that the consequences of the flood were fully addressed. Did the contractors provide assurance that all water damaged construction materials were replaced and there is no unnecessary residual damp material, particularly not in clinical areas. As previously advised by our ICD Dr Inverarity, damp building materials that are left in place to dry out over time are predisposed to growing moulds and fungus and that could take some time to show. The clinical risk that can result in depends on where the damp material is situated e.g. theatre or isolation room designed to protect patients from infection. Did the contractor provide a comprehensive assessment for residual damp in clinical areas or was this checked by an external authority to the contractor as I think was recommended by Dr Inverarity at the time.

Alex I have copied Lindsay and Donald as they may also wish to comment as Lead Nurse and Lead ICD

Hopefully the following will be useful:

Infection Control

We can confirm that the Board's Infection Control have been involved from the early stages in the project including competitive dialogue, evaluation of some parts of the submission; actively contributing with the clinical teams to the clinical area design development and approval process reviewing relevant specifications for items such as sanitary ware, flooring, vent coverings etc.

We have been fortunate in that there has always been a nominated IPCN for Reprovision and they have been an integral part of the process participating in key meetings and, if they could not be present at meetings, taking the opportunity to comment on meeting outputs where required and following up on issues in consultation with project and other clinical staff.

Throughout each of the stages of the project they have provided expert advice on elements such as isolation room design and functionality, room ventilation design, and HAI Scribe.

They have also joined project team personnel in reviewing the rooms for adherence to design brief, quality of finish and functionality, (including ease of cleaning and compliance with SHTM and HEI guidance).

Let me know if you need more on HAI Scribe and contractual obligations.

Ventilation

Through witnessing of commissioning activities we can verify that the correct grade of filters are installed in the various air handling units and the ductwork is designed in accordance with relevant guidance. Regular inspections are carried out and alarm monitoring also occurs via the building management system and warns of deteriorating filter conditions.

Judith

We will summarise what involvement Infection Control have had in the project to date, how HAI Scribe works and contractual obligations in terms of infection control standards.

The specific ventilation issues raised at Glasgow will also be responded to in relation to this project as I said earlier.

Subject: RE: Infection control- RHCYP

Hi again Brian,
Most of this details the standard daily infection control measures we would expect to operate once the building is open. Presumably we can say the building has been built to industry standards (and that's a start) but I would expect the QEUH could have done the same?

If (and I do mean; if) our own infection control team was not involved specifically, then :

- is there something explicit in the contract that gives us assurance that the building was designed to satisfy all latest infection control standards?
- Retrospectively, do we know it doesn't have the same design weaknesses (in ventilation duct design and safety alarms) that is the issue with QEUH?

On that first point , there's been reference to the HAI Scribe but I don't know what (or who??!) the scribe is. Not looking for the contract – just a means by which we can describe in layperson's terms how we derive assurance that the design takes account of infection control requirements.

Thanks!

Judith

PROUD HISTORIES | NEW CHAPTERS

From: MACKAY, Judith (NHS LOTHIAN) [redacted]
Sent: 11 March 2019 07:39
To: Currie, Brian; Graham, Iain
Cc: Crombie, Jim
Subject: Infection control- RHCYP

Morning all,

I anticipate questions from media today about the formal involvement of Infection Control expertise in the design of RHCYP / DCN in the wake of criticisms about the apparent lack of documented evidence of their involvement in the design / commissioning / handover of QEUH.

Please see this piece from yesterday's Sunday Herald.

https://www.heraldscotland.com/news/17489840.50m-repair-bill-for-glasgows-troubled-queen-elizabeth-university-hospital/

Can we state categorically that Infection Prevention and Control Team were fully and formally (in a governance sense) involved in the commissioning or handover process of RHCYP/DCN?

We are also likely to be asked explicitly if we know / have assurance that the design does not suffer from the same ventilation duct / safety alarm weaknesses as QEUH.

Since these were 2 of the issues that led to some delay late last year am I correct in thinking we were are satisfied RHCYP does not share same design issues on those counts?

Thanks for your help with this,

Regards

Judith

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie, Clinical Director Dorothy Hanley, RHSC Commissioning Lead Fiona Halcrow, Project Manager	**Date of Original Assessment:**	05/07/17. Reviewed 29/1/18
Manager Responsible:	Janice MacKenzie		
Department:	RHSC & DCN Reprovision Project		

Subject of Assessment: Consider Task or Environment.

Bedroom Ventilation design in 4 bedded rooms does not meet the recommendations of SHTM 03-01, as the current design has the 4 bedded rooms as being positive pressure.

To allow cohorting of patients with the same air-borne infections these rooms require to be balanced or negative pressure.

The Board have previously accepted that there is no need for cohorting of patients within DCN as they can operationally manage this due to the number of single rooms and types of patients and the need for cohorting of infectious patients would be extremely rare.

Whilst the Board can rationalise the number of 4 bedded rooms where the ventilation needs to change within RHCYP it should be noted that this does reduce overall flexibility and future-proofing. A further review was undertaken with the Children's CMT in January 2018 of the initial risk assessment completed in July 2017 to ascertain what 4 bedded rooms would be essential. Given the different patient groups related to specific wards, separate risk assessments have been undertaken (see attached). Individual risk assessments have identified that the need for cohorting of patients is only an issue for the Children's Service. Risk assessment highlights that it is **essential** to change the ventilation in 7 of the 4 bedded rooms within RHCYP. It would be **desirable** to change the ventilation in 6 of the 4 bedded rooms within RHCYP. No change to 7 of the 4 bedded rooms in RHCYP and DCN

The risk assessments have been discussed with the Children's CMT and Infection Control & Prevention who have confirmed that not having the ability to cohort patients is not acceptable from a patient safety perspective. A summary of risk for each area is provided after Section 3.

Step 1: What are the Hazards?

Overall Risks:-

- The inability to cohort patients with air-borne infections in a clinically safe environment
- Clinical risk to isolating babies and children under two years of age with airway compromise i.e RSV
- Need for increased staffing requirements due to the observation and interventions required in this patient group if nursed in singe rooms
- Reduction in overall flexibility and future proofing would be limited if change of use of a ward/s was required
- Reputational risk as one of the key drivers, as outlined in the FBC, is to provide improved modern facilities that overcome the challenges currently faced within the existing facilities that cannot be adapted to provide the best services possible.

See separate risk assessments for inpatient ward/s as the risk rating for each ward/s is different dependent upon the patient group and clinical risk

Step 2: Who might be harmed and how?

See separate risk assessments for specific ward/s

Step 3: What are you already doing? (Existing Precautions)

Generic Precautions

- Isolation rooms have positive pressure lobby which acts as an air curtain and also have a hepa-filter to prevent the transfer of air-borne infection from the corridor into the room or the room into the corridor.
- All single rooms have balanced or slightly negative pressure.
- Increase in the number of single and isolation rooms (See separate risk assessment for the number of isolation and single rooms by ward) from 30% to 62%.
- Ability to flex beds between adjacent wards giving greater flexibility
- Within RHCYP wards there will be technology to remotely monitor patient oxygen saturation levels and heart rate

Summary of Risk by Ward/s (Essential to have ventilation changed)

Ward/s	Proposed Action	Risk Rating If No Change	Risk Rating if Change Implemented
RHCYP - PARU	All three 4bedded rooms (A2- 028, 046 & 054)	15	4
RHCYP – Medical Inpts	All two 4bedded rooms(C1.1-018 & 046)	10	3
RHCYP – Critical Care	One 4 bedded room low acuity HDU (B1-	9	3

	063) & 3 bedded room surgical neonates (B1-065)		

Summary of Risk by Ward/s (Desirable to have ventilation changed)

RHCYP – Critical Care	4 bedded room intensive care (1-B1-009)	8	2
RHCYP – Surgical Long Stay Ward	All two 4 bedded rooms (C1.2-023 & 026)	6	2
RHCYP - Neurosciences	All two 4 bedded rooms (C1.3-011 & 013)	6	2
RHCYP – Medical Day Case Unit	One 3 bedded room (D9-022)	6	2

Summary of Risk by Ward/s (No change to ventilation)

RHCYP – Surgical Short Stay Ward	No change to ventilation in the two 4 bedded rooms	1	
RHCYP – Critical Care	No change to high acuity 4 bedded room (B1-031)	1	
RHCYP – Haematology Oncology Day Care	No change to ventilation in the two multi-bed day care areas	1	
DCN – Acute Care Ward	No change to ventilation in the two 4 bedded rooms	1	

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
Clear Guidance in the Building Users Guide as to what 4 bedded rooms can be used to cohort patients with air-borne infections See separate risk assessments for specific actions by ward/s	Jane Campbell	March 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project - **RHCYP PARU (A2)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within PARU

Step 1: What are the Hazards?

Significant clinical risk to isolating babies and children under two years of age with airway compromise, some of whom may have co-morbidities where isolation in single room carries additional clinical risk.

If PARU has no cohort areas the hazards are:-

- There is a risk that the 6 shelled beds would require to be opened and additional staffing resource would be required
- Additional staffing would be required to safely care for these patients in single rooms due to the level of observation and intervention required. This has not been accounted for in the agreed workforce plan.
- Reduction in the overall capacity within RHCYP as more single rooms would be required to be used to board patients potentially resulting on the cancellation of elective patients.
- Reliance on remote patient monitoring for oxygen saturation and heart rate to ensure patient safety is increased

The Children's CMT have confirmed that all three of the 4 bedded rooms to have negative/balanced pressure

Step 2: Who might be harmed and how?

Patients: -

- Boarding of patients into other specialities is a recognised clinical risk.
- Patients from whom cohorting may be safest clinical option despite the availability of a single room e.g a child under two years of age with respiratory infection plus co-morbidity (cardiac or neurological) who because of their complex underlying condition need constant observation.

Step 3: What are you already doing? (Existing Precautions)

PARU has 34 beds:-

- 3 x 4 bedded rooms
- I x isolation room
- 21 x single rooms

Increased number of beds in single rooms and 4 bedded rooms as opposed to 6 bedded rooms (in existing hospital).

Procuring a remote monitoring system for oxygen saturation and heart rate to alert staff to a potential deterioration in patient's condition

Level of Risk with no cohort area 15

Level of Risk with cohort area 4

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
Careful selection of patients for boarding	Nursing & Medical Teams	Ongoing	
Use of remote technology to assist with monitoring of patients in single rooms	Nurse in Charge & Consultant	Ongoing	
Clear guidance in the Building Users Guide regarding cohorting of patients with air-borne infections	Jane Campbell	March 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director		
Department:	RHSC & DCN Reprovision Project – **RHCYP Medical Inpatients (C1.1)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Medical Inpatients

Step 1: What are the Hazards?

Despite the fact it is planned that PARU will take all of the acute general admissions, reliance on a cohort area within this ward is only marginally reduced, particularly in times of peak activity when PARU would be unable to accommodate all of the RSV patients.

The Children's CMT have confirmed that all three of the 4 bedded rooms to have negative/balanced pressure

Step 2: Who might be harmed and how?

Patients from whom cohorting may be safest clinical option despite the availability of a single room e.g a child under two years of age with respiratory infection plus co-morbidity (cardiac or neurological).

Step 3: What are you already doing? (Existing Precautions)

Increased number of single and isolation rooms within medical inpatients:-

- 2 x 4 bedded bays
- 4 x Isolation Rooms
- 11 x single rooms

Procuring a remote monitoring system for oxygen saturation and heart rate to alert staff to a potential deterioration in patient's condition

Level of Risk if no change made 10

Level of Risk with Cohort Areas 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
Careful selection of patients for boarding	Nursing & Medical Teams	Ongoing	
Use of remote technology to assist with monitoring of patients in single rooms	Nurse in Charge & Consultant	Ongoing	
Clear guidance in the Building Users Guide regarding cohorting of patients with air-borne infections	Jane Campbell	March 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Fiona Halcrow	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP Critical Care (B1)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Critical Care Unit

Step 1: What are the Hazards?

Clinical risk is still relatively high if no cohort area available and therefore operationally to retain the ability to cohort within B1-063 (low acuity HDU) and B1-065 (surgical neonates) is essential and it would be clinically and operationally desirable for B1-009 (intensive care).

The Children's CMT have confirmed that all three of the 4 bedded rooms to have negative/balanced pressure

Step 2: Who might be harmed and how?

Patients through spread of infection.

Step 3: What are you already doing? (Existing Precautions)

Critical Care (B1) – 24 beds

- 1 x 4 bedded rooms (low acuity)
- 2 x 4 bedded bays (intensive care & high acuity)
- 1 x 3 bedded room (surgical neonates)
- 4 x isolation rooms
- 5 x single rooms

The increased number of single rooms and a higher nurse to patient ratio within the Critical Care Unit will help mitigate the risk of nursing patients in single rooms

Level of Risk if no cohort area 9

Level of Risk if cohort retained 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that two 4 bedded rooms (ITU & high acuity high dependency) and one three bedded room (surgical neonates) cannot be used to cohort patients with air-borne infections	Jane Campbell	March 2018	
Careful placement of patients within the designated areas	Senior Nurse in Charge & Consultant	Ongoing	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Fiona Halcrow	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP – Surgical Wards (C1.2 & C1.8)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients with air-borne infections within the Surgical Wards

Step 1: What are the Hazards?

- It would be clinically and operationally desirable for the 2x 4 bedded rooms in Surgical Long Stay (C1.2-023 & 026) to provide future proofing and flexibility
- Clinical risk is low as increased number of single rooms within Medical wards reduces the need to board patients into the surgical wards from the medical wards
- Compromise possible in not altering ventilation in the 4 bedded rooms in Surgical Short Stay but reduces flexibility and future proofing

Step 2: Who might be harmed and how?

Patients through spread of infection.
Potential cancellation of elective surgical cases as staff group will be required to deliver 1:1 care who potentially could be cared for within a cohort area

Step 3: What are you already doing? (Existing Precautions)

There are two surgical wards:-

Surgical Short Stay has 14 beds:-
- 2 x 4 bedded rooms
- 6 x single rooms

Surgical Long Stay has 15 beds:-
- 2 x 4 bedded rooms
- 7 x single rooms

Increased number of beds within PARU and medical inpatients to reduce the need to board patients

Level of Risk if no cohort area in either ward 6

Level of Risk if cohort retained in Surgical Long Stay 2

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	March 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP – Neurosciences (C1.3)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Neurosciences Ward

Step 1: What are the Hazards?

- It would be clinically and operationally desirable for the 2x 4 bedded rooms to provide future proofing and flexibility
- Clinical risk is low as increased number of single rooms within Medical wards reduces the need to board patients into the neuroscience ward from the medical wards

Step 2: Who might be harmed and how?

Patients through spread of infection.
Potential cancellation of elective cases as staff group will be required to deliver 1:1 care who potentially could be cared for within a cohort area

Step 3: What are you already doing? (Existing Precautions)

The Neurosciences Ward has 12 beds

- 2 x 4 bedded rooms
- 1 x isolation room
- 3 x single rooms

Increased number of single rooms including one isolation room within this ward to allow the ward to care for neurosciences patients with an infection within the ward and not board in other wards which is the case in the existing hospital.

Level of Risk if no cohort area 6

Level of Risk if cohort retained 2

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	Mach 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP – Medical Day Case Unit (D9)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Medical Day Case Unit

Step 1: What are the Hazards?

- It would be clinically and operationally desirable for the 3 multi-bedded room to provide future proofing and flexibility
- Clinical risk is low as increased capacity and number of single rooms within Medical wards reduces the need to have to open the MDCU for medical inpatients

Step 2: Who might be harmed and how?

Patients through spread of infection.
Potential cancellation of elective surgical cases as staff group will be required to deliver 1:1 care who potentially could be cared for within a cohort area

Step 3: What are you already doing? (Existing Precautions)

The Medcial Day Case Unit has:-

- 1x3 bedded room (less sqm per space than an inpatient ward)
- 2 x single rooms

Increased capacity within the medical wards andsingle rooms and isolation rooms within these wards

Level of Risk if no cohort area 6

Level of Risk if cohort retained 2

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	Mach 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)
08/02/19	Janice Mackenzie	Consideration of IT feedback and ongoing discussions with IHSL	Approved by CMT 29/1/18

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP Haematology/Oncology Ward (C1.4)**		

Subject of Assessment: Consider Task or Environment.

Patient pathway for day care patients with a known infection

Step 1: What are the Hazards?

This is a combined inpatient and day care facility, however the design separates these two areas. Operationally the clinical team have already agreed a compromise where patients with infections coming to day care would be dealt with in the consulting room within day care or the inpatient facility. The Board have previously accepted that they can operationally manage these areas without a change in ventilation to the 2 day care rooms.

Step 2: Who might be harmed and how?

N/A

Step 3: What are you already doing? (Existing Precautions)

Haematology/Oncology Ward has 17 inpatient beds and 9 day care beds/trolleys:-

- 5 x isolation rooms
- 12 x single rooms
- 1 x 6 bedded day care room
- 1 x 3 bedded day care room

Operational policy has been agreed for the management of day care patients with an infection

Level of Risk 1

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state the type of pressure in the Day Care areas	Jane Campbell	March 2018	
Written patient pathway and operational policy for the management of day care patients with an infection	Charge Nurse & Lead Consultant	March 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Fiona Halcrow	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Hester Niven, Clinical Nurse Manager DCN		
Department:	RHSC & DCN Reprovision Project – **DCN Wards**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients with air-borne infections within DCN wards

Step 1: What are the Hazards?

The Board have previously accepted that they can operationally manage these wards due to the number of single rooms and types of patients and the need for cohorting of infectious patients would be extremely rare

Step 2: Who might be harmed and how?

N/A

Step 3: What are you already doing? (Existing Precautions)

DCN has three wards:-

DCN Acute Care (L1) – 24 beds
- 2 x 4 bedded rooms
- 1 x isolation room
- 15 x single rooms

DCN Inpatients Wards (L2) – 43 beds
- 2 x isolation room
- 41 x single rooms

Significant increase in the number of single rooms as compared to existing facility

Level of Risk 1

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	March 2018	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

Hi Ronnie
Please find attached my first stab at preparing a quotation for you, please accept this as an indication of costs and may change following your meeting with Paul tomorrow.
Please do not hesitate to contact me with any queries you may have.
Kind Regards,
Alison

Subject: Independent Validation
Importance: High

Hi Alison,
Good to talk to you earlier.
As discussed we are looking for independent validation to SHTM 03-01 of 10 theatres (7 of which are UCV but can also be used as conventional), 19 isolation rooms, 1 angiography procedures room, 1 intra-operative MRI, and ITU/HDU/NNU. There are also 3 standard MRI's, & 2 CT's, which are non interventional, if these are required under 03-01.
Due to the large volume I will forward all relevant drawings tomorrow and look to set up an introduction and planning meeting for early next week with a view to carrying the validation out week beginning 17/6.
If you could liaise with your Edinburgh office and confirm availability for that week as well as indicative time and cost I will raise the order.
Thanks and best regards
Ronnie

For the attention of Ronnie Henderson
NHS Lothian
Royal Infirmary of Edinburgh

Dear Ronnie

Thank you for your recent enquiry regarding the validation and testing of 3 Conventional Operating Theatres, 7 UCV Theatres, 19 isolation rooms, angiography procedures room, 1 intra-operative, ITU, HDU, NNU, 3 standard MRI's and 2 CT's.

IOM will carry out the following tests in accordance with SHTM 03-01 and will include the following testing;

Conventional Operating Theatre

- Supply and extract airflow measurements in each theatre and associated peripheral rooms with subsequent calculation of air change rates
- Airflow measurements within the Recovery areas if applicable
- Pitot duct traverse to measure total quantities of fresh air supply (where possible)
- Pressure differentials across doors to provide the pressure cascade figures
- Electronic particle counting to assess the air filtration efficiency between inlet air and theatre supply air
- Noise measurements in the theatre and peripheral rooms, using a Type 1 Integrated sound level meter
- Audit of air handling units in accordance with Appendix 1, Part B of SHTM 03-01. This audit will include a thorough internal and external visual inspection of all sections of the air handling unit to assess the condition of the unit and its associated services and plant
- Audit of the operating suite in accordance with Appendix 2, Part B of SHTM 03-01
- UKAS accredited airborne microbiological sampling and enumeration in an empty theatre, to include 4 airborne sample plates and a control plate per theatre, incubated at 37°C for 24h±2h followed by 22°C for 24h±2h.
- Check that the fire damper proving tests has been carried out (para. 8.28 SHTM 03-01)

- Check controls/warning lights and surgeons panel display function
- Dirty filter simulation to assess whether the AHU can deliver the design airflow volume even under dirty filter conditions
- Smoke visualisation test to assess mixing / dilution
- Full validation report

Ultra Clean Ventilation

- Airflow measurements at 2m and 1m below the UCV canopy
- Pitot duct traverse to measure total quantities of fresh air supply (where possible)
- Particle count check at the face of the HEPA filters and seals to check for potential leakage paths
- Entrainment testing of the UCV canopy using an electronic particle counter
- Noise measurements under UCV canopy and in peripheral rooms, using a Type 1 Integrated sound level meter
- Supply and extract airflow measurements in associated peripheral rooms
- Airflow measurements within the Recovery areas if applicable
- Pressure differentials across doors to provide the pressure cascade figures
- Pressure differentials to be checked with the UCV canopy in setback
- Audit of air handling unit in accordance with Appendix 1, Part B of SHTM 03-01. These audits include a thorough internal and external visual inspection of all sections of the air handling unit to assess the condition of the unit and its associated services and plant
- Audit of the operating suite in accordance with Appendix 2, Part B of SHTM 03-01
- Check that the witnessing of the fire damper proving tests has been carried out (para. 8.28 SHTM 03-01)
- Check controls/warning lights and surgeons panel display function
- Dirty filter simulation to assess whether the AHU can deliver the design airflow volume even under dirty filter conditions
- Smoke visualisation test to assess mixing / dilution
- Full validation report

Charges

The total price to undertake the measurements as described above will be £27,459.00* plus VAT.

Any additional time required on site, for example, due to delays and system unavailability which is beyond IOM's control, or where IOM are requested to assist with adjustments to airflows and balancing, will be charged at £80.00 per hour.

Please do not hesitate to contact me should you wish to discuss any aspect of this quotation in further detail.

Yours sincerely

[redacted]

Alison Parton
Healthcare Ventilation Dept.

IOM CONSULTING LIMITED

STANDARD TERMS AND CONDITIONS OF SERVICE ("these Conditions")

Interpretation

1 In these Conditions:-

"Authorised Person" means an employee of IOM holding the office of project manager in relation to the Services, an employee holding the office of director or a legally appointed director of IOM;

"Client" means the party named in the Quotation for whom IOM has agreed to provide the Services;

"IOM" means IOM Consulting Limited, a company incorporated under the Companies Acts (Company Registration Number SC205670), having its registered office at Research Avenue North, Riccarton, Edinburgh, EH14 4AP;

"Quotation" means IOM's quotation for the Services provided to and accepted by the Client; and

"Services" means the services to be provided by IOM to the Client as set out in the Quotation and, where applicable, as varied under these Conditions.

The Services

2.1 IOM will carry out the Services with all the reasonable skill, care and diligence to be expected from a professional person or firm in the performance of similar services under these Conditions and in accordance with relevant industry standards current at the time. IOM may provide the Services using members of staff from various geographic locations across the United Kingdom.

2.2 IOM will promptly notify the Client if any aspect of the Services is found to be, or expected to be, significantly different from that addressed in the Quotation as a result of (a) site conditions; (b) new information; and/or (c) safety and/or environmental factors if this is likely to have an effect on the fees and expenses payable by the Client or schedule of the Services. In such circumstances, IOM reserves the right to vary the Services on the basis that the Client agrees to bear the costs of additional work in accordance with the terms of clause 3.4.

2.3 Unless otherwise agreed between the Client and IOM, all reports produced in the performance of the Services will be addressed to the Client only. Reports shall only be used by the Client for the purpose set out in the Quotation and shall not be relied upon or used for any other purposes or by any other party without the prior written permission of an Authorised Person.

Charges and Payment

3.1 In consideration for the provision of the Services, the Client shall pay to IOM the fees (including the fees of sub-contractors where appropriate), inclusive of VAT, and expenses specified in the Quotation.

3.2 The estimate of fees and expenses for the Services are as set out in the Quotation. Both the estimate and the charge out rates and expenses quoted in the Quotation will remain valid for a period of 30 days from the date of the Quotation. IOM reserves the right to apply an increased level of fees (such increase to be notified to the Client) in the event that the period during which the Services are provided extends beyond a period of 6 months.

3.3 Unless otherwise stated in the Quotation:-

3.3.1 the charge out rates quoted shall be charged for all consultant time spent on the provision of the Services, including travelling time; and

3.3.2 all expenses will be charged at cost plus a reasonable handling charge.

3.4 Any increase in the scope or extent of the Services from that specified in the Quotation will be subject to additional charges, such charges being calculated at the charge out rates agreed in respect of the Services, or, if no specific rates were agreed for that specific type of work, at the charge out rates charged by IOM for that type of work.

3.5 IOM reserves the right to charge a cancellation fee for any work cancelled at short notice and for any pre-authorised non-refundable expenses that are quoted in addition to the fees. The cancellation fee will apply as follows:

100% fee Less than 1 working days' notice prior to the scheduled works
75% fee Less than 3 working days' notice prior to the scheduled works
50% fee Less than 5 working days' notice prior to the scheduled works

3.6 This agreement is divisible. Where more than one report is produced in the performance of the Services, each report shall be deemed to arise from a separate agreement and shall be invoiced separately. Any invoice for a report produced in the performance of the Services shall be payable in full within 14 days of the date of the invoice, without reference to and notwithstanding any defect or default in delivery of any other report produced in the performance of the Services. Notwithstanding this, IOM may issue interim fees to the Client if IOM, in its sole discretion, considers it reasonable and appropriate to do so in the circumstances.

3.7 In the event that the Client fails to pay any invoice in full within 14 days of the due date, IOM reserves the right (without prejudice to the terms of clause 10.2 below) to:-

3.7.1 charge interest on the amount outstanding at the rate of 5% per annum over the base rate from time to time of the Bank of England. Notwithstanding this, IOM may in the alternative claim interest at its discretion under the Late Payment of Commercial Debts (Interest) Act 1998; and

3.7.2 suspend the provision of the Services until the amount outstanding has been paid, it being expressly agreed that IOM shall have no liability for any loss, injury or damage suffered by the Client or any other person as a result of the suspension of provision of the Services pursuant to this clause.

Confidentiality

4.1 Neither party will, at any time, disclose any information of a confidential nature relating to the other party acquired during the performance of the Services to any third party (other than to its employees, officers, representatives or advisers who need to know such information for the purposes of carrying out its obligations under the Quotation) without the prior written consent of the other unless (a) such information is already in the possession of the third party prior to its disclosure (other than as a result of the breach of any obligation of confidence owed to the party in question); (b) such information is already common knowledge or becomes so through no fault of that party; or (c) either party is compelled to disclose such information under a duty or obligation owed to or imposed by any court of competent jurisdiction, regulatory or government authority or body.

4.2 For the avoidance of doubt, the duty of confidentiality set out in clause 4.1 shall continue to apply without limit of time after the completion or termination of the provision of the Services subject to the exclusions detailed in that clause.

Intellectual Property

5.1 All copyright, trademark, patent and other intellectual property rights in all original drawings, designs, proposals, reports, recordings and other original works, discoveries or inventions made by IOM in the course of the provision of the Services or otherwise as a result of the provision of the Services shall belong to and remain vested in IOM and shall be treated as confidential by the Client in accordance with clauses 4.1 and 4.2.

5.2 IOM will grant a personal, non-exclusive, non-transferable royalty free perpetual licence in favour of the Client to use the same for the purposes specified in the Quotation subject always to the right of IOM to terminate the licence in the event that the Client fails to make payment of IOM's fees and expenses on the due date.

IOM Personnel

6.1 During the provision of the Services, and for a period of 12 months after termination of the provision of the Services, neither the Client nor any company associated with the Client, shall offer employment to any member of staff of IOM involved in the provision of the Services nor solicit or attempt to entice away any such employee without the prior written agreement of a director of IOM.

Liability and Insurance

7.1 Other than in respect of death or personal injury caused by IOM's negligence, IOM shall not be responsible for any loss, damage, delay, loss of market, costs or expenses of whatsoever nature or kind and howsoever sustained or occasioned, except as provided for in these Conditions.

7.2 Subject to clause 7.1, IOM shall under no circumstances whatever be liable to the Client, whether in contract, delict (including negligence), breach of statutory duty, or otherwise, for any loss of profit, or any indirect or consequential loss howsoever arising.

7.3 IOM's liability shall be limited to the extent of any damage, injury or loss that is directly attributable to the failure of IOM, its employees, subcontractors and/or agents to comply with the obligations on the part of IOM as provided in these Conditions. For the avoidance of doubt, IOM shall have no liability to indemnify the Client in respect of any indirect or consequential losses or damages whatsoever and howsoever arising.

7.4 The Client acknowledges and accepts that the fees and expenses do not contain a premium sufficient to cover IOM's risk of unlimited liability in respect of the Services and that a limitation of liability is reasonable bearing in mind the relevant circumstances, including the cost and availability or otherwise of insurance cover. Without prejudice to the remainder of this clause, IOM shall be liable to the Client for such direct losses of the Client as are attributable directly to IOM's work limited to an aggregate amount equivalent to ten times the fees charged subject always to a maximum of £5,000,000.

7.5 IOM will maintain cover in respect of public liability and professional indemnity insurance during the course of provision of the Services and for a period of one year thereafter, provided always that such insurance is available at commercially reasonable rates. Details of the policies are available on reasonable request. In the event that IOM ceases to carry such cover as a result of it ceasing to be available at commercially reasonable rates, IOM will promptly notify the Client of that fact.

7.6 Where in the provision of the Services any employee of IOM is required to act in a representative capacity by carrying out instructions or acting on behalf of the Client, IOM shall be deemed to be acting as the Client's agent. The Client hereby agrees to indemnify both IOM and IOM's employee(s) against any claim for which IOM and IOM's employee(s) may be liable for as a result of acting as the agent of the Client by reason of the acts or omissions of the Client.

Force Majeure

8.1 If IOM is delayed in the provision of the Services by any act or default of the Client or any other party or by any cause beyond the reasonable control of IOM, the period of completion of the Services shall be extended by a reasonable period and IOM will be entitled for payment of any additional costs reasonably incurred which are attributable to the delay.

8.2 Neither party shall be liable or deemed liable to the other party for failure or delay in meeting any obligation hereunder due to acts of God, warfare, industrial dispute (whether of its own employees or those of others), acts of terrorism, flood, fire, environmental incident, any other natural disaster, acts of Government or regulatory authority or any other cause beyond the reasonable control of the party which has a duty to perform provided that the affected party has given the non-affected party prompt written notice, with full details, following the occurrence of the cause relied upon. In such circumstances, the affected party shall be entitled to a reasonable extension of the time for performing such obligations provided that if the period of delay or non-performance continues for 90 days, the non-affected party may terminate the provision of the Services by giving not less than 14 days' written notice to the other party.

Communication

9.1 IOM frequently makes use of e-mail when communicating with clients and any other advisers or parties involved in providing the Services. The Client authorises IOM to use e-mail communication as IOM see fit in the course of providing the Services. The Client understands and acknowledges that the electronic transmission of information by e-mail on the Internet or otherwise has inherent risks and that such communications may become lost, delayed, intercepted, corrupted or be otherwise altered, rendered incomplete or fail to be delivered. IOM shall use reasonable endeavours to ensure that electronic communications that are sent are free from viruses and any other material which may cause inconvenience or harm to any other computer system and the Client undertakes to do likewise with any electronic communications they may send to IOM. However, because the electronic transmission of information cannot be guaranteed to be secure or error-free and its confidentiality may be vulnerable to access by unauthorised third parties, IOM shall have no responsibility or liability to the Client on any basis other than our bad faith or wilful default in respect of any error, omission, claim or loss arising from or in connection with the electronic communication or information to the Client (or the Client's reliance on such information). Without prejudice to the foregoing, IOM may advise the Client from time to time of methods of authentication and validation of electronic communications which IOM may wish to use and which IOM may also require the Client to use.

9.2 All correspondence shall normally be by first class mail, facsimile or electronic mail other than correspondence dealing with termination, which shall be by recorded delivery.

Termination

10.1 Either party may terminate the provision of the Services by serving one month's written notice on the other party.

10.2 IOM may terminate the provision of the Services, without liability, by serving written notice on the Client where:-

10.2.1 the Client fails to make any payment of an invoice on the due date; or

10.2.2 the Client is unable to pay its debts within the meaning of section 123 of the Insolvency Act 1986, or being an individual or partnership is declared bankrupt; or

10.2.3 a trustee, receiver, administrative receiver or similar officer is appointed in respect of the whole or any part of the business or assets of the Client.

10.3 In the event of termination under this clause 10, the Client will pay IOM for the Services performed up to and including the date of termination.

Status of These Conditions

11.1 These Conditions constitute the entire agreement and understanding between IOM and the Client and supersedes any previous arrangement, understanding or agreement between the parties relating to the provision of the Services.

11.2 No variation to these Conditions shall be binding unless agreed in writing and signed on behalf of IOM by an Authorised Person.

11.3 No rights or obligations may be assigned or delegated by either party without the prior written agreement of the other party.

11.4 No waiver by IOM of any breach of these Conditions by the Client shall be considered as a waiver of any subsequent breach of the same or any other provision.

11.5 The provisions of these Conditions are severable and if any provision is held to be invalid or unenforceable by any court of competent jurisdiction, then such invalidity or unenforceability shall not affect the remaining provisions of these Conditions.

11.6 These Conditions shall be governed by and construed in accordance with Scots Law. The Client agrees that the Scottish Courts shall have exclusive jurisdiction over any dispute that arises between the parties.

IHS LOTHIAN LTD **Disputed Works Schedule Appendix 1 Item 18 (Formally Project Co Change 050)**

Date – 28/08/2018	**Reference IHSL - 050**

Title - Neutropenic Patients Ventilation

1.0 Detail of Change

Financial Close Position

At Financial Close, Project Co proposed the following design and construction solution for single bed rooms within the Haematology and Oncology Department (C1.4)

Room Type & Department	FM Room Code	Pressure (Pascals) Differential to Corridor	Air Change / Hour
Single Bed Rooms Haematology and Oncology	3-C1.4-059	0 (balanced)	4
	3-C1.4-057	0 (balanced)	4
	3-C1.4-055	0 (balanced)	4
	3-C1.4-046	0 (balanced)	4
	3-C1.4-032	0 (balanced)	4
	3-C1.4-018	0 (balanced)	4
	3-C1.4-016	0 (balanced)	4
	3-C1.4-013	0 (balanced)	4
	3-C1.4-010	0 (balanced)	4

Furthermore, the following single rooms were added as part of Board Change Notice (RHSC DCN 032 & 035) for the expansion of the Haematology and Oncology Department following the removal of the Biochemistry Department (U1).

Single Bed Rooms	3-C1.4-074	0 (balanced)	4
	3-C1.4-076	0 (balanced)	4
	3-C1.4-078	0 (balanced)	4

Proposed Project Co Change

Project Co are not proposing to alter the design. However, the Boards view is that the design is non-compliant with Schedule Part 6, Sub Section C, Clause 2.1 (Approach to Design) and Clause 8 (Mechanical & Electrical Engineering Requirements) of and Sub Section D, C1.4 Haematology & Oncology Inpatients & Day Care Clinical Output Based Specification and SHTM 03-01 (Ventilation for healthcare premises Part A – Design and validation) Table A1 (Appendix 1: Recommended air change rates).

In summary, the Haematology and Oncology Department treat a range of medical issues which can be dealt with in a number of situations. The Financial close design proposes this solution as a mix of single bedrooms and full isolation suites. The Board would have preferred all single rooms in haematology and Oncology to have been suitable for neutropenic patients.

2.0 Reasons

Project Co's Financial Close design assigned balanced pressure to the neutropenic single bedrooms. The conclusion of design workshops held throughout the Construction Phase confirmed that, a balanced pressure regime will be managed operationally and is acceptable on the basis that 5 isolation suites are provided in accordance with SHTM 03-01.

3.0 Implications

Project Co require relief from the following:

- Section 2.1 (Approach to Design) of Sub-Section C (General Requirements) of Section 3 (Boards Construction Requirements) of Schedule Part 6(Construction Matters), which states:
  Project Co shall take cognisance of all the architectural and building services implications of the requirements described in the Board's Construction Requirements in this Schedule Part 6 Section 3 Sub-Section D (Specific Clinical Requirements) and Sub-Section E (Specific Non-Clinical Requirements).

- Section 8 (Mechanical & Electrical Engineering Requirements) of Sub-Section C (General Requirements) of Section 3 (Board's Construction Requirements) of Schedule Part 6 (Construction Matters), which states:
  Project Co shall take cognisance of all the building services implications of the requirements described in Section D (Specific Clinical Requirements) and Sub-Section E (Specific Non-Clinical Requirements) of Sub-section C of the Board's Construction Requirements.

- Section 1.1.1 (Scope of the Service) of C1.4 (Haematology & Oncology Inpatients & Day Care Clinical Output Based Specification) of Sub-Section D (Specific Clinical Requirements), which states:
  The paediatric Haematology and Oncology Unit, (Inpatient and Day Care services), is to provide a 24 /7 service for the care of all patients with cancer or blood dyscrasia (a pathologic condition in which any of the constituents of the blood are abnormal in structure, function, or quality, as in leukaemia or haemophilia). Patients and families will attend for assessment, investigations, treatment, ongoing care planning, and palliative and end of life care.

  The type of services provided include:

  - *Chemotherapy*
  - *High dose therapy with autologous bone marrow or peripheral*
  - *blood stem cell transplant*
  - *Psycho-social support and counselling for patients and families.*
  - *Management of children with febrile neutropenia*
  - *Management of any complications relating to cytotoxic therapy*
  - *including chemotherapy and radiotherapy*
  - *Administration of immunotherapy*
  - *Blood transfusion*
  - *Immunoglobulin infusion*
  - *Management of chicken pox (primary infection and*
  - *contact)/shingles in haem/onc patients*
  - *Management of haemophilia patients*
  - *Management of patients with sickle cell disease/crisis.*
  - *Palliative care*

- Table A1 (Appendix 1: Recommended air-change rates) of Scottish Health Technical Memorandum (SHTM) 03-01, Ventilation for healthcare premises Part A – Design and validation, as follows:

Application	Ventilation	ac/Hour	Pressure (Pascals)	Supply Filter	Noise (NR)	Temp (°C)	Comments For further information see Section 6
General ward	S / N	6	-	G4	30	18-28	
Communal ward toilet	E	10	-ve	-	40	-	
Single room	S / E / N	6	0 or –ve	G4	30	18-28	
Single room WC	E	3	-ve	-	40	-	
Clean utility	S	6	+ve	G4	40	18-28	
Dirty utility	E	6	-ve	-	40	-	
Ward Isolation room	-	-	-	-	-	-	See SHPN 4; Supplement 1
Infectious disease Iso room	E	10	-5	G4	30	18-28	Extract filtration may be required
Neutropenic patient ward	S	10	+10	H12	30	18-28	

Due to the current design, the Board is required to prepare specific standard operating procedure for management of infection and patients not using the isolation rooms within this department.

There is an executive briefing session at 8.30 tomorrow morning. Jacquie would Iain and yourself be able to brief Tim and others of the position as of tonight and also re theatre ventilation and what the realistic position is for going live on Friday? I am sorry I am not around but I have also copied Judith from comms in.

Subject: Summary email or critical care ventilation

Please correct or amend any misunderstandings:

• IOM have tested critical care ventilation in RHCYP in 4 bedded and single rooms

•It delivers 4 air changes at balanced or slight negative pressure in the multiple occupancy 4 bedded rooms. (Single rooms are not affected).

•The required standard as per SHTM 03-01 Appendix 1 (version 2 February 2014) for Critical Care areas is 10 air changes and less than 10 air changes per hour may facilitate airborne spread of viruses more than if 10 was achieved.

•the only known way to improve air changes with current plant is to accept positive pressure ventilation (ie increasing further the opportunity for spread primarily of pathogens with airborne transmission e.g. respiratory viruses between individuals (staff, visitors and patients) in 4 bedded rooms)

• a bigger plant would be required to deliver the correct air changes – the team are identifying what potential for existing system capacity enhancements might be (ie ramping up the existing air handling plant) and / or within the constraint of the existing ducting (so it would only be the external plant affected).

•this leads us to question whether the space is fit for purpose

•If occupied now, there is risk to patients, visitors and staff of airborne virus transmission (?how much) and difficulties in correcting (would probably require a decant*)

• if not occupied now, move needs postponed

Note - This*would be needed for lesser timeframe) for a planned maintenance programme of works over the course of occupation of the facility.

Importance: High

Wallace / Darren

Following various joint meetings and workshops this week, I can confirm, on behalf of NHS Lothian, that you are requested to proceed with adjusting the installed ventilation system in Critical Care to achieve air change rates as per option A on the attached schedule. You are to provide as a minimum 7 air changes/hour in all single bedrooms (with the exception of room 1 B1 037) and 5 air changes/hour in all four bedded rooms (with the exception of room 1 B1 063).

You have intimated that you shall commence the necessary activities on Thursday, 4th July and you anticipate completion on Saturday, 6th July, 2019 at which stage the air change rates in the relevant critical care rooms shall achieve the air change rates as per Option A of the attached schedule. This instruction is subject to the terms of the Project Agreement and other than the above changes to air rates, all other current Project Agreement standards and requirements (including those for the ventilation system) apply to this instruction.

Please liaise with the project team's Commissioning Manager Ashley Hull and Project Clinical Director, Janice Mackenzie regarding access, coordination and area prioritisation.

Documentation formalising the position will follow in due course. Meantime the Board is proceeding to instruct that these works are urgently undertaken under reservation of its rights.

Many thanks

Regards

Brian

To: Currie, Brian
Subject: RE: RHCYP + DCN - Little France - Critical Care Ventilation
Importance: High

MAJOR CONCERNS RAISED ABOUT THE RISKS OF DOING THE PERMANENT WORKS WITH PATIENTS IN SITU. TIM / JACQUIE joined the call with HFS and HPS.

The level of duct replacement works – based on Glasgow experiences, sceptical about timeframes and suggestions of simplicity. Really need to have the assurances that the solution will be deliverable.

Other concerns / assurances needed:

Include – Heat levels
Humidity levels
Noise at outlets, diffusers
Pressure regime during works being maintained
Fire damper implications
Changing / implications on filtration – needs to be upped to ensure that the ACH

Safer to stay put – contingency if it doesn't work or needs patients moved on.

6 months in abeyance.

Iain

MAJOR CONCERNS RAISED ABOUT THE RISKS OF DOING THE PERMANENT WORKS WITH PATIENTS IN SITU. TIM / JACQUIE joined the call with HFS and HPS.

The level of duct replacement works – based on Glasgow experiences, sceptical about timeframes and suggestions of simplicity. Really need to have the assurances that the solution will be deliverable. Existing ductwork retained except new supply and extract branch to connection point

Other concerns / assurances needed:

Include – Heat levels Ventilation will be on during works until final point of break in and a/ch rates will be 5 to multi bed and 7 to single bed
Humidity levels
Noise at outlets, diffusers This is a potential risk but not quantifiable at the moment
Pressure regime during works being maintained Yes except at point of break in for approx 5 hours.
Fire damper implications CSFD's installed to new branches and fire wall breaches
Changing / implications on filtration – needs to be upped to ensure that the ACH Will be accounted for in final design

Safer to stay put Existing location greater clinical risk – contingency if it doesn't work or needs patients moved on.

NHSL successfully carried out a major project in critical care at RIE in similar circumstances.

6 months in abeyance.
