Infection Prevention Society

Competencies Framework for Infection Prevention & Control Practitioners

Competencies for infection prevention and control practitioners (IPCPs) were first introduced by the Infection Control Nurses Association (ICNA) in 2000 and subsequently revised by the Education and Professional Development Committee of the Infection Prevention Society (IPS). A competent practitioner can be defined as a person who has acquired a set of skills with the ability to apply and measure these skills against set standards (Winchcombe, 2000). Infection prevention and control (IPC) competences provide a framework to enable IPCP to develop and enhance their knowledge and skills to help increase patient safety and care quality (Burnett, 2011). They can also assist in the design of education programmes; staff appraisal and personal development plans and reviewing team structures and requirements.

Using the IPS Competencies Framework

Members of IPS can use the IPS Competencies Platform on the IPS website to build a portfolio of their competencies. This tool allows competencies to be documented, linked to evidence that demonstrates the relevant knowledge and skills acquired and signed-off by a mentor. The tool enables members to generate a progress report to summarise competencies achieved and areas that requiring further development. This report can be used to support appraisal, personal development, career progression and professional revalidation.

The IPS competencies reflect the broad range of competencies that a proficient IPCP would be expected to gain. They may not reflect all the higher-level competencies required of an IPCP who is managing the IPC service and not all domains, competencies or practice indicators will be relevant to all IPCP roles.

The competency framework comprises Core Competencies and four domains:

- Clinical Practice
- Quality Improvement & Research
- Education
- Leadership and Management

The following terms may be helpful to support assessment of competence:

1. **Working towards**
   Has acquired some experience of performing the skill, task or responsibility but still requires support or supervision

2. **Competent**
   Able to perform the skill, task or responsibility as an autonomous practitioner

Infection Prevention Society

Core competencies (CC)

Competency	Practice Indicator	Knowledge	Skills	Working towards/ Competent
CC1	***Deliver appropriate and effective information, advice and guidance on infection prevention & control***			
CC1.1	Apply the principles of microbiology, immunology and epidemiology to designing and implementing strategies to prevent and control infection.	Evidence underpinning IPC including: o Microbiology o laboratory methods and reporting o Immunology o antimicrobial agents, resistance and treatment of infection o epidemiology of HCAI o infection transmission and prevention o infection prevention in relevant invasive devices and procedures	Critical evaluation of guidelines, research and other sources of evidence and application of findings to clinical practice	
CC1.2	Communicate IPC information effectively in a verbal and/or written form at an appropriate level for the target audience.	Strategies for delivering information effectively	Communicate complex messages clearly and effectively Evaluate effectiveness of communication	
CC1.3	Identify IPC risks and develop appropriate strategies to manage, mitigate, minimise or contain them.	Principles of risk assessment, management, governance and assurance; systems for documenting, monitoring and reviewing risk	Evaluates current risk assessments, appropriately escalates them and communicates risks with appropriate persons. Design strategies to manage or mitigate IPC risks	
CC1.4	Recognise gaps in knowledge, skills and competence of self and others in relation to IPC and develops improvement strategies.	Evidence underpinning infection prevention and control practice	Critical evaluation of guidelines, research and other sources of evidence and application of findings to clinical practice	
CC1.5	Communicate confidently and competently to staff, including providers, stakeholder and partner organisations, and service users and the public about infection and IPC at a level to suit the audience.	Appropriate and timely IPC information	Uses a wide range of communication strategies to meet the needs of their audience i.e. leaflets, dashboards, reports	
CC1.6	Critically evaluate research and other forms of evidence to underpin IPC advice.	Interpretation of research findings, assessment of study quality and validity of study findings or recommendations	Apply research findings to clinical practice	
CC1.7	Develop, assist and encourage staff and team members to practice effectively and efficiently including engagement events with service users and the public where applicable and appropriate to do so.	Evidence underpinning infection prevention and control practice	Identify and build effective relationships	
CC1.8	Apply methodologies to develop, support and maintain effective root cause analysis processes or other similar processes.	Evidence underpinning infection prevention and control practice	Critical evaluation of guidelines, research and other sources of evidence and application of findings to clinical practice.	
CC1.9	Build and sustain effective working relationships, influencing others to recognize the importance of IPC practice in promoting, improving and maintaining patient safety.	Relationship management	Identify, build and maintain key relationships	
CC1.10	Develop a strategy for providing and sustaining an effective infection prevention & control service aligned to organisational objectives and vision.	Evidence underpinning infection prevention and control practice.	Critical evaluation of guidelines, research and other sources of evidence and application of findings to clinical practice	

Competency	Practice Indicator	Knowledge	Skills	Working towards/ Competent
Domain: Clinical practice (CP)				
CP1	***Use surveillance data to inform infection prevention & control practice***			
CP1.1	Design, implement and/or utilise existing effective surveillance systems to inform practice based on epidemiological principles.	Methods of surveillance and their application	Utilise and analyse surveillance and other infection-related data,	
CP1.2	Apply the principles of epidemiology to the analysis and interpretation of data and use to inform appropriate interventions.	Understanding of the principles of statistics and limitations of data	Interpret surveillance reports	
CP1.3	Generate reports from surveillance and other sources of infection related information and feedback appropriately to key stakeholders.	o Understanding epidemiological metrics such as incidence and prevalence, significance of microbiological and diagnostic results and action/ implementation of results. o Reporting surveillance data. o National, regional and local surveillance systems for HCAI, legislation and National guidance	o Apply findings from surveillance to evaluate policies and programmes and identify action plans and priorities for infection prevention and control. o Prepare reports appropriate to the target audience. o Evaluate and review surveillance programmes against organisational IPC objectives	
CP2	***Advise on infection prevention & control in relation to the built environment and clinical equipment***			
CP2.1	Assess any IPC related risks and provide advice on their prevention and control in the design, construction, modification and maintenance of facilities.	o Evidence for infection risks associated with the built environment e.g. air handling, plumbing, water systems, and effective prevention and control strategies	Work with internal departments e.g. estates, facilities, capital planning and external contractors, other organisations	
CP2.2	Ensure key services supporting the IPC agenda e.g. cleaning and waste management are meeting the needs, requirements and specification of the service, assessing and identifying any risks or gaps in provision.	o The principles of decontamination, including relevant methods their application, effectiveness and limitations	Evaluate the IPC risks associated with equipment, medical devices and the environment, and identification of appropriate decontamination methods	
CP2.3	Assess the IPC risks associated with equipment and the environment and advise on appropriate actions to optimise decontamination processes promoting patient safety.	o Methods and processes for decontamination of the environment, medical devices (for example, endoscopes, surgical instruments) and equipment. o Local and national decontamination policies, guidelines and procedures for equipment, medical devices and the environment. o Evidence for the role of cleaning technologies in all decontamination processes. o Incorporate Health and Safety legislation and guidance in relation to the built environment (e.g. Health Technical Memoranda, Health Building Notes). o Consider national guidelines and legislation during the Tendering process for services. o Systems for waste management and laundry management, potential infection risks and control strategies and relevant National guidance	Incorporate infection prevention and control advice into tenders	

Infection Prevention Society

Competency	Practice Indicator	Knowledge	Skills	Working towards/ Competent
CP3	***Develop and implement evidence-based policies and guidelines for the prevention and control of infection.***			
CP3.1	Develop different forms of guidance based on the critical analysis of research evidence and interpretation of National guidelines	Evidence underpinning infection prevention and control practice	Critical evaluation of guidelines, research and other sources of evidence and application of findings to clinical practice i.e. SOP's, flow charts, policy and procedures.	
CP3.2	Work in partnership with key stakeholders to develop policies and guidelines that are evidence-based, relevant and understandable to health and social care staff	Legislation, national and local polices, guidelines and strategies relevant to infection prevention and control	Work in partnership with stakeholders to design, develop relevant and understandable polices/guidelines	
CP3.3	Monitor and evaluate the effectiveness of IPC policies and guidelines and identify areas for improvement	Principles of process and outcome audit	o Use audit to support quality improvement in relation to IPC. o Develop effective strategies to address deficiencies in practice	
CP3.4	Promote the application of evidence to infection prevention and control practice	Effective strategies for disseminating and implementing infection prevention and control polices and guidelines	Design and plan the effective implementation of polices and guidelines which follow local governance processes	
CP4	***Recognise, report and manage incidents and outbreaks.***			
CP4.1	Recognise and appropriately escalate significant incidents and outbreaks, and identify the evidence required to determine the nature, scale, and prevention strategies	Routes of transmission of micro-organisms, risk factors for transmission, common causes of outbreaks of HCAI, and sources of data on outbreaks e.g. national surveillance systems and factor in epidemiological links and risks	Identify and define outbreaks and incidents	
CP4.2	Work in partnership with others to agree and implement prevention and control measures, evaluate their effectiveness and adapt them if new information becomes available	Evidence for effectiveness of strategies to prevent outbreaks of HCAI	Interpret microbiological data and other information to inform effective prevention and control measures	
CP4.3	Communicate clear, accurate and timely information throughout the outbreak /incident to ensure risk is effectively managed	o Definitions of outbreaks/incidents of infection. o Data required to control outbreaks and analysis of data to understand factors responsible for transmission and identify efficacy of control measure	o Collect, analyse and interpret outbreak data. o Identify and communicate with relevant stakeholders. o Develop and communicate an outbreak management plan o Outbreak management plans should factor within a health economy approach i.e. acute & community o Identify the end of an outbreak o Report on lessons learned and recommendations for improvements to avoid reoccurrence o Present reports of outbreak to relevant stakeholders	
Domain: Education (ED)				
ED1	***Develop own knowledge and skills in infection prevention & control***			
ED1.1	Identify and evaluate own development needs, including strengths and limitations, to meet current and emerging work demands and organisational objectives.	Personal portfolio, documentation, organisational and professional revalidation requirements	Maintain a personal portfolio and identifying gaps in knowledge and skills or other development needs	
ED1.2	Develop clear plans, actions and outcomes to build and maintain expertise as part of ongoing professional development.	Formal and informal education and training opportunities	Take responsibility for addressing development needs and developing action plans	

Competency	Practice Indicator	Knowledge	Skills	Working towards/ Competent
ED1.3	Maintain knowledge and skills in infection prevention and control practice utilising a breadth of resources across both academic and professional practice.	Sources of academic literature underpinning the science and practice of IPC i.e. academic journals and courses and participating in other educational and learning activities and opportunities.	Critical evaluation of published literature and research studies and application of findings to practice	
ED2	***Identify and respond to infection prevention & control learning needs in others***			
ED2.1	Influence others to recognise infection prevention and control as an essential learning need for all healthcare staff.	Resources available to support IPC training and education	Identify knowledge and training needs of workforce	
ED2.2	Use scoping exercises to identify emerging IPC risks and related learning needs.	Emerging IPC issues, innovations in practice, new technologies. Strategies for training and education	o Deliver training/education that meets the learning needs of the participants and organisation o Identify and negotiate opportunities for IPC training o Integrate IPC training with organization training and development programmes	
ED3	***Provide expert advice and education on infection prevention & control to staff and service users and providers***			
ED3.1	Design communication strategies, learning resources/information and educational events that are appropriate to the needs of the target audience.	National and local policies and guidelines that inform IPC practices	o Design evidence-based training/education on IPC appropriate for a range of audiences o Engagement in public awareness campaigns (local, national and international).	
ED3.2	Deliver flexible and creative education and training that supports effective learning.	o Strategies for delivering effective training and education o Sources of information on IPC for staff, patients, service users, service providers and the public	o Deliver IPC information to a range of audiences using a variety of presentation approaches and styles o Design effective evidence-based material to clearly communicate relevant information to staff, service users and providers. o Design and develop study days and conferences locally and nationally where applicable	
ED4	***Evaluate educational strategies for infection prevention & control***			
ED4.1	Work in partnership with others to ensure infection prevention is an integral part of staff learning and development.	Organizational objectives for staff training and development	Work collaboratively to develop effective training	
ED4.2	Provide support and expert advice to improve knowledge of infection prevention across the organisation.	Key stakeholders in determining Organisational strategy for staff training	Influence training and development strategies to address IPC training needs	
ED4.3	Evaluate the effectiveness of educational strategies and make recommendations to improve the knowledge, skills and competence of the workforce.	Evaluation strategies	Evaluate teaching and take account of feedback in revising teaching materials or strategy	
Domain: Quality improvement and Research (QR)				
QR1	***Use improvement methodologies to enhance and sustain infection prevention & control***			
QR1.1	Identify opportunities for improving the quality and safety of patient care	Methodologies used to drive improvement including route cause analysis, stakeholder analysis, process mapping, driver diagrams and improvement cycles such as PDSA	Work collaboratively to drive improvement applying appropriate improvement methodologies.	

Competency	Practice Indicator	Knowledge	Skills	Working towards/ Competent
QR1.2	Apply improvement science methodologies to drive quality improvement through behavioural and system changes	Approaches to measurement to determine if change is effective.	Select appropriate measures of improvement	
QR1.3	Evaluate, review and refine improvement initiatives	o Knowledge and understanding of theories that inform improvement e.g. improvement science, human factors and ergonomics, behaviour change theory how these impacts on behavioural change o Methodologies to support effective root cause analysis	Apply the principles of root cause analysis to IPC incidents and/or outbreaks and work collaboratively to develop solutions	
QR2	***Minimise the risk of antimicrobial resistant (AMR) pathogen emergence and transmission***			
QR2.1	Promote and implement initiatives to prevent the transmission of antimicrobial resistant pathogens	The infection process, management of infection including the principles of antimicrobial prescribing	o Work collaboratively to implement and promote local AMR strategies and stewardship initiatives e.g. AMR stewardship groups. o Engagement of staffing groups on AMR campaigns.	
QR2.2	Utilise surveillance and prescribing data to identify report trends and inform IPC strategies	Mechanisms of resistance acquisition, strategies for preventing the emergence of resistance, epidemiology of resistant pathogens in the UK and world-wide	Use surveillance data to develop and inform improvement strategies	
QR2.3	Promote and implement strategies that encourage effective antimicrobial stewardship	Principles of antimicrobial stewardship. Surveillance of AMR and antimicrobial prescribing	Communication strategies	
QR3	***Use research to inform clinical practice***			
QR3.1	Critically assess and evaluate research and apply findings to inform evidence-based practice.	Research methods including quantitative and qualitative study design, assessing research quality and validity, influence of bias and confounding, measures of effect and basic statistics	Identify, critically review and synthesise research findings and apply them to clinical practice	
QR3.2	Design and participate in research independently and/or collaboratively.	Systematic literature searching to answer a clinical question	Apply the principles of research methodology to IPC interventions to provide evidence of efficacy	
QR3.3	Disseminate and apply findings of research to clinical practice.	o Developing research questions and selecting appropriate methods to answer them. o Principles of writing publications for peer review describing research, quality improvements and evidence review	Analyse data using appropriate methodologies	
Domain: Leadership and management (LM)				
LM1	***Lead and manage a range of strategies to prevent and control infection***			
LM1.1	Set realistic objectives (personal and teams) and work with staff, partner organisations, patients, carers and the public	Leadership and management styles and their application to practice	o Discuss personal scope of practice (professional ethical and legal) linked to organisational and governance structures. o Manage risk and maintain safety o Support and guide the performance of others.	

Competency	Practice Indicator	Knowledge	Skills	Working towards/ Competent
LM1.2	Assess and evaluate performance of self, individuals and/or teams and provide constructive feedback in a manner most likely to sustain and assist in the prevention and control of infection	o Legislation and guidance related to the management of employees. o Change management strategies. Human factors and implementation theory	o Participate in peer review and actively seek feedback on performance of self and others o Manage staff, including developing work plans and feedback on performance.	
LM2	***Develop and lead a high-quality infection prevention and control team and services.***			
LM2.1	Set realistic objectives, work and professional development plans with individual team members	Leadership styles and their application to practice	o Role model values of IPC team and organisation o Support and guide the performance of others within teams and organisations	
LM2.2	Develop, coach, assess and encourage team members to practice effectively and efficiently providing feedback when and where appropriate	o Performance reporting (IPC) as per organisational requirements. o Performance appraisals and staff management and wellbeing systems. o Legislation and guidance related to the management of employees including HR processes o	o Initiate and develop effective relationships within teams and across organisations. o Manage junior staff, including developing work plans, supervision and feedback on performance o	
LM2.3	Develop, supervise and participate in the development and implementation an annual IPC programme in partnership with key stakeholders and in line with organisational objectives and available resources.	o Principles of planning services, aligning to budget and resources o Governance arrangements, and the role of the IPC, in assuring patient safety	o Identify, measure and respond to outcomes and key performance indicators o Managing resources effectively	
LM2.4	Develop and sustain partnerships and networks to support the development of a high-quality IPC service	o Internal and external organisational contacts. o Local and National agencies and partners linked to IPC	o Develop communication engagement and network strategies for self and teams o Assess and evaluate effectiveness self and team	
LM2.5	Horizon scan to support building a strategic vision and identify and adopt innovation to improve service safety and quality	Epidemiology of emerging health threats to the local population.	o Recognize new and emerging threats in relation to infection prevention & control. o Identify opportunities for improvement and innovation. o Develop IPC practice in response to changing needs and priorities.	
LM3	**Design, plan and monitor care services to assure quality and safety in relation to infection prevention & control**			
LM3.1	Utilise data and other information to influence planning and inform service redesign	Evaluate and interpret surveillance and other infection-related data, including and understanding of the principles of statistics and limitations of data	Developing systems for measuring outcomes, processes and key performance indicators	
LM3.2	Develop performance management systems that monitor defined outcomes or indicators against defined standards linked to IPC	Systems for monitoring processes and outcomes	o Using and monitoring data to inform, drive and sustain quality improvement. o Liaising with key stakeholders (internal and external to organisation)	

Education Framework for the Infection Prevention and Control Practitioner (IPC) Workforce

The framework sets standards and identifies learning outcomes for the professional development and growth of the IPC practitioner workforce, promoting confidence and leadership skills to ensure practitioners can lead, challenge, and implement safe standards of IPC practice.

October 2023

Contents

1. Foreword

The SARS-CoV-2 pandemic highlighted the importance of Infection Prevention and Control (IPC). The contribution of our IPC practitioner workforce continues to be vital as the NHS moves forward in delivering the national commitments outlined in the NHS Long Term Plan, the UK 5-year action plan for antimicrobial resistance 2019-2024, The UK's 20-year vision for antimicrobial resistance and the NHS Operating Framework.

We must progress the learning from the pandemic, including the recommendations in the Healthcare Safety Investigation Branch's independent report: COVID-19 transmission in hospitals: management of the risk – a prospective safety investigation, to develop a national IPC strategy which includes ambitions to enhance IPC capacity and capability across England.

This Education Framework for IPC Practitioners will form part of a national IPC workforce and education plan. The framework sets out clear outcomes for the development and growth of a skilled workforce, to promote the confidence and leadership skills necessary to ensure practitioners challenge, and effectively support the reliable implementation of safe standards of care for the patients we serve.

The framework supports the NHS Long Term Workforce Plan in upholding IPC as a valued career option. This framework provides a clear direction for career progression and aims to encourage the recruitment and retention of a skilled IPC workforce. This in turn contributes to the NHS Patient Safety Strategy, supporting and empowering IPC Practitioners with the ability, self-assurance and means to succeed.

I would like to thank all IPC practitioners across the NHS and social care in England for their expertise and commitment to safety. I encourage them and their organisations to use this framework to progress a capable and resilient IPC workforce.

Dame Ruth May,
Chief Nursing Officer, England.

2. Statements of Support

UKHSA are very pleased to have contributed to the Education Framework for the IPC practitioner workforce. This is a valuable resource to support the delivery of consistent IPC practice in healthcare.

Sarah Gigg, **Deputy Director Nursing, Midwifery and Allied Health Professionals**
UK Health Security Agency

The Infection Prevention Society (IPS) is pleased to support the Education Framework for Infection Prevention and Control (IPC) Practitioners developed by NHS England. As co-contributors to the Education Framework, we are encouraged that the importance of the contribution of the IPC workforce in the strategy to deliver of the NHS Long Term Plan and the Five-year Antimicrobial Resistance National Action Plan has been recognised.

Since its inception, one of the key activities of the IPS has been to deliver IPC-focused education and training for our health and care workforce, the Education Framework is relevant to IPC Practitioners working at all levels, and this is essential if we are to ensure the sustainability of our specialist and valued workforce.

The Education Framework for IPC Practitioners will support the professional development, improve capability and capacity of our IPC teams. In addition, we will continue to support and encourage the formation of a diverse, inclusive and resilient IPC workforce to improve the quality of IPC practice and improve health outcomes.

The Infection Prevention Society (IPS)

The Healthcare Infection Society (HIS) welcomes the production of this Education Framework for the Infection Prevention and Control Practitioner Workforce; a comprehensive plan designed to provide **ALL** healthcare workers with the knowledge and skills they need to prevent and control the spread of infections in healthcare settings.

The Framework provides clear outcomes for the development and growth of a skilled workforce as a basis for multidisciplinary IPC teams and promotes IPC as a career option for a wide range of individuals and gives a clear direction for career progression.

As a learning provider, the educational material and events produced by HIS fit well into this framework. HIS will further utilise this to inform the design and delivery of additional education and training programmes, in line with the Society's current strategic plan, aligning with the distinct levels of practice identified in the Framework.

Sarah Adibi, Chief Executive Officer, Healthcare Infection Society

I am pleased to support the development and introduction of the Education Framework for Infection Prevention and Control (IPC) Practitioners developed by NHS England.

The introduction of this Framework alongside the Infection prevention and control education framework published in March 2023, this now completes the practice and learning expectations of the entire health and care IPC workforce, it presents us with a unique opportunity to support a highly valued and respected group of individuals and teams in delivering high quality IPC practice and improving outcomes for individuals, patients and communities.

Professor Steve Hams, Chief Nursing Officer, North Bristol NHS Trust

As Chair of the Steering Group which has overseen the work to develop this framework, I am delighted to endorse this NHS England *Education Framework for IPC Practitioners*. The Steering Group have been involved in the co-design of the framework, and as a result it has received overwhelming support.

Many years spent working as a specialist IP practitioner have taught me the importance of effective education and career development for Infection Prevention and Control Practitioners, both in terms of specialist knowledge for practice, and the ability to lead and influence your team, organisations and networks.

I believe this education framework will assist Higher Education Institutions, employers, and IPC Practitioners to develop, support and utilise a range of educational opportunities which better meet the needs of our specialist workforce. The result will be an increasingly well-trained specialist workforce, who are better able to provide the expert advice and leadership needed to protect people from infections across the spectrum of health and social care. Ultimately, this will improve both patient/client safety and staff safety and support increased role satisfaction and staff retention of specialist IPC Practitioners.

Tracey Cooper, Chair of Education, Workforce & Leadership Steering Group.
Independent Nurse Consultant Infection Prevention, Lecturer in Health Sciences (Infection Prevention and Control) Bangor University, Past President IPS

The Independent Healthcare Providers Network (IHPN) welcomes the publication of the NHSE Education Framework for IPC Practitioners.

The framework enhances the development and growth of the Infection Prevention and Control (IPC) practitioner workforce within the NHS and the Independent Sector and will support a more resilient and skilled IPC workforce of the future.

The framework is a crucial step in the right direction in the promotion of consistency in IPC education and practice across health care systems. It will significantly strengthen IPC as a career of choice, as well as helping retain and develop those currently in an IPC role.

We will promote this important framework within our membership to improve practice, reduce infection, and maintain the safety of our patients, while attracting, retaining and developing our current and future workforce.

Dawn Hodgkins, Director of Regulation, on behalf of Independent Healthcare Partners Network.

3. Introduction and Background

NHS England have committed to deliver the actions outlined in the NHS Long Term Plan (2019) and the Five-year Antimicrobial Resistance (AMR) National Action Plan (2019).

NHS England commissioned Skills for Health (SfH) to review and develop an Infection Prevention & Control (IPC) Framework for those individuals who would be considered part of the **IPC Practitioner workforce**, to improve the quality of IPC practice and health outcomes, as well as promote IPC as a positive place to work and increase its reach to those who would consider a career in IPC.

The Framework provides clear outcomes for the development and growth of a skilled workforce, promoting confidence and leadership skills to ensure practitioners can lead, challenge, and implement safe standards of IPC practice for the patients we serve.

This Framework supports the NHS Long Term Workforce Plan in promoting IPC as a career option for a wide range of individuals, giving clear direction for career progression and supporting recruitment and retention of the IPC workforce. This in turn contributes to the NHS Patient Safety Strategy, supporting and empowering IPC Practitioners with the skills, confidence and mechanisms to improve safety and saving lives.

4. Purpose of Framework

The framework identifies outcomes for the development and growth of the IPC practitioner workforce, to help build confidence and leadership skills to lead, challenge and implement safe standards of IPC practice.

It is important to note this framework is not intended for the wider health and care workforce, a separate framework has been produced for them and can be located here: IPC Education Framework

Roles and responsibilities for IPC is outside the scope of this document: a national strategy for IPC Workforce and Education is currently being developed and will include a “blueprint” for an IPC service along with defined roles and responsibilities for IPC within an organisation.

The framework identifies **four distinct levels of practice** which create an incremental pathway for the IPC practitioner workforce, ranging from someone starting their IPC career through to someone working at advanced level IPC practice. There is also a section outlining the role of the non-IPC trained Director of Infection Prevention and Control (DIPC).

It is important to note however, the framework **is not suggesting** there are 4 roles/jobs within IPC practice; therefore, individuals may have many more ‘job-steps’ in their overall

IPC career and employers are not limited to the number/types of roles they wish to have in their services.

The framework **aims to support** managers, in growing and developing a skilled workforce as a basis for multidisciplinary teams within health and social care organisations.

The framework will assist with curriculum design and development to support the advancement of IPC practitioner capability and capacity. In turn, this will support the development of a skilled and competent IPC workforce and supporting organisations in maintaining a resilient and sustainable IPC service.

Learning providers and professional training bodies **are encouraged to consider** this document to inform the development of curricula for the courses and training they deliver and qualifications they award.

The framework enables the development of required outcomes for practice and supports professional growth and workforce transformation.

The framework **is not** intended to replace current relevant frameworks but supplement them.

5. Who will be interested in this framework?

Service commissioners

The framework sets out clear expectations about what the IPC practitioner workforce needs to do. The outcomes identified support the development and planning of the workforce to meet need and support a common understanding and expectation of this workforce.

Employers

The framework enables employers and managers to demonstrate that IPC practitioner staff they employ/manage meet the outcomes identified or have developmental plans in place along with the necessary supervision to ensure safety and meet the needs of the service and organisation(s).

This underpins and supports the need for continuing professional development of staff to ensure their practice is safe, effective, remains up-to-date and supports the process of quality assurance to ensure the safety and effectiveness of primary care roles. It can be used as part of appraisal processes.

Education and training providers

Educational institutions can use the framework to inform the design of their curricula and the delivery of education, training, and development programmes, including identifying learning outcomes. This will ensure that their learning and development provision contributes to the full range of knowledge to support the outcomes required to make individuals safe and effective members of the workforce.

The framework will inform those who design and deliver training and development opportunities to focus on the key outcomes that learners need to achieve and maintain. This in turn, will guide the content to be included and the use of appropriate learning and teaching strategies.

Use of this framework also supports organisational and system wide effectiveness and efficiencies by encouraging the delivery of education and training that is focused on developing identified outcomes and optimises opportunities for interprofessional learning; focused on outcomes-based curricula which equips individuals with the attributes required to meet the needs of the population. In so doing, it should help to increase consistency in knowledge and skills development, prevent unnecessary duplication in education and training delivery and strengthen skill mix and teamworking.

Current and future staff

The framework promotes IPC as a career option for a wide range of individuals as well as giving a clear sense of the ways in which to progress.

It provides clarity about characteristics and requirements to practice at each level and offers a structure of outcomes that enable practice at each level.

It can be used to conduct formal or informal appraisal, alongside a training needs analysis, comparing current skills and knowledge with required skills and knowledge.

This framework may assist staff in the development of a portfolio of evidence.

6. Structure of the framework

The framework is comprised of three components:

A. Levels of practice for IPC professionals (with a detailed practice descriptor)
B. Identified Domains
C. Outcomes for practice (for each level of practice and identified domain).

These three components are explained in more detail on the following pages.

This framework aims to support the sustainability and growth of the IPC workforce and facilitate the professional development of staff within IPC services. It also provides insight into what characteristics are required to work at each level of practice.

This framework **does not** mandate roles/ or specific jobs; nor does it suggest the amount of renumeration or terms and conditions that maybe associated with jobs/roles which must be dealt with locally by employers.

The framework does; however, identify **potential** roles that **may be** seen at each level of practice.

7. A. Levels of Practice for IPC Professionals

Description of Levels

Each Level of Practice is further detailed by the following Practice Descriptors.

8. A. Practice Descriptors

<table>
<tr><td colspan="2">Practice Descriptor: Introduction Level

This level describes people for whom IPC is not their main role. This role is taken on in addition to their main role. Staff may or may not be supported by a substantive IPC team or IPC practitioner.

People at this level
• Require knowledge of facts, principles, processes, and general concepts of IPC.
• Carry out a wide range of duties and will have some responsibility for the delivery of IPC care, but with further guidance, support, and supervision appropriately available when needed.</td></tr>
<tr><td>Indicative learning and development</td><td>Potential roles at this level</td></tr>
<tr><td>Appropriate units of learning that enable the capabilities identified to be achieved, for example:
• Development of relevant IPC clinical practice outcomes; (typically delivered by senior IPC professionals).
• Supporting the development and delivery of training events.
• Completing audits and supporting quality improvement work.</td><td>• Link practitioners.
• IPC Champions.
• Surveillance staff.
• Care home IPC leads.
• Administrative roles supporting IPC Teams.</td></tr>
</table>

Practice Descriptor: Foundation Level

Staff working at this level will be occupying a role where IPC practice forms the core and substantive part of their role.

All staff at this level

- Will be working towards an IPC qualification/agreed level of training to obtain a comprehensive and thorough knowledge of IPC and can use knowledge to solve problems, make judgements which require analysis and interpretation; however, they will have an awareness of the boundaries of their knowledge.
- Will have responsibility for the delivery of staff training and supporting the development needs of identified staff.
- May carry out a wide range of duties and will have some responsibility for the delivery of care, with guidance and supervision available when needed. They will contribute to service improvement and are responsible for their own self-development.
- Recognise and work within the boundaries of their practice, knowing when and to whom to refer patients/situations. They may delegate work or work with other members of the multidisciplinary team and take accountability for the delegated activity.

Indicative learning and development	**Potential roles at this level**
Appropriate units of learning that enable the outcomes identified to be achieved, e.g. • Further development of relevant IPC and AMS clinical practice knowledge & outcomes. • Principles of leadership and behavioural change. • Principles of data collection, audit, and research. • Facilitating learning events and principles of effective teaching	• Newly appointed IPC practitioner staff. • Surveillance Staff.

Practice Descriptor: Enhanced Level

Enhanced practice registered professionals will have typically completed some form of post graduate education (level 7) (e.g., post-graduate diploma) relevant to their area of practice and role.

Enhanced practice is a level of practice used to describe the practice of highly experienced, knowledgeable IPC professionals.

Staff in this role usually work as part of a multidisciplinary team and apply their enhanced skills, knowledge, and experience to contribute to episodes of care.

Enhanced IPC Practice professionals:

- Provide a high standard of complex, enhanced care for patients, using enhanced levels of clinical judgement, skills, and knowledge.
- Critically evaluate and analyse clinical problems using their expertise and clinical knowledge, seeking out and applying relevant evidence, enhanced clinical assessments, diagnostics, interventions, and equipment to make clinical decisions.
- Deliver complex care in the context of continual change, challenging environments, different models of care delivery, innovation and rapidly evolving technologies using critical analysis and their underpinning knowledge to manage complex interventions.
- Teach and advise others and/or support the multi-disciplinary team to do so.
- Participate in clinical audits, research projects, and implement changes as required, including the development, and updating of practice protocols/guidelines and procedures. They will work within national and local protocols where these exist.
- Continuously update their knowledge, enhance their clinical practice, and provide support, mentoring and supervision of others.
- Recognise and work within the boundaries of their practice, knowing when and to whom to refer patients/situations. They may delegate work or work with other members of the multidisciplinary team and take accountability for the delegated activity.

Indicative learning and development	**Potential roles at this level**

Appropriate units of learning that enable the outcomes identified to be achieved, for example: • Evidence of appropriate post-graduate learning in IPC relevant to scope of role; ensuring the outcomes for practice at this level are met. • Continuing Professional Development (CPD) that enables the delivery of care aligned to role and level of practice. • Practice Supervisor/Assessor status. • Leadership, influencing, and behaviour change relevant to role. • Quality Improvement.	• Specialist infection prevention control practitioner. • Clinical specialist – infection prevention. • Healthcare Scientist.

Practice Descriptor: Advanced Level

- Advanced Practice is a level of practice characterised by a high degree of autonomy and complex decision making, that encompasses the four pillars of clinical practice, leadership and management, education, and research.
- Advanced practice is a level of practice in which a practitioner has demonstrated their ability to work autonomously at a high-level (level 7/ Masters level IPC training).
- Advanced Practice embodies the ability to manage clinical IPC care in partnership with individuals, families and carers and the requirement to work in close partnership with all members of the multi-professional team.
- Advanced Practice is designed to transform and modernise pathways of care, enabling the safe and effective sharing of IPC skills across traditional professional boundaries.

Advanced Practitioners

- Demonstrate initiative and are creative in finding solutions to IPC problems.
- Have responsibility for IPC performance and service development.
- Operate in the context of continual change, challenging environments, different models of care delivery, innovation and rapidly evolving technologies using critical analysis and underpinning knowledge to manage complex interventions in relation to IPC.
- Act as a role model, educator, supervisor, coach, and mentor in relation to IPC, seeking to instil and develop the confidence of others.
- Where the IPC Practitioner has completed level 7 IPC training, they may also hold the Deputy/Associate or DIPC (for more information on the DIPC role see Appendix 1.

Indicative learning and development	Potential roles at this level

Appropriate units of learning that enable the outcomes identified to be achieved, e.g. • Advanced-level practice is underpinned by a full post-registration MSc programme that enables the development and demonstration of the capabilities articulated in the *multi-professional framework in advanced clinical practice for England* (Health Education England, 2017) across the four pillars of practice (clinical, leadership and management, education, and research), including in ways that meet area-specific (IPC) needs. • CPD that is relevant to the scope of role and workplace setting. • Advanced learning in relation to leadership, research, influencing and behaviour change. • The potential for practitioners to demonstrate equivalence of the above through the successful completion of the Centre for Advancing Practice's e-Portfolio (supported) route. • Potential progression to level 8 (doctoral level) learning/award as part of practitioners' ongoing development from their advanced practice role, where this fits with workforce development/deployment and service delivery needs.	• Advanced clinical practitioner (IPC). • Non-medical consultant practitioner. • Consultant in Infection specialities (Medical microbiology/ virology/ infectious diseases). • Consultant level practitioner. • Consultant clinical scientist. • Lead Nurse IPC. • Deputy / Associate DIPC (who is trained in IPC. • Infection Control Doctor • IPC trained DIPCs* (Non-IPC trained DIPCs do not fall into this category)

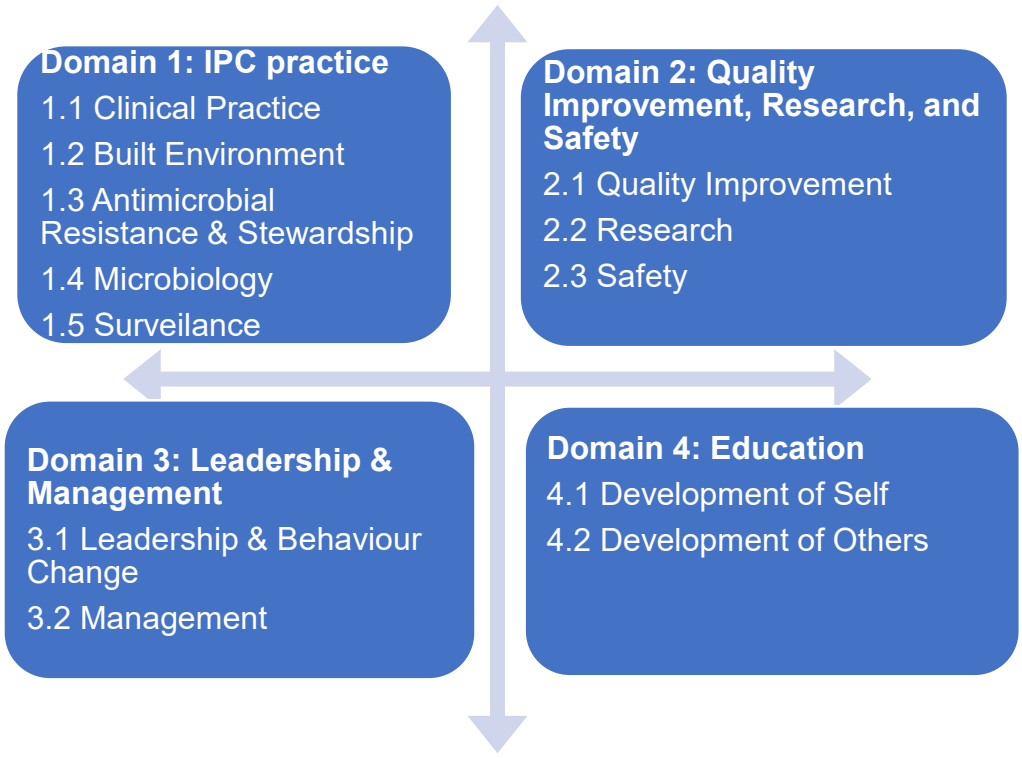
*Further information about the DIPC role can be found in Appendix 1

9. B. Framework Domains

The Framework identifies the following four domains:

- Domain 1. Clinical Practice.
- Domain 2. Quality Improvement, research, and safety.
- Domain 3. Leadership and Management.
- Domain 4. Education.

Within each Domain there are a number of sub-domains as shown below, which are numbered for ease of reference.



10. C. Outcomes for Practice

The framework articulates outcomes for practice necessary for safe and effective IPC care delivery.

They are written at a relatively ‘high-level’ and allow for the ability to contextualise them to suit the environment of care in which their service operates and the many roles they utilise. It is also for employers to agree a scope of practice and a job description with their employees.

The outcomes for practice **do not** indicate a prescribed pathway or process.

The outcomes for practice are incremental, building across the four practice descriptors (e.g., advanced level statements assumes that those people to whom they are applicable, possess those at preceding levels (to minimise unnecessary repetition).

Domain 1: IPC Practice				
1.1 Clinical Practice				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Act as a point of contact on IPC matters.	x	x	x	x
2. Advise on IPC measures related to cleaning, disinfection, and sterilisation processes.	x	x	x	x
3. Establish and maintain good communication with patients/clients/residents and relatives regarding their IPC care.	x	x	x	x
4. Communicate IPC action plans with healthcare staff maintaining appropriate records of work per agreed protocols.	x	x	x	x
5. Always apply Standard Infection Control Precautions, for all individuals (whether infection is known to be present or not), to ensure the safety of everyone.	x	x	x	x
6. Implement on IPC measures related to invasive devices and procedures.	x	x	x	x
7. Utilise current evidence-based guidance, policies, and protocols to inform IPC practice.	x	x	x	x
8. Apply Transmission Based Precautions when indicated by using clinical judgement and making risk assessed decisions based on: ▪ Suspected/known infectious agents and the severity of the illness caused. ▪ Transmission route of the infectious agent. ▪ Care setting and procedures undertaken.	x	x	x	x
9. Encourage individuals to give feedback on guidance, policies, systems, procedures, and practices and how improvements could be made.	x	x	x	x

10. Contribute to and participate in IPC monitoring, audit, and significant event reporting.	x	x	x	x
11. Form respectful relationships with individuals, teams and organisations representing diverse constituencies, seeking regular input to better understand equality, diversity & inclusion issues.	x	x	x	x
12. Plan, monitor and review guidance, policies/procedures designed to promote good IPC.			x	x
13. Recognise circumstances or settings which create barriers to effective delivery of IPC and take appropriate action to overcome these barriers.			x	x
14. Investigate outbreaks using appropriate methods and interpretation of outbreak findings, by working with others to: • Establish the case definition. • Identify the parameters of the investigation and the case-finding methodology. • Make hypotheses and identify the source and mode of transmission.			x	x
15. Undertake IPC assessments of clinical areas, providing feedback, identifying areas of good practice and areas for remedial activity.			x	x
16. Evaluate clinical areas; ensuring any improvement plans are being acted upon.			x	x
17. Develop IPC policies and guidelines, which are evidence-based, clinically relevant and accessible to those who will follow them.			x	x
18. Evaluate IPC assessments, noting trends/patterns at a team/department/organisational level; working with clinical leads and others to embed required changes.				x
19. Lead how IPC risks are managed in unpredictable and complex situations, including where a precedent has not been set.				x

20. Lead the ongoing development of IPC pathways, standards, policies, guidelines, procedures, service improvement and practice accreditation.				x
21. Adapt national guidance, policies, and standard operating procedures to local needs.				x
22. Put in place a joint review of IPC services through peer reviews, audits and evaluations of safety, quality, and health outcomes.				x
23. Establish professional IPC practice across pathways, services, organisations, and systems, working with individuals, families, carers, communities and others.				x
24. Collaborate with key stakeholders to ensure that measures are in place to effectively recognise and respond to an infectious disease threat.				x
25. Ensure IPC is an integral element in formal systems for collecting and reviewing feedback from patients/service users/carers and staff across services are in place; working with service teams to identify and put in place any actions as a result of their feedback.				x
Domain 1: IPC Practice				
1.2 Built Environment				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Support interventions which tackle climate change and broader sustainability issues, in the context of providing high standards of IPC practice.	x	x	x	x
2. Support estates department, hygiene services and others with IPC advice on cleaning standards and cleaning specifications for the working environment.		x	x	x
3. Engage and collaborate with stakeholders to promote IPC in the built environment.			x	x

4. Complete IPC risk assessments and advise on IPC key measures for the built environment, taking into consideration current building guidance and legislation.			x	x
5. Provide IPC advice on water safety, specialist ventilation, decontamination, personal protective equipment, and investigations.			x	x
6. Assess the potential IPC risks on design, construction and renovation that may impact on patient care and provide recommendations to minimise such risks.				x
7. Audit and monitor implementation of IPC recommendations related to the built environment, reporting, and advising on corrective actions.				x
8. Ensure key services supporting IPC (e.g., cleaning and waste management) are meeting the needs and requirements of the service.				x
Domain 1: IPC Practice				
1.3 Antimicrobial Resistance (AMR) & Antimicrobial Stewardship (AMS)				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Deliver education in relation to AMR and AMS.	x	x	x	x
2. Apply AMS principles and good practice, using evidence-based guidance and local policies.	x	x	x	x
3. Report patient safety incidents related to antimicrobial use (e.g., hospital admissions for potentially avoidable life-threatening infections, infections with C. difficile or adverse drug reactions such as anaphylaxis).	x	x	x	x
4. Identify, challenge, and take action to rectify and report inappropriate antibiotic prescribing	x	x	x	x

5. Support the implementation of IPC measures and transmission-based precautions when caring for people colonised or infected with resistant microorganisms.	x	x	x	x
6. Support incident reviews and remedial actions related to AMR and AMS.		x	x	x
7. Integrate audit into existing quality improvement programmes in relation to AMR/AMS.			x	x
8. Work collaboratively with key stakeholders in implementing national IPC guidance on Healthcare Associated Infections (HCAIs), AMR and AMS.			x	x
9. Support efforts to minimise AMR, including diagnostic and AMS initiatives, reporting multidrug-resistant microorganisms, according to local and national requirements.				x
10. Use multimodal strategies to implement IPC measures to reduce AMR and HCAIs Infections.				x
11. Enable an effective system for ongoing surveillance and rapid alert/detection of AMR at organisational level.				x
12. Evaluate antimicrobial prescribing and how this relates to local resistance patterns by working with AMS teams and laboratory staff to provide regular feedback to individual prescribers in all care settings.				x
13. Work with AMS and IPC committees to develop and update plans to reduce AMR in healthcare, based on local AMR determinants and data including the consumption of antimicrobial agents.				x

Domain 1: IPC Practice				
1.4 Microbiology				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Apply knowledge of the microorganisms that cause infection in humans in healthcare and community settings.	x	x	x	x
2. Support with diagnostic and antimicrobial stewardship programmes when required.	x	x	x	x
3. Recognise key characteristics of pathogenicity, transmission, virulence, and other risk factors associated with chain of infection.	x	x	x	x
4. Apply knowledge about clinical manifestation and presentation of infection, diagnostic, laboratory testing and screening methods to interpret reports and advise others in line with organisational protocols and guidance.			x	x
5. Advise in discussions on the microbiological specimens to be taken in specific infection cases and/or outbreaks.			x	x
6. Provide advice and support in applying standard and transmission-based precautions depending on the modes of transmission and virulence patterns identified through microbiological tests.			x	x
7. Communicate in a timely and effective manner about modes of transmission and risks of specific pathogens and necessary microbiological investigations.			x	x

Domain 1: IPC Practice				
1.5 Surveillance				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Contribute and participate in IPC monitoring, audit, and significant event reporting.	x	x	x	x
2. Use surveillance data to reduce the risk of Healthcare Associated Infections among patients, staff, and others.			x	x
3. Develop protocols for a surveillance programme with clearly defined objectives and goals that are relevant for the target areas, procedure, population, or event of interest.			x	x
4. Work with wider stakeholders to determine organisational priorities for surveillance, based on available evidence and resources.				x
5. Develop plans to collect data: choose surveillance protocols, create or adapt practical data collection forms and identify data collection systems.				x
Domain 2: Quality Improvement, Research, and Safety				
2.1 Quality Improvement				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Identify opportunities to improve the quality and performance of IPC practice to promote efficacy, safety and improve patient care outcomes.	x	x	x	x

2. Implement a range of identified improvement activities to enhance quality IPC practice – working in partnership with key stakeholders.	x	x	x	x
3. Monitor guidance, policies, systems, procedures, and practices to identify improvements for IPC practice.		x	x	x
4. Evaluate and adapt Quality Improvement (QI) methodologies using a variety of styles to sustain or drive improvements in IPC practice.			x	x
5. Lead collaboration across a wide system of professionals and agencies, fostering collaboration and co-production to ensure IPC practice is optimal.				x
6. Critically evaluate and assimilate relevant IPC data and information from a range of sources to ensure complex decisions regarding IPC practice, reflect the analysis of several different perspectives.				x
7. Lead strategic development, improvement, inquiry and innovation across specific workstreams that informs and responds to system objectives and supports commissioners and senior leaders with their decision-making in IPC practice and service delivery.				x
Domain 2: Quality Improvement, Research, and Safety				
2.2 Research				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Contribute to the development of new knowledge through supporting research in IPC.		x	x	x
2. Critically evaluate published literature, research studies and application to IPC practice.			x	x

3. Develop a combined approach to practice focused research, academic inquiry and innovation across the IPC service/pathway.			x	x
4. Develop a culture of sharing knowledge that values research, evaluation and academic inquiry & its importance to contemporary IPC practice.			x	x
Domain 2: Quality Improvement, Research, and Safety				
2.3 Safety				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation level**	**Enhanced Level**	**Advanced Level**
1. Work with those affected by IPC safety incidents to understand and answer IPC related questions, signposting to additional support as required.	x	x	x	x
2. Use information to identify, monitor and report trends, informing IPC priorities and areas of concern.	x	x	x	x
3. Learn from action and analyse information from IPC reporting systems.		x	x	x
4. Enable an approach to IPC safety that prioritises compassionate engagement with those affected by IPC incidents.			x	x
5. Embed IPC incident responses within a wider system of improvement.				x
6. Initiate activities and measure impact to guide future IPC risk reduction based on experience and awareness.				x
7. Collaborate, support and provide advice to occupational health and health and safety professionals to develop and adapt evidence-based guidance/ national recommendations to undertake risk assessment, inform practice, monitor				x

performance, evaluate practice and respond to situations and adverse incident/s.				
Domain 3: Leadership & Management				
3.1 Leadership & Behaviour Change				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Support and encourage colleagues in implementing changes relevant to best IPC practice.	x	x	x	x
2. Encourage colleagues to ask questions, make suggestions and seek clarification in relation to the IPC work they have been allocated.	x	x	x	x
3. Provide values-based leadership across the IPC care pathway, services and systems in complex and changing situations.	x	x	x	x
4. Review changes made – identifying any 'lessons learned' for future IPC work activities.		x	x	x
5. Critically evaluate the culture present within IPC teams and enable an optimal working environment through positive compassionate role modelling and leadership skills.			x	x
6. Lead change processes: ensuring collaborative working to improve the quality of IPC practice.			x	x
7. Lead with emotional intelligence, in line with NHS constitution values of compassionate leadership to enable individuals/ teams to flourish, grow and deliver high standards of IPC.			x	x

8. Enable others to positively contribute to IPC service improvements and better ways of working, recognising their own role in such endeavours.			x	x
9. Ensure support is made available for staff to be able to innovate IPC practice, balancing such innovation with service requirements and overall clinical safety and effectiveness.				x
10. Lead the development of IPC strategy and ensure collaborative working with others to advocate practice development and improve the quality of care and professionalism of others, upholding the profession in the face of adversity.				x
11. Critically evaluate an outcomes-based approach to IPC practice, developing and leading on strategies for dissemination with a wider audience.				x
12. Build and maintain sustainable partnerships across organisations and systems, drawing on standards and best practice evidence to guide decision-making.				x
Domain 3: Leadership & Management				
3.2 Management				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Allocate work to others by taking account of their skills, knowledge, competence, backgrounds and experience.			x	x
2. Provide opportunities for colleagues and peers to get to know each other's strengths and weaknesses and build mutual respect and trust.			x	x
3. Enable the wider IPC team to positively contribute to better ways of working.			x	x

4. Implement IPC interventions working with multidisciplinary teams, using multimodal strategies, and campaigning as required.			x	x
5. Recruit, interview and appoint team members, align workloads, prioritise, and motivate members of IPC team/s to ensure delivery of high-quality care through excellent teamwork.				x
6. Work collaboratively with key stakeholders in conducting facility/organisational wide IPC risk assessments, developing plans to manage risks as a strategy for compliance with IPC elements of national quality standards.				x
7. Demonstrate an ability to examine problems/situations and find solutions through creative application of knowledge, experience, data, and evidence.				x
8. Coordinate required preparedness and response to requests for advice, education, support, and planning including emerging infectious disease, emergencies, and threats at organisational, system and national level.				x
9. Manage assurance systems and processes to develop robust outcome indicators for clinical practice and other aspects (such as clinical governance).				x
Domain 4: Education				
4.1 Development of self				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Remain up to date with contemporary IPC practice.	x	x	x	x
2. Engage in a range of appropriate learning and development, continually reflecting on their IPC practice to maximise their capabilities.	x	x	x	x

3. Be open to feedback on IPC practice by colleagues to promote ongoing development.	x	x	x	x
4. Evaluate at appropriate intervals, the current and future requirements of their practice.	x	x	x	x
5. Identify any capability gaps in their IPC practice, agreeing personal development plans with line manager through activities such as induction and appraisal.	x	x	x	x
6. Review and update personal development plans in the light of performance, any development activities undertaken, and any wider changes as identified.	x	x	x	x
Domain 4: Education				
4.2 Development of others				
The IPC Practitioner will be able to:	**Introduction Level**	**Foundation Level**	**Enhanced Level**	**Advanced Level**
1. Deliver an identified range of IPC education and learning programmes; targeted to meet the needs of the individual learner(s) and the care environment in which they operate.	x	x	x	x
2. Support practice development by acting as a mentor and/or clinical supervisors as appropriate.		x	x	x
3. Contribute to the planning and evaluation of IPC learning activities.		x	x	x
4. Use a range of learning methods and resources to help the learners acquire/develop their IPC practice as identified.		x	x	x
5. Use information gained from learner evaluations to inform the development of future learning activities		x	x	x

6. Deliver rapid training refresher courses in the case of change of policies and/or in special situations, such as during the response to outbreaks and emergencies.		x	x	x
7. Recognise the importance of taking account of career and personal goals when supporting professional development of others.			x	x
8. Advocate for and contribute to a culture of learning to inspire future and existing staff.			x	x
9. Undertake Appraisals with IPC team members and support their Personal Development Plans as appropriate.			x	x
10. Identify collective learning and development needs of the IPC team(s).			x	x
11. Design and develop a suitable range of IPC learning activities/education and learning programmes which equip learners with relevant IPC capabilities needed to deliver safe and effective practice.			x	x
12. Evaluate the effectiveness of learning activities/programmes using appropriate IPC data sets as well as learner feedback.			x	x
13. Facilitate collaboration of the wider team and support peer review processes to identify individual and team learning and support them to address these.			x	x
14. Continually synthesise current practice and wider knowledge to inform IPC learning & development activities.			x	x
15. Build capacity and capability to support learning and collaborate with education service providers and education commissioners to ensure IPC workforce/learner needs are met.				x
16. Lead planning, implementation, and evaluation of educational interventions at a local, regional and national level for individuals, informed by training needs analysis and in response to IPC policy and strategy.				x

17. Enable the IPC team to build individual/team/organisational capacity and capability in IPC through work-based and interprofessional learning, and the application of learning to practice.				x
18. Build capacity and capability to support learning and collaborate with education service providers and education commissioners to ensure workforce/learner needs are met.				x

11. Appendix 1 – Directors of Infection Prevention & Control

Whilst this Education Framework focusses on defining levels of practice and not roles; there is one role where it is felt helpful to provide additional clarity – namely Directors of Infection Prevention & Control (DIPC).

DIPCs are accountable for the planning, delivery, and monitoring of IPC services within an organisation in accordance with the Health and Social Care Act (2008) Code of Practice on the prevention and control of infections and other relevant standards.

DIPCs are required to be in place in all registered NHS care providers under current legislation (Health and Social Care Act 2008) and compliance with these regulations is monitored by the Care Quality Commission (CQC).

The Director of Infection Prevention and Control:

- Has executive authority and responsibility for ensuring that strategies are developed and implemented to prevent avoidable healthcare associated infections (HCAIs) at all levels in the organisation and that the organisation meets its requirements; this will include leading on the development and implementation of an effective, organisational wide, IPC service.
- Has executive authority and responsibility for ensuring that strategies are developed and implemented to prevent avoidable healthcare associated infections (HCAIs) at all levels in the organisation and that the organisation meets its requirements; this will include leading on the development and implementation of an effective, organisational wide, IPC service.
- Are accountable to the Board and have a vital role in operational and board level decision making regarding IPC, for example closing/opening of facilities and/or provision of additional capacity.
- The DIPC is responsible for the development and implementation of operational and strategic plans for the IPC service, and for ensuring the development of a progressive and responsive service within a robust clinical governance framework.

It is acknowledged that the professional background of DIPCs is varied across the country and includes Medical, Nursing, Allied Health Professions and Clinical scientists and where IPC is not the principle role of the DIPC, it is really **important** that the DIPC is

supported by a blended workforce of foundation, enhanced and advanced level IPC practitioners, in order to discharge their duties under the current legislation. This will include the DIPC working collaboratively with colleagues, particularly if IPC is not their area of personal expertise, to ensure that their executive function and advocacy is fully informed by appropriate IPC expertise.

Outcomes for Practice for DIPCs	
Governance, Assurance and Quality Improvement	
1.	Responsible for the development and implementation of operational and strategic plans for the IPC service, and for ensuring the development of a progressive and responsive service within a robust clinical governance framework.
2.	Has executive authority and responsibility for ensuring that strategies are developed and implemented to prevent avoidable healthcare associated infections (HCAIs) at all levels in the organisation and that the organisation meets its requirements; this will include leading on the development and implementation of an effective, organisational wide, IPC service.
3.	Has either has a **board executive leadership role** (most likely the Chief Nursing Officer or Chief Medical Officer), reporting to the Chief Executive Officer (CEO), or a senior clinical role with direct access to the CEO and Board. They are responsible for providing assurance to the Board that systems and processes are in place and correct policies and procedures are adhered to across the organisation, to ensure safe and effective healthcare.
4.	Accountable to the Board and involved in operational and board level decision making regarding IPC e.g., closing/opening of facilities/provision of additional capacity.
5.	Is a member of the Board and relevant board sub committees such as Quality Assurance Committee.
6.	Ensures IPC is integral in formal systems for collecting and reviewing feedback from patients and service users, carers and staff across services, working with service teams to identify and put in place any action needed as a result of feedback.
7.	Reviews changes made – identifying any ‘lessons learned’ for future IPC work activities.

8. Facilitates continuous improvement in relation to IPC which will be demonstrated, in part, by the achievement of national targets, such as MRSA and Clostridium difficile reduction targets, as well as other quality standards.
Leadership and Management
9. Highly visible, authoritative individual, responsible for providing assurance to the Board that systems are in place and correct policies and procedures adhered to across the organisation to ensure safe and effective healthcare.
10. Models a strong, visible presence, open and trusting relationships with both internal and external partners to achieve IPC service objectives, based on a foundation of self-awareness and emotional intelligence.
11. Demonstrates strong executive authority with leadership visibility and presence.
12. Critically evaluate the culture within IPC teams and enable an optimal working environment through positive compassionate role modelling and leadership skills.
13. Provide values-based leadership across the IPC care pathway, services and systems in complex and changing situations.
14. Leads with emotional intelligence, in line with the NHS constitution values of compassionate leadership to enable individuals and team/s to flourish, grow and deliver high standards of IPC practice.
15. Demonstrate understanding and flexibility to support others during uncertainty, as IPC practice continues to evolve on the health agenda and with ever changing demands.
16. Develop a culture of sharing knowledge that values research, evaluation and academic inquiry & its importance to contemporary IPC practice.
17. Provides advice and guidance at all levels of an organisation with a focus on delivery of high quality, safe, effective and person-centred care, achieving the best outcomes for patients.
18. Leads on how IPC risks are managed in unpredictable and complex situations, including where a precedent has not been set.
19. Lead collaboration across a wide system of professionals and agencies, fostering collaboration and co-production to ensure IPC practice is optimal.
20. Lead strategic development, improvement, inquiry and innovation across specific workstreams that informs and responds to system objectives and supports commissioners and senior leaders with their decision-making in IPC practice.

21. Ensure support is available for staff to innovate IPC practice, balancing innovation with service requirements, overall clinical safety and effectiveness.
22. Build and maintain sustainable partnerships across national/international systems, drawing on standards and best practice to guide decision-making.
23. Collaborate with key stakeholders to ensure that measures are in place to effectively recognise and respond to an infectious disease threat.
24. Be open to feedback on IPC practice by colleagues to promote ongoing development.
25. Engage in a range of appropriate learning and development, continually reflecting on their IPC practice to maximise their capabilities.
Strategy and Policy
26. Implements a joint review of IPC services through peer reviews, audits and evaluations of safety, quality and health outcomes.
27. Work with AMS and IPC committees to develop and update plans to reduce AMR in healthcare, based on findings related to local AMR determinants and data including the consumption of antimicrobial agents.
28. Work collaboratively with key stakeholders in implementing national IPC guidance on HCAI, AMR and AMS.
29. Establish IPC practice across pathways, services, organisations and systems, working with individuals, families, carers, communities and others.
30. Ensure key services supporting IPC (e.g., cleaning, waste management) meet the needs and requirements of the service.
31. Engage and collaborate with stakeholders to advocate for IPC in the built environment.
32. Work with wider stakeholders to determine organisational priorities for surveillance, based on available evidence and resources.
33. Develop plans to collect data: choose surveillance protocols, create or adapt practical data collection forms and identify data collection systems.
Standards and Practice

34. Adapt national guidance, policies and standard operating procedures to local organisation's needs.
35. Support and encourage colleagues in implementing changes relevant to best IPC practice.
36. Apply knowledge of the microorganisms that cause infection in humans in healthcare and community settings.
37. Contribute and participate in IPC monitoring, audit, and significant event reporting.
38. Use surveillance data to reduce the risk of Healthcare Associated Infections among patients, staff and others.
39. Be an advocate for AMS best practice and deliver education in relation to AMR/AMS.
40. Apply AMS principles and good practice, using current evidence-based guidance and local policies.
41. Engage with others in implementing change in IPC practice.
42. Support efforts to minimise AMR, including diagnostic and AMS initiatives and reporting of multidrug-resistant microorganisms, according to local and national requirements.
43. Communicate in a timely and effective manner with stakeholders about modes of transmission, risks of specific pathogens and necessary microbiological investigations.
44. Encourage colleagues to ask questions, make suggestions and seek clarification in relation to the IPC work they have been allocated.
45. Enable others to positively contribute to IPC service improvements and better ways of working, recognising their own role in such endeavours.
46. Ensure support is made available for staff to be able to innovate IPC practice, balancing such innovation with service requirements and overall clinical safety and effectiveness.
47. Leads the ongoing development of IPC pathways, standards, policies, guidelines, procedures, service improvement and practice accreditation.

Knowledge, skills, and Behaviors required by DIPCs to support workforce development activities.

Knowledge	Skills	Behaviours
• Evidence of continued advanced study/action learning/CPD. • Demonstrable in-depth knowledge of healthcare systems, modern methodology, service redesign and project management. • Demonstrable sound theoretical knowledge to support the clinical aspects of commissioning. • Proven clinical knowledge skills in relation to infection prevention and control including: o SICPs and TBPs o Regulatory requirements for IPC o Key national IPC policies, guidance o HCAI surveillance and reporting requirements	• Proven advanced clinical skills in relation to infection prevention and control. • Advanced IT and analytical and interpretation skills. • Awareness of the political agenda. • Effective interpersonal and influencing skills. • Demonstrable negotiation skills. • Proven record of effective team leadership. • Able to deal with/respond appropriately to unpredictable emergency situations. • Demonstrated formal presentation skills. • Evidence of excellent relationship skills with partners resulting in demonstrable quality improvements. • Confidence and ability to communicate highly complex/ contentious information with a variety of audiences. • Ability to successfully engage with patients, public and clinicians relating to the field of Infection Prevention and Control and Antimicrobial Stewardship. • Experience of significant budgetary management.	• Self-confidence and personal drive. • Ability to deal with conflicting demands and pressures. • Ability to solve complex problems. • Results focused. • Resilience. • Commitment to equalities in employment and the promotion of diversity in the workplace. • Flexible, positive, outward looking. • Approachable, compassionate • Working collaboratively with colleagues, particularly if IPC is not their area of personal expertise to ensure that their executive function and advocacy is fully informed by appropriate IPC expertise.

National Infection Prevention and Control Manual for England (NIPCM)

The NIPCM provides an evidence-based approach to IPC practice across all health and social care in England. This policy manual should be adopted as mandatory guidance in NHS settings or settings where NHS services are delivered, and the principles should be applied in all care settings.
C1244_National-infection-prevention-and-control-manual-for-England_April-2022_v1.1.pdf

Infection Prevention Society Competencies Framework for IPC Practitioners

Competencies for infection prevention and control practitioners (IPCPs) were first introduced by the Infection Control Nurses Association (ICNA) in 2000 and subsequently revised by the Education and Professional Development Committee of the Infection Prevention Society (IPS). IPC competencies provide a framework to enable IPC Practitioners to develop and enhance their knowledge and skills to help increase patient safety and care quality. They can also assist in the design of education programmes; staff appraisal and personal development plans and reviewing team structures and requirements.
https://www.ips.uk.net/resources/view/IPS-R-QMVNQ2HHNX3P9L6

NICE Quality standard [QS61] Infection prevention and control

This quality standard covers IPC in adults, young people and children receiving healthcare in primary, community and secondary care settings. It includes preventing healthcare-associated infections that develop because of treatment or from being in a healthcare setting, describing high-quality care in priority areas for improvement: https://www.nice.org.uk/guidance/qs61

Multi-professional framework for advanced clinical practice in England

This multi-professional Advanced Clinical Practice (ACP) framework set out a new and bold vision in developing this critical workforce role in a consistent way to ensure safety, quality, and effectiveness. It has been developed for use across all settings including primary care, community care, acute, mental health and learning disabilities. This framework recognises that the health and care system rapidly evolve to deliver innovative models of care, health and care professionals have adapted, to meet the increasing demands of individuals, families and communities.

multi-professionalframeworkforadvancedclinicalpracticeinengland.pdf (hee.nhs.uk)

Health Education England: Enhanced Practice.

Enhanced practice makes a significant and essential contribution to health and care. The Long-Term Plan (2019) signalled the need to realise the full trained potential of the workforce and the need for meaningful career pathways to retain our valued staff in clinical roles.

See here for more information: Enhanced practice | Health Education England (hee.nhs.uk)

Health Education England: Consultant.

Enhanced practice makes a significant and essential contribution to health and care. The Long-Term Plan (2019) signalled the need to realise the full trained potential of the workforce and the need for meaningful career pathways to retain our valued staff in clinical roles.

More information can be found here: Consultant - Advanced Practice (hee.nhs.uk)

Core Skills Training Framework (CSTF)

Since its launch in 2013, the CSTF has become widely regarded as the benchmark for statutory/mandatory training in the health sector. The aim is to help ensure the quality and consistency of such training and to prevent unnecessary duplication of training. The CSTF comprises 11 subjects including Infection Prevention and Control.

Skills for Health and Health Education England are currently working in collaboration to ensure the sustainability of a robust CSTF with agreed requirements for learning outcomes, training standards and frequency of refresher training for NHS Trusts in England. The aim is to ensure CSTF alignment, which is assured and related data which transfers efficiently, safely and accurately between employer organisations. For more information see here: https://skillsforhealth.org.uk/info-hub/category/cstf-for-nhs-trusts-in-england/

Care Certificate Standards

The Care Certificate is a set of standards that define foundation knowledge, skills and behaviours expected of roles in the health and social care sectors. Designed with the non-regulated workforce in mind, the Care Certificate was launched in 2015 and developed jointly by Skills for Health and Skills for Care and is based on 15 standards, including:

- Standard 15. Infection prevention and control.

Individuals need to complete all 15 standards before they can be awarded their certificate. Each standard is underpinned by full learning outcomes and assessment criteria.

For further information about the Care Certificate see Skills for Health and Skills for Care.

National Occupational Standards (NOS)

National Occupational Standards (NOS) are statements of the standards of performance for individuals when carrying out functions in the workplace, together with specifications of the underpinning knowledge and understanding.

NOS are developed for employers by employers through the relevant Sector Skills Council or Standards Setting Organisation.

The following NOS are offered as guidance to help further underpin IPC practice.

Reference	NOS for Infection Prevention & Control
IPC1.2012	Minimise the risk of spreading infection by cleaning, disinfecting and maintaining environments
IPC2.2012	Perform hand hygiene to prevent the spread of infection
IPC3.2012	Clean, disinfect and remove spillages of blood and other body fluids to minimise the risk of infection
IPC5.2012	Minimise the risk of exposure to blood and body fluids while providing care

IPC6.2012	Use personal protective equipment to prevent the spread of infection
IPC7.2012	Safely dispose of healthcare waste, including sharps, to prevent the spread of infection
IPC8.2012	Minimise the risk of spreading infection when transporting and storing health and care related waste
IPC10.2012	Minimise the risk of spreading infection when transporting clean and used linen
IPC11.2012	Minimise the risk of spreading infection when laundering used linen
IPC12.2012	Minimise the risk of spreading infection when storing and using clean linen
IPC13.2012	Provide guidance, resources and support to enable staff to minimise the risk of spreading infection

Additional suites of NOS (such as Leadership & Management) are also available from the Skills for Health Tools web site.

14. Appendix 4. How the framework was developed

Development of the framework was guided by a ‘short life working group’ (SLWG) representing key stakeholders including clinical practitioners, professional bodies, and IPC experts.

Oversight of the SLWG was provided via the Education, Workforce and Leadership (EWL) Steering Group.

Initial desk research was undertaken to identify key references, resources and significant themes or issues for consideration – further references and resources continued to be identified during the development of the framework. (See Appendix 2. Bibliography).

Initial iterations of the framework were developed based on the findings of the desk research and consultation with the SLWG.

Subsequently, in June 2023, wide consultation of the framework was undertaken through the networks/contacts of SLWG and other identified stakeholders.

Based on analysis of comments received, further amendments and refinements were undertaken.

15. Acknowledgements

This framework was commissioned by the Infection Prevention and Control (IPC) Team at NHS England and development was guided by a Short Life Working Group (SLWG) chaired by Professor Steve Hams and project management was provided by Andrew Lovegrove, Senior Consultant at Skills for Health.

A note of thanks is given to all members of the SLWG and their networks, for providing guidance, expertise, and support during the development of this framework.

Advice, guidance and intelligence

Infection prevention and control standards

For health and adult social care settings

May 2022

NHS SCOTLAND

A47310563

We are committed to advancing equality, promoting diversity and championing human rights. These standards are intended to enhance improvements in health and social care for everyone, regardless of their age, disability, gender reassignment, marriage and civil partnership, pregnancy and maternity, race, religion or belief, sex, sexual orientation, socioeconomic status or any other status. Suggested aspects to consider and recommended practice throughout these standards should be interpreted as being inclusive of everyone living in Scotland.

We carried out an equality impact assessment (EQIA) to help us consider if everyone accessing health and social care services will experience the intended benefits of these standards in a fair and equitable way. A copy of the EQIA is available on request.

Healthcare Improvement Scotland is committed to ensuring that our standards are up-to-date, fit for purpose and informed by high-quality evidence and best practice. We consistently assess the validity of our standards, working with partners across health and social care, the third sector and those with lived and living experience. We encourage you to contact the standards and indicators team at his.standardsandindicators@nhs.scot to notify us of any updates that the infection prevention and control standards project team may need to consider.

First published May 2022

Contents

Introduction

Infection prevention and control (IPC) is critical to keeping people safe when they are receiving health and social care. Effective IPC can help reduce the risk of infection and ensure the safety of people receiving care, staff and visitors. IPC is integral to quality health and social care delivery because anyone is at risk of developing an infection in these settings. Factors that are known to increase this risk include extremes of age (for example being older or very young), the complexity of interventions that are part of a person's care and prolonged or inappropriate use of antimicrobials.[1]

Good IPC practice can help to reduce the prevalence of infections (including healthcare-associated infections - HAIs[2]) that are associated with the delivery of care in hospitals, long-term care facilities (including care homes) and other care settings (such as ambulances, prisons, hospices and independent healthcare facilities).

HAIs can occur as a direct or indirect result of healthcare and treatment including the environment or setting where care is delivered.[3] Some HAIs are acquired through medical or surgical treatment (for example catheter-associated urinary tract infections) or from exposure to a pathogen within a health or social care environment (for example spread of an influenza virus within a hospital ward or care home). Common examples of HAIs include respiratory, urinary tract and gastric infections.

HAIs range from minor infections that require minimal intervention to more significant infections which cause illness and can have serious emotional and medical consequences for people. These consequences have financial implications for the health and social care system in Scotland.[1, 4]

All health and social care staff have an important role to play in preventing the spread of infection by recognising that IPC is everybody's responsibility. Though, not all HAIs are preventable because of factors including a person's pre-existing conditions or the complexity of the treatment they are receiving.

Infection prevention and control standards

IPC standards are a key component in the drive to reduce the risk of infections in health and social care in Scotland. Standards support:

- organisations to quality assure their IPC practice and approaches, and
- the IPC principles set out in the National Infection Prevention and Control Manual.[2]

A single set of standards has been developed for use across health and adult social care. This will support the *Once for Scotland* approach and further integration of health and social care.

Standards underpin Healthcare Improvement Scotland's programme of inspection of the safety and cleanliness in acute and community hospitals.

The Care Inspectorate inspects services using self evaluation frameworks (which include IPC practice) that are informed by standards and the National Infection Prevention and Control Manual.[2, 5-7]

These standards are informed by current evidence, best practice and stakeholder recommendations and supersede Healthcare Improvement Scotland's HAI standards published in 2015. More information about the standards development process can be found at Appendix 1.

Policy context

Since March 2020, services across health and social care have responded to the significant challenges of the COVID-19 pandemic. The pandemic has reinforced the importance of a strategic organisational approach to IPC to ensure that people receiving health and social care, their representatives, staff and visitors experience safe, effective and person-centred care, including in the environment where care is delivered.

The health and care built environment where health and care is delivered can play a significant role in reducing the transmission of infection. In June 2021, NHS Scotland Assure was launched by NHS National Services Scotland. This new national body aims to strengthen IPC in the built environment through oversight of the design, construction and maintenance of major infrastructure developments within the NHS. NHS Scotland Assure will play a pivotal policy and guidance role in relation to incidents and outbreaks across NHSScotland.

In addition, the Care Inspectorate has developed guidance that sets out design, planning and construction considerations for new or converted care homes for adults.These standards align with and support the work of NHS Scotland Assure and the Care Inspectorate.[8]

IPC standards have been developed to complement the National Infection Prevention and Control Manual and Infection Prevention and Control Manual for older people and adult care homes.[2] **Please note: one reference to the National Infection Prevention and Control Manual (which includes the Infection Prevention and Control Manual for older people and adult care homes) has been cited in these standards. Organisations should apply the context specific elements of the manual to their area of practice.**

In addition to local guidance and standard operating procedures, the standards should be read alongside other relevant legislation, policies and guidance. In particular:

- National Infection Prevention and Control Manual[2]
- HAI Compendium: Guidance and resources[9]
- Health and Social Care Standards: my support, my life[10]
- National Health and Wellbeing Outcomes Framework[11]
- Queen Elizabeth University Hospital/NHS Greater Glasgow and Clyde Oversight Board: final report[12]
- Recover, Restore, Renew. Chief Medical Officer for Scotland Annual Report[13]
- Healthcare Improvement Scotland (Requirements as to Independent Health Care Services) Regulations 2011[14]
- Social Care and Social Work Improvement Scotland (Requirements for Care Services) Regulations 2011[15]
- Vale of Leven Hospital Inquiry[16]
- UK 5-year action plan for antimicrobial resistance 2019 to 2024[17]
- Patient Rights (Scotland) Act 2011[18]
- Scotland's public health priorities, and
- other applicable Healthcare Improvement Scotland guidance, including Scottish Intercollegiate Guidelines Network (SIGN) guidelines and Scottish Antimicrobial Prescribing Group (SAPG) guidance and Antimicrobial Resistance and Healthcare Associated Infection (ARHAI) Scotland guidance.

IPC standards are intended to complement, not duplicate, existing standards and guidelines. Reference to appropriate and relevant documentation has been made throughout the standards to signpost organisations and staff to further information. These references are not an exhaustive list. Organisations, services and staff should continue to refer to appropriate and applicable professional guidance, policy and best practice appropriate to the setting where care is being delivered.

Scope of the standards

These standards were commissioned by the Chief Nursing Officer Directorate on behalf of the Scottish Government and co-produced with national and local stakeholders. They are based on current evidence and best practice and are considered to be a requisite of safe, high-quality care in all settings. As such, it is the Scottish Government's expectation that they will be adhered to across all health and social care settings including NHSScotland settings, independent healthcare and adult social care including care homes. The Care Inspectorate and Healthcare Improvement Scotland will take these into account during all relevant scrutiny and regulatory activities.

For more information about Healthcare Improvement Scotland's scrutiny work, see reporting on quality and safety of healthcare in Scotland (healthcareimprovementscotland.org) and for information about how Healthcare Improvement Scotland regulates the Independent Healthcare sector see Regulation of independent healthcare (Healthcareimprovementscotland.org). For more information on regulatory framework in social care settings see the Care Inspectorate's quality framework for care homes for adults and quality frameworks.

All other health (including independent healthcare) and adult social care organisations and settings (including adult day care) are encouraged to adopt the standards as good practice.

Where a principle or criterion applies to a specific setting this has been highlighted throughout the document. The standards should be reviewed pragmatically by service providers. Individual criteria will be applied by service providers in different ways in recognition of the breadth of services and support delivered across health and social care in Scotland.

While NHSScotland and older people and adult care home organisations and settings are expected to meet the standards, the detailed implementation of this document is for local determination.

The standards cover the following areas:

- leadership and governance
- education and training
- communication
- assurance and monitoring systems
- optimising antimicrobial use*
- infection prevention and control policies, procedures and guidance
- clean and safe care equipment
- the built environment, and
- acquisition and provision of equipment.

* including, but not limited to antibiotics.

Using the standards for self evaluation, assurance and improvement

All our standards follow the same format. Each standard includes:

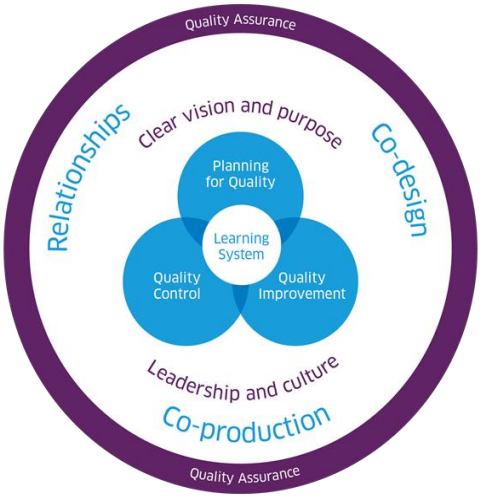
- a statement of the level of performance to be achieved
- a rationale providing reasons why the standard is considered important
- a list of criteria describing the required structures, processes and outcomes
- what to expect if you are a person experiencing care
- what is expected if you are a member of staff, and
- what the standards mean for organisations, including examples of evidence of achievement.

These standards have been published to inform organisational internal quality improvement, self evaluation and improvement. Organisations and services, for example NHS boards or older people and adult care home providers are responsible for implementing and monitoring compliance against these standards.

Healthcare Improvement Scotland and the Care Inspectorate may use these standards in a range of assurance and inspection activities. They may be used to assess registration applications, where appropriate, and review the quality of health and social care services.

Healthcare Improvement Scotland Quality Management System

The Healthcare Improvement Scotland Quality Management System (QMS) describes the key components and functions of a common framework that can be applied across different settings to support delivery of high-quality care.



Within a QMS, services take a holistic and evidence-informed approach to plan for quality including assessing what needs to change; apply quality improvement approaches to measure that changes have delivered improvement; and establish quality control mechanisms to ensure that changes are embedded and sustained in the system. A learning system is the way services use knowledge, evidence and evaluation to keep improving, measure how they are meeting their aims, and to learn and share with others.

Health and social care services are facing considerable financial and workforce challenges. These pressures could lead to a reduction in the quality of care being delivered. This in turn increases the need for a consistent approach to the management of quality, built on evidence and best practice. More information about this framework is available on the Healthcare Improvement Scotland website.

Terminology

Wherever possible, we have incorporated generic terminology, written in plain English, that can be applied across all health and social care settings:

- ‘healthcare organisations’ refers to all services delivered by NHS boards and independent healthcare providers
- ‘social care organisations’ specifically refers to providers of adult social care, and
- ‘staff’ refers to health and social care staff, students and volunteers.

Some sections of the standards document are technical, for example they outline specific aspects of care. Where technical terms have been included, for example *invasive device* or *antimicrobial stewardship*, these are defined in the glossary in Appendix 3. Hyperlinks to these definitions have been included throughout the document.

Summary of standards

Standard 1: **Leadership and governance**

The organisation demonstrates effective leadership and governance in IPC.

Standard 2: **Education and training**

Staff are supported to undertake IPC education and training, appropriate to their role, responsibilities and workplace setting, to enable them to minimise infection risks in care settings.

Standard 3: **Communication**

The organisation implements robust communication systems and processes to enable person-centred decision making, continuity of care and effective IPC throughout a person's care experience.

Standard 4: **Assurance and monitoring systems**

The organisation uses robust assurance and monitoring systems to ensure there is a co-ordinated and rapid response to reduce the risk of infections and to drive continuous quality improvement in IPC.

Standard 5: **Optimising antimicrobial use**

The organisation demonstrates reliable systems and processes for antimicrobial stewardship to support optimal antimicrobial use.

Standard 6: **Infection prevention and control policies, procedures and guidance**

The organisation uses evidence-based IPC policies, procedures and guidance.

Standard 7: **Clean and safe care equipment**

The organisation ensures that care equipment is cleaned, maintained and safe for use.

Standard 8: **The built environment**

The organisation ensures that infection risks associated with the health and care built environment are minimised.

Standard 9: **Acquisition and provision of equipment**

The organisation demonstrates the acquisition and provision of equipment that is safe for use in health and social care settings.

Standard 1: Leadership and governance

Standard statement
The organisation demonstrates effective leadership and governance in IPC.

Rationale

Leadership in IPC underpins an organisation's commitment, approach and mechanisms to reduce the risk of infection.[19]

Effective governance provides assurances that organisations have robust IPC measures in place. These measures include risk and adverse event management, escalation procedures and data monitoring and response.[12, 20] The organisation's governance arrangements adhere to, and support implementation of relevant statutory Duty of Candour regulations and responsibilities.[21]

A transparent IPC assurance and accountability framework, with clearly defined roles and responsibilities, is required to support strategic and operational decision making. It is important that staff are aware of their organisation's accountability and reporting structures, including which teams to contact for IPC leadership and expertise.

All staff working in health and social care have a responsibility to apply IPC measures. Effective IPC requires a strategic and co-ordinated approach and consistent action at all levels within an organisation. This is underpinned by high-quality role-specific education, training and support.

Assessment, monitoring and assurance of IPC is fundamental to reducing the risk of infection. Organisational commitment to a culture of quality improvement encourages teams to continuously assess their performance, identify areas for improvement and measure the results to achieve and maintain improvements.[22]

Criteria

1.1 Appropriate and responsive governance and accountability mechanisms are in place.

a **Healthcare organisations** have:

- an executive lead with accountability for IPC and responsibility for overseeing and providing assurances on IPC within their organisation
- an IPC manager with responsibility for leading local IPC teams and reporting IPC issues to the executive lead,[23] and
- local IPC and health protection teams (HPT) with the necessary expertise, leadership skills and resources to support their organisation.

b **Social care organisations** have:

- an appropriate management structure and/or system that sets out clear accountability and responsibility for IPC within the organisation
- an appropriately trained lead person to co-ordinate IPC within the organisation, and
- access to appropriate health and social care teams for IPC expertise, advice and support.

1.2 The organisation has an IPC assurance and accountability framework that specifies, as a minimum:

- defined roles and responsibilities
- quality monitoring and assurance arrangements
- reporting and escalation structures, and
- an IPC risk management strategy with clear lines of responsibility.

1.3 The organisation has clear systems in place to ensure that it takes a strategic and co-ordinated approach to IPC. This includes, as a minimum:

- compliance with IPC policies, procedures, guidance and standards[9] with appropriate follow-up action where there is non-compliance
- access to specialist IPC advice, guidance and support
- implementation of staff induction, role-specific education and training programmes
- ongoing and consistent data assurance and monitoring with improvement plans
- prompt identification of people who are colonised or are at risk of developing an infection
- accountability and responsibility arrangements for reporting adverse events, in line with the national adverse events framework and national reporting requirements,[24, 25] and
- adherence to Duty of Candour regulations and responsibilities.[21]

1.4 There are well-defined and locally agreed processes to enable:

- an effective multidisciplinary and multiagency approach to IPC
- cross-organisational support including access to specialist advice when indicated
- compliance with mandatory HAI reporting,[9] where required
- staff to implement, monitor and improve their compliance with IPC policies, procedures, guidance and standards[9]
- accurate and prompt communications and information exchange following consent (where applicable) from the individual and within, and between, services and settings, and
- communication and engagement with people that use services, staff, visitors and the public on matters related to IPC, including reducing specific risks.

1.5 The organisation demonstrates effective management of outbreaks, including:

- preparedness
- assessment of a person's care and safety
- reporting, and
- improvement plans.

1.6 The organisation communicates and engages with people/the public on matters related to IPC, including information on reducing specific infection-related risks.

1.7 The organisation communicates and uses information, data and learning from a variety of internal and external sources to support good practice and continuous quality improvement in IPC.

1.8 The organisation ensures that there is continuous engagement with staff, visitors and people that use services and their representatives to capture feedback and inform service improvements.

What does the standard mean for the person receiving care or visiting a health or social care setting?
People are confident that: • the organisation has effective leadership and governance, and is committed to continuously improving the quality of its IPC • staff work together to provide safe, effective and person-centred care • information about them and their care is shared with consent and in line with national guidance, as appropriate • the organisation communicates clearly and openly with them and their representatives, where appropriate • their feedback is used to improve services • the organisation has a system in place for learning, including where there has been an event that resulted in, or could have resulted in, harm.
What does the standard mean for staff?
Staff, in line with role, responsibilities and workplace setting: • are fully informed about their organisation's assurance and accountability framework • understand IPC policies, procedures, guidance and standards, and their role and responsibilities in IPC, including outbreak management • are supported to undertake learning and reflection from adverse events and outbreaks, and • have clear guidance on how to: o identify people at risk of infection o identify IPC-related risks, including those associated with the health and care built environment o report and escalate adverse events o adhere to organisational Duty of Candour regulations and responsibilities, and o share their feedback to inform service improvements.
What does the standard mean for organisations?
Organisations, in line with workplace setting: • demonstrate their commitment to IPC through effective leadership and governance • have a transparent and accessible IPC assurance and accountability framework • have clear systems in place to ensure that there is a co-ordinated and strategic approach to IPC • comply with Duty of Candour regulations and responsibilities • monitor data and use learning to support continuous quality improvement, and • take a multidisciplinary and multiagency approach to IPC.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- An organisational assurance and accountability framework describing lines of accountability, roles and responsibilities, and reporting and escalation structures.
- Implementation of an IPC risk management strategy with records demonstrating that risk registers are regularly reviewed and updated.
- Improvement plans, underpinned by quality improvement methodology, that demonstrate implementation of the IPC standards.
- Accessible documentation demonstrating evidence of staff and team performance, for example audit and improvement activity.
- Organisational responses to assurance visits with appropriate action taken, where required, which are accessible.
- Improvement work including improvement plans, data collection and review of data (for example feedback from people receiving care) and national benchmarking.
- Completion of Reporting of Incidents, Diseases and Dangerous Occurrences. Regulations (RIDDOR)[26] form, and notification to the Health and Safety Executive.
- Duty of Candour monitoring including evidence of organisational openness, honesty and supportiveness.
- Feedback from people receiving care and their representatives, and evidence of learning from complaints or feedback.

Practical examples: healthcare organisations

- Executive board reports or minutes.
- Infection control committee and internal clinical governance group reports Healthcare organisation use of risk assessment tools and risk registers.
- Quarterly reports on current and emerging issues being used for quality improvement.
- Outbreak management plans, including details of the incident management team, as instigated by the healthcare organisation.
- IPC key performance indicators.
- Healthcare Associated Infection Report Template (HAIRT).[2]

Practical examples: social care organisations

- Board reports or minutes.
- Minutes of staff meetings.
- Clinical and care governance group reports.
- Internal risk assessments.
- Quality assurance, risk and audit programme with improvement plans.
- Care Inspectorate notifications.[24]
- Communication and engagement with a person's representatives, for example a family member, in line with relevant governance arrangements and with consent.

Standard 2: Education and training

Standard statement

Staff are supported to undertake IPC education and training, appropriate to role, responsibilities and workplace setting, to enable them to minimise infection risks in care settings.

Rationale

All staff play a vital role in minimising the risk and spread of infection in health and social care settings. Accessible IPC education and training, as part of an organisation's training and development plan, enables staff to develop and maintain their knowledge, skills and competencies in line with national guidance.[2, 27-33] Access to role-specific resources is available to staff, as required. This supports staff to further develop in areas essential to their role, responsibilities and workplace setting.

Embedding positive working and learning environments across an organisation enables staff to continuously develop and improve their IPC knowledge, skills and confidence as part of their role. This includes evaluation of the effectiveness of the education and training programme and assessment of staff knowledge and competence, including how knowledge and skills are embedded into everyday practice.[34]

Empowering staff to act autonomously, confidently and skillfully within their professional and organisational codes, with opportunities to feed back on their experiences, underpins high-quality and person-centred health and social care.

Criteria

2.1 The organisation implements a comprehensive and accessible IPC education and training programme, in line with role, responsibilities and workplace setting, which includes:

- any local or national mandatory staff induction and training
- information on current IPC policies, procedures and guidance, including the National Infection Prevention and Control Manual[2]
- assessment of staff education and training requirements
- tailored education and training, for example infection-specific management and insertion and maintenance of invasive devices, where required
- allocation of dedicated time and resources for staff to access and undertake relevant IPC education and training, including refresher training
- learning and sharing of IPC best practice across settings and sectors
- application of quality improvement methodology for IPC, and
- evaluation of the provision, uptake and effectiveness of IPC training, including providing staff with opportunities to feedback on the education programme and training provided.

2.2 The organisation's training plan includes IPC education and training, in line with role, responsibility and workplace setting, to ensure that staff:

- are supported to maintain role-appropriate levels of skill, knowledge and competency in IPC
- have access to ongoing support, and
- have access to continuous professional development in IPC.

2.3 Staff, in line with role, responsibility and workplace setting have access to clear guidance and support:

- on their role and responsibilities in relation to IPC
- to identify and address their own ongoing continuous professional development, education and training needs
- on what to do when they experience barriers to implementing IPC measures
- on career frameworks and development opportunities in IPC, where relevant, and
- on infection-specific management, including outbreak management.

2.4 As part of educational monitoring across the organisation, organisations use local and national IPC-related data and information to:

- evaluate staff knowledge, skills, competency and confidence in IPC
- identify areas for improvement in relation to staff IPC practice, and
- improve staff IPC practice through further provision of education and training.

What does the standard mean for people receiving care or visiting a health or social care setting?

People are confident that:

- staff are appropriately educated, trained and competent in IPC, in line with their role, responsibilities and workplace setting
- staff have a clear understanding of their role and responsibilities in IPC, and
- the care and support they receive is informed by evidence and best practice.

What does the standard mean for staff?

Staff, in line with role, responsibilities and workplace setting:

- have knowledge and demonstrate skills, competence and confidence in IPC
- use their learning to ensure that they provide safe, effective and person-centred care, and
- can access and undertake relevant training to achieve, maintain and continuously improve their knowledge, skills and competencies including role-specific resources, where appropriate.

What does the standard mean for organisations?

Organisations, in line with workplace setting:

- demonstrate a continuous quality improvement approach and learning culture to ensure that the knowledge and competency of staff in IPC, in line with role, responsibilities and workplace setting, is developed and maintained, and

- ensure that staff are supported to access and undertake training and education appropriate to their role, responsibilities and workplace setting.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- Training and development plans and records, for example induction, e-learning, completion of competencies, safety briefs, conference or study-day attendance.[35, 36]
- Competency frameworks, appropriate to role and workplace setting.
- Where appropriate to role, responsibilities and workplace setting, staff access and participate in quality improvement methodology education and training, for example modules provided by NHS Education for Scotland.[37]
- Where appropriate to role and workplace setting, staff access national learning platforms and systems for health and social care staff, for example Turas Learn, LearnPro, Scottish Social Services Council (SSSC) Learning Zone.[36, 38-40]
- Availability of IPC-related information, which includes appropriate guidance, standards, manuals and audit tools and how they link to IPC practice.
- Where appropriate to role, demonstration of staff having access to regular supervision, appraisal and support to identify training needs.
- Dedicated learning time and support for staff included in the organisation's IPC education and training programme.
- IPC education and training that is easy to access and delivered in formats appropriate for staff learning styles and workplace setting.
- Use of adverse event reports to support training and education programmes.
- Evaluation of training needs and training programmes.
- Staff feedback being used to improve IPC education and training.

Practical examples: healthcare organisations

- Participation records in the organisation's IPC education and training programme, for example Scottish Ambulance Service Learning in Practice.

Practical examples: social care organisations

- Participation records for the NHS Education for Scotland Care Home Train the Trainer Programme.[41]
- Uptake of the Scottish Infection Prevention and Control Education Pathway.[30]
- Uptake of relevant SSSC learning resources.[38]

Standard 3: Communication

Standard statement

The organisation implements robust communication systems and processes to enable person-centred decision making, continuity of care and effective IPC throughout a person's care experience.

Rationale

Communication is fundamental to safe, effective and person-centred IPC. People receiving health and social care can be vulnerable to contracting infections and some present an infection risk to others, including staff and visitors. A person's care experience can involve multiple services and settings, which can increase infection risks. Continuity of care is underpinned by robust and reliable communication within, and between, health and social care organisations and providers.[16]

High-quality, accessible and timely IPC-related information underpins effective communication with the person receiving care, and their representatives where appropriate, and:

- enables informed choice
- supports person-centred decision making, and
- encourages people and their representatives to have meaningful discussions about their care, which can improve their care experience and personal outcomes.[42]

Criteria

3.1 All IPC-related communications with people, and their representatives where appropriate, are documented in the person's care record and used to inform their plan of care.

3.2 Staff are provided with clear, timely and responsive information and guidance on IPC to enable them to provide safe and effective care.

3.3 Staff, IPC teams and HPTs have effective and appropriate communication:

- when information and specialist advice for people receiving care is required
- when there is a known or suspected outbreak or incident, and
- throughout the outbreak management process.

3.4 Staff communicate and work collaboratively within, and between, health and social care settings. This is in line with relevant governance arrangements, including consent to share information, where applicable, to:

- support continuity of care, and
- minimise harm associated with infection, including when people are transferred between services.

3.5 People who are at risk of developing an infection, and their representatives where appropriate, are provided with high-quality and timely communication and information in a format that is right for them. This supports people to:

- understand the impact, consequences and risks of having an infection
- implement IPC precautions, where appropriate
- understand what actions they can take to minimise the risk of developing an infection
- understand what action the organisation is taking to minimise infection risks, and
- make informed decisions and ask questions about their care.

3.6 People that have become colonised or have developed an infection, and their representatives where appropriate, are:

- promptly notified of their infection
- provided with information in a language and format that is right for them
- signposted to support on IPC-related care and procedures
- informed about any impact their infection may have on their care
- given accessible and relevant information about minimising the infection risk to others, and
- provided with opportunities to ask questions about their care.

3.7 Where there is an IPC-related adverse event, the person, and their representatives where appropriate, are informed about this in line with organisational Duty of Candour[21] and professional codes of conduct.

3.8 There is continuous quality improvement of all IPC-related communication systems and processes. This includes:

- monitoring the effectiveness of communications, and
- evaluating and using feedback from staff, visitors and people receiving care and their representatives.

What does the standard mean for people receiving care or visiting a health or social care setting?
People: • receive information in a language and format that is right for them • are listened to and involved in decisions, and • are confident that the organisation or service that provides their care has processes in place to ensure that people have the right information at the right time.
What does the standard mean for staff?
Staff, in line with role, responsibilities and workplace setting: • ensure that people receive effective communication to help minimise infection risks • regularly communicate within, and between, relevant teams for expert information and advice

- effectively communicate with people receiving care, and their representatives where appropriate, regarding the mitigation of risks to the person and other people in the health and social care setting, and
- are competent in communicating risks within, and between, health and social care settings, to enable continuity of care, and to mitigate risks to other people in the health and social care setting.

What does the standard mean for organisations?

Organisations, in line with workplace setting, have IPC-related communication systems or processes in place:

- to enable safe, effective and person-centred communications throughout a person's care experience
- to ensure the availability of appropriate and easily accessible information in a range of languages and formats
- to ensure that communication of infection-related information and guidance is clear and timely, and
- that support collaborative working within, and between, health and social care settings.

Organisations evaluate and respond to feedback on IPC-related communications taking appropriate actions to learn and improve communication.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- Availability of information provided in alternative formats and languages.
- Timely communications and collaboration between health and social care settings detailing any infections, for example handovers, discharge summaries and admission letters.
- Mechanisms for communication regarding IPC issues within, and between, health and social care settings, for example electronic staff communication systems.
- Examples of person-centred communication with a person's representatives where a person has reduced capacity or is unable to make their own decisions.[43]
- Availability and use of information leaflets appropriate to individual need.[44]
- Duty of Candour monitoring.[21]
- Feedback from staff, visitors and people receiving care and their representatives, and evidence of learning from complaints or feedback.

Practical examples: healthcare organisations

- Enquiries and responses to and from the IPC team.
- Examples of completed care records/plans (anonymised) for communication between people receiving care and their representatives and healthcare staff about HAIs throughout a hospital episode. Examples include a person's methicillin-resistant *Staphylococcus aureus* (MRSA) status and cause of death.

Practical examples: social care organisations

- Enquiries and responses to, and from, the HPT.
- Minutes of relevant meetings.
- Care Inspectorate notifications.[24]
- Safety huddle and outbreak reporting tools.

- Setting-specific information, for example relative information leaflets and information provided through approved online platforms.
- Implementation of the Care Inspectorate's quality frameworks, for example 'A quality framework for adults'.[45]

Standard 4: Assurance and monitoring systems

Standard statement

The organisation uses robust assurance and monitoring systems to ensure there is a co-ordinated and rapid response to reduce the risk of infections and to drive continuous quality improvement in IPC.

Rationale

Robust assurance and monitoring systems support organisations to reduce infection risks and improve people's outcomes. The most effective systems enable organisations to:

- systematically collect, monitor, analyse and interpret data on an ongoing basis
- seek expertise that is proportionate to the complexity and seriousness of the incident, and
- act on the findings appropriately.

It is important that organisations understand the risk factors associated with the different groups of people they care for and support to ensure that the care and support is responsive to an individual's needs.

Monitoring results drives continuous quality improvement and reduces infection risks by enabling organisations to:

- inform, support and improve practice for clinical, care and support service staff
- analyse the effectiveness of responses
- monitor trends and identify areas for targeted improvement
- review the impact that responses and interventions have on reducing infections
- share learning across the organisation and with external partners, and
- report and communicate infection rates to people/the public.

Criteria

4.1 The organisation has robust assurance and monitoring systems and processes in place, with appropriate triggers:

- to carry out mandatory national and local surveillance of infections and alert organisms, in line with national guidance[2, 9]
- that enable access to multidisciplinary support from professionals and teams with specialist IPC knowledge and expertise, where required
- that enable prompt detection, response and ongoing monitoring of any variance from normal local infection limits, including incidents and outbreaks, in line with national guidance[2, 9]
- to respond to all infection-related incidents and outbreaks, in line with the National Infection Prevention and Control Manual,[2] and
- to help identify and plan areas for targeted learning and improvement.

4.2 The organisation reviews and evaluates assurance and monitoring activity to ensure that:

- information from assurance and monitoring systems is used to help reduce infection risks
- appropriate action is taken, where required, to further reduce infection risks, and
- learning can be shared across settings and sectors.

4.3 The organisation's assurance and monitoring system enables information and interpreted data to be communicated, in an accessible format, to:

- relevant health and social care teams, and
- people in receipt of care, and their representatives and visitors, as appropriate.

4.4 Staff that use assurance and monitoring systems:

- have their training needs assessed in line with career and development frameworks appropriate to their role, responsibilities and workplace setting, and
- undertake relevant and up-to-date training on the organisations system.

4.5 **Healthcare organisations** report performance against local and national measures:

- through internal reporting structures
- to external partners, for example ARHAI Scotland, and
- publicly at board meetings.

4.6 **Healthcare organisations** review and report assurance and monitoring system data, including new, emerging and re-emerging infection-related risks, in line with the National Infection Prevention and Control Manual.[2] This information is shared with external partners.

What does the standard mean for people receiving care or visiting a health or social care setting?
People: • can expect to be cared for in an environment where staff, teams and organisations work together to monitor, minimise and manage infection risks, and • can be confident that services are safe and effective.
What does the standard mean for staff?
Staff, in line with role, responsibilities and workplace setting: • understand how they support monitoring, reporting and responding to infection risks in line with the organisation's assurance and accountability framework as described in standard 1 – leadership and governance • participate in, and implement learning from, relevant education and training programmes as described in standard 2 – education and training • are empowered to report and escalate issues within the multiagency team • work collaboratively with multidisciplinary and multiagency teams to ensure that infection-related issues are understood and responded to as necessary to reduce infection-related risk

- know how to seek specialist support from relevant professionals and teams, where required, and
- use infection and IPC-related data and intelligence to drive improvements in care and support.

What does the standard mean for organisations?

Organisations, in line with workplace setting, can demonstrate that:

- assurance and monitoring systems are in place to support IPC practice and ensure that infection-related incidents are detected and responded to, and
- infection and IPC-related data are reviewed to ensure that assurance and monitoring activity is effective in reducing infection risks.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare organisations and social care organisations

- Local and national reporting and escalation of infection surveillance, incidents and outbreaks.
- Access and uptake of quality improvement training for staff, where appropriate, in relation to assurance and monitoring systems.
- Audit and improvement plans.
- Staff understanding of organisational monitoring, for example local standard operating procedures and guidance documents, with detail on how they would escalate.
- Responses to trigger alerts with improvement plans.
- Availability of communications on assurance and monitoring information in staff and public areas, for example audit result charts and graphs.

Practical examples: healthcare organisations

- Completed Healthcare Infection Incident Assessment Tool (HIIAT) assessments, where required.[2]
- Minutes of meetings from internal governance groups, for example problem assessment groups, incident management teams, ‘hot debriefs’ and infection control and clinical governance committees.
- Submission of data for national audit and surveillance programmes.
- Incident Management Team meeting minutes with improvement plans, where required.

Practical examples: social care organisations

- Reporting to public health departments on infection-related incidents and notifiable infections.
- Minutes of board meetings and internal governance groups, for example clinical and care governance.
- Care Inspectorate notifications.[24]

Standard 5: Optimising antimicrobial use

Standard statement

The organisation demonstrates reliable systems and processes for antimicrobial stewardship to support optimal antimicrobial use.

Rationale

Antimicrobial resistance is a significant threat to public health.[46] Overuse and misuse of antimicrobials (including antibiotics) drives the development of drug resistant pathogens that can adapt and find ways to survive the effects of antimicrobials.[47, 48] A key element of optimising antimicrobial use is that people receive the most appropriate antibiotic (type, dose, route and duration) promptly for their infection, according to local and national policy and guidance. An organisational approach to optimising antimicrobial use, in the form of a co-ordinated antimicrobial stewardship programme, ensures that antimicrobial use is safe, clinically effective and person-centred.

Criteria

5.1 All organisations can access appropriate antimicrobial expertise.

a **Healthcare organisations** have a core multiprofessional Antimicrobial Management Team, with defined roles and responsibilities, for the oversight and co-ordination of all aspects of antimicrobial use within the NHS board.

b **Social care organisations** access antimicrobial expertise through the local NHS board to ensure that there is optimal antimicrobial use for people receiving care.

5.2 All organisations support optimal antimicrobial use.

a **Healthcare organisations** implement and evaluate a planned programme of education for optimising antimicrobial use.[49] The programme is provided to all staff involved in the prescribing, supply and administering of antimicrobials.

b **Social care organisations** support optimal antimicrobial use through**:**

- promoting awareness to all staff involved in prescribing, supplying and administering antimicrobials, and
- enabling all staff involved in prescribing, supplying and administering antimicrobials to access relevant education and training.

5.3 **Healthcare organisations** support optimal use of antimicrobials by ensuring that:

- local antimicrobial policies are produced and updated at least every three years, or when indicated, in line with current national policy, guidance and best practice
- local antimicrobial policies and guidance are accessible to all health and social care staff, and
- staff who prescribe, supply and administer antimicrobials are alerted to any changes in antimicrobial practice policy and guidance.

5.4 **Healthcare organisations**, through the Antimicrobial Management Team, maintain an annual programme for antimicrobial stewardship.[50] This programme includes:

- monitoring data, including all adverse events relating to antimicrobial use
- providing feedback on prescribing practice to clinical teams
- targeted quality improvement interventions to address poor clinical practice in the use of antimicrobials,[50, 51] and
- reporting findings, including risk assessments, and improvement plans where appropriate, through internal governance structures.

5.5 To ensure that the **healthcare organisation** optimises its antimicrobial use through a quality improvement approach, the Antimicrobial Management Team:

- works with the multidisciplinary team to support and promote antimicrobial stewardship across health and social care
- participates in the implementation of an antimicrobial stewardship programme of education for optimising antimicrobial use
- reviews antimicrobial prescribing and resistance data in line with the annual programme for local surveillance of antimicrobial use[50, 52]
- feeds back the main findings of the review to clinical and management teams, and
- responds to data that indicate poor antimicrobial stewardship with targeted improvement interventions.[53]

What does the standard mean for people receiving care or visiting a health or social care setting?
People are confident that: • they will receive the most appropriate antibiotic (type, dose, route and duration) promptly for their infection, according to local and national policy and guidance • they will be involved in discussions regarding the reason for antimicrobial treatment, the intended duration and any potential adverse reactions • their care plan is updated with all information relating to their antimicrobial treatment, and • staff, in line with role, responsibilities and workplace setting, are appropriately trained and demonstrate knowledge of local and national antimicrobial prescribing policies, procedures and guidance.
What does the standard mean for staff?
Staff, in line with role, responsibilities and workplace setting: • are aware of the importance of their role in optimising antimicrobial use for the benefit of people receiving care and the wider public, and can demonstrate this in practice • are aware of the risks associated with poor prescribing and support colleagues where poor practice is identified • participate in education and training on appropriate antibiotic use as part of their continuing professional development, and • can demonstrate knowledge, skills and competences on rationales for antibiotic use.

Staff that prescribe antimicrobials:

- can demonstrate their competencies in relation to safe and effective antimicrobial prescribing for the treatment and prophylaxis of infection
- are enabled to access local antimicrobial policy and guidance, and
- engage in interventions to optimise antimicrobial prescribing.

What does the standard mean for organisations?

Organisations, in line with workplace setting:

- recognise the risks of antimicrobial resistance from poor antimicrobial use
- are assured that they have a programme in place for antimicrobial stewardship, including evaluation of the delivery of the annual work plan, and
- are assured that systems are in place to detect and respond to data on poor prescribing and administering practices.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- Availability of antimicrobial guidance, for example signposting to the Antimicrobial Companion[54] and Scottish Antimicrobial Prescribing Group guidance.
- Improvement plans to address areas for quality improvement and evidence of progress against improvement plans.
- Support for staff to access education and training on optimal antimicrobial use.
- Multidisciplinary working to support and promote antimicrobial stewardship.
- Processes in place to access advice from local experts on the use of antimicrobials.
- Audits on appropriate antimicrobial prescribing in line with current guidance and best practice with improvement plans.

Practical examples: healthcare organisations

- Local antimicrobial policies that are produced and updated at least every three years.
- Regular audit and surveillance, including improvement plans, of antimicrobial use in line with Scottish Antimicrobial Prescribing Group policy and guidance.
- Feedback from the Antimicrobial Management Team provided to all teams involved in the prescribing, supply and administering of antimicrobials.
- Antimicrobial stewardship reporting through internal governance structures.
- Availability of organism- and body-system-specific treatment decision making aids, for example urinary tract infection, respiratory tract infection and MRSA.
- Prescribing and resistance data have been used to inform continuous quality improvement.
- Information exchange with multidisciplinary teams, for example through email, electronic portals and regular reporting of antimicrobial data.
- Membership, terms of reference, minutes and annual programme/plan of the Antimicrobial Management Team.
- JRCALC (Joint Royal Colleges Ambulance Liaison Committee) app[55] for Scottish Ambulance Service staff.

Practical examples: social care organisations

- Education and training records.

- Availability of antimicrobial information and guidance, for example signposting to Scottish Antimicrobial Prescribing Group guidance.[48, 56]

Standard 6: Infection prevention and control policies, procedures and guidance

Standard statement

The organisation uses evidence-based IPC policies, procedures and guidance.

Rationale

Implementation of evidence-based and accessible IPC policies, procedures and guidance can help reduce the risk of infection and ensure the safety of people receiving care, staff and visitors. A consistent and evidence-based approach to IPC:

- enables staff to apply effective standard and transmission-based precautions
- can reduce unwarranted variation by reinforcing robust IPC practice, and
- helps to align IPC practice, monitoring, quality assurance and quality improvement.

Criteria

6.1 The organisation ensures that the National Infection Prevention and Control Manual[2] appropriate for the specific care setting is adopted, implemented and accessible to staff.

6.2 The organisation has, and implements, an annual IPC work programme in line with national requirements and the National Infection Prevention and Control Manual.[2, 57]

6.3 The organisation has systems and processes in place to ensure that:

- staff are alerted to any changes in IPC policy, procedures and guidance, including the National Infection Prevention and Control Manual,[2] that may impact practice
- risk assessments, with mitigating actions, are put in place and reviewed when staff are unable to adopt and implement the National Infection Prevention and Control Manual[2]
- audit data and information, including risks, are fed back to staff, leadership teams, the executive team and registered services, as appropriate
- when an audit programme is not undertaken within the agreed timescales the risks are discussed, agreed and recorded through internal governance structures
- an improvement plan with clearly defined responsibilities and evidence of review is developed in response to audit data
- data and themes emerging from audit(s) are used to inform staff education and training and drive improvement in IPC practice
- there is access to appropriate specialist clinical advice for IPC and the diagnosis, treatment and management of infections, and
- learning from instances where staff are unable to adopt and implement the National Infection Prevention Control Manual[2] is shared.

What does the standard mean for people receiving care or visiting a health or social care setting?

People are confident that:

- they receive care in a clean and well-maintained environment without unnecessary exposure to infection, and
- staff that provide their care have knowledge and can demonstrate competencies in IPC practices.

What does the standard mean for staff?

Staff, in line with role, responsibilities and workplace setting:

- are fully informed about where to access up-to-date and relevant IPC policies, procedures and guidance
- can access and implement relevant IPC policies, procedures and guidance, including the National Infection Prevention and Control Manual[2]
- are fully informed about their organisation's IPC work programme, including audit data and information
- can evidence their safe IPC practice
- know how to respond and escalate if they have insufficient resources or support to minimise infection risks, and
- can access specialist IPC advice and support to enable them to effectively implement guidance.

What does the standard mean for organisations?

Organisations, in line with workplace setting, ensure that:

- relevant policies, procedures and guidance are available and accessible for staff in line with role and responsibilities
- the current National Infection Prevention and Control Manual[2] is adopted, implemented and accessible for staff
- an annual IPC work programme is implemented, and
- effective systems are in place to monitor, report and respond to audit data and information.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- IPC education programme and training records.
- Environmental and equipment cleaning schedules.
- Membership, terms of reference and minutes of internal governance groups.
- National Infection Prevention and Control Manual[2] compliance audits and improvement plans.
- Audits with improvement plans.
- Completed improvement plans following an outbreak or adverse event.
- Risk assessments.
- Accessible up-to-date policy information displayed to staff.
- Lessons learned document themes are shared with appropriate improvement plan.

Practical examples: healthcare organisations

- Completed care plans for people with an alert organism.
- Completed rapid event investigations into HAIs, for example *Staphylococcus aureus* bacteraemia.

Practical examples: social care organisations

- Feedback from people receiving care and their representatives is used for service improvement.
- Care Inspectorate inspection reports.

Standard 7: Clean and safe care equipment

Standard statement
The organisation ensures that care equipment is cleaned, maintained and safe for use.

Rationale

Care equipment can be easily contaminated with infectious agents that can transfer during care delivery.[2] The effective cleaning or decontamination of care equipment is essential to minimise the risk of transmission of infectious agents between people.[2, 58, 59]

Organisations must demonstrate ongoing compliance with statutory legislation and implement national guidance to ensure that all care equipment is clean, maintained, free from damage and safe for use.[2, 9, 60, 61]

Please note: the decontamination of reusable invasive equipment, for example surgical instruments and endoscopes, is not within the scope of these standards.

Criteria

7.1 The organisation has, and implements, cleaning and decontamination policies and procedures in line with current:

- statutory legislation,[60] and
- national guidance.[2, 9, 61]

7.2 The organisation has effective cleaning and decontamination systems and processes in place to ensure that:

- all care equipment is clean, maintained and safe for users at the point of use to minimise the risk of cross-infection
- all care equipment is stored, installed, serviced, maintained, repaired, decommissioned and appropriately disposed of in line with the manufacturer's instructions, where relevant
- cleaning and decontamination of care equipment is carried out in line with the manufacturer's instructions and current national guidance, where relevant
- reporting and escalation of any cleanliness and maintenance issues are routinely undertaken, including evidence that issues have been addressed
- there is specialist input and guidance where cleaning or decontamination issues are identified, or existing activity does not meet requirements
- safety notices for care equipment are responded to
- there is accurate record keeping and documentation, where relevant, and
- feedback from people receiving care, staff and visitors is sought on the cleanliness and maintenance of care equipment and acted upon, where appropriate.

7.3 The organisation carries out regular audit to inform risk assessment, with mitigating actions, where any part of the cleaning or decontamination process cannot or has not been followed.

7.4 Where there is an adverse event associated with the cleaning or decontamination of care equipment, the organisation:

- investigates the reason for the adverse event and reports this using the HIIAT tool,[2] where relevant
- reviews processes during and following the adverse event or near miss in line with the national adverse events framework,[25] and
- reports through national reporting mechanisms,[24, 62] where required.

What does the standard mean for people receiving care or visiting a health or social care setting?
People are confident that any equipment used in their care is safe, clean and free from contamination at the point when it is being used.
What does the standard mean for staff?
Staff in line with role, responsibilities and workplace setting: • can articulate their individual role and responsibilities in the cleaning and decontamination of care equipment, including when there is an incident or outbreak • are aware of their organisation's cleaning and decontamination systems and processes relevant to their area of work • report and escalate issues and incidents, and • are committed to implementing learning from cleaning and decontamination-related incidents to support continuous quality improvement.
What does the standard mean for organisations?
Organisations, in line with workplace setting: • are compliant with the relevant regulations, cleaning and decontamination guidance and technical requirements and local policies and procedures • have effective systems and processes in place to assure the provision of clean, maintained and safe reusable care equipment • implement risk assessment mitigating actions, and • communicate and work collaboratively with agencies to share learning.
Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*
Practical examples: healthcare and social care organisations • Compliance with legislation and national guidance. • Records of the adverse event with improvement plans and evidence of learning. • Completed and signed cleaning schedules and records. • Minutes of local governance meetings. • Circulation of safety action notices to appropriate teams. • Maintenance records. • Risk assessments. • Education and training records. • Audits of care equipment with improvement plans. • Records/minutes showing how risk assessments for care equipment are regularly reviewed. • Audit reports of decontamination processes with improvement plans.

Practical examples: healthcare organisations

- Completion of HIIAT tool, where relevant.[2]
- Facilities monitoring tool feedback being used to inform service improvements.
- National reporting to Incident Reporting and Investigation Centre (IRIC).

Practical examples: social care organisations

- Care Inspectorate inspection reports and outcomes/findings.
- Care Inspectorate notifications, where appropriate.[24]
- Audits in line with the safe management of care equipment with improvement plans.

Standard 8: The built environment

Standard statement

The organisation ensures that infection risks associated with the health and care built environment are minimised.

Rationale

The health and care built environment (the environment) where health and care is delivered can play a significant role in the transmission of infection.[63] It is important that infection risks associated with these environments, for example water and ventilation systems, are minimised and managed through a co-ordinated and multidisciplinary approach. Organisational compliance with legislation, regulations and guidance, for example HAI-SCRIBE and Scottish Health Technical Memoranda (SHTM), underpins this approach.[2, 8-10, 61, 64, 65]

High standards of environmental cleanliness, IPC practice and ongoing maintenance of the environment can minimise the risk of the transmission of infection.[2] It is essential that the organisation provides a clean, well-maintained and safe environment.

Criteria

8.1 The organisation has, and fully implements, current policies and procedures to minimise the risk of infection across all areas of the environment in line with:

- statutory legislation and regulations, and
- national guidance and processes.[2, 8, 9, 61, 64, 65]

8.2 There are clear and agreed channels of communication and prompt information exchange across all relevant organisations, teams and settings to enable early assessment of potential and existing IPC risks associated with the environment.

8.3 The organisation ensures that IPC risks associated with construction, renovation, maintenance and repair of the environment are minimised by demonstrating that:

- building, refurbishment and maintenance work follow agreed processes and are planned, appropriately risk assessed, authorised, documented and carried out in ways that minimise infection risks and disruption to staff, people receiving care and visitors[61, 65]
- risks and issues are identified and communicated through appropriate mechanisms at the planning stage of building, refurbishment and maintenance work; a formal risk assessment with mitigation is put in place and acted on appropriately with key staff and teams involved at relevant stages
- there is regular monitoring and audit of maintenance and repair services to ensure that this is carried out in line with an agreed schedule[61]
- there is robust reporting, with follow-up action, including associated documented decision making and derogations,[61] where the environment cannot be accessed for maintenance or repair
- there is robust reporting, escalation, follow-up action, sign off and documentation of any IPC-related issues associated with the environment, and
- records and reports relating to maintenance, repair and refurbishment of the environment are accessible and regularly updated and reviewed.

8.4 The organisation ensures that the environment is safe and clean by demonstrating that:

- environmental cleanliness is in line with national guidance[61, 64]
- there is robust monitoring and audit of cleaning, including an escalation plan, where required
- there is robust decision making and reporting with appropriate follow-up action and escalation where the environment cannot be accessed for cleaning
- records and reports relating to the cleanliness of the environment are accessible and regularly updated and reviewed, and
- there is active engagement with people receiving care, staff and visitors to obtain feedback on the cleanliness of the environment. This includes development of an improvement plan, as appropriate.

8.5 Staff have access to information, specialist guidance and support to minimise infection risks associated with the environment. This ensures that staff are clear on their roles and responsibilities when:

- IPC risks and issues are identified in the environment
- additional cleaning activity is identified as necessary
- there is planned refurbishment or maintenance work in the environment
- there is emergency building or repair work to be undertaken
- known or suspected outbreaks and incidents relating to the environment are identified
- there is an alteration in the function or purpose of an area
- there is a change of use to an area, and
- the area cannot be accessed.

8.6 Learning from incidents, outbreaks and building and maintenance projects is shared throughout the organisation and across sectors to support continuous quality improvement in IPC.

What does the standard mean for people receiving care or visiting a health or social care setting?
People are confident that the environment is clean, maintained and safe.
What does the standard mean for staff?
Staff, in line with their role, responsibilities and workplace setting: • can articulate their individual role and responsibilities in providing a clean, maintained and safe environment • understand the risks associated with the environment and how to mitigate them • are aware of the level of cleaning required for the area that they are working in • are assured that there are effective systems in place to ensure a clean, maintained and safe environment, and • know who to escalate IPC risks and issues to in the event of a known or suspected environment incident or outbreak.

What does the standard mean for organisations?

Organisations, in line with workplace setting:

- are compliant with legislation, guidance and technical requirements associated with the environment
- have effective systems and processes in place to assure the provision of a clean, maintained and safe environment
- have transparent decision making and governance processes in place where derogations are required
- ensure staff are provided with the education and training, in line with role, responsibilities and workplace setting, to manage environment incidents and outbreaks and mitigate associated risks, and
- have quality assurance measures in place, including audits, to ensure compliance with systems and processes to mitigate risk associated with the environment.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- Compliance with legislation and national guidance, including the National Infection Prevention and Control Manual.[2]
- Evidence that learning has been shared within and across organisations.
- Assurance mechanisms and accreditation checks when working with external partners.
- Water safety policy.
- Water outlet monitoring records.
- Infection-related risk assessment, for example Legionella risk assessment.
- Inspection reports and improvement plans.
- IPC audits with improvement plans, for example audits in line with the Safe Management of the Care Environment.[61]
- Feedback from people receiving care and their representatives, and evidence of learning from complaints or feedback.

Practical examples: healthcare organisations

- National facilities monitoring tool.[61]
- Annual validation and verification of ventilation systems.
- IPC audits with improvement plans, for example Scottish Ambulance Service vehicle and station audits.
- Patient feedback, for example, Care Opinion reviews.
- Incident and outbreak data and reports.
- HAI-SCRIBE documentation.[61]
- IPC committee, water safety group, and ventilation and pressure systems management group minutes.
- Ventilation systems management records.
- Compliance with Scottish Capital Investment Manual including completion of NHS Scotland Design Assessment Process, where required.[65]
- Completion of key stage assurance reviews, where required, and improvement plans.
- National Infection Prevention and Control Manual compliance data.[2]

Practical examples: social care organisations

- Compliance with Building Better Care Homes for Adults.[8]
- Records of compliance with National Cleaning Services Specification[64] or equivalent.
- Completed cleaning schedules.
- Development/refurbishment plans.
- Quality assurance records with improvement plans.
- Maintenance logs and reports.
- Care Inspectorate reports and complaint findings.

Standard 9: Acquisition and provision of equipment

Standard statement

The organisation demonstrates the acquisition and provision of equipment that is safe for use in health and social care settings.

Rationale

In this context, equipment that is acquired and provided for use in health and social care settings relates to any equipment that is:

- procured
- donated
- loaned
- manufactured in house, and
- used within a trial or for research purposes.

Infection risks to people receiving care, staff and visitors can be minimised when there is an acquisition process in place to ensure that equipment is safe for its intended use and can be effectively cleaned or decontaminated in line with manufacturer's instructions.[59]

Please note: the scope of this standard does not apply to personal items/equipment that are brought into a health or social care setting for personal use.

Criteria

9.1 The organisation has, and implements, policies and procedures for acquiring equipment in line with current:

- statutory legislation and regulations,[66-68] and
- national guidance.[9, 58, 61, 69]

9.2 There is IPC consideration and multidisciplinary involvement in the acquisition process prior to procurement. This includes the acquisition of new equipment.

9.3 The organisation has systems and processes in place to ensure that:

- all acquired equipment is compatible with national guidance[2, 61]
- all acquired equipment that cannot be effectively cleaned or decontaminated is removed from use, and
- feedback is provided to relevant teams on equipment that cannot be effectively cleaned or decontaminated to support continuous quality improvement.

9.4 All adverse events associated with equipment are:

- reported through the organisations local adverse event system
- reported through national reporting mechanisms, where required,[24, 62] and
- managed in line with the organisation's adverse event policy and the national adverse events framework.[25]

What does the standard mean for people receiving care or visiting a health or social care setting?

People are confident that all equipment used by staff or used in health and care settings meets the required level of safety, quality and performance.

What does the standard mean for staff?

Staff, in line with role, responsibilities and workplace setting:

- demonstrate competency, where appropriate, in applying policies and procedures in relation to the acquisition and provision of equipment
- can describe their involvement in the acquisition process and how it impacts on IPC, where appropriate
- are confident in the safety, quality and performance of all equipment, and
- can describe the process for reporting non-compliant equipment.

What does the standard mean for organisations?

Organisations, in line with workplace setting, have systems and processes in place that demonstrate the effective and efficient acquisition and provision of equipment that is safe for use.

Practical examples of evidence of achievement *(NOTE: this list is not exhaustive)*

Practical examples: healthcare and social care organisations

- Compliance with statutory legislation, regulations and guidance.
- Assessment of compatibility of all equipment, which impacts on IPC, with existing cleaning or decontamination processes.
- Adverse event reporting, where indicated.
- The implementation of a loan policy.
- The implementation of a procurement policy.

Practical examples: healthcare organisations

- Multidisciplinary involvement in decision making on the acquisition of equipment, where required.
- Procurement policy, procedures and records related to the acquisition of care equipment that impacts IPC.

Practical examples: social care organisations

- A procurement process that demonstrates consideration of IPC and cleaning or decontamination requirements.
- Care Inspectorate notifications, where appropriate.[24]

Appendix 1: Development of IPC standards

The IPC standards have been informed by current evidence and best practice recommendations and developed by group consensus.

Evidence base

A systematic review of the literature was carried out using an explicit search strategy devised by an information scientist in Healthcare Improvement Scotland. Additional searching was done though citation chaining and identified websites, grey literature and stakeholder knowledge. Searches included Scottish Government, Public Health Scotland, NICE, SIGN, NHS Evidence and Department of Health websites. This evidence was also used to inform all relevant impact assessments.

Development activities

A standards development group, chaired by Professor Hazel Borland, Executive Nurse Director, NHS Ayrshire & Arran was convened in April 2021 to consider the evidence and to help identify key themes for standards development.

Membership of the development group is set out in Appendix 2.

To ensure each standard is underpinned with the views and expectations of service staff from across health and social care, independent and third sector representatives and people/the public in relation to IPC, information has been gathered from a number of activities, including:

- a three-week scoping engagement period, and
- six development group meetings between April and August 2021.

Draft IPC standards were published on 12 October 2021. An 8-week consultation period was held to capture stakeholder feedback on the draft standards.

A summary of all feedback received during the consultation process, and details of any changes made to the final standards as a result, can be found on the Healthcare Improvement Scotland website.

Quality assurance

All development group members were responsible for advising on the professional aspects of the standards. Clinical members of the development group were also responsible for advising on clinical aspects of the work. The chair had lead responsibility for providing formal clinical assurance and sign off on the technical and professional validity and acceptability of any reports or recommendations from the group.

All development group members made a declaration of interest at the beginning of the project. They also reviewed and agreed to the development group's terms of reference. More details are available from the Healthcare Improvement Scotland website.

Healthcare Improvement Scotland also reviewed the standards document as a final quality assurance check. This ensures that:

- the standards are developed according to agreed Healthcare Improvement Scotland methodologies
- the standards document addresses the areas to be covered within the agreed scope, and

- any risk of bias in the standards development process as a whole is minimised.

For more information about Healthcare Improvement Scotland's role, direction and priorities, please visit: www.healthcareimprovementscotland.org/

Appendix 2: Membership of the IPC standards development group

Hazel Borland (*Chair*)	Executive Nurse Director/Deputy Chief Executive, NHS Ayrshire & Arran (until April 2022)
Lara Allan	Policy Manager, Chief Nursing Officer's Directorate, Scottish Government
Linda Bagrade	Consultation Microbiologist and Infection Control Doctor, NHS Greater Glasgow and Clyde
Michael Cassells	Principal Architect, Health Facilities Scotland
Alison Cockburn	Lead Antimicrobial Pharmacist, NHS Lothian
Linda Dalrymple	Lead Infection Prevention and Control Nurse, NHS Tayside
Karen Davidson	Podiatrist, NHS Dumfries and Galloway
Lynda Davidson	Health Protection Nurse, NHS Highland
Jackie Dennis	Senior Improvement Advisor, Care Inspectorate
Sandra Devine	Acting Infection Control Manager, NHS Greater Glasgow and Clyde
Jane Douglas	Chief Nurse, Care Inspectorate (until September 2021) Transforming Workforce Lead Nursing, Scottish Care (from October 2021)
Kay Duncan	Senior Charge Nurse, NHS Grampian
Hazel Dunsmuir	Care Home Manager, Abbotsford Care Home
Sofie French	Principal Educator, NHS Education for Scotland
Rhona Gardiner	Head of Service, Cross Reach
Susan Grant	Principal Architect, Health Facilities Scotland
George Grindlay	Public representative
Lindsay Guthrie	Associate Nurse Director Infection Prevention and Control, NHS Lothian
Lynda Hamilton	Specialist Advisor – Infection Prevention and Control, ARHAI Scotland
Sulisti Holmes	Head of Decontamination and IRIC, Health Facilities Scotland
Jonathan Horwood	Infection Control Manager, NHS Forth Valley
Laura Imrie	Lead Consultant, ARHAI Scotland
Jacqueline Jowett	Inspector, Healthcare Improvement Scotland
Ann Kerr	Lead Surveillance Nurse, NHS Greater Glasgow and Clyde
Grace MacDonald	Learning and Development Advisor, Scottish Social Services Council
Vince McCluskey	Lead Infection Prevention and Control Advisor, Scottish Ambulance Service
Donna McConnell	Infection Prevention and Control Nurse Lead, NHS Greater Glasgow and Clyde
Justine McCuaig	Health Protection Nurse, NHS Dumfries and Galloway
Pauline McIntyre	Deputy Director of Care, Erskine
Marie McKerry	Chief Nurse, Care Inspectorate
Alex McMahon	Executive Director of Nursing, Midwifery and Allied Healthcare Professionals, NHS Lothian (until December 2021)
David McNeill	Principal Engineer, NHS National Services Scotland

Fiona Mitchell	Nurse Manager, NHS Grampian
Fiona Mitchelhill	Lead Nurse, Aberdeen City Health and Social Care Partnership
Alison Moore	Senior Health and Safety Advisor, NHS Highland
Jacqui Neil	Lead Nurse, Scottish Care (until August 2021)
Sabine Nolte	Principal Educator, NHS Education for Scotland
Elaine Ross	Professional Nurse Advisor, HAI ARM Policy Unit, Scottish Government
Lesley-Ann Shand	Facility Support Manager, NHS Greater Glasgow and Clyde
Ian Smith	Head of Quality of Care, Healthcare Improvement Scotland
Jacqueline Sneddon	Project Lead, Scottish Antimicrobial Prescribing Group (until October 2021)
Diane Stark	Infection Prevention and Control Nurse Lead/Chair Infection Prevention Society Scotland, NHS Highland
Ian Storrar	Head of Engineering, NHS National Services Scotland
Lynsey Sutherland	Associate Nurse Director, Lanarkshire Health and Social Care Partnership

We would like to thank Helen Buchanan, former Executive Nurse Director, NHS Fife and chair of the IPC standards scoping group, for all of her input and support.

We would also like to thank the following colleagues for their support in finalising the standards:

Karen Jackson	Senior Engineer, Health Facilities Scotland
Frances Kerr	Project Lead, Scottish Antimicrobial Prescribing Group
Abigail Mullings	Clinical Lead, National Community ARHAI Programme, ARHAI Scotland

The standards development group was supported by the following members of Healthcare Improvement Scotland's Standards and Indicators Team:

Rebecca McGuire	Project Officer
Donna O'Rourke	Programme Manager
Christine Stuart	Administrative Officer
Fiona Wardell	Team Lead

Appendix 3: Glossary

adult social care organisations and settings	all organisations and settings that provide any form of personal and practical support for adults who need extra support including care homes, care at home, housing support services (for example sheltered housing services) and support services (for example adult day care).
adverse event	an event that resulted in, or could have resulted in, harm to people or groups of people. An event that could have resulted in harm is often referred to as a near miss.
alert organism(s)	an organism that is identified as being potentially significant for IPC practices. A full list of alert organisms is set out in the National Infection Prevention and Control Manual.[2]
antimicrobial	a term used to describe substances that kill micro-organisms or prevent them from growing. Antibiotics and disinfectants are examples of antimicrobials.
antimicrobial resistance	when pathogens adapt and find ways to survive the effects of an antimicrobial (including antibiotics) they become 'antimicrobial resistant'. The antimicrobial is no longer effective at treating infections.
antimicrobial stewardship	a co-ordinated programme that promotes the appropriate use of antimicrobials (including antibiotics). An organisational antimicrobial stewardship programme can help health and social care staff improve a person's outcomes and minimise harms. Improving the appropriate use antibiotic prescribing can decrease the spread of infections caused by micro-organisms that have become resistant to certain antibiotics.
assurance and monitoring systems	systems that enable organisations to monitor the outcomes of current practice and provide timely feedback to clinicians and care professionals to ensure practice improvement and better outcomes for people receiving care.
care equipment	within these standards the term care equipment refers to single individual use equipment (this can be reused by the same person, for example nebuliser equipment) and reusable non-invasive equipment (this can be reused on more than one person following cleaning or decontamination between each use, for example a commode or bath hoist. This is also referred to as 'communal equipment').
colonised/colonisation	the presence of micro-organisms on a person's body surface (such as the skin, mouth, intestines or airway) that do not cause disease in the person or signs of infection.
health and care built environment	this term covers all aspects of IPC associated with the construction and adaptation of health and care buildings,

	as well as the design and provision of care in these settings.
decontamination	the appropriate cleaning, disinfecting and sterilising of reusable medical devices, care equipment and the environment. Decontamination is essential to lower the number of cross-infections between people and also to prevent HAIs. Processes need to be in place within health and care settings to ensure the environment and equipment, for example a person's room or commode, is decontaminated properly.
derogation	the process of defining and applying a solution that is not fully in line with current guidance but the service can demonstrate the outcome would be of the same or a better standard than if the guidance been fully adhered to.
health protection team (HPT)	a team of healthcare professionals whose role it is to protect the health of the local population and limit the risk of them becoming exposed to infection and environmental dangers. Every NHS board has a HPT.
healthcare associated infection (HAI)	infections associated with the delivery of care in hospitals, long-terms care facilities, care homes and other care settings such as prison facilities. The term HAI covers a wide range of infections that are caused by pathogens such as bacteria, fungi or viruses.
Healthcare Infection Incident Assessment Tool (HIIAT)	used by the IPC team or HPT to assess every healthcare infection incident, that is all outbreaks and incidents including decontamination incidents or near misses in any healthcare setting (the NHS, independent contractors providing NHS Services and private providers of healthcare).
Healthcare Associated Infection System for Controlling Risk in the Built Environment (HAI-SCRIBE)	an online risk management tool that supports organisations to identify infection risks, and collaborate with others to manage or mitigate risks.
Infection Prevention and Control (IPC) team	a multidisciplinary team responsible for preventing, investigating and managing an infection incident or outbreak.
infectious agent(s)	a micro-organism which has the ability to cause disease.
invasive device(s)	a device which penetrates the body, either through a body cavity or through the surface of the body, for example a urinary catheter.
NHS board	NHSScotland consists of 14 regional NHS boards that are responsible for the protection and the improvement of their population's health and for the delivery of frontline healthcare services.
pathogen(s)	an organism that causes disease, for example bacteria, viruses and fungi.
representative(s)	any person an individual experiencing care choses to be involved in their care and support. This includes, but is not limited to, next of kin, a power of attorney,[70, 71] carers, family or an independent advocate.
reusable invasive equipment	equipment that is used once and then decontaminated eg surgical instruments and endoscopes.

social care	within these standards the term social care does not apply to children and young people's services. It refers to all forms of personal and practical care for adults who need extra support. It describes services and other types of help, including care homes and the support provided by unpaid carers. Social care services can be provided by local authorities, health and social care partnerships (HSCP), independent bodies and the voluntary sector to support people to live their lives as fully and as independently as possible.

The majority of the descriptions in this glossary have been taken directly from the National Infection Prevention and Control Manual.[2]

Outcome competences for practitioners in infection prevention and control

Infection Prevention Society and Competency Steering Group

Emma Burnett, Lead Coordinator, Infection Prevention Society Education and Professional Development Committee, University of Dundee, Scotland. Email: e.burnett@dundee.ac.uk*

**Corresponding author*

1. Foreword

As Chair of the steering group overseeing this work it is my great pleasure on behalf of the four United Kingdom Chief Nursing Officers to commend this document to you. The work, which was funded by the Department of Health, led by the Infection Prevention Society, developed in conjunction with government leads for infection prevention and control, and supported by Skills for Health is a milestone in the evolution of infection prevention and control practice in the UK. This is a real example of what can be achieved through effective collaboration, cooperation and consultation between the professions, stakeholders and practitioners in the field.

Although infection prevention and control has been an established part of the NHS landscape for many years, for a number of those years it has been seen as the domain of a small group of designated specialists and has mainly focused on acute care. More recently, the determination of all four UK governments to address public concerns about healthcare associated infection and to drive improvements in patient safety throughout the health and social care system has placed infection prevention and control at the very top of the health and social care agenda and radically changed the expectations and requirements of practitioners working in this important area of practice.

Today's infection prevention and control practitioners can come from a range of professional and occupational backgrounds and require a much broader range of competences than ever before. They know that a robust knowledge of infection prevention and control is not enough, they need to be looking ahead to future threats; developing the evidence base and working across the whole health and care system. They also need high-level leadership and team working skills if they are to effect strategic change at a national organisation level, and the interpersonal skills to use improvement science-based methods to sustain behavioural change in everyone involved in the care of patients and clients.

We, in turn have to ensure that our expectations of practitioners in infection prevention and control are clear and consistent and that appropriate education, training and development is in place to ensure that the right people with the right capabilities are available today and in the future as we take infection prevention and control forward. This competency framework provides a solid foundation on which to do that and I look forward to seeing it used to meet expectations.

Ros Moore, BSc (Hons) Nursing, MA, RGN, RNT
Chief Nursing Officer, the Scottish Government

2. Introduction

With our rapidly changing healthcare systems, a more flexible response is required from infection prevention and control (IPC) practitioners to be able to address the challenges that healthcare associated infection presents. We are continually being pulled in many different directions in order to improve the quality of healthcare delivery and to respond to the patient safety agenda and the zero tolerance culture to healthcare associated infection. Infection prevention and control practitioners continue to play a key role in improving the safety and quality of care delivered to patients by providing clinical colleagues with robust expertise, advice, support and guidance enabling them to prevent and control healthcare associated infections.

Competences were first developed and published by the Infection Control Nurses Association (ICNA) in 2000, followed by the second edition in 2004. These competences provided an overarching framework to enable IPC practitioners to develop and enhance their knowledge and skills to increase the safety and quality of patient care. Taking into account the changes in healthcare delivery throughout the United Kingdom (UK), the current political and economic drivers around healthcare associated infection and the evolving nature and diversity of infection prevention and control teams, we are now delighted to present the new competences framework developed by the Infection Prevention Society (IPS) the successor organisation to the ICNA. This framework has also been aligned with NHS Knowledge and Skills Framework and Skills for Health, National Occupational Standards.

The Infection Prevention Society recognises that IPC practitioners will already possess a higher level of knowledge, understanding and skills in accordance with their role and responsibilities. The purpose of this framework is not to define specific roles, but to assist practitioners to continually increase their existing knowledge, understanding and skills in order to reach our ultimate goal of safe, improved quality of care for our patients through reduction in the burden of disease and avoidable illness caused by healthcare associated infections.

The IPS Education and Professional Development Committee are privileged to have worked in partnership to produce this competency framework with:

- Scottish Government Health Department
- Department of Health, England
- Department of Health, Social Services and Public Safety Northern Ireland
- Welsh Assembly Government

10.1177/1757177410395797

- Lindsay Mitchell, Prime R & D Ltd
- Skills for Health
- Council of Deans

Emma Burnett, MSc, PGCert, BN, SPQ, RGN Lead Co-ordinator Education and Professional Development Committee, Infection Prevention Society

3. Why do we need competences for infection prevention and control practitioners?

The focus on reducing healthcare associated infections continues throughout the UK and the introduction of patient safety improvement programmes has highlighted the role of healthcare associated infections as incidents that have an adverse effect on public safety and quality of care. The prevention, management and control of these infections is therefore a priority area for each of the four UK governments. It requires action by all organisations involved with health and social care.

Infection prevention and control practitioners have a key role to play in scanning the environment for new and emerging threats to safety, as well as improving the safety and quality of care delivered to individuals and populations. They provide colleagues across all health and social care settings with robust clinical expertise, advice, support and guidance so that they can work in partnership to prevent, manage and control healthcare associated infections

Infection prevention and control practitioners increasingly come from a wide range of professional or occupational backgrounds and often bring very different knowledge, skills and experience to the role. These competences have been produced by expert practitioners and academics in the field and endorsed by the UK health departments, to provide a consistent set of standards and expectations for the role across the UK.

The majority of practitioners working in NHS organisations (excluding medical personnel) will be working within the NHS Knowledge and Skills Framework (KSF) (Department of Health, 2004) and Career Framework for Health (Skills for Health, 2010). The role of IPC practitioner has therefore been positioned at senior practitioner level in the Career Framework for Health. There is an expectation that post-holders work at advanced-level practice (or are working towards that level), and are in possession of the qualifications and specialist knowledge commensurate with a senior practitioner. However, to retain flexibility and accommodate differences in the UK healthcare systems and between local service providers (for example, different patient/client case mix, staff skills mix and organisational structures) decisions about job titles, qualifications, pay bands and rewards should be made by the organisation that is employing the practitioner. It is also the employer's responsibility to ensure that practitioners working at an advanced level in infection prevention and control:

- have access to the qualifications at an appropriate level, ie at level 7 of the Framework for Higher Education Qualifications (FHEQ) (QAA, 2008) in England, Wales and Northern Ireland and level 11 of the Scottish Credit and Qualifications Framework (SCQF) (SCQF, 2009)
- are provided with appropriate certificated training
- have designated authority to carry out the competences safely and independently.

4. Who are these competences for?

These competences are designed for use by a number of people, including:

- organisations who are looking for an expert to drive forward their safety and quality agenda and prevent and manage healthcare associated infections
- managers of health and social-care services, so they can understand the expert advice that should be available to them and that they can draw on
- educational commissioners and providers, so that they can ensure that education and training provision meets service needs and promotes quality and safety
- practitioners working in IPC, so that they can better understand their role in all its aspects
- practitioners who contribute to IPC and who have an interest in developing their knowledge, understanding and skills in this area in the future.

Infection prevention and control practitioners are experienced and educated members of the multidisciplinary health and social-care team who work both on their own and in partnership with others. They have an extensive knowledge base that includes an understanding of microbiology, epidemiology and immunology, coupled with organisational strategy and operational practice. They use a range of skills, including:

- influencing and negotiating
- communicating
- complex decision making
- influencing strategic decision making
- information and knowledge management
- engagement and facilitation
- leadership and risk management.

These advanced practitioners ensure safe, high-quality services for the public, and support improvement so that the safety and quality of care is continually enhanced.

Infection prevention and control is a constantly changing field with emerging threats from new and resistant micro-organisms, new challenges arising, and new ways of managing healthcare associated infections being developed all the time. Practitioners working at an advanced level need to keep abreast of these threats and emerging methodologies, so that they can be proactive in dealing with the challenges faced by their organisations.

5. Who employs infection prevention and control practitioners?

A wide range of organisations in the public, private sector and voluntary sectors are interested in employing people working in IPC. These practitioners can be found in:

- acute and community healthcare settings
- the ambulance service
- mental health and learning disability services
- adult and paediatric services
- social-care services
- public health departments
- university departments
- the prison service
- policy and service development roles at national level in and outside the NHS.

6. Who works in infection prevention and control?

Traditionally, infection prevention and control practitioners have come from a nursing background. However, as the prevention, management and control of infection have developed, so has the pool of people who have developed their knowledge and skills in the area. Given the breadth of knowledge, understanding and skills that individuals need to be able to work in this area, practitioners will generally come from a clinical or healthcare-science background, and include nurses, podiatrists, paramedics and biomedical scientists. Examples of the career pathways of, and options for, practitioners in infection prevention and control are described in section 14, which also has some

real-life case studies of individuals who have developed their careers in this field.

7. How do these competences link to other frameworks?

These competences provide further, detailed content related to infection prevention and control to support the use of the generic Knowledge and Skills Framework (KSF) within the NHS. These competences can be used by organisations to develop the detailed content of KSF post outlines for practitioners working at an advanced level in infection prevention and control, and through this they can guide and support their ongoing learning and development while in post. Indicative links to the NHS KSF, which have been approved by the KSF Group of the NHS Staff Council, are shown attached to each of the competences.

The competences have been structured against the four domains within the Advanced Practitioner toolkit (Scottish Government, 2008) for Modernising Nursing Careers – the career and development framework for nursing. As with the KSF, the competences show the detailed specification of advanced practice in infection prevention and control.

The NHS Leadership Qualities Framework (LQF) is also of relevance to this work (DH, 2002). The LQF sets the standard for leadership in the NHS by describing the qualities expected of existing and aspiring leaders both now and in the future. The LQF will help individuals develop their leadership skills and understanding of leadership. This will therefore support the achievement of this competency framework for advanced practice in infection prevention and control.

Additionally, this framework resonates with the Department of Health's 'Advanced Level Nursing: A Position Statement' (DH, 2010) in that practitioners working at an advanced level will use complex reasoning, critical thinking, reflection and analysis to inform their assessment, clinical judgement and decisions.

Skills for Health, the Sector Skills Council for the health sector, has linked these competences to National Occupational Standards (NOS). These links are shown attached to each of the competences. Four of the competences have been adapted from Skills for Health National Occupational Standards, and full intellectual copyright for the original material rests with Skills for Health. We would like to express our gratitude to Skills for Health for giving permission to use this particular version of these national occupational standards in this work.

8. What competences are included?

There are 17 competences included in this resource set out against the four advanced practice domains as shown in Box 1.

9. How can the competences be used?

The competences are designed to be an information resource for a range of possible uses as shown in the diagram below.

The competences are designed to be a multi-purpose tool that will support and inform strategic planning, workforce development and

Box 1: Domains and competences

Clinical practice

1 Improve quality and safety by developing and implementing robust, high-quality policies and guidelines that prevent and control infection
2 Collate, analyse and communicate data relating to preventing and controlling infection for surveillance purposes
3 Manage incidents and outbreaks
4 Improve quality and safety through the application of improvement methodologies
5 Advise on the design, construction and modification of facilities to prevent and control infection in the built environment
6 Evaluate, monitor and review the effectiveness of decontamination processes for equipment and environment

Education

7 Develop own knowledge, skills and practice
8 Lead the development of the knowledge, skills and practice of the infection prevention and control team
9 Develop and implement learning and development opportunities and solutions to improve infection prevention and control
10 Work with others to develop, implement, evaluate and embed infection prevention and control within workforce development strategies

Research

11 Access, appraise and apply robust evidence of all types from a range of research and other sources, to the domains of the role
12 Lead high quality infection prevention and control services
13 Share best practice through the dissemination of evidence and knowledge

Leadership and management

14 Improve quality and safety through networking, influence, proactivity and challenge
15 Improve quality and safety through the design, planning, monitoring and development of services
16 Lead high quality infection prevention and control services
17 Lead and manage the work of the infection prevention and control team to achieve objectives

management at strategic and unit level. They will also provide guidance for educational commissioning and will structure the content of education and training programmes, whether these are developed internally by employing organisations or are university accredited. The competences will also enhance local accountability and support the role and development of current and aspiring infection prevention and control practitioners.

Some examples of how the competences might be used are set out below.

Service and strategic level

- Service reviews
- Workforce/role design and profiling
- Education commissioning, planning and provision

Unit and managerial level

- Recruitment and selection
- Staff appraisal
- Education, training and development planning and delivery
- Career development and advice
- Design of professional and vocational qualifications

Individual and team level

- Career progression
- Self assessment and personal development planning
- Coaching
- Clinical supervision
- Professional revalidation/registration

The competences:

1. Provide clarity for organisations as to what they can expect IPC practitioners to do, that is, the competences will identify the unique contribution that IPC practitioners make to the work of the organisation and hence the value that they bring to it
2. Provide benchmarks for organisations to use in the recruitment, selection, development, appraisal and performance management of IPC practitioners
3. Contribute to the development of specifications for IPC services by identifying the outcomes that IPC practitioners can be expected to deliver
4. Contribute to the education and training of individuals who are aiming to become IPC practitioners – both for organisations that are looking to commission education and training for practitioners to work at this level and for organisations providing that education and training
5. Contribute to the Continuing Professional Development (CPD) of individuals when they are in post in order to maintain and improve their competence
6. Contribute to the development of workforce specifications by identifying the role and contributions of IPC practitioners
7. Can be used as the basis of a skills and career framework for those whose interest lies in infection prevention and control (including IPC practitioners), for example in demonstrating how people develop to a consultant-level post
8. Support the mapping of the role of IPC practitioners with different regulatory requirements.

How can I continue to develop in infection prevention and control?

You can use these competences to inform your development. It does not matter what your starting point is – you might already be close to achieving all of these competences or might be a long way off and have a lot of development to undertake. The thought processes you need to go through and the actions you need to take will be similar, the difference will be in the amount of development that is needed. These competences describe what it is that an individual is expected and able to do when they are fully functioning at an advanced level.

To continue to develop yourself, you need to follow the process set down in competence 7 of this document and undertake an honest assessment of your current level of knowledge and skills and your ability to apply them in practice. It is recommended that you seek the help of others (for example, your colleagues, peers and your manager) as they are likely to have a different view of your current level of competence as well as an understanding of the exact meaning of the competences. This is particularly important when you are new to the area as some of the explanations might look simpler than they in fact are.

Once you have a realistic assessment of your own current level of knowledge, skills and competence against the advanced level competences, ie you have identified your learning needs, you will then need to plan how you can best develop yourself to the level required. This might be through self-study, undertaking learning programmes and/or academic qualifications, or seeking learning opportunities in the workplace, such as mentoring and job shadowing. As your learning and development progresses, you will need to revisit the competences and continue to assess yourself to identify your progress in achieving all of the competences. An example of how to do this against one of the competences is shown in section 15.

10. How can the competences be applied in workforce development and management?

As shown above, these competences can be used to recruit and select new staff by building job requirements and person specifications

Figure 1. Using the competences

around the four domains of advanced practice (with local stakeholders agreeing the essential and desirable elements). However, as part of the selection process, all new IPC practitioners should be able to provide evidence of the generic infection prevention and control competences expected in their previous role, as well as their willingness to work towards the full range of specialist advanced competences described in this document. On recruitment, a self and peer review of current levels of competence against the framework will be required, and a Personal Development Plan (PDP) with agreed timescales must be developed to fill identified learning needs. The PDP can then be used as a framework for coaching and for agreeing education, training and development.

For staff already in post the PDP can be used in the same way. However, it is important to note that as practitioners operate in an organisational context and work as part of a wider team and culture, the competences are not themselves a performance management tool. But they do have a clear part to play in that process. As the competences are intended to specify what it is that an individual should achieve, they do not include service outcomes or performance measures. Even though these practitioners should have a clear impact on the rates of healthcare associated infections and adverse effects, it is not possible to draw a firm, direct relationship between the two. The overall effectiveness of a practitioner will be affected by the support and priority that an organisation gives to their work. As well as using these competences to contribute to job descriptions, organisations might wish to add measurement indicators of safe, clean, high-quality care into an individual's personal objectives and include them in appraisal systems.

11. How are the competences structured?

The competences have been structured to focus on the outcomes of performance – that is, what is expected of an individual when they are fully functioning at an advanced level in IPC, and influencing key strategic decisions related to public safety and care quality.

Not all jobs for people working at an advanced level of IPC will incorporate all the competences that have been set out in this document. Similarly, not all individuals working in IPC will be able to demonstrate achievement of all the competences that have been specified. Individuals will need to develop their knowledge, skills and practice over time in order to show that they can function at this advanced level of practice. They also need to have the opportunity to do so within their employing organisation.

The competences have been structured as illustrated in Box 2.

There are some generic knowledge, understanding and skills that apply to all the competences. These are shown in Box 3.

The knowledge, understanding and skills that are more specific to each of the competences and to infection prevention and control are shown with the relevant competence to which they apply.

Box 2: Competency structure

1 **Domains of practice** – the four domains that describe the major components of advanced-level practice, that is:
   a clinical practice
   b education
   c research
   d leadership and management
2 **Competence statements** – these are the broad role expectations of practitioners working at an advanced level of practice in IPC. They describe the 'what has to be done'.
3 **Performance indicators** – aligned to each of the competence statements, the performance indicators describe what competent performance in advanced-level practice in IPC looks like. The indicators describe the level and scope of competent practice – that is, the indicator against which competence would be judged.
4 **Knowledge, understanding and skills** – these descriptions identify the knowledge, understanding and skills that a practitioner would need to develop in order to achieve the competences to the level of performance required in the indicators. These statements do not have a one-to-one relationship with the performance indicators, because to achieve one indicator it is often necessary to use a range of different knowledge and apply different skills.

Box 3: Generic knowledge, understanding and skills

a Influencing and advice strategies, including risk assessment to balance broader organisational needs with infection prevention and control requirements
b Action planning and follow up
c Change-management skills
d Partnership and team-working skills
e Communication skills
f Negotiating skills
g Leadership skills
h Report preparation (including annual reports) for the organisation and external agencies
i Developing and delivering training and education.

12. The competences' statements and performance indicators structured against the four domains

Box 4: Domain 1: Clinical practice

1 Improve quality and safety by developing and implementing robust, high-quality policies and guidelines that prevent and control infection

Performance indicators

1 Provide guidance for those working in all areas of health and social-care practice through critically analysing and interpreting national quality and safety resources and initiatives and presenting the information in a way that is suitable for the people concerned
2 Evaluate the effectiveness of existing policies and guidelines and identify areas for improvement
3 Promote evidence-based improvements in policies and guidelines through demonstrating their value in terms of safety and quality in the context concerned
4 Work in partnership with individuals, the population and colleagues to develop clear and robust policies and guidelines that prevent and control infection
5 Work in partnership with others to plan the effective implementation of policies and guidelines to prevent and control infection
6 Provide expert advisory support for the implementation of policies and guidelines to prevent and control infection
7 Monitor the implementation of infection prevention and control policies and guidelines, taking any corrective actions as and when necessary
8 Identify the need for improvements in infection prevention and control policies and guidelines in the light of implementation and the changing knowledge base and evidence
9 Provide expert infection prevention and control input to the development of broader policies and guidelines.

Knowledge, understanding and skills

a Applied microbiology in relation to the chain of infection and the infection process, alert micro-organisms and conditions, body defence mechanisms
b The significance of microbiological results, interpreting the diagnostic laboratory results, practices designed to break the chain of infection, including standard and transmission-based precautions including the placement of populations and individuals in care settings
c Hand hygiene (including social hand hygiene, antiseptic hand hygiene, surgical scrub)
d Safe management of invasive devices and prevention of device-related infections
e Asepsis
f Antimicrobial stewardship – prudent prescribing of antimicrobials and the surveillance of antimicrobial-resistant organisms
g Aligning infection prevention and control with the quality and safety agenda (using outcomes, risk assessment matrix, programmes and systems) and making use of health information exchange systems
h Legislation, national guidance and outcomes/indicators related to preventing and controlling infection in health and social-care environments and facilities (including ventilation, water sources, waste management, hygiene, isolation facilities, laundry management, food hygiene)
i Legislation, national guidance and outcomes/indicators related to preventing and controlling infection for individuals and populations in health and social-care environments and facilities (for example, communicable disease control; immunisation; prevention and management of injuries (including sharps); post-exposure prophylaxis; specific controls in specialist areas such as burns, critical care, renal and transplant, maternity, neonatal, children, operating rooms, mental health, dentistry and ambulance services)
j The evidence base on which infection prevention and control policies should be based
k Knowledge of national and organisational strategies, objectives, structure and accountability and how to present information in a manner that fits within the strategic context
l Policy development skills.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

Core 4 Service improvement Level 4
HWB3 Protection of health and wellbeing Level 4

Links to national occupational standards

The following national occupational standards relate to this competence:

GEN67: *Establish quality policy and quality assurance systems for the delivery of a service or function* – see https://tools.skillsforhealth.org.uk/competence/show?code=GEN 67

Clinical practice

2 Collate, analyse and communicate data relating to preventing and controlling infection for surveillance purposes

Performance indicators

1 Obtain and link data using appropriate methods and systems for the surveillance of infection
2 Structure and analyse the data correctly to identify patterns, trends and anomalies that may be significant in relation to preventing and controlling infection
3 Critically assess the strengths and limitations of the data using methods of analysis that are appropriate to the nature and form of the data and the purpose for which the results are to be used
4 Identify areas that might require further investigation or analysis in relation to potential risks
5 Analyse potential risks and reach conclusions appropriate to the risks
6 Critically assess the conclusions reached, identifying the strengths and limitations of the analysis undertaken
7 Act upon the risks identified, communicating them effectively to the appropriate people
8 Enable health and social-care staff to understand the data and make the necessary changes to achieve improved outcomes
9 Take the appropriate action when surveillance methods and data can be improved

Knowledge, understanding and skills

a Applied microbiology in relation to the chain of infection and the infection process, alert micro-organisms and conditions, body defence mechanisms
b The significance of microbiological results, interpreting the diagnostic laboratory results and practices designed to break the chain of infection, including standard and transmission-based precautions including the placement of populations and individuals in care settings
c Definitions, methods and types of surveillance, data handling, data analysis, interpreting outcomes, assessing limitations of data
d Epidemiology, descriptive and applied (that is, the application and evaluation of epidemiologic discoveries and methods in public health and health and social-care settings, including applications of aetiological research, priority setting and evaluation of programmes, policies and services)
e Principles of epidemiology, incidence, prevalence
f Principles of statistics and variation
g Feedback and reporting mechanisms.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

HWB3 Protection of health and wellbeing Level 4
IK2 Information collection and analysis Level 3

Links to national occupational standards

This competence used NOS HP2 *Collate, analyse and interpret surveillance data to assess risks to population health, wellbeing and safety* as its starting point for the development of the IPC competences. There are a number of similarities between the two sets of performance indicators/criteria but full intellectual copyright for the original material rests with Skills for Health. See https://tools.skillsforhealth.org.uk/competence/show?code=HP2

Clinical practice

3 Manage incidents and outbreaks

Performance indicators

1 Assess the information available on the incident/outbreak and seek any necessary further evidence to establish its nature and scale
2 Establish the appropriate response using local incident/outbreak/emergency planning guides
3 Inform and involve relevant colleagues and partner organisations in a timely manner consistent with incident or emergency plans
4 Facilitate the development of an outbreak/incident management team, ensuring that the appropriate organisations and functions are represented
5 Communicate clear, accurate and timely information with colleagues, partner organisations and others throughout the incident in a manner that effectively manages risk and supports effective team working
6 Establish agreement on the control measures to be taken to minimise exposure to hazards and to reduce risks and prevent secondary or further spread or exposures

(*Continued*)

3 Manage incidents and outbreaks — Continued

7 Review the availability of resources to implement the control measures throughout the duration of the incident/outbreak
8 Ensure accurate records of the investigation and management of the incident/outbreak are maintained throughout the process
9 Lead review of the investigation and management of the incident/outbreak and modify measures as a result
10 Produce a final report of the incident/outbreak and communicate it to all concerned
11 Evaluate the incident/outbreak and make recommendations for future improvement

Knowledge, understanding and skills

a Alert micro-organisms, baseline
b Defining and recognising outbreaks
c Investigation of outbreaks, data collection
d The significance of microbiological results; interpreting the diagnostic laboratory results; practices designed to break the chain of infection, including standard and transmission-based precautions including the placement of populations and individuals in care settings
e Control measures
f Epidemiology, descriptive and applied (that is, the application and evaluation of epidemiologic discoveries and methods in public health and health and social-care settings, including applications of aetiological research, priority setting and evaluation of programmes, policies and services)
g Principles of epidemiology, incidence, prevalence
h Principles of statistics and variation
i Feedback and reporting mechanism
j Epidemics, pandemics, endemic
k Public health dimension; public health epidemiology
l Methods of performing post-outbreak evaluation; report evaluation feedback; serious untoward incident tools
m Emergency systems and procedures for managing incidents and outbreaks
n The roles and responsibilities of national, regional and local agencies and departments in managing incidents and outbreaks
o Knowledge of sources of advice and expertise that can be drawn upon to contribute to investigating and managing the hazard
p Legal frameworks (that is, legal powers and duties, responsibilities and accountability) and organisational and professional policies and protocols when there is an outbreak or incident.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:
HWB3 Protection of health and wellbeing Level 4

Links to national occupational standards

This competence used NOS HP15 *Coordinate a team investigating and managing an incident or outbreak* as its starting point for the development of the IPC competences. There are a number of similarities between the two sets of performance indicators/criteria but full intellectual copyright for the original material rests with Skills for Health. See https://tools.skillsforhealth.org.uk/competence/show?code=HP15

Clinical practice

4 Improve quality and safety through the application of improvement methodologies

Performance indicators

1 Identify the need for change in practices and environments
2 Work in partnership with others to develop practice innovations and service re-design solutions to improve safety and quality
3 Lead the organisation's infection prevention and control programme to improve safety and the overall quality and experience of care through linking it with the work of internal and external partners and influencing direction
4 Ensure that audit, surveillance, epidemiology and risk register data are collated, communicated, used and interpreted effectively
5 Access existing and create new databases to manage and use data and information related to improving quality and safety
6 Guide practice in infection prevention and control through the critical analysis and effective communication of national quality and safety resources and initiatives
7 Work in partnership with individuals, populations, staff and others to develop improvement programmes that are in line with the culture and context of the area
8 Lead the implementation of improvement programmes, working in partnership with all involved

(*Continued*)

4 Improve quality and safety through the application of improvement methodologies — Continued

9 Evaluate the effectiveness of improvement programmes in partnership with individuals, populations, staff and others, identifying the improvements that need to be made in practice
10 Prepare and present infection prevention and control reports and recommendations to individuals, populations, staff, members of the organisation and others
11 Confirm that agreed actions have been taken to improve safety and the quality of health and social-care practice
12 Take the necessary action to escalate concerns when there is a failure to act which compromises safety and quality.

Knowledge, understanding and skills

a Clinical governance, quality assurance, clinical effectiveness, quality improvement framework and service improvement frameworks
b Risk identification, assessment and management including: risk register analysis, action planning, feedback and re-evaluation
c Serious untoward incident and root cause analysis
d Review of audit findings, action planning, feedback and re-evaluation
e Available quality and safety resources and initiatives
f Outcome measures including measures that are reported by individuals receiving health and social-care services
g Corrective and preventive actions
h Development, implementation and evaluation of evidence-based achievable metrics and outcome measures that can be audited
i Improvement and change methodologies.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

Core 4 Service improvement Level 4
HWB3 Protection of health and wellbeing Level 4

Links to national occupational standards

The following national occupational standards relate to this competence:

M&L B6: *Provide leadership in your area of responsibility* – see http://www.ukstandards.org.uk/Admin/DB/0033/B5%202009.pdf
M&L B5: *Provide leadership for your team* – see https://tools.skillsforhealth.org.uk/competence/show?code=M%26L+B5

Clinical practice

5 Advise on the design, construction and modification of facilities to prevent and control infection in the built environment

Performance indicators

1 Work with others on plans for the design, construction and modification of facilities to improve safety and quality through infection prevention and control
2 Advise on the infection prevention and control risk assessment criteria prior to a new build and in advance of any demolition or modification of a building consistent with current building guidance and legislation
3 Liaise with key health and social-care staff and others prior to and at every subsequent stage of the build, demolition or modification to ensure that infection prevention and control advice is effectively incorporated into the works
4 Work in partnership with key health and social-care staff to reduce the risk of infection to individuals, populations, staff and others during construction, demolition or modification activities
5 On the completion of the works, review with individuals, populations, staff and others the effectiveness of the development for preventing and controlling infection.

Knowledge, understanding and skills

a Applied microbiology in relation to the chain of infection and the infection process, alert micro-organisms and conditions, body defence mechanisms
b The significance of microbiological results, interpreting the diagnostic laboratory results; practices designed to break the chain of infection – for example, standard and transmission-based precautions including the placement of individuals and populations within care settings
c Antimicrobial stewardship – prudent prescribing of antimicrobials and the surveillance of antimicrobial resistant organisms

(*Continued*)

5 Advise on the design, construction and modification of facilities to prevent and control infection in the built environment — Continued

d Legislation, national guidance and outcomes/indicators relating to the design, construction and modification of the built environment in general and health and social-care facilities in particular (for example, ventilation, water sources, waste management, hygiene)
e Organisational strategy for new builds, refurbishments, planned programme maintenance
f Interpretation of architects', estates' and facilities' plans for new builds, refurbishment and modification

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

EF2 Environments and buildings Level 4

Links to national occupational standards

The following national occupational standards relate to this competence:

HSC 3117 *Conduct a health and safety risk assessment of a workplace* – see https://tools.skillsforhealth.org.uk/competence/show?code=HSC3117

Clinical practice

6 Evaluate, monitor and review the effectiveness of decontamination processes for equipment and environment

Performance indicators

1 Provide evidence-based infection prevention and control input in the development of decontamination policies and procedures
2 Audit decontamination methods to determine their effectiveness
3 Report the outcomes of the audit, drawing specific attention to the risks to safety and quality that have been identified
4 Advise on the actions that are required to improve quality and safety when decontamination processes are ineffective and the timescale in which they need to be implemented
5 Confirm that the required actions have been effectively undertaken to control infection and promote safety and quality
6 Take the necessary action to escalate concerns when there is a failure to act which compromises safety and quality.

Knowledge, understanding and skills

a Applied in relation to the chain of infection and the infection process, alert micro-organisms and conditions, body defence mechanisms
b The significance of microbiological results; interpreting the diagnostic laboratory results; practices designed to break the chain of infection – for example, standard and transmission-based precautions including the placement of individuals and populations in care settings
c Antimicrobial stewardship – prudent prescribing of antimicrobials and the surveillance of antimicrobial-resistant organisms
d Levels of decontamination – lifecycle and cycle parameters, use of various tests, water quality tests (for example, TVC levels)
e Methods and processes of decontamination (for example, physical and chemical disinfection, sterilisation)
f Methods and processes of decontamination for: medical devices (for example, endoscopes, surgical instruments), equipment and environments
g Risk assessment of processes, environments and systems used for decontamination
h Evaluation of application of decontamination processes in clinical practice
i National guidance on decontamination processes for equipment and reusable medical devices (for example, Health Technical Memorandum (HTM), Scottish HTM) and the evidence base on which they are built
j Legislation, national guidance and outcomes/indicators on decontamination processes for the built environment and the evidence base on which they are built
k Regional and local policies which differ from national guidance and the rationale for this.

This competence relates to the following dimensions and levels within the NHS KSF:

EF1 Systems, buildings and equipment Level 4
EF2 Environments and buildings Level 4

Links to national occupational standards

The following national occupational standards relate to this competence:

DEC6: *Monitor procedures and operate tracking systems and procedures* – see https://tools.skillsforhealth.org.uk/competence/show?code=DEC6

Box 4: Domain 2: Education

7 Develop own knowledge, skills and practice

Performance indicators

1 Evaluate own development and application of knowledge and skills to meet current and emerging work demands and organisational objectives
2 Identify own development needs and set own personal development objectives, including professional development
3 Develop a personal development portfolio, recognising strengths and limitations, with clear learning needs, plans, actions and outcomes
4 Develop own knowledge, skills and practice through active engagement in a range of learning and development opportunities
5 Continually maintain an up-to-date knowledge of infection prevention and control through a range of different activities (including reading peer-reviewed journals, accessing other sources of published information, and peer review sessions)
6 Seize opportunities to learn new knowledge and skills and apply them in the development of practice

Knowledge, understanding and skills

a Self awareness of competence and level required
b Critical analysis, evaluation and appraisal skills
c Critical analysis and evaluation of published literature and peer-reviewed research studies
d Writing for publication and reviewing journal articles
e Knowledge management and knowledge sharing
f Dissemination of best practice, internal to the organisation, at conferences and in journals.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:
Core 2 Personal and people development Level 4

Links to national occupational standards

The following national occupational standards relate to this competence:
GEN13: *Synthesise new knowledge into the development of your own practice* – see https://tools.skillsforhealth.org.uk/competence/show?code=GEN13

Education

8 Lead the development of the knowledge, skills and practice of the infection prevention and control team

Performance indicators

1 Encourage others to make accurate and credible assessments of their knowledge and skills, challenging complacency and actions that are not in the interests of safety and quality
2 Identify and address gaps in knowledge, skills and competence of staff working within the infection prevention and control team
3 Develop an environment that values learning and development and promotes a learning culture in the workplace
4 Develop and inspire all members of the team to use their abilities to practise effectively and efficiently to deliver the infection prevention and control programme
5 Work in partnership with members of the infection prevention and control team to include professional development as part of their personal development planning
6 Alert relevant others to resource issues that affect learning, development and performance

Knowledge, understanding and skills

a Staff appraisal, feedback, action plan and re-evaluation skills
b The meaning of the term 'learning culture' and how it can be facilitated
c Facilitating work-based learning, practice development and research activities
d Staff development skills (including mentoring and coaching)
e Effective methods of levels of delegation and support
f Leadership models and styles and their application to practice.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:
Core 2 Personal and people development Level 4

(*Continued*)

8 Lead the development of the knowledge, skills and practice of the infection prevention and control team — Continued

Links to national occupational standards

The following national occupational standards relate to this competence:

HSC43: *Take responsibility for the continuing professional development of self and others* – see https://tools.skillsforhealth.org.uk/competence/show?code=HSC43

CMF1: *Provide clinical leadership and take responsibility for the continuing professional development of self and others* – see https://tools.skillsforhealth.org.uk/competence/show?code=CM+F1

Education

9 Develop and implement learning and development opportunities and solutions to improve infection prevention and control

Performance indicators

1 Identify the learning and development needs of individuals and teams through the use of epidemiological, surveillance and audit data
2 Evaluate with the relevant people the current approaches to learning and development related to infection prevention and control and identify areas for improvement
3 Work in partnership with individuals, populations and other relevant people to identify learning and development opportunities and solutions that offer best value for money and are targeted to address key issues
4 Develop a range of evidence-based learning and development activities that are tailored to the needs of specific groups of health and social-care staff and offer best value for money
5 Lead the implementation of learning and development activities to ensure that they are fit for purpose and improve infection prevention and control
6 Ensure the necessary modifications are made to learning and development activities to improve their effectiveness
7 Advise others on how to effectively include infection prevention and control in their own learning and development programmes and activities
8 Provide consultancy services on infection prevention and control to individuals and teams inside and outside the organisation

Knowledge, understanding and skills

a Models and theories of learning (for example, learning styles)
b Learning processes, methods and opportunities including innovative approaches to learning
c How to identify learning needs
d Types and methods of assessment
e Integration of learning and development with organisational strategy and objectives for infection prevention and control.

Education

10 Work with others to develop, implement, evaluate and embed infection prevention and control within workforce development strategies

Performance indicators

1 Work with others to build infection prevention and control into workforce development strategies
2 Provide expert advice and support in implementing a strategy for developing the workforce to improve infection prevention and control
3 Influence and persuade others to see infection prevention and control as an integral part of the learning and development culture in health and social care and essential to safety and quality
4 Evaluate the effectiveness of workforce development strategies in improving infection prevention and control
5 Make recommendations to improve the knowledge and skills of the workforce to prevent and control infection

Knowledge, understanding and skills

a Risk management and quality improvement programmes
b Learning culture
c Integration of learning and development with organisational strategy and objectives for infection prevention and control
d Identifying and negotiating training programmes
e Clinical education and clinical teaching
f Preparation of practitioners for different roles in the infection prevention and control team and for preventing and controlling infection more generally
g Evaluation of the effectiveness of workforce development strategies including specific education and training programmes.

Box 4: Domain 3: Research

11 Access, appraise and apply robust evidence of all types, and from a range of research and other sources, to the domains of the role

Performance indicators

1 Appraise the validity, sufficiency and relevance of research methodologies and other information sources applicable to infection prevention and control
2 Critically appraise the literature to establish its validity and application to practice
3 Synthesise and analyse the arguments of others, identifying strengths and weaknesses
4 Apply the findings of the appraisal to practice
5 Evaluate the outcomes and findings of research and other literature to determine their impact on, and potential for, improving infection prevention and control

Knowledge, understanding and skills

a Organisational strategies and objectives
b The research process
c Research approaches and design
d Qualitative and quantitative research skills
e Literature searching
f Literature reviewing
g Peer review
h Secondary sources

(*Continued*)

11 Access, appraise and apply robust evidence of all types, and from a range of research and other sources, to the domains of the role — Continued

i Critical analytical skills
j Application of research evidence to practice.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

IK2 Information collection and analysis Level 3

Links to national occupational standards

This competence uses NOS PHS22 *Appraise, plan and manage research related to improving health and wellbeing* as its starting point and adapted it for advanced-level practice in infection prevention and control. The competence set out above is very similar to NOS PHS22 and full intellectual copyright for the original material rests with Skills for Health. See https://tools.skillsforhealth.org.uk/competence/show?code=PHS22

Research

12 Build the evidence and knowledge base to improve and develop infection prevention and control strategies and practices through participation in, or completing research and other related activities, including audit

Performance indicators

1 Determine priorities for research and development within infection prevention and control, working in partnership with individuals, populations and colleagues (at national and local level and within services and academia)
2 Identify, select and summarise research and other related activities from a variety of sources that are applicable to infection prevention and control
3 Work with others to develop clear proposals that are consistent with identified priorities
4 Present clear, succinct, valid, reliable and cost-effective proposals to appropriate people and organisations
5 Collect, collate, analyse and synthesise qualitative and quantitative data and information using appropriate methods
6 Ensure projects are delivered and reported to time, addressing the questions or issues posed
7 Reach agreements with key people and stakeholders about the need for applying research outcomes and findings to infection prevention and control practice and how best to do this
8 Monitor and review implementation against anticipated outcomes and findings and make necessary adjustments in agreement with others

Knowledge, understanding and skills

a Skills of interpreting research and related literature
b Skills for evaluating research and other related literature in relation to:
  – research questions
  – research design
  – study analysis
  – limitations of the study
  – clinical implications of the study
  – implications for practice
c Strategies for implementing findings in practice
d Role of the funder.

Links to the NHS Knowledge and Skills Framework

See https://tools.skillsforhealth.org.uk/competence/show?code=PHS23

Research

13 Share best practice through the dissemination of evidence and knowledge

Performance indicators

1 Communicate findings and outcomes in various ways, to relevant people and stakeholders in a manner that is appropriate to their needs
2 Defend the intellectual basis of the evidence underpinning findings and outcomes
3 Reach agreements with key people and stakeholders in applying the findings and outcomes to infection prevention and control practice
4 In collaboration with others, apply evidence and knowledge in developing policy and driving forward improvement

Knowledge, understanding and skills

a Skills of interpreting research and project outcomes
b Skills of communicating research and project outcomes
- implications for practice
- report writing
- writing for publication
- oral presentation skills

c Strategies for implementing research findings in practice.

Box 4: Domain 4: Leadership and management

14 Improve quality and safety through networking, influence, proactivity and challenge

Performance indicators

1 Scan worldwide developments for emerging threats to safety and quality, emerging measures to address threats, and opportunities for action
2 Measure the future risks and threats; infection and prevention control measures
3 Proactively develop and sustain new partnerships and networks to influence and improve safety and quality working across professional, organisational and system boundaries
4 Develop and sustain a strategic vision and related plans, and gather evidence of improved quality, safety and infection prevention and control, using a range of different skills and drawing on own and others' expert knowledge
5 Seize appropriate and timely opportunities to stress safety and quality across different pathways, health and social-care settings and institutions
6 Continuously assess and monitor the risks to safety and quality and challenge others' actions and decisions when they put individuals, populations and others at risk
7 Advise key people of the effect that their decisions will have on safety and quality and the risks of not taking actions related to infection prevention and control
8 Recommend courses of action to key people that will improve safety and quality and bring other related benefits
9 Develop quality and safety improvement practices through understanding the implications of epidemiological, micro-biological, demographic, social, political and professional trends and developments and applying them to the context and environment following horizon scanning
10 Effectively communicate key messages to wider audiences to influence the wider safety and quality agenda
11 Take the necessary action to escalate concerns when safety and quality are compromised and there is a failure to act

(*Continued*)

14 Improve quality and safety through networking, influence, proactivity and challenge — Continued

Knowledge, understanding and skills

a The national and local strategic context, and sources of information about relevant factors and trends

b How to present information in a manner that fits within the strategic context

c Organisational strategy, objectives, structure and accountability

d Local, regional and national networks.

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

Core 1 Communication Level 4
HWB3 Protection of health and wellbeing Level 4
G2 Development and innovation Level 3

Links to national occupational standards

The following national occupational standards relate to this competence:

GEN32: *Search information, evidence and knowledge resources and communicate the results* – see https://tools.skillsforhealth.org.uk/competence/show?code=GEN32

Leadership and management

15 Improve quality and safety through the design, planning, monitoring and development of services

Performance indicators

1 Promote a vision of improved quality and safety and better infection prevention and control within health and social-care and related services to meet the needs of the population(s) that they are designed to serve

2 Actively engage with individuals and populations about their needs and priorities in relation to infection prevention and control

3 Enable different health and social-care providers and professionals within health economies to understand the need for, and commit to, common goals and objectives

4 Work with others to develop the standards of infection prevention and control that health and social-care services should meet so that they increase public confidence and deliver high-quality outcomes

5 Determine the needs of individuals and populations, and the outcomes they require from health and social-care services, from an analysis of hard and soft public health data

6 Draft specifications for services which contain clear and specific outcomes and indicators, sufficient levers to change practice, and identify the consequences of achieving or not achieving these

7 Secure the agreement of providers to the delivery of the specified services within available resources

8 Confirm that health and social-care providers have the necessary systems, policies, procedures and governance structures in place to provide high-quality and safe services and that they comply with national environmental standards

9 Analyse data on performance from service providers to determine if standards, indicators and outcomes are being met in service provision

10 Actively monitor and review the delivery of services against specification, outcomes and indicators (for example, through making unannounced visits) and take timely action when issues arise, including escalating to others if required

Knowledge, understanding and skills

a Effective engagement methods with individuals and populations about their needs and priorities in relation to infection prevention and control

b Engagement strategies with health and social-care providers and professionals to build common goals and interests

c Development of standards, indicators, outcome measures and so on

d Skills in analysing public health data (hard and soft) to identify the needs and interests of individuals and populations

e Service specifications – contents, driving quality and safety, specifying standards for monitoring and assurance, performance management requirements (services will include those relating to health and social-care services themselves and related services, for example, facilities management – cleaning, food, waste disposal, linen)

f Clinical governance, quality assurance, clinical effectiveness, quality improvement framework and service improvement frameworks

g Improvement and change methodologies.

(*Continued*)

15 Improve quality and safety through the design, planning, monitoring and development of services — Continued

Links to the NHS Knowledge and Skills Framework

This competence relates to the following dimensions and levels within the NHS KSF:

Core 4 Service improvement Level 4

HWB3 Protection of health and wellbeing Level 4
G3 Procurement and commissioning Level 3
G5 Services and project management Level 4

Links to national occupational standards

The following national occupational standards relate to this competence:

ENTO HSP1: *Develop and review the organisation's health and safety strategy* – see https://tools.skillsforhealth.org.uk/competence/show?code=ENTO+HSP1

ENTO HSP13: *Influence and keep pace with improvements in health and safety practice* – see https://tools.skillsforhealth.org.uk/competence/show?code=ENTO+HSP13

Leadership and management

16 Lead high quality infection prevention and control services

Performance indicators

1 Communicate a vision of infection prevention and control that is related to major organisational objectives and captures the interests of key people
2 Develop a strategy for an effective infection prevention and control service
3 Negotiate and agree deliverables, outcomes and resource allocations for the infection prevention and control service and specific projects
4 Develop and facilitate the implementation of the infection prevention and control annual programme in partnership with key people
5 Review outcomes, plans, methods, processes and systems related to infection prevention and control and modify them to improve effectiveness
6 Prepare and present relevant and focused infection prevention and control reports and other forms of communication to key people

Knowledge, understanding and skills

a Organisational management strategy
b Individual and organisational management strategy
c Principles and methods of planning, resourcing, monitoring and controlling
d Leadership theories and styles (for example, situational leadership, transformational leadership, servant leaders, distributed leadership) and their application to practice
e Organisational and directorate communication strategy.

Leadership and management

17 Lead and manage the work of the infection prevention and control team to achieve objectives

Performance indicators

1 Agree and communicate clear team and individual objectives and work plans
2 Ensure objectives and work plans are realistic and achievable, making adjustments where necessary
3 Develop, coach and encourage all members of the team to use their abilities to practise effectively and efficiently to deliver the infection prevention and control programme
4 Ensure that team members have access to sufficient resources to deliver the programme
5 Assess the performance of the team and individuals at appropriate times, using valid and reliable information
6 Provide feedback to teams and individuals in a situation and in a manner most likely to maintain and improve their performance, including providing recognition of achievements
7 Where necessary, help team members to address poor performance
8 Encourage and support good relationships between the team and other teams and departments within the organisation

Knowledge, understanding and skills

a Leadership theories and styles (for example, situational leadership, transformational leadership, servant leaders, distributed leadership) and their application to practice
b Staff support mechanisms
c Resource management to deliver organisational strategy and objectives
d Time management
e Budget management
f Legislation, national guidance and outcomes/indicators related to the employment, management and development of employees.

The following national occupational standards relate to this competence:

M&L B5: *Provide leadership for your team* – see https://tools.skillsforhealth.org.uk/competence/show?code=M%26L+B5

13. Examples of career paths for IPC practitioners

There is no set career path for IPC practitioners, nor is there a 'typical career path' any more. Today's IPC practitioners increasingly come from diverse occupational or professional backgrounds, environments and disciplines, and enter at different points on the career ladder.

Like Rashid in the case study below, people often start their career in clinical practice or healthcare science, develop a passion or interest in IPC, and then pursue continuing education courses to develop specific expertise that qualifies them for the role.

Nor is there a single end point. Let's see how this worked for Jo:

Case study 1

Rashid

Rashid started his nursing career in general nursing. He took up his first post in acute elderly medicine, which allowed him to consolidate his basic nursing skills. He then moved to an acute general surgery setting and also completed his Masters in Healthcare Ethics. Experience in a number of specialties allowed him to progress through the nursing ranks, culminating in a lead-nurse role on a plastics, burns and maxillofacial ward. An interest in infection prevention led him to take up a post with the infection prevention team and to complete a management of infection prevention and control programme. He continues to work in this field as a matron for infection prevention, and he often draws on his previous nursing experience to support him in this role.

Case study 2

Jo

Jo trained in general nursing then specialised in intensive care and medicine. Her interest in infection control led to a seconded project in developing surveillance and a full-time infection prevention and control post. This provided her with opportunities to develop her expertise over 10 years. She then took up senior posts in both acute and community care, completing an MSc in professional development, and fulfilling regional and national roles in the Infection Prevention Society. As Consultant Nurse in a large university teaching hospital, she had input into university programmes as a lecturer. A role as Deputy Director of Infection Prevention and Control followed. Development opportunities arose at regional level and on the Department of Health's MRSA programme. Jo is still the Director of Infection Prevention and Control in a large acute trust, and has a continuing passion for professional development, supporting improved patient safety and use of competency frameworks.

Case study 3

Pat

Following general nursing and specialising in intensive care nursing, Pat was offered a part-time Infection Control Nurse (ICN) position while managing an acute unit in an independent healthcare company. The full-time ICN position provided opportunities to develop enhanced knowledge and skills, including quality improvement at national and local level, development of strategy, and policy skills.

But Pat's story does not stop there…

Case study 3A

Pat (continued)

A continuing interest in population health led Pat to an NHS public health protection post with wider public health activities and national working (for example, with government). This led to a number of national roles – a government advisory position leading a national IPC programme, and a consultant role in a health protection organisation, and in a non-NHS national organisation regulating all adult, child and independent healthcare services.

The role of IPC practitioner can take you in exciting new directions when you least expect it:

Case study 4

Rani

After training as a healthcare scientist, Rani was inspired to move outside the lab by the local infection control consultant, and seized the opportunity of a career progression into the specialty. A spell at a district general hospital and a large teaching hospital culminated in her involvement in pioneering improvement work. This took her to the national and international arena, working latterly for the World Health Organization in Geneva and its regional and country offices, ministries of health and professional medical, nursing and academic institutions, as well as with clinical staff in healthcare settings in South East Asia, the Americas and Africa.

IPC practitioners can also decide to pursue a clinical academic career like Megan:

Case study 5

Megan

After working as a general nurse in various specialities (orthopaedics, medicine, urology, surgery, A & E and care of the elderly), Megan then joined the infection prevention and control team, having responsibilities within both the acute and community setting. Twelve years later, Megan was appointed to an associate lecturer's role in the university. This allowed her to split her work between her clinical roles and the university (teaching in the undergraduate and postgraduate nursing and midwifery curriculum) and Megan also completed her Masters at that time. Following 18 months as an associate lecturer she took up the post of a full-time lecturer and gained her teaching qualification. After engaging in a number of research projects, her role then extended to that of a lecturer and researcher and she is now undertaking her PhD.

These real-life case studies suggest that IPC practitioners do need to plan ahead, but they also need be flexible. Most of all, they need to be open to new interests and opportunities.

14. Example of assessing oneself against the competences and planning learning

Zara has been working as an IPC practitioner for four years, with four others at the same band/grade. She is interested in developing herself so that she is able to apply for a higher banded/graded post in IPC. She is interested in this primarily because recently she has been working closely with her line manager and has had an insight into the leadership and management aspect of infection prevention and control and feels she has the qualities to be able to effectively deal with the challenges that this role presents.

Zara's current post is multifaceted, but her main responsibilities are responding to specific laboratory diagnosed infections; contributing to outbreak management; undertaking audit and surveillance; and the development and implementation of infection prevention and control education to multidisciplinary healthcare workers. Since Zara has been considering progressing her career, she has become increasingly conscious that whilst she has the fundamental knowledge, skills and competence to do some of the work undertaken by an advanced level practitioner, such as using some improvement methodologies – competence 4 – and using surveillance data – competence 2), there are broader aspects of the role that would be very challenging for her at the moment without further development.

One of the competences that Zara has identified as currently challenging is competence 5 related to advising on the design, construction and modification of facilities, because this aspect of the role has been predominantly dealt with by her line manager. Zara assessed herself against competence 5 and also asked for feedback from her line manager, Sam. Their initial assessments are shown in Box 5.

Conclusions on Zara's learning needs in relation to this competence

Zara and Sam agreed that Zara's main learning needs in relation to this competence are initially in the knowledge, understanding and skills area, ie

- Legislation, national guidance and outcomes/indicators relating to the design, construction and modification of the built environment in general and health and social-care facilities in particular (for example, ventilation, water sources, waste management, and hygiene)
- Organisational strategy for new builds, refurbishments, planned programme maintenance
- Interpretation of architects', estates' and facilities' plans for new builds, refurbishment and modification
- And the application of these to practice.

To meet these learning needs, Zara and Sam identified the following learning activities for Zara to undertake (see Box 6).

When Zara had undertaken the planned learning activities, she would provide appropriate evidence to her manager to demonstrate her developing competence. There would then be a need for her and her manager to review progress, address further learning needs, and for her to re-assess herself against the competences.

Box 5

5 Advise on the design, construction and modification of facilities to prevent and control infection in the built environment	**Zara's self-assessment**	**Sam's feedback**
Performance indicators		
1 Work with others on plans for the design, construction and modification of facilities to improve safety and quality through infection prevention and control	(1) I am used to working with people in healthcare teams and think I do this well, but have no experience of working with architects, surveyors etc. Similarly I definitely have learning needs in relation to knowledge of building regulations and the application of IPC principles to design and construction.	One of your skills, Zara, is working effectively with others and I have seen you do this with many different people including senior managers without a healthcare background. I agree your main learning needs to be developed around building guidance, regulations and legislation and who the key members of the team are. This will also allow you to see how the infection prevention and control strategy aligns with this type of work.
2 Advise on the infection prevention and control risk assessment criteria prior to a new build and in advance of any demolition or modification of a building consistent with current building guidance and legislation	(2) Are the IPC risk assessment criteria the same for construction as I realise that I'm not sure and would need to confirm this? I also don't know about building guidance and legislation!	The IPC risk assessment criteria that you need to look further into is around the assessment of proposed sites for the development of a healthcare facility; the design and planning stages; the construction and refurbishment stages and ongoing maintenance issues
3 Liaise with key health and social-care staff and others prior to and at every subsequent stage of the build, demolition or modification to ensure that infection prevention and control advice is effectively incorporated into the works	(3) Think I might be okay on this one as long as I can understand building plans, legislation etc!	
4 Work in partnership with key health and social-care staff to reduce the risk of infection to individuals, populations, staff and others during construction, demolition or modification activities	(4) Again this seems to build on my fundamental learning needs identified above.	
5 On the completion of the works, review with individuals, populations, staff and others the effectiveness of the development for preventing and controlling infection.	(5) Ditto	
Knowledge, understanding and skills		
a Applied microbiology in relation to the chain of infection and the infection process, alert micro-organisms and conditions, body defence mechanisms	(a) – (c) this is one of my strengths in relation to this competence I think	Agree with this assessment Zara. The major learning needs are in relation to the aspects identified in (d) – (f). I note your concerns about (f) – I had the same worries when I started my development in this area – but with the right support I am sure you have the ability to develop your knowledge and skills in this area.

Box 5 — Continued

b The significance of microbiological results, interpreting the diagnostic laboratory results; practices designed to break the chain of infection – for example, standard and transmission-based precautions including the placement of individuals and populations within care settings

c Antimicrobial stewardship – prudent prescribing of antimicrobials and the surveillance of antimicrobial resistant organisms

d Legislation, national guidance and outcomes/indicators relating to the design, construction and modification of the built environment in general and health and social-care facilities in particular (for example, ventilation, water sources, waste management, hygiene)

e Organisational strategy for new builds, refurbishments, planned programme maintenance

f Interpretation of architects', estates' and facilities' plans for new builds, refurbishment and modification

(d) – (f) and here are my weaknesses, I really don't know where to start on these except for the basic knowledge I have already related to the above such as in relation to hygiene and waste management. But there are the broader aspects and the link of this into building design etc. (f) is a definite learning need which I am worried about as I don't have much confidence in interpreting plans etc.

Box 6

Learning needs	Learning and development activities	Actions and timescale
1 Legislation, national guidance and outcomes/indicators relating to the design, construction and modification of the built environment in general and health and social-care facilities in particular (for example, ventilation, water sources, waste management, hygiene)	These three learning needs are inter-linked. It is not a particularly easy area on which to find learning programmes in the local area as it is so specialised and only attracts fairly small numbers. The following possible activities have been identified: • An accredited online e-learning module • Book(s) and journal articles • Locate resources available from the Infection Prevention Society website and communicate with members on their online discussion forum • Locate resources available from the Infection Prevention Society website and communicate with members on their online discussion forum • Tutorial help from the architectural postgraduate student on placement in the organisation helping them meet their development opportunities as well?	1 Zara to find out about available e-learning packages asap as this seems to be the ideal possible starting point. 2 Sam to find references to the books used in own development for Zara to access from the library 3 Zara to look on the Infection Prevention Society website and discussion forum and contact relevant members or committees for their help and possible support. 4 Zara to do a literature search and look for relevant books in the library 5 Sam to make contact with the line manager of the student to explore possibility – end of next month's planned strategy meeting best time probably as can raise informally. 6 Aim is for Zara to have completed development in relation to these learning needs within 6 months
2 Organisational strategy for new builds, refurbishments, planned programme maintenance 3 Interpretation of architects', estates' and facilities' plans for new builds, refurbishment and modification 4 And the application of these to practice	• Opportunities for shadowing colleagues in relation to the planned refurbishment for the local podiatry clinic and the new build day surgery unit? • Talk to colleagues outwith own clinical setting to gain further insight into specific issues and challenges that others have faced and addressed	Structured shadowing in this area to follow development activities above. Sam also to consider whether possible for Zara to attend one or more planning meetings for the refurbishment of the podiatry clinic and planning stages of the new build for the day surgery unit.

16. Glossary

Aetiology
Study of causes or origins.

Alert organisms
A set of pathogens that are considered to be indicators of real or potential infections.

Antimicrobial stewardship
Multifaceted approach to preventing the emergence of antimicrobial resistance including the prudent prescribing of antimicrobial agents, surveillance of antimicrobial-resistant organisms, audit, monitoring and education.

Career framework for health
The purpose of career frameworks is both to help individuals plan their development routes and organisations develop a flexible workforce to meet current and future needs. The NHS Career Framework consists of nine different levels from level 1 initial entry-level jobs to more senior staff at level 9. Skills for Health show pathways through the NHS Career Framework through the use of competences.

Clinical audit
A quality-improvement process that seeks to improve patient care outcomes through systematic review of care against explicit criteria and the implementation of change.

Commissioning
The process of meeting needs at a strategic level for whole groups of service users and/or whole populations, and of developing policy directions, service models and the market, to meet those needs in the most appropriate and cost-effective way.

Competences
There are different forms of competences such as: those that focus on the underlying characteristics or attributes of an individual; the learning outcomes that individuals need to achieve at the end of a programme of education and training; or the outcomes that individuals need to achieve in a particular field of activity such as work. These competences use the latter concept describing the outcomes that individuals need to achieve at work, specifically the work associated with an advanced level of practice in infection prevention and control.

Competent
Broadly, this can be seen as the ability to perform to a standard through applying knowledge, skills and attributes.

Critical analysis skills
The ability to make expert judgements to inform infection prevention and control processes.

Decontamination
A combination of processes, including cleaning, disinfection and/or sterilisation used to achieve decontamination of the environment and equipment, and to make reusable surgical instruments safe for further use. The term also applies to hand hygiene.

Emerging infections
Those organisms that have been newly identified as a potential threat, usually to humans, but can be related to birds, animals, plants or the environment.

Epidemiology
The study of the distribution and determinants of disease and their impact upon a population.

Horizon scanning
Looking ahead to systematically examine potential threats, challenges, opportunities and likely future developments, through critical thinking and planning.

Leadership quality framework
This framework profiles the characteristics of leadership and the effective behaviours and qualities that can enable successful leadership to take place.

Learning culture
A set of attitudes, values and practices to support the process of continuous learning in an organisation.

National occupational standards
National Occupational Standards (NOS) describe performance as outcomes of a person's work. They focus on what the person needs to be able to do, as well as what they must know and understand to work effectively.

NHS Knowledge and Skills Framework
The NHS Knowledge and Skills Framework (the NHS KSF) defines and describes the knowledge and skills that NHS staff need to apply in

their work in order to deliver quality services. It provides a single, consistent, comprehensive and explicit framework on which to base review and development for all staff. The NHS KSF and its associated development review process lie at the heart of the career and pay progression strand of Agenda for Change and it applies across all of the NHS in the UK for all staff groups who come under the Agenda for Change Agreement

Qualitative research
Qualitative research is the study of things in their natural settings in order to make sense of phenomena in terms of the meanings people bring to them.

Quantitative research
Quantitative research uses scientific method and generates numerical data in order to test hypotheses and establish causal relationships between two or more variables, using statistical methods to test the strength and significance of the relationships.

Surveillance
The ongoing, systematic collection and analysis of data about a disease or organism that can lead to action being taken to control or prevent the disease.

Annette
This email chain relates to a difference of opinion about the 'involvement' of IPCT in the project and hand over as part of settlement.

I had advised that IPCT had not completed the stage 4 SCRIBE at the time of settlement, or indeed at March 2019 – Fiona summarised that discussion and our position at the time. This is subsequent email trail.

Thanks Donald

I have discussed with Alex. Alex has suggested Wednesday 20th March at 1130.

I have copied this email to Lindsay, Fiona and Sarah so they can also confirm if they can attend.

Thanks
Kal

Hi Kal,
Probably at 9am but there is an Incident Management Team Meeting being chaired by Public Health at 11am about an issue at a community dental practice that I need to participate in and 2 hours may not be long enough for the walk round of the whole building. We would also need the input of Sarah Sutherland and Lindsay Guthrie (or deputy) from the Infection Control Nurses.
Thanks
Donald

Sent: Friday, 15 March 2019 3:34 PM
To: McMahon, Alex
Subject: RE: Infection control + Ventilation Issues from Sunday Herald Article on Glasgow QEH- RHCYP

Dear Alex,
Thanks for letting me see this.
The pdf attachment relates primarily to the decisions around the design of the building and its ventilation. Janette Rae (Richards) was heavily involved in that planning and design process as outlined by Brian. She did often contact me for my advice when she had questions about the design or ventilation when she required another opinion and I think we all agree there was active involvement by the Infection Control team in the design and planning process.
With regards to point 2 about water quality for clarity my comment that there was no further communication had been there was no further communication after receiving the e-mail from Ronnie (which was the one I had sent you). Perhaps I could have been clearer in that email that the person best placed to answer the question, "whether the presence of Psedomonas species is an indicator of future risk of Pseudomonas Aeuriginosa" is the Authorising Engineer for Water and not me as infection control doctor/medical microbiologist as it is a question about water and environmental microbiology and that strictly is not part of my training as a medical microbiologist. I had suggested contacting Alan Hambridge to answer that particular question as I believed he was still the NHS Lothian Authorising Engineer for Water. Alan replied to Ronnie promptly on 21st Feb to advise that he was no longer contracted by NHS Lothian to provide such advice. At that point I was no longer included in any e-mail communication regarding how this had been resolved. (Having met John Bryson at the DCN IMT on Wednesday I believe he and Westfield Caledonian were then involved.) So that is the context of the comment that there was "no further communication." It is reassuring from Brian's e-mail that corrective work seems to have currently dealt with the Legionella water contamination issues but I still don't know where in the building they occurred. I was told they were not in an augmented care area but I had been hoping for more specific information about the location(s) to be able to assess the clinical risk once the building is occupied.

Regarding point 3 about windows in the isolation rooms not being able to open. I'm very pleased if that's no longer the case but the room Ewan, Lindsay and myself were shown had a window that opened when we were there in December 2018 and it wasn't in a lobby but the actual patient room.

Regarding theatre ventilation validation Point 4. I'm glad there is an independent validation of these results although when the new theatres were commissioned at SJH in 2017 we were issued with a clear validation report that assured us all was well and functional (attached as an example of the sort of document we were hoping to receive). This is in line with SHTM 03-01 where it states the IPCT can legitimately request the validation report when a theatre is commissioned. I've pasted the relevant section from SHTM 03-01 below:

Ventilation system commissioning/validation report

8.64 Following commissioning and/or validation a full report detailing the findings should be produced. The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

8.65 The report shall conclude with a clear statement as to whether the ventilation system achieved or did not achieve the required standard. A copy of the report should be lodged with the following groups:

- the user department;
- infection control (where required);
- estates and facilities.

I've spoken with Sarah Sutherland this afternoon and both of us would welcome the opportunity to assist with a walk round as news that the commissioning was complete and the building was now accepted by NHS Lothian had been a surprise to us both.

Best wishes
Donald

Susan

Thanks for passing on further correspondence from Alex and Donald Inverarity.

I respond to various points contained in numerous recent emails as follows:

1 Infection Control involvement in the project

I reiterate my email of 12/03/19 at 8.06 and 12/03/19 at 10.09 with further clarification in yellow:

On further reading of the chain of emails from Lindsay Guthrie to Alex can we just advise that Sarah Jane Sutherland, Lead HAI Scribe Advisor, and IPCN Emma Collett last visited the project on Monday 28th January, 2019 at 9.15am.

The purpose of this visit was to reassure Sarah Jane that Janette (recently retired HAI Scribe advisor) was fully involved in the room review process and in anticipation of an imminent completion or handover of the facility. Janette was provided with the timetable for our first and second round of reviews and she chose which ones she wanted to attend. To ensure a consistent approach was taken to the reviews a checklist of what to look at was developed, which was discussed with Janette. The project team have been consistently checking that previous observations made by them have been addressed and to identify any further observations that have occurred since the 2nd room reviews though to completion.

A further meeting on 27th February with one of the project's Commissioning Managers also took place to review previous documentation signed off by Janette Richards.
However, it is accepted that given the uncertainty of the actual completion date, to almost the day before it occurred, ICPT were not involved in the actual day of completion. It is worth emphasising that patients will not occupy the facility until 9th July, 2019. It is our intention to carry out a pre handover check when all construction activity by IHSL/MPX completes in June.

We can confirm that the Board's Infection Control have been involved from the early stages in the project including competitive dialogue, evaluation of some parts of the submission; actively contributing with the clinical teams to the clinical area design development and approval process reviewing relevant specifications for items such as sanitary ware, flooring, vent coverings etc.

We have been fortunate in that there has always been a nominated IPCN for Reprovision and they have been an integral part of the process participating in key meetings and, if they could not be present at meetings, taking the opportunity to

comment on meeting outputs where required and following up on issues in consultation with project and other clinical staff.

Throughout each of the stages of the project they have provided expert advice on elements such as isolation room design and functionality, room ventilation design, and HAI Scribe.

They have also joined project team personnel in reviewing the rooms for adherence to design brief, quality of finish and functionality, (including ease of cleaning and compliance with SHTM ~~and HEI guidance~~) and advised us on aspects of the building that they felt HEI inspectorate may consider during any future inspections.

2 Water Quality

Before updating you on the current water quality status on site we are at a loss to understand Donald's comment that "there was no further communication". The email attached to Donald's email is clearly a response (text in red) from our Hard FM Commissioning Manager. Indeed, we have still to receive a response to our request from Donald on whether the presence of Psedomonas species is an indicator of future risk of Pseudomonas Aeuriginosa

Current update is that all test results from latest full batch of sampling have come back clear for Legionella. Pseudomonas positives were found in 2 of 14 samples with elevated TVC counts, this from a total sample of 115. Further disinfection has taken place and the 14 elevated TVC locations will be re-sampled with results due by 20/03/19, until such times as these come back clear MPX are continuing with their responsibilities for water safety management. Further sampling will be carried out by Bouygues in the next 2 weeks once the current batch are all confirmed as clear and in addition there will be a further round of sampling at a time to be agreed prior to full operation. In the intervening period between the last two sampling exercises, Bouygues will implement a robust water management system involving flushing of little used outlets as per the positive obligation in the settlement agreement. It will be for the NHSL water safety management group to decide if this is enough reassurance as it complies with SHTM 04-01.

3 Ventilation to Isolation Rooms

All windows to isolation rooms and their lobbies are fixed pane windows (they do not open) except lobby 1-B1-033 which has been reported as a defect. I suspect Donald viewed room 1-B1-068 where works to correct an earlier identified defect were incomplete, this has now been resolved.

4 Theatre Ventilation Validation

Theatre ventilation commissioning, include cascade and UCV validation took place between October 2018 and February 2019 and all certificates and reports have been examined and verified by Arcadis as Independent Tester. These are available on the project data storage system 'Zutec'. These have however been rendered void by the agreed post completion works to enhance fire safety across the site and will be fully re tested and validated which will be witnessed by NHSL and the Independent Tester once these works are complete. In the meantime the information on the system can be reviewed by ICD and IPC at any time to ensure they meet their requirements. MPX will carry out air sampling on completion of their builders clean

and prior to NHSL equipping the area. It is assumed IPC will wish to repeat this prior to theatres becoming fully operational.

5 Sub optimal Air Exchange Rates in clinical areas

During the review of the environmental matrix it was identified that air exchange rates within the single and 4 bedded rooms did not meet the recommendations of SHTM 03-01. Risk assessments were carried out and discussed with infection control staff (sample attached). A workable solution has been implemented which includes mixed mode ventilation where natural ventilation provides the difference between 4 and 6 ac/hr.

6 Consequences of water damage event

The project's Clinical Director and a Commissioning Manager toured the Facility on 5th July, 2019 with Janette Richards, Dr Pota Kalima and MPX and the remedial and reinstatement process proposed by IHSL/MPX was accepted in addressing the departments that were affected by the water damage. Donald's recommendation, in his email of 25/07/2018 to the project's Clinical Director that a building survey using a moisture meter to assess dryness of walls should be undertaken at the appropriate time will be undertaken. We assume the outcome of such a survey would suffice in providing the reassurance being sought by Fiona. To the best of our knowledge, and we believe also the Independent Tester's, all materials and systems damaged by water have been replaced.

We hope this clarifies the communications with Infection Control to date but needless to say we would welcome a walk round by Donald and members of the IPCT at any time as suggested by Alex.

All

I caught up with Donald after the DCN IMT. He said he would send me this email and I have his permission to forward on. For transparency I have copied Donald in.

The content gives me some cause for concern. Jim and Tracey can we take the opportunity to discuss this with Donald tomorrow afternoon. I know Jim you and I are meeting others at 4 but I think if we can take 5 mins just for a quick discussion that would be helpful.

In the meantime happy to take thoughts but one action we I am going to instruct is that Donald and members of the IPCT do a walk around of the whole building with the appropriate personnel.

Donald asks for sight of reports as set out below, Jim/Susan can we make these available as well.

Alex

Subject: RE: Infection control + Ventilation Issues from Sunday Herald Article on Glasgow QEH-RHCYP
Sensitivity: Confidential

Dear Alex,
Following our discussion after the DCN IMT today, I'd like to raise a further issue that relates to water quality and ventilation in the new hospital site.
Please see the (confidential) e-mail dialogue attached which was sent to me by the commissioning team in the week before the building was handed over to NHS Lothian. It was highlighted that there were concerns about Pseudomonas aeruginosa and more concerningly Legionella in the water. Despite replying expressing concern particularly over the finding of Legionella, there was no further communication with me about the issue. I don't know where in the building this was found and I don't know what corrective action is/has been taken. Consequently it is not possible to risk assess whether there is a clinical risk to immunocompromised patients when they occupy the building without knowing if there are water issues in the clinical areas where such patients will be managed. Even if they have been addressed and corrected by the time patients are admitted later in the year, they would still count as higher risk areas that would deserve more scrutiny to ensure the level of Legionella remains low and would present a persisting clinical risk if in a clinical area.
I also mentioned to you the paediatric isolation rooms which are designed as positive pressure ultraclean rooms with HEPA filtered air and yet the windows open to the outside unfiltered

Edinburgh air defeating the purpose of the room. I don't know if any corrective action has taken place regarding this design flaw which was identified by Lindsay, Ewan Olsen and myself when we were invited to review the design of the room and its ventilation pre handover.
Although given assurances that pre hand over there would be validation performed on all theatre ventilation, as ICD I've never seen any of these validation reports and neither have any of my consultant microbiologist colleagues albeit we were given a tour of the ventilation system and theatres as they were being built.
All the best
Donald

Subject: RE: Infection control + Ventilation Issues from Sunday Herald Article on Glasgow QEH-RHCYP

Brian

Alex sent on your email I am unsure what HEI guidance you are referring to. Healthcare Environment Inspectorate do not have standards for buildings. I can confirm any reviews, recommendations IPC made would be in alignment with the SHTM guidance by HFS for building works. I agree we did have involvement and a dedicate person i.e. our HAI SCRIBE lead involved. However as per communications with Alex IPC were not involved in handover as per SCRIBE guidance recommendations

I cannot reliably say if all our recommendations were accepted. I am aware as a result of the cancelled FOI there was discussion re air exchanges rates perhaps being suboptimal in clinical areas and we don't know what the outcome of that report was. The HAI SCRIBE documents or minutes of your project meetings should be able to confirm.

Another example IPCT can only assume the building engineer who accepted the building on behalf of NHS Lothian saw evidence of theatre validation See p114-124 of SHTM 03-01. IPC to the best of my knowledge have not seen a validation report (section 8.64-8.65 of SHTM 03-01). The validation/commissioning report should be a clearly understood document that outlines that the theatre is working optimally, not just engineering data, which allows us to have confidence in the efficiency of theatre ventilation and would go some way to provide the board with a level of assurance.

In addition not have we seen what evidence was provided to give NHS Lothian assurance that the consequences of the flood were fully addressed. Did the contractors provide assurance that all water damaged construction materials were replaced and there is no unnecessary residual damp material, particularly not in clinical areas. As previously advised by our ICD Dr Inverarity, damp building materials that are left in place to dry out over time are predisposed to growing moulds and fungus and that could take some time to show. The clinical risk that can result in depends on where the damp material is situated e.g. theatre or isolation room designed to protect patients from infection. Did the contractor provide a comprehensive assessment for residual damp in clinical areas or was this checked by an external authority to the contractor as I think was recommended by Dr Inverarity at the time.

Alex I have copied Lindsay and Donald as they may also wish to comment as Lead Nurse and Lead ICD

Hopefully the following will be useful:

Infection Control

We can confirm that the Board's Infection Control have been involved from the early stages in the project including competitive dialogue, evaluation of some parts of the submission; actively contributing with the clinical teams to the clinical area design development and approval process reviewing relevant specifications for items such as sanitary ware, flooring, vent coverings etc.

We have been fortunate in that there has always been a nominated IPCN for Reprovision and they have been an integral part of the process participating in key meetings and, if they could not be present at meetings, taking the opportunity to comment on meeting outputs where required and following up on issues in consultation with project and other clinical staff.

Throughout each of the stages of the project they have provided expert advice on elements such as isolation room design and functionality, room ventilation design, and HAI Scribe.

They have also joined project team personnel in reviewing the rooms for adherence to design brief, quality of finish and functionality, (including ease of cleaning and compliance with SHTM and HEI guidance).

Let me know if you need more on HAI Scribe and contractual obligations.

Ventilation

Through witnessing of commissioning activities we can verify that the correct grade of filters are installed in the various air handling units and the ductwork is designed in accordance with relevant guidance. Regular inspections are carried out and alarm monitoring also occurs via the building management system and warns of deteriorating filter conditions.

Judith

We will summarise what involvement Infection Control have had in the project to date, how HAI Scribe works and contractual obligations in terms of infection control standards.

The specific ventilation issues raised at Glasgow will also be responded to in relation to this project as I said earlier.

Subject: RE: Infection control- RHCYP

Hi again Brian,
Most of this details the standard daily infection control measures we would expect to operate once the building is open. Presumably we can say the building has been built to industry standards (and that's a start) but I would expect the QEUH could have done the same?

If (and I do mean; if) our own infection control team was not involved specifically, then :

- is there something explicit in the contract that gives us assurance that the building was designed to satisfy all latest infection control standards?
- Retrospectively, do we know it doesn't have the same design weaknesses (in ventilation duct design and safety alarms) that is the issue with QEUH?

On that first point , there's been reference to the HAI Scribe but I don't know what (or who??!) the scribe is. Not looking for the contract – just a means by which we can describe in layperson's terms how we derive assurance that the design takes account of infection control requirements.

Thanks!

Judith

Sent: 11 March 2019 07:39
To: Currie, Brian; Graham, Iain
Cc: Crombie, Jim
Subject: Infection control- RHCYP

Morning all,

I anticipate questions from media today about the formal involvement of Infection Control expertise in the design of RHCYP / DCN in the wake of criticisms about the apparent lack of documented evidence of their involvement in the design / commissioning / handover of QEUH.

Please see this piece from yesterday's Sunday Herald.

https://www.heraldscotland.com/news/17489840.50m-repair-bill-for-glasgows-troubled-queen-elizabeth-university-hospital/

Can we state categorically that Infection Prevention and Control Team were fully and formally (in a governance sense) involved in the commissioning or handover process of RHCYP/DCN?

We are also likely to be asked explicitly if we know / have assurance that the design does not suffer from the same ventilation duct / safety alarm weaknesses as QEUH.

Since these were 2 of the issues that led to some delay late last year am I correct in thinking we were are satisfied RHCYP does not share same design issues on those counts?

Thanks for your help with this,

Regards

Judith

Hi Donald, yes I have and again many of our proposals in the paper I sent you are based on the Glasgow experience. I was a little hesitant in the paper to sight Glasgow directly but I guess you can assume it is strongly inferred. However good that Brian can review this report more fully rather than the potted summary I could share.

I do think it is important that this is discussed at the water quality group on the 4 th March and would be helpful in advance if Lindsay or Fiona are aware of the contents of this report. Possibly because it was conducted by HPS they are already aware.

It would also be helpful if Lindsay could attend, Brian do you wish to invite them along. I know we have good ICN representation but possibly needs more senior input.

Much appreciated George.

NHS LOTHIAN
Healthcare Governance Committee

12th March 2019

Jim Crombie

BRIEFING ON WATER QUALITY & PEST CONTROL ASSURANCE MEASURES

1 Purpose of the Report

1.1 This update is necessary to provide reassurance on the safety of our inpatient sites in light of recent Estates related matters within another Health Board. These issues have been linked to two patient deaths and also a number of blood stream related infections.

2 Recommendations

The Committee are asked to note the contents of this paper

2.1 Endorse this report as providing moderate assurance, evidence based on our governance, policy and procedures related to the management and to control of critical ventilation systems and Scottish Health Technical memorandum 03-01.

2.2 Endorse this report as providing moderate assurance on the operational management and control of our water quality systems. Evidence based on adherence to and congruence to our Policy and Procedures, and following guidance within Scottish Health Technical Memorandum (Water Quality) 04-01 and updated guidance from Health Protection Scotland.

2.3 Endorse this report as providing moderate assurance for the design, implementation and validation of new projects, reprovisions within Lothian and that these follow guidance contained within the Scottish Technical Health Guidance and involve necessary stakeholders direct support, Estates, Infection Control, Fire Liaison, Micro Biology, Professional Clinical Expertise, Capital Planning and Strategic Planning.

2.4 Endorse the proposal to move to new testing regimes as outlined within the HPS Guidance update pre-Christmas. Albeit we are yet unaware of total financial exposure of moving to a methodology of testing for legionella and pseudomonas in augmented patient groups. This position is supported by Facilities and infection Control Leads.

2.5 Endorse the proposal to request that NHS Lothian Laboratory Services investigate and fully cost out moving to an accredited water testing facility. Three months time scale.

2.6 Take responsibility for potential loss of activity in high pressure services, augmented patient groups. This as a result of introducing a testing regime that monitors samples for pseudomonas.

2.7 The group endorse that the Infection Control Lead and the Facilities Director monitor the implementation of this interim guidance over two cycles, (Water Safety Group) and a sustainable plan for this be developed for the longer term and full adoption of the guidance of the UK guidance HTM 04-01.

3 Discussion of Key Issues/Pest Related, Water Quality, Quality Project Delivery and Links to Hospital Acquired Infections

3.1 Two patients who died within another Scottish Health Board at the turn of the year showed they had contracted infections caused by inhaling the Cryptococcus Fungus, which can be found in pigeon droppings.

3.2 This Board has put forward a hypothesis that pigeons were able to access a ventilation plant room containing machinery within the hospital through a small hole in the wall, leading to harmful fungus/bacteria from their droppings entering the ventilation systems and being inadvertently distributed throughout clinical and non-clinical areas, and an area used by immune comprised patients. As yet the transmission route remains theoretical and not proven.

3.3 Birds such as pigeons can carry a variety of diseases such as Ornithosis, Listeria and E-coli that can be transmitted to humans not only from the droppings but also the birds themselves. Nesting can also be harmful encouraging mites, ticks, fleas, beetles, larvae and flies.

3.4 NHS Lothian may be less susceptible to causing such infections as it deploys a number of control measures including a professional pest control company (Excel Environmental) to manage and control bird and other pest infestations (captured in 3.7). The services provided include both planned inspections and ad-hoc visits. Currently they are inspecting our acute sites and thus far, have not escalated to Estates teams any adverse activity.

3.5 PFI(6)/HUBCO(5) type properties follow a similar model however the service is provided by a number of different companies, but do follow our protocols.

3.6 Estates have collaborated with Infection Control leads and can confirm in the past 26 months there have been no reports of incidents similar to that experienced elsewhere in the Scottish setting. This is not to say that we have had no Cryptococcus but not linked to a source of pest contamination within our inpatient environments.

3.7 NHS Lothian does have relevant experience in managing such an event. There were two incidents (Aug 2016 & Feb 2017) at the RIE PFI campus involving pigeon infestations which resulted in the temporary closure of three patient activity areas to facilitate remedial estates type actions and the performance of domestic services terminal cleans. There is no evidence to suggest that these incidents were a source of the infection. A problem solving group was established early on in the process, it had representation from Clinicians Infection Control, Estates and Microbiology. An action plan of mitigation measures was implemented and most of these measures now continue as good housekeeping, and the basis for our assessment of moderate assurance.

- All plant rooms to be secure and have adequate (authorised) access controls in place at all times.
- Plant rooms (particularly ventilation), ducts and attic spaces checked for any “bird or vermin” activity/evidence.
- Netting and anti-bird roosting/resting systems checked – effective and in place.
- Building/roof checks for openings/gulley’s/hones/air intake/ventilation grilles/chimneys/broken open windows/other – protection in place or required.
- Winter tanks – confirm tank covers fitted and secure plus vent/overflow screens fitted.
- Pest control professional/experts – further analysis of previous inspections/observations of “bird” activity – where there have been concerns requests immediate re-inspection.
- Additional bird prevention/proofing/control measures and recommendations re above report(s).
- Droppings if found – cleaned up appropriately.
- All critical ventilation systems to be inspected and maintained in line with SHTM 03-01: Ventilation in healthcare premises – as per existing schedules and method statements. (The RIE currently operates to SHTM 2025, which is being assessed for appropriateness)
- Standard Operating Procedures for the management of plant rooms are in place and being followed.
- IPCT, H&S & Facilities teams to establish regular review meetings to review the above actions and share examples of best practice.

- The above controls are in line with instructions for the Specialist Ventilation for Healthcare Society (SVHSoc) and Scottish Government. These arrangements are on a Pan Lothian requirement.

3.8 Our reviews and audits undertaken and the analysis of these help evidence and demonstrate reasonable control and the measures are appropriate.

3.9 Scottish Government, Mr Paul Gray has written to all Boards seeing assurance on certain aspects of maintenance, validation commissioning of water systems and more recently, on plant rooms checks and critical ventilation systems. Copies of these are attached within the Appendices along with our replies.

Water Quality

3.10 Further patients receiving treatment at this Health Board Hospital also presented with a number of blood stream infections. These infections appear to have links to known water borne contaminants, namely Cupriavidus pauculus, Pseudomonas, Aeruginosa positive and Stenotrophomonas maltophilia. These specific organisms were identified following review of high total viable counts (TVC) which is a general indicator of the potential presence of harmful organisms.

3.11 These high TVC values were observed at the commissioning stage and later on in the full operational phase 2015-2016. This facility is now subject to a very in-depth review to establish the cause and effect of these organisms within the water system. It will be some time before the outcome of this report is known. Recommendations will be of a National nature and will also contain local arrangements. However, the issue of how the system became contaminated is assumed to be regressional contamination and/or contamination at installation/commission in both hypotheses these rule out patient contract route.

3.12 Facilities have led on compiling this report to NHSL Executives to provide assurance on such a likelihood occurring within its estate. If comparing estates and functions, there is a risk (high) purely on comparison with those of this similar sized Board. However when considering Lothian's control measures and management arrangements, this would reduce to medium. Attached is briefing that outlines aspects of our policy and procedures that provide evidence to the "medium risk assessment" and moderate assurance on overall conformance.

3.13 In addition, this facility was built to SHTM 04-01 dated circa 2009. The SHTM 04-01 was reviewed and updated in 2015. In our own recent re-provision Facilities conform to this newer version which has been substantially updated.

3.14 Furthermore, NHS Lothian Water Quality Group is reviewing conformance to the most recent guidance for water quality and the UK guidance (HTM 04.01 published circa 2017). This is substantially more onerous than the current SHTM 04.01. Moving to this guidance will only improve our level of quality assurance on our water systems and will enhance safety to our most vulnerable patients.. This review is also considering the most recent guidance issued from Health Protection Scotland on sampling and testing for pseudomonas Aeruginosa in vulnerable client groups.

New Guidance

3.15 A number of serious healthcare associated outbreaks of Pseudomonas aeruginosa in augmented care units have been reported in the UK in recent years. The most notable, Belfast, where there were 4 deaths including neonates as a consequence of these infections. Further evidence can be provided on request as to specific incidents. There is evidence to show that these outbreaks are associated with contaminated water systems and components (e.g. flow straighteners, taps, sinks, drains, flexible hoses).

3.16 Health Protection Scotland (HPS) have issued interim guidance on the requirements for water testing in augmented care areas (i.e. Transplant units, Neonatal units, Haematology oncology units, critical and intensive care, renal units, respiratory units, Cystic fibrosis units). Compliance with the interim guidance is not mandatory, but is recognised as best practice.

3.17 The interim guidance advises that routine sampling should be undertaken every 6 months as a minimum to establish baseline levels and provide ongoing assurance of water quality and safety to the organisation. This paper recommends moving to these arrangements.

3.18 The interim guidance is consistent with guidance in Health Technical Memorandum 04-01 (HTM 04-01) and the approach taken in other UK countries and is consistent with our own preferred guidance route.

3.19 Scottish guidance for neonatal units (NNUs) (levels 1,2 &3), adult and paediatric intensive care units (ICUs) (2018) is due for review in 2019. It is anticipated that the revised guidance will reflect the requirements of HTM 04-01 in full.

3.20 HPS recognise that routine water sampling for *P. aeruginosa* in augmented care areas may require an assessment of the costs and impact across Scotland.

Next Steps:

3.21 The interim guidance and update to HTM04-01 will impact on a significant number of clinical areas in all NHS Lothian acute hospital sites. Specifically:

- WGH – Wards CAU,1, 3,4, 6, 8 & 8u, 11, 20, 54, 58, satellite renal dialysis unit and (Ward 33 HDU beds – pending move to RIE campus)
- RIE – Labour ward, Neonatal unit; wards 111, 112, 114, 115, 116, 117,118; 204, 205, 206, 206,215, Transplant; renal dialysis unit
- SJH – Labour ward, Neonatal unit, ITU, satellite renal dialysis unit, Burns unit; ward 21, 25, oncology day unit
- RHSC – ITU, HDU, Ward 1; Ward 2; Ward 6
- Once the new DCN and Children's hospital opens on the RIE campus, this list will need to be revised to reflect new clinical service configuration.
- NHS Lothian laboratories do not hold accreditation for water testing. This service, where required, is provided through an external accredited laboratory and is costly and we have to compete for priority. It is also a Monday –Friday service and may not help when we have a positive result.

3.22 Depending on the results from baseline sampling, and where specific criteria are met, the frequency of sampling would increase to weekly sampling for a period of at least 4 weeks and there for a period at quarterly intervals.

3.23 NHS Lothian Facilities is to begin these new sampling arrangements the week beginning 11.02.2019. The cost to implement the regular testing is not yet known but is being supported by the Facilities Directorate. It is expected to be in the region of £30K.

New Builds/Re-provisions

3.24 It is clear that these arrangements must apply to all areas of our organisation. Design, Commission, Validation and smooth transfer into the operation phase must be managed, monitored just as vigorously as other aspects.

3.25 NHSL has worked extremely hard to ensure it has governance and appropriate control measures to ensure strict adherence to industry best practice and Health Technical guidelines is followed.

3.26 NHSL Water Quality Group does have Capital Planning representatives. Capital Planning when at all stage of the procurement also have a dedicated resource from Estates and Facilities and injection control.

3.27 All derogations to technical guidance are discussed, debated and if approved signed off by senior officials of our organisations. Prior to these arrangements each and individual derogation is agreed at Project Programme Boards as part of our comprehensive governance of such issues.

4 Key Risks

4.1 As a result of testing for specific organisms the likelihood of positive sampling is high. This could lead to impacts on patient activity reduction specifically in areas where services are under pressure to meet time to treatment guidance.

4.2 The framework for Management and Control is not followed leading to exposure of potential failure of a system leading to risk of hospital acquired infections.

4.3 Reporting mechanisms from staff out with Estates breakdown leading to reduced awareness and monitoring of local and or isolated areas.

4.4 Engineering staff do not recognise potential risk from systems and their related transmission routes. It is key we put in place rigorous training and control frameworks that remove such a risk.

4.5 Because of the national concerns, expert advice input is removed or significantly reduced.

4.6 The current hypothesis on transmission routes is proven to be wrong, and new routes not under our control are determined.

4.7 Relevant Stakeholders, Estates, Infection Control and Microbiology do not engage or provide insufficient resource to ensure all aspects of our organisation controls are followed. Our governance is the main control for this risk.

4.8 Design, validation and commission criteria policy and procedures are not followed. The enforcement of Estates, Infection Control leads within projects and use of independent testers will substantially reduce this.

4.9 Outbreaks and recurring water issues experienced in other parts of NHS Scotland have proven complex to manage, and have been associated with increased public concern and negative media interest.

4.10 NHS Lothian has had recurring issues with water quality in the Neonatal unit and Lothian Birth Centre. As part of water testing, ‘positive’ results showing the presence of microorganisms could not be used to provide assurance of water safety as they did not provide information about specific organisms (e.g. P. aeruginosa) in line with guidance. As part of the risk assessment and management of this issue, the birthing pools were taken out of use until this could be provided. This created significant disruption for staff and patients, and had a detrimental impact on patient experience (increased demand an analgesia including epidurals).

5 Risk Register

5.1 Legionella, pseudomonas and pest infestations are all captured within the Facilities Directorate risk register and reviewed regularly.

6 Impact on Inequality, Including Health Inequalities

6.1 Not applicable

7 Duty to Inform, Engage and Consult People who use our Services

7.1 This is a whole organisation arrangement and as such relevant stakeholders have been influential in the construct of the report. This specifically includes Infection Control, Estates, Facilities, Health Protection Scotland and Health Facilities Scotland.

7.2 This will help inform Clinical Teams who will need to assess individual service requirements and access arrangements.

8 Resource Implications

8.1 These issues described in the paper have been challenging to resource. In most circumstances there has not been any investment from the financial plan to support

8.2 We have self resourced some 7 Band 6 Assurance Posts (£250k).

8.3 Independent water quality risk assessments and water sampling (£100K)

8.4 In addition NHSL will have additional costs associated with moving to the interim guidance. Cost for six monthly Pseudomonas testing: this is being costed and will be of the order of around £30K.

8.5 Cost for removing and discarding contaminated water system elements and replacing with new. This would be costed at time of incident. NHSL has sought evidence on costs UK wide but this has not proved successful.

8.6 There will be a need to review our systems and identify high risk components and cost these for removal.

- Water straighteners
- Taps
- Flexible hoses

In high risk areas these should be removed.

Subject: Water Management in New Builds and Refurbishments. Information Requests

Dear [redacted],

In light of an ongoing water incident within a healthcare facility within NHS Scotland the HAI policy Unit at the Scottish Government have requested that HPS/HFS carry out a review of all other new builds and significant refurbishments across NHS Scotland.

In the first instance we would seek a response to the following questions by 3rd January 2019.

1 Please provide details of all areas across your NHS Board that have had significant refurbishment that has required installation of new water systems since January 2013 until present.

2 Please provide details of all new builds across your NHS Board area since January 2013 until present (including those in progress not yet handed over to your board).

3 Were any results of microbiological water testing undertaken in both hot and cold systems during commissioning, handover and thereafter in those areas identified in questions 1 and 2 positive for micro-organisms (including fungi) or TVCs greater than 10? If yes, please provide details of location/s.

4 Has there been any water treatment/dosing/sanitisation carried out in any area identified in Q1 or Q2 across your NHS Board since January 2013 to present?

Copy to Directors of Estates

25 January 2019

Dear Colleague

Queen Elizabeth University Hospital – follow up actions

This letter sets out actions following the meeting of the Strategic Facilities Group on Wednesday 23 January. There are a number of controls that I would like you to confirm are in place and working effectively:

- All plant rooms must be secure and have adequate access controls in place at all times;
- All plant rooms maintained clean and free of vermin;
- Standard Operating Procedures for the management of plant rooms are in place and being followed;
- All critical ventilation systems inspected and maintained in line with 'Scottish Health Technical Memorandum 03-01: Ventilation for healthcare premises'.

I have asked Health Facilities Scotland to co-ordinate the responses and would ask that you reply to [redacted] copied to [redacted] by Friday 1 February.

In addition to these control measures, the Strategic Facilities Group has undertaken to share best practice on relevant Standard Operating Procedures and anti-pest management. The Ventilation Group, which reports direct to the Scottish Engineering and Technology Advisory Group (SETAG), is also considering urgently whether SHTM 03-01 needs to be revised and updated in view of recent developments. I will ensure that you are kept in touch with any changes to that.

Yours sincerely

Appendix 3

NHS Lothian has been asked by Scottish Government to provide assurance on the quality and capability of our water services within our facilities. These assurances on the back of recent events at the recently opened new facilities in Queen Elizabeth in Glasgow, Queen Margaret in Kirkcaldy and the new acute hospital in Dumfries and Galloway. These new facilities on opening have seen significant contamination in the water systems and have led to concerns of patient safety from water borne contaminants such as;

- Legionella
- Pseudomonas
- High TVC counts suggesting more rare contaminants

Following review of these issues we are led to believe that failings have been discovered in the following; design, construction, and operational phases of the implementations of the new builds. The period we have been asked to provide assurance on is ten years.
NHS Lothian can assure its Executives that it has a robust framework of governance and control mechanisms implemented by Capital and Estates limits the risk of the issues occurring within Lothian.
Any new build is closely scrutinised at the design stage by water quality experts within our own Board. These experts consist of our lead for water quality (Director of Facilities), Infection Control, Lead Microbiologist, Authorising Engineer, Authorised Person, Decontamination Committee chaired by our Executive for Public Health. In addition to the above we resource the projects with externally appointed technical advisors, appoint an Estate Projects Officer and a Project Director. These latter individuals ensure design, installation and the operational validations on capability are in line with best industry practice and more importantly adhere to SHTM 0401Water Systems and Quality and our own water quality policy that adheres to the SHTM. Where high TVC counts have been found, remedy measures with our operational protocol were undertaken and systems continue to be functionally suitable and safe.
Please provide details of all areas across your NHS Board that have had significant refurbishment that has required installation of new water systems since January 2013 until present.
Please provide details of all new builds across your NHS Board area since January 2013 until present (including those in progress not yet handed over to your board).

- Day Case Surgery , SJH
- Royal Victoria Building , WGH
- Mid Lothian Community Hospital (PFI)
- Wards120, 220, 116-118 RIE (PFI)
- Royal Edinburgh Phase 1 (Hub)
- East Lothian Community Hospital Out Patient Block (Hub)
- NHSL Partnership Centres (Allermuir, Blackburn & Pennywell All Care Centre) (Hub) Ratho Health Centre (Leased Property)
- Builds still to be handed over
- RHSC/DCN (NPD)
- REH Phase 2 (Hub)
- East Lothian Community Hospital Phase 3 in patient Facility (Hub)

Were any results of microbiological water testing undertaken in both hot and cold systems during commissioning, handover and thereafter in those areas identified in questions 1 and 2

positive for micro-organisms (including fungi) or TVCs greater than 10? If yes, please provide details of location/s.

Validation tests and sterilisation of systems has been conducted and signed off for these facilities. In addition ongoing testing for various contaminants is undertaken monthly and levels of TVCs are within agreed limits.

Two locations REH Phase 1 and Royal Victoria Building tested positive for TVC s greater than 10. Both installations were rectified through disinfection and ongoing testing and monitoring regimes implemented.

I can confirm that where there has been reoccurrence of low TVC counts we have undertaken further testing to reassure there is no risks to patients or staff.

These results are all available for external validation should that be necessary.

NHS Lothian however has experienced difficulties with HUB and PFI providers and has had to be very robust in holding such providers to account. This is something that could be improved through improvements to the Standard form of Contracts for Hub and NPD.

ailsa.atkinson[redacted]

Dear Paul

Queen Elizabeth University Hospital – follow up actions – NHS Lothian Response

With reference to your letter dated 25th January 2019, following extensive discussions with internal and external stakeholders across the whole of the NHS Lothian estate I can confirm the following;

- All plant rooms are secured and have adequate authorised access controls in place at all times.
- All plant rooms are maintained, clean and free of vermin.
- Standing Operating Procedures for the management of plant rooms are in place and being followed.
- Planned preventative maintenance (PPM) is carried out on critical ventilation systems. However the current method statements and frequencies do not meet the guidelines specified within SHTM 03-01, therefore our PPM schedules are being updated, and this will be completed within the next 4 weeks. We are being supported by our Authorising Engineer (AE) for ventilation.

I trust the above provides the necessary assurance required.

Yours sincerely

Appendix 5

Second Draft

Interim guidance on managing the risk of fungal contamination from bird droppings in air handling plant areas.

Background

The production of this guidance is prompted by recent experience of infection, and presence of fungus, in areas occupied by immuno compromised patients. Investigations are ongoing and further guidance may be issued as evidence emerges. This guidance should be read in conjunction with Scottish Health Technical Memorandum (SHTM) 03-01 Ventilation for healthcare premises, Scottish Health Facilities Note 30 Part a – Manual and part b – HAI-SCRIBE.

Fungi are ubiquitous in the external environment and, whilst generally harmless to healthy people, susceptible patients can be infected by various fungi, not just those associated with bird droppings. For that reason ventilation systems serving areas housing patients susceptible to fungal infection are designed to minimise the risk of transmission of fungus into the occupied space by means of appropriate filtration and pressure differentials between relatively clean and less clean environments.

Ventilation systems serving general patient and non patient areas are designed primarily to dilute contaminants in the occupied space and maintain comfort conditions. Although the filters used will reduce contamination from external sources, they are not designed to eliminate fungus. More detailed information is given in SHTM 03-01. The guidance contained herein is intended to reduce the challenge ventilation systems face from fungi and to reduce the risks, particularly recognising that patients in general hospital environments may have reduced immunity for a number of reasons, whilst not requiring specialised environments. It is not intended to make areas served by non-specialised ventilation systems safe for patients who should be accommodated in specialised protective environments.

Fungi can enter general healthcare environments via doors, people's clothing, apertures in building fabric, supplies etc. Although the filtration in non specialised ventilation systems is not intended to eliminate spores, keeping plant areas free of vermin and bird droppings is good practice and helps prevent spores entering the occupied space.

Specialised advice on the management of ventilation systems, including the protection of plant from contamination from bird droppings should be sought as needed from the Board's appointed Authorising Engineer (Ventilation).

Plant rooms

To minimise the risk of contamination of ventilation systems with fungus, plant rooms should be maintained clean and free of vermin. Where bird droppings are found, the area should be cleaned, taking care not to produce dust or aerosol, and an investigation commenced into the source of the contamination.

External ventilation plant

External plant areas are more difficult to protect and measures should reflect the risks involved. NHS Boards should have a record of all external ventilation plant, which should identify the areas and patient groups served. The inspection and maintenance of external ventilation plant should be in accordance with the requirements of SHTM 03-01 and should include steps to reduce the risks from fungal contamination from bird droppings.

Where external plant serves areas where patients are considered to be susceptible to fungal infection, or housing immuno compromised patients, measures to minimise the risk of contamination by fungus from bird droppings should be considered, including bird netting, anti roost devices, partial enclosure combined with bird netting, enclosing the plant in a fabricated housing and/or regular inspection and cleaning as appropriate to the risk.

Solutions will need to take account of local conditions such as layout, weather exposure, roof

loading and maintainability. Integrity of any solution needs to be taken into account as a poorly designed or maintained solution might increase roosting risk.

Bird dropping contamination at air intakes

Bird droppings, in areas where they might be able to produce airborne fungus, which might be drawn into the system, should be cleaned taking care not to produce dust or aerosol. Where droppings are not likely to be disturbed and not close to air intakes, they are unlikely to shed spores in greater quantities that that present in outside air.

If regular inspection identifies places where contamination repeatedly builds up and needs to be cleaned, then appropriate steps should be take to deter birds from using that place, such as by placement of anti roosting spikes or netting. Prevention of bird dropping contamination is preferred to cleaning.

The measures adopted should be determined by risk assessment involving appropriate clinical, microbiology, IPC and estates disciplines, and should take account of patient susceptibility, filtration, location of plant, practicability of protective measures and other issues identified by those undertaking the assessment.

Removal of bird droppings

The fungi associated with bird droppings presents a risk to those engaged in its removal and any associated work should only be carried out following an appropriate risk assessment and following a procedure developed to control the risks. Microorganisms such as fungi may be substances hazardous to health as in the Control of Substances Hazardous to Health Regulations 2002 http://www.hse.gov.uk/coshh/.

Whether specialist contractors or in house staff are used to remove bird droppings, they should be appropriately trained and use appropriate methods and equipment, including personal protective equipment, as identified in the risk assessment and procedure above. Clothing, equipment and tools should be appropriately decontaminated or disposed of at the end of work in accordance with the risk assessment and procedure.

Health and safety assessments, records and other documentation should be updated in accordance with decisions made, risk assessments and work procedures.

Bird droppings should be removed using techniques designed to minimise the risk of releasing airborne fungi. As the risk of releasing airborne fungi increases when droppings are dry and can produce dust when disturbed, wet removal techniques are likely to be best. Pressure washing should be avoided as this will aerosolise and spread the droppings. When droppings are being removed, the associated ventilation systems should be off and isolated where practicable. Chemical inactivation of fungus during the removal process should be used, although this should not be relied on as a substitute for other protective measures.

Bird management

This guidance does not set out to address bird management in general, which is a complex multifactorial issue, although it should be noted that management of the bird population in the vicinity of buildings can affect the accumulation of droppings and the risk of contamination from fungi should be part of a bird management strategy.

1. Background

Owing to the need to provide clear and practicable guidelines for infection control practitioners and others in operating theatres, the Hospital Infection Society (HIS) established a working party (WP) on infection control and operating theatres in 1999 to examine many of these issues. The remit of this group was:

(1) to review the scientific and other evidence for current infection control practices in theatre and following this, to make recommendations on which practices are essential, which are preferred and which are optional or are of little perceived benefit.
(2) to produce rational, feasible and applicable guidelines for the environmental monitoring (including bacteriological air sampling) of operating theatre facilities, and specifically to address when monitoring is indicated, how it should be carried out and what action should follow if abnormal.
(3) to consider optimal theatre facilities including when ultraclean or conventional theatre ventilation is required in the light of recent changes in surgical practice such as the increasing use of minimally invasive surgery. Work on this area is ongoing, and the conclusions reached will be available on the HIS website (www.his.org.uk) in the next 12 months or so.

The WP included microbiologists/infection control doctors, an infection control nurse, an operating theatre nurse, general surgeon, orthopaedic surgeon, aerobiologist, engineer and representatives of NHS Estates. The WP reviewed the literature in the relevant areas so that, as far as possible, the guidelines would be evidence-based. The WP also consulted with healthcare professionals and others as appropriate, and achieved consensus following discussion amongst the members on areas where scientific evidence was not available.

Draft documents were widely circulated to professional groups and organizations seeking comment and suggestions, and posted on the HIS website in early 2001. During the second half of 2001, the documents were revised in the light of this feedback, circulated to WP members and what follows is the result of this wide consultation exercise.

The members of the WP were: Gordon Bannister, Allan Bennett, Terie Chesworth, Chris Dobson, Ian Fraser, Marjory Greig, Peter Hoffman, Hilary Humphreys (Chair), Liz Jones, Geoff Ridgway, Ed Smyth, Andrew Stacey (Honorary Secretary), Eric Taylor, John Williams and Kate Woodhead; The members of the Commissioning and Monitoring subgroup were Alan Bennett, Chris Dobson, Ian Fraser, Peter Hoffman (Lead), Geoff Ridgway, Andrew Stacey and John Williams.

2. Introduction

Surgical operations and interventional procedures are performed in areas with various levels of microbiological control of the ventilation. The following areas are recognized:

(1) Conventionally ventilated operating suites
(2) Ultraclean-ventilated (UCV) operating theatres
(3) Unventilated theatres
(4) Treatment rooms

There is no technical difference between an unventilated theatre and a treatment room. This section refers only to conventionally ventilated and ultraclean-ventilated theatres. Discussion as to which procedures should be performed in which facilities will form a separate WP report.

Limited advice exists on conventionally ventilated and UCV theatres in the UK Health Technical Memorandum (HTM) 2025.[1] The HTM gives limits on the microbiological (bacterial and fungal) content of air in empty and working theatres, but states in a margin note ‘precise guidance is

inappropriate and will depend on local circumstances'. Whilst this remains true, it is apparent that many would welcome some advice on infection control aspects of these matters. This report seeks only to interpret HTM 2025 in a manner appropriate to infection control practitioners; we are not rewriting the standards within it.

HTM 2025 (volume A—Management Policy) gives the following role (paragraph 2.29) 'Infection Control Officer—or consultant microbiologist, if not the same person, nominated by the management to advise on monitoring infection control policy and microbiological performance of the system. Major policy decisions should be made through an infection control committee.'

It also states (paragraph 2.14) 'Increased health risks to patients will occur if the more specialised ventilation systems installed to supply high quality air to operating departments do not achieve and maintain the required standards. The link between postoperative infection and theatre air quality has been well established. Plants serving conventionally ventilated operating departments, for instance, will be required to ensure the separation of areas within the suite by maintaining a specific direction of airflow between rooms, even when doors are opened. They will also maintain the selected operating department environmental conditions regardless of changes in the outside air conditions or activities within the space. In addition ultraclean operating ventilation systems which are designed to provide an effectively particle-free zone around the patient while the operation is in progress, have been shown to reduce significantly postoperative infection in patients undergoing deep wound surgery. Their use for similar forms of surgery may well be indicated.'

One role of the infection control officer (ICO) in theatre commissioning and monitoring is to ensure the quality of the ventilation with respect to infection control issues. The ICO or infection control team (ICT) should be familiar with the outline structure, function and interrelationship of those engineering aspects that have an impact on infection control. A list of common problems in this respect and possible actions forms Annex A to this report.

3. Overall principles

The function of operating theatre ventilation is to prevent airborne microbial contaminants from entering surgical wounds. Under normal circumstances, the main source of airborne microbial contaminants is microscopic skin fragments given off by staff in theatre. A proportion of these skin fragments will be contaminated with microcolonies of bacteria resident, or perhaps transiently present, on that individual's skin. Whilst individuals will have different dispersion levels, overall dispersion is increased with movement and numbers of individuals present.[2]

Other sources of airborne micro-organisms are usually less significant. These include improperly filtered outdoor air, contaminated fabrics worn by theatre staff and backtracking of contaminated air from outside the theatre. The patient is not usually a significant source of airborne contamination; their movement is usually minimal. However, there exists the potential that power tools can create an aerosol from the tissues and any micro-organisms within them.

Airborne micro-organisms can enter surgical wounds by one of two routes: they can either fall directly into wounds or they can land on exposed instruments, and possibly surgeons' hands, and can later be transferred into the wound. The significance of this latter route will vary with the area of exposed instruments and the duration of their exposure, but is thought usually to exceed the contribution of direct wound contamination.[3]

4. Commissioning

Commissioning must occur before an operating theatre is first used and after any substantial modifications that may affect airflow patterns in pre-existing theatres (as part of a re-commissioning process). It is important that the ICT is involved at all stages from pre-design through to opening and that adequate time for commissioning is built in to the schedule, including an allowance of time for microbiological assessments. This may need particular consideration for facilities built under private finance initiatives. Contractual conditions should allow commissioning before handover of the theatre or have delayed acceptance after handover such that faults can be rectified.

4.1 Summary for conventionally ventilated theatres

Conventionally ventilated operating theatres must be commissioned before being used, after being built or

modified substantially. Commissioning is a task for both the Estates Department and the ICT, and co-operation and co-ordination between them is important. Below is a summary of matters that should be addressed when commissioning conventionally ventilated theatres (and by whom) and the section covering it in this report:

- The theatre interior should be checked for obvious defects (ICT), Section 4.1.1.
- The air distribution within the theatre and between rooms in the theatre suite should be checked by smoke tracing (ICT), Section 4.1.2.
- The air handling unit supplying the theatre should be properly constructed, the theatre should be properly constructed, finished and functioning (Estates Department and reported to ICO), Sections 4.1.2, 4.1.4 and Annexes D and E.
- Where 'setback' (reduction of ventilation rates when theatre is not in use) is in place, there should be indications in theatre of its function and safeguards against setback operating whilst the theatre is in use (Estates and ICT), Section 4.1.2.1.
- The air change rates in theatre and preparation room should be satisfactory (either Estates Department, or ICT with data supplied by Estates Department), Section 4.1.3.
- Airborne microbial contamination in an empty theatre should be satisfactory (ICT), Section 4.1.5.

4.1.1 Theatre interior

Inspection of the theatre interior before it is handed over from the building contractors to the hospital is the last convenient occasion to rectify faults. The following observations should be made:

- pressure-release dampers should move freely and be partially or fully open when doors are closed and move to shut when doors are opened;
- doors must close properly;
- the flooring should have no cracks or gaps in it and its coving joins to the wall;
- painted surfaces and finishes should be smooth, complete and without cracks;
- that there are minimal fixtures, shelves etc.;
- the windows should be sealed;
- the ceiling should be solid.

4.1.2 Ventilation engineering

The risk from airborne micro-organisms is minimized in the ventilation of conventionally ventilated theatres in three ways:

(1) by filtration of supplied air;
(2) by dilution of contaminated air in the theatre; and
(3) by preventing entry of contaminated air from areas outside the theatre.

The ICO/T should carry out airflow visualization (smoke testing) to ensure turbulent airflow in the theatre, particularly around the position of the operating table (a puff of smoke should disperse within seconds of creation). It should also be established that supplied air does not 'short-circuit', i.e., take a direct route out of the theatre such that it cannot entrain contamination generated in the theatre. Sources of such 'airflow indicators' are in Annex B. Large volume smoke generators are useful for tracing larger airflow patterns (also in Annex B). Fire alarms systems in the theatres should be disabled during testing.

Airflow visualization should also be used to establish that air flows in the desired direction between rooms in the suite (with all doors closed):

- from the theatre into
  - the anaesthetic room,
  - the disposal room,
  - the corridor;
- from the anaesthetic room and scrub area into the corridor;
- air should either flow from the preparation room into the theatre if it is used for lay-up or they should be at equal pressure if used as a sterile pack store (i.e., no direction of flow between them). Air should flow into the corridor from a preparation room used either for lay-up or as a sterile pack store.

Diagrams showing examples of suggested operating suite layouts (for example, with and without disposal corridors) and directions of airflow are in volume B of HTM 2025 (1994),[1] Design Considerations, Figures 6.1a and b. Figure 1 in this paper shows one of the suggested layouts.

The ICO should request a signed document from a senior member of the Estates Department that the ventilation to the theatre suite, including the air-handling unit, has been inspected and that the theatre is satisfactorily constructed, finished and is functioning to specifications. A sample letter forms Annex D to this report. Guidance on completion of this letter forms Annex E.

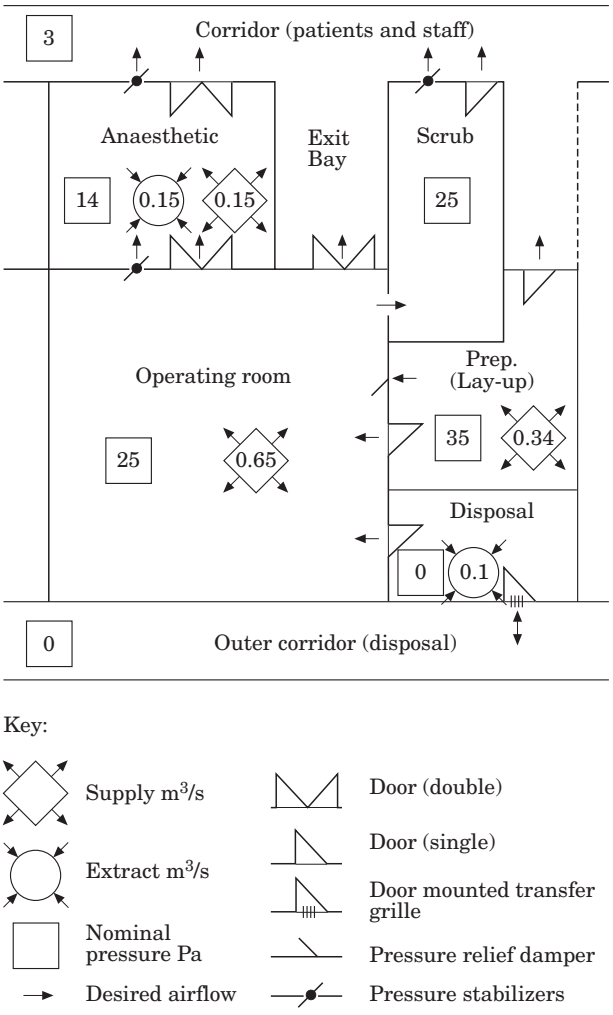

Figure 1 One of the eight 'suggested air movement schemes' from HTM 2025, volume B, Design considerations (Figures 6.1a and b, plan 5b).

4.1.2.1 Setback status

As an economy measure, ventilation rates can be 'set back' when the theatre is not in use. Ventilation should not be turned off completely, but volumes can be reduced provided that pressure relativities are maintained between the different areas of the operating suite to prevent backflow of contamination into clean areas. If a setback system is in place, there must be a clear visual indication in the theatre of whether the ventilation is on setback or normal flow rates. If pressure relativities are maintained during setback, all air in the theatre will have passed through the filters in the air-handling unit and there will be little microbial dispersion in an unused theatre; therefore we consider that the theatre will be usable 15 min after full ventilation has been restored. Control of setback is normally on a timed basis and there should be an override linked to the operating light or a movement detector so that set-back does not occur when lists over-run. There must be a setback override to allow for unforeseen use of the theatre to occur.

4.1.3 Air change rates

Details of ventilation rates to the theatre should be obtained from the Estates Officer and used to calculate air change rates (see Annex D). An air change is defined as occurring when a volume of air equivalent to the volume of the room has been supplied to or removed from that room (whichever airflow is greater). The rate of air change is usually given in terms of air changes per hour (ACH) and is derived from the volume of a room and the ventilation rate. Design and commissioning engineers do not however express ventilation parameters in terms of air change rates; they will express ventilation rates in terms of volume of air supplied or extracted per unit time, usually as cubic metres of air per second.

Worked example:

Room volume: An operating theatre measures 7 m long by 6 m wide by 3 m high: a total volume of 126 m^3.

Ventilation rate: If it has four ventilation supply grilles with observed flow rates of 0.18, 0.19, 0.18 and 0.17 m^3/s, it will have a total air supply (the sum of the individual grille flow rates) of 0.72 m^3/s (engineering air supply data is usually given as volume per second—either in cubic metres or litres; 1 m^3 is 1000 L) equivalent to 2592 m^3/h.

Air change rate: The air change rate is calculated by dividing the air supply rate by the room volume: $2592 \div 126 = 20.6$ ACH.

The Joint working party on ventilation in operating suites (1972)[4] ('The Lidwell Report') advised that clean areas (operating theatre and preparation room) should have ventilation equivalent to 20 ACH. If theatres are built to the size specifications in HBN 26[5] and have ventilation rates specified in HTM 2025,[1] there should be between 19.5 and 23 ACH in the theatre (i.e., ventilation rates in operating theatres should equate to around 20 ACH or above).

The air change rate in preparation rooms used for laying-up sterile instruments should be around 37 ACH; a greater air change rate than in theatres

(the main route of airborne contamination entering surgical wounds is probably via instruments[3]). If preparation rooms are used only as sterile pack stores, the ventilation rate should be around 11 ACH.

If either the operating theatre or preparation room have been built to dimensions different from those in HBN 26,[5] ventilation rates given in HTM 2025 should be adjusted to achieve the required rate of air changes. Effective air changes will only occur if airflow is turbulent and there is no short-circuiting. These should have been established by smoke testing (see 4.1.2).

4.1.4 Pressure differentials and airflow

The direction of airflow between rooms in a theatre suite is used to ensure that there is no backflow of air from either 'dirty' rooms in the suite or from contaminated areas in the hospital. Air flowing between rooms can be measured in terms of the pressure differential between those areas. The pressure differential results from the volume of air flowing between those areas per unit of time and the size of the gap though which it flows. It is usually measured in units of pascals or sometimes in terms of inches or millimetres of water. Pressure differentials between rooms in the theatre suite are given in HTM 2025, volume B (Design considerations). The desired pressure differentials are small and not easily measured (usually either by an electronic micromanometer or inclined fluid manometer). The desired pressure differentials between the different rooms will vary from around 9 to 30 Pa (1 Pa is equivalent to the pressure exerted by 0.004 or 0.1 mm of water, i.e., a very small amount of pressure).

We advise that the ICO request a signed document from a senior member of the Estates Department that the pressure differentials have been assessed by the commissioning engineer and are satisfactory (see Annex D). However as the value of the differentials are as much a reflection of the size of the gaps that the air flows through, as well as the volume of air flowing through those gaps and the robustness of flow is related more to the volume flowing through a gap than the pressure across that gap, we do not consider the actual values of pressure differential to be vital in terms of infection control. The ICO/T should have carried out airflow visualization with smoke tubes to observe robust directional flow at the same time as determination of turbulent airflow in theatre (see 4.1.2).

4.1.5 Microbiological sampling

HTM 2025,[1] volume C (validation and verification) states (paragraph 5.33). 'The level of airborne bacteria introduced by the supply air can be checked by closing all doors and leaving the operating room empty with the ventilation system running for one hour, after which a bacterial sampler mounted on the operating table should be activated remotely. Aerobic cultures on non-selective medium should not exceed 35 bacterial and/or fungal particles per cubic metre of ventilating air'.

When to sample The most appropriate time for microbiological commissioning of an operating theatre should be shortly before it comes into use. The theatre should have had an 'in-depth' clean and be thoroughly clean and dust-free. The air handling unit should have been operating at normal flow rates (i.e., not on setback ventilation) continuously for at least 24 h before sampling. Given the usual timeframe for sampling, it is usually only the production of satisfactory microbiological sampling that is required to enable a new or refurbished theatre to come into use. It is therefore vital that:

(a) the checks on the engineering aspects listed above should have already occurred and be satisfactory before microbiological sampling is done;
(b) false-positive microbiological results (primarily from airborne contamination dispersed by the person doing the test) do not cast doubt on the adequacy of the ventilation.

The protocol given in the HTM is skeletal and one purpose of these guidelines is to record the practical experience of those who have been involved in this field.

How to sample In a clean, well-ventilated operating theatre, the main source of airborne contamination will probably be contaminated skin particles dispersed from people, even when wearing theatre clothing. It is vital that any microbial air sampler is only operated once all people are out of both the operating room and any area that feeds air into the operating room (such as the preparation room). Also, before the sampler operates, sufficient time must be allowed for the ventilation to dilute and disperse the contamination generated during the setting-up of the sampler. It is not good enough to switch the sampler on and then stand away from it. This will be one of the considerations affecting the choice of a suitable sampler. Some samplers can be operated remotely via a cable from outside the theatre, by an infra-red remote control

or by a time-delay mechanism on the sampler. HTM 2025 advises that the theatre be empty for 1 h before sampling. This can make commissioning a suite with more than one operating theatre time-consuming. Each change of air will, given perfect mixing, produce a 63% reduction in pre-existing air and its entrained contamination. If there are, for example, 20 air changes per hour in a operating theatre (one air change every 3 min), in 1 h airborne contamination levels will be reduced to 0.0000002% of their former levels by dilution alone (there will be additional losses due to particles settling-out over this time). It does not seem unrealistic to leave the operating theatre unoccupied for 15 min before sampling, in which time airborne contamination should have been reduced to less than 1% (actually 0.67%) of its former levels, if the ventilation is working adequately. If the ventilation is defective, either in the rate of airflow or its distribution (such as short-circuiting out of the theatre without diluting pre-existing air), it may be more evident if left for 15 min rather than 1 h (the contamination dispersed by the person setting the sampler up will not have been diluted out or have had a chance to settle-out). A gap of 15 min between set-up and sampling will also allow time for generation of a duplicate sample, useful for confirming unexpected results.

Clothes worn when doing microbiological testing in theatre are unimportant. Local dress codes should be observed but normal theatre wear does little to reduce dispersion; besides which remote operation of the sampler and the time gap between leaving the theatre and taking the sample make such dispersion unimportant.

How much to sample The volume of air to be sampled is not specified in the HTM. It is left to the individual directing the sampling and will be determined by the microbial numbers being sought and the sampling equipment. We suggest that sampling volumes around 1 m^3 (1000 L) are optimal. Using volumes above this generates no substantial problems until either the colonies on the incubated plate get too crowded to enumerate accurately or the agar starts to dry out due to the volume of air passed over it. Using volumes lower than this may result in interpretational difficulties and tends to make the data more qualitative as the volume decreases. It also gives undue weight to plate contaminants. We cannot be prescriptive on this matter, but advise sampling volumes greater than 0.25 m^3 (250 L) and optimally around 1 m^3 (1000 L). Whatever air volume is chosen, the sampler used should be capable of sampling it without causing excessive drying of the recipient agar surface.

It is important to ensure that the sampler is clean before use. It should also be run briefly in the theatre before the agar is loaded to blow any contamination out of the sampler. We recommend taking at least two samples per theatre, as this lessens the possibility of technical errors interfering with successful commissioning of a theatre. A short summary of the attributes of the common samplers available is given in Annex C.

4.1.5.1 Sampling media

HTM 2025,[1] volume C (validation and verification) states (paragraph 5.34): 'The results should be examined to establish the broad category of organisms present. A high preponderance of fungal organisms may be an indication of inadequate filtration for the particular installation.'

The choice of growth medium and recovery conditions can be varied according to the nature of the exploration and perceived problems. Nutrient agar incubated for two days at 37°C is an acceptable method for general work. If there is a more specific investigation, appropriate media and culture conditions can be used. The larger the plate used, the greater volume of air it can sample before drying-out of the agar interferes with bacterial recovery (e.g., large volume slit samplers, which can sample several cubic metres of air, use 15 cm plates). The plates should be poured such that the surface is flat (no lumps, no slope).

If the quality of the agar plates is at all suspect, pre-incubation (under conditions that match the incubation of the samples to be taken) will allow those plates with contaminants to be discarded.

4.2 UCV theatres

UCV theatres must be commissioned before being used, after being built or modified substantially. Commissioning is a task for both the Estates Department and the ICT, and co-operation and co-ordination between them is important. The following is a list of matters relevant to infection control that should be addressed (and by whom) and the section of this report in which they are covered:

- The theatre interior should be checked for obvious defects (ICT), Sections 4.1.1 and 4.2.1.
- The airflow between a preparation room used for instrument lay-up and the theatre is satisfactory

(ICT), Section 4.1.2, and the preparation room has an adequate air change rate (either Estates, or ICT with data supplied by Estates), Section 4.1.3.
- The air-handling unit supplying the theatre is properly constructed, the theatre is properly constructed, finished and functioning (Estates and reported to ICO) Annexes D and E where applicable, Section 4.2.2.
- The air velocities in the ultraclean zone are satisfactory (Estates and reported to ICO), Section 4.2.3.1 and Annexes F and G, the terminal high-efficiency particulate air (HEPA) filter is effective and the ultraclean airflow can resist particle penetration from outside (Estates and reported to ICO), Section 4.2.3.2 and Annexes F and G.
- The ultraclean zone resists ingress of air from outside, shown by smoke tests (ICT), Section 4.2.3.1.
- Airborne microbial contamination in the ultraclean zone is satisfactory (ICT), Section 4.2.4. This test is not necessary if the tests of the HEPA filter and the ultraclean airflow above have been done but, if agreed locally, can still be done with a sample taken in the centre of the ultraclean zone.

4.2.1 Theatre interior

See section 4.1.1 for general theatre interior requirements. In addition, the operating lights should ideally be of a type that offers minimal interruption to the airflow pattern, but in reality such a choice may well be a compromise between illumination efficacy and airflow considerations.

4.2.2 Ventilation engineering

Control of postoperative infection caused by airborne micro-organisms is achieved in UCV theatres by exclusion of contamination from the wound. Filtered air descends in a uni-directional flow over the patient, creating a 'clean zone', rapidly removing contamination generated within that zone and preventing entry of contaminated air. The large volumes of air required to maintain this zone make it necessary to recirculate air from within the theatre. Filtration of this recirculated air is essential to prevent contaminated particles also being recirculated. The filters used are HEPA filters (see Annex H). The existence of this clean zone largely negates the need for control over air movement between rooms in the theatre suite. However, there is still a need for the preparation room to be at positive pressure relative to other areas, and to have a high airchange rate if used for laying-up instruments.

4.2.3 Air change rates and velocity

UCV theatres need to be tested to ensure:

(1) that the velocity of air within the clean zone is sufficient to result in a robust, unidirectional flow capable of resisting ingress of contaminated air from outside the zone (Section 4.2.3.1);
(2) that filters are intact and properly seated so as to remove microbial contamination from both incoming and recirculated air (Section 4.2.3.2).

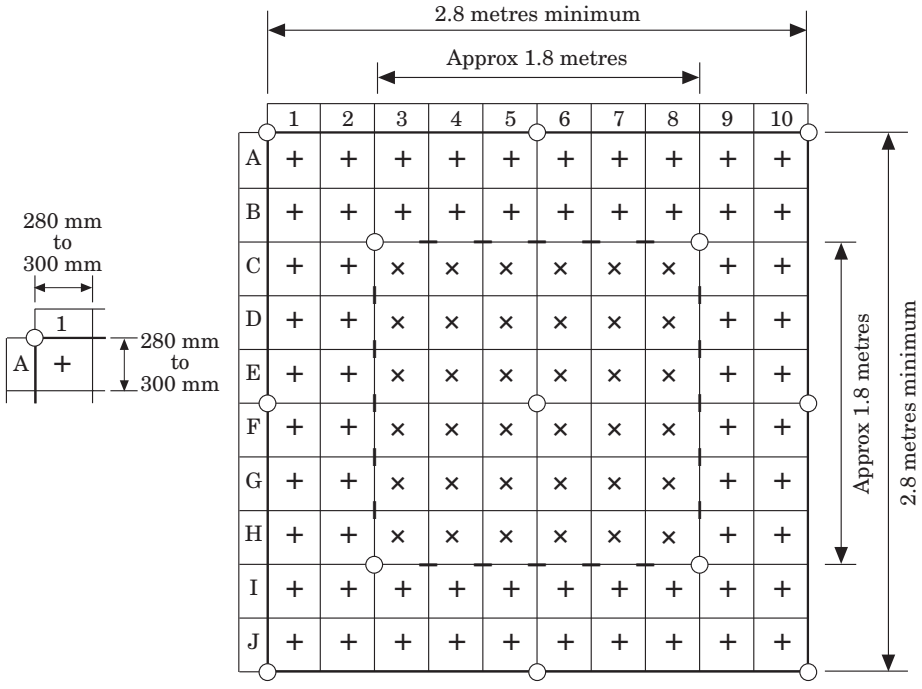
4.2.3.1 Air velocity and flow characteristics

A grid is marked out in the clean zone (at least 2.8 metres square) such that the area is delineated into 100 squares (10 by 10), each about 280 to 300 mm^2 (see Figure 2). In each of these squares, air velocity measurements are taken at 2 m above floor level. The air velocity should average 0.38 m/s if there are partial walls around the clean zone ending at a height of around 2 m above floor level (the usual case), or 0.3 m/s if there are full walls to 1 m or less above floor level. In the central 36 (6 by 6) squares, the velocity is also measured 1 m above floor level and should be at least 0.2 m/s. These data should be generated by the commissioning engineer and passed to the local Estates Department.

Airflow visualization of the resistance of the unidirectional flow to ingress from outside provides useful reassurance of the robustness of the system. Smoke should be aimed at the unidirectional flow from outside the area with various objects that may interfere with the airflow, principally the operating theatre light, in a variety of realistic positions and lack of ingress observed.

4.2.3.2 Contamination removal

To assess that the tested filters are intact and properly seated so as to remove microbial contamination from both incoming and recirculated air is tested by either microbiological air sampling or exclusion of tracer particles generated outside the clean zone. Volume C of HTM 2025 (1994) (Validation and



Key:

+ Measure air velocity 2 m above floor level

× Measure air velocity 2 m above floor level and also measure air velocity 1 m above floor level (min 0.2 m/s)

○ Bacteriological sampling position

Figure 2 Ultraclean-ventilated theatre test grid. (from HTM 2025, volume C, validation and verification, chapter 5, Figure 1).

verification), paragraph 5.36a states 'air leaving the final diffuser or final filters should contain not more than 0.5 CFU/m^3 of air. If the air filters have been tested after installation by a particle penetration test, this test is not necessary.' We consider particle testing to be a better test of filter integrity than bacteriological sampling: it poses a greater challenge to the filter assembly (there will be a far greater number of tracer than microbiological particles) and is less prone to technical errors (sampling for very low numbers of airborne bacteria is a skilled exercise). In addition to this test, there is a test to assess the capacity of the airflow in the clean zone to resist penetration from outside. Details of this test can be found in the same volume, paragraphs 5.28–5.31. In essence, after the filter installation has been shown to prevent passage of particles (i.e., the filters are not holed or mis-seated), DOP (dispersed oil particles) or other appropriate particles are generated outside the clean zone and their ability to enter into the clean zone assessed. This test would be done by expert consultants acting for the Estates Department or the commissioning engineers and the ICO should be informed of the result.

As the uni-directional flow in the clean zone will resist contamination from outside, there is no necessity to have the air movement control schemes (i.e., air moves from the cleanest to progressively less clean areas) that should exist in conventionally ventilated theatres. However there is still the problem of instruments being contaminated with airborne micro-organisms transferring that contamination into the wound.[3] Thus if instruments are laid up in a preparation room, that room should have air, filtered to the same specification as for the operating theatre, supplied such that it is at a positive pressure to surrounding areas. The air change rate in preparation rooms used for laying-up sterile instruments should be around 37 ACH.

It is important to prevent contamination of instruments exposed in the theatre, whether they have been laid up in a preparation room or in the theatre itself. Ideally, exposed instruments should be kept within the clean airflow, just as the wound is. However, the minimum size of the clean zone is 2.8 m × 2.8 m. It is, in practice, usually impossible to site all laid-up instruments within this area. Other than the diluting effect of ventilation on airborne contamination outside the clean zone, control of such contamination on exposed instruments can only be by limiting the duration of their exposure. This will require good co-operation between the team in only laying-up those instruments that can be accommodated within the clean zone yet providing all instruments as soon as they are required. If the clean area could be sufficiently large to accommodate laid-up instruments, there would be a higher quality assurance of contamination prevention. This matter should be considered at the design stage.

4.2.4 *Microbiological sampling*

When commissioning an ultraclean theatre by microbiological sampling, HTM 2025 (1994) volume C chapter 5, Figure 1 shows 13 sampling points reproduced in Figure 2 of this document:

(1) one at each corner of the unidirectional airflow zone perimeter,
(2) halfway along each side of the perimeter,
(3) one at each corner of the inner zone,
(4) one in the centre.

Volume C of HTM 2025 (1994) (Validation and verification), paragraph 5.36a states 'air leaving the final diffuser or final filters should contain not more than 0.5 CFU/m^3 of air. If the air filters have been tested after installation by a particle penetration test, this test is not necessary.' However, it is not uncommon, if the theatre has already been tested by particle generation, for single or duplicate microbiological samples to be taken at the centre of the clean zone. The air should contain less than 0.5 CFU/m^3, or one colony for every 2 m^3 sampled (HTM 2025, volume C paragraph 5.36a). Accurate sampling for such low levels of bacterial contamination involves stringent technical requirements and operator skill. There is no need for the person operating the sampler to be outside the theatre when the sample is taken, as the unidirectional airflow should exclude ingress of contamination from outside that zone, but the sampler should still be operated remotely from outside the unidirectional flow canopy (someone bending over the sampler to switch it on and off would greatly compromise air quality). The sampler must be absolutely clean and should be run for a while in the clean air to remove any contamination from it before the plate is inserted. The ventilation should have been operating at full supply rate for at least 5 min before sampling occurs.

So that airflow patterns are not unduly disturbed by the act of sampling, the pump for the sampler should be either outside or close to the edge of the clean zone and its discharge, if directional, should be directed out of the clean zone. The larger the volume of air sampled, the greater the assurance of an accurate result; to detect 0.5 CFU/m^3, the volume sampled must be at least 2 m^3, preferably more, so high volume samplers are essential. Using 15 cm wide Petri dishes, the agar will dry out to levels that discourage bacterial growth after more than about 10 m^3 has been passed over its surface. As low numbers of plate contaminants can significantly affect results of commissioning UCV theatres, poured agar should be pre-incubated before use (under conditions that match the incubation of the samples to be taken) to exclude plate contaminants. Incubation, as with conventionally ventilated theatres, should normally be at 37°C for two days.

5. Monitoring

5.1 Conventionally ventilated theatres

5.1.1 *Routine monitoring*

Provided that engineering parameters are satisfactory and regularly monitored, microbiological air sampling in conventionally ventilated theatres need not be done on a routine basis, unless by local agreement. Microbiological air sampling of empty, conventionally ventilated theatres should be done either as part of an investigation into theatre-acquired infection with a possible airborne element or after any changes that may affect airflow supply rates or distribution patterns. This would include alterations to the fabric of the theatre or changes to the ductwork distribution that may affect airflow to

or within a theatre suite, but would not include routine filter changes. Such sampling should be identical to that on initial commissioning of the theatres.

5.1.2 Sampling in a working theatre

Microbiological sampling during normal working can be done as part of the microbiological commissioning process. HTM 2025,[1] volume C (Validation and verification) states (paragraph 5.35): 'A check of airborne bacteria should be carried out as soon as possible after handover. Unless there are unusually high numbers of personnel or extensive activity in the room, the number of airborne bacteria and/or fungal CFUs averaged over a five minute period, should not exceed 180 per cubic metre. This work should be carried out by the nominated infection control officer or consultant microbiologist if not the same person.' This standard has subjective elements to it: the existence of excessive numbers of personnel in the room and an assessment of their activity levels. The need to average the sample over a 5 min period means, in effect, taking a continuous sample over that time or a sequential series of continuous samples.

The positioning of the sampler in relation to the incoming flow of clean air or the dispersing sources (theatre staff) will also have an effect on the microbial numbers recovered. Sampling in a working theatre is very much a secondary check on engineering parameters. If, for example, airborne counts in excess of 180 CFU/m^3 were to be found, remedies other than engineering-based are not readily applicable (these would be to reduce the number of staff in theatre, their activity levels or their individual dispersion levels). The only practicable course of action is reassessment of the ventilation parameters. This would comprise rechecking the commissioning engineer's airflow data with the local Estates Department; re-assessing air distribution patterns to ensure effective dilution and possibly re-balancing or redirecting ventilation output to achieve more effective contamination dilution.

Sampling in a working theatre is as much a check on how that theatre is being used as on the engineering parameters. We do not consider that it should be done as a routine exercise. Such sampling should be employed selectively where use of a theatre may have an effect on surgical wound infection.

5.1.3 The air handling unit

Annex 1 of HTM 2025, volume D (Operational Management) requires that the humidifier and cooling coil in air handling units be disinfected at least six-monthly. It also states 'if any suspicion arises as to the possible contamination of the system then the microbiologist should be requested to take swab tests from all drain trays and cooler battery/cooling coil tubes and fins'. We consider it inappropriate to carry out such microbiological investigations on cooling coils as they do not contribute significantly to the microbial quality of air delivered by the system. We also consider it inappropriate to carry out such investigations on humidifiers since they should generate humidity via steam, in which case they pose a negligible risk. Humidifiers that aerosolize recirculated water (spinning disk humidifiers) pose too high a hazard to require routine microbiological assessment: they should not be used.

Annex 1 of volume C (Validation and verification) makes similar recommendations for ventilation plant about to come into service. Again we consider that physical cleaning, rather than disinfection with microbiological monitoring, is more appropriate.

If there is a build-up of biofilm on a cooling coil, the five parts per million chlorine recommended for disinfection is unlikely to make any contribution to its removal, even on a temporary basis. Use of a steam cleaner, given as an alternative to chlorine, may be more appropriate but any effective method of physical removal of biofilm is acceptable.

5.2 UCV theatres

5.2.1 Routine monitoring

The pattern of airflow in a UCV theatre should be stable given reasonably constant air velocities. HTM 2025 volume D (Operational Management, para 5.8 and 5.9) recommends that air velocity assessment and bacteriological air sampling in a working theatre are done annually. As has already been noted, sampling in a working UCV theatre is a difficult exercise and we consider that, given no change in the ventilation, equipment or use of the theatre, such sampling is unlikely to give fresh data and is thus difficult to justify.

We recommend that UCV theatres are re-commissioned annually and on HEPA-filter

replacement or disturbance. We recommend that, in empty UCV theatres, such testing is best accomplished by using inert particles rather than by bacteriological testing. Sampling in a working UCV theatre, as with conventional ventilated theatres, need not be done routinely but can form part of specific investigations.

5.2.2 Sampling in a working UCV theatre

Microbiological sampling during normal working can be done as part of the microbiological commissioning process. HTM 2025,[1] volume C (Validation and verification) states (paragraph 5.36 b and c):

(b) air sampled close to the wound site during operations, that is within 300 mm of the wound should on average, contain less than 10 CFUs/m^3 of air using conventional cotton clothes. Levels less than 1 CFU/m^3 can be expected when using occlusive clothing or body exhaust systems;

(c) air sampled at the perimeter of the clean zone during surgery should contain not more than 20 CFUs/m^3 using conventional clothing and levels less than 10 CFUs/m^3 when using occlusive clothing or body exhaust systems.

However, as with sampling in working conventionally ventilated theatres (5.1.2), such a course of action is more an indirect assessment of operating theatre procedures, personnel and practices than of engineering parameters. Given adequate airflow and engineering controls, it is factors such as individual dispersal, behaviour and clothing that will affect the airborne bacterial count. It is unrealistic to expect that if it is satisfactory on one occasion, it will consistently be satisfactory (and vice versa). Such sampling provides only a 'snapshot' of the effects of other parameters that could be better observed and addressed as matters of theatre practice. As such, these matters are best observed directly and dealt with as matters of theatre procedure and discipline; there should be no need repeatedly to prove their need by the results of bacterial sampling. In addition, sampling air within 300 mm of the wound during ultraclean surgery, is a highly exacting exercise where minor technical errors may lead to false-positive or -negative results. We therefore do not recommend air sampling in ultraclean ventilated operating theatres during surgery as a commissioning exercise. If performed by technically skilled operators, it has a role in specifically directed investigations but this is not interchangeable with routine, undirected sampling.

Annex A: Problems and actions

A risk assessment should be carried out involving an assessment of the abnormal bacteriological results, the likely cause and the ease of rectifying this, the type of theatre and the procedures carried out there, and the consequences of theatre closure.

Table I. *Problems and actions*

Problem	Action
Conventionally ventilated theatre fails bacteriological sampling (empty theatre)	Check that sampling technique is satisfactory, then repeat sampling. If it still fails, discuss possibilities with people experienced in theatre testing. Explore possible engineering causes of failure (see Table II). Infection control team to discuss implications and options.
UCV theatre fails bacteriological testing (empty theatre)	Check that sampling technique is satisfactory (check with someone experienced in such sampling), then repeat sampling. If still fails, test particle penetration of filters outside clean zone to inside zone; test air velocity within clean zone.
Conventionally ventilated theatre fails bacteriological sampling (working theatre)	Test theatre empty, check airflow rates and distribution. If satisfactory, assess staff numbers inside theatre, activity levels and test again.
UCV theatre fails bacteriological testing (working theatre)	Test theatre empty as above; check that sampling technique is satisfactory. Repeat sampling. If still fails, discuss possibilities with people experienced in theatre testing.
Clusters of infection known or suspected (having excluded more obvious causes such as changes in operative procedures)	If an airborne component is suspected or needs to be excluded, do a full check on the ventilation: filters in air-handling unit, ventilation rates, airflows in theatre (and prep room), airflows between rooms, bacteriological air sampling in empty theatre, ascertain if anything has changed since before the cluster occurred.
Theatre staff 'uncomfortable'	This is primarily a problem for the Estates Department, but if staff are uncomfortable because of draughts (i) ensure that ventilation rates are not altered and (ii) if airflows are redirected by adjusting fins on outlets, smoke test to ensure air is still sufficiently turbulent at the table to disperse contamination.

Table II. *Possible engineering causes of microbiological test failures of theatres*

Problem	Possible engineering defects
Microbiological tests fail: possible engineering causes	Insufficient air volume Check no water-pooling in air-handling unit or ductwork (condensation or faulty drainage) Incorrect airflow direction between rooms in theatre suite Airflow pattern in working area poor Filters incorrectly fitted or damaged (gaps in filters or around filter housing) Filters very dirty Wrong filters fitted Temperature gradient too large across doorways from clean to dirty areas causing reverse flow Debris in ductwork and air-handling unit Incorrect interlocking of supply and extract fans, i.e., extract stops before supply

Annex C: Air samplers for use in operating theatres

Until the 1980s the only microbial air samplers commercially available for measuring the microbial concentration of the air in operating theatres were the slit sampler and the sieve impactor. All the microbial aerosol levels recommended in guidance and in the papers of Whyte, Lidwell and others are based on experiments carried out with the large volume (700 L/min) slit samplers. New types of microbial air samplers have appeared since then. However, sampling air in operating theatres does not form a substantial section of this market, so many are not suitable.

The following points need to be considered in selection:

(1) Can it sample a suitable volume of air (greater than $2\,m^3$ may be needed in UCV theatres) within a reasonable length of time (e.g., 10 min) or before dehydration effects may occur?
(2) Can it be operated remotely (e.g., infra-red control or via extension lead)?
(3) Is it easy to use and clean?
(4) If unusual plates, strips or filters are used, how much do they cost? (Some can cost up to £5 per unit).
(5) Is it required to get close to the wound in a working ultraclean theatre?
(6) Has it been demonstrated to be reasonably effective in the published literature?

Table III *Characteristics of most available microbial air samplers*

Sampler	Flow rate (L/min)*	Collection method	Plate/strip/filter
Andersen sampler	28.3	Sieve impaction	Standard plate
Biotest RCS	40	Centrifugal impaction	Pre-filled strips
Biotest RCS Plus[1]	50	Centrifugal impaction	Pre-filled strips
Biotest HiFlow[1]	100	Centrifugal impaction	Pre-filled strips
Casella (high volume)[2]	700	Slit impaction	150 mm plate
Casella (low volume)[2]	30	Slit impaction	Standard plate
Mattson Garvin	28.3	Slit impaction	150 mm plate
Merck MAS[3]	100	Sieve impaction	Standard plate
Microbio 1	100	Sieve impaction	55 mm contact plates
Microbio 2	100	Sieve impaction	55 mm contact plates
Millipore	140	Sieve impaction	Pre-filled cassette
Negretti	100	Sieve impaction	55 mm contact plates
New Brunswick	28.3	Slit impaction	150 mm plate
Sampl'air	86–200	Sieve impaction	Standard plate
Sartorius MD8	42–133	Filtration	Gelatine filters
SAS 90	90	Sieve impaction	55 mm contact plates
SAS[2]	180	Sieve impaction	55 mm contact plates

* $1\,m^3$ is 1000 L
1 Infrared remote operation possible
2 Remote operation via cable possible
3 Delay of up to 60 min possible

Annex D: Model letter for operating theatre engineering compliance

This is a model letter requesting certification that an operating theatre has been assessed and complies with its design brief, HTM2025, the Component Database and other HTMs or standards relevant to infection control.

Letter should be on management's headed paper.

Microbiologists should check that the recipient of the letter is the person who is the Designated Person (an individual who has overall responsibility for the operating theatre systems within the premises and who has a duty under the Health and Safety at Work Act 1974, to prepare and issue a general policy statement on health and safety at work, including the organization of and arrangements for, carrying out that policy.)

To [(1)]

Certification of compliance for operating theatres.

Please confirm that the following have been tested and certified as to be correct to the design brief and the relevant standards and guidance by signing and returning to me the attached certificate (Certificate of Compliance)

Location [(2)]

Signed (Microbiologist)

(1) Insert name of person who has designated authority for the operating theatres with respect to Estates matters.
(2) Insert location and operating theatre identification.

CERTIFICATE OF COMPLIANCE

Location: . . . . . .

Details of the installation

(1) Does the system comply with the design brief? Yes ☐ No ☐

Details of departures (if any) from design brief:

(2) Does the system comply with HTMs 2025, 55, 56, 60, 61, 63 & Model Engineering Specification CO4 (Mechanical ventilation and air conditioning)? Yes ☐ No ☐

Details of departures (if any) from HTMs

(3) Has the system been formally commissioned and independently witnessed? Yes ☐ No ☐

Name of independent body:-

.....

Date of commissioning:-.....

Details of departures (if any) from HTM 2025

(4) Ventilation system hygiene. Level of cleanliness of ductwork. Does the ventilation plant and ductwork internal cleanliness comply with DHSS Standard Engineering Specification document CO4: DW/TM2 in the Guide to Good Practice Internal Cleanliness of New Ductwork Installations issued by the Heating & Ventilation Contractors Association? Yes ☐ No ☐

To what level?:
Basic Yes ☐ No ☐
Intermediate Yes ☐ No ☐
Advanced Yes ☐ No ☐
Details of departures (if any) from guidance:

(5) Level of filtration fitted to the air handling unit:

Primary filter –

Secondary filter –

Details of departures (if any) from guidance

(6) Air-change rate and room pressurization for the following:
(All areas not shaded should be filled-in)

Theatre suite zone	Room or area	Nominal pressure (Pa)	Air supply rate (m^3/s)	Room volume (m^3)	Air change rate (ACH)	Is an extract system in place & working?
'Sterile'	Operating room or area (and scrub bay)					
	Preparation room (lay-up)					
	Preparation room (sterile pack store)					
Clean	Scrub room					
	Anaesthetic room					
Transitional	Recovery room					
	Clean corridor					
	General access corridor					
	Changing rooms					
	Plaster room					
'Dirty'	Disposal corridor					
	Disposal room					

See the guidance notes on this table in Annex E.

Airflow direction between areas and rooms (check both with relevant door closed and door open), as in HTM 2025, Volume b (design considerations), table 6.6:

From lay-up to operating room	Yes/no
No flow between sterile pack store and operating room	Yes/no
From operating room to disposal room	Yes/no
From operating room to corridors (clean and/or disposal)	Yes/no
From operating room to anaesthetic room	Yes/no
From anaesthetic room to corridor	Yes/no
From lay-up or sterile pack store to corridor	Yes/no
From scrub area/room to corridor	Yes/no
No flow between disposal corridor and disposal room	Yes/no
From clean corridor to disposal room	Yes/no

(7) Confirmation of turbulent air distribution within operating theatre and other clean rooms, either by measurement of average air speed or by observation of turbulent smoke

Operating theatre table	average . . . . . m/s} working height
OR turbulent smoke	Yes/no
Preparation lay-up	average . . . . . m/s} working height
OR turbulent smoke	Yes/no

(8) Confirmation that drainage systems on the air-handling unit comply with HTM 2040 The control of legionella in healthcare premises code of practice. Yes ☐ No ☐

Details of departures (if any) from guidance:

Queries regarding completion to:

Name: Contact details:

Annex E: Guidance for completion of the model letter for operating theatre engineering compliance certificate

Submission of certificate:

Separate certification needs to be made for each operating theatre.
Certificates need to be completed for each operating theatre whether owned or leased by the Trust.

GUIDANCE NOTES FOR INDIVIDUAL QUESTIONS

Question Number

1 Does the system comply with the design brief? Details of departures (if any) from design brief.

Does the final project comply with design brief details and appropriate health building standards? Assessment should be based upon following:

Appropriate space standards (from HBN 26)
Layout of operating theatre which may compromise airflow control (e.g., dirty utility opening on to outdoors)
Engineering standards and installation (examples: position of fresh air inlet, situation of air-handling plant, layout of plant & position of air inlet diffusers or grilles into the operating room
Compliance with BSI DD ENV 12097 'Ventilation for buildings: Ductwork requirements for ductwork components to facilitate maintenance of ductwork systems'

2 Does the system comply with HTMs 2025 (ventilation), 55 (windows), 56 (partitions), 60 (ceilings), 61 (flooring), 63 (fitted storage systems) & Model Engineering
Specification CO4 (Mechanical ventilation and air conditioning)? Details of departures (if any) from HTMs.

Does the installation comply with the above standards and guidance for the following:

Minimum air volumes
Air pressures between areas and rooms
Air filtration
Ductwork cleanliness

(further details required under question 6)

HTM 55 Windows
Where windows are installed in operating theatre suites then the installation and materials used shall comply with HTM55. Areas which could affect microbiological standards are:

Weathertightness
Thermal performance (are windows correctly designed or specified to prevent airflow pattern distortion and condensation forming)
Amenable to cleaning, disinfection and maintenance

HTM 56 Partitions
Where partitions are installed in operating theatre suites then the installation and materials used shall comply with HTM56. Areas which could affect microbiological standards are:

Stability to prevent cracking and movement
Biological attack resistance
Mechanical damage resistance
Hygrothermal performance
Hygienic finishes
Thermal performance (may affect airflow patterns)
Amenable to cleaning, disinfection and maintenance

HTM 60 Ceilings
Ceiling installations in operating theatre suites shall comply with HTM60.

Areas which could affect microbiological standards must be scrubbable and have a completely sealed finish.
Lighting fitting shall be sealed fittings to IP56 (ingress protection number under Guidance note 1 of BS 7671 & BSEN 60947-1: 1999), or Chartered Institute of Building Services Engineers LG2

HTM 61 Flooring
Flooring in operating theatre suites shall comply with HTM61. Areas which could affect microbiological standards are:

Stability to prevent cracking and movement from weight or use
Hygienic finishes
Manufacturer's information supplied on suitable cleaning, disinfection and maintenance procedures
Impervious, smooth and jointless

HTM 63 Storage systems
Storage systems in operating theatre suites shall comply with HTM63. Areas which could affect microbiological standards are:

The performance and strength are such that the units will resist surface cracking, absorbence etc. (Manufacturer's data should be supplied)
Surface finishes
Hygienic finishes
Moveable units can be easily disinfected (wheels etc)

3 Has the system been formally commissioned and independently witnessed?

The independent body carrying out the witnessing shall be accredited by UKAS.
Is the theatre performing to the design intent in respect of:

Air dilution and turbulence
All inlet air passes through the filters.
Air pressures
Air change rate
Plant layout and installation
Operating theatre suite configuration

4 Ventilation system hygiene. Level of cleanliness of ductwork

Detail level of cleanliness of ductwork and air-handling plant carried out under the contract. Model Engineering Specification CO4 (Mechanical ventilation and air conditioning) requires compliance with good practice guide DW/TW2 (internal cleanliness of new ductwork installations). There are three levels with six control means for cleanliness in the code of practice. DHSS standard specification for ventilation systems CO4 calls for intermediate level of cleanliness unless otherwise specified to a higher standard. Cleanliness should be to a minimum of 'intermediate' standard.

Level	Factory seal	Protection in transit	Protection during site storage	Clean on-site	Cap-off on site	Special clean once installed
Basic	No	No	No	No	Risers only	No
Intermediate	No	No	Yes	Yes	Yes	No
Advanced	Yes	Yes	Yes	Yes	Yes	No

Note: Site storage shall be permanently clean, dry and dust-free.

5 Level of filtration fitted to the air-conditioning system

The level of air filtration to be installed is in HTM 2025. Filters should comply with BS EN 779 and should be installed in air-handling units in accordance with figure 4.1 of HTM 2025, volume B; in essence the secondary filter should be the last piece of equipment installed in the air-handling unit and must be situated after the fan.

Primary filter suitable G3 (possibly G2)

Secondary filter suitable F8 (depends on inlet air pollution level; F7 in lower particulate pollution areas and in much pre-existing ventilation plant)

6 TABLE: Air change rate and relative pressures between rooms

Detail air change rates in the operating and preparation rooms. The air change rate depends upon the control scheme for the operating theatre suite as detailed in HTM2025, volume B (Design considerations) paragraph 6.19 and 6.20: systems 1a to 5b.

Target air change rates can be calculated from ventilation volume rates given in HTM 2025 and room dimensions given in HBN 26: The numbers (1a, 1b etc.) refer to suggested layouts given in HTM 2025, Design considerations (volume B), Figures 6.1a and b.

The air change rate for operating theatres should, as a minimum, be around 20 air changes per hour (ACH). If room dimensions are as in HBN 26 and airflow rates are as in the various suggested layouts in HTM 2025, volume B, Figures 6.1a and b (this shows eight suggested layouts:
1a & b, 2a & b, 3, 4 and 5a & b), air change rates should be as below:

Conventionally ventilated operating room plan:

1a, 2a & 5a 22.5 ACH
1b, 2b & 5b 19.5 ACH
3 24 ACH
4 23 ACH
(These do not apply to ultraclean ventilated operating theatres)

Preparation room plan:

1a, 2a, 4 & 5a 11 ACH (Preparation room suitable for sterile pack storage)
1b, 2b & 5b 37 ACH (Preparation room suitable for instrument lay-up)
(These also apply to preparation rooms for UCV operating theatres)

If room dimensions differ from those in HBN 26, ventilation rates should have been adjusted to compensate such that the above air change rates are still achieved.

Extract rate related to the pressure requirements see table 6.1 HTM 2025, volume B.

Notes on question 6 table.
These values relate to the Figures 6.1 in HTM 2025 Design for suggested air movement control systems in conventionally ventilated operating suites (shaded boxes do not need to be filled in).

Only the air change rates and pressures in preparation rooms and anaesthetic rooms are applicable to ultraclean ventilated operating theatres, but see the notes at the start of Annex F.

Theatre suite zone	Room or area	Nominal pressure* (Pa)	Air supply rate (m^3/s)	Room volume (m^3)	Air change rate (ACH)	Extract system in place and working
'Sterile'	Operating room (and scrub bay)	25	0.65–0.75		$\geq$20 See note 6	No
	Preparation room (lay-up)	35	0.33		$\geq$37 See note 6	No
	Preparation room (sterile pack store)	25 ± 5	0.1		$\geq$11 See note 6	No
Clean	Scrub room	14–25 See note 1				No
	Anaesthetic room	14 See note 2	0.15 supply 0.15 extract		See note 2	Yes
Transitional	Recovery room	3 See note 3	See note 3		15	Yes
	Clean corridor	3 See note 4				Yes
	General access corridor	3 See note 4				Yes
	Changing rooms	3 See note 4				Yes
	Plaster room	3 See note 4				Yes
'Dirty'	Disposal corridor	0 See note 5				Yes
	Disposal room	0 to -5 See note 5	0 to -0.41 Extract			Yes

*A 'nominal' pressure is the pressure relative to ambient (i.e., outside the theatre suites). A pressure differential or relative pressure is the difference in nominal pressures; for example, if an operating theatre is at a nominal pressure of 25 Pa and the adjacent anaesthetic room is at 14 Pa, the pressure between these areas is 11 Pa.

Notes

(1) Scrubroom: Normally the scrub and handwash facility are part of the operating room often a bay. If a separate room is required then a door between the scrub room and operating room is an inconvenience to scrubbed staff and should be replaced by a permanent opening larger than a doorway. In this case the room pressure should be 25 Pa (If a door is in place, the nominal pressure should be 14 Pa).
(2) Anaesthetic room: This ventilation is primarily for the dilution of anaesthetic gases, not infection control. It should have a balanced inlet and extract (i.e., equal volumes supplied and extracted) with the air entering from the operating room sufficient to pressurise the room to 14 Pa, being lost to the corridor.

(3) Recovery room: The precise pressure differential of 3 Pa is very difficult to achieve or measure and in general it should have a pressure of 0 or be slightly positive. If the recovery room is positioned as indicated in HBN26 or HTM 2025 then the room should have a negative pressure with respect to sterile and clean areas and positive with respect to dirty areas. The extract rate of 15 ACH is for the removal of anaesthetic gases with the inlet air volume being balanced to the extract rate. The supply and extract rate will depend upon the size of the recovery: e.g., for a suite of four theatres, the recovery extract and inlet will be 1 m^3/s.
(4) Clean corridor, general access corridor, changing rooms and plaster room: A slightly pressurized or zero value is acceptable as long as the area is positive with respect to dirty areas and negative with sterile or clean areas.
(5) Disposal room and disposal corridor: dirty areas should be negative with respect to clean, transitional and sterile areas. From a practical point of view dirty areas should have a negative air pressure of 25–30 Pa with respect to the operating theatre.
(6) This is the variable that is important in terms of dilution of airborne contamination. If room volume varies from standard, air supply volume should be adjusted to achieve an adequate air change rate.

Air movement control transfer devices and open door shall comply with Table 6.6b and 6.6c of HTM 2025 Design considerations.

7 Confirmation of turbulent air distribution within operating theatre and other clean rooms

This test is to confirm that there is an airflow in the region of the operating table to ensure that dilution of pollutants takes place.

8 Confirmation that drainage systems on the air-handling unit comply with HTM 2040. The control of legionellae in healthcare premises code of practice

This is a visual check compliance with HTM2040 paragraph 7.0, in particular the existence of an air break soon after the outlet from the air-handling unit drain point. This will prevent contamination of the ventilation system by the drainage system.

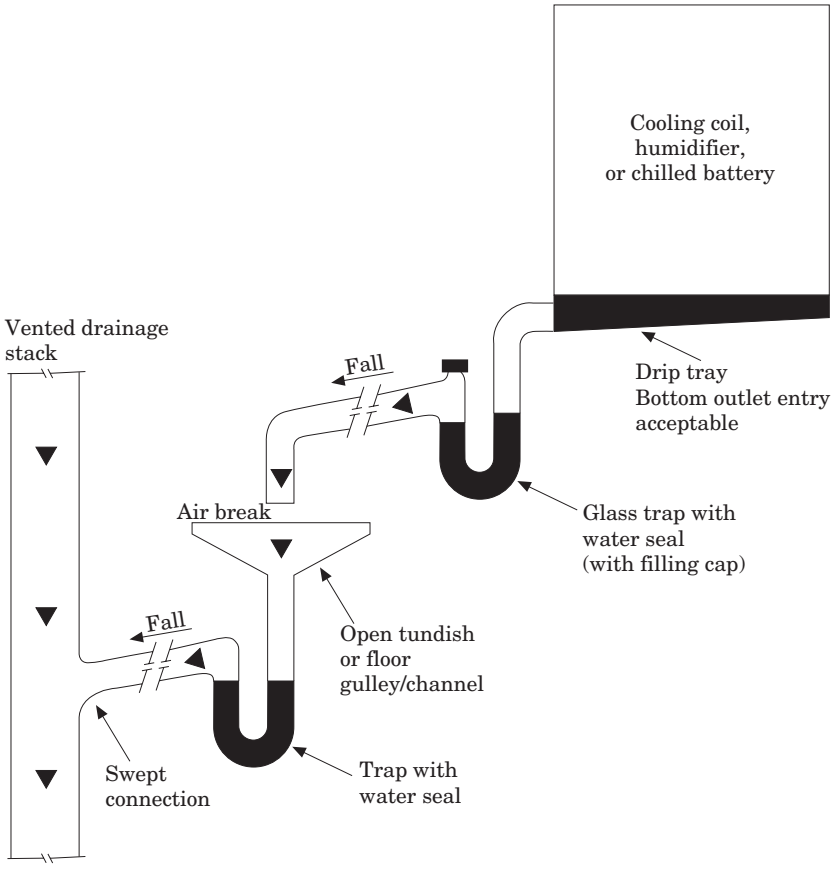

Figure 3 Typical air-conditioning plant drain.

9 Outstanding defects

The outstanding defects listed should be those that relate to hygiene, air change rate and airflow pattern.

10 Comments related to possible microbiological problems

The comments should be concerns relating to possible microbiological contamination.

Annex F: Supplementary certificate for UCV theatres

This should be completed in addition to the basic certificate (Annex D)

General note: Whilst it states in HTM 2025, volume B (Design considerations) paragraph 6.77 'There is no strict requirement when using a UCV system to have an air movement control system, except in the preparation room', surrounding areas should be controlled such that they do not interfere with the integrity of the UCV enclosure. In general, if those areas surrounding UCV operating theatres are ventilated as for similar areas surrounding conventionally-ventilated theatres, this will not compromise the integrity of airflow in the UCV enclosure.

(1) HEPA grade and efficacy of filter assembly

Grade of HEPA filter fitted:

Results of in situ particle testing:

(a) Terminal filter installation test (HTM 2025, volume C, para 5.26)

(b) Lack of entrainment from outside clean zone (HTM 2025, volume C, para 5.28–31)

(2) Monitoring system to show clean and dirty state of HEPA filter: Specify system

Clean/dirty pressure differentials

(3) Type of system fitted:
Vertical flow
Horizontal or cross flow

(4) Test procedure for verification of system parameters:

Brief description of tests and results:

(5) Vertical discharge ultraclean system.
(a) Discharge within the clean zone velocity at 2 m above floor finish (average velocity 0.38 m/s with fixed walls terminating 2 m above floor or 0.3 m/s with fixed walls terminating 1 m above floor):

Test results:

(b) Discharge within the clean zone velocity at 1 m above floor finish (average velocity 0.2 m/s)
Test results:

(6) Comments related to possible microbiological problems:

Name (BLOCK LETTERS) . . . . . Position . . . . . .

Date . . . . . .

Signature . . . . . .

For and on behalf of: . . . . . .

Specify

Annex G: Guidance for completion of supplementary certificate for UCV theatres

To be completed on commissioning and on annual re-commissioning

1 HEPA grade and efficacy of filter assembly.

The HEPA filter should comply with BSEN1822 and be site tested to BSEN1822 parts 4 and 5.

The penetration resistance of the UCV clean zone is set out in HTM 2025 Validation and verification, paragraphs 5.30 and 5.31.

The grade of HEPA filter depends on the specification of the manufacturer of equipment.

2 Monitoring system to show clean and dirty state of HEPA filter.

Describe monitoring method and indicate pressure readings on filters when clean and when dirty.

3 Type of system fitted.

Indicate manufacturer and type of system. Horizontal or cross-flow systems are not recommended by HTM2025.

4 Test procedure for verification of system parameters.

Test method should follow HTM2025, volume C (Validation and verification), paragraph 5.0: The following test applies to a typical UVC system. Any unit which does not comply with this standard design should have its method of verification agreed and documented. Data should include discharge area, diffuser height (from 2.45 to 2.9 m from finished floor level subject to local conditions and operating lamp selection) and whether full or partial walls are fitted.

Air velocity test. Grid size: 2800 mm × 2800 mm. Test measurements taken at 2.00 m above finished floor level

	1	2	3	4	5	6	7	8	9	10
A										
B										
C										
D										
E										
F										
G										
H										
I										
J										

Average velocity over area = m/s

Note: average velocity must not be less than 0.38 m/s for fixed partial walls finishing 2 m above finished floor level
average velocity must not be less than 0.3 m/s for full walls finishing 1 m above finished floor level.

Comments:

Air velocity test. Grid size: 1800 mm × 1800 mm. Test measurements taken at 1.0 m above finished floor level

	1	2	3	4	5	6
A						
B						
C						
D						
E						
F						

All grid velocities must not be less than 0.2 m/s

5 Vertical discharge ultraclean unit.

Test results inline with HTM2025.
The test results should comply with HTM2025 validation and verification Chapter 5 (Performance tests) and the results tabulated as detailed in tables above.

6 Comments related to possible microbiological problems

Comments regarding any problems that could compromise microbiological standards.

Annex H: Air filters

Sub-HEPA filters are classified by BS EN 779: 1993. Under this standard they are graded by either percentage retention ('arrestance') of a test dust of assorted particle sizes (grades G 1–4) or by the passage ('efficiency') of a finer test dust, again of assorted particle sizes.

Arrestance (%)	
G1	(A) < 65
G2	65 > (A) < 80
G3	80 > (A) < 90
G4	(A) > 90

Efficiency (%)	
F5	40 < (E) < 60
F6	60 < (E) < 80
F7	80 < (E) < 90
F8	90 < (E) < 95
F9	(E) > 95

As the test dusts used are of assorted sizes, it is not possible to make accurate predictions about retention of particles of any particular size.

HEPA filters are classified by BS EN 1822-1: 1998. HEPA filters are tested against particles of a definite size range relevant to microbiological applications (mean particle diameter 0.4 μm). The efficiencies (H) of HEPA grades 10 to 14 are:

Initial efficiency (%)	
H 10	85
H 11	95
H 12	99.5
H 13	99.95
H 14	99.995

There also exist 'ultra-low penetration air' filters ('ULPA')
Grades U15 to U17. These are not relevant to operating theatre ventilation.

Filter Applications

G2/3 Filter for air-handling systems not requiring any great degree of cleanliness.
Primary filter for operating theatre air-handling plant.
G4 Where low to moderate cleanliness is required.

F5 Final filter where decor protection is not required.
F6 Final filter but better decor protection than 5.
F7 Final filter used when decor protection is required.
F8 High degree of protection no dust staining.
F9 High quality filtration but where HEPA filters are not justified. (If manufacturer agrees, rigid F9 filters can be tested to BS3928 and therefore classified as a HEPA filter.)
H13 Fitted in ultraclean ventilation terminals, but the grade used will depend upon manufacturer's specifications.

MEETING REPORT

The future of the UK infection control doctor: report of a one-day Association of Medical Microbiologists organized workshop

B. Cookson[a,*], E.L. Teare[b], R. Slack[c]

[a]*Specialist and Reference Microbiology Division, Health Protection Agency, 61 Colindale Avenue, London NW9 5HT, UK*
[b]*Mid-Essex Hospitals NHS Trust, New Writtle Street, Chelmsford, UK*
[c]*Health Protection Agency East Midlands (North), Nottingham Office, Standard Court, Nottingham, UK*

Received 27 March 2004; accepted 12 May 2004

Available online 3 September 2004

Background

Several years ago the UK's Association of Medical Microbiologists (AMM) proposed a job description for an infection control doctor (ICD). Since that time there have been many changes in healthcare delivery, and it is now recognized that infection control needs to be integrated into clinical and corporate governance processes. The AMM therefore convened a workshop and produced recommendations for the way forward. The workshop was at the London headquarters of the National Audit office.

At the beginning of the workshop, four lectures were delivered, illustrating different perspectives of the topic. Attendees were then divided into three groups to debate three different areas chosen before the meeting. The outcome of debate and recommendations were discussed in an afternoon plenary session. All members of the AMM PIC (Prevention of Infection Committees, the organizing group) either attended the workshop or made contributions in writing. There were no attendees officially representing the Welsh, Northern Ireland and Scottish AMM members or infection control professional groups.

Section 1: roles and responsibilities of the ICD in the acute sector

Key recommendations were as follows

1. The job description and competencies of the ICD need to be reviewed and re-written. Infection control is an integral part of a hospital consultant medical microbiologist's (CMM) role and there are insufficient CMMs to have full-time ICDs other than in major centres. In the longer term, there may be 'infection control professionals' drawn from a variety of professional disciplines. The membership examination of the UK's Royal College of Pathology (MRCPath) should remain a requirement for the ICD as described in the new MRCPath syllabus. If the ICDs are medical staff with other backgrounds, e.g. in infectious diseases, cross-cover needs to be addressed. The Diploma in Hospital Infection Control (DipHIC) is a desirable qualification for the ICD.

*Corresponding author. Tel.: +44-2082004400 x4249; fax: +44-2082007449.
E-mail address: barry.cookson@hpa.org.uk

doi:10.1016/j.jhin.2004.06.018

2. CMMs need time and funding to attend educational events and courses for their further professional development.
3. The group reviewed all the listed activities in the current AMM ICD job description (JD) and felt that the infection control team (ICT) should be involved jointly in these, and that the ICD did not necessarily have to take the lead. However, the group felt that incident and outbreak management, particularly with unusual organisms and antimicrobial prescribing control, were areas where the ICD would lead, as the CMM/ICD competencies were particularly relevant.
4. One could not be prescriptive about the amount of time the CMM spends in the ICD role. There was a consensus that this had to be appropriate for agreed objectives, e.g. controls assurance targets and Department of Health performance indicators. The current AMM job description recommends one-third of a full-time ICD for a typical district general hospital. The parameters on which this is based, e.g. the number of beds and specialties included, should be stated. Although many ICD activities could not be timetabled, some could be, e.g. policy writing. The amount of time needed could be decided using a similar scheme to that for calculating CMM numbers, which has been prepared by the Royal College of Pathologists.
5. The ICD is advisory and not executive, and should be managerially accountable to the Chief Executive (CE) and professionally accountable to the Medical Director.
6. The Infection Control Committee Chair should be a trust board member.
7. There needs to be a review of the need for and requirements of an infection control budget. Funding of multi-disciplinary infection control training needs to be addressed. There were problems in funding or even finding the time for link nurses to attend educational activities. We need recommendations for the funding of outbreak and important incident investigations and control in line with the Clinical Negligence Scheme for Trusts (CNST) level two recommendations. There should be information technology (IT) support from the trust to the ICT.

Section 2: accountabilities within and of the ICT

Key recommendations were as follows:

1. The key functions of the ICT should be identified.
2. ICTs are accountable to the CE for delivery of agreed targets. Accountabilities within the ICT should relate to the targets in this agreed infection control programme.
3. The CE is accountable for agreed standards reviewed through external peer review. This is reviewed by external bodies such as the Commission for Health Audit and Inspection (CHAI) and perhaps the Inspector of Microbiology in the future. It was noted that the CHAI-led Review Coordination Group (CHAI, CNST, Health and Safety Executive, Cabinet Office etc.) were considering harmonising current infection control and risk assessments performed in reviews.

The group did not favour targets such as specific reductions in healthcare-associated infections. Instead it recommended the identification of specific deliverables from activities related to education, surveillance, audit and risk assessment.

Section 3: inter-relationships between acute and community infection control professionals

Key recommendations were as follows:

1. There should be access to appropriate infection control advice in primary care at all times.
2. An infection control service in a primary care trust (PCT) or community-based trust could be provided by a doctor and/or a nurse, but the group felt that the lead could be the infection control nurse.
3. The lead infection control person could be called the 'primary care infection control practitioner'.
   The lead may be the clinical governance officer in a lead PCT, provided she or he had sufficient authority and experience to be responsible. Some PCTs have inherited certain functions, e.g. renal services, that need specialized input. Many PCTs are too small to be self-sufficient, so there may need to be a lead PCT.
4. Consideration should be given to the role of strategic health authorities, given their performance management function.
   All PCTs need to be represented at each infection control committee meeting, taking ratified policies back to their respective PCTs for local endorsement and implementation. Health protection officers, environmental health officers and veterinary practitioners will be involved in Health Protection Agency

(HPA) consultant in communicable disease control-chaired (CCDC) large-scale district committees, that will manage community outbreaks and incidents.

5. There should be national policies and guidance for community infection control.

   The UK National Institute for Clinical Excellence guidelines on the prevention and control of infection in primary and community care settings were currently out for consultation. There is also a newly published book on infection control in the community (Infection Control in the Community, edited by Jean Lawrence and Dee May, Churchill Livingstone, 2003).

6. There should be defined and accredited training for infection control in the community.

General discussion

Summary points of the afternoon sessions were as follows.

There was concern that there is insufficient infection control expertise in the proposed HPA establishment. It is essential for there to be greater 'ownership' of infection control by clinical teams within the context of corporate and clinical governance, and for this to be supported by the CE.

Standards documents with clear statements will help ensure that infection control is taken with the seriousness it deserves. The analogy was made that, in the UK, fire-safety exercises have a legally enforced system to ensure that they take place annually, whereas we only 'fire fight' for infection control.

IT and management are critical to the success of ICTs. The infection control committee should report to the risk assessment or clinical governance committees.

Overall recommendations and follow-up

- The infection control committee should sit within an appropriate acute trust committee structure, to improve integration with corporate and clinical governance.
- Specific deliverables for infection control should be identified, e.g. education, surveillance, audit and risk assessment.
- The value of a link infection control person in directorates could be explored.
- The roles, responsibilities and lines of accountability for infection control staff in the acute and community sectors should be agreed.
- The core competence required for the different infection control specialists should be agreed.
- The AMM and Infection Control Nurses Association should revise the job descriptions for the ICD and infection control nurses, respectively.
- There must be adequate resources and time for education and training in infection control in the acute and community sectors.
- There should be harmonization of infection control standards initiatives.

Acknowledgements

We would like to thank Dr Judith Richards, Dr Hilary Pickles and all the attendees for their participation as well as Ms Karen Taylor and Ms Judith Sedgwick of the National Audit Office for kindly providing the venue and refreshments for the workshop meeting.

NSS Health Facilities Scotland

Lessons Learned & Recommendations Report on Cowlairs CDU Incident Nov 2018

September 2019

A47310563

Executive summary

The NHS Greater Glasgow & Clyde (GG&C) Central Decontamination Unit (CDU) at Cowlairs in Glasgow was the subject of an unannounced audit by their Notified Body on 13th November 2018. As a result of the audit findings, principally related to inadequate cleanroom environmental controls, the Notified Body instructed the CDU management to halt production.

Over the eleven days of downtime there were principally two streams of work, one being the continuation of a sterile service making use of contingency support from other decontamination units and the other being remedial actions required to return the Cowlairs CDU to an operational state.

Suspension of the sterile service provision from the Cowlairs CDU had a profound effect on patient operations. There were also significant financial, staff and reputational impacts. This became a national event due to the support required from other decontamination facilities across multiple healthboards.

The Strategic Facilities Group (SFG) requested that a lessons learned report be prepared via a short term working group.

The working group identified the root causes of the production shutdown from the lack of environmental control in the cleanroom used in production. There were concerns over cleanroom design, maintenance, microbial monitoring, document control, staff training and corrective action effectiveness. The overall cause was assigned to not dealing with audit non conformities in a timely manner. These failings were across the quality management system.

Based on feedback collected from contingency providers it was concluded that the tracking systems did not work well between different decontamination units. There was mixed feedback on staffing and communication while the contingency was in use.

From review of the incident details available a series of recommendations are made based on both prevention measures and those applicable should there be a future shutdown of production.

It is noted that in the short term should a large scale output central decontamination unit have an unplanned prolonged shutdown the contingency support required would be national in nature and not local.

The recommendations should be considered by each healthboard and an update on progression monitored through the expert steering group, Reusable Medical Device-Decontamination Operational Group (RMD-DOG) starting at their December 2019 meeting.

Content

1. Introduction

The NHS Greater Glasgow & Clyde (GG&C) Central Decontamination Unit (CDU) at Cowlairs in Glasgow was the subject of an unannounced audit by their Notified Body on 13th November 2018. As a result of the audit findings the CDU's production was ceased on 15th November until 26th November. Contingency support was sought from other healthboards and the private sector during this time. This removal of sterile service provision from Cowlairs had a profound effect on patient operations, with around one thousand operations being cancelled over November/December with NHS GG&C. There were also financial, staff and reputational impacts. Subsequently the Strategic Facilities Group (SFG) requested that a lessons learned report be prepared within 2019. This would be used with the intention of preventing a reoccurrence of this incident. To develop the report a short term working group was convened (its terms of reference including membership is in appendix 1) and meetings were held on 16th May and 19th June 2019.

2. Background

2.1 The NHS Greater Glasgow & Clyde (GG&C) Central Decontamination Unit (CDU) at Cowlairs in Glasgow was the subject of a routine surveillance audit in July 2018 by their contracted Notified Body (number 0088), Lloyd's Register Quality Assurance (LRQA). A number of non conformities were raised at the surveillance audit. LRQA then issued a three year EC certificate from 4th August 2018 as shown in appendix 2.

2.2 Three months later, the CDU at Cowlairs in Glasgow was the subject of an unannounced one day audit (on 13th November 2018) by their contracted Notified Body Lloyds Register Quality Assurance (LRQA) three persons assessment team. Numerous major non conformities were identified during the unannounced audit. On 15th November LRQA issued a suspension notice to Cowlairs CDU (dated 13th November) LRQA reference LRQ 4002546 number on their Annex V – Production Quality Assurance Certificate number LRQ 4002546/B and instructed that production should cease immediately. The suspension letter of 13th November indicated the relevant European Competent Authorities would be informed of their decision. The associated report LRQA reference LRQ 4002546/ 1988562 stated MDD, 93/43/EEC and ISO 13485:2016 certificates were suspended.

2.3 The audit report highlighted the principal issues related to inadequate cleanroom environmental controls. These included:

- The process of record control was not effective;
- The process of corrective action was not effective;
- The process of training and competence was not effective;
- The process of validation of processes for production was not effective.

These matters relate to failures across the quality management system. LRQA lifted their suspension on the afternoon of 22nd November.

2.4 GG&C Infection Control required additional checks to be made before start-up of production could commence. Agreement was reached on the afternoon of 25th November that the cleanroom environmental monitoring results were satisfactory and production started midday on the 26th.

2.5 Over the two week down time of production at Cowlairs (due to the cleanroom being out of service) it has been reported that in excess of 1000 operations were cancelled. The impact of this rare event was widespread making it a national event. Aspects of fragility around the cleanroom were highlighted.

2.6 Over the period of downtime there were principally two streams of work, one being the continuation of a sterile service making use of other decontamination units and the remedial actions required to return the Cowlairs decontamination unit to an operational state.

HFS support in returning the CDU to an operational state

2.7 Support by way of advice and information was provided to NHS GG&C Senior management, Tom Steele (the principal contact, Director of Estates and Facilities) and Jane Grant, Chief Executive.

2.8 Advice and information was provided to Head of Maintenance, David Shaw as remedial works/corrective actions were progressed.

2.9 Advice and support in liaising with their notified body LRQA and assisting with management of the LRQA follow up audit conducted on 20th November was provided.

2.10 Advice and support was provided to the CDU management with regard to NHS GG&C Teresa Inkster/John Hood (Infection Control), requests/requirements to enable the start-up of production on 26th November.

2.11 Multiple daily meetings were held principally at the Cowlairs CDU.

HFS initial set of national recommendations November 2018

2.12 An initial set of national recommendations (Table 1) were prepared on 25th November for early discussion with the Strategic Facilities Group (SFG) at their December 2018 meeting.

Reference	Subject	Recommendation
1	Fragility	Communicate the fragility identified in this event. Capture the things that have worked during the event and the things that have not worked and communicate these to the Service.
2	Contingency	Contingency for CDUs in Scotland should be reviewed again particularly looking at high volume & long opening hours units & at the age & condition of CDU buildings.
3	Critical Maintenance priority	Maintenance & testing of decontamination equipment & building fabric needs to be allowed to take place & not put off due to production pressure. Support should be given from senior management at the HB to allow essential maintenance.
4	Scrutiny monitoring	Auditing of CDUs by NHSScotland experts from outwith each CDU should be considered to identify non conformities/ concerns.
5	Specification for national guidance	Consider the introduction of a national specification for microbial limits in the cleanroom. Ensure there are separate limits for bacteria and fungi (yeasts/moulds).
6	Responsibility	Review each board's approach to recovery back to production in the event that a certificate suspension takes place defining who has final say on start up.

7	Responsibility	All HBs / CDUs should ensure that the roles identified in SHTM 01-01 are filled by appropriately trained staff who are familiar with the facility. The Infection Control Doctor/ Microbiologist (Decontamination) role should be a particular focus.
8	Responsibility	Discussions should take place between NSS, SG & HBs to ensure that suitably qualified and experienced Quality Managers are in post.
9	Responsibility	Consideration should be given to the creation of a Regional CDU Quality Control Manager at the 3 Regions in Scotland. Postholders should be responsible for detailed contingency planning & arranging for shutdowns for essential maintenance, equipment replacement.
10	Education/training	Review the cleanroom training of all staff interacting with the cleanroom including those involved in investigations.
11	Notified Bodies and MHRA	NSS should have discussions with both LRQA & MHRA about the decision to close Cowlairs & their slow response in assisting with recovery.
12	Notified Bodies and MHRA	NSS should review the position of LRQA as a Notified Body (NB) in Scotland & the requirement for CDUs to be accredited under the quality management system standard EN ISO 13485.

Table 1

Future Design and upgrade work involving the cleanroom

2.13 Design out the presence of liquids above the cleanroom ceiling. This includes drain pipes and wet fire systems. If not possible, protection measures from liquids for the ceiling should be in place along with monitoring measures. The cleanroom floor must be laid and be of the required quality to prevent the introduction of cracks over time. Given that all production passes through the cleanroom which tends to be a single room consider solutions that may enable duplex cleanrooms.

Root cause of the lack of cleanroom environmental control

Design and construction of the cleanroom

2.14 A single cleanroom through which all production flows was and is in use. Consequently all on-site production ceases at times of significant maintenance (including any recovery period) of the cleanroom. There is no on-site backup that allows production to continue.

2.15 There are other design issues around protection of the cleanroom fabric that contributed to this incident. These include the floor quality required to ensure no cracks develop, the ceiling quality and protection measures for the cleanroom ceiling. Pipework carrying liquids (e.g. drain water) was installed directly above (and through) the cleanroom ceiling when the facility was built. This built in fragility as the cleanroom ceiling and (hence the room) is compromised by exposure to liquids which

break up the fabric or result in formation of unacceptable levels of biocontamination on the inside of the cleanroom ceiling. Damage to the cleanroom floor and the cleanroom ceiling did occur and was observed during the audit.

Maintenance of the cleanroom environment - Production downtime required.

2.16 Access for planned critical maintenance of the cleanroom fabric, such as cracks in the floor and water damage to the ceiling, which required a significant production downtime was limited due to production pressures.

Action to be taken based on environmental monitoring results

2.17 The microbial air samples (active and passive) limits were based on a total count of bacteria and fungi. Had separate action limits been set for bacteria and for fungi the requirement for corrective action in the cleanroom may have been confirmed earlier through review of the test results. It is also noted there were gaps in sampling exercises.

Other aspects impacting on environmental control

2.18 The other aspects highlighted in the audit report such as document control, staff training and corrective action effectiveness are standard matters covered by the in-house quality management system. These were not effectively managed in the months prior to the unannounced audit.

Interim work undertaken to bring the cleanroom environment back in control.

2.19 Repairs to the cleanroom fabric were undertaken. The cleanroom floor cracks were sealed. The cleanroom ceiling was repaired on the clean side and work was done in the ceiling void above to reduce the likelihood of future water leaks onto the ceiling. In addition routine visual inspection of the cleanroom ceiling void and plant room floor was introduced onto the preventative maintenance register. After the repair work was completed the cleanroom internal fabric was subjected to high level cleaning and then exposed to a chemical disinfection process. On completion of this a microbial monitoring exercise commenced (with the cleanroom in the at-rest condition) and was carried out on three days Mon 19th, Wed 21st and Fri 23rd November. The results were carefully scrutinized and agreement was reached with Infection Control that the microbial levels found were satisfactory and that based on this production commenced in a staged manner. Initial cleanroom recommendations were supplied to NHS GG&C by HFS on 27th November 2018.

3. Feedback from contingency providers

Activities keeping the service operational during the shutdown event

Feedback from the boards who provided contingency

Table 2 outlines the positive feedback from some boards who provided a contingency service during the incident.

Table 3 outlines the negative feedback from some boards who provided a contingency service during the incident.

Board feedback - site	Things that worked well
A	Staffing "The supervisor that was sent was very good".
B	Staffing "Our supervisor controlled packaging and consumable goods and ensured adequate stocks were maintained."
B	Production "We managed two work streams within the Department which worked well and avoided any confusion".
B	Logistics "Drivers and goods arrived as agreed"
C	Staffing "All staff worked well in difficult circumstances. Staff cooperation at the provider sites was excellent. Cooperation from other facilities support services e.g. domestics was excellent."
C	"Partnership – union participation from the start was critical."

Table 2 – positive feedback from contingency providers (anonymised)

Board feedback - site	Things that did not work well
A	Tracking system "found the tracking a nightmare especially matching up the trays to tray lists was difficult because of the coding and missing items locating trays that were priority as labels or user departments were difficult to see ".
A	Staffing "Some of the staff didn't work as efficiently as mines which causes unrest when [redacted] staff were working on Glasgow work." "The length and the number of breaks their staff had in comparison to ours were awful especially under the circumstances." "Some of the staff did not accept that they would have to work as my staff do abiding by the cleanroom rules and procedures of [redacted]."
A	Capacity "Our department is not big enough to hold the number of staff so may have been better coming out of hours."
B	Communication "Same question being asked by a number of people – one point of contact would have been beneficial".
B	Tracking system "IT tracking system compatibility – manual recording of sets was very time consuming".
B	Instruments "Repair/ replacement of items for repair, missing etc."
C	Staff safety "Safety of [redacted] unit providing contingency potentially became compromised – too much work, equipment, staff and deliveries were too frequent."
C	Communication "Communication and listening could have been better."
C	Tracking system "Incompatible IT systems a problem"
C	Staffing "Productivity of visiting (Cowlairs) staff was a major issue. Including travel time in shift there was a huge impact on productivity – a 7.5 hour shift lost 3 hours due to travel and breaks that visiting (Cowlairs) staff expected in full. Staff working too many hours with occasional accidental breached in employment law, we need to learn from this."

Table 3 – negative feedback from contingency providers (anonymised)

4. Conclusions

Cause of the shutdown

4.1 The main cause was not dealing with non conformances including the minor ones in a timely manner.

4.2 It is concluded a number of factors were responsible for the shutdown of production. Design issues around the cleanroom, including the site location being close to sources of vibration and the quality of finishes and protection measures employed for the cleanroom fabric impacted adversely on the long term condition of cleanroom leading to its closure and cessation of production. Interpretation of the cleanroom environmental monitoring trend results (microbial) with respect the in-house limits was unclear which contributed to a delay in corrective action prior to the shutdown. Documentation control, staff training and corrective action effectiveness were also not as required in the run up to the incident.

Cause of the time to recovery of production

4.2 It is concluded that there were two elements involved in returning the decontamination unit to production. The first element related to the time taken for remedial works in the cleanroom and convincing the notified body that the cleanroom environment was back in control. The time taken for this activity was exacerbated by the slow response of the notified body at a time of great need of their services. The second element of the time delay related to the further cleanroom testing required to demonstrate to Infection Control that the environment was fit for use. It is concluded that CDU design guidance and operational procedures require to be improved taking account of these findings.

Cause of the lack of available contingency at the time of need

4.3 The national fragility related to both the scale of processed RMDs required and the extended time over which alternative arrangements for processing were required. One large scale output decontamination unit required unplanned immediate assistance from other decontamination units that had little or no spare capacity individually to help. Therefore assistance for processing RMDs was required from multiple decontamination units from around Scotland and beyond. As a consequence this became a huge logistics exercise with no notice period.

Contingency providers

4.4 From the feedback from contingency providers over the incident it is concluded that the tracking systems did not work well. Given that RMDs were being sent to and being returned from multiple sites the absence of a GS1 coding over tracking systems had a profoundly negative impact on the processing of RMDs and the service to Users. There was mixed feedback on staffing and communication.

Short term impact of large scale CDUs being closed

4.5 In the short term, should one of the large scale production CDUs be closed for more than a few days due to an unplanned event, there would likely be a national impact on cancellation of patient operations due to lack of processed product. Patient care

would be impacted by the closure of small scale CDUs, though the impact would be local.

5. Recommendations - Steps to improve performance

Prevention measures

Notified body audit non conformities

5.1 Assurance should be given to the government that the service takes immediate corrective actions to deal with the non-conformities raised and highlight risks for potential future non conformities.

5.2 Minimise the number of notified body non-conformities raised through the increase of internal audit or peer review audits.

5.3 The establishment of a NHSScotland specific quality management system standard and National Procurement Framework should be explored.

5.4 Feedback from audit activities non conformities should be included on Boards' clinical governance. The actions dealing with non conformities should be timely, monitored and reported to senior management as a part of escalation process.

5.5 Audit non conformities should be shared with other Boards through the agenda for the National expert steering group RMD-DOG, the Quality Group and other stakeholders.

Notice of suspension of production quality certification

5.6 A system with clear lines of communication (including backup contacts) is established to ensure that where a notified body recommends the suspension of a CDU's production quality certificate, the following organization are contacted prior to a decision by the notified body to suspend the certificate: HFS - who will liaise with MHRA. Note: HFS have had discussions with MHRA. It was agreed, for future serious incidents including suspension, both parties should be informed and discuss immediately.

Building design – Central Decontamination Unit (CDUs)

5.7 Seek a mandate letter from government directing Board design teams and their contractors to follow the planning note for Central Decontamination Units SHPN 13 Part1 and be compliant with guidance GUID 5014 – Requirements for compliant CDUs. Revise SHPN 13 Part1 taking account of new recommendations.

5.8 New build/refurbishment of cleanrooms - Design out the presence of liquids above the cleanroom ceiling. This includes drain pipes and wet fire systems. If not possible, protection measures from liquids for the cleanroom ceiling should be in place along with monitoring measures.

5.9 When considering the location (including an offsite build) for a new CDU consider risks from the surrounding environment that may adversely affect the building structure/fabric.

Maintenance

5.10 Critical maintenance in the cleanroom - Maintenance & testing of decontamination equipment & building fabric needs to be allowed to take place & not put off due to production pressure. Support should be given from senior management at the healthboard to allow essential maintenance. There should be adequate provision of estates staff to enable this maintenance to be completed in a timely manner. There should also be a procedure to describe what to do in the event of unplanned maintenance work arising from example water passing through the ceiling or the floor being flooded. There should be a national programme of major maintenance and equipment replacement.

5.11 If maintenance activities are undertaken while production is live there should be clear evidence that the cleanroom continues to meets its required performance over this period.

Cleanroom microbial limits

5.12 Consider the introduction of a national specification for microbial limits in the cleanroom to complement the existing non-viable contamination specification ISO class 8. Ensure there are separate limits for bacteria and fungi (yeasts/moulds).

Training

5.13 Review the cleanroom training of all staff interacting with the cleanroom including those involved in investigations including Infection Control Doctors, Microbiologists (Decontamination) and Estates staff etc.

5.14 Regular refresher training on staff dealing with auditors should be in place.

5.15 Establish training in the use of SHPN 13 Part 1 for Boards developing outline business cases and as a commissioning tool for Users.

5.16 There should be provision of Quality Management System (QMS) training particularly for the manager, quality manager and supervisors.

5.17 Cleanroom expertise comprising of microbiology/engineering and controlled environments required and employed in internal audits.

Contingency and Capacity

5.18 A sufficiently sized workforce should be developed to aid contingency provision.

5.19 Robust business continuity and national contingency plans, that have been tested, should be developed.

5.20 Existing contingency plans should be reviewed with respect to this report.

5.21 Arrangements should be made to enable Staff to be familiar with the equipment, facility etc of other CDUs providing contingency.

5.22 A review of CDU capacity should be undertaken with a view to increasing capacity.

5.23 Where the board requiring contingency has supplied staff to work at the contingency site, the supervisors' authority must be clear for all concerned at the contingency provider site.

5.24 An electronic tracking system which is compatible across all NHSScotland boards should be in place.

Measures to be taken in the event of a production shut down

5.25 Immediately notify HFS and HPS and senior management and the comms officer.

5.26 Within the site recovery plan have a detailed start-up/recommissioning plan for the cleanroom in the event of a significant shutdown period. This would define those responsible for approving the start-up of production.

5.27 Implement the tracking system agreed between user and providers of a contingency service.

5.28 A communications plan should be in place for CDU staff, theatre staff, government and press.

5.29 Clear guidance on staffing should be employed ensuring staff representative involvement.

5.30 Follow procedure with regard to extra instrumentation and dealing with missing or damaged instruments.

5.31 Follow procedure on transport and storage as relevant to the situation.

6. Action Plan

The recommendations should be considered by each healthboard and an update on progression monitored through the expert steering group RMD-DOG starting at the December 2019 meeting. Updates on progression will be forwarded to SFG.

Appendix 1: Short Life Working Group ToR

Short Life Working Group Critical Incident Review -Cowlairs November 2018

Terms of Reference

Purpose

The purpose of the short life working group is to learn from the incident at Cowlairs Central Decontamination Unit which occurred over November 2018. This is intended to prevent repetition of similar incidents in the future and minimise impact on the service.

Remit

To gain an understanding of the nature of the incident that took place in Cowlairs Central Decontamination Unit on November 2018, when the notified body issued a suspension certificate.

To learn lessons from the incident and to share learning with the Boards via the Strategic Facilities Group (SFG). The Reusable Medical Device – Decontamination Operational Group (RMD-DOG) will manage the roll out of these lessons.

Membership

The list of group members is as follows.

Title	Health Board/Organization/Group
Eddie McLaughlan (Chair)	Health Facilities Scotland
Sulisti Holmes	Health Facilities Scotland
Andrew Tweedie	Health Facilities Scotland
Paul Howard	Health Facilities Scotland
Tom Steele and Lynsay Gracie	NHS Greater Glasgow and Clyde
George Curley	NHS Lothian
Paul Allen/Juliette Watson/Gavin Payne	NHS Grampian
Phyllis Watt	Inverclyde _ NHS GGC
Barbara Casey	Golden Jubilee National Hospital
Anne Cosh	NHS Highland
Laura Burnside	NHS Ayrshire & Arran
Annette Rankin/Heather Wallace	Health Protection Scotland

Timeline

The group will meet on two occasions set for 16th May and 19th June 2019. The final output will be to SFG in September 2019.

Output

An action plan will be prepared (after the June group meeting) and submitted to SFG by September 2019 for their consideration.

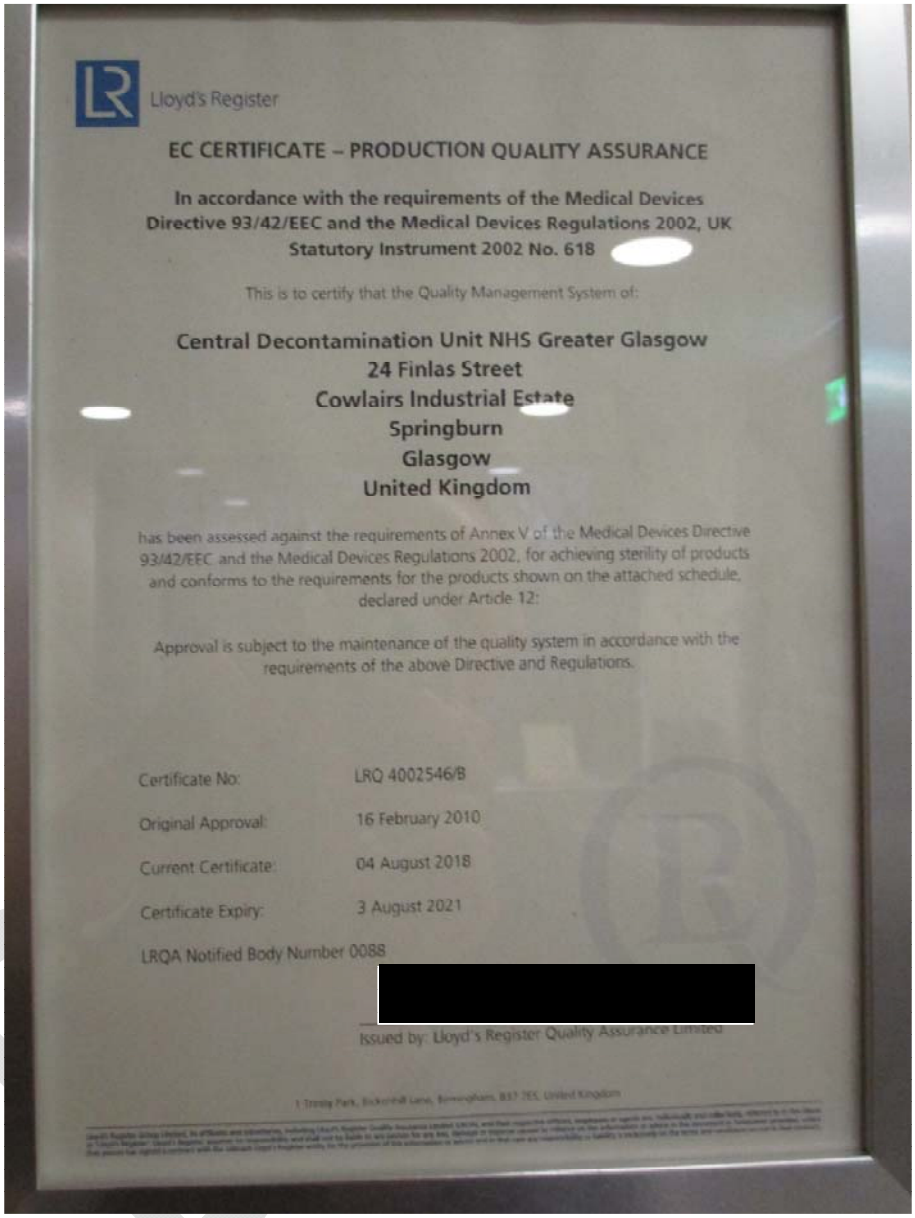
Secretariat and Support

Secretarial support is provided by HFS providing detailed action notes. The group meets as required at National Services Scotland's office or other nominated locations. Teleconference facility will be provided.

Chair of the Group

The Chair of the group is Eddie McLaughlin.

Appendix 2 – Cowlairs EC Certificate – Production Quality Assurance



Lloyd's Register

EC CERTIFICATE – PRODUCTION QUALITY ASSURANCE

In accordance with the requirements of the Medical Devices Directive 93/42/EEC and the Medical Devices Regulations 2002, UK Statutory Instrument 2002 No. 618

This is to certify that the Quality Management System of:

Central Decontamination Unit NHS Greater Glasgow
24 Finlas Street
Cowlairs Industrial Estate
Springburn
Glasgow
United Kingdom

has been assessed against the requirements of Annex V of the Medical Devices Directive 93/42/EEC and the Medical Devices Regulations 2002, for achieving sterility of products and conforms to the requirements for the products shown on the attached schedule, declared under Article 12:

Approval is subject to the maintenance of the quality system in accordance with the requirements of the above Directive and Regulations.

Certificate No: LRQ 4002546/B

Original Approval: 16 February 2010

Current Certificate: 04 August 2018

Certificate Expiry: 3 August 2021

LRQA Notified Body Number 0088

[redacted]

Issued by: Lloyd's Register Quality Assurance Limited

Doc control

D0.01 – 14/06/19 – initial release

D0.02 – prepared 21/6/19 - post meeting of 19/6/19, the ToRs were amended and information was supplied from boards (FV and A&A) that provided contingency.

D0.03 – 4/7/19 – Information supplied from Inverclyde on their contingency

Sulisti comments on D0.02 on 25/6/19.

D0.04 – 5/8/19 – revised based on Sulisti's comments on D0.03 on 2/8/19 on recommendations – removed sections on 'Scrutiny' and 'Specialist expertise in cleanrooms'.

D0.05 - 5/8/19 – removed complaint item with respect to LRQA.

D0.06 – 10/9/19 – amended based on the analysis of the August 2019 feedback from the short life working group.

D0.01 Discussed with working group at meeting of 19th June-

D0.05 Raised at RMD-DOG meeting of 4th September 2019

The Infection Prevention and Control Doctor in Scotland - Report on current position

Version	Date	Release	Author	Reviewed	Approved
1.0	07-09-2020	Draft	AM		
2.0	29-11-20	Draft	AM		
3.0	21-12-20	Draft	AM		
4.0	10-03-21	Draft	AM		
5.0	29-3-21	Final	AM		

1. Introduction

There is a recognised lack of clarity surrounding the role of the Infection Prevention and Control Doctor (IPCD). Following the Vale of Leven inquiry the roles and responsibilities of the Infection Prevention and Control Manager (IPCM) were detailed but this piece of work was never completed for the IPCD. Additionally, since then the role has changed, becoming more involved and with a greater emphasis on the impact of the built environment on healthcare associated infection.

The Scottish Microbiology and Virology Network (SMVN) IPCD subgroup has discussed this subject with the aim of providing clarity at local and national level around the role to ensure the broad range of skills and knowledge are utilised effectively for the health and safety of patients and staff working in healthcare premises.

A draft of a roles and responsibilities document has existed since 2015 (Philips et al) and this paper builds on this. Additionally a number of helpful documents have been published in this area by WHO and ECDC and this paper takes account of these. It aims to set out some of the functions of the IPCD as directed by what is currently in place in Scotland and highlights some key current issues. A small list of recommendations for additional work are detailed at the end. This report does not carry out a systematic evidence based review of the role of the IPCD.

Infection Prevention and Control Doctors (IPCD) have a broad range of knowledge and skills and are subject matter experts to varying degrees depending on experience, in microbiology, laboratory work, epidemiology, antimicrobial usage and Infection Prevention and Control including environmental issues such as water, air, decontamination. It is a unique cross speciality role. In addition, they will be gathering and interpreting often complex data and give advice on the correct response to these data including advice on risk assessment

Although the IPCD term is used some aspects of the role may be filled by clinical scientists.

It is recognised that Infection Prevention and Control (IPC) is a core function in the job of all clinical microbiologists and other infection specialists. IPC considerations should feature in any clinical interaction. However effective input to and co-ordination of the activities of the IPC team requires specialist expertise from the nominated IPCD. Additional advice may be given to the Infection Prevention and Control Team (IPCT) by any clinical microbiologist however the nominated IPCD would usually lead on longer term activities described in more detail below.

Finally, COVID19 has exacerbated problems with access to expert IPC advice on specialist issues such as dental infection control including respiratory PPE, control of aerosols, AGP fallow period, practice (& dental hospital) ventilation risk assessment and Legionella control.

2. The Infection Prevention and Control Doctor in Scotland

2.1 Models of Infection Prevention and Control Doctor provision

It is recognised that across Scotland the different sizes and geographies of health boards may lend themselves to different models of provision of the IPCD role. Some boards may wish to have a single individual with adequate time dedicated in their job plan for the majority of the functions detailed below. Others may wish to have a number of individuals with a smaller amount of time dividing this either by specialist area (such as water, ventilation, decontamination or by alert condition) or geographic area. Some larger health boards with a number of individuals contributing time to the IPCD role may designate a lead or co-ordinating IPCD. Additionally some aspects of cover may be provided for smaller boards through service level agreements.

Selection of individuals for management positions should be by competitive recruitment. As the role of the IPCD has developed there is recognition that it is becoming in some boards too large for a single individual. Multiple individuals contributing to the IPCD role can allow cross cover for leave and provide reassurance for the board. However, if there are other Medical staff undertaking some of the IPC duties there must be clear roles, responsibilities and lines of accountability written and communicated, including for periods of leave.

There has been recent debate about the benefit or otherwise of increasing specialisation within the role. It is widely recognised that some areas of the infection control doctor's role benefit from additional experience and time dedicated to these areas and as with other areas of microbiology such as paediatrics or transplant microbiology these may lend themselves to being covered by a person or persons with specialist interest. Increasing specialisation however may come with risks and it is important that these are actively explored. Adequate attention to succession planning is vital to prevent an organisation becoming too dependent on a single person. Additionally some areas of microbiology might be less popular and the tendency might be for other microbiologists to delegate these. It is key to remember that infection control really is everyone's business and should be part of every clinical interaction rather than some aspects of an interaction being ascribed to the infection control team.

2.2 Recruitment

Recruitment into this role has sometimes been a challenge and in some settings the most recently appointed consultant clinical microbiologist is given the role as part of their job plan. This situation is both undesirable and critical to avoid. Lack of formal recognition of the role, lack of a formally recognised training programme and often lack of sufficient time along with increasing media scrutiny and a fear of litigation may make the role of IPCD less desirable. As more experienced consultants move out of the IPCT key skills are lost.

However Infection Prevention and Control training across Europe is becoming increasingly formalised and good quality training is available. It is conceivable that with better recognition of the role of the IPCD and a more defined training then recruitment issues may be resolved.

2.3 Roles and Responsibilities

The main functions of the IPCD may be summarised under the headings below. These have been generated through consensus between the current practicing IPCDs in Scotland.

- Clinical Leadership for Infection Prevention and Control

  The IPCD is the clinical link for the IPCT, who in partnership with IPCM and Lead Infection Control Nurses, and the surveillance team will develop and implement a comprehensive and effective Infection Prevention and Control Service and prioritise resources to meet the organizational objectives relating to Infection Prevention and Control. There is a role in ensuring the Team functions effectively and the IPCD works with the IPCM in job descriptions, shortlisting and appointing other key team members.

  The IPCD will promote an organisational culture of Infection Prevention and Control as a priority patient and staff safety measure. The key feature should be on prevention and developing a culture where this is paramount.

- Expert knowledge

  The IPCD will act as an expert clinical resource in the delivery of the IPC service being a member of, and working in partnership with, all members of both the Health Protection Team (HPT), Occupational health and others as required. Such matters may include surveillance and control of hospital and community infection, sterilisation and decontamination methods, types of ventilation, operating theatres, isolation facilities, kitchens, laundries, housekeeping, waste disposal, pest control, and Infection Prevention and Control aspects of clinical procedures.

The IPCD will lead (or give direction) on the investigation and management of outbreaks, clusters and incidents of hospital infection in close collaboration as required with other infection experts such as virologists, Infection Prevention and Control Nurses and infectious diseases physicians. They will liaise as required with Health Protection Team in outbreaks in community settings as well as the medical microbiology service in the direction and interpretation of typing information in close collaboration with relevant reference laboratories. They will direct additional sampling including environmental sampling such as may be warranted by the nature of the outbreak. The IPCD in partnership with the senior IPCT, management and communications teams will formulate the outbreak communications strategy as well as ensuring that duty of candour considerations are adequately addressed in partnership with the relevant clinicians.

The IPCD in partnership with the senior IPCT will develop and guide implementation of lessons learned from outbreaks to inform quality assurance measures.

The IPCD will contribute expert knowledge to facilitate the day to day functioning of the IPCT through interpretation of diagnostic and reference lab data in terms of surveillance and the knowledge of microbial habitats, pathogenesis of infection and virulence factors.

- Governance

The IPCD contributes to effective structures for risk management such as error reporting and dissemination of lessons learned, challenges inappropriate practices and policies which impinge on effective IPCT. They will contribute to ensuring that hospital acquired infection (HAI) prevention policies are integrated with other risk management policies.

This aspect is also discussed under item 2.6.

- Assurance

The IPCD will contribute to the design, functioning and interpretation of an effective HAI surveillance and audit programme and will input into to the development of annual reports, including the Infection Prevention and Control Annual report. They will be involved in setting of local quality standards in respect to HAI and audit.

- Development and research

The IPCD will contribute to policy development and update; implementation of standards; support the promotion of prudent antimicrobial prescribing; surveillance programmes. The IPCD will also guide and contribute to relevant research.

The IPCD will contribute advice on barriers to compliance and work to promote and evaluate compliance.

They will advise on developments in IPC and contribute to the development of business cases to allow necessary development.

- HAI Education

The IPCD will contribute to the development and implementation of the annual Infection Prevention and Control programme of education and will be involved in assessment of the training needs of the organisation, integration with current training programmes and ensuring that training programmes are up to date and accurate. The IPCD will also contribute to the monitoring of the effectiveness of the training programmes provided.

Additionally the IPCD will be involved in providing specialist IPCD training to joint infectious diseases/microbiology trainees if there are any within the department. More senior IPCDs may also have a mentoring role for other IPCDs who have more recently taken up positions.

- Effective Communication and team working skills

Professional and management objectives shall be met through close working relationships with medical microbiology, other relevant clinical services such as infectious diseases, the health protection team, the antimicrobial management team and senior management of the organisation. In aspects of the built environment the IPCD will also liaise closely with estates, facilities and the relevant authorising engineers.

Meetings that require input include IPCT meeting, healthcare governance meetings, meetings of the health protection unit, antimicrobial management team as well as meetings involving specialist estates and facilities sectors such as water, and decontamination. This list is not exhaustive.

The IPCD will work with the microbiology management team to ensure that those individuals providing out of hours Infection Prevention and Control cover have the knowledge and skills to carry out the first response to an incident or outbreak.

2.4 Time requirements

An effective IPCD has a thorough understanding of the hospitals they cover, the staff and their processes. A physical presence is required for effective IPC. This along with prompt reaction to issues requires an appropriate allocation of time.

The European Centre for Disease Control (ECDC) has a recommended formula of number of beds per whole time equivalent Infection Prevention and Control nurse of 1 per 250 beds. No such formula exists in Scotland currently for IPCDs. The TRICE study in 2010 indicated that ratios for IC/HH doctors per bed or admission were recommended in 54% of respondent countries (18/33), although not always monitored in their application. For example France has a requirement for 1 whole time equivalent Infection Prevention and Control practitioner per 800 beds and Germany uses a formula based on number of beds and additional weighting is added for specialties which require more IPC involvement such as transplant units with immunosuppressed patient. Numbers of sessions across Scotland vary from between 1 session per 111- 425 acute beds (data still to be verified). However it is widely accepted that the role is not the same as it was at the time of writing of the Watt and Vale of Leven inquiry reports. To develop a proactive service and with the expanding recognition of the importance of the built environment adequate time for this function is vital. For boards with large or complex geography sessions must include travel time to remote areas. It is appreciated that large sessional requirements might be difficult to achieve in smaller Boards or Island Boards in which case the situation should be risk assessed and controls in place to ensure protection of patients and staff from infection.

A suggestion is that boards should have a minimum number of sessions to cover the minimum requirements, this would then be supplemented depending on the number of beds and weighted for the acuity of the specialities covered as well as the geography involved.

The requirement for CPD must be recognised in time allocations, as for complex and developing areas such as this built environment this is likely to be significant.

Expected involvement since the onset of the Covid-19 pandemic has been dramatically different with expansion in some boards into care homes etc. This needs to be taken into consideration as well as coverage of specialist areas such as dental schools.

2.5 Training

The majority of IPCDs have a background in clinical microbiology, however this does not exclude other training backgrounds with equivalent qualifications and experience such as Public Health and Infectious Diseases from taking on the IPCD role.

For microbiologists it is considered that the FRCPath is an essential qualification. Other relevant post graduate qualifications may include FFPH or FRCP in public health or infectious diseases. Whatever the background, the amount of Infection Prevention and Control in the current postgraduate curriculum is limited and the

experience that pre-certificate of completion of training (CCT) trainees obtain is variable. Microbiology post graduate training has now been combined with infectious diseases reducing the time spent in each speciality. This further reduces the time available specifically for Infection Prevention and Control, making post CCT in post training even more vital. Some countries have opted to develop a separate speciality of the IPCD with a distinct post graduate curriculum.

In Scotland traditionally experience has been gained in post, supplemented by a variety of courses which are listed in Appendix A. These would be tailored to the needs of the specific position and organisation.

It is vital that an appropriate proportion of continuous professional development (CPD) time is spent on IPCT related activities and leadership and team working skills should be included within this. Annual appraisal specifically covers the Infection Prevention and Control aspect of a job description and this should include inquiry about challenges and problems encountered in the role, including team effectiveness. Critical incidents where Incident Management Teams present dilemmas and challenges should provide candid and confidential material for discussion with a view to continuous improvement.

It is considered good practise that a newly appointed IPCD should have access to an experienced mentor.

Some countries use a system of a junior and senior IPCD and this might be a system which could be considered and which would take account of a period of in role training.

For clinical scientists the qualifications above would be suitable.

2.6 Governance structures

IPCDs provide a key safety function for the board, as such they need to be sitting on board level clinical governance groups to allow issues to be flagged at the highest level wherever there is concern that the standard routes of communication are insufficient. Many boards have the IPCD as a permanent member of Healthcare Governance Committees, and a direct line of access to the Board Chief Executive Officer and the HAI executive lead, to discuss issues of IPC concern. This should be regarded as vital.

The feeling that the current system is a title without executive power has possibly fed into current recruitment issues.

Currently IPCDs are most frequently consultant microbiologists and this would be the route of line management. In terms of professional accountability for IPC matters this would be to the HAI executive lead for the organisation.

2.7 Built environment and decontamination

The increased focus on the role of the built environment on HAI with the QEUH inquiry report and the Covid-19 pandemic means that the IPCD role in this area deserves particular mention. The demands for infection control expertise in the built environment have increased dramatically in less than a decade.

The IPCD is in a unique position to give advice at the interface between estates, facilities and clinical teams. For building projects the IPCD is critical to guide in interpretation of national guidance for the local situation and the needs of the clinical population in question. They can offer insight into first principles of Infection Prevention and Control in areas where guidance is not available.

As supported by the recommendations of the QEUH inquiry report the IPCD will be involved in the full cycle of the SCRIBE process for new builds or major refurbishment projects. This involvement will be sustained throughout the life of the project. However for this to function effectively a culture where this involvement is welcomed needs to be fostered with the understanding from the full design team that improvements in the design of a building from an Infection Prevention and Control point of view have wide ranging implications for patient care. The IPCD should not however be considered to have a compliance function in relation to

behaviours of contractors or design teams as this is out with the scope of the role and would be more appropriately be carried out by a 'clerk of works' etc.

For large building projects the time required to give well considered IPCD input is significant and this function for large building projects should not be considered as an add on the usual function of the IPCD. Dedicated time from an appropriately experienced individual should be allocated with backfill of the usual duties of this individual or outsourcing to an IPCD with appropriate built environment expertise and knowledge.

While some courses are available these do not substitute for a competency based training or experience gained during practice and this may differ markedly across boards depending on ongoing projects. Some consideration may be given in smaller boards to centralising or regionalising part or all of this function through service level agreements in order to maintain competence whereas large boards will usually have enough ongoing projects to warrant dedicated IPCD resource. Succession planning for this function is vital.

While the involvement of the IPCD in large new build projects has been a particular focus in recent months the IPCD input with regards to older estate should also not be under-estimated and never more so than during the challenges of the Covid-19 pandemic. Understanding the complexities and differences of the older and aging estate with regards their impact on the prevention and control of infection for a broad range of clinical specialities is a significant part of the role of the IPCD and a good working relationship with the estates and facilities team is vital. In health boards with PFI buildings this interaction may be different but is still vital.

In terms of decontamination the IPCD works in close partnership with estates, engineering and facilities colleagues and in liaison with national bodies in the interpretation of microbiological testing results either on commissioning of new equipment or in the ongoing management of equipment as well as advising on outbreaks or incidents with a decontamination focus. The IPCD provides expert opinion on the level of clinical risk posed by an incident as well as guiding the adequate decontamination of medical devices.

In both IPC in the built environment and decontamination it is recognised that the multi-disciplinary team is key and the value of the IPCD is in working in collaboration with other professional backgrounds and technical expertise.

2.8 Support

The IPCD must have adequate administrative support to facilitate the organisation and minuting of meetings, reports, policy documents and effective communications.

The IPCD must have access to adequate data and surveillance support.

3. Recommendations for further development

1. A post of speciality adviser to the chief medical officer in Scotland is created for Infection Prevention and Control Doctors.

2. A formal review of training and ongoing CPD requirements for IPCDs should take place with input from training professionals such as NHS Education for Scotland (NES). There should also be particular discussion regarding how to increase training and expertise for infection prevention and control with regards to the built environment.

3. HAI policy unit should give thought to guiding the number of IPCD sessions across health boards using the type of formula described above to provide equity and ensure a proactive rather than reactive service with the aim of driving down HAI and AMR and improving patient care.

4. Enhancements to the pre CCT Infection Prevention and Control training programme for Scotland should be explored and developed along the lines of the currently weekly national teaching for microbiology trainees with the possibility of supplementary training days.

5. A problem based model of experience sharing should be developed and facilitated by the SMVN IPCD network.
6. Some aspects of the role of the IPCD may benefit from being centralised and bodies such as ARHAI and NHS Assure may consider their own IPCD resource in areas such as ventilation and water.
7. The SMVN IPCD subgroup would welcome the opportunity to be involved in early stage policy and guideline discussions regarding IPC.
8. As the roles and responsibilities of the other members of the IPCT are reviewed this should be done in tandem with the roles and responsibilities described here to ensure that the members of the IPCT interact in an efficient way.

Hi Donald the new RHSC will have 17 of these rooms with isoltion lobbies through out the hospital and there will be some in the new DCN. However to do planned miantenance or if there were a malfunction would mean moving haem/onc patietns to other areas that is why I also think that there should be more than one air handling unit in that area,
Thanks
Janette

Subject: FW: For comments

I'm comfortable with air handling units serving more than one room but one unit serving the entire 5 rooms of the paediatric cancer unit seems to be a problem waiting to happen.
I think there needs to be guidance from the paediatric cancer clinical team as to what sort of patients would be managed in these rooms in order to gauge the risk. The risk to a bone marrow transplant patient from not having access to a positive pressure single room would be greater than for a solid organ post chemo patient. If the rooms were occupied and there was a malfunction, where on the site is there capacity for them to be managed (ward 215 springs to mind from a room design perspective but then there would be children on an adult ward). They could not remain in those 5 rooms while corrective work is being undertaken from a patient safety perspective. There needs to be an explicit agreed contingency plan as to where those 5 children would be managed in event of ventilation failure before embarking on a one air handling unit serves all rooms with no redundancy approach.
Pota is included in the reply as this relates to RHSC.

Hi Janette and Pota, I wonder if I could prevail on you to attend a meeting with me/ Janice to discuss the ventilation for single rooms within the new haematology/ oncology ward in the new building. There would appear to have been a need for contractors to deviate from an SHTM in order to achieve the output specification signed off at Financial close. Just need to make sure before the contractors proceed further that we are all in agreement around any operational issues/ balance of potential risks to patients.

Having spoken to Mark this morning, and checked Ann's off duty, they would be available on ward 2 late morning or early afternoon on Thursday 23rd Feb. The contractors will give me airflow drawings to share at the meeting so we can be clear on these

Can you please confirm if you are able to make this date and what time might suit you best, within Mark's suggested range

Many thanks

Hi Donald

Thanks very much for both of these documents which myself, Fiona, Dorothy & Ronnie have done an initial review of and I attach our comments for your consideration.

As yet we have not consulted with the clinical teams but plans in place to start this, as summarised below:-

· Workshop with DCN on Wednesday afternoon

· Meeting with the CF team on Friday

I have a call out to Eddie Doyle to ask how he wants to tackle consultation with the RHSC teams, my view would be that the focus would be on the areas that we have identified as a higher risk and would aim to have a workshop next week with key individuals.

Kind regards

Janice

Subject: First draft of risk assessment relating to addressing HAI risks in RHCYP clinical areas taking account of design ventilation and its delivery

This is what Lindsay and I have compiled so far. Note it does not cover critical care and does not cover risk from hospital water. The focus at present is around providing narrative to describe what the anticipated risks would be in a particular area and how the ventilation delivery may or may not influence such HAI risk.

Please direct any comments or suggested edits back to me and Lindsay.
Thanks
Donald

RHCYP DCN – Accommodation profile and HAI/IPC risk assessment August 2019

August 2019Ward	Total Beds	Multi bed Room	Single Room	Isolation Room	Clinical Specialties/Patient type/Procedure type	HAI/IPC Risk	Comments/Mitigation
Dalhousie: Medical Inpatients	23	3x4	3 (transitional care) 4	1 (transitional care) 3	Transitional care – awaiting discharge/home care and step down from critical care Main ward: • Diabetes • Cystic Fibrosis • Rheumatology • Cardiology • Infectious Diseases • Meningitis (non critical care) • End of life care	Immunocompromised patients Drug induced neutropaenia (Rheum patients) • Known alert organism colonisation • Respiratory infection • Loose stool or diarrhoea • Febrile Rash • Febrile returning traveller	Transitional care not used for CF patient care
Kildrummy: Sleep Lab	2	0	2	0	Sleep studies Elective only - well children		
Lochranza: Haematology/ Oncology	17*	0	12	5	Solid organ cancers Haematology ID immunocompromised	Mixture of solid organ cancer & haematology Fluctuating demand for haematology beds	In pt – *only 10 funded opened at any one time (any configuration of multi/single/isolation

SBAR- Draft Risk Assessment regarding Impact of Design Ventilation on managing HAI risk in RHCYP & DCN clinical areas (not including Paediatric Critical Care)

1. Situation:

NHS Lothian are required by the National Oversight Group "*to consider its clinical service model in light of the ventilation arrangements in place for general wards and other non critical areas (incorporating literature review and design information not yet available)*".

This relates to the project design provided which aims to deliver the 6 air changes required by SHTM 03-01 Part A to shared bed spaces and single room accommodation through mechanical supply for 4 air changes and 2 air changes through natural ventilation (although investigation is underway to establish if this is deliverable through window opening as had been designed).

Independent verification (by IOM) of the ventilation system has highlighted some areas where the ventilation performance requires further review and adjustment to ensure this performs in line with the design specification outlined above. This includes shared bed spaces and single room accommodation. NHS Lothian have been asked to demonstrate through risk assessment, that the Board is assured that the provision of 4 air changes per hour on mechanical supply, rather than 6 air changes per hour on mechanical supply does not compromise patient safety by introducing either an increased risk of transmission of infection or acquisition of healthcare associated infection.

2. Background:

In line with mandatory guidance (SHPN04-01 Adult In-patient facilities; HBN 23 Hospital accommodation for children and young people), RHCYP & DCN building provides a high percentage (greater than 50%) of single room accommodation for both children and adults. RHCYP provides 62% single room accommodation, and DCN 88% single room accommodation. This represents a significant increase in single room capacity over that which is currently available.

SHTM 03-01 part A (appendix 1) and SHPN 04 Supplement 1: Isolation facilities in acute settings define the air change rates, filter requirements, mode of delivery and pressure differentials required for hospital ventilation systems. The ventilation system at RHCYP & DCN was designed to deliver the following ventilation

	SHTM 03-01 requirement	Design specification	Current performance	Comments
General ward (multi-bedded bays)	6 air changes per hour (Ach/hr) – mix of supply and natural at balanced or slightly negative pressure	4 air changes per hour supply	Awaiting clarification from IOM	
Single en-suite rooms	6 air changes per hour - mix of supply, extract and natural	4 air changes per hour supply	Awaiting clarification from IOM	

	ventilation Balanced or negative pressure	Balanced or negative pressure		
Isolation rooms (Positive pressure ventilated lobby-PPVL)	10 air changes per hour Lobby at 10 Pascals positive pressure	10 air changes per hour Lobby at 10 Pascals positive pressure	Compliant	
Treatment Room	10 air changes per hour Positive pressure		Awaiting clarification from IOM	

The ventilation design and performance for some multi-bedded bays and single rooms does not conform to SHTM 03-01 part A, in terms of supply ventilation[Independent verification (by IOM) of the ventilation system has highlighted some areas where the ventilation performance requires further review and adjustment to ensure this performs in line with the design specification .

Lochranza ward (Haematology Oncology) does not have HEPA filters in the air supply ventilation to the single rooms which is indicated for rooms where neutropenic patients would be managed. The grade of air filter fitted in the supply air for these rooms (F9) is of a higher standard than the filters advocated for general ward areas or single rooms in SHTM 03-01 Part A Appendix 1 (G4 filter). As such the supply air in the single rooms of Lochranza is of a “cleaner” quality than a general ward but is not of a High Efficiency Particulate Air (HEPA) standard and this benefit would be immediately removed by opening a window to outside air as windows in the single rooms will open. The supply air ventilation in the 5 PPVL isolation rooms does pass through HEPA filters in the room lobbies. The 5 PPVL rooms do perform to the parameters set in SHTM 03-01 for rooms where all neutropenic patients can be safely placed. Windows in the PPVL isolation rooms are sealed units and do not open.

It is understood that all multi bedded bays and single rooms which do not have an opening window are provided with 6 air changes per hour (achieved through mechanical supply and extract) and positive pressure maintained to the corridor. This will be confirmed on receipt of the IOM report on the performance of all rooms against the design specification.

Assessment:

3.1 A review of all clinical departments was undertaken by the clinical leads from the project team (Janice Mackenzie, Dorothy Hanley, Fiona Halcrow); lead infection prevention and control nurse (Lindsay Guthrie) and lead infection control doctor & consultant microbiologist (Dr Donald Inverarity). This was discussed with key clinical colleagues in paediatrics and neurosciences for comment and input prior to submission to the NHS Lothian Executive Steering Group: Royal Hospital for Children and Young People and Department of Clinical Neurosciences for approval.

3.2 In view of planned revision of ventilation systems in Critical Care & Neonatal Unit to meet conformance with SHTM 03-01, it was agreed that these locations did not require to be part of this review, and will not be considered further in this paper.

3.3 A summary table of all wards, bed configuration and clinical service types which informed this risk assessment is provided in appendix 1. This outlines the risk profile of patients being cared

for in each area based on the clinical speciality, known patient risk factors and type of treatment or interventions provided. It also identifies anticipated HAI/IPC risks associated with each clinical area.

3.4 The highest risk patient groups are defined as:

- Any haematology/oncology patient
- Any neutropenic patient
- Any other immunocompromised patient (related to underlying disease process or treatment induced)
- Any patient with Cystic Fibrosis
- Any patient with a complex wound dressing or burn treated in the Plastics Dressing Clinic (or Dunvegan Ward)
- Any patient with a known infection alert (known colonisation or history of infection with alert organism)
- Any patient presenting with a suspected or confirmed infection transmitted by contact, droplet or airborne transmission

This categorisation of patient risk is in line with the definitions provided in Scottish Health Facilities Note 30 Part B: HAI Scribe Implementation strategy and assessment process; Health Protection Scotland interim guidance for routine sampling of Pseudomonas in augmented care areas (2018); and HPS National Infection Prevention and Control Manual.

3.5 Paediatric renal dialysis is not provided at RHCYP. Any child or young person requiring this is referred to QEUH in Glasgow.

3.6 Paediatric organ transplantation is not provided at RHCYP. Any child or young person requiring this is referred to QEUH in Glasgow or specialist services in NHS England. The number of patients requiring transplantation are small, but following treatment they may be admitted to RHCYP to either a surgical ward (Tantallon) or medical ward (Dalhousie).These patients would be considered immunocompromised and managed in line with the NHS Lothian Prioritisation of Isolation Guidance (attached as Appendix 2).

3.7 Within Lochranza (Haematology/Oncology), although the five PPVL isolation rooms provide 10 Air Changes/hour and 10 Pascals positive pressure from lobby to corridor, none of the single rooms available meet the specification for 'Neutropenic patient ward' defined in SHTM 03-01 Appendix 1 (also 10 Air Changes plus 10 Pascals positive pressure). Based on current occupancy, it is estimated by clinicians that currently there may be 5-10 neutropenic patients being cared for in RHSC on any given day. Although it is acknowledged that not all chemotherapy regimens result in the same intensity of immunosuppression and neutropenia, within the new facility, there may be a shortfall in the number of rooms which meet the SHTM 03-01 standard for safe placement of all neutropenic patients.

3.8 Appropriate patient placement and management is considered against the HPS National Infection Prevention and Control Manual (Appendix 11) and NHS Lothian Prioritisation of Isolation Guidelines. The latter was developed by the IPCT in Lothian to assist clinical teams to risk assess and provide safe, effective patient care where demand for isolation or single room accommodation is exceeded by demand. Paediatric and Neuroscience teams have previously been directed to use this document which is applicable for placement of both paediatric and adult patients.

3.9 The review group agreed that the wards with the highest perceived overall risk of demand for isolation exceeding capacity (and thereby potential risk of onward transmission of infection) are: Castle Mey ward (Paediatric acute receiving unit); Dalhousie ward (Medical in-patients); Lochranza ward (Haematology/Oncology)

3.10 Ventilation in healthcare premises is designed to achieve a number of objectives including management of temperature and humidity, removal of odour (particularly required in wards with cancer patients receiving chemotherapy), provide a clean air path directing flow from 'clean' to 'dirty' and dilution of airborne contaminants. These latter two points are of most significance from infection prevention & control perspective.

3.11 The burden of seasonal respiratory viruses is recognised as a risk, particularly for RHCYP. This risk is however mitigated via the provision of a significantly increased availability of en-suite single room accommodation with doors. HPS National Manual Appendix 11 advocates that patients are cared for in such rooms. The risk of droplet transmission is greatest within 3 feet/1 metre of the patient. The primary protection therefore offered by en-suite single rooms is physical separation greater than 1 metre and containment of infectious patients by means of a closed door. The impact on transmission risk of a reduced air exchange rate from 6 to 4 air changes per hour in each shared bed space is unknown.

3.12 A review of all alert organism reports in the past 2 years for the current wards at RHSC and DCN demonstrates that the Paediatric Acute Receiving Unit (Castle Mey) is likely to experience the highest burden of patients with presentations due to respiratory viral infections, loose stool or diarrhoeal illness and will have both the highest turnover of patients and the highest demand on isolation and single rooms.

3.13 The risk of transmission of infection is also mitigated by application of other aspects of transmission based precautions i.e. enhanced cleaning with chlorine 1000ppm av chlorine, use of dedicated or single use equipment, use of appropriate facial or respiratory protection The application of standard infection prevention and control measures such as personal protective equipment used optimally, optimal hand hygiene and access to alcohol based hand rub across all clinical areas will also mitigate some risk of transmission of infection.

3.14 HFS have also asked that NHS Lothian risk assess and define the actions required if one or more air handling unit fails resulting in the loss of isolation room supply ventilation, noting that between 1 and 5 isolation rooms are provided off single air handling units in the new building. This specifically affects both Lochranza and Dalhousie wards. Taking cognisance of the above assessment, in the absence of an infectious disease of high consequence, and providing all other standard and transmission based precautions required by HPS NIPCM are in place, the risk of infection to patients, staff or visitors is likely to be low as SICPs would remain in use and physical isolation in a single room with doors would be maintained. Additionally an air flow from room to toilet air extract would likely continue even if supply air ventilation failed rendering the rooms at slight negative pressure or balanced pressure to the corridor with doors shut.

3.15 Depending on the nature and duration of the AHU failure, and in line with NHS Lothian Prioritisation of Isolation Guidance, a clinical risk assessment would be required in conjunction with the IPCT to determine any further actions required on a case by case basis. This would take account of: the patient's overall clinical condition, the ward type, the infection risk and mode of transmission, the risk profile of adjacent patients and isolation room capacity unaffected by the outage. Additional mitigating actions specific to infectious diseases of high consequence (such as

MERS or Multi Drug Resistant TB) would also be required in the event of supply ventilation failure.

3.16 In discussion with the senior Paediatric Haematology/Oncology clinical and management team, it was agreed that based on the changing risk appetite in NHS Scotland and changes in clinical practice which mean some children are rendered neutropaenic by palliative treatment, that it would be appropriate to bring all single room ventilation to the required specification for managing neutropenic patients. This is possible due to the delay in the migration of paediatric services onto the site. NHS Lothian instructed this additional work through a board change request on 6th September 2019.

3.17 In discussion with senior clinicians who care for children with Cystic Fibrosis, it was agreed that a service specific SOP will be developed in conjunction with IPCT to guide appropriate CF patient placement and management of transmissible infections affecting this patient group (including Mycobacterium abscessus). This will include patient placement, ventilation requirements and environmental decontamination. It is anticipated this will be concluded at a meeting on September 23rd.

3. Recommendations

4.1 Staff at RHCYP and DCN should refer to and implement the NHS Lothian Prioritisation of Isolation Guidelines to ensure that all patients with a suspected or known infection risk, or who are vulnerable to opportunistic infections, are placed appropriately within all clinical care environments.

4.2 All NHS Lothian staff should continue to implement standard and transmission based precautions in line with national policy. This includes, but is not limited to, ensuring that patients with known or suspected infections are cared for in single or isolation room accommodation and the door to the room remains closed.

4.3 All children, young people or adults cared for in RHCYP & DCN who are receiving chemotherapy, radiotherapy or who are considered to be immunosuppressed should be prioritised for single room or isolation room accommodation where possible.

4.4 In line with national policy, co-horting of children with confirmed respiratory viral illness should be considered where this is clinically appropriate and demand for single room isolation has been exceeded. Strict application of standard and transmission based precautions is required for the duration of this

Haematology Oncology provision in RHCYP

Situation

The events in Glasgow and the delayed move into RHCYP has led to questions and discussion about the room specifications in Lochranza, the designated ward for Haematology Oncology patients in the new building

Background

This ward is designed as a 17 bedded ward, with all single rooms. There are 5 isolation rooms and 12 single rooms, around a courtyard. The single rooms are to the standard ward specification (of 6 air changes/hour) rather than the specification for neutropaenic patients (of 10 air changes/ hour at 10 Pa positive pressure with a HEPA filter). The isolation rooms meet the current standards.

It was known in 2017 that the SHTM was not met and this was progressed to Project Co through the normal routes. They were not able to change the design or build and it was accepted that this would need to be managed by clinical risk assessments to support the preferential placement of certain patients in the isolation rooms (those with the most severe neutropaenia and those at most risk of fungal infections). This was agreed and signed off by the clinical team, the project team and Infection Control colleagues as the only option at the time.

Assessment

The situation has changed as of mid 2019 with the following developments:

- The building has not been occupied as planned, so there will be a time window of opportunity prior to occupation in which to undertake rectifications and bring the 12 single rooms up to the required standard.
- The risk appetite across NHS Scotland has changed with regard to the care in hospital of neutropaenic patients with an increasing recognition of the potential impact of the environment. For example, the refurbishment of the adult haematology ward at WGH will deliver this standard for all rooms, and it would be hard to explain why this is not also delivered for children requiring inpatient care in a state of the art new facility.
- The current chemotherapy regimes in use are more effective but in doing so induce more neutropaenia, and are used in clinical situations where previously there was no therapeutic option.
- Increasing numbers of children from the East Coast are managed for inpatient care in Edinburgh where they might previously have received care in Grampian or Tayside
- The helipad is by the courtyard and there is a risk of downdraughts blowing particles into the air inlets and windows.

Recommendation

A board change should be developed and progressed to bring the 12 single rooms up to the required specification for the care of neutropaenic patients. This will involve:

- Increase the air changes from 6 to 10 per hour

- Increase the positive pressure to 10pa
- Fit HEPA filters to the air inlets for the rooms (H12 grad)
- Seal windows and trickle vents

Importance: High

Dear Ian,
Thank you for agreeing to look at this in Donald's absence a response is required as soon as possible. We have had information from HFS re air changes in this type of room with regards to a requirement of more than 8 air changes per hour that has been suggested. There are needle biopsies planned to be carried out in the area, there are Thr pendants with nitrous oxide for use and there will be ventilated cases transferred from DCN or RHSC respectively.

Guidance from SHTM 03-01 Ventilation attached pgs 141-142 states requirements for various clinical areas. We have been advised that there will be savaging in the CT rooms for when gas is in use but I have to re iterate that this is **a Health and Safety issue**. If comparing the CT scanner room to a treatment room then at least 10 air changes are required.

HFS have commented and so has the consultant M&E person along with the external expert person who is responsible for ventilation for NHS Lothian.

Ronnie has Health and safety been asked?

Regards
Janette

Ronnie

I would remind you that anaesthetic gas scavenging (AGSS) is provided in the CT rooms to deal with the exhaust from the anaesthetic machine when in use and this should not require the wholesale increase in room ventilation rate above those stated in SHPN guidance, unless there is a specific clinical requirement when AGSS is not sufficient.

Dear Ronnie,
The requirement for 15 air changes is in relation to the use of anaesthetic gases e.g. Nitrous Oxide., and as such is a Health and Safety issue. I strongly recommend that you consider that a decision is about to be made against the advice of HFS, IPCT and suggest you have input from health and safety. I attach Donald's response for those who may not have been aware of his considerations.

All,

In an attermpt to progress this to conclusion we have collectively looked at available current guidance and can conclude that the maximum quoted anywhere for a CT room is 10 ac/hr (SHPN 06, Engineering Requirements Para 7.4) and as such is the maximum that Multiplex can/will design to with available guidance.

If the decision by IPCN is that it must be 15ac/hr, this will need to be submitted as a formal change request that may result in significant cost increase and programme delay, please confirm that you wish me to submit this change request.

Scottish Health Technical Memorandum 03-01

Ventilation for healthcare premises
Part A – Design and validation

Health Facilities Scotland
Engineering and Environment

February 2013

Contents

Acknowledgements

Health Facilities Scotland would like to thank the principal contributors and the Steering Group led by the Department of Health for their efforts in producing the HTM 03-01 Part A document.

HTM 03-01 Part A has been updated and amended by Health Facilities Scotland for use in NHSScotland as SHTM 03-01 Part A and the contribution from the National Heating & Ventilation Advisory Group is gratefully acknowledged.

Preface

About Scottish Health Technical Memoranda

Engineering Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of Scottish Health Technical Memorandum guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle.

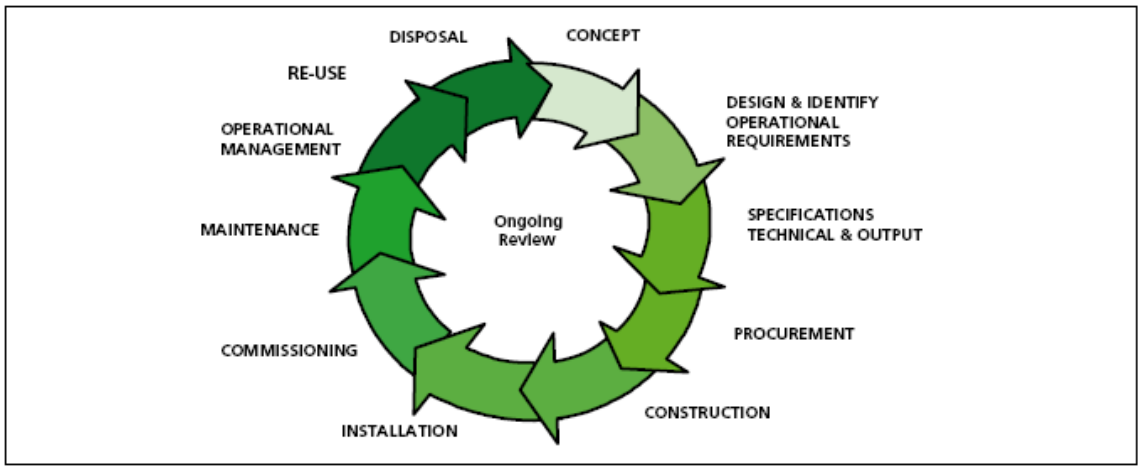
Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Engineering Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.



Healthcare building lifecycle

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of eight core subjects:

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Scottish Health Technical Memoranda in this series).

Scottish Health Technical Memorandum 01: Decontamination.

Scottish Health Technical Memorandum 02: Medical gases.

Scottish Health Technical Memorandum 03: Heating and ventilation systems.

Scottish Health Technical Memorandum 04: Water systems.

Scottish Health Technical Memorandum 05: Reserved for future use.

Scottish Health Technical Memorandum 06: Electrical services.

Scottish Health Technical Memorandum 07: Environment and sustainability.

Scottish Health Technical Memorandum 08: Specialist services.

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

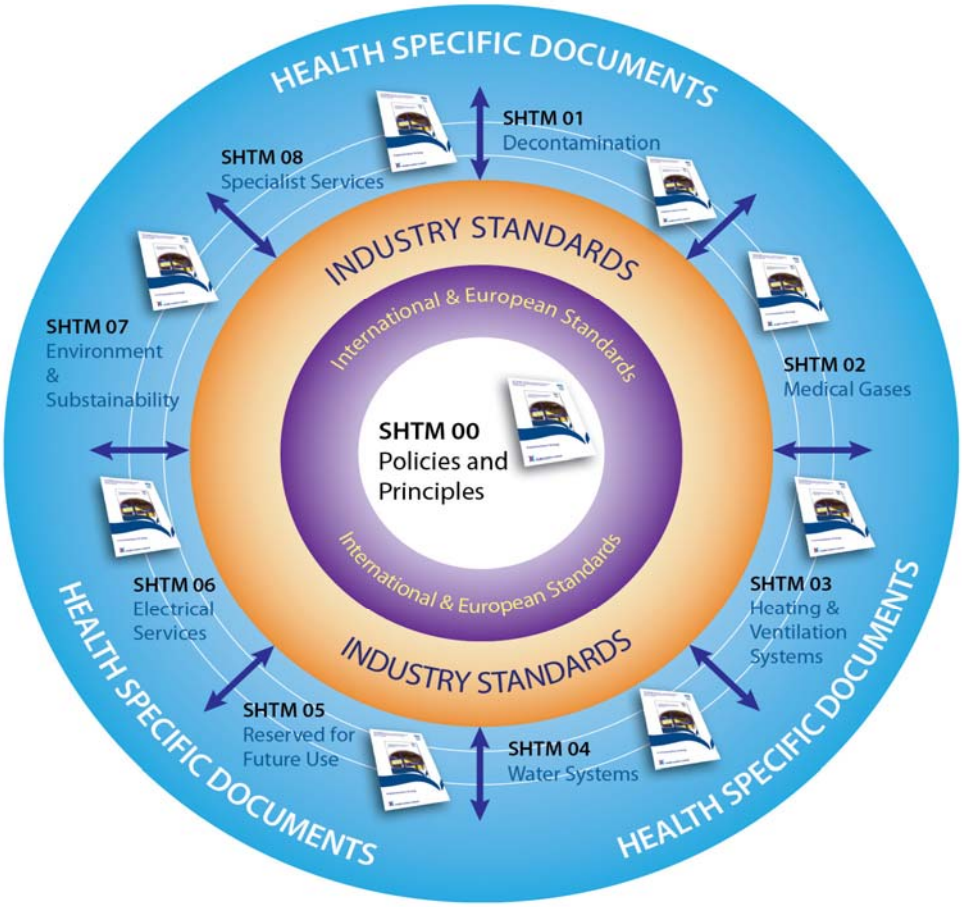
Example: Scottish Health Technical Memorandum 06-02 Part A will represent: Electrical Services – Electrical safety guidance for low voltage systems.

In a similar way Scottish Health Technical Memorandum 07-02 will simply represent:

Environment and Sustainability – EnCO_2de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.



Engineering guidance

1. Introduction

1.1 Ventilation is used extensively in healthcare premises or primary patient treatment in operating departments, high dependency units and isolation facilities. It is also installed to ensure compliance with quality assurance of processed items in pharmacy and sterile supply departments and to protect staff from harmful organisms and toxic substances, for example, in laboratories.

1.2 This edition of Scottish Health Technical Memorandum 03 'Ventilation in healthcare premises' is published in two sections. It is equally applicable to both new and existing sites. It gives comprehensive advice and guidance to healthcare management, design engineers, estate managers and operations managers on the legal requirements, design implications, maintenance and operation of general and specialised ventilation in all types of healthcare premises.

1.3 Current statutory legislation requires both 'management' and 'staff' to be aware of their collective responsibility.

1.4 'Ventilation' is also provided in healthcare premises for the comfort of the occupants of buildings. More specialised ventilation will also provide comfort but its prime function will be to control closely the environment and air movement of the space that it serves in order to contain, control and reduce hazards to patients and staff from airborne contaminants, dust and harmful micro-organisms.

1.5 Ventilation systems in themselves present little danger to patients or staff. However, they do possess the ability to transmit hazards arising from other sources to large numbers of people. The danger may not become apparent until many patients and staff have been affected.

1.6 The sophistication of ventilation systems in healthcare premises is increasing. Patients and staff have a right to expect that it will be designed, installed, operated and maintained to standards that will enable it to fulfil its desired functions reliably and safely.

1.7 The Health and Safety at Work etc Act 1974 (HSW Act 1974) is the core legislation that applies to ventilation installations and these installations are intended to prevent contamination, control closely the environment, dilute contaminants or contain hazards. Their very presence indicates that risks to health have been identified.

Statutory requirements

1.8 The Control of Substances Hazardous to Health (COSHH) regulations place upon management an obligation to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised

ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and safety cabinets.

1.9 The existing requirements to provide ventilation, implicit under HSW Act 1974 and COSHH, have been made explicit by the Management of Health and Safety at Work Regulations 1999, the Workplace (Health, Safety and Welfare) Regulations 1992 and the Provision and Use of Work Equipment Regulations 1998, all issued as a result of European Directives.

1.10 Where specialised ventilation plant is provided as part of the protection measures there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of the COSHH regulations requires that the plant be inspected and tested at least every 14 months by an independent organisation and that management maintain comprehensive records of its performance, repair and maintenance.

1.11 Certain substances have Occupational Exposure Limits (OEL) set out in Guidance Note EH 40 published annually by the Health and Safety Executive. If special ventilation systems are provided in order to achieve these standards they will be subject to the COSHH regulations as above.

1.12 All ventilation systems should conform to the principles set out in the Approved Code of Practice and guidance document entitled “Legionnaires’ disease: the control of *Legionella* bacteria in water systems” (commonly known as ‘L8’) published by the Health and Safety Executive and Scottish Health Technical Memorandum SHTM 04-01: The control of *Legionella*, hygiene, “safe” hot water, cold water and drinking water systems.

1.13 Special ventilation plants installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified organisms, may be subject to particular legislation with regard to their operation in addition to that mentioned above. Further information is given by the Health and Safety Executive Health Services Advisory Committee in:

- safe working and prevention of infection in clinical laboratories;
- safe working and prevention of infection in clinical laboratories: model rules for staff and visitors;
- safe working and prevention of infection in clinical laboratories in the mortuary and post-mortem room.

1.14 Plants installed in units manufacturing medicinal products to the standards set out in the current European Guide to Good Manufacturing Practice may also be subject to particular legislation with regard to their operation in addition to that mentioned above.

1.15 Records should be kept of equipment design and commissioning information. The Health and Safety Executive, Medicines Inspectorate and other interested bodies have a statutory right to inspect them at any time. All records should be kept for at least five years.

1.16 The fire regulations require that if ventilation ductwork penetrates the fabric of a building it should be designed and installed so as to contain the spread of fire. (for further information refer to Firecode Series SHTMs 81, 83 and 85)

1.17 Increased health risks to patients will occur if the more specialised ventilation systems installed to supply high quality air to operating departments do not achieve and maintain the required standards. The link between post-operative infection and theatre air quality has been well established. Plants serving conventional operating departments, for instance, will be required to ensure the separation of areas within the suite by maintaining a specific direction of air flow between rooms, even when doors are opened. They will also maintain the selected operating department environmental conditions regardless of changes in the outside air conditions or activities within the space. In addition ultra-clean operating ventilation systems that are designed to provide an effectively particle-free zone around the patient while the operation is in progress, have been shown to reduce significantly post-operative infection in patients undergoing deep wound surgery. Their use for other forms of surgery may well be required.

1.18 Ventilation systems that can be shown to be inappropriate, inadequate or ineffective and that give rise to proven failures can result in a civil suit by the patient against the operators.

1.19 If the plant has been installed to dilute, extract or contain harmful substances (the definition of which now includes microorganisms) its failure may expose people to unacceptable levels of hazard. Proven failures can give rise to a civil suit against the designers and operators by the individuals who have been affected. This would be in addition to the actions brought as a result of breaching the statutory requirements.

1.20 There is a statutory requirement to provide ventilation in all enclosed workspaces. It may be provided by either natural or mechanical means. The following are some of the factors that determine the ventilation requirements of a workspace:

- human habitation (minimum fresh air requirement);
- the activities of the department, that is, extraction of odours, aerosols, gases, vapours, fumes and dust – some of which may be toxic, infectious, corrosive, flammable, or otherwise hazardous (see Control of Substances Hazardous to Health (COSHH) regulations;
- dilution and control of airborne pathogenic material;
- thermal comfort;
- the removal of heat generated by equipment (e.g. catering, wash-up, sterilising areas, electrical switch rooms, uninterruptible power supply (UPS) cupboards and some laboratory areas);
- the reduction of the effects of solar heat gains where other forms of reducing the solar effect is not available or practical, i.e. solar blinds;

- the reduction of excessive moisture levels to prevent condensation (for example Hydrotherapy pools);
- combustion requirements for fuel burning appliances (see BS5376, BS5410 and BS5440);
- 'make-up' supply air where local exhaust ventilation (LEV) etc., is installed.

Mechanical ventilation systems are expensive in terms of capital and running costs, and planning solutions should be sought which take advantage of natural ventilation either where the use of the area in question is not critical to airflow patterns or pressures, or where backup systems are available when natural ventilation cannot be achieved.

1.21 When new ventilation systems are accepted for use, full information as to their designed mode of operation together with recommended maintenance procedures should be provided as part of the handover procedure.

Requirement	Reason	Application
Statutory	Health and Safety at Work etc Act	Operating department Laboratories Pharmacy
	COSHH regulations	Areas containing identified biological or chemical hazards Areas containing oxygen displacing gases
	Local Exhaust Ventilation (LEV)	Enclosed work-spaces Workshops
Functional	Comfort	Situations where the quality of the environment for staff and patients is critical to their general performance and well-being
Clinical	Post-operative infection reduction	Operating suites used for general surgery, casualty, obstetrics/gynaecological and maternity procedures
	Reduction of deep wound sepsis	Ultra-clean operating suites for transplant, deep wound surgery, hip replacement, bone grafting and bone marrow transplant procedures
	Isolation from contact with bio hazards	Isolation units for patients who present a biological, chemical or radiation hazard to others. Isolation units for patients with a reduced immune system

Table 1: Reasons for providing ventilation

Functional overview – Terms in use

1.22 The terms 'ventilation' and 'air-conditioning' are often incorrectly used to describe the same equipment. A general explanation of the terms is given below.

Ventilation

1.23 Ventilation is a means of removing and replacing the air in a space. In its simplest form this may be achieved by opening windows and doors. Mechanical ventilation systems provide a more controllable method. Basic systems consist of a fan and either collection, (extraction) or distribution (supply) ductwork. More complex systems may include the ability to heat and filter the air passing through them. Ventilating equipment may be required in order to remove smells, dilute contaminants and ensure that a supply of 'fresh' air enters a space.

Air-conditioning and mechanical cooling

1.24 Air-conditioning is the ability to heat, cool, dehumidify and filter air. For full air-conditioning, humidification may also be provided. This means that the climate within a space being supplied by an air-conditioning plant can be maintained at a specific level regardless of changes in the outside air conditions or the activities within the space. Mechanical cooling may be provided where close control of 'comfort conditions' within a space is required but humidity control is not needed.

Special ventilation

1.25 In healthcare premises, certain activities will necessitate the provision of ventilation equipment with additional special features in order to achieve and maintain specific conditions. These may be needed in order to assist with the treatment of patients or maintain the health and safety of staff. The precise reason for providing special ventilation will depend upon the intended application. The list below indicates some of the more typical reasons:

- to remove, contain or dilute specific contaminants and fumes;
- to ensure the isolation of one space from another;
- to preserve a desired air flow path from a 'clean' to a 'less clean' area;
- to provide control of the cleanliness of a space;
- to provide 'close' control of temperature;
- to provide 'close' control of humidity.

1.26 The following departments will usually have specialised ventilation requirements, either for a single room or throughout a suite of rooms:

- operating department;
- laser surgery unit;
- intensive treatment unit;
- infectious diseases isolation unit;
- manufacturing pharmacy;
- specialised imaging, X-ray and scanning unit;

- pathology containment laboratories;
- mortuary and dissection suite;
- research laboratory;
- sterilising and disinfecting unit (SDU);
- endoscopy unit;
- renal dialysis suite;
- ultrasound facilities;
- audiology room.

1.27 Ventilation may be provided in a wide variety of ways. These will include:

- extensive purpose-built air-conditioning units housed in their own plant rooms;
- proprietary 'packaged' systems often sited outside on a roof or;
- wall-mounted electric fans located at the point of use.

1.28 A fixed volume of air may be supplied, often expressed in terms of the resulting number of air changes per hour (ac/h) within the space being ventilated. It may also be expressed in terms of litres/second/person. Alternatively the volume of air supplied may be varied in order to maintain a specific pressure relationship between the area supplied and other surrounding areas. In some situations a combination of both methods may be adopted.

1.29 Modern plants are fitted with the means to recover energy from the extract air where this can be justified without causing contamination of the incoming supply air.

1.30 Ultra-clean systems use the same basic plant and equipment as standard air-conditioning but are in addition fitted with a terminal device that supplies the air in a unidirectional manner to the working area. Their standard of filtration will be capable of delivering air with a very low particle count to the space that they serve.

Local exhaust ventilation

1.31 Local exhaust ventilation (LEV) is a term used to describe systems installed to prevent hazardous substances from entering the general atmosphere of the room in which they are being used. Their primary function is to protect staff from the effects of their work activity.

1.32 Simple LEV systems comprise a capture hood, extract ductwork and fan. These are used to contain industrial types of hazard such as fumes from welding processes, gas discharges from standby battery banks and dust from woodworking machinery. The vapour given off when large quantities of chemicals are decanted into ready-use containers and fumes from X-ray film processing units are further examples of chemical hazards often controlled by LEV systems.

1.33 In laboratories, pharmaceutical manufacturing facilities and operating suites, LEV systems usually take the form of semi-open fronted cabinets within which the hazardous substance is manipulated. These cabinets either have their own filtered air supply or are fed with air from the room. The air extracted from the cabinet is passed through a high-efficiency filter before being discharged either to the atmosphere or back into the room. Microbiological safety cabinets, laboratory fume cupboards, cytotoxic drug cabinets and fixed or mobile disinfection enclosures are all examples of this type of facility.

1.34 Mortuaries and dissection suites may have LEV systems incorporated within the dissection table, specimen bench and bone saw.

Management action

1.35 The guidance contained in this SHTM should be applied in full to new installations and major refurbishments of existing installations.

1.36 Ventilation will need to be provided:

- as a requirement for patient care;
- in order to fulfil a statutory duty.

1.37 In assessing the need for more specialised ventilation and the standards desired for patient care, managers will need to be guided by their medical colleagues and by information published by Health Facilities Scotland.

1.38 The statutory need for ventilation falls into two categories:

- in the first, the need for specialised ventilation and the standards to be adopted are clearly set out in specific pieces of legislation. An excellent example of this is the current legislation surrounding the manufacture of medicinal products in the European Community. The managers of the departments affected by this type of legislative requirement should be aware of their needs and be able to advise on the standards to be achieved;
- the second type of statutory requirement arises due to the interpretation of both the Health and Safety at Work etc Act and the Control of Substances Hazardous to Health (COSHH) regulations. The person tasked with conducting COSHH assessments will be able to advise as to the need for, and standard of, ventilation in each particular case.

Design and validation process

1.39 It is essential when undertaking the design of a specialised ventilation system that the project be considered as a whole. The process model set out below should ensure that all relevant factors are considered.

Step	Question	Design statement and information required	Comment
1	Why is the system required?	Healthcare applications Statutory elements Non-healthcare applications	
2	What is the required system performance?	Room air flow pattern Air change rate Differential pressures Air quality Room air condition Noise limits	
3	What are the constraints on the distribution system?	Location, Size, Materials Dampers, Access, Insulation Fire considerations Room terminals	
4	What are the minimum requirements for the AHU(s)?	Intake / Discharge positions *Legionella*, Health and Safety Access, Fire, Electrical safety Leaks, Insulation, Cleanliness Filtration, Drainage	
5	What control functions are required?	User control requirements Estates control functions Energy management Environmental conditions Control sequence logic Run, Set back, Off philosophy	
6	How will the system performance be validated?	Validation methodology Instruments used Design information required [*Design air flow rates* *Design air velocities* *Pressure differentials* *Noise levels* *Air quality* *Installation standard*]	
7	The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.		
8	Handover to client	Basic design information Commissioning results Validation report	

Table 2: Design and Validation process model

Use and function of typical equipment used in ventilation plant

1.40 Typical equipment used in ventilation systems is listed below together with a brief description of both function and use.

General

1.41 The equipment built into the ventilation system and its ductwork should be of a type that will neither cause nor sustain combustion. No materials that could sustain biological activity should be used in the construction or assembly of the system.

Air Intake

1.42 An uncontaminated air supply to the system is essential. In order to achieve this, the air intake will be positioned so that air discharged from extract systems or other dubious sources cannot be drawn in. Exhaust fumes from vehicles can present particular problems. The area surrounding the intake will need to be kept clean and free of vegetation and waste material in order to reduce the possibility of biohazards or fire. The intake itself will be protected by a louvre and mesh screen to prevent rainwater, vermin and insects etc from entering the system.

Damper

1.43 Several types may be fitted:

- automatic dampers fitted immediately behind the air intake and extract louvres. They will automatically close when the system is shut down in order to prevent an uncontrolled circulation of air;
- balancing dampers are fitted into each branch of the air distribution ductwork system so that the design air flow rate can be set during the commissioning process;
- where ductwork passes through a fire compartment wall, ceiling or floor a fire and/or smoke damper may be required;
- plant isolating dampers are fitted so that the main plant can be isolated from its air distribution duct system. They are manually operated and enable cleaning and maintenance of the air-conditioning equipment to be carried out.

Ducting

1.44 The means by which air is conveyed from the intake to its point of use. Ducting is usually constructed of galvanised steel and will normally be insulated to reduce noise and conserve energy. Ducts can also be formed in concrete, brickwork, stainless steel or plastic and may be rigid or flexible.

Fan

1.45 A series of rotating blades that move the air in the direction required. Fans are usually powered by electric motors either directly connected to them or driven through belts and pulleys. A fan may be arranged either to force air into or draw air from a ductwork system.

Attenuator / silencer

1.46 A device that will contain and absorb the noise emitted by a fan. They may be required to reduce disturbance caused by noise breaking out through the air intake and also noise transmitted along the ductwork to the conditioned space.

Filter

1.47 A filter consists of a labyrinth of fibrous material contained in a frame. It is designed to capture and hold particles being carried in the airstream. Because of the size range and number of particles that exist in air no filter can remove them all. The purpose of filtration is to reduce their number and size range to an acceptable level. Filters of progressively higher grades are fitted through the ventilation system:

- primary filters (coarse) are designed to collect the larger particles and are intended to keep the air-conditioning plant clean;
- secondary filters (fine) will remove the staining particles from air and keep the conditioned space visibly clean;
- high efficiency particulate air filters (HEPA/absolute) will remove virtually all particles from air. These may be required in order to reduce contamination in the working area either biologically or in terms of particle count.

Filters may be fitted to extract systems to protect energy recovery devices. They may also be fitted to remove biological, radiation or chemical hazards and if so, are often contained in a ‘safe change’ facility in order to protect those carrying out maintenance.

Activated carbon filters will reduce odours in extracted or recirculated air.

Heater battery / heater coils

1.48 A series of heater batteries or heating coils with or without fins through which steam or hot water is circulated. Heat is given up to the air passing over the battery thus increasing its temperature. Heating is usually carried out in stages, the final battery being controlled by the end user. Small batteries may be electric.

Humidifier

1.49 A device for increasing the humidity of air by adding moisture. For ventilation in healthcare premises this is normally achieved by releasing ‘clean’ steam into an

air supply duct. The steam will be completely absorbed into the air, increasing its humidity. The level of humidity may be preset or controlled by the end user.

Cooler battery / cooling coil

1.50 A series of finned coils mounted in the air supply duct. Either chilled water or refrigerant is circulated through the coils causing heat to be removed from the air. This will reduce its temperature and may also condense moisture out of the air. As free moisture in a duct can be a source of contamination the coil will be fitted with an eliminator and drainage system.

Eliminator

1.51 A device for catching and removing water droplets from an air stream. It may form part of a cooling coil or be a separate device.

Drainage system

1.52 A means of removing water from ductwork and disposing of it safely. Typically it will consist of a tray mounted in the duct to catch moisture, a glass water seal trap, continuously falling drainage pipework and an air break in the drain run to prevent waste water returning and contaminating the duct.

Access doors and observation ports

1.53 Doors and removable panels providing access for routine maintenance and cleaning. The doors should be fitted with glazed ports and suitable lighting provided so that the correct operation of devices such as cooling coils, humidifiers and filters can be easily observed without needing to switch off the plant.

Energy recovery

1.54 Many plants are fitted with the means to recover energy from the extract air without causing contamination of the incoming supply air. These devices will be fitted with a drainage system and may incorporate an eliminator. Several types of energy recovery systems are available.

1.55 Precise definitions of ventilation and air-conditioning terms are given in the Chartered Institution of Building Services Engineers (CIBSE) Guide B.

Typical plant

1.56 The layout of a typical plant that conforms to the requirements for healthcare applications is shown in Figure 1 overleaf. It contains most of the equipment described above.

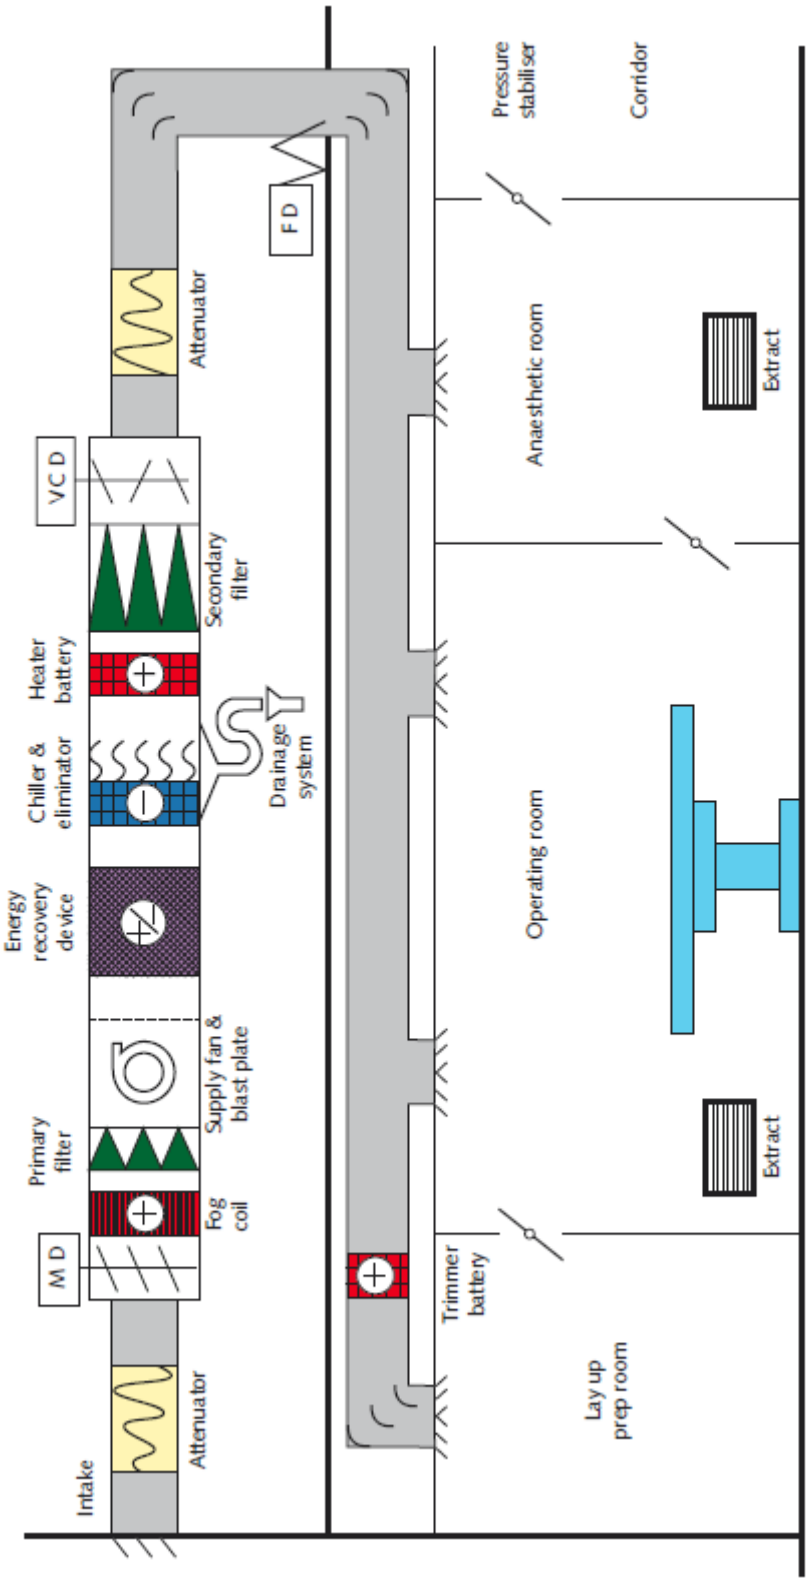


Figure 1: Design and Validation process model

A47310563

2. Provision of ventilation in healthcare buildings

2.1 It is acknowledged that planning constraints imposed by the building shape and/or functional relationships of specific areas will invariably result in some measure of deep planning thus reducing the opportunity for natural ventilation. However, ventilation costs can be minimised by ensuring that where practicable, core areas are reserved for rooms that have a functional requirement for mechanical ventilation. Examples are sanitary facilities, dirty utilities and those rooms where clinical or functional requirements have specific environmental needs; and where for reasons of privacy, absence of solar gain etc., windowless accommodation is acceptable. Other spaces appropriate to core areas are those that have only transient occupation and therefore require little or no mechanical ventilation, for example circulation and storage areas.

Natural ventilation

2.2 Natural ventilation is usually created by the effects of wind pressure. It will also occur if there is a temperature difference between the inside and the outside of the building. The thermo-convective effect frequently predominates when the wind speed is low and will be enhanced if there is a difference in height between inlet and outlet openings. Ventilation induced by wind pressures can induce high air change rates through a building provided air is allowed to move freely within the space from the windward to the leeward side.

2.3 As the motivating influences of natural ventilation are variable, it is almost impossible to maintain consistent flow rates and ensure that minimum ventilation rates will be achieved at all times. This variability is normally acceptable for general areas including office accommodation, general wards, staff areas, libraries rooms, dining rooms and similar areas which should, where possible, be provided with opening windows of a design that facilitates natural ventilation.

2.4 Current guidance restricts the amount windows can be opened for safety reasons and as many designs are top-hung, their ability to permit natural ventilation is limited. It may therefore be necessary to provide dedicated ventilation openings in the fabric of the building to allow a sufficient natural flow of air into and out of the space. Paragraph 2.20 also refers.

2.5 In all cases, excessive heat gain, indoor air quality requirements or external noise may limit or preclude the use of natural ventilation.

Extract ventilation systems

2.6 Separate extract ventilation will be required for sanitary facilities, lavage areas, dirty utilities and in rooms where odorous, but non-toxic fumes are likely, in order to ensure air movement into the space. 10 air changes per hour have been found necessary, particularly in geriatric and psychogeriatric

accommodation. This will assist with infection control procedures. A single fan/motor unit can be suitable for individual rooms, but multi-room systems should be provided with duty and standby fans or motors to meet this need.

2.7 Toilets should have an extract ventilation rate as set out in the building regulations. Where WC's are located in shower and bathroom spaces, the ventilation required for the WC will normally be adequate for the whole space.

Supply only ventilation

2.8 Mechanical supply ventilation will be required in areas where it is important to maintain a positive pressure in order to prevent the ingress of less clean air, e.g. in pharmacy aseptic suites, sterile supply packing rooms, operating theatres and their preparation rooms (air change rates are given in Table A1).

Supply and extract ventilation

2.9 Mechanical supply and extract ventilation should be provided in rooms where there is a need to control room pressure in relation to adjacent spaces. Intensive Care Units, (ICU), isolation suites and treatment areas are typical applications.

Mechanical or comfort cooling

2.10 Cooling is very expensive in terms of energy costs and should be provided only where necessary to maintain a comfortable environment for staff and patient, or to ensure satisfactory operation of equipment. The imaging department in particular may require cooling to offset the equipment load.

2.11 Calculations and thermal modelling should be undertaken to ensure that during the summertime, internal temperatures in patient areas do not exceed 28ºC (dry bulb) for more than 50 hours per year taking into account the level of design risk for the application.

2.12 Certain non-patient areas may also require cooling and will typically include some laboratories, central wash-up and other areas that are subject to high equipment heat gains.

2.13 Where deep planning of other continuously occupied spaces, for example offices, is unavoidable, there will also be occasions when acceptable levels of comfort can only be maintained by cooling. Planning solutions of this type however will be exceptional.

2.14 Refrigeration plant should be of sufficient capacity to offset heat gains and maintain areas at a temperature that does not exceed the external design shade temperatures by more than about 3ºC taking into account the level of design risk for the application.

Air-conditioning

2.15 Full air-conditioning is only required in a very small number of areas within healthcare buildings and due to the capital and running cost its inclusion should be kept to a minimum. Paragraphs 3.14 - 3.15 and 4.91 - 4.93 also refer.

2.16 Areas whose functions may warrant the installation of air-conditioning include operating departments, intensive therapy units, manufacturing pharmacies and areas with particularly sensitive equipment.

Specialised ventilation

2.17 Due to the nature and extent of activities carried out in healthcare buildings, there will be a need for a wide range of specialised ventilation systems. The types of system which are generally required in individual departments and typical arrangements are given in Section 7.

2.18 The activities within some departments will require the provision of local exhaust ventilation (LEV). This is a statutory requirement under COSHH wherever the escape of chemicals, toxic fumes, biological material or quantities of dust into the general area would present a hazard to the occupants.

Ventilation for general areas

2.19 Table A1provides recommended air change rates, temperatures and pressures for general areas that require mechanical ventilation in healthcare buildings.

Use of natural ventilation

2.20 The air tightness of new buildings has improved to the point that infiltration through building leakage can no longer be relied upon to provide sufficient air-flow. Attention must therefore be given to the provision of purpose-made ventilation openings to achieve the necessary flow rates. The air entering the openings may need to be controlled by motorised dampers linked to temperature and / or occupancy sensors in the ventilated space.

2.21 Internal partitions, fire compartment walls and closed doorways can often impede the flow path, and when this happens, the process will be more dependent on single-sided ventilation. Nevertheless, even with this degree of compartmentation, acceptable ventilation may still be achieved without window openings that would prejudice safety, security or comfort.

2.22 Some types of window, for example, vertical sliding, can enhance single sided air change by temperature difference, and these will improve the overall rate of natural ventilation in protected or sheltered areas where the effect of wind pressure is likely to be minimal.

2.23 It is generally considered that natural cross-flow ventilation is able to give reasonable air distribution for a distance of up to 6 metres inwards from the

external façade, provided that reasonably clear air paths are maintained. Beyond this distance in areas where clear air paths cannot be maintained and in areas where high minimum air change rates are specified, mechanical ventilation should be provided.

2.24 Further information can be found in SHTM 55 'Windows', BS5925 'Code of practice for ventilation principles and designing for natural ventilation' and CIBSE Applications Manual AM10: 'Natural ventilation in non-domestic buildings'.

Mixed mode ventilation

2.25 This comprises an assisted form of natural ventilation. Fans are fitted in the purpose made damper-controlled ventilation openings. Alternatively a separate ventilation unit may be installed. In both cases the dampers and fans are controlled under the dictates of temperature and occupancy sensors to ensure a minimum air flow rate while taking advantage of natural ventilation effects when present.

2.26 Where natural or mixed mode ventilation is adopted with complex air paths, the designer should produce an air flow diagram in order to ensure correct provision of air transfer devices. CIBSE Applications Manual AM13: 'Mixed mode ventilation in non-domestic buildings' gives guidance.

Mechanical extract ventilation

2.27 General extract systems can vary in complexity from a single wall-mounted fan to a ducted air system with dual extract fans.

2.28 Replacement air is generally provided by a central supply system (as described below). Unless special precautions are taken, the latter may result in an unacceptable level of draughts occurring in winter, and possible risk of unacceptable levels of noise transmission.

2.29 If individual systems are used, the ventilation can be operated intermittently, provided it continues to run for at least 15 minutes after the room is vacated, as with light switch-operated fans in individual toilets.

2.30 If general exhaust systems are used; it is recommended that filtered and tempered replacement air is provided via a central supply plant to adjoining lobbies or corridors, to prevent the risk of discomfort caused by the ingress of cold air. Fire compartmentation requirements must be maintained.

2.31 Information on specialised extract systems is given in Section 7.

Mechanical supply systems

2.32 Where mechanical supply systems are required, the fresh air should be tempered and filtered before being delivered to the space, to avoid discomfort.

2.33 The air should be heated using a constant or variable temperature source, but generally only to the space air temperature. In most instances, the low-pressure hot water heating (LPHW) should offset any fabric loss, so that setback room temperatures can be maintained during unoccupied periods without the need for the ventilation system to operate.

Balanced ventilation

2.34 Balanced ventilation systems are merely a combination of a supply and extract systems of equal volume; and either a single space or a whole building may be considered to be balanced. A balanced system is necessary in instances where it is essential to maintain consistent air movement within an area, for example, treatment rooms.

Cascade ventilation

2.35 In operating departments it is normal practice to supply air to the operating room, and allow it to pass through less clean areas – corridors, utility rooms etc. (from where it is eventually extracted).

Recirculation systems

2.36 Due to the nature of the use of mechanical ventilation systems within healthcare buildings, there are few opportunities for the application of recirculation air systems. They are however normally used for HEPA filtered clean room applications where the extract air is significantly cleaner than the outside supply. Recirculation is also routinely used in the canopy section of Ultra Clean Operating theatre ventilation systems.

2.37 Where the designer is considering the installation of a recirculation air system, due account must be taken of:

- minimum fresh air supply volume required by the Building (Scotland) Regulations 2004 (currently 20%);
- prevention of contamination of supply air from vitiated air in extract systems;
- prevention of stratification occurring within plenum chambers and mixing boxes which may result in freezing of downstream coils;
- ensuring sufficient velocities through control dampers (ideally 5-6m/s) to provide suitable authority; and good shut-off;
- modulating control of mixing to provide optimum on-plant conditions;
- use of ‘free cooling’ by cycling the dampers to minimum fresh air when the enthalpy of the outside air is above that of the extract air under conditions when cooling is required.

Chilled beams

2.38 The use of chilled beams for the provision of heating, cooling and ventilation is increasingly common in healthcare premises. The use of Active Chilled Beams providing tempered filtered air to a heating / cooling device within the room can provide effective local control of environmental conditions.

2.39 Care should be taken in positioning chilled beams to ensure the avoidance of cold draughts particularly when used in the cooling mode. The control settings should ensure that the external elements of the beam are always above dewpoint.

2.40 Consideration should be given to the ease with which specific types of chilled beam units can be accessed for cleaning having regard to the need to control the infection risk. The impact of maintenance requirements on room availability should also be considered.

Split comfort air-conditioners

2.41 Split comfort air-conditioners, room conditioners or cassette units are used increasingly where there is a small local requirement for cooling for operational purposes. They can provide an effective economic solution to cooling needs, where a central refrigeration system is not practicable.

2.42 The units re-circulate room air so provision for a fresh air make up, either by natural or mechanical means, to the standard required by the Building (Scotland) Regulations must be provided.

2.43 The recirculation of room air presents problems with indoor air quality (IAQ) and may increase the risk of healthcare associated infection (HAI). Split units should not therefore be used in critical patient areas.

2.44 Split units may be used for single room applications or as multiple linked units that can independently provide either heating or cooling, all served by a single outdoor unit. These systems enable good temperature control of a number of rooms with maximum energy efficiency.

2.45 Whether single or multiple systems are used, it is essential that the designer gives due consideration to the source of electrical supply, location of the heat rejection unit, environmental effects to the refrigerant used and drainage provision for the cooling coil condensate.

2.46 The units will require routine maintenance for filter change and cleaning; they should therefore be installed in an accessible position.

Dilution ventilation and clean air flow paths

2.47 Dilution ventilation has in the past been used to control levels of hazardous substances in a space. This approach is no longer considered acceptable. The COSHH Regulations require that known hazardous substances should

be substituted by safe alternatives. If this is not possible then they should be controlled at source by the use of closed systems such as anaesthetic gas scavenging units or exhaust protective enclosures such as fume cupboards.

2.48 The exposure of staff to casual spillages of substances such as medical gases in anaesthetic rooms should in the first instance be dealt with by establishing a clean airflow path. Air should be supplied at high level and extracted at low level directly behind the anaesthetic equipment position. The philosophy of establishing a clean air-flow path from the supply point; to the staff; on to the patient and out via a low level extract would also apply in recovery rooms and maternity delivery rooms including labour, delivery, recovery & post partum (LDRP) Rooms. A suitable air change rate will provide dilution ventilation as an additional safeguard; see Table A1, Table A2 and Note c.

2.49 In operating theatres the patient will be on a closed breathing circuit in a room with a high air change rate. Under these circumstances the dilution effect would be considered sufficient to control any casual exposure to anaesthetic gases.

Mechanical ventilation systems

System selection

2.50 Natural ventilation is always the preferred solution for a space, provided that the quantity and quality of air required, and the consistency of control of ventilation to suit the requirements of the space, are achievable with this method. If this is not the case, a mechanical ventilation system will be required.

Choice of central/local plant

2.51 Mechanical ventilation is expensive to operate, and as such, should be controlled to operate when the space being served requires to be ventilated. In addition, loads on refrigeration plant are rarely constant owing to changes in solar gain, occupancy and use of heat-generating equipment and lights, therefore control of temperature is critical.

2.53 If the ventilation loads throughout a department or building are in phase, or are not significant, a central plant with single zone control can be adopted. However, this is rarely the case, and elsewhere, the condition or quantity of supply air to different areas or zones of the building must be varied accordingly. This can be done by providing either individual plants to each zone, or separate zone terminal control. Where there is a high density of rooms with similar ventilation requirements in an area of a building or department, it is usually economical to combine them into a central system.

2.54 In large buildings, a choice between a single distribution system and multiple smaller systems may arise. Large distribution systems and their plant can have the advantage of lower operating costs, but require more space for vertical shafts and horizontal distribution. In general, very long runs of ducting should be avoided to prevent undue heat losses or gains, excessive leakage, and difficulties in balancing during commissioning. As the pressure losses in the

long runs will be greater and a higher initial static pressure will be required, this will lead to a more expensive class of ductwork. Multiple smaller distribution systems may be more expensive in capital and operating costs but they avoid long runs, large ducts and vertical shafts, and this may reduce overall building costs. They also provide a more robust service as the failure of an individual system does not prevent the use of the rest of the building.

Zoning of the building

2.55 The efficiency and effectiveness of any ventilation or air-conditioning installation depends largely on the zoning and control of the installation. The factors to consider when determining the zoning of a ventilation system for a building or department are:

- periods of occupancy;
- fresh air/ventilation requirements;
- smoke control.

2.56 Where the ventilation system is not merely tempering the air, but also providing the heating and/or cooling requirements, the following additional factors will need to be considered:

- internal or peripheral location;
- orientation of windows;
- variation in internal loads;
- level of control required.

2.57 For single zone plant in staff areas, local control (with a run-on timer if required) is recommended, as this can be turned off when the space is not in use, thus saving both thermal and electrical energy. Most supply and extract systems, conversely, are required to operate continuously while the department is occupied, thus some form of time or use control is necessary.

2.58 The control of individual plant items is covered in Section 4, with examples of typical control strategies in Section 6. For control of particular specialised ventilation and air-conditioning systems refer to Section 7 of this document.

2.59 On very rare occasions a duplicate standby air handling plant may be justified. If installed it must be provided with a gas-tight damper at its junction with the supply distribution duct, so that no back-flow can occur. Standby plants can become sources of contamination if warm moist air is allowed to dwell within them. Their design and control system must ensure that this cannot happen.

Specific requirements for hospital departments

2.60 Specific requirements for individual spaces and departments are included in the Health Building Notes (HBNs) and Activity Database (ADB) A-Sheets, or Scottish Health Planning Notes (SHPNs).

3. Assessment of service requirement

Selection of design criteria

External design conditions

3.1 The most accurate data that is available for the summer and winter conditions at the site should be used. The Metrological office can supply data for the United Kingdom.

3.2 Healthcare mechanical ventilation systems will normally be 'full fresh air'.

3.3 Local adjustments such as for height above sea level, exposure factor, or other climate peculiarities, should be made as appropriate.

Internal design conditions

3.4 The design conditions selected within patient areas must strike a balance between the comfort requirements of staff and patients, who often have very different levels of clothing and activity.

3.5 Recommendations for the dry resultant temperature and humidity of individual spaces are shown on Activity Database (ADB) A-Sheets. Table A1 gives a summary.

Minimum fresh air requirements

3.6 For most applications involving human occupancy, the dilution of body odours is the critical factor in determining ventilation requirements. Where natural ventilation or mechanical full fresh-air systems are used, all ventilation air will be fresh.

3.7 Where odour dilution is the overriding factor, it is recommended that 10 litres/second/person should be taken as the minimum ventilation rate.

3.8 Smoking is not permitted in healthcare premises. If permitted for example in residential care, it will be confined to designated areas. It therefore follows that these areas will contain a high percentage of smokers so the ventilation rate would be at least 36 litres/second/person for these applications (CIBSE Guide A; Table 1.10 refers).

3.9 In non-standard applications such as laboratories, aseptic suites, operating departments, etc., the particular requirements for each area should be considered independently in order to determine the overriding minimum requirement for ventilation.

Limiting supply air conditions

3.10 For most applications in healthcare buildings, it is the temperature differential between the supply and room air, rather than the actual temperature of the supply air which is the critical factor. The maximum recommended supply-to-room air temperature differential is:

summer cooling: - 7K

winter heating: + 10K

3.11 It is also necessary to keep supply air humidity below 70% during winter in order to minimise risks associated with condensation.

Air purity

3.12 In healthcare premises, the standard of filtration will depend on the activities within the occupied spaces. With the exception of special areas, (for example manufacturing pharmacies), the requirement for aerobiological needs is not stringent and filtration is only required to:

- maintain hygienic conditions for the health and welfare of occupants, or for processes such as food preparation;
- protect finishes, fabrics and furnishings; to reduce redecoration costs;
- protect equipment either within the supply air system; that is, to prevent blocking of coils, or in the space itself to prevent dust collection.

3.13 Given that almost all viable particles will originate from the occupants of a space and not from the incoming air, dilution is the more important factor aerobiologically. Therefore, for general areas a G4 filter will be suitable. More critical areas will require a F7 filter. HEPA filters will only be required in Ultra Clean systems.

Humidity control requirements

3.14 Providing humidification is expensive in terms of plant, running costs and maintenance, and therefore its use should be restricted to where it is necessary for physiological or operational reasons.

3.15 Humidification was originally required for some healthcare applications, e.g. operating theatres, in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement.

Maximum noise levels

3.16 Noise will be generated in an air distribution system by the fan, ductwork fittings, dampers and grilles. The specified maximum noise level will depend on the activities within the occupied spaces.

3.17 The overall noise levels should not exceed the values given in Scottish Health Technical Memorandum 08-01: 'Acoustics', although general requirements are given in Table 3.

3.18 Attenuation should be incorporated into the ductwork system or plant arrangement as necessary to reduce noise from fans and plant items in order to achieve the acceptable limits within the rooms at the design air flows.

3.19 Plant noise should not be greater than 80dB(A) within the plant room from the fans, coolers, heaters, humidifiers etc. when starting up or running, and should be reduced to lower noise levels where the plant is near to departments sensitive to noise.

3.20 Attention must be given to the reduction of tonal components. High tonal components from air diffusers etc. can seriously disturb concentration over longer periods even when the overall noise level is low. Broadband noise causes less annoyance. Reference should be made to SHTM 08-01: 'Acoustics'.

3.21 The designer requires knowledge of the total hospital layout and operational policies, to assign acceptance magnitudes to all the possible noise sources, in order to arrive at the correct rating.

Room	Overall noise level - NR	Ventilation plant commissioning - NR	Ventilation plant design - NR
Operating department	50 (55)	45	40
Ward areas	33	30	30
Sanitary facilities	45	40	35
Industrial areas	50	45	40
Circulation areas	50	45	40

Table 3: Interior noise level

3.22 In Table 3, above, the overall noise level takes account of all internal and external noise sources. The commissioning noise level is the level measured with a sound level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. When occupied and in use, this commissioning level will constitute a continuous background noise which will allow the overall noise level to be achieved. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise that must be considered in the overall design, that is, in specifying the attenuation of walls, partitions, ceilings, etc.

3.23 The recommended criterion is measured as the "A" weighted sound pressure level expressed in decibels, which should not be exceeded for more than 10% of the time.

3.24 The designer must also consider noise escaping to the external environment and this must not be unacceptable to occupants of adjacent buildings.

Calculation of building loads

Air infiltration

3.25 Air infiltration occurs due to a complex combination of wind pressure, thermal effects, location relative to other features and the construction standard of the building. The infiltration rate is governed by the size and number of openings in the building envelope and the complexity of internal air paths.

3.26 CIBSE Guide A (2006) Section 4 provides information and formulae for the calculation of air infiltration and natural ventilation of buildings. In all cases the requirements of the appropriate section of the Building (Scotland) Regulations must be met.

Summertime temperatures

3.27 The calculation method for determining the summertime temperature is described CIBSE Guide A (2006) Section 5. However, it is very important to select the time of day and time of year of peak loadings for the calculations. These will be dependent on the orientation and proportion of solar to total heat gain. In establishing outside design values, the design risk having regard to the function and occupancy of the building should be considered.

3.28 Where calculations indicate that internal temperatures will frequently exceed the selected design external shade temperature by more than 3K for a period that exceeds the building design risk, methods of reducing temperature rise should be implemented. Options include: - reducing solar and casual gains, the use of chilled beams or ceilings, increasing ventilation rates or providing mechanical cooling. In some situations it may be possible to alter the thermal mass of the structure to 'move' the peak temperature event time so that it occurs outside of the occupancy period. Calculations and thermal modelling should be undertaken to ensure that during the summertime internal temperatures in patient areas do not exceed 28°C dry bulb for more than 50 hours per year. It has been found that there is a relationship between preferred indoor temperatures and mean outside temperature. Fig A2 in CIBSE Guide A indicates this relationship.

Peak heating load

3.29 Peak heating local calculations are necessary on all mechanical supply systems to establish the size of heater batteries and subsequently the central plant.

3.30 Where ventilation systems provide tempered air to spaces that have supplementary LPHW to offset the building fabric losses, the plant heating load should be calculated based on the external winter design temperature, the design internal air temperature, and the calculated total air volume (including a suitable allowance for leakage).

3.31 Where the ventilation system is the only means of heating a space, an increase in load equivalent to the calculated fabric heat losses from the space should be added to the ventilation load. A check of supply temperature difference should be made. If it exceeds 10K the ventilation supply volume should be increased to suit.

Condensation risk

3.32 A check should be made to ensure that the selected air condition will not lead to surface condensation on low-temperature elements of the ventilated space.

3.33 Where there are local sources of moisture that would require excessive levels of ventilation to avoid condensation, the designer should consider the capture and removal of moisture at the source of the evaporation via an exhaust hood or similar device.

3.34 In intermittently heated buildings, it is necessary to consider the condensation risk at night setback conditions as well as during normal operation. Calculation methods for this assessment are given in CIBSE Guide A.

Peak cooling load

3.35 In addition to the base data of airflow rates and temperatures, when calculating cooling loads, the designer must take into account:

- solar cooling loads;
- surface conduction cooling loads;
- internal gain cooling loads;
- cooling loads due to high-level humidity control;
- method of control of internal conditions;
- fluctuations in internal temperatures.

3.36 When the peak internal loads have been assessed and a suitable allowance made for non-coincidence, the supply temperature can be calculated.

3.37 Once the lowest required supply temperature of the air handling unit has been established, and an allowance made for temperature rise through the fan and ductwork (usually 1K for low pressure systems), the off-plant enthalpy can be established from a psychrometric chart or table.

3.38 The cooling loads for all plants on the chilled water system should be calculated at each of the individual peak times in order to establish accurately the required (diversified) capacity of the chiller.

Annual energy consumption

3.39 Annual energy consumptions of heating-only ventilation systems are simple to calculate based on supply-to-external air temperature rise, and frequency of occurrence of external temperatures as given in CIBSE Guide A.

3.40 Minimum air volumes are usually fixed by the room loads or fresh air requirements. However, the designer may increase airflow to some rooms or zones in order to balance loads, as detailed in the following paragraphs on "Calculation of plant requirements."

3.41 The method of zoning and control can significantly influence energy consumption.

3.42 The nature of air-conditioning operation, comprising cooling and reheating for humidity or zonal temperature control, makes prediction of energy consumption very complex. It is imperative that these calculations are performed to ensure optimum energy efficiency.

3.43 The concept of load and plant operation charts is outlined in the CIBSE Guide A. The method requires the designer to establish the minimum and maximum loads on all zones across the range of external temperatures between winter and summer design conditions. Once the load chart is complete, the plant chart converts the loads to supply temperatures, which are then superimposed on external air temperatures.

3.44 When all temperatures for all zones are plotted on the plant operation chart, set points and resetting schedules can be established. From this information, the outputs of individual heaters, coolers and humidifiers can be established at any given external temperature. When those loads are computed against annual frequency of occurrence of external temperatures as given in CIBSE Guide A, the annual energy consumption of individual elements, and thus the air-conditioning system, can be established.

3.45 In order to prevent surface condensation occurring, it is necessary to provide sufficient ventilation to maintain the maximum and ambient dew-point temperature below the lowest surface temperature, the coldest usually being the glazing. Paragraphs 3.33 and 3.34 also refer.

Calculation of plant requirements

Air supply volumes

3.46 The minimum air supply volume for a room is determined by the greatest of these three criteria:

- the minimum fresh-air requirement;
- the minimum supply volume for the room load as determined by the maximum heating or cooling supply temperature differential;
- the desired/required air change rate.

Plant sizing

3.47 Once the design airflow has been established the cross-sectional area of the air-handling unit can be calculated based on a maximum coil face velocity of 2.0 m/s.

3.48 In order to establish the length of the air-handling unit, it will be necessary to refer to manufacturers' literature, ensuring all necessary access panels and components are included as detailed in Section 4.

3.49 The fan duty should be calculated by adding the resistances of all elements that contribute to the pressure drop of the index circuit.

3.50 The main elements that must be considered are:

- inlet or discharge louvres;
- plant entry and discharge;
- attenuators;
- components within the air-handling unit;
- duct-mounted heaters and filters (including a dust allowance);
- ductwork distribution;
- ductwork fittings, including: fire dampers, volume control dampers, bends and sets, tees, changes of section;
- air terminal device;
- discharge velocity.

3.51 Where packaged air-handling units are installed, the fan pressure drop is usually quoted as external plant resistance, and thus the designer does not need to calculate the resistances of individual plant items. The designer should, however, ensure that an allowance has been made for filter clogging; and confirm whether the fan pressure quoted is fan total or static pressure.

3.52 Resistances of ductwork and fittings may be obtained from the CIBSE Guide A. However, the designer should exercise some care when using tabulated pressure loss information for fittings that are relatively close together.

3.53 Upon completion of the resistance calculation exercise, the designer should make allowances for calculation and construction tolerances as indicated in Table 4.

Criteria	Low pressure systems	Medium/high pressure systems
Volume flow rate margin for leaking and balancing requirements	+5%	+5%
Total pressure loss margin A. for increase in volume flow rate (above)	+5%	+5%
B. for uncertainties in calculation	+5%	+10%
Combined total pressure loss margin	+10%	+15%

Table 4: Typical fan volume and pressure margins

Plantroom size and location

3.54 The ventilation plant and associated equipment should be positioned to give maximum reduction of noise and vibration transmitted to sensitive departments; while at the same time, achieve an economic solution for the distribution of services.

3.55 It is not recommended that noise and vibration generating plant be housed either directly above or below sensitive areas (for example, operating or anaesthetic rooms) unless there is no alternative, in which case, additional care and attention must be given to the control measures.

3.56 The plant must also be located so that it is remote from possible sources of contamination, heat gains and adverse weather conditions. The design should ensure that wind speed and direction have a minimal effect on plant throughput.

3.57 Safe access to and around plant is essential to facilitate inspection, routine maintenance, repair and plant replacement.

Provision of primary services

3.58 Where more than one air-handling plant requires cooling, remote central cooling plants with piped chilled water are preferred. In the case of a single plant, a multi-stage direct-expansion cooling coil with refrigerant piped from an adjacent compressor/condensing plant could be considered. If this option is selected, a refrigerant gas detector mounted in the base of the duct and an alarm system audible to the end-user will also need to be provided (as dictated by COSHH Regulations).

3.59 Clean dry steam is preferred for humidification, provided that the boiler water treatment does not render the steam unusable for direct humidification.

3.60 If a suitable supply of steam cannot be obtained from the steam main, a steam generator should be provided locally, or a self-generating humidifier installed. Electric humidifiers require considerable electrical loads and if a gas supply can be derived, this would be preferable. The location of a local steam generator is critical if condensate is to drain back into it.

Inlet and discharge sizing and location

3.61 Air intakes and discharge points should preferably be located at high level, to minimise the risks of noise nuisance to surrounding buildings, contamination and vandalism.

3.62 Intakes and discharges should be designed and located so that wind speed and direction have a minimal effect on the plant throughput.

3.63 Helicopter landing pads in the vicinity of ventilation intakes and discharges can result in large short-term pressure changes. This can cause pressure surges in supply systems and reverse airflows in extracts. Exhaust fumes from the helicopter may also be drawn into intakes. For general information, refer to Health Building Note (HBN) 15-03 – Hospital helipads.

3.64 Intake points should also be situated away from cooling towers, boiler flues, vents from oil storage tanks, fume cupboards and other discharges of contaminated air, vapours and gases, and places where vehicle exhaust gases may be drawn in.

3.65 Where intakes have necessarily to be sited at or near ground level, the area around them should be paved or concreted to prevent soil or vegetation being drawn in. They should also be caged or located within a compound to prevent rubbish being left in the vicinity. The likely proximity of vehicle exhausts should also be taken into account when determining the protected area around the intake.

3.66 The discharge from an extract system must be located so that vitiated air cannot be drawn back into the supply air intake or any other fresh-air inlet. Ideally, the extract discharge will be located on a different face of the building from the supply intake(s). In any event, there must be a minimum separation of 4 metres between them, with the discharge mounted at a higher level than the intake.

3.67 Discharges from LEV systems should preferably be vertical and usually not less than 3m above roof level. They should not be fitted with a cowl that could cause the discharge to be deflected downwards.

3.68 Each intake and discharge point should be fitted with corrosion-resistant weatherproof louvres or cowls to protect the system from driving rain. Louvres should be sized based on a maximum face velocity of 2 m/s in order to prevent excessive noise generation and pressure loss.

3.69 The inside of the louvres should be fitted with a mesh of not less than 6mm and not more than 12mm to prevent leaves being drawn in and infestation by vermin.

3.70 The duct behind louvres should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system.

3.71 Cleaning access must be provided either from the outside via hinged louvres or by access doors in the plenum behind the louvre. Where a common plenum is provided, cleaning access should be via a walk-in door.

Heat rejection devices

3.72 The design conditions given in Section 2 make no allowance for the elevated temperatures that can occur on the roof of buildings. Refrigeration condensers should, if practicable, be shaded from direct solar radiation, or the design adjusted to take account of the gain.

3.73 Air-cooled condensers must always be the first choice for heat rejection from any refrigeration plant. Evaporative cooling systems must not be used in healthcare premises.

3.74 Reference should be made to Scottish Health Technical Memorandum 04-01: 'The Control of *Legionella*, hygiene, 'Safe' hot water, cold water and drinking water systems, Part A: Design, Installation and Testing, and Part B: Operational Management, published by Health Facilities Scotland, 2011.

4. Air handling unit design and specification guidance

General requirements

Location and access

4.1 Air-handling units should be located in an accessible area secured from unauthorised entry. Siting units in ceiling voids above occupied spaces is not appropriate.

4.2 Units located on roofs must have a safe means of access together with suitable precautions to prevent personnel or equipment falling or being blown off during maintenance activities.

4.3 Units located at ground level should be secured within a locked compound to prevent unauthorised access. Measures should be taken to exclude vehicles from the vicinity to ensure that exhaust fumes will not be drawn into intakes.

4.4 Units may have a working life of approximately 20 years. It can be anticipated that over this period there will be a need to access every element within the unit for deep cleaning. It is also quite possible that the main fan and individual heater and chiller batteries will need replacement. Suitably positioned service connection joints and adequate spacing should permit these items to be withdrawn without the need to dismantle other installed plant or equipment. Batteries significantly wider than 1 metre should be split to permit withdrawal from both sides.

4.5 It is essential that air-handling units are positioned so that all parts are easily and safely accessible for routine inspection and service. If a unit is located against a wall or backs onto another unit then access to all parts must be available from the front. Units greater than 1 metre wide should preferably have access from both sides or access doors large enough to permit the full and safe entry of maintenance personnel.

4.6 Water may be used during routine cleaning or spilt when maintenance is being undertaken. The area around the unit should be tanked to prevent water penetration to adjacent areas and adequately drained.

4.7 Fire precautions should be incorporated in accordance with Firecode. Guidance is available in BS5588: Part 9 and Sections 5 and 6 of this document.

4.8 Combustion equipment must not be located in a fire compartment that houses air-handling equipment.

Technical requirements

4.9 The basic technical requirements of the whole of the ventilation system should meet the relevant clauses of the Model Engineering Specification. It should be noted that the Specification contains a menu of clauses that cover a wide range of applications, so it is important to select only those that are relevant to the specific application.

Note 1: At the time of writing, Model Engineering Specification C04 was listed for revision in order to bring it into line with the revised standards as set out in this Scottish Health Technical Memorandum. Where conflicts in specification arise, the Scottish Health Technical Memorandum takes precedence.

4.10 It is essential that the main plant/ductwork is located far enough above the floor to permit the correct installation of drainage systems for cooling coils, humidifiers and heat recovery systems. Easy access for maintenance of drainage systems and their associated pipework must be provided.

4.11 Organic materials or substances that can support the growth of microorganisms must not be used in the construction of the plant or its distribution system. The water fittings and materials directory lists suitable materials for sealants and gaskets.

4.12 The plant and its distribution system must not contain any material or substance that could cause or support combustion.

4.13 Plants should have a high standard of air-tightness. The double-skin method of construction with insulation sandwiched between two metal faces is recommended. The panels may be available in a variety of colours at no additional cost. This can aid identification by colour coding of units in a plant room (for example green for general ventilation; blue for theatres; red for laboratories and isolation facilities; grey for extract etc).

4.14 The inside of the plant should be as smooth as possible. Channels, rolled angles or formed sections that could trap or hold moisture should be kept to a minimum. If stiffeners are required, they should be fitted externally. If internal bracing has to be fitted it must be of a design that will not trap or hold moisture.

4.15 Airflow across air treatment components such as filters, heat exchangers and humidifiers will be influenced by the pattern of the approaching airstream. If unsatisfactory conditions are created, the performance of the component will be reduced.

4.16 Access to items that require routine service such as filters, frost batteries and chiller batteries should be via hinged doors. The doors should be large enough (for example 500mm minimum) to allow easy access. Items requiring infrequent access such as attenuators may be via bolted-on, lift-off panels. All doors and panels should be close-fitting and without leaks.

4.17 Care should be taken during installation to ensure that electrical and mechanical services are not installed in positions that will reduce or impede access.

4.18 It can be difficult to turn off AHUs in order to inspect filters and drainage trays. Viewing ports and internal illumination will therefore facilitate routine inspection of such items. Viewing ports should be at a convenient height so that temporary ladders are not required. Internal illumination should be provided by fittings to at least IP55 rating. Fittings should be positioned so that they provide both illumination for inspection and task lighting. All of the lights in a unit should be operated by a single switch.

4.19 Access to AHUs and items in the distribution system such as filters or heater / chiller batteries should be via fixed ladders and platforms or pulpit-style moveable steps. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow the pulpit steps to be easily wheeled into position.

AHU drainage system

4.20 All items of plant that could produce moisture must be provided with a drainage system. The system will comprise a drip tray, glass trap, air break and associated drainage pipework.

4.21 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent 'pooling', it is essential that the drain connection should not have an upstand; and that a slope of approximately 1 in 20 in all directions should be incorporated to the drain outlet position. The tray must be completely accessible or, for smaller units, easily removable for inspection and cleaning.

4.22 Each drip tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed thus giving an early indication of corrosion, biological activity or contamination within the duct. The trap should have a means for filling and incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting it to the drainage tray should have a continuous fall of not less that 1 in 20.

4.23 Traps fitted to plant located outside or in unheated plant rooms may need to be trace-heated in winter. The trace-heating must not raise the temperature of water in the trap above 5°C.

4.24 Water from each trap must discharge via a clear air gap of at least 15mm above the unrestricted spill-over level of either an open tundish connected to a foul drainage stack via a second trap, or a floor gully (or channel). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish providing each has its own air break.

4.25 Drainage pipework may be thermoplastic, copper or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22mm and a fall of at least 1 in 60 in the direction of flow. It should be well supported and located so as not to inhibit access to the AHU.

Layout of air handling unit

4.26 The AHU should be arranged so that the majority of items are under positive pressure. Any item of plant requiring a drain should be on the positive pressure side of the fan. A recommended layout is given in schematic from in Figure 3.

4.27 A separate extract unit will generally be required for the area served by each supply unit.

4.28 An energy recovery system will normally be fitted between the supply and extract units.

Provision of dampers

4.29 Fire- or smoke-actuated dampers shall be provided at the locations required by Firecode. (See Paragraphs 5.17 - 5.21).

4.30 Motorised low-leakage shut-off dampers should be located immediately behind the intake and discharge of each supply and extract system respectively. They should be of the opposed-blade type, opening through a full 90° and must close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow.

4.31 The quality of motorised dampers is critical. They should be rigid, with square connections fitted with end and edge seals of a flexible material and with minimal play in linkages. The leakage on shut-off should be less than 2%.

4.32 A manually operated isolating damper should be installed between the main AHU and its distribution system to enable the unit to be isolated when cleaning is in progress.

4.33 Good practice will require the fitting of a main volume control damper so that the design airflow rate can be set at commissioning. The damper should be lockable in any position. If it will also be used for plant isolation, it should be capable of being reset to give the design airflow without the need for re-measurement.

4.34 Internal plant isolating dampers or provision for the fitting of shut-off plates between items within a unit are not required.

Vibration

4.35 Vibration from a remote plantroom can be transmitted by the structure of the building, may be regenerated and may sometimes be magnified many times. Units should be selected to have the minimum vibration generation and installed on suitable anti-vibration mounts. Pipe and ductwork should incorporate anti-

vibration couplings, preferably in two planes at right angles, as close to the vibration source as possible. Consideration should be given to the use of anti-vibration pipe hangers and supports.

Sequence of components

4.36 The following arrangement of plant components is typical although in many instances not all elements will be required:

- fresh air intake;
- motorised isolation damper;
- frost / fog coil;
- pre-filter;
- energy-recovery device;
- attenuator;
- fan;
- blast plate;
- attenuator;
- chiller battery;
- eliminator;
- heater battery;
- humidifier;
- final filter;
- isolation / volume control damper.

Note 2: Attenuators may be located in the intake and discharge duct if they are of a suitable type (See Paragraphs 4.159 - 4.162)

There may be instances where the above arrangement is not appropriate and the plant arrangement should be planned accordingly.

Fans

General requirements

4.37 The fan should be selected for good efficiency and minimum noise level, but the overriding factor should be the selection of a fan characteristic such that the air quantity is not greatly affected by system pressure changes due to filters becoming dirty or external wind effects.

Acceptable types

4.38 Fans can be of the axial, centrifugal, cross-flow, mixed-flow or propeller type, depending upon the requirements of the system.

4.39 Where used, centrifugal fans should preferably be of the backward-blade type. Alternatively, where noise levels are more critical and pressure requirements are lower, forward-curved blade fans are acceptable. For high-power applications, aerofoil-blade fans may be appropriate.

Selection

4.40 Generally, large ventilation systems will use centrifugal fans due to their efficiency, non-overloading characteristics, and developed pressures.

4.41 Forward curved centrifugal fans can overload if allowed to handle more air than they are designed for.

4.42 Alternatively, it may be appropriate to use mixed flow fans in high-pressure systems.

4.43 Axial flow or propeller fans are generally only used in local through-the-wall systems, or systems with very low pressure requirements.

4.44 Cross-flow fans have very low operating efficiencies, and thus their use is restricted to applications such as fan coil units.

Location and connection

4.45 Fans are normally positioned to ‘blow through’ the central plant so that the cooling coil and humidifier drains will be under positive pressure.

4.46 The fan performance figures given by manufacturers in their catalogue data are based on tests carried out under ideal conditions, which include long uniform ducts on the fan inlet/outlet. These standard test connections are unlikely to occur in practice, the designer should therefore ensure as far as is practical that the fan performance will not be significantly de-rated by the system. This objective can be approached by ensuring that the fan inlet flow conditions comprise uniform axial flow velocities with low levels of turbulence.

4.47 Where the outlet duct is larger than the fan discharge connections, there should be a gradual transition, with a following section of straight duct, having a length equivalent to three duct diameters.

4.48 The design of the fan intake connection must be carefully considered to avoid swirl in the airstream. When the air spins in the same direction as the impeller, the performance and power consumption of the fan are reduced. When the air spins in the opposite direction to the impeller the power consumption and noise will increase with hardly any pressure increase. Airstream swirl is usually induced by large variations across the fan intake caused by the air passing round a tight bend immediately before the intake.

4.49 Where a centrifugal fan is located with an open intake, the clear distance between the suction opening and the nearest wall should be not less than half the diameter of the inlet. If two fans with free inlets are positioned within the same chamber, their adjacent suction openings should be at least 1 diameter apart.

4.50 Airtight flexible joints should be provided at fan inlet and outlet connections. They should be equal in cross-section to the points of connection and be neither longer than 200mm nor shorter than 100mm.

4.51 For centrifugal fans, a diffuser screen / blast plate should be fitted immediately downstream of their discharge.

Supply fan drive arrangements

4.52 Where the fan drive is via a motor-driven belt and pulley, it should be external to the air stream. This arrangement has the following advantages:

- the fire risk is reduced;
- the drive is visible so it is simple to check that the belt is still there;
- particles shed from the drive belt are outside of the air stream;
- if the belt slips, the “burning rubber smell” is not transmitted down into occupied areas of the premises;
- noise generated by the motor and drive will not be transmitted along the ductwork;
- waste heat is excluded from the system;
- the drive may be through a vee or toothed belt and pulley. The latter have the advantage of eliminating belt squeal on start up and have a longer service life. They are particularly suitable where the fan drive motor is fitted with a soft start and should be located external to the air stream.

4.53 The drive train should be easily visible without the need to remove access covers. Protecting the drive train with a mesh guard is the preferred option. For weatherproof units designed to be located outside, the fan drive will be external to the duct but enclosed. It should be easily visible through a viewing port with internal illumination and access via a lockable hinged door.

4.54 For direct-coupled fan and motor units, the motor should be out of the air stream.

4.55 For induction drive ‘plug’ motor arrangements (where the motor is fitted within the fan and is integral to it) and in line axial fans with a pod motor; the fan / motor combination may be within the air stream provided the motor windings are protected from over temperature by a thermister and lockout relay.

Extract fan drive arrangements

4.56 The preferred method where the fan drive is via a motor driven belt and pulley arrangement will be to locate it external to the air stream.

4.57 The fan drive and motor may be located inside the duct within the air stream provided the motor windings are protected from over-temperature by a thermister and lockout. The drive train should be easily visible through a viewing port, have internal illumination and access via a lockable hinged door.

4.58 Where the system air is explosive, aggressive or has high moisture content, the extract fan motor must be located outside the air stream. This is generally achieved with axial fans by using a bifurcated unit.

Control

4.59 Fans in healthcare applications are normally either single or two-speed. Where there is a requirement for two-speed operation, this is generally via a local user control (for example, in a hood extract system to provide a boost facility) or via a time schedule for energy saving during unoccupied periods.

4.60 Normally only a single motor is required with a standby motor available for fitting as necessary or fitted but not belted. Twin, run and standby motors - with the standby being jockeyed around - are not required.

4.61 Where there is a specified requirement for standby fans, the system should incorporate an automatic changeover facility activated via an airflow sensor. Fault indication should be provided.

4.62 The control of fans in terms of start-up and run is increasingly being vested in computer software. Inverter-drive, variable-speed, soft-start systems are becoming a standard approach. It should be remembered that most healthcare applications require known amounts of air to be delivered while the system is in use. Constant volume systems that deliver specified air-change rates are therefore the norm. Duct- or room-pressure-controlled, variable-speed systems have a very limited application in healthcare.

4.63 It is necessary to ensure that - should the computer control system or its software develop a fault - then the fan can be switched to a direct-start, fixed-speed, manual operation. This is particularly important for critical care systems serving operating suites, high-dependency care units of any type, patient isolation facilities, laboratories and pharmaceutical production suites. Off-site software support is no substitute for the ability of on site staff to override the automatic control and keep the system operating in an emergency. Under these circumstances actions that may shorten the life of the plant are considered of secondary importance to that of preserving the health and safety of patients and staff.

Heater batteries / heater coils

General requirements

4.64 Frost batteries are installed to protect the downstream filters from low-temperature, high-humidity intake air conditions. As they handle unfiltered air they should be constructed of plain tubing without fins and be as near to the outside as possible to minimise condensation during cold weather. Access for cleaning will need to be provided to both sides of the coil.

4.65 Where steam coils are used for a frost battery, they may be constructed using spiral-finned copper tube. As they will be prone to fouling the tube layout and spacing should permit easy access for regular cleaning.

4.66 Main and branch heater-batteries should be constructed of solid-drawn copper-tube coils with copper fins, generally connected in parallel.

4.67 Where there is a wet heating system in the areas served, the main heater-battery should be sized for the ventilation requirements only, and not for the fabric loss.

4.68 Access for cleaning must be provided to both sides of all frost batteries and heater-batteries.

Acceptable types

4.69 Electric, water or steam heater-batteries may be considered. However, electric heater-batteries are expensive to operate and where there are alternatives, their use should be restricted to low-power use (for example trimming control).

4.70 Where steam-supplied heater-batteries are used, their control, venting and trapping systems should be designed so that a vacuum cannot occur within the coil. The condensate drainage arrangements should not allow pressure to build in the main resulting in a back-up of condensate in the coil.

Location

4.71 Where possible, wet-trimmer heater-batteries should be located in plant areas.

4.72 Where it is necessary to locate heater-batteries in false ceilings etc, consideration should be given to the use of electric heaters. If this is not practicable, drip-trays should be installed under both the battery and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. In any event, to facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.

4.73 Auxiliary fan coil units should not be installed in the ceiling above an occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the department that they serve.

Control

4.74 LPHW frost coils should be controlled by an off-coil temperature sensor operating a motorised valve to provide a minimum plant "on temperature" of between 2°C and 5°C. The off-coil temperature of the frost coil is generally sensed by a serpentine thermostat downstream of the coil or upstream of the next plant item. This thermostat will shut the fan down if any part of the air stream is below the minimum set-point.

4.75 Steam-supplied frost coils should be fitted with an on/off control operated by a temperature sensor mounted upstream of the battery. These are normally set to open the control valve fully when the outside temperature drops to +1°C. This will ensure that there is no standing condensate in the base of the coil.

4.76 The main heater-battery should be controlled in the same manner under the dictates of either an off-coil temperature sensor, or a room temperature sensor, depending on the plant configuration and method of control. Trimmer heater-batteries are generally controlled by one or more averaging temperature sensors within the room or rooms in the zone.

4.77 Heater-battery control valves should drive to a closed position on system shutdown or fan failure. The control system should then automatically set to provide frost protection.

Cooling coils

General requirements

4.78 Cooling coils will need to be decontaminated periodically. They must have good access both up and downstream. Hinged access doors with viewing ports and illumination inside the duct should be provided both sides of the coil.

4.79 An eliminator will be required downstream of all cooling coils. The eliminator may take the form of an extension of the coil fins or be a separate device. If a separate device it should be removable as a unit to permit cleaning of the coil face.

4.81 4.80 All cooling coils must be fitted with their own independent drainage system as specified above. A baffle or similar device must be provided in the drip tray to prevent air bypassing the coil. The tray should be large enough to capture the moisture from the eliminator, bends and headers. Where coils are greater than 1m high, intermediate drip-trays will be required.

4.82 Condensate traps manufactured from Borosilicate Glass will allow easy visual inspection and incorporate a self-cleaning smooth non-porous internal surface, complying with ISO 3585 and BS2589 Part 1.

Selection

4.83 Cooling coils supplied with chilled water are the preferred option. For small loads or where chilled water is not available, direct expansion coils may be used.

4.84 Care must be taken in selection to minimise electrolytic action resulting from condensation on the airside. Coils constructed from copper tubes with copper fins extended on the downstream side in the form of an eliminator and electro-tinned after manufacture are preferred. Aluminium fins should only be used if vinyl-coated.

4.85 All parts of the coil and its associated ductwork in contact with moisture must be manufactured from corrosion-resistant materials. Pressed steel coil headers, even if treated, have been shown to be prone to corrosion over time and should not be used. Steel mounting frames and casings present similar problems hence stainless steel is preferred.

Location

4.86 Microorganisms that multiply in moisture cannot be avoided when the coil is dehumidifying. However, locating the final filter downstream of the coils will reduce the risk of infection.

4.87 Cooling coils in AHUs should be located upstream of the final filter.

4.88 Where any cooling coil has to be located above a ceiling, drip-trays should be installed under both the coil and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. To facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.

Control

4.89 There are two basic methods of control for cooling coils:

- off-coil control – used in multi-zone systems or single-zone systems where close humidity control is required, to provide a constant maximum off-plant condition which satisfies the temperature and high humidity requirements of the zone with the highest load;
- sequential control – used in single-zone systems, or multi-zone systems with averaging sensors where close control is not required. A room or duct temperature sensor controls the cooling coil and heater battery in sequence to maintain constant room conditions.

4.90 The advantage of off-coil control is that accurate humidity control can be provided without relying on humidity sensors, which are prone to inaccuracy and drift. Off-coil control is however, expensive to operate in terms of energy consumption, due to the fact that there is no feedback of room loads, and thus

at low loads and in systems where there are large zonal variations, significant over-cooling and reheating will occur.

4.91 On systems with two-speed operating, it is usual to isolate the cooling coil upon selection of low speed. In addition, on system shutdown, low airflow or fan failure, the cooling coil must be isolated.

Humidifiers

Design need

4.92 Humidification was originally required for some healthcare applications in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement.

4.93 Operating-theatre AHUs do not generally require humidifiers but provision for their retrofitting in terms of space provision and a capped drainage system should be provided.

4.94 Where humidification is required, it will be subject to the specific requirements set out below. These are intended to ensure that the unit will operate safely and not become a source of contamination.

General requirements

4.95 The most important requirement for a humidifier is to create complete mixing of the steam with the air. The manufacturers' instructions should be followed regarding minimum distances which should be allowed before bends or other components. This is particularly important with respect to a filter mounted downstream. If it becomes saturated by the humidifier, organisms can grow through the filter and be released into the duct. These may then be carried on the airstream into an occupied space.

4.96 The section of ductwork containing the humidifier may need to be periodically decontaminated. Hinged access doors with viewing ports and internal illumination should be provided. A label warning that the device emits live steam and should be isolated prior to opening should be affixed to the access door.

4.97 All parts of the humidifier and its associated ductwork in contact with moisture must be manufactured from corrosion-resistant materials. Stainless steel is preferred.

4.98 The electrodes of self-generating electrode-boiler type humidifiers should be stainless steel.

4.99 All humidifiers must be fitted with their own independent drainage systems as detailed in Paragraphs 4.20 - 4.25 or 4.72 and 4.87.

4.100 For self- and locally-generated steam humidifiers, the cleanliness of the water supply is essential for their safe operation. Provision should be made for draining down supply pipework and break tanks for periodic disinfection and cleaning during periods when they are not required in service.

4.101 The addition of treatment chemicals for continuous control of water quality for humidifier/air handling units should be avoided. Consideration could be given to installing a UV system to control microbiological growth. Given the limitations of UV systems, however, this will require filtration to high quality to ensure the effectiveness of exposure of organisms to the UV irradiation. As with all water treatment systems the unit should be of proven efficacy and incorporate UV monitors so that any loss of transmission can be detected.

Acceptable types

4.102 Only steam-injection manifold-type humidifiers are considered suitable for use in health building air-conditioning systems. Water humidifiers of any type should not be used.

4.103 Steam may be derived from the central steam supply provided that it does not contain any treatment carry-over, or generated locally either within or adjacent to the humidifier.

4.104 The introduction of steam should be by an appliance specially designed to discharge dry steam into the air-conditioning system without objectionable noise or carry-over of moisture.

4.105 During the design stage, consideration should be given to the proposed methods for the regular cleansing of the humidifier(s) and their components.

Selection

4.106 The number and length of steam-injection manifolds to be used is dependent on various factors such as duct cross-sectional area, air velocity, dry-bulb temperature and manifold design. Guidance from the manufacturer should be followed closely.

4.107 A mains steam humidifier can be noisy and will be difficult to control if it is operated at an excessive steam pressure. It should be sized for an operating pressure of approximately 1 bar. The pipework supplying it should be provided with a dirt pocket, pressure reducing valve and steam trap installed as close as practicable to the humidifier, so that the steam condition at entry is as dry as possible. A temperature switch on the condensate line (or equivalent design provision by the humidifier manufacturer) should be incorporated to prevent 'spitting' on start-up.

4.108 Most operational problems with mains steam humidifiers arise because of back-pressure in the condensate discharge line which will result in flooding into the duct. Unless the condensate from the device can be discharged and collected at atmospheric pressure, it should be discharged directly to drain.

4.109 A local steam generator, where used, must be fed with potable quality water. Additional water treatment to the standard set out above may be required. If the humidifier is unused for a period exceeding 48 hours, it must automatically drain its water content, including that contained in the supply pipework, right back to the running main and leave itself empty.

4.110 Some steam generators are of a type that requires regular cleaning and descaling. The design must allow for them to be installed such that they can be physically isolated from the air duct in order to prevent contamination of the supply by cleaning agents while this is taking place.

Location

4.111 Careful siting of the humidifier injection manifold is required to prevent the steam impinging onto the side(s) of the duct, condensing and generating excess moisture.

Control

4.112 Accurate humidity control can only be provided on single-zone systems, or multi-zone systems with zonal humidifiers. In the above systems, humidity sensors control the humidifier for low-level humidity control, and override the temperature controls to open the cooling coil valve for high-limit humidity control.

4.113 Multi-zone systems are more usually controlled by a minimum humidity sensor located in the supply duct(s) following the last heater-battery.

4.114 Overriding controls separate from the normal plant humidistat should be installed. Their purpose is to prevent excessive condensation in the conditioned space when starting up. A time delay should be incorporated into the humidifier control system such that the humidifier does not start until 30 minutes after the ventilation/plant start-up. In addition, a high-limit humidistat should be installed to limit the output of the humidifier so that the saturation in the duct does not exceed 70%. This humidistat is to control the added moisture. It is not necessary to install a de-humidifier to reduce the humidity of the incoming air if it already exceeds 70%. The humidifier control system should ensure that the humidifier is switched off when the fan is not running.

4.115 On systems with two-speed operating, it is usual to isolate the humidifier upon selection of low speed. In addition, on system shutdown, low airflow or fan failure, the humidifier should be isolated.

Filtration

General requirements

4.116 The purpose of filtration is to reduce the level of airborne contamination in an air stream. It is generally carried out in stages.

4.117 Filters must be securely housed and sealed in well-fitting frames that minimise air by pass. Air by pass significantly reduces filter efficiency, the higher the filter grade the greater the effect. Mounting frames should be designed so that the air flow pushes the filter into its housing to help minimise air bypass. Mounting frames that withdraw so that the filter can be changed without having to reach into the unit are preferred.

4.118 Neither the filter media, nor any material used in the construction of the filters, should be capable of sustaining combustion. The filter media should be such that particles of it do not detach and become carried away by the airflow.

4.119 Filters need to be readily accessible for replacement so a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.

4.120 All filters should be provided with a means of visually checking the differential pressure across them. Direct-reading dial-type gauges marked with clean and dirty sectors are preferred.

4.121 A complete spare set of filters must be provided at handover.

Definition of filter terms

4.122 Particulate air filters are divided into four categories:

- general ventilation filters grades G1 to G4;
- fine filters grades F5 to F9;
- high efficiency particulate filters (HEPA) graded H10 to H14;
- ultra-low particulate air filters (ULPA) graded U15 to U17.

4.123 General filters are graded in terms of their ‘Synthetic dust weight ‘Arrestance’. This represents the percentage of a test dust captured by a filter. ‘Arrestance’ provides a good indication of a filter’s ability to remove the larger, heavier particles found in outdoor air. These are of a size to block finned batteries and large enough to settle out in the air distribution system.

BS EN 779 grade (Eurovent grade)	% Arrestance	Notes and typical healthcare application
G1 - (EU1)	< 65	Metal mesh grease filter
G2 - (EU2)	65 to < 80	Coarse primary filter
G3 - (EU3)	80 to < 90	Primary air intake; return air; energy recovery device protection
G4 - (EU4)	> 90	General purpose tempered air supply

Table 4: General Filters

4.124 Fine filters are graded in terms of their ‘Atmospheric dust spot Efficiency’. This is a measure of the filter’s ability to remove the very fine staining particles found in outdoor air. It will indicate how ‘visibly’ clean a filter will keep a ventilated space. The staining particles are approximately the same size as most

common bacteria so it is also a rough measure of the filter's ability to remove microorganisms.

BS EN 779 grade (Eurovent grade)	% Efficiency	Notes and typical healthcare applications
F5 - (EU5)	40 to 60	General purpose panel / bag filter
F6 - (EU6)	60 to < 80	Basic grade bag filter
F7 - (EU7)	80 to < 90	Medium grade bag or pleated paper Conventional operating theatre supply air
F8 - (EU8)	90 to < 95	High grade bag or pleated paper
F9 - (EU9)	> 95	Basic HEPA filter – Level 8 clean rooms

Table 5: Fine Filters

4.125 High efficiency filters (HEPA and ULPA) are graded in terms of their ability to capture their 'Most Penetrating Particle Size' (MPPS). High-efficiency filters self-select the particle that they are least able to trap, hence the MPPS. They are then tested against that size of particle. These filters are designed to provide very high-efficiency filtration of particles in the sub-micron size range.

BS EN 1822 grade (Eurovent grade)	% Efficiency @ MPPS	Notes and typical healthcare application
H10 - (EU10)	85	Ultra-clean theatre terminal
H11 - (EU11)	95	
H12 - (EU12)	99.5	
H13 - (EU13)	99.95	
H14 - (EU14)	99.995	Pharmacy aseptic suite Category 3 room extract
U15 – U17	-	Not generally used in healthcare

Table 6: High Efficiency (HEPA) Particulate Filters

Selection primary filters

4.126 All filters should be of the dry type. Panel filters are cheap and disposable with relatively low dust-holding capacity. They are generally used as pre-filters to eliminate large particles that would otherwise clog or cause damage to the fan and finned heating and cooling batteries. Stainless steel frames that hold disposable pre-cut filter pads are preferred.

4.127 General ventilation supply plant should incorporate primary air filters of grade G3, sized for a maximum face velocity of 2.0 m/s. Additional coarse pre-filters may be justified where the intake air is exceptionally polluted. They are sometimes fitted as a temporary measure when building work is being carried out in the vicinity of the air intake.

Secondary filters

4.128 Where a higher standard of filtration is required, secondary bag or pleated paper panel filters would be used. Rigid frame filters incorporating pleated

A47310563

paper elements are preferred over bag filters for critical care applications such as operating theatres.

4.129 In urban or other areas of high atmospheric pollution, a higher standard of filtration may be justified to reduce the level of staining to internal finishes.

Extract air filters

4.130 Extract filtration will generally only be required where heat-recovery devices are installed. There are a very limited number of specialised applications (microbiological safety cabinets and similar LEV systems) where contaminated air is required to be filtered prior to discharge to atmosphere. If it is safe for staff to work in a room without wearing respiratory protective equipment, it is safe to discharge the room air to atmosphere without filtration.

Return-air filters

4.131 They are used to reduce the load on HEPA filters in recirculating applications such as Ultra Clean operating suite ventilation canopies and pharmacy aseptic suites.

High-efficiency filters – HEPA and ULPA

4.132 HEPA filters are expensive so their use should be kept to a minimum. Applications requiring HEPA filters include the air supply to aseptic suites in manufacturing pharmacies, the discharges from microbiological safety cabinets and isolation facilities.

4.133 If used, HEPA filters should be of the replaceable panel type with leak-proof seals. They should be installed in a manner that permits on-site validation of the filter and its housing. This may involve the release of a Dispersed Oil Particle (DOP) challenge smoke through an injection point upstream of the filter and a measurement of the DOP penetration across the downstream face. Alternatively a particle-counting method may be used.

4.134 HEPA filters are sometimes fitted in extract systems to capture hazardous substances or organisms. Design provision must be made for the subsequent safe handling of contaminated filters by maintenance staff. This may be achieved by:

- sealing the hazardous substance into the filter before it is removed;
- providing a system to fumigate the filter to kill any organisms;
- housing it in a ”safe change” unit that permits the filter to be ejected into a bag and sealed without staff having to come into direct contact with it.

4.135 In view of the costs and problems associated with placing HEPA filters in extracts, it is recommended that a full risk assessment be carried out at the design stage. This should include defining the true need for HEPA filters in an

extract; validation of its performance at installation; the method of safely changing a contaminated filter; and its subsequent disposal.

4.136 ULPA filters are very expensive and are designed to remove particles below a size that are either surgically or aerobiologically significant. There would have to be exceptional circumstances in order to justify their use in healthcare ventilation systems.

Activated carbon filters

4.137 Activated carbon filters are able to remove gases and vapours from an air stream and are graded according to the range of substances they can remove. They are not normally fitted in air-conditioning supply systems.

4.138 They are occasionally fitted retrospectively because the main air intake has been poorly sited and is drawing in traffic fumes. Where used they must be protected by a particulate air filter.

4.139 Activated carbon filters are more commonly used in specialised fume extraction systems when the location of the discharge means that dilution cannot be relied upon to disperse noxious fumes.

Location

4.140 The primary filter should be positioned on the inlet side of the supply fan, downstream of the frost coil. The secondary filter, when fitted, should be on the positive-pressure side of the fan. This will prevent air being drawn into the system after the filter and capture any particles shed by items of equipment within the AHU.

4.141 The filter installation must be arranged to provide easy access to filter media for cleaning, removal or replacement, with side or front withdrawal as required.

Control

4.142 Differential-pressure transducers should be provided to monitor and alarm remotely on excessive filter pressure drop. In critical areas dirty-filter indication lights should be provided at the point-of-use.

Energy-recovery

General requirements

4.143 Energy recovery will normally be fitted to all healthcare ventilation systems. It may be omitted only where it would clearly be uneconomic. Where the economic case is marginal, space should be allowed for the retrofitting of an energy recovery system.

4.144 For systems in healthcare premises, a plate heat exchanger or ‘run-around coil’ system is suitable. Thermal wheels may be used providing they are fitted with a

purge sector. The small amounts of air leakage across those devices are not considered significant. Other systems such as heat pumps or heat pipes are

also suitable. Selection should be based on relative locations of the supply and extract units, ease of maintenance and practicality. Cleaning access will be required to both sides of any energy-recovery device.

4.145 The following are the minimum energy transfer efficiencies required for devices handling equal air volumes:

- run-around coil – 45%;
- plate heat exchanger – 50%;
- thermal wheel – 65%;
- any other energy-recovery device – 50%.

4.146 If a plate heat exchanger is chosen, the plates should be constructed of metal. Plastic should not be used for internal bypass dampers and drive gears.

4.147 Whichever energy-recovery device is chosen the extract side will need to be protected by a G3 filter and provided with a drainage system as described in Paragraphs 4.20 - 4.25, to remove condensate.

Location

4.148 Energy-recovery devices should be located downstream of the frost battery and pre-filter, prior to the cooling coil or main heater battery on the supply side.

Control

4.149 It is essential to consider the control of both the energy recovery device and the frost battery when assessing the economics of recovery, as all energy provided by the frost battery will directly reduce the heat exchange of the recovery device. To this end, the off-coil setting of the frost coil should be the minimum possible to protect the primary filter (for example +2°C).

4.150 The energy-recovery device should be controlled in sequence with the main heater battery, and should incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the required plant set point.

4.151 In instances where the plant is cooling the air, it may be possible to remove heat from the supply air at high ambient conditions, under the dictates of enthalpy sensors in the intake and extract ducts.

Attenuation

General requirements

4.152 Noise will be generated in an air distribution system by the fan, plant items and airflow. The ductwork is a very effective transmitter of this noise hence there is generally a need to limit the noise transmission to meet the requirements of the building. This normally involves the provision of sound attenuation treatment as part of the overall ductwork system design.

4.153 A thorough assessment of the design should be made to assess the noise impact. This should take into account the following primary factors:

- fan- and plant-noise generation;
- air-flow generated noise in ductwork fittings and dampers;
- noise generated at grilles, diffusers and other terminals;
- noise break-in and break-out of ductwork;
- cross-talk and similar interference;
- the noise limitations for the building and surrounding areas;
- external noise generation.

4.154 A method of assessment of these factors and the sound attenuation requirements of ductwork systems is given in CIBSE Guide B.

4.155 The fan is usually the main source of system noise. The sound power that it generates varies as the square of the fan pressure, and thus to limit the fan noise level the system resistance should be kept as low as economically possible. As a general rule the selected fan should operate close to its point of maximum efficiency to minimise its noise generation. Where there is disturbance to the airflow at the fan inlet, the manufacturer's stated fan noise levels should be increased by up to 5 dB(A). More precise guidance on this aspect may be available from the manufacturers.

4.156 Fans radiate noise through both the inlet and outlet connections and it may be necessary to provide attenuation to limit the noise from both of these connections. It is always preferable and more economic to control noise and vibration at source, or as close to source as possible. It should be noted that attenuators offer a resistance to airflow. The resistance must be included in the fan and ductwork calculations.

4.157 Provided care is taken in the design and construction of low-pressure systems to avoid significant noise generation in the ductwork, attenuation should only be needed to absorb fan noise.

4.158 Noise breakout from all equipment housed in the plantroom must be taken into consideration if control is to be satisfactory. Any ductwork within the plantroom after the silencer should be acoustically insulated to prevent noise break-in or the silencer relocated at the point of entry or exit of ductwork to and from the plant room.

4.159 There is no complete means of control over external noise generation from such as road traffic, aircraft, factory and community noise. Consideration must be given to this at the design and planning stage.

Acceptable types and location

4.160 The noise levels produced by ventilation and other plant should be reduced by either lining the inside of the duct with sound-absorbing material or fitting bespoke attenuator units.

4.161 In supply systems, sound-absorbing material should not be applied to the inside surface of a duct system downstream of the final filter, owing to the risk of mechanical damage and the subsequent dispersal of the media into the ventilation system.

4.162 In supply and extract systems, sound-absorbing material must not be applied to the inside of a duct within 1 metre of a fire damper. The material should be non-particle-shedding and fire-resistant (further guidance can be found in SHTM Firecode suite of documents). Where sound-absorbing material is applied in a section of duct that will be routinely exposed during maintenance activities it should be protected from mechanical damage.

4.163 Bespoke attenuator units with a sound-absorbing infill suitable for the quality of air being handled and protected by a perforated sheet metal casing are the preferred option for critical systems. Absorption of moisture, dirt and corrosive substances into the ‘in-fill’ and the release of fibrous particles into the airstream should be prevented by the use of a membrane. The membrane material should have a declared service life of at least 25 years. If these conditions can be met then the attenuator may be located in the supply ductwork downstream of the final filter. When so located, cleaning access should be provided at both ends of the attenuator unit.

5. Air distribution system

Air distribution arrangements

Ductwork distribution systems

5.1 Ductwork systems for ventilating and air-conditioning applications are referred to by their velocity or pressure category, that is, as low, medium or high velocity (or pressure) systems. Heating & Ventilating Contractors Association (HVCA) limits are up to 10 m/s or 1,000 Pa; 20 m/s or 1,750 Pa: and 40 m/s or 3,250 Pa in the case of conventional low, medium and high pressure systems respectively. High-pressure systems are disappearing because of the constraints of the Building Regulations but existing systems may sometimes need to be altered or extended.

5.2 For normal applications in healthcare buildings, low velocity systems are recommended. The use of higher velocities than those recommended is not likely to be economical. Future trends are likely to be towards even lower optimum duct velocities; however, velocities below 2 m/s are unlikely to be justified.

5.3 The site will often dictate the main routing of ductwork systems, but in general, the design should seek to make the layout as symmetrical as possible; that is, the pressure loss in each branch should be as nearly equal as possible. This will aid regulation and may reduce the number and variety of duct fittings that are needed.

5.4 Main distribution ductwork should not be routed above sleeping areas. Where there is no alternative route, additional acoustic insulation will be required.

5.5 Where auxiliary cooling units, fans, filters or trimming devices are installed in the distribution system, they must be independently supported and fitted with a suitable drainage system where appropriate. If they are a source of vibration they should be linked to the distribution ductwork via flexible connections.

5.6 The fan of a Local Exhaust Ventilation (LEV) system provided under the COSHH Regulations should be located outside of the building so that all of the ductwork within the building is under negative pressure. Where the fan has to be within the building it should be located as close as practicable to the outside with an absolute minimum run of discharge ductwork within the building. The discharge ductwork within the building will be under positive pressure so it must not be penetrated by test holes or inspection hatches.

Ductwork materials and construction

5.7 The choice of duct material should take account of the nature of the air or gas being conveyed and the environment in which the duct will be placed.

5.8 Galvanised-sheet-steel is generally suitable and most economical for normal ventilating and air-conditioning applications. Its inherent mechanical strength renders it resistant to casual damage both during the construction phase and throughout its service life when mechanical and electrical services around it are altered. It also readily withstands the impacts sustained when rotary equipment is used to for internal cleaning.

5.9 In instances where moisture levels and/or corrosive elements in the air being conveyed are very high, aluminium, stainless steel, PVC or GRP (glass-reinforced plastic) ducts should be used. Stainless or black steel are the only suitable materials for high-temperature ductwork.

5.10 In inherently wet areas, such as the base of fresh air inlet ducts and some extract systems, the ductwork may require draining to prevent a build-up of standing water. The layout of the drains should be as specified in Paragraphs 4.20 - 4.25.

5.11 Where builderwork plenum chambers or ducts are used, these may be constructed of various materials. However all such ducts must be rendered and sealed to prevent dust shedding. A greater allowance may need to be made for leakage.

5.12 Galvanised, black and stainless steel ductwork should be manufactured and installed to the current HVCA specification for sheet metal ductwork DW144, but excluding the use of bolt-through supports.

5.13 GRP and PVC ductwork should be manufactured and installed to the current HVCA specification for plastic ductwork DW154.

5.14 Where phenolic-board ductwork is considered, care should be taken to ensure that it is fabricated to a quality standard and installed strictly in accordance with the manufacturers' instructions. Its pressure rating and degree of support should be suitable for the application and ducts should be fitted with mechanical protection where required. Designers should be fully conversant with installation techniques and Installers should be experienced having received training in the techniques required and certified to this effect by the manufacturers. Due consideration should be given to the impact on ductwork pressures created by the closing of dampers. Phenolic-board ducting should not be installed in plant rooms or any other areas where it could be vulnerable to impact damage. Internal cleaning using mechanical (rotary) means is also liable to cause damage to the integrity of surfaces.

5.15 Flexible ductwork is unsuitable for air distribution in healthcare applications. It should only be used to make the final connection to a terminal (See Paragraphs 5.54 and 5.55).

5.16 The inside of the ductwork should be free from structural projections and as smooth as possible. Flanged, gasketed joints are preferred.

Fire aspects, damper types and locations

5.17 It is essential that all relevant fire aspects of ducting systems are agreed with the fire officer before the design is finalised.

5.18 Ductwork must be fire-stopped where it penetrates fire compartment walls, floors and enclosures, cavity barriers and sub-compartment walls or enclosures, and provided with weatherproof collars where roofs or external walls are penetrated.

5.19 Fire/smoke dampers shall be provided at the locations required by SHTM Firecode. The fire-damper mounting frame must be securely attached to the building fabric. Where a fire-damper is not mounted directly in a fire compartment wall, it must be correctly supported and the ductwork between it and the firewall must posses the same fire rating as the firewall that it penetrates. The fire-rated portion of ductwork must not be penetrated by test holes or inspection hatches. All fire/smoke dampers shall be capable of remote re-setting via the Building and Energy Management System (BEMS) or equivalent, after periodic testing procedures.

5.20 An access hatch shall be provided adjacent to each fire damper so that its correct operation can be directly observed.

5.21 Smoke-diverting dampers must be provided on recirculation air systems to divert automatically any smoke-contaminated return air to the outside of the building in the event of a fire; and arranged so that the normally open smoke-diverting damper on the return-air branch to the input unit closes and all the return air is exhausted through the extract fan. Guidance is available in SHTM 81 and BS5588: Part 9.

Duct sections

5.22 Ducting is generally available in rectangular, circular and flat oval sections, although other sections may be made for special situations.

5.23 Rectangular ducting is most common on low-pressure systems, for the following reasons:

- it can readily be adapted to fit into the space available;
- fittings are cheaper than those for circular or flat oval ductwork;
- it can readily be joined to such component items as heating and cooling coils, and filters.

5.24 When sizing ductwork, the designer should take into account:

- both installation and operating costs;
- space limitations imposed by the structure and other services;
- operating noise levels;

- requirements of regulation at the commissioning stage.

5.25 For overall economy and performance, the aspect ratio should be close to 1:1, since high aspect ratios increase the pressure loss, heat gains or losses and overall cost (for example, changing the aspect ratio from 1:1 to 1:4 can typically increase the installed cost of the ductwork by 40% and add 25% to the heat gains or losses).

5.26 Rectangular ducting should not be the first choice for high pressure systems, and should be avoided in systems operating at high negative pressures, because the strengthening of the flat sides and the sealing requirements necessary to make rectangular ducts suitable for these high pressures are costly.

5.27 Circular ducting is preferable for high-pressure systems, and for systems operating at high negative pressures. In the case of the latter, additional stiffening rings may be necessary. Machine-formed spirally-wound ducting and a standard range of pressed and fabricated fittings can sometimes make circular ducting more economical, particularly in low pressure systems having a relatively low proportion of fittings.

5.28 Flat oval ducting provides an alternative to circular ducting, principally where there is a limitation on one of the dimensions in the space available for the duct run.

5.29 Other sections may be used, such as triangular sections to pass through roof trusses. Such sections present difficulties in the provision of fittings, and connections to standard plant items, and are likely to be more expensive than traditional sections.

Standard ductwork fittings

5.30 All fittings should conform to current HVCA specification DW144. Wherever possible, long radius bends, large radius main branches, not more than 45° angle sub-branches and long-taper transformations should be used.

5.31 Fittings should be arranged with vanes in sub-branches connected directly to grilles and diffusers, and turning vanes in square bends (when used). When vanes are used, additional cleaning access will be required.

5.32 The number of duct fittings should be kept to a minimum and there should be a conscious attempt to achieve some standardisation of types and sizes. Increasing the number and variety of fittings in a system can markedly raise its overall cost.

5.33 Bad design in relation to air flow can lead to vibration of flat duct surfaces, increases duct-generated noise and pressure loss, unpredictable behaviour in branch fittings and terminals, and adverse effects on the performance of installed plant items (such as trimmer batteries).

Branches

5.34 There are many designs of branches and junctions in use. The important features are that the flow should be divided (or combined) with the minimum interference and disturbance. Changes in duct sizes should not be made at the branch but a short distance downstream (or upstream). A good dividing branch design cannot be effective if the flow entering the branch is not uniform across the section.

Changes of section

5.35 The expansion of a duct section should be formed with sides having a total included angle of no more than 30°, and preferably less than 20°. If the angle of expansion is greater, the flow is not likely to remain attached to the walls of the duct and large eddies will be formed with flow reversal at the walls. This leads not only to a high-pressure loss, but also to non-uniform velocity pattern at the outlet. Where there is insufficient space for a gentle expansion and a greater angle is necessary, internal splitters should be used.

5.36 A contraction in a duct section is less critical, but the total included angle of the taper should not exceed 40° (or 20° where the contraction is made on one side of the duct only)

5.37 The most economical way to change the section of a rectangular duct is to restrict the change of duct size to one side only. If the calculated reduction or increase to the side dimension is 50mm or less, it is usually not economical to change the size at the position. The minimum size of a rectangular duct should usually be 150mm x 100mm.

Other fittings

5.38 As a general rule, fittings should avoid abrupt changes in direction and also sharp edges that cause the flow to separate and form eddies, thus limiting pressure loss and causing noise generation. If the fitting leads to the flow preferentially attaching to one side of the outlet, then a significant length of straight downstream duct is necessary before the next branch or fitting; this length should be greater than five equivalent diameters.

Thermal insulation

5.39 Thermal insulation is applied to ductwork to reduce heat exchange, and to prevent condensation.

5.40 In a duct system, the air temperature changes can be significant, especially when passing through untreated space, and these have the effect of reducing the heating or cooling capacity of the air and of increasing the energy input to the system. The heat transmission to and from the surrounding space can be reduced by effective insulation of the ducts. Extract ductwork conveying air from which heat recovery will be derived should be thermally insulated to the same standard as with associated supply ventilation ductwork.

5.41 Condensation can arise in ductwork systems conveying cooled air and, apart from creating conditions conducive to corrosion of ductwork, condensation affects the heat and vapour-resisting properties of insulating materials themselves which may induce further condensation.

5.42 In normal circumstances, the insulation thickness for heat resistance is sufficient to prevent surface condensation, but in extreme conditions the insulation thickness for vapour resistance may be greater than that for heat resistance. When cold ducts pass through areas of high dew-point, carefully selected vapour barriers should be applied externally to the insulation.

Noise generation within the ductwork

5.43 Noise is generated in ductwork at sharp edges, by tie rods, damper blades, duct obstructions and sharp bends etc. This air-flow-generated noise becomes an important factor if it is about the same or greater level than the upstream noise level. (Air-flow-generated noise is often referred to as “regenerated noise”).

5.44 The noise level generated by airflow in ductwork is very sensitive to the velocity. The sound power of this noise is approximately proportional to the sixth power of the velocity; that is, a doubling of the duct velocity will increase the sound power by a factor of 64. The duct velocities should therefore be kept as low as possible. In general, duct fittings that have lower pressure loss factors in similar flow conditions will generate less noise.

5.45 Ductwork serving quiet areas should not be routed through noisy areas where noise break-in can occur and increase the noise level in the ductwork.

5.46 Grille, register and louvre noise should be kept to the minimum by selecting types having low noise-producing characteristics, without high tonal noise, and should be fitted with acoustically treated external inlet and outlet louvres.

5.47 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. They will normally be of the ‘through-the-ceiling, ‘up-and-over’ type and may include a fire damper if required.

Volume control damper locations

5.48 Manually operated balancing dampers are needed generally:

- in the main duct downstream of the fan;
- in branches of zone ducts;
- in sub-branch ducts serving four or more terminals;
- at terminals not covered by the previous item.

5.49 Dampers integral with terminals should only be used for final trimming of air volumes, otherwise noise and air distribution problems may ensue.

5.50 Dampers in rectangular ducts should be single-bladed when the longer side is up to 450mm but be of the opposed-blade multi-leaf type above this size. In circular ducts, iris-type dampers are recommended. Dampers must be accessible, incorporate a position indicator and means of locking in the commissioned position. Dampers should be located as far away as possible from adjacent branches or plant items.

Cleaning and access door locations

5.51 Cleaning and access doors are required to facilitate access to plant items and ductwork components for inspection, maintenance, cleaning and replacement, and must be of sufficient size to permit safe access for the required functions. Consideration should also be given to the number of doors to be provided. Older installations may be deficient in the provision of access doors and consideration will be necessary to have these incorporated in the course of any refurbishment in the accommodation served.

5.52 Recommended locations for access doors are given in the current HVCA specification DW144 and are generally provided to give access to:

- every regulating damper;
- every fire and motorised damper;
- filter (to facilitate filter withdrawal);
- both sides of cooling/heating coils;
- humidifiers;
- fans; and
- motors and impellers.

5.53 Care should be taken when siting access doors to ensure that no other services to be installed will prevent reasonable access.

Flexible ducting

5.54 Flexible ductwork may be used for final connections to grilles and diffusers provided it is constructed to meet the fire precautions recommended in BS8313. It must not pass through fire compartment walls, floors or enclosures of sub-compartment walls or enclosures, or through cavity barriers.

5.55 Flexible ducting will cause a significant frictional loss and may be difficult to clean and should never be used in lieu of a bend. Where installed it should take the most direct route and be as short as possible, never exceeding 1 metre in length.

Diffuser and grille selection and sizing

5.56 The effectiveness of all ventilation and air-conditioning systems depends on the methods by which air is introduced to, and vitiated air is removed from, the

space. The usual results of poor air-terminal selection and/or positioning are: draughts, stagnation, poor air quality, large temperature gradients and excessive noise.

5.57 Air can be supplied to a space in a number of ways, although any device can be broadly placed into one of two categories: that producing a diffused supply, or that producing a perpendicular jet. Diffusers may be radial or linear, and normally utilise the Coanda effect (that is, adhesion of the air stream to an adjacent surface), to reduce the risk of excessive room-air movement. A perpendicular jet is formed by discharging air through grilles, louvres or nozzles, which are generally adjustable.

5.58 Air-flow patterns produced by both types of terminal are dependent to a large extent on the presence of the Coanda effect.

5.59 Supply air terminals can be incorporated into any room surface, for example, floors, walls (high or low level), desktop etc.

5.60 As they operate on the jet principle, the use of sidewall and linear grilles is restricted to areas where air change rates are low, that is, less than 10 per hour. Perforated rectangular diffusers can provide acceptable conditions within the occupied zone at up to 15 air changes per hour. In areas where a higher air change rate is required, square or circular ceiling mounted diffusers should be used.

5.61 The performance of supply air terminal devices is provided, based on three criteria: throw, spread and drop.

- **throw** is defined as perpendicular or parallel distance from the terminal to the point at which the air velocity is 0.5 m/s isovel;
- **spread** is defined as the width of the 0.5 m/s isovel; and
- **drop** is defined as the vertical distance from the centre line of the terminal to the bottom edge of the 0.25 m/s isovel.

5.62 It is necessary to consider each of these parameters in both summer and winter conditions to ensure satisfactory operation of the air-terminal device, as warm jets behave very differently from cold jets.

5.63 A warm jet tends to rise until it attaches itself to a horizontal surface, while a cold jet falls. Care must be taken to ensure that this does not lead to unacceptable temperature gradients in winter or excessive air velocities in the occupied zone in summer.

5.64 In order to ensure satisfactory air movement within a space, it is necessary to consider interaction between air movement from adjacent terminals, and ceiling mounted fixtures (light fittings etc), as well as interaction between air movement and room surfaces.

5.65 If the supply and extract terminals are too close, short-circuiting may occur, while if they are too far apart, stagnant zones may be formed. Where two

opposing air streams meet, the individual velocities must not be greater than 0.25 m/s.

5.66 Supply and extract grilles and diffusers should be fitted with opposed-blade dampers for fine balancing purposes.

5.67 Further guidance on the selection of grilles and diffusers is given in the CIBSE Guide B.

5.68 In operating theatres, the supply terminals must be able to produce a down-flow movement of air in the operating zone 1 metre above floor level. Ceiling mounted diffusers with fixed directional vanes that provide a downward turbulent airflow are the preferred option. Plenum boxes fitted with perforated screens to produce a parallel downward flow are also acceptable. Nozzles or jets of any type are not acceptable. Sidewall-mounted linear diffusers that utilise the Coanda effect to send air across the ceiling and 'drop' it into the operating zone are also not suitable. However linear ceiling mounted diffusers that provide a direct downward airflow around the operating zone may be used.

Transfer grille - size and location

5.69 Air-transfer grilles in walls, partitions or doors form an integral part of the building's air distribution system. Modern doorsets have very low leakage rates so cannot be relied upon to permit even quite small airflows. Failure to make adequate provision for air to move from room to room will result in excessive pressure differentials and 'door whistle'.

5.70 Transfer grilles are required in locations where there is a significant imbalance between the supply and extract rates in a room. They will relieve any pressure differentials that may affect the operation of the spaces and/or the ventilation system and permit airflow in a known direction. However, transfer grilles are vulnerable to damage and, in many instances, as long as the equivalent free area is provided, they can be substituted with undercut door.

5.71 Care needs to be taken to ensure that the positioning of transfer grilles does not interfere with the fire or smoke integrity of the building. In general, the air-transfer grilles should not be installed within fire-resisting boundaries, although if this is unavoidable, they should be fitted with fire- or smoke-dampers.

5.72 Where installed, transfer grilles should be of the non-vision type, sized for a maximum face velocity of 1.5 m/s.

5.73 In photographic dark rooms, lightproof transfer grilles will be required.

5.74 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. (See also Paragraphs 5.43 - 5.47).

Pressure stabilisers - size and location

5.75 Pressure stabilisers are required in lieu of air-transfer grilles in areas where it is necessary to maintain pressure differentials between adjacent rooms to prevent reversal of airflows for example, in operating suites, isolation facilities and clean rooms. (See also Paragraphs 7.24 - 7.28).

5.76 Fire precautions for pressure stabilisers are the same as for transfer grilles. For sizing criteria, refer to Paragraph 7.23

5.77 Pressure stabilisers should be of the balanced-blade type, with the facility to make fine adjustment of the pressure setting. They should be silent in operation and give a seal as tight as practicable when closed. The materials of construction and method of assembly should allow for cleaning and disinfection.

5.78 Pressure stabilisers should be installed in a visible location so that their operation can be readily observed.

5.79 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where confidentiality is required. In these cases, the pressure stabiliser and cross-talk attenuator should be mounted in a short length of ductwork within the ceiling void.

5.80 Pressure stabilisers may need to be fitted with a stand-off baffle on their discharge side to prevent a sight line in situations where a laser will be used. Baffles may also be required to preserve privacy or prevent discharge air causing draughts or disturbing the air distribution pattern in the adjoining room. They are also useful in low-level locations to prevent the airflow path being obstructed by portable equipment.

6. Automatic controls

6.1 Various options for control of single and multi-zone air-conditioning systems are given in CIBSE Guide B.

General requirements

6.2 The basic requirements for an automatic control system are as follows:

- facilities to start, set-back and stop the plant;
- facilities to control the volumetric air-flow;
- facilities to control the system or room pressure;
- temperature control and indication;
- humidity control and indication;
- devices to monitor and indicate the plant's operating state;
- alarms to indicate plant failure, low air-flow, and filter state.

The control functions actually provided will depend on the purpose of the ventilation system.

6.3 There will also be a need to determine the control strategy in the event of a fire either within the zone being served or within an adjoining zone.

6.4 The designer should consider whether it is necessary for the supply and extract fans to be interlocked, either so that the supply fan will not operate unless air-flow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served.

6.5 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratory and pharmacy areas that also contain fume cupboards, safety cabinets and other LEV systems.

6.6 Alarms should be provided to show 'filter fault' and 'low air-flow'. The "filter fault" alarm should be initiated by a predetermined increase of pressure differentials across the filter. The 'low air-flow' alarm should be initiated when the supply air quantity falls to 80% of the design value.

Objectives of control system

6.7 The primary objective of ventilation plant control system is to maintain the space served within the required environmental control limits, at the appropriate times, regardless of external conditions or internal loads and with the minimum energy consumption.

6.8 Often, it is not possible to predict accurately building load variation at the design stage, and thus optimum set points cannot be assessed. Information provided by monitoring the operation of the plant via a Building and Energy Management System (BEMS) will enable optimum set points to be established and energy consumption reduced. Control of most systems will be via a BEMS. This will enable the operating conditions and control tolerances to be set and monitored. The BEMS may also be set to log the actual energy consumed by the system together with that recovered by the energy-recovery device. This will provide a useful check on overall operating efficiency and provide evidence that energy targets are being achieved.

6.9 BEMS incorporating self-adaptive control algorithms that automatically adjust the set-point to the suit the usage and load are preferred. The provision of movement sensors within the controlled space in order to determine the actual occupancy will facilitate this process.

6.10 The failure of specialised ventilation systems can have grave consequences for the delivery of healthcare. Control systems should therefore be simple, robust and reliable.

6.11 Computer-software-driven control systems are becoming the norm in building services. However, it should be remembered that healthcare ventilation systems need to be available to operate outside of normal working periods when software support is not available. Should the software fail, it will be left to site staff, who may have little knowledge of the control algorithms to restart the ventilation system. It is therefore essential to ensure that a simple means of re-starting critical systems in the event of a software failure is provided (see also Paragraphs 4.62 - 4.63)

Location of controls

6.12 Whether within the plant, duct or room, sensors should be located to provide accurate measurement of the condition of the air being monitored.

6.13 Sensors and control items such as control valves should be located close to the element being sensed or plant item being controlled, in order to minimise time lags within the system which may create over-shoot of conditions beyond the design envelope and result in additional energy consumption.

6.14 There are practical advantages in locating all control valves for an air-handling unit in a bank (at a convenient height) at one end of the unit. (This will not normally result in an undue additional control lag.)

6.15 Some applications require intermittent mechanical ventilation, frequently at a high air-change rate, (for example, in bathrooms and treatment rooms.) Local controls to facilitate this mode of operation should be placed in a prominent position to encourage economical use.

6.16 Local controls that enable the user to select more than one mode of operation should be clearly labelled to identify the particular mode selected. Where the system allows different room pressures to be selected then a direct-reading

pressure gauge should be fitted within the eye line of the users to provide an independent confirmation of the resultant mode of operation. A clear description of the selectable modes of operation should be mounted adjacent to the control switch.

Fire aspects

6.17 A fire control panel should be mounted at the entrance of the area that the ventilation serves. The panel should have restricted access for the fire officer and include independent on/off controls and indication of the supply and extract systems.

6.18 In certain critical care departments it is preferable to maintain the supply ventilation in case of a fire within the area. For example, in an operating department, while undergoing surgery, the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department, or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke. This will allow time for the patient to be stabilised so that he/she can be safely evacuated if necessary. A similar situation occurs for patients in ITU and other critical care units. In all of these cases the ventilation to the critical area should continue to operate unless the AHU starts to draw in smoke. For these departments, a notice should be affixed to the fire control panel drawing attention for the need to liaise with departmental staff before switching off fan units.

6.19 All supply AHUs should have a smoke sensor mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the supply air fire damper to close and shut down the AHU.

Time switching

6.20 Facilities to start, set-back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location, for example, at the reception or staff base or, in theatres, within the Surgeon's Panel.

6.21 Many ventilation systems may be completely shut down when the area served is not in active use. Alternatively, where there is a need to maintain a background condition, the ventilation output can be reduced by "setting back" the system. This will significantly reduce energy consumption and extend the life of filters and other system components.

Start-up control

6.22 The plant's start control should contain a control logic that will start the plant in the sequence set out in the following algorithms, Figures 2 - 5

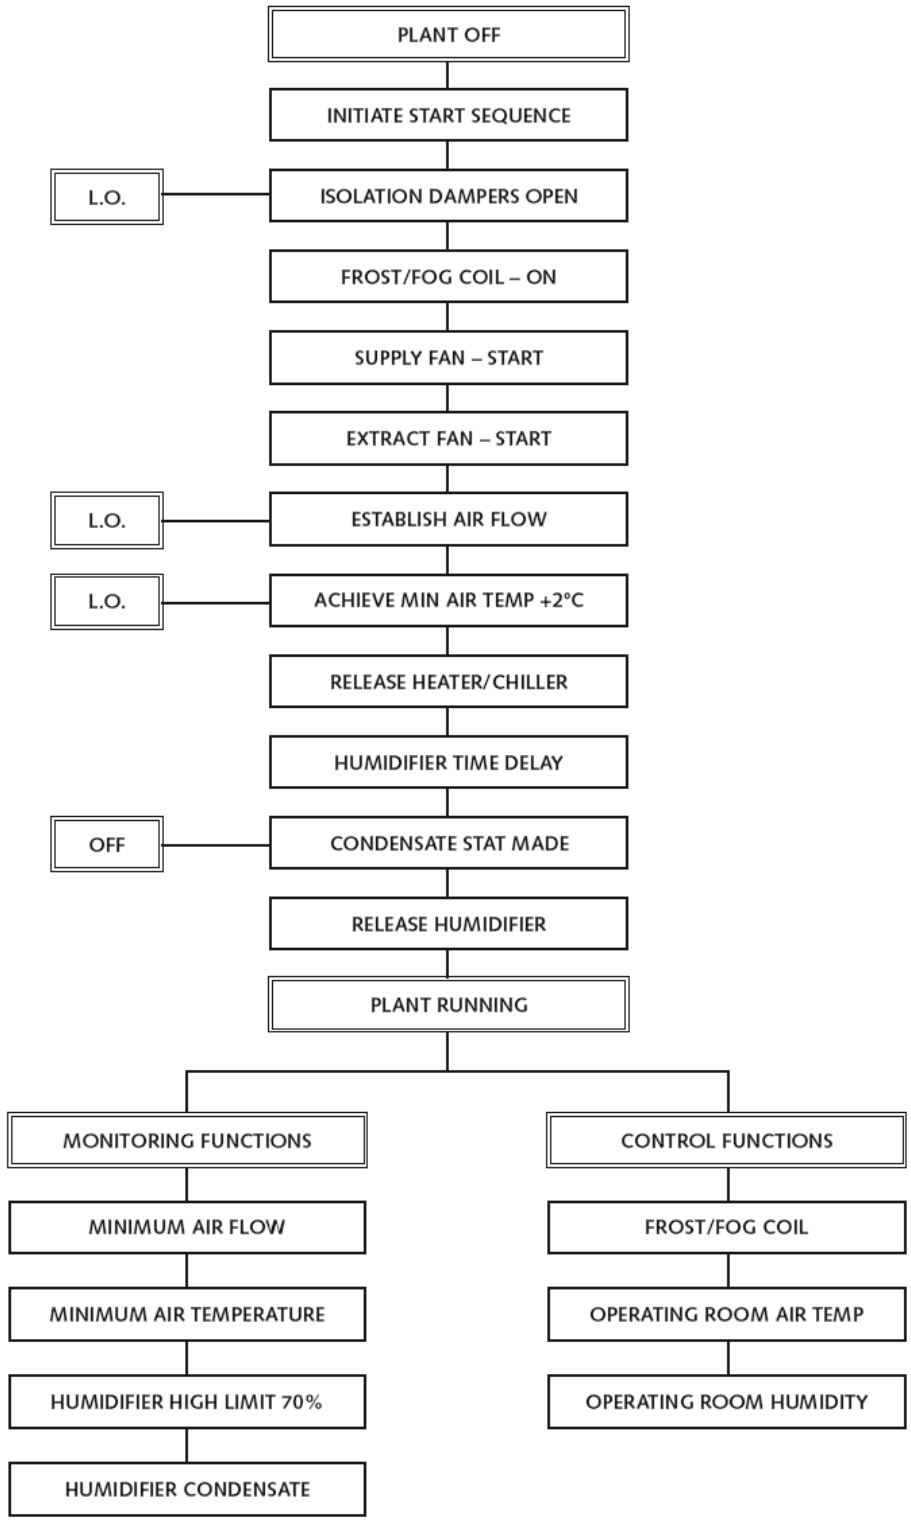

Figure 2: Typical plant control algorithm – normal start-up sequence

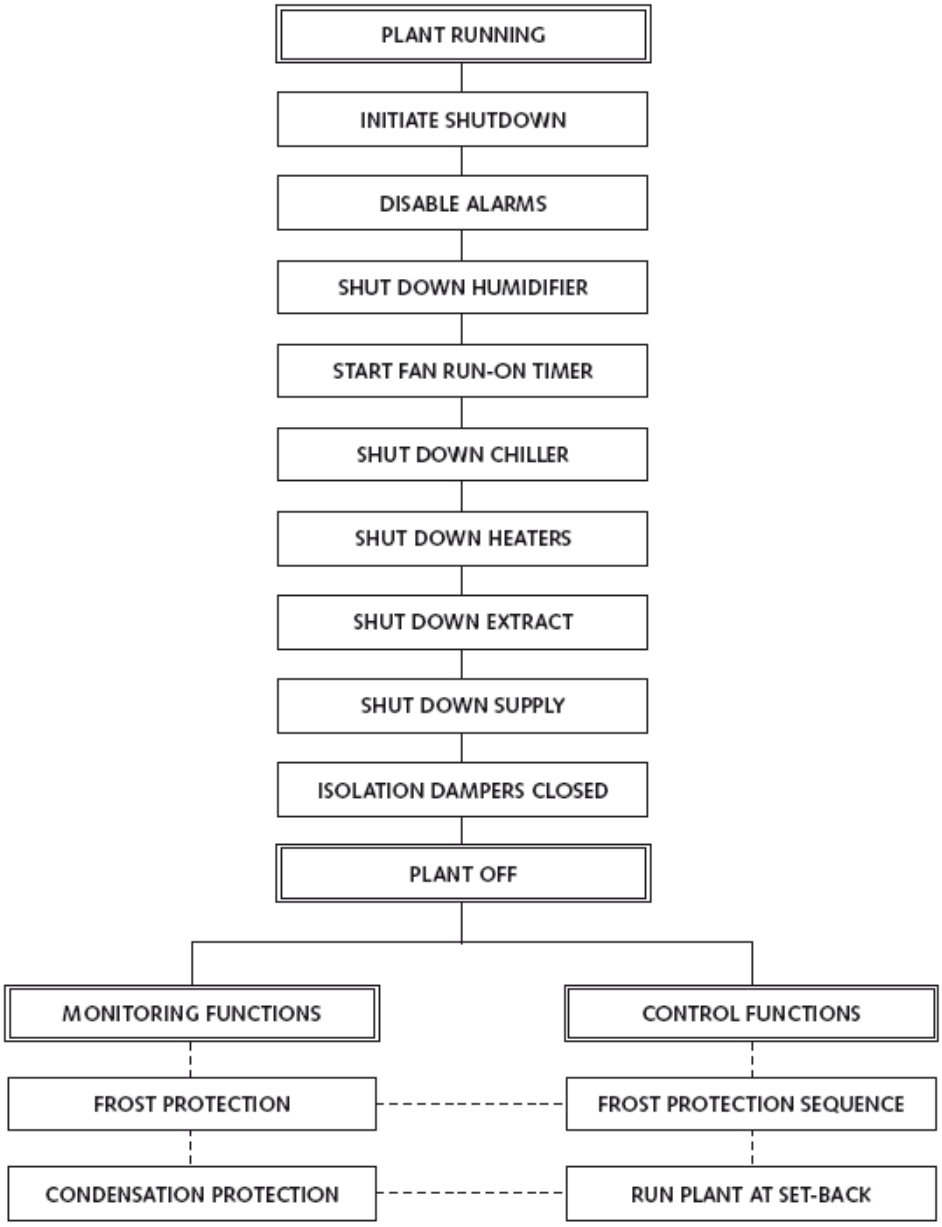

Figure 3: Plant control algorithm – normal shutdown sequence

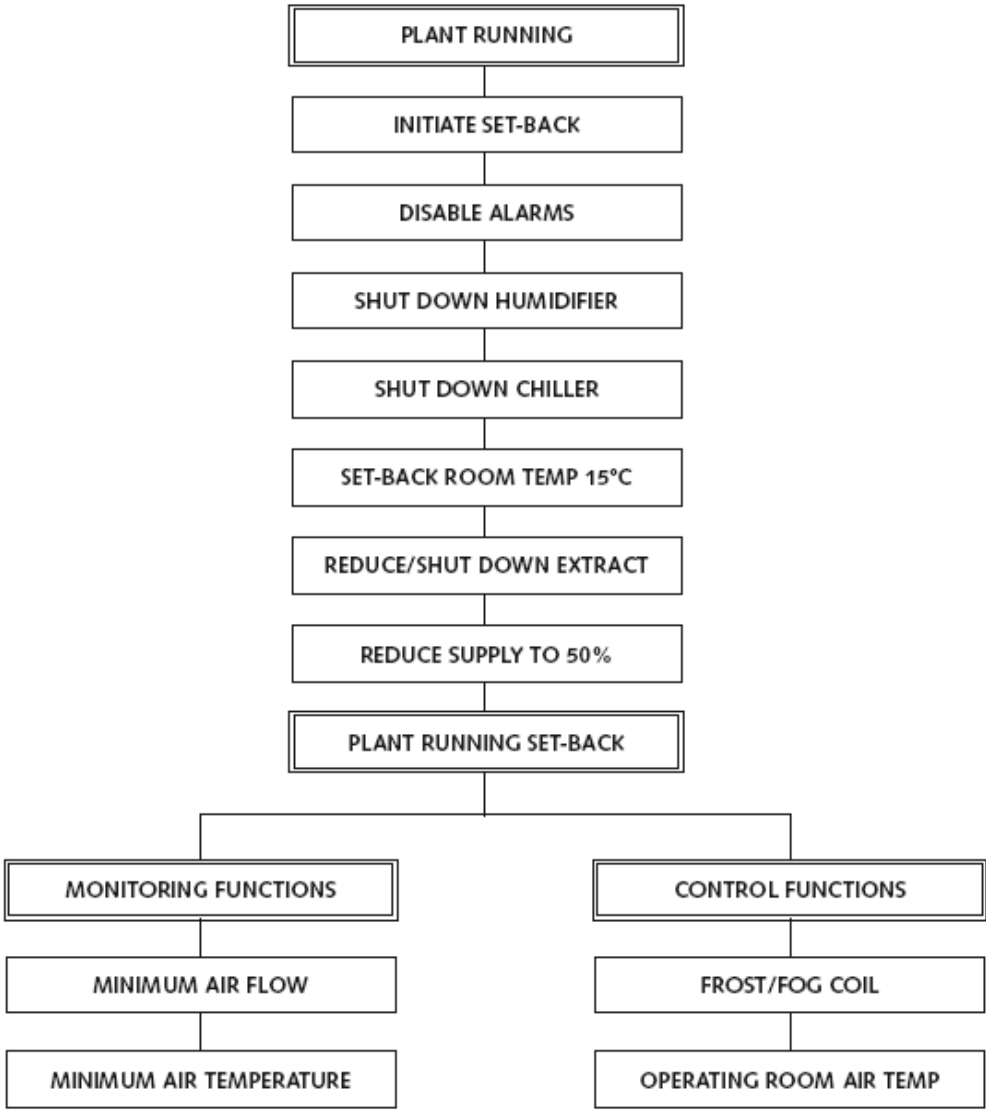

Figure 4: Plant control algorithm – set back sequence

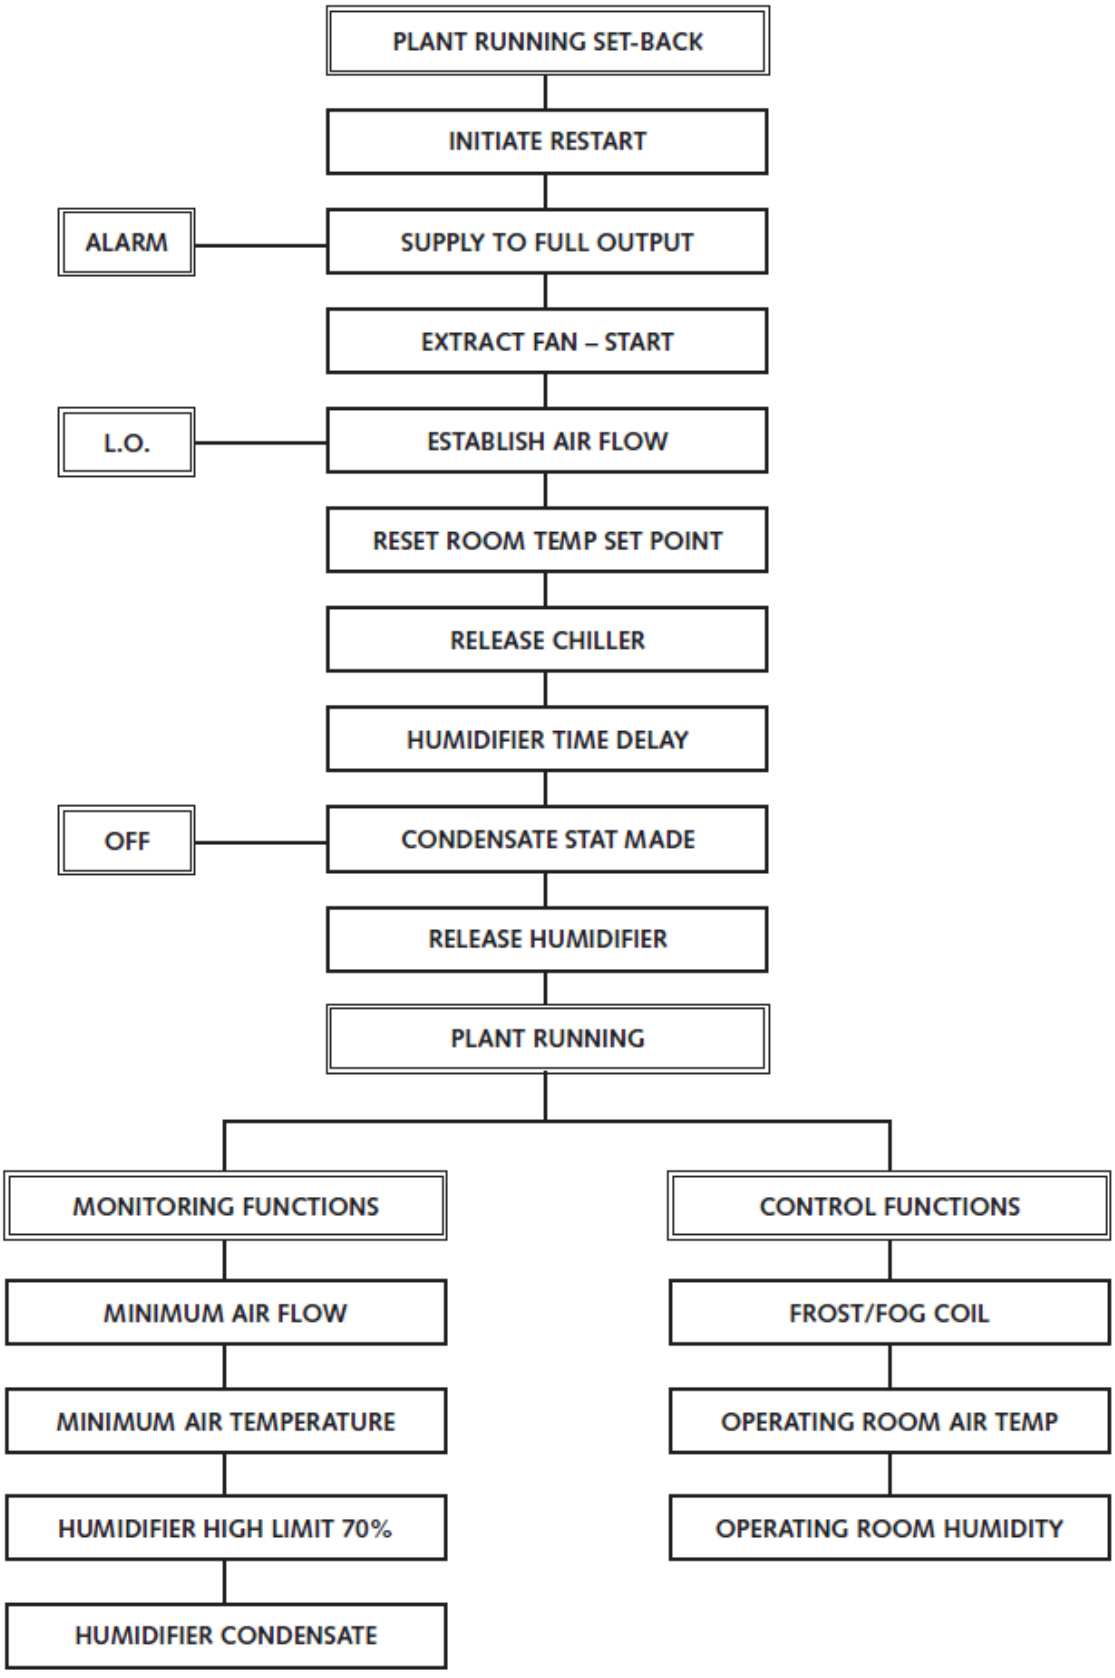

Figure 5: Plant control algorithm – restart from set-back

A47310563

Set-back control

6.23 Where variable speed controls are installed, the setback facility for each plant should depress the control temperature to around 15°C; exclude any humidification and cooling from the system; and reduce the supply and extract air volumes to around 50%. The extract fan can also be turned off as long as the desired direction of air movement from clean to less clean will be maintained (See also Figures 2 - 5).

Use control

6.24 The installation of movement detectors allows for “use control” of ventilation systems. A simple control logic that reduces the system to a “set-back” condition if there has been no movement detected in the space for, say, 30 minutes and that switches the system “off” if no movement is detected for one hour is recommended for many applications, including operating suites.

6.25 A variation on this can be provided by linking ventilation controls to lighting. For example, in an operating theatre, the system may be off outside of working hours, could run at set-back when the general lighting was switched on and increase to full speed when the operating lamp is switched on. As with movement detection, a 30-minute run-on should be provided at each stage when the lights are turned off.

6.26 Either of the above control strategies may be refined by linking to the BEMS to provide a control logic related to normal working hours and associated ‘real-time’ movement within the zone being controlled. This should result in significant energy savings.

Environmental control

Temperature control methods and application

General

6.27 All control valves must fail safe, that is, close in the event of power or air-flow failure, with the exception of the fog/frost battery control valve, which should open upon power or airflow failure.

6.28 Control valves should be located in an accessible position. Isolation valves should be provided to enable the control valve to be removed for service without the need to drain-down the system.

6.29 Care should be taken to ensure that the installation of control valves and their associated pipework do not obstruct access to the AHU inspection doors and hatches.

Room temperature control

6.30 The limits for room temperature set point are generally between 16°C and 25°C depending on the particular application, and in some specialised instances (for example, operating departments) are adjustable within a predetermined range by the user.

6.31 The selection of temperature set point for each room or zone may be by a control facility in the room / zone, or remotely at the control panel or BEMS. Where the control device is mounted within the room / zone and adjustable by the user, it should be marked either 'raise' and 'lower' or '+' and '-'. It should control within a specified temperature range to suit the user requirement with a control tolerance of ±1K. All other control set-points should be selectable either on the control panel or at the BEMS interface.

6.32 Where local control is provided, an indication of temperature will be required locally, or at a staff base (if appropriate), using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example, at the operating table in a theatre). This may be mounted in a supervisory or, 'surgeon's' control panel, with the signal repeated on the main system control panel or BEMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.

6.33 Where the supply and extraction systems are designed for ventilation only and there is a wet heating system to provide background heating, care must be taken to avoid one system trying to heat the space while the other system is trying to cool the area.

Frost battery control

6.34 Steam-supplied frost batteries must be operated as on/off devices with their sensor mounted upstream of the battery. This will give 'open loop' control. A set point of +1°C is recommended.

6.35 Low pressure hot water (LPHW)-supplied frost batteries should be controlled using the proportional mode. Their sensor should be located downstream of the battery to give 'closed loop' control. A set point of between 2°C and 5°C is recommended.

6.36 If the temperature downstream of the frost battery, as sensed by a serpentine thermostat, falls below the required set point over any part of the coil, the plant must automatically shut down in order to prevent damage to the other batteries. The serpentine thermostat must not be in direct contact with the coil.

Off-plant control

6.37 The control logic must prevent the chiller and pre-heater being on at the same time.

Humidity control methods and application

6.38 In order to prevent excessive condensation when starting up from a total plant shut-down, a time delay should be incorporated into the control system such that the humidifier does not start until 30 minutes after the ventilation plant starts up.

6.39 Irrespective of the method of control, a high-limit humidistat should be installed to ensure that when the humidifier operates, the condition of the air in the duct does not exceed 70% saturated, particularly during plant start-up.

6.40 With certain types of steam humidifiers, it may be necessary to install a thermostat in the condensate line from the humidifier's steam supply, to ensure that the steam at the control valve is as dry as possible before it is injected into the air supply.

6.41 The humidifier and cooling-coil control must be interlocked so that they cannot be on at the same time.

6.42 The humidifier control system should ensure that it is switched off with the fan. It is preferable to design the control system so that the humidifier is isolated for an adequate time before the fan is turned off so as to purge humid air from the system.

6.43 All control valves must fail safe (that is, close in the event of power failure) and the humidifier must be interlocked with the low airflow switch.

Multi-zone control methods and application.

6.44 Close control of all air-conditioning parameters may be difficult to achieve with multi-zone systems, since each zone will in theory require a re-heater and humidifier to give total control of humidity if that is what is required. In reality such close control is rarely required in practice. It is therefore usual with multi-zone systems to provide control of zonal temperature only, with humidity control where fitted being based on average conditions within all zones, or minimum conditions within one zone.

6.45 Where there is a requirement for close control of air-conditioning parameters in a number of zones (e.g. an operating department) separate plants should be provided for each zone in order to avoid the need for expensive over-cooling and reheating of individual zones.

6.46 Most multi-zone systems within healthcare premises are controlled based on off-coil control within the central plant, with trimmer heater batteries on individual zones.

Alarms and indication

6.47 Supply and extract systems should include indicator lamps on the control panels to confirm the operational status of each system. Where the usage is on

a regular daily pattern, time control with a user-operated timed manual over-ride should be provided.

6.48 Where a system is provided for a particular space, the indicator should be in, or immediately adjacent to, that space and local controls should be provided with labels clearly defining their function (eg. isolation suites.)

6.49 The 'plant failure' and 'low air-flow' alarms should be initiated by a paddle switch or other device located in the main air supply duct. This should operate when the air quantity fails to reach or falls to around 80% of the design value and will give indication of fan failure, damper closed, access door left open, or any other eventuality that could cause a reduction of air quantity. Monitoring the current drawn by the fan motor is not a substitute for a sensing device that is directly affected by the air-flow.

6.50 The 'filter fault alarm' should be initiated by a predetermined increase of pressure differential across the filters, thereby indicating a dirty filter.

6.51 Direct-reading gauges or manometers should be installed across filters to give maintenance staff an indication of their condition.

6.52 Visual indication should be provided at a manned staff location (for example, the reception or staff base) and on the main control panel and BEMS to show 'plant failure' and 'low air flow'.

BEMS

6.53 Control of most systems will be via a Building Energy Management System (BEMS). This will enable the operating conditions and control tolerances to be set and monitored. The BEMS may also be set to log the actual energy consumed by the system and recovered by the energy recovery system. This will provide a useful check on the overall operating efficiency and provide evidence that energy targets are being achieved.

7. Specialised ventilation systems

7.1 This section contains design information for a range of healthcare ventilation applications.

7.2 The following departments will require a degree of specialised ventilation.

- the Operating department;
  - treatment rooms;
  - endoscopy, day case and minimum invasive suites;
  - cardiology and operative imaging suites;
  - conventional operating theatres;
  - Ultra-clean ventilation (UCV) operating theatres;
  - barn theatres;
  - recovery and ancillary areas.
- Obstetrics;
  - maternity theatres;
  - birthing rooms;
  - LDRP Rooms;
  - SCBU.
- critical areas and high-dependency units of any type;
- Isolation facilities;
  - infectious diseases units;
  - bone marrow and other transplant units;
  - chemotherapy and oncology units.
- Sterile Supply and Decontamination Units;
  - wash rooms;
  - inspection and packing rooms;
  - sterile pack stores.
- the Pharmacy departments;
  - aseptic suites;
  - extemporaneous preparation areas;
  - radio pharmacies.
- the Pathology department;
  - laboratories;

  - cat 3 and 4 rooms.
- the Mortuary and Post mortem suite;
  - mortuaries;
  - post-mortem rooms;
  - specimen stores.
- Hydrotherapy units;
- Burns units;
  - burns theatres;
  - treatment rooms;
  - isolation rooms;
  - tissue banks.
- Emerging specialties;
  - gene therapy units;
  - stem-cell laboratories.
- Infrastructure;
  - plant rooms housing combustion equipment;
  - welding facilities;
  - wood working workshops;
  - electric vehicle charging areas.

7.3 Design information for many of these applications is given in Appendix 1 Table A1, Appendix 2 and in the following Chapters within this section.

7.4 It is not possible within this existing document to give definitive guidance for every healthcare specific ventilation application. Additional detailed guidance may be issued in due course in the form of supplements.

General information

7.5 The section on operating theatres is the most extensive and contains much information that is common to other applications. Each theatre suite should have its own dedicated air-handling unit and extract fan. Where no specific guidance is given the principles set out below should be followed:

- the foregoing sections of the document contain general information on healthcare-specific aspects of ventilation system design and specification;
- a set of standard solutions for the design of general operating theatre suites to conform to past and new standards is given in new standard layouts Nos 1, 3, 5 and 7 and those for UCV theatres in new standard layouts Nos 2, 4, 6 and 8 within Appendix 3;

- the CIBSE Guides A & B contain basic information on ventilation design that can be applied to most applications;
- where a British or European standard exists that is specific to the application (for example, a clean room) it should be used as the basis of the design requirement;
- air should always move from clean to less-clean areas. A hierarchy of room cleanliness is given in Table A2;
- differential pressure will prevent contamination between areas when doors are closed. Information on air leakage through closed doors and hatches for a range of differential pressures is given in Table A3;
- the flow of air will prevent contamination between areas when doors are open. Information on air leakage through open doors and hatches for a range of differential pressures is given in Table A4;
- if anaesthetic gases are used, 15 air changes per hour will be required;
- a methodology for calculating a design solution for a non-standard suite of operating rooms is given in Appendix 4. This may be adapted as necessary to suit other less complex applications where air is required to cascade from clean to less clean areas.

7.6 The supply of air to a room has four main functions:

- to dilute airborne contamination;
- to control air movement within such that the transfer of airborne contaminants from less clean to cleaner areas is minimized;
- to control the temperature and if necessary the humidity of the space;
- to assist the removal of and dilute waste gases where used.

7.7 Because of the complexities of controlling air-movement patterns, much design effort will be required for this aspect. It is important that the design makes the best possible use of the air available, as excessive supply airflows for the control of air movement should not be used. The amount of air supplied will be determined by the number of doors and desired air-change rate.

7.8 There are four routes whereby airborne contaminants may appear in a room:-

- through the supply air;
- shed directly by the room occupants;
- arising as a result of the work activities;
- transferred from adjacent spaces.

7.9 Particles entering with the supply air can be controlled by the selection of suitable filter grades.

7.10 Particles shed directly by the room occupants can be controlled by:

- restricting access to essential persons only;

- the choice of the occupants' clothing;
- the room's air-change rate.

7.11 Particles arising as a result of the work activity can be controlled by:

- enclosing, semi-enclosing or otherwise controlling the work-based source;
- the room air-change rate.

7.12 The transfer of particles from adjacent spaces can be controlled by:

- differential pressure;
- air-flow paths.

7.13 Air change rates are given in Table A1. These figures have been found to give sufficient dilution of airborne contaminants, provided the mixing of room air is reasonably uniform.

7.14 A downward-displacement turbulent air distribution is generally preferred. The supply and extract diffusers should be positioned to ensure that all parts of the room are actively ventilated and that where necessary the staff will be in a clean air-flow path. (See Section 5 for additional guidance on supply terminals).

7.15 Horizontal-flow room-air distribution with or without a Coanda effect can be a source of draughts and difficult to set up correctly. Its use should be confined to non-critical areas.

Air movement control

7.16 The design of the system should seek to minimise the movement of contaminated air from less clean to cleaner areas. Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room pressure differentials. When closed they prevent significant reverse air-flow.

7.17 The relative locations of supply and extract terminals and their design air-volume rates will determine the basic airflow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces ensuring a flow from the clean to less clean areas. Failure to provide such devices will lead to uncontrolled air flows when personnel move between rooms. They may also result in doors being held partially open by air pressure

Temperature and humidity control

7.18 To achieve the required room conditions, supply flow rates are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the base heating load will be provided by a heating

system. In critical systems the room or suite being considered will be within the heated building envelope so the ventilation will be sized to suit the casual gains or losses.

7.19 Temperature differences of up to 10K for winter heating and 7K for summer cooling must not be exceeded.

7.20 It is acceptable for the humidity to swing uncontrolled between 35% and 70% saturation.

Removal and dilution of waste anaesthetic gases

7.21 Anaesthetic gases are subject to occupational exposure limits. Waste anaesthetic gas must be contained and removed by a suitable gas-scavenging system. Some leakage from the anaesthetic equipment and the patient's breathing circuit will occur with all systems, particularly during connection and disconnection; and from the interface with the patient. The air movement scheme should ensure that this leakage is diluted and removed from the room. Anaesthetic agents are heavier than air so placing the supply terminal at high level with an extract at low level, adjacent to the anaesthetic gas terminal units will ensure that staff are in a clean air-flow path.

7.22 In LDRP and delivery rooms the use of anaesthetic gas is controlled on demand by the patient. This may result in significant leakage which, in order to reduce staff exposure, will need to be controlled by establishing a clean airflow path. A supply at high level at the foot-end of the bed with extract at low level at the head-end will provide such a path.

Fire aspects

7.23 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system, to limit smoke spread in the event of a fire.

Door protection

7.24 Air should flow from the cleaner to the less clean areas as shown in Table A2. There are several factors that affect the likelihood of a reverse air- flow through doorways:

- when a person passes through a doorway, both the passage of the person and the movement of the door flap cause a transfer of air between the areas separated by the door;
- when a door is left open there is a transfer of air between the two areas separated by the doorway. This is caused by air turbulence, but is greatly increased by any temperature differential between the areas (a 1.4m wide doorway may allow the transfer of 0.19 m^3/s of air in each direction when there is no temperature difference, but when the temperature differential increases to say 2K, the volume transferred may increase to 0.24 m^3/s).

7.25 Two methods of door protection are used in order to reduce the likelihood of contamination of clean area by a reverse air-flow from a less clean area:

- closed door protection – a pressure differential is created across a closed door so that any air leakage is from the clean to the less clean area. Table A3 gives details of closed door leakage rates for a range of differential pressures;
- open door protection – the pressure differential drops (See Table A5) and is effectively replaced by a flow of air through the doorway from the clean to the less clean area. The flow of air needs to be sufficiently large to ensure that significant reverse airflow cannot occur and will be related to the relative cleanliness of the areas being considered. Table A4 gives air-flow rates for open door protection related to door / opening size and classification of the adjoining areas.

7.26 Pressure stabilisers enable the room differential pressure to be set when the doors are shut, thus providing closed-door protection. When a door is opened the stabilisers will close, forcing air to be directed through the doorway thus providing open-door protection.

7.27 The recommended air-flow rates to achieve this are given in Table A3. Provided that the dilution criteria in Table A1 are met, the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.

7.28 In applications where it is critical to maintain a specific airflow and /or pressure regime (for example isolation rooms) all windows in the zone should be locked shut or sealed. Trickle vents, if fitted, will also need to be sealed.

Systems design

7.29 The design of the ventilation system for an area depends on the overall configuration of the department. Where the department is served by more than one AHU, the control of the units may need to be interlocked so that reverse air-flow patterns do not occur.

7.30 Dual-duct high velocity systems have advantages, but are noisy, costly and may give rise to unacceptable values of humidity. Single-duct, low velocity/pressure systems are preferred.

7.31 Extract grilles should be sited and balanced to promote air movement in the desired direction.

7.0 (a) Operating department ventilation systems

7.32 The information given in this section relates to general operating suites. It will be applicable to other types of theatre suite such as maternity, burns, cardiac, etc. The standard values given may need to be adjusted to reflect non-standard room sizes, pressure regimes and air change rates.

7.33 A method of obtaining a design solution for non-standard theatres is given in Appendix 4.

7.34 Additional information for Ultra-clean ventilation (UCV) theatres is given in Section 7.0 (b).

General

7.35 The supply of air to an operating room has four main functions:

- to dilute airborne contamination;
- to control air movement within the suite such that the transfer of airborne contaminants from less clean to cleaner areas is minimized;
- to control the temperature and if necessary the humidity of the space;
- to assist the removal of, and dilute, waste anaesthetic gases.

7.36 Because of the complexities of controlling air-movement patterns, much design effort will be required for this aspect. It is important that the design makes the best possible use of the air available, as excessive supply airflows for the control of air movement should not be used. The amount of air supplied to the operating room will be determined by the number of doors and desired air-change rate.

7.37 The detailed considerations upon which the supply air-flow rate is based are as follows.

Dilution of airborne bacterial contaminants

7.38 There are four routes that airborne contaminants may appear in an operating room:

- through the supply air;
- shed by operating staff;
- produced by the surgical activities;
- transferred from adjacent spaces.

7.39 Supply flow rates for the main rooms of the operating suite are given in Appendix 3. For the other areas where room sizes and activities vary from site to site, air-change rates are given in Table A1. These figures have been found to give sufficient dilution of airborne bacterial contaminants, provided the mixing of room air is reasonably uniform.

7.40 A downward-displacement air distribution is preferred; it may be either turbulent or laminar flow. For turbulent flow the supply-air diffusers should be positioned either in the centre of each quadrant of the ceiling or along a line between the centres of each quadrant. This should ensure that all parts of the room are actively ventilated and that there will be adequate air movement at the operating table. Laminar flow would be provided by a perforated plenum terminal centred

above the operating table. (See Section 5 for additional guidance on supply terminals).

7.41 Suspended articulated equipment is usually fitted in theatres. These require significant structural steelwork in the ceiling void to cater for the loads imposed by the resulting bending moments. It is important to ensure that the void is deep enough to accommodate both the steelwork and the ventilation ducts. The location of the steelwork must not prevent a suitable layout of the ventilation ductwork and correct positioning of the supply air terminals. It needs to be recognised that the correct ventilation of an operating theatre plays a significant part in controlling healthcare acquired infections and is not subordinate to the desire to make equipment easy to move.

7.42 Horizontal flow distribution with or without a Coanda effect can be difficult to set up correctly and are unlikely to be as effective in Theatre applications. It should not be used in new installations. However space constraints may force its retention or replacement when refurbishing existing installations. Where fitted, the supply grilles will require a means of directional adjustment.

7.43 For general operating theatres, the air supply would be filtered in the AHU. Terminal HEPA filters are not generally required.

Control of air movement within the suite

7.44 The design of the system should seek to minimise the movement of contaminated air from less clean to cleaner areas. Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. In older designs suitably dimensioned door undercuts were often used in lieu of transfer grilles. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room-pressure differentials.

7.45 The relative locations of supply and extract terminals and their design air-volume rates will determine the basic air-flow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces ensuring a flow from the clean to less-clean areas of the suite. Failure to provide such devices will lead to uncontrolled airflows when personnel move between rooms and doors being held partially open by air pressure.

Temperature and humidity control

7.46 Supply flow rates to achieve the required room conditions, are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the room being considered will be within the heated building envelope.

7.47 Temperature differences of up to 10K for winter heating and 7K for summer cooling must not be exceeded.

7.48 It is acceptable for the humidity to swing uncontrolled between 35% and 60% saturation.

Removal and dilution of waste anaesthetic gases

7.49 Anaesthetic gases are subject to occupational exposure limits. The air-movement scheme should ensure that staff are in a clean air-flow path. (See Paragraph 7.21).

7.50 Air extracted from operating suites should not be re-circulated, as it may contain malodorous contaminants. However an energy recovery system should be fitted in the extract in order to reduce the plant energy consumption. (See Paragraphs 4.142 - 4.147).

Fire aspects

7.51 When considering the overall air-flow movement, careful thought needs to be given to the operation of the ventilation system, to limit smoke spread in the event of a fire. However, this is a highly staffed department with a low fire risk/load status and these factors need to be recognised when developing the fire strategy. It is considered satisfactory to treat the complete operating department as a single fire compartment providing there are at least two exits from it. Over-compartmentalisation can lead to difficulties in establishing clean air-flow paths and room-air dilution rates. This will lead to an increased risk of healthcare-associated infections. Staff areas within the department should be treated as a sub-compartment. (See Paragraph 6.18).

Door protection

7.52 Air should flow from the cleaner to the less clean areas as shown in Table A2. The factors that affect the likelihood of a reverse airflow through doorways are discussed in Paragraphs 7.24 - 7.26.

7.53 It is not possible to design an air-movement scheme, within the restraints of the amount of air available that will protect the operating room when two doors are simultaneously opened. The design process that has been used considers that each door is opened in turn and ensures that the direction and rate of air-flow through any open doorway is sufficient to prevent any serious back-flow of air to a cleaner area.

7.54 Provided that the air-change rates in Table A1 are met, dilution will be sufficient to ensure that the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.

7.55 The following general points should be taken into consideration during the design of operating suites:

- Number of exits – the fewer the number of rooms (and therefore doorways) leading from the operating room the better, as traffic is reduced and less complicated air-movement control schemes are required.
- Scrub and hand-wash facilities – these may be a part of the operating room, often in a bay. The bay would count as part of the operating room volume and should have a low-level active or passive extract to remove the moisture-laden air. Should a separate room be required for the scrub area, a door between the scrub-up room and the operating room is an inconvenience to scrubbed staff, and could be replaced by an opening. This opening should be larger than a normal single doorway, but the scrub would not, in these circumstances, be considered part of the operating room volume.
- If an alcohol scrub regime is employed, individual theatre scrubs may not be required and would be replaced by a common departmental pre-/post-operation scrub position in the corridor. This would require local extract to prevent a build-up of moisture.
- Preparation 'Sterile Pack Store' (SPS) – if it is intended to 'lay-up' instruments in the operating room, the preparation room is then used simply as a sterile pack store. The nominal room pressure can therefore be the same as that of the operating room and the airflow between the two rooms in either direction. Air supplied to the preparation room may be directed into the operating room either through a door mounted transfer grille or if no door is fitted, through the opening. Alternatively, stock ready-use sterile items can be located in a bay within the theatre. In this case, a portion of the total theatre supply air should be provided in the bay to ensure it is actively ventilated.
- Preparation room 'lay-up' – when the preparation room is used as an instrument 'lay-up' room, it should be regarded as being of greater cleanliness than the operating room, and the design should minimise the transfer of air from the operating room to the preparation room. Air supplied to the room may be directed to the operating room through a pressure stabiliser taking care not to compromise the airflow pattern in the operating room. The air may also be directed into a corridor;
- Service corridor – if materials to be disposed of are placed in impervious material for transportation, it is not necessary to have a separate corridor for this purpose. However, a service corridor has many operational advantages it terms of the flow of materials through the theatre suite. It also permits routine service and maintenance access without compromising the use of adjacent theatre suites.

Standard air-movement control schemes

7.56 In the previous versions of this guidance standard air movement control schemes were given that provided a range of design solutions to typical operating suite layouts. These were satisfactory design solutions for 'standard' sized rooms within the suite but were never intended to be universal for any sized room or suite. Guidance on operating suites contained in HBN 26 (2004) has increased the recommended size of operating room from approximately

35m^2 to 55m^2. Associated room sizes and air change rates have also increased. This means that the original standard solutions are no longer appropriate for new-build installations.

7.57 Because of the resulting increase in the volume of air supplied to the theatre, provision needs to be made either to actively remove it or allow it to escape passively through pressure stabilisers. The increase in room size has also made the number and position of air-supply terminals critical to the effective ventilation of the room.

7.58 Four new standard solutions have been developed to reflect the current guidance on theatre suite layout and room sizes given in HBN 26 (2004) as well as the general increase in air-change rates.

7.59 The most commonly used original standard solutions have been revised and updated. They have been retained in this guidance, as they will remain applicable to older theatre suites that are being refurbished to their original performance standards. They will also be applicable in existing departments where space constrains do not permit the upgrading of suites to the latest standard of performance or where a pre-built "shell" is being fitted out.

7.60 It is important to recognise that in any situation where a "non-standard" room size or theatre suite layout is being considered, the designer must return to first principles when developing a solution. Examples of non-standard configurations would be:

- cardiac theatres that typically have an operating room half as big again as normal, a perfusion laboratory and no anaesthetic room;
- operating departments served by a central instrument lay-up preparation area rather than individual prep rooms;
- balanced-flow theatres for infectious cases.

Appendix 4 contains a methodology for assisting the designer to arrive at a suitable solution.

7.61 The new and revised standard design solutions are as follows:

No 1 – Typical Conventional theatre – room sizes as HBN 26;

No 2 – Typical UCV theatre – room sizes as HBN 26;

No 3 – HBN 26 illustrated Conventional theatre;

No 4 – HBN 26 illustrated theatre with UCV terminal fitted;

No 5 – Pre-2006 Conventional theatre, single corridor (former SHTM 2025; 1b);

No 6 – Pre-2006 UCV theatre, single corridor (former SHTM 2025; 1a);

No 7 – Pre-2006 Conventional theatre, two corridor (former SHTM 2025; 5b);

No 8 – Pre-2006 UCV theatre, two corridor (former SHTM 2025; 5a).

7.62 Details of these standard solutions are given in Appendix 3. They contain diagrams that show the relationship of rooms and the various doors and transfer devices between them, **but should not be regarded as architectural layouts.** The schemes have been developed using the calculation procedure described in Appendix 4. Important features of the solutions are:

- Zone trimmer heaters – a trimmer heater battery is advocated when calculations indicate that the temperature differential between rooms may be greater than 2K. Generally this will only be the case in the preparation room when designated as a lay-up.
- The preparation room (sterile pack store)/operating room interface – these rooms are deemed to be of equal cleanliness, and thus a transfer grille is required between these rooms or the door can be replaced with an opening wider than a standard door.
- Preparation (lay-up)/disposal room interface – pressure relief dampers are recommended here to provide an air path when doors are closed, while preventing back-flow when a door is opened elsewhere.
- Operating room/anaesthetic room interface – pressure stabilisers, or in some cases, carefully sized transfer grilles are recommended here, and between the anaesthetic room and corridor, and between the operating room and corridor.
- Operating room/scrub room interface – an opening is provided between these rooms. The flow of air through the opening provides protection, and gives bacterial dilution within the scrub room; the air is then exhausted to the corridor via a pressure stabiliser.

7.63 No mechanical supply or extract ventilation is provided in the scrub room, and thus when a door is opened elsewhere in the suite, the stabiliser will close, allowing the air to be re-directed to help protect the doorway. If the scrub is a bay within the theatre then a suitably positioned pressure stabiliser and / or active extract should be provided to ensure air movement and prevent a local build-up of moisture.

7.64 Any other scheme may be used and the standard solutions applied, if the following conditions are met:

- room relationships in air network terms are as shown in the plans;
- door-gap measurements approximate to those given in Scottish Health Technical Memorandum 58: ‘Internal doorsets’, (but see also Table A3 and Note 3);
- casual heat gains are accounted for;
- a trimmer battery is installed in the air supply system to the preparation room;
- leakage through the structure is kept to a minimum.

Note 3: It should be noted that many doors are now fitted with cold smoke seals as standard. These will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design door leakage is factored into the sizing of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air gap whistles and doors being held partially open by air pressure.

7.65 It is recommended that every effort should be made to adopt one of the schemes described above.

Air terminals and air distribution within rooms

7.66 The selection and sighting of air diffusers will be critical in establishing an efficient pattern of mixing. To this end the diffusers selected must be fit for purpose. Ceiling mounted circular 'air master' style, square 'four-way blow' or similar diffuser designs that provide a downward displacement, turbulent airflow are the preferred option. (See Paragraph 5.68).

7.67 Plenum-type 'laminar'-flow-style diffusers with a footprint that encompasses the operating site are acceptable but may be prone to buoyancy effects as a result of temperature difference. Manufacturers' type-test data should be consulted to ensure that the terminal will achieve the required performance envelope. Note that these are not true laminar-flow systems in the strict sense of the word but produce a downward-displacement parallel-flow style of air distribution.

7.68 The diffuser equipment chosen should not cause 'dumping' and it should provide a velocity 1 metre above floor level at the operating position of between 0.2 m/s and 0.3 m/s.

7.69 In the operating room, the supply air terminals must be at high level, and should all be adjustable for rate of flow as well as being easily cleaned and silent in operation.

7.70 In order to ensure that all parts of the operating room are actively ventilated, there should be an air-out path on each face or in each corner of the theatre. This may be provided by a pressure stabiliser, transfer grille, active or passive extract terminal. A minimum of three, but preferably four, air-out paths - approximately equally spaced - should be provided.

Automatic control

7.71 The automatic control of ventilation in operating suites needs to be simple and robust. Over-reliance on complex room pressure and flow relationships linked to automatic fan speed control is unnecessary and in the long term have been shown to be unreliable. Complex software algorithms that can only be accessed and interpreted by off-site specialists should not be used. Whichever control strategy is chosen it is important that on-site staff have the facility to override the control system and keep the ventilation operating at least until the surgical procedure is complete. (See also Paragraph 6.11)

7.72 Theatre air-conditioning control sensors should be actively ventilated. They would typically be located in a sampling extract duct mounted in the surgeon's panel, positioned at normal working height (1.8m above finished floor level) and be accessible for cleaning and the removal of fluff and lint.

7.73 Wall-mounted passive-temperature and humidity sensors are not recommended.

7.74 Controls should be provided to enable operating department ventilation plants to be closed down when the operating suites are unoccupied. (See also Paragraphs 6.24 - 6.26)

7.75 When in the 'off' mode, the control system should ensure that the ventilation plant is automatically reinstated if the space temperature falls below 15°C.

7.76 The theatre control panel should include plant status indication; clearly-readable temperature and humidity indicating gauges; and means of adjusting the set point for temperature. Theatre ventilation plant status indication should be located at the staff control base.

7.77 Where it is considered necessary to fit a humidifier, it should be selected to humidify to 40% saturation at 20°C during the design winter outside conditions. The cooling coil should be able to remove sufficient moisture so that 60% saturation at 20°C is not exceeded during the design summer outside conditions.

7.78 Each operating suite should be served by an independent supply and extract plant.

Ventilation of operating department ancillary areas

General

7.79 There are advantages in providing mechanical ventilation to all areas of the department. Maintaining operating suite airflow patterns is simpler and grilles and diffusers can be sited to eliminate condensation on windows. Where radiators or embedded wall or ceiling panels are installed they should be confined to the corridors and staff-only areas of the department.

Ventilation requirements

7.80 Table A2 gives guidance on the operating department areas in descending order of cleanliness, and this should be considered in the overall design of the department ventilation systems. The specified flow rates of air through doors given in Table A4 for the operating suite are not necessary for other areas of the department. However, the air-flow directions must be maintained from the clean to the less clean areas.

7.81 All windows in the department should be double-glazed and hermetically-sealed in order to ensure that the desired airflow pattern is maintained under all

external environmental conditions and to avoid infestation. Trickle vents if fitted will need to be sealed.

Systems design

7.82 The design of the ventilation system for the ancillary rooms depends on the overall configuration of the department. The plant for the ancillary rooms may need to be interlocked to the theatre suite plants so that reverse air-flow patterns do not occur.

7.83 Extract grilles should be sited and balanced to promote air movement along the clean and access corridors towards the reception/transfer areas. This should not affect the air distribution in the operating suite(s).

Reception

7.84 The aim in these areas is to provide comfortable conditions having regard to the movement control requirements of the department as a whole. The number of air changes will depend on the particular design.

Sterile pack bulk store

7.85 The store needs to be maintained at a positive pressure in order to preserve the cleanliness of the outside of the packs; 6 air changes are recommended.

Recovery

7.86 The air-change rate in the recovery room will be rather higher than that needed merely to provide clean, comfortable conditions, as it is necessary to control the level of anaesthetic gas pollution; 15 air changes are recommended, with a balanced air flow.

7.87 The supply air terminals should be ceiling mounted above the foot-end of the recovery bed positions. Extract should be at low (bed height or below) level behind the bed head positions or in the corners. This will establish a clean airflow path so that staff do not inhale anaesthetic gases exhaled by recovering patients.

7.0 (b) Ultra-clean ventilation systems

General requirements

7.88 The design philosophy of a conventionally ventilated operating suite is based on the need to dilute contaminants and control both the condition and movement of air in an operating suite. Ultra-clean ventilation (UCV) is a means of significantly increasing the dilution effect by providing a large volume of clean filtered air to the zone in which an operation is performed and sterile items are exposed. Air is discharged above the operating zone and while not truly laminar, its downward displacement purges the clean zone of contaminants and

particles generated by the activities within it. The airflow in and around the clean zone also serves to prevent particles originating outside the zone from entering it. The resulting reduction in contaminants has been shown to reduce significantly post-operative sepsis following certain orthopaedic procedures.

7.89 The number of bacteria that are present in the air at the wound site and exposed surgical items is dependent on the operating team, their procedural discipline, choice of clothing and the type of UCV system. Ultra-Clean air is defined as that containing not more than 10 CFU/m^3.

7.90 UCV systems are very successful in reducing contaminants at the wound site so it is often considered that there is no need for complex air movement control schemes in the rest of the suite. However, when designing the ventilation scheme, it should be noted that the users may switch the UCV terminal to "set-back" when non-orthopaedic surgery is taking place. This is because the high airflow rates can cause increased moisture evaporation of exposed tissue that may be detrimental to the surgical outcome. In recognition of this, the ventilation scheme should be capable of providing operating conditions to at least a "conventional" theatre standard throughout the suite with the UCV in set-back mode. It should also be remembered that suitable levels of ventilation will always be required in the peripheral rooms.

7.91 UCV systems can be designed and built from first principles or a range of bespoke modular units of varying shapes and sizes are available with each manufacturer having a slightly different approach to UCV design. Some systems are fitted with partial or full walls to delineate the clean zone and direct a laminar or exponential downflow of air within it. Other designs utilise slotted linear supply terminals to produce an air curtain around the clean zone together with laminar-flow diffusers to provide a downward-displacement supply within it. **Notwithstanding any variation in the design philosophy, all UCV systems will be required to achieve completely the performance standard set out in the "Validation" section of this document**. (Section 8)

7.92 As with conventional theatres, each UCV operating suite should have its own dedicated air handling unit (AHU) to the standard set out in Section 4 of this document. To ensure operational flexibility and permit routine maintenance, air handling units should not be shared between suites.

7.93 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances an AHU may be shared between not more than two operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre so that the primary air volume to each UCV canopy can be determined. In addition the branch supply and extract should be capable of being physically isolated and the main air-flow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.

7.94 An inherent feature of a UCV system is its large airflow so it is essential to re-circulate the air supplied to the operating theatre and/or to recover its energy in order to optimise operating costs.

7.95 The primary fresh-air volume supplied to a UCV suite will be the same as in a conventional suite and it should be dispersed to the rooms in the suite in the same manner. This is an important aspect of the design and requests by UCV suppliers for increased primary air-supply volumes should be resisted.

7.96 Laying-up in the clean zone is preferable for infection control reasons. Where a Sterile Pack Store (SPS) Preparation room is provided a transfer grille will be required in the preparation room / theatre door.

7.97 If the Preparation room is intended to be used for laying-up instruments, a pressure stabiliser will be required between the prep room and theatre. It should be fitted with a stand-off baffle to prevent air transfer interfering with the ultra-clean airflow distribution.

7.98 Separate scrub-up or disposal facilities are not necessary for air cleanliness although operational policy may prefer such a provision. A separate anaesthetic room should, however, be provided.

7.99 There is no aerobiological reason why two or more UCV systems should not be installed in a common area as long as adequate spacing is provided. These are known as “barn theatres” and require special design considerations and operational discipline. The relative positions of the UCV units, temperature control range and location of doors and openings to other areas will all significantly affect the airflow at the operating positions.

Types of UCV system

Remote plant systems

7.100 In a remote plant system, all the air-conditioning equipment is located outside of the operating room, except for the unidirectional air-flow terminal, terminal filter, air diffuser and the return-air grilles (see Figure 6).

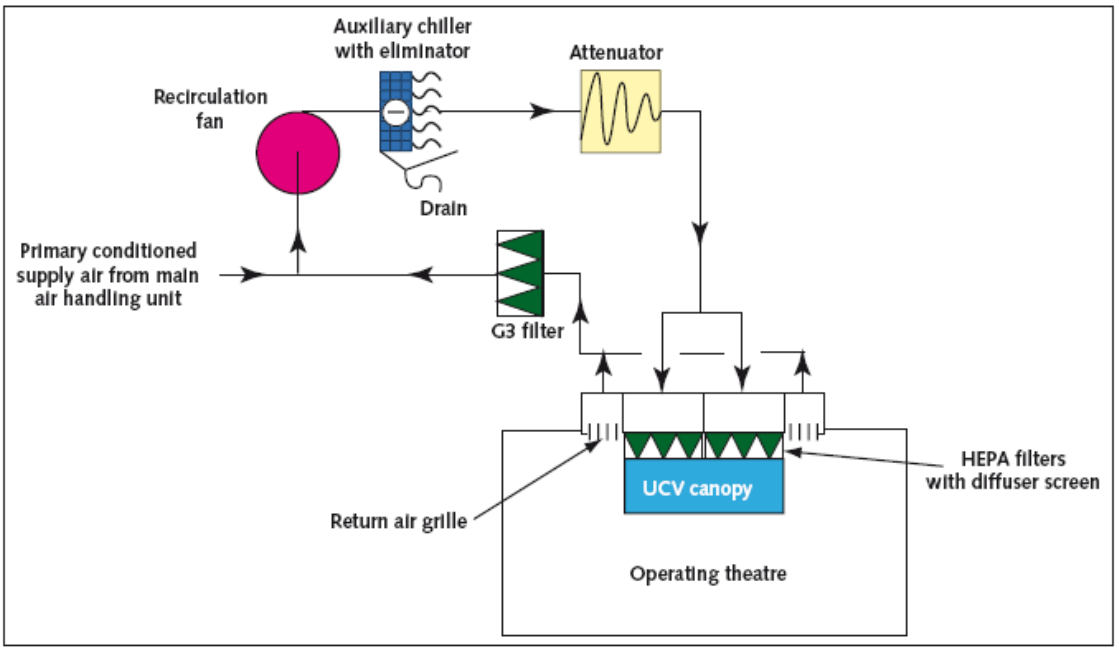

Figure 6: UCV theatre with remote air recirculation

7.101 This arrangement is the preferred option for new installations as it has the following advantages:

- the recirculation fans are out of the theatre thus reducing noise. Multiple recirculation fans can be replaced by a single fan unit with its drive out of the air stream;
- casual heat gains from recirculation fan(s), canopy lights, equipment and people within the theatre can be removed by a chiller battery in the return air stream. This will prevent heat build-up in the theatre;
- the return-air filters can be changed without needing access to the theatre making routine maintenance more feasible;
- the opportunity exists to locate the HEPA filter in the primary supply duct rather than the theatre terminal. This will reduce the number of filters required and allow them to be changed without entering the theatre.

Modular systems

7.102 Modular systems are frequently used in retrofit applications. Vertical or horizontal units are available.

7.103 Vertical-flow modular units comprise a ceiling-mounted air-terminal module containing return-air filters, return-air fans, final filter and air diffuser. Primary air is supplied by a remote air-conditioning unit at the volume and to the standard required for a conventional operating suite. (see Figure 7)

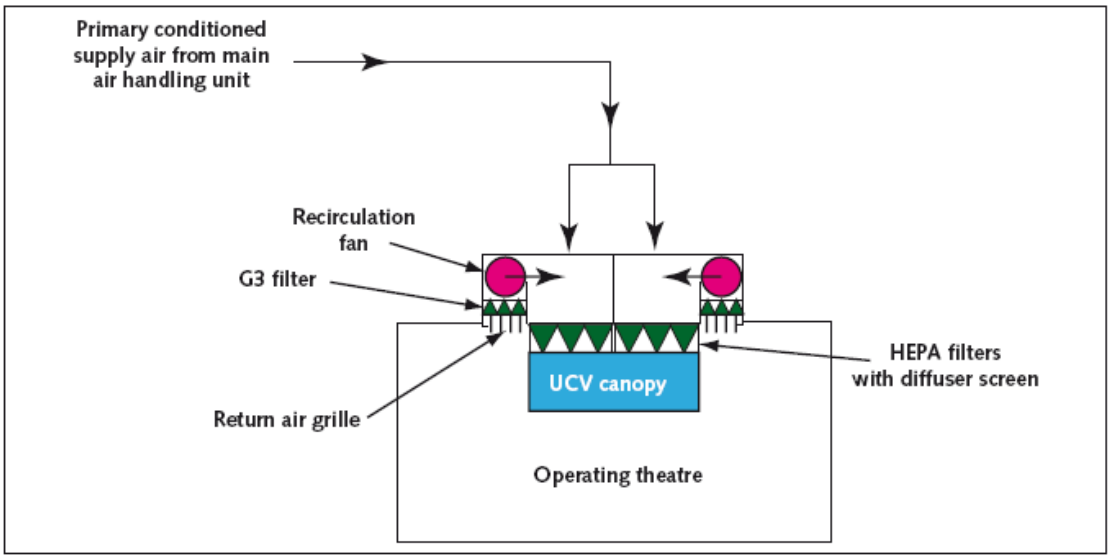

Figure 7: UCV theatre with modular system

7.104 Horizontal or cross-flow modular units comprise a wall-mounted air-terminal module standing vertically to produce a horizontal flow of air and containing final filter/diffuser, return-air filters and fans. The module may incorporate a cooling unit or be supplied with 'fresh air' from a separate primary cooling system.

Vertical flow UCV systems

7.105 Vertical-flow systems have a superior performance and are more effective at reducing infection risks. Air-curtain or partial-wall systems are acceptable, but are known to be more susceptible to problems arising from performance deterioration, poor operating-team discipline and high occupancy rates than is the case with full-wall systems. A full-wall is considered to be any wall terminating not more than one metre above the finished floor level.

7.106 Because of the large volume of air being moved in a relatively small space, the siting of the return-air grilles can cause short-circuiting of the air discharged through the UCV terminal. If the return-air grilles are positioned at high level, partial walls should be provided to control short-circuiting. The partial-walls shall be not less than 1m from the operating room walls and terminate at least 2m above floor level. The clearance should be increased proportionally for larger terminals (that is, 1.15m for 3.2m x 3.2m units and 1.25m for 3.5m x 3.5m units). In all cases, the sidewalls should terminate at 2m above floor level.

7.107 Siting the return-air grilles around the periphery of the theatre at low level will eliminate short-circuiting, remove the need for partial walls and give an improved airflow path. In any event there should be an air-out path on each face or in each corner of the theatre. These may be provided by combination of pressure stabilisers and passive or active low level extract grilles. Failure to provide air-out paths on all faces of the theatre may result in the surplus air causing entrainment into the clean zone.

7.108 Vertical systems should have a clean zone large enough to encompass the operating site and all of the instrument trays likely to be needed for the surgical procedures to be undertaken. Ophthalmic and minor hand surgery would

typically require a 1·4m circular or rectangular terminal. For major orthopaedic procedures a minimum size of 2·8m x 2·8m will be required. This is the area projected on the floor under the supply air terminal within the partial walls, full walls or air curtain. Any air outside this zone cannot be guaranteed to be ultra-clean although given the dilution factor the level of microbiological contamination will be much lower than the general level in a conventional operating room. The use of lines or a coloured area on the floor delineating the extent of the clean zone will assist staff and is therefore essential.

7.109 When upgrading an existing conventional theatre to an ultra-clean standard the only solution may be the installation of a modular system. In these units, the heat gains from the return-air fans and terminal lights may warrant the inclusion of supplementary cooling within the module although modern luminaries contribute substantially less unwanted heat. However issues of cooling coil drainage, condensate removal and maintenance access within the space constraints of the module may make this option impracticable. The additional cooling load should then be catered for by conditioning the primary air to compensate.

7.110 If an existing AHU is to be retained, it may require modification to ensure that it achieves the minimum standards set out in Section 4 of this document. The fan may need re-rating to accommodate the change in system resistance. The cooling coil may also need to be upgraded to cater for the increased load resulting from the return air fans and terminal lights. Failure to make adequate provision for this may make the theatre unusable during prolonged warm spells.

7.111 A factor affecting the air-flow pattern is the supply or room air temperature difference. When the supply-air temperature is significantly above room temperature, buoyancy effects will reduce the volume of air reaching the operating zone. If it is anticipated at design stage that this will be a regular occurrence, then a system incorporating full-walls should be used. Demountable extensions that convert a partial-wall to a full-wall unit are available.

7.112 Convection up-currents from the surgical team and operating lamp tend to counter the movement of clean air towards the operating site, hence the air velocity reaching the operating level is critical. The minimum velocity given below has been selected to take account of these factors and is greater than the theoretical minimum value.

7.113 For all vertical UCV systems the design discharge velocities will be as follows:

Air velocity 2 metres above floor level:

- partial-wall system = 0.38 m/s average;
- full-wall system = 0.30 m/s average.

Air velocity 1 metre above floor level:

- all systems = 0·2 m/s minimum within the operating zone.

The validation Paragraphs 8.75 – 8.86, gives details of the method of measurement.

7.114 Variable-speed recirculation fans with differential pressure control may be the most suitable solution for maintaining consistent performance and energy saving.

Horizontal UCV systems

7.115 Horizontal UCV air-flow systems have been shown to be less effective than vertical systems and are not the preferred solution. There may be occasions, however, where architectural, engineering, economic or workload considerations prevent the installation of a vertical-flow system and only a horizontal-flow system can be installed.

7.116 Horizontal- or cross-flow modular units comprise a wall-mounted air terminal standing vertically to produce a horizontal flow of air across the operating field. The terminal module contains the final filters, air diffuser, return-air grilles, filters and fans. The module may incorporate a full air-conditioning unit or be supplied with 'fresh-air' from a separate primary air-conditioning system. In the latter case the return-air fan power may warrant the inclusion of a supplementary cooling coil within the module.

7.117 The system should have sidewall panels at least 2·4m apart. The panels may fold to facilitate cleaning of the theatre. The minimum height of the terminal should be 2·1m and a deflector at the top of the filter/diffuser will be acceptable as an alternative to a full roof. These dimensions reflect currently available equipment and may impose operational constraints in addition to a lower level of performance common to these systems.

7.118 In the horizontal flow systems, personnel working between the filter and surgical wound will disperse bacteria that are more likely to contaminate exposed surgical instruments and enter the wound. This may be minimised by the use of improved clothing and operating procedure to reduce dispersion of bacteria. The use of lines on the floor delineating the extent of the clean zone and hatching or colour coding the 'no-entry' zone between the air diffuser and patient will serve to prompt staff and are therefore essential.

7.119 The air discharge velocity as measured 1m from the diffuser face should have a mean value of 0·4 m/s. The validation Section 8 gives details of the method of measurement.

Filters

7.120 The main plant primary and secondary filters should be to the standards and in the location set out in Section 4.

7.121 Terminal filters should be provided within the airflow terminal or in the air supply to it. High efficiency particulate air (HEPA) filters grade H10 as specified in BS EN 1822 will be required as a minimum. There is no aerobiological benefit in

fitting filters of a higher grade than this, although for practical reasons most UCV manufacturer recommend the fitting of H12-grade filters.

7.122 In some modular UCV units, the terminal filter is used as a pressure equaliser to balance airflow and filters of a higher grade with a greater pressure drop may be recommended by their manufacturer. The increased resistance may affect the velocity of air reaching the operating level and there will be penalties in terms of installed fan power and higher noise levels.

7.123 The final filters should be installed in a leak-proof housing in a manner that allows the terminal unit, filters and their seals to be validated. A challenge test will be carried out during commissioning to prove the effectiveness of the complete installation.

7.124 Where UCV units are constructed in sections, a means of measuring the pressure drop across the terminal filters in each section should be provided. The pressure test-points should be located outside of the partial wall, capped to prevent air leakage and accessible within the theatre without the need to open the unit inspection panels. Alternatively direct-reading pressure gauges should be fitted.

7.125 The UCV system will require a return-air filter to capture the relatively coarse particles that would otherwise significantly reduce the life of the final filter. This should be at least a G3 grade to BS EN 779. In remote recirculation systems there may be advantages in fitting a higher grade return air filter, as it will reduce the load on the terminal HEPA filters and extend their life.

Noise level

7.126 If sound-attenuating material is used to line any portion of the inside of the UCV unit it should be non-particle-shedding and fire-resistant. (Further guidance can be found in SHTM Firecode suite of documents).

7.127 The maximum noise level in an operating room fitted with a UCV terminal of any type shall not exceed 50 NR. The validation section gives details of the method of measurement.

Lighting and operating lights

7.128 CIBSE lighting guide LG2 and BS EN 12464-1 give detailed information of lighting requirements. Operating luminaires should comply with the photometric requirements detailed in relevant sections of BS EN 60601.

7.129 The position of the UCV light fittings and style of partial walls, where fitted, should neither adversely disturb the airflow nor result in significant spatial variations in illuminance levels.

7.130 In vertical units, specialised task lighting should be provided by toroidal, cruciform or small multiple dome-shaped luminaires as they have good aerodynamic properties. The ideal luminaire will have a minimal effect on the airflow regardless of where it is positioned. Large-diameter saucer-shaped

luminaires should not be used in vertical-flow systems as they will occlude the airflow in the critical central zone. It is important to consider the suitability of existing luminaires when retrofitting UCV systems.

7.131 In vertical UCV installations a minimum of 2·75m from floor to underside of the diffuser is required to allow for supporting mechanisms and lamp articulation. When upgrading existing systems this dimension may not be achievable. However, when parked, the lowest point of the central light stem, luminaire and articulation arms should never be less than 2m above floor level.

7.132 The traditional means of light support is a central column that passes through the UCV terminal and is rigidly fixed to the building structure. The position of the support therefore prevents air being supplied at the centre of the terminal. Separate supports displaced from the centre of the clean zone would lead to improved airflow. This approach was advocated in the 1994 version of HTM 2025 but at the time of writing no UK manufacturer has chosen to adopt this solution.

7.133 In horizontal units the size or shape of the specialised task luminaire has little effect on the air-flow pattern.

Controls and instrumentation

7.134 The functions of the supply AHU and extract ventilation should be continuously monitored by a BEMS control unit. The controls and instrumentation for the main plant are set out in Section 6.

7.135 UCV systems will additionally require:

- a set-back facility that can reduce the air supplied through the UCV terminal to a volume that equates to not less than 25 air changes per hour of the operating room gross volume whilst still leaving the supply AHU operating at full speed;
- a facility to turn the entire system, supply AHU and UCV terminal, off. (an emergency stop is not required);
- a read-out sufficiently large to be clearly visible from the operating table that shows the temperature of the air being supplied by the UCV terminal;
- a read-out sufficiently large to be clearly visible from the operating table that shows the relative humidity of the air being supplied by the UCV terminal;
- a red indicator light that will illuminate when either the supply AHU or the UCV terminal fails, either or both are switched off or are at set-back;
- an amber indicator light that will illuminate when the UCV terminal is at set-back and the supply AHU is running;
- a green indicator light that will illuminate when both the supply AHU and UCV terminal are operating at full speed;
- a blue indicator light that will illuminate when the UCV terminal air flow, as detected by a differential pressure sensor, falls below 80% of the design flow rate.

AHU	UVC terminal	Indicator light	Comment
Off or Fault	Off or Fault	Red	Ventilation not operating at a suitable level to commence surgical procedures
Off or Fault	On (set-back)		
Off or Fault	On (full speed)		
On (set-back)	Off or Fault		
On (full speed)	Off or Fault		
On (set-back)	On (set-back)		
On (full speed)	On (set-back)	Amber	Ventilation provided to at least conventional theatre standard
On (full speed)	On (full speed)	Green	Full UCV standard conditions
-	-	Blue	HEPA-filter resistance causing low air flow

Table 7: Indicator light logic table

7.136 The switching devices and indicators should be incorporated in the surgeon's panel and their functions clearly labelled. In retrofit installations an auxiliary panel for the UCV may be the most practical option. If fitted it should be mounted adjacent to the surgeon's panel and their control functions interlocked as necessary.

7.137 When a system is designed to have partial walls with full-wall extensions, a volume control facility may be incorporated to allow the system to be run with reduced velocity when the demountable full-walls are in place. It would be the responsibility of the user to ensure correct operation of the system. To assist the user an explanatory notice should be included on the theatre control panel.

7.138 A direct-reading gauge should be fitted in the theatre to show a representative pressure drop across the final filters. If the UCV control box is located out of the theatre and has a means of manually adjusting the return air-fan speed then it should also be fitted with a direct-reading differential pressure gauge. The means of adjusting the return-air fan speed should be lockable to prevent casual adjustment. The direct-reading gauges should be fitted with a means of indicating the correct operating pressure range.

7.139 The UCV-unit manufacturer's control box should be located in an accessible position preferably in the operating department adjacent to the operating theatre that it serves. A service corridor, if provided, is an ideal location. The control box should be clearly labelled with the identity of the operating theatre that it serves.

7.0 (c) Extract systems

7.140 Extracts may be provided for a variety of reasons including:

- simple odour control (for example in a WC or mortuary);
- to receive and remove moisture-laden air (for example, in a kitchen);
- as part of a combined supply/extract balanced system (for example, in an operating suite);

- to capture a hazardous substance at source (for example a safety cabinet).

7.141 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as Local Exhaust Ventilation (LEV) systems under the COSHH Regulations.

7.142 An LEV system may comprise a self-contained unit incorporating its own carbon filter such as a simple bench-top fume cupboard. Alternatively it may be a complete "ventilation system" comprising a make-up air supply, multiple-exhaust-protected work stations, branch and central extract ductwork, duplex extract fans and a high-level discharge terminal. It may also incorporate a special filtration system appropriate to the hazardous substance being controlled. Such systems could be required for workshops containing woodworking machinery or large centralised pathology laboratories housing multiple safety cabinets, dissection benches, fume cupboards and specimen stores.

7.143 It is important to recognise at the design stage whether an extract is being provided for comfort or as an LEV system. Typical systems in healthcare include:

- microbiological safety cabinets and Category 3 containment rooms;
- fume cupboards;
- welding-fume extracts;
- woodworking machinery duct collectors;
- battery-charging bay extracts;
- powered plaster and bone saws;
- pharmaceutical preparation cabinets and tablet machines;
- dissection benches, cut-up tables and some specimen stores;
- medium- and high-risk infectious disease isolation facilities;
- decontamination facilities;
- dental furnaces, grinders and polishers.

7.144 General design information and guidance for LEV systems is produced by the Health and Safety Executive (HSE) as HS(G)37. Information on the design and installation of microbiological safety cabinets is given in BS5726 and that for fume cupboards is given in BS EN 14175. Their recommendations should be closely followed.

7.145 LEV systems are statutory items that will be subject to an independent inspection every 14 months.

Hood extract systems

Special requirements

7.146 Extract canopies will be required over steam-and-heat-emitting appliances, for example sterilisers, catering and washing equipment; and for the extraction of toxic fumes over benches used for mixing, sifting and blending procedures.

7.147 Perimeter-drain gulleys and corrosion-proof grease eliminators should be provided on kitchen hoods.

Typical arrangements

7.148 The air-flow rate must be sufficient to ensure an adequate capture velocity in the vicinity of the process; typical values are as follows:

- evaporation of steam and like vapours 0.25 m/s to 0.5 m/s;
- chemical and solvent releases 1.0 m/s;
- vapour of gases 5 m/s to 6 m/s;
- light dusts 7 m/s to 10.0 m/s.

Excessive velocities will be wasteful of power and generate noise.

7.149 The lowest edge of the canopy should be 2m above finished floor level, with a minimum of 300mm overhang beyond the edge of the equipment on all sides.

7.150 A compact arrangement of equipment (but with access for maintenance) will minimise the canopy area, and hence reduce the air volume necessary to achieve the optimum capture velocity.

7.151 Hoods required for the control of heat gain and vapours may be connected to the general extract system when it is convenient to do so, but where non-corrosive ductwork materials are necessary, a separate discharge is preferred.

7.152 Lighting and internal divider plates are often required to be built into the perimeter of large canopies. However, built-in shelving systems are not recommended, as they interfere with the air-flow, and constitute a maintenance problem.

Control of hood extracts

7.153 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the hood extract and any associated supply can be shut down. To this end, local control should be provided.

Bench extract systems

Special requirements

7.154 Bench extract ventilation is required in departments such as pathology and mortuary, where activities involve the release of malodorous or toxic fumes that should not be inhaled. Where hazardous substances are being controlled, the system should be designated an LEV.

Typical arrangements

7.155 Each ventilated position will usually be accommodated in a continuous run of benching, which should not be more than 650mm from front to rear and which should be provided with a continuous upstand at the rear. Each position should have a 1200mm x 150mm linear extract grille mounted on a purpose-designed plenum box (incorporating guide vanes as necessary), with its face flush with the upstand. The bottom of the grille should be as close as practicable to the level of the working surface (usually 75mm above, to allow for cleaning). The minimum velocity across any part of the grille should be 1 m/s. The grille should be readily demountable to allow for cleaning.

Control of bench extract systems

7.156 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the bench extract and any associated make-up supply can be shut down. However, a run-on timer with a minimum setting of 30 minutes must be provided. To this end, local or automatic-use control should be provided.

7.157 Processes that produce hazardous vapours, fumes, dusts or noxious vapours should be enclosed or semi-enclosed in a suitable cabinet or exhaust protected workstation.

Safety cabinet and fume-cupboard extract systems

7.158 Safety cabinets and fume cupboards are devices that use an inflow of air to control exposure of staff to hazardous substances. The units, their exhaust systems, filters, fans and discharge terminals are all classified as Local Exhaust Ventilation (LEV) systems under the COSHH Regulations. The make-up air system to a room that contains an LEV system should also be considered as an essential part of the system and be included in the LEV classification. Information on the design and installation of microbiological safety cabinets is given in BS5726 and that for fume cupboards is given in BS EN 14175. Their recommendations should be closely followed.

7.159 The Advisory Committee on Dangerous Pathogens (ACDP) publishes 'The Management, Design and Operation of Microbiological Containment Laboratories' covering the general environment in which they are used and operational considerations.

Special requirements

7.160 The supply-air system should not distort the unidirectional and stable air pattern required for fume cupboards and microbiological safety cabinets. In general, supply-air ceiling diffusers should not discharge directly towards fume cupboards or safety cabinets, unless the terminal velocity is such that the air-flow pattern of the cabinet is unaffected. The design should ensure that high air-change rates, and/or the opening and closing of doors do not have any adverse effect on the performance of safety cabinets or fume cupboards. A damped door-closure mechanism may help.

7.161 In order to safeguard the user, all safety cabinets and fume cupboards must be fitted with a clear indication that they are operating correctly. Direct-reading gauges or falling-ball indicators are preferred (in addition to electronic pressure indicators). The system should be set to alarm audibly if the face velocity falls below the minimum safe operating level.

Arrangements for safety cabinet installations

7.162 The manufacture and installation of microbiological safety cabinets must be in accordance with the relevant national standards and guidance issued by the Advisory Committee on Dangerous Pathogens (ACDP).

7.163 A Class 1 microbiological safety cabinet must be specified for routine work involving Group 3 pathogens. It should be housed in a Category 3 containment room. Specific design information on containment rooms is issued by ACDP in conjunction with the Health and Safety Commission.

7.164 Siting and installation of microbiological safety cabinets are of particular importance because:

- the protection afforded to the operator by the cabinet depends on a specific and stable unidirectional air flow through the open front;
- the protection to the environment by the cabinet depends on the high efficiency particulate air (HEPA) filters. The exhaust air should never be considered as totally free from microbiological hazard.

7.165 Microbiological safety cabinet is HEPA filtered prior to being discharged to outside. The extract ductwork should as far as practicable be kept under negative pressure while inside the building.

7.166 Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2m); such an installation however, is likely to be noisy and is not recommended for use in new buildings.

7.167 The discharge from the cabinet should be fitted with a back-draft damper. In multiple installations where several cabinets discharge into a common extract and discharge duct, it must be possible to isolate each cabinet from the system when not in use.

7.168 Roof-level discharge, wherever practicable, is preferred since it removes much of the uncertainty over air re-entering the building through ventilation inlets and/or windows. In such an installation, the extract fan should be situated separately from the cabinet and close to the discharge outlet, to maintain the duct within the building under negative pressure. The discharge point on a flat roof should be through a 3m high terminal. This is required to safeguard staff who may need to access the roof periodically for maintenance. This requirement will also be applicable to fume-cupboard discharges.

7.169 Where this is impracticable, discharge into the room via a double HEPA filter has been accepted. The preferred method, however, is to discharge 3m above the roofline in line with the similar standard for fume cupboard designs.

Arrangements for fume cupboard installations

7.170 The manufacture and installation of fume cupboards must be in accordance with the relevant national standards and associated guidance.

7.171 The primary factors that contribute to the effective performance of fume cupboards include:

- an adequate volume of supply air;
- an effective exhaust system to promote the safe dispersal of waste products to atmosphere.

7.172 The air velocities through sash openings must be sufficient to prevent hazardous materials from entering the laboratory while avoiding excess flow rates that interfere with the investigation process. Average face velocities should be between 0.5 and 1.0 m/s, with a minimum at any point within 20% of the average, the upper end of the range being applicable to the containment of materials of high toxicity. The design velocity must be maintained irrespective of whether the sash opening is varied, or whether doors or windows are open or closed. Variable Air Volume (VAV) cupboards are available which offer a reduction in energy use.

7.173 The possibility of a fire or explosion that may not be contained by a fume cupboard must always be considered. A fume cupboard should not, therefore, be sited in a position where exit to an escape route will necessitate passing directly in front of it.

7.174 Fume-cupboard fans should be installed as near as possible to the termination of the duct, thus maintaining the maximum amount of ductwork at negative pressure.

7.175 Where there are adjacent buildings with opening windows, or where downdraughts occur, it may be necessary to increase the height of discharge ducts in order to achieve adequate dispersal. In complex locations, airflow modelling or wind tunnel tests may be required to determine the optimum height of the stack (see also Paragraph 7.167).

7.176 Fume-cupboards for certain processes must have separate extract systems. However, where appropriate, individual fume-cupboard exhaust systems may discharge via non-returning dampers into a single collection duct rather than having a large number of separate stacks. The collection duct should have a large cross-sectional area to minimise its effect on the individual exhaust systems; be open to atmosphere upstream of the first connection; and be designed to discharge a total air volume at least equal to the combined individual extract systems.

7.177 Individual fume-cupboard extract systems, discharging either directly to atmosphere or into a collection duct, do not require duplex fans. However, a collection duct designed to provide dispersal of effluent from a number of individual extracts, should have duplex fans with automatic changeover.

7.178 Some fumes are particularly corrosive, so the choice of material for the ductwork, and type of extract fan fitted should reflect the nature of the fume being conveyed.

Control of extract systems

7.179 It is desirable to provide local control of safety cabinets in order to maximise the life of the HEPA filter, and to permit the sealing of the cabinet and room for fumigation if spillage occurs.

7.180 To cope with the risk of an accident or spillage outside safety cabinets, a 'panic button' should be provided to switch off the supply to that area; and discharge all extracted air to atmosphere.

7.181 In pathology departments, it will be necessary to have one or more microbiological safety cabinets and one or more fume cupboards available for use at all times, including weekends, therefore, local overriding controls for all these items and any associated ventilation plant will be necessary.

7.0(d) Plantroom ventilation

General requirements

7.182 Plant rooms are required to be ventilated in order to maintain acceptable temperatures for satisfactory operation of the plant and controls, and for maintenance activities. In the case of plant rooms housing combustion equipment, a secondary function of the ventilation is to provide make-up air for the combustion process.

7.183 The air required for these purposes should be introduced into the space through inlets positioned to minimise the discomfort to occupants; they should be unlikely to be blocked, closed deliberately (except in the case of fire shutters if required), or rendered inoperative by prevailing winds.

7.184 Plantroom ventilation air should not be used for any other purposes, such as make-up air for extract; and where the plantroom contains combustion equipment, the appliance pressure must not fall below the outside air pressure.

7.185 Specialised healthcare air handling equipment must not be located in a fire compartment that houses combustion equipment.

7.186 Statutory regulations for plantroom ventilation are contained in the Scottish Building Regulations, and further guidance is given in CIBSE Guides A & B.

Assessment of ventilation levels

7.187 Ventilation requirements must take into account all heat sources within a plantroom, and where there are large glazing areas, solar gains. The ventilation rate should limit the maximum temperature within the plantroom to 32°C.

7.188 As the level of equipment operating during mid-season and summer is often lower than the winter condition, and the cooling effect of the outside air is reduced, it is necessary to calculate the minimum volume for each season of operation, and the inlet and outlet grilles or fan sizes should be chosen to cater for the largest seasonal air volume.

7.189 Replacement air should not be drawn through pipe trenches or fuel service ducts. Where metal ducts penetrate walls and floors, effective sealing should be provided to confine the ventilation to the boiler room and to meet fire protection requirements. Penetration of fire barrier walls by ventilation ducts should be avoided if possible.

7.190 Fire dampers in plant room ventilation ducts should be electrically interlocked with the boiler plant.

7.191 Care must be taken to prevent any noise generated in the boiler room emerging from natural or mechanical ventilation openings to the detriment of the surrounding environment. Particular care is necessary with mechanical flue draughts and fan-diluted flue systems.

7.192 Information on required air volumes in contained in the CIBSE Guide A & B.

7.193 Where combustion plant is installed, the high-level (outlet) openings should be sized to cater for the total ventilating air quantity; and the low-level (supply) openings sized to cater for the total combined ventilating and combustion air quantity.

Choice of ventilation system

7.194 Ventilation air may be introduced and exhausted by either natural or mechanical means or a combination of both. However, natural systems are preferred where possible.

7.195 Generally, small installations at or above ground level should have their combustion and ventilation air provided by natural means, employing both high- and low-level openings.

7.196 Basement, internal and large installations at or above ground level will usually require a combination of natural and mechanical ventilation. If the airflow rate is difficult, both supply and extract may require mechanical means.

7.197 Whether natural or mechanical, the system should be designed to avoid both horizontal and vertical temperature gradients. Both inlet and outlet openings should be placed on opposite or adjacent sites of the building to reduce the effect of wind forces.

7.198 Where mechanical air supply is employed, electrical interlocks with the boiler plant should be provided to prevent damage in the event of failure of the supply fan(s) once the air volume is established.

7.199 The necessary free opening areas for a naturally ventilated plantroom may be calculated using either the method in A4 of the CIBSE Guide A or the table in section B13 of CIBSE Guide B.

7.200 A combined natural and mechanical ventilation system should allow for natural extract at high level, to take advantage of convective forces in the room, with mechanical supply at low level. The high level natural ventilators should be sized to cope with the total quantity of ventilation air, as above.

7.201 To prevent leakage of flue gases and to ensure that the flue draught is not impeded at any time, the air pressure in the boiler room must not exceed the prevailing outside pressure. Therefore, the fan duty should exceed the calculated total combined combustion and ventilation air quantity by at least 25%. Fan-powered inlets should be arranged to flow outside air into the space at a point where cross-ventilation will ensure pick-up of heat without causing discomfort to occupiers.

7.202 Where it is impractical to provide sufficient natural ventilation to remove the heat emitted by the plant, both mechanical supply and extract will be required.

7.203 The high-level extract should be sized to cater for the total ventilating air quantity and the low-level supply should exceed the total combined combustion and ventilating air quantity by at least 25%, as above.

7.0(e) Ventilation of hydrotherapy suites

General requirements

7.204 In a hydrotherapy suite heat recovery should be via heat pump.

7.205 The quantity of supply air should be calculated as 25 litres/sec/m^2 wetted surface, with the wetted surface taken as 110% of the pool water surface area.

7.206 A re-circulation plant is recommended, with a minimum of 20% fresh air.

7.207 As far as practicable, re-circulated pool air should be provided to the ancillary changing and recover accommodation, with the only extract from the toilets, laundry/utility room and pool hall.

7.208 Supply air to the pool hall should be introduced at high level and directed towards the perimeter to mitigate condensation, with extract air taken from directly over the pool. Dampers should not be located over the pool water.

Control of hydrotherapy pool installations

7.209 The supply and extract fans should be interlocked so that the supply fan does not operate until flow is established within the extract system.

7.210 Time-clock control should be provided, with a local override switch to extend the normal operating period as required.

7.211 Night setback temperature (in the range of 21°C -25°C) and high humidity control (in the range of 60-75% sat) should be provided to override the time clock in order to prevent condensation. The exact set points should be ascertained post-installation.

7.212 A remote indication panel should be provided in the pool hall, giving a visual display of the pool water and pool air temperature.

8. Validation of specialised ventilation systems

Definitions

Commissioning - Commissioning is the process of advancing a system from physical completion to an operating condition. It will normally be carried out by specialist commissioning contractors working in conjunction with equipment suppliers. Commissioning will normally be the responsibility of the main or mechanical services contractor.

Validation - A process of proving that the system is fit for purpose and achieves the operating performance originally specified. It will normally be a condition of contract that "*The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.*"

Note: Commissioning is often sub divided into sections e.g. air handling unit, automatic controls, airside balance, building fabric and fittings. Each section may be commissioned by its specialist installer and they are often accepted in isolation. Validation differs from commissioning in that its purpose is to look at the complete installation from air intake to extract discharge and assess its fitness for purpose as a whole. This involves examining the fabric of the building being served by the system and inspecting the ventilation equipment fitted as well as measuring the actual ventilation performance.

It is unlikely that 'in house' staff will possess the knowledge or equipment necessary to validate critical ventilation systems such as those serving operating suites, pharmacy clean rooms and local exhaust ventilation systems. Validation of these systems should therefore be carried out by a suitably qualified independent Authorised Person appointed by the NHS Board.

It is anticipated that training in the validation of specialised healthcare ventilation systems for independent Authorised Persons will become available during the life of this SHTM.

Commissioning general

8.1 Commissioning is an essential process for ventilation systems. It is therefore important that adequate provision for the process be made at the design stage of the project. Procedures for commissioning air-handling systems are given in CIBSE Commissioning Codes and BSRIA Application Guide Set COMPAK 1.

8.2 The duct-sizing procedure should take into account the requirements of system balancing, and the position and number of regulating dampers included in the design should be sufficient for this purpose.

Location of dampers and test holes

8.3 Balancing/commissioning dampers will be required in each branch of the distribution ductwork.

8.4 Test holes for the measurement of air-flow will be required at carefully selected points in main and all branch ducts. The number and spacing of holes are given in the BSRIA Application Guide Set COMPAK 1. Their positions must be identified at the design stage.

8.5 The test positions need to be accessible for commissioning to take place. They may also be required for subsequent annual verification of the system performance, so they should not be covered by permanent lagging.

8.6 The measurement point should be in a straight length of duct as far away as possible from any upstream bends, dampers or other elements that could cause disturbance to the airflow. The actual location should be:

- at least 1.5 duct diameters upstream of sources of turbulence such as dampers and bends;
- if this is not possible, 10 diameters downstream of dampers, bends or tees, and 5 diameters downstream of eccentric reducers;
- where there is enough space round the duct to insert the pitot tube and take readings;
- where the duct has a constant cross-sectional area.

8.7 Test holes for measuring total airflow from a fan should be located either 4 diameters upstream or 10 diameters downstream of the fan. Provision should also be made for measuring the speed of rotation.

Information to be provided

8.8 It is essential that the designer should pass on his intentions fully to the commissioning engineer by indicating which parts of the system are high, medium and low pressure, and by providing:

- relevant parts of the specification;
- schematic drawings indicating performance data as indicated in Table 8;
- equipment schedules;
- controller and regulator schedule;
- fan performance curves;
- wiring diagrams for electrical equipment, including interlock details.

Items in system	Information to be provided
Fans	Fan total pressure Volume flow rate at high and low speed Maximum motor current
Plant items	Type and identification numbers from equipment schedules Fluid and air volume flow rates Fluid and air side pressure losses Dry bulb temperatures Wet bulb temperatures Humidity
Dampers, including motorised and fire dampers	Identification numbers from equipment schedules Location Identification number Volume flow rate
Main and branch ducts	Dimensions Volume flow rates and velocities Identification numbers from equipment schedules
Terminal	Location Identification number Grille or diffuser factor Volume flow rate and neck velocity Operating static pressure
Test holes and access panels	Location Identification number
Controllers	Set points

Table 8: Information to be provided on schematic drawings

Notes: For Table 8

1. Fan total pressure is the difference between the total pressure (static pressure + velocity pressure) at the fan outlet and the total pressure at the fan inlet.

2. Where volume flow rates are variable, maximum and minimum values should be provided.

Commissioning personnel

8.9 As one individual is unlikely to possess all of the required commissioning skills, a commissioning team is therefore usually needed. The objective of commissioning is to ensure that the necessary performance and safety requirements are met.

8.10 During the commissioning process a great deal of information will be generated which will form an invaluable future source of reference about the plant. It is essential to ensure that it is collected together in the form of a commissioning manual and handed over to the client on completion of the contract together with the 'as fitted' drawings. This information should be both in hard copy and electronic format.

8.11 In order to be successful the commissioning process must start before achieving practical completion as many parts of the system will become progressively less accessible. The correct installation of those parts will need to be witnessed and leak-rate tests carried out as construction proceeds. Failure to establish responsibility for commissioning early enough will delay the completion of the project or lead to unsatisfactory plant performance.

Commissioning brief

8.12 The commissioning team will require a detailed brief from the system designer. This should include:

- a 'user' brief comprising a description of the installation and its intended mode of operation;
- the precise design requirements with regard to the scheme of air movement, room static pressures, supply and extract air-flow rates and acceptable tolerances;
- full details of the design conditions both inside and out, for winter and summer together with the control strategy;
- equipment manufacturer's type test data, commissioning, operation and maintenance recommendations;
- drawings showing the layout of the system, positions of air-flow measurement test points, dampers, regulating devices and filters within the duct runs, together with sizes of ducts and terminal fittings. It will save time if these drawings are annotated with the design volumes and static pressures required at each branch and outlet point;
- wiring diagrams for all electrical equipment associated with the air handling systems including motor control circuit details and any interlocking and safety devices such as emergency-stop buttons adjacent to the item of plant.

8.13 The CIBSE Commissioning Code, Series 'A' – "Air Distribution", provides full guidance on the information that will be required by the commissioning team.

8.14 The designer should include in the contract document instructions on verifying the accuracy of test instruments that should be supported by reference to relevant calibration certificates.

8.15 The system, on completion, should be operated by the contractor as a whole and subject to performance tests in accordance with the contract requirements.

For critical systems, these may include independent validation of the system performance on behalf of the client.

8.16 Prior to dynamic commissioning, it is essential that builders' work in the area served by the system is complete, all rubbish and dust is removed, concealed plumbing (IPS-type) panels are in position and ceiling tiles are in place and clipped. Floors should be mopped and visible dust removed from all other surfaces.

8.17 Once the system is shown to meet the design intent the handover documentation should be completed. In the event of performance not being acceptable, the matter should be dealt with in accordance with the contract arrangements.

Pre-commissioning checks

8.18 The pre-commissioning checks consist of visual inspection, manual operation of equipment, static measurements and functional tests of individual components. They should be carried out prior to setting the system to work and undertaking the dynamic commissioning process set out in Paragraph 8.29 onwards of this guidance.

Standard of installation

8.19 During the installation of the system the following must be witnessed:

- that the plant and installations have been provided and installed in accordance with the design specification and drawings;
- that only approved sealants have been used in the installation;
- that all components function correctly;
- that the satisfactory sealing of access doors and viewing ports have been carried out;
- that air pressure tests and air-leakage tests on ventilation ducting have been carried out in accordance with the methods set out in the HVCA's DW/143: Ductwork Leakage Testing. It is usual to carry out these tests, a section at a time, as the ductwork is installed and before its insulation is applied. The results must be recorded in the commissioning manual;
- that gaps around doors and hatches are as specified in the design;
- that the correct operation of pressure stabilisers, control dampers, isolating and non-return dampers have been checked and installed in the correct orientation for air-flow;
- that test holes have been provided in their specified locations and are sealed with suitable grommets;
- that control dampers are secured and their quadrants fitted correctly;
- that any interlocks are operative and in accordance with specification;

- that the electric circuits are completed, tested and energised;
- that electric motors have been checked for correct direction of rotation both at full speed and set-back;
- that cooling and heating media are available at correct temperatures and pressures and in specified quantities;
- that the air-conditioning plant components and controls function correctly;
- that the air-conditioning plant interlocks and safety controls function correctly;
- that the plant is physically complete, insulation is applied and all ducts and pipework are identified as specified;
- that the building housing the ventilation plant is generally in a fit condition for commissioning and performance tests to commence, that is, windows, doors, partitions etc are completed, surfaces sealed and their final finish applied;
- that the areas containing the ventilation plant and those being served by it are clean;
- that access to all parts of the system is safe and satisfactory.

Cleanliness of installation

8.20 During installation it must be established that ductwork is being installed to the 'advanced level' as defined in the HVCA (2005) 'TR/19 – Guide to good practice: internal cleanliness of ventilation systems'. This specifically includes ensuring that ductwork sections arrive on site and are stored with their open ends sealed and that open ends remain sealed during installation to prevent the ingress of builders' dust.

8.21 Should any doubt exist whether the guidance has been observed, the ducts must be cleaned internally to restore them to this standard before being taken into use.

8.22 "Builders work" ducts of brick or concrete must be surface sealed to prevent the release of dust before being taken into use.

8.23 The area around the supply air intake must be free of vegetation, waste, rubbish, builders' debris or any other possible source of contamination.

Certification of equipment

8.24 The following test certificates should be assembled by the commissioning team and be available for inspection at any time during the contract period. They will form part of the handover information and should be placed in the commissioning manual:

- type-test performance certificates for fans;
- pressure-test certificates for:

  - heater-batteries;
  - cooling coils;
  - humidifiers (if appropriate);
- type-test certificates for attenuators;
- type-test certificates for primary and secondary filters;
- individual test certificates for high efficiency particulate air (HEPA) filters.

Equipment tests

8.25 Prior to setting the system to work, the checks in Paragraphs 8.26 - 8.28 should be witnessed, and proving tests should be carried out as detailed.

Filters

8.26 The quality of filter housing and in particular, the seals is a critical factor in maintaining the efficacy of the filtration system by ensuring that air does not bypass the filter panels. Therefore, the following checks should be made:

- filter seals should be fitted and in good condition;
- filters should be installed correctly with respect to air flow;
- bag filters should be installed so that the bags are vertical and their pockets free;
- HEPA filters should be installed in a sealed housing and their seals tested to DIN 1946 if specified;
- all filters should be checked to ensure they are free of visible damage;
- the differential pressure indicators should be checked for accuracy and that they are marked with the initial and final filter resistance.

Drainage arrangements

8.27 The drain should conform in all respects to the “Design considerations” of this SHTM. In addition the following must be proved:

- that the drain tray is easily removable;
- that a clear trap is fitted and is easily removable;
- that the drain has a clear air gap of at least 15mm;
- that the pipework is supported so that the air break cannot be reduced;
- that the drain system from each drain tray is independent up to the air break;
- that the operation of the drainage system is proved by introducing water into the duct at the drain tray and observing that it completely drains out. This check is to be repeated both at normal speed and set back once the fans

have been commissioned. At this time the clear trap can be marked to indicate the normal water level with the fan running.

Fire dampers

8.28 The following must be witnessed and proving tests should be carried out as detailed:

- the operation of all fire dampers;
- the access provided to enable the dampers' to be visually inspected and / or re-set should be sufficient for the purpose;
- indication should be provided of the dampers' position (open/tripped);
- indication of the fire dampers' location should be provided both on the ductwork and at a visible point on the building fabric if the ductwork is concealed.

Dynamic commissioning

Air-handling and distribution system

8.29 The fan drive, direction of rotation, speed and current drawn should be set in accordance with their manufacturer's instructions.

8.30 After the installation has been checked to ensure that it is in a satisfactory and safe condition for start-up, it should be set to work and regulated to enable the plant to meet its design specification. The proportional balancing method described in the CIBSE Commissioning Code "A" must be followed. The air-flow rates must be set within the tolerances laid down in the design brief. This will normally be the design airflow rate +10% -0%.

8.31 When combined supply and extract systems are to be balanced and the area that they serve is to be at or above atmospheric pressure then the supply should be balanced first with the extract fan switched off, and then the extract balanced with the supply fan(s) on.

8.32 For combined systems where the area that they serve is to be below atmospheric pressure then the extract should be balanced first with the supply fan switched off and then the supply balanced with the extract fan on.

8.33 On completion of the balance all volume air-flows in supply and extract ducts and from grilles and diffusers must be measured and recorded. The true air change rate can them be calculated from the data obtained.

8.34 The main supply and extract duct volume control dampers must be locked and their position marked.

8.35 All grille and diffuser volume control registers must be locked to prevent alteration and their final position marked.

Room air distribution

8.36 The pressure-relief dampers and pressure stabilisers must be set to achieve the specified room static pressures and locked. The grille direction control vanes and diffuser cones must be set to give the specified air-movement pattern. Visualisation techniques may need to be employed in order to prove that the required air-flow pattern is being achieved. This may be a potential requirement when commissioning LEV systems or rooms that contain them.

Air-conditioning plant

8.37 The specified flow rate and/or pressure drops must be set for all heater batteries, cooling coils and humidifiers. The methods described in the CIBSE Commissioning Codes "W" and "R" should be followed. On completion their regulating devices must be locked to prevent alteration.

Control system

8.38 The control system should not be commissioned until both the air distribution system and air-conditioning equipment have been commissioned.

8.39 Because of the specialised nature of control systems and the fact that each manufacturer's system will contain its own specialist components and settings, the commissioning should be completed by the supplier and witnessed by a representative of the user.

8.40 The location of all control and monitoring sensors should be checked and their accuracy proved.

8.41 The control system's ability to carry out its specified functions must be proved.

8.42 If the plant is provided with a "user's" control panel in addition to the one located in the plantroom then the operation of both must be proved. This will typically apply to operating departments and laboratory systems.

Specific performance standards

Air movement

8.43 The performance of the system should be measured and compared with information provided by the designer.

Plant capacity and control

8.44 When setting to work and proving the design, both the manufacturer of the air-handling plant and the control specialist should attend site together and jointly commission the system.

8.45 If any doubt exists as to the capacity of the installed system, then its ability to achieve the specified inside design conditions with the plant operating at winter

and summer outside design conditions must be proved. Artificial loads will be required in order to simulate the internal gains/losses and the outside design conditions.

8.46 On completion of the plant performance test, recording thermo-hygrographs should be placed in each room/area served by the plant and also the supply air duct upstream of the frost battery. The plant should be run for 24 hours with all doors closed. During this period the inside conditions must stay within the tolerances specified. The BEMS should be used to obtain the information required wherever possible. Periodic tests will be required during the defects liability period.

Noise levels - general

8.47 The commissioning noise level is the level measured with a sound-level meter in the unoccupied room and taking account of the external noise together with the noise generated by the ventilation system. When occupied and in use this commissioning level will constitute a continuous background noise that will allow the overall noise level to be achieved. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise.

8.48 The noise levels apply at the maximum velocity for which the system is designed to operate. Acoustic commissioning tests should be carried out with all plant and machinery running normally and achieving the design conditions of airflow, temperature and humidity.

8.49 An industrial-grade sound-level meter to BS3489 or IEC 651 Type 2 will normally be sufficient to check the noise level.

8.50 The noise level readings are to be taken at typical normal listening position 1.5m above floor level and at least 1m from any surface and not on any line of symmetry. In critical rooms the noise should be measured at the centre of the room and at the centre of each quarter. The mean of the 5 readings should then be calculated.

8.51 In the event of a contractual deficiency, a Type 1 precision-grade sound-level meter should be used and the noise level determined by the procedure given in Scottish Health Technical Memorandum 08-01 (2011).

Filter challenge

General ventilation filters

8.52 In-situ performance tests will not normally be required for primary and secondary filters and their housings. However the filters should be visually inspected for grade, tears, orientation and fit within their housing. Filters should be clean and a replacement set available. Bag filters should be installed so that

their bags are vertical and spaced so that air can move through them freely. Any filter found to be wet should be replaced and the cause investigated.

HEPA filters (for exhaust protective enclosures and laboratories)

8.53 Pathogenic material may be discharged through damaged or badly installed HEPA terminal filters. The complete installation must be tested using the method set out in BS EN: 14644 'Method of Testing for the Determination of Filter Installation Leaks'.

8.54 The challenge tests may be carried out using either of the following techniques:

- use Dispersed Oil Generator (DOP) to provide the challenge and a photometer to detect leaks;
- use a Discrete Particle Counter (DPC) to detect leaks. (In order to obtain a sufficient challenge it may be necessary to remove temporarily the supply AHU secondary filters).

8.55 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the HEPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.

8.56 A challenge aerosol of inert particles of the type produced by a DOP generator should be introduced into the air, upstream of the HEPA filter. The downstream face of the filter, its mounting seal and housing would then be scanned for leakage using a photometer. A leak should be deemed to have occurred if a steady and repeatable reading on the photometer at any point exceeds 0.01% of the upstream reading.

8.57 Alternatively a Discrete Particle Counter (DPC) may be used. For the Discrete Particle Counter method the filter face is sampled at several points to establish the smallest non-penetrating particle size. If particles at or above this size are detected when subsequent scans of the filter face, its seal and housing are made, then there is deemed to be a significant leak at, or near, the test position.

8.58 Should the HEPA filter fail this test it must be replaced. Should the filter mounting seal or housing fail this test it may be repaired and the test repeated.

Bacteriological sampling

General ventilation systems

8.59 Bacteriological sampling will not normally be required for either general or local exhaust ventilation (LEV) systems unless otherwise specified.

Conventional operating rooms

8.60 The level of airborne bacteria introduced by the supply air can be checked by closing all doors and leaving the operating room empty with the ventilation system running for 15 minutes. An active air sampler set to 1 cubic metre and mounted on the operating table should then be activated remotely. Aerobic cultures on non-selective media should not exceed 10 bacterial and/or fungal colony forming units per cubic metre (CFU/m^3).

8.61 The results should be examined to establish the broad category of organisms present. A high preponderance of fungal organisms may be an indication of inadequate filtration for the particular installation. Precise guidance is inappropriate and will depend on local circumstances.

8.62 It may be appropriate to carry out a check of airborne bacteria during a surgical operation. If required this should be carried out as soon as possible after handover. Unless there are unusually high numbers of personnel or extensive activity in the room, the number of airborne bacterial and/or fungal CFU averaged over any five-minute period, would be unlikely to exceed 180 per cubic metre.

8.63 Information on the additional validation testing of UCV Operating suites is given in Section 8.0(a).

Ventilation system commissioning/validation report

8.64 Following commissioning and/or validation a full report detailing the findings should be produced. The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

8.65 The report shall conclude with a clear statement as to whether the ventilation system achieved or did not achieve the required standard. A copy of the report should be lodged with the following groups:

- the user department;
- infection control (where required);
- estates and facilities.

8.0(a) Validation of UCV operating suites

General

8.66 Commissioning of a UCV terminal will normally be carried out by its supplier. Commissioning of the air-handling unit, fire dampers, distribution ductwork and control systems may be undertaken by different teams. It is therefore important to recognise that the UCV terminal is only one element of the specialised ventilation system serving the operating suite and it cannot be accepted in isolation.

8.67 In order to ensure that the complete system operates correctly it will be necessary to validate the system as a whole from the air intake through to the extract discharge. It is unlikely that "in house" staff will possess the knowledge or equipment necessary to undertake this process. Validation of Ultra-Clean operating theatre ventilation systems should therefore be carried out by a suitably qualified independent Authorised Person appointed by the client.

8.68 It is anticipated that training in the validation of specialised healthcare ventilation systems for independent Authorised Persons will become available during the life of this SHTM.

8.69 The following regime of inspection and testing should be applied to the validation of new installations designed to provide Ultra-Clean conditions in an Operating suite. The test regime has been devised to ensure that the system as installed fully achieves the design requirement for these systems as set out in Section 7.0(b) of this document.

Basic requirement

8.70 The operating suite to be validated should be physically complete with final finishes applied. All ventilation systems serving it should be operating correctly and delivering the design air-flow rates.

8.71 In order to avoid pre-loading the UCV terminal's recirculation ducts and HEPA filters, the Operating suite should be free of any obvious dust and at least "builders clean" before the recirculation fans are set to work.

8.72 The validation procedure for a conventional theatre suite should have been satisfactorily completed to the standard set out in Section 8 prior to attempting to validate the UCV unit. In particular:

- the supply AHU will have achieved the minimum standard;
- the operation of all fire dampers will have been proved;
- the supply and extract air-flow rates as measured in ducts and at room terminals will achieve their design values +10%; -0%;
- room differential pressures will be correct.

Evidence of the satisfactory achievement of the foregoing standard should be available for inspection and independently measured as necessary *prior to validating the UCV unit.*

UCV unit validation procedure

8.73 Tests to validate the suitability and performance of an ultra-clean operating suite should be undertaken in the order that they appear below. Should an item fail to meet the required standard it should be rectified and successfully retested before passing on to the next test.

Summary of test regime

- Challenge tests to ensure that:
  - the UCV terminal unit is correctly assembled and sealed so that no air will bypass the filters;
  - the terminal filters are correctly sealed in their housings;
  - the terminal filters are of the same grade, of uniform quality and undamaged.
- Air velocity measurements to ensure that
  - a sufficient quantity of air is being delivered by the terminal;
  - the terminal quadrants are in balance;
  - the air flow has sufficient velocity to reach the working plane.
- An entrainment test to ensure that contaminants arising outside of the UCV terminal footprint are not drawn into it.
- Visualisation techniques to gain an understanding of the overall system performance.
- Noise measurement to ensure that working conditions are satisfactory.
- Control system checks to ensure that the system operates as specified.
- Biological monitoring to determine how effective the system is in use.

Test and measuring conditions

8.74 While validating the UCV terminal, the conditions in the Operating room shall be stable and within the given ranges.

temperature: – 19°C - 23°C dry bulb.

humidity: – 30 – 65% relative humidity.

Test and measuring equipment

8.75 Any test or measuring equipment used should have a certificate to prove that it has been validated within the previous 12 months at a calibration facility using traceable national standards.

8.76 In the case of a noise meter, its “matched sound source” should have a certificate to prove that it has been validated within the previous 12 months at a calibration facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

Test grid – vertical units

8.77 A test grid should be constructed on the floor within the ultra-clean terminal footprint as projected by the inside dimensions of the sidewalls or boundary air

curtain. A suitably marked test sheet will provide a consistent standard of test grid.

8.78 The test grid should comprise test squares of 280mm each side.

8.79 The test grid should be aligned along the centre lines of the terminal footprint with its centre under the centre point of the terminal.

8.80 Any test square with 80% of its area within the UCV footprint should be used as a test position.

8.81 An inner zone should be designated that is not less than 36% of the total footprint. It should be made up of a number of test squares distributed symmetrically about the terminal footprint centre line. Regardless of the shape of the terminal footprint, the inner zone should comprise a minimum grid of 6 x 6 test squares.

8.82 Unless specified otherwise, a test position should be in the geometric centre of a test square.

8.83 Test position 1 should be the leftmost test square in the row nearest to the operating room wall that houses the surgeon's panel.

(For an example of a grid for a 2.8 x 2.8 metre terminal see Figure 8)

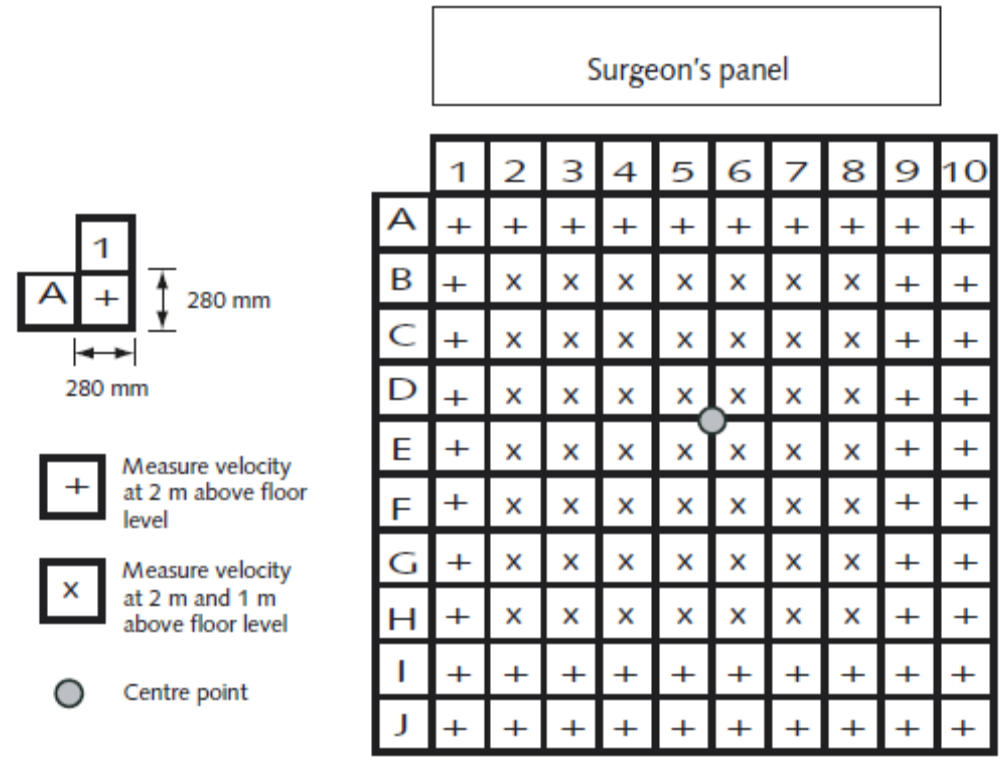

Figure 8: Example of a Test Grid for a 2.8m x 2.8m UCV Terminal

Test grid – horizontal units

8.84 A line of test positions should be marked on the floor 1m in front of the face of the UCV terminal.

8.85 A test position should be marked in the centre of the line. Additional test positions should be marked at 280mm spacing along the line either side of the centre position, up to the full-face width of the unit.

UCV terminal challenge tests (Vertical and horizontal systems)

8.86 The diffuser screen fitted below the face of the terminal HEPA filters should be lowered or removed while the challenge tests are being carried out.

8.87 The installed HEPA filters should be checked to ensure that their grade accords with the design specification and that their performance has been certified by the manufacturer.

8.88 The challenge tests may be carried out using either of the following techniques:

- use DOP to provide the challenge and a photometer to detect leaks;
- use a DPC to detect leaks. In order to obtain a sufficient challenge it may be necessary to remove temporarily the supply AHU secondary filters.

8.89 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the HEPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.

8.90 For the DOP test this should be set as the reference level and a leak will be declared significant if penetration greater than 0.01% of the range is detected. (See Paragraph 8.56 for details).

8.91 For the DPC method the filter face is scanned to establish the smallest non-penetrating particle size. If significant particles at or above this size are detected when subsequent scans are made then there is deemed to be a significant leak at, or near, the test position. (See Paragraph 8.57 for details)

UCV terminal unit clean zone leak test

8.92 This test will confirm that there is no unfiltered air bypassing the HEPA filter.

8.93 The joints and service penetration points under the UCV terminal within its side walls or boundary air curtain should be scanned to prove that there are no leaks.

8.94 A leak is defined as a significant rise above the background level.

Terminal HEPA filter seal leak test

8.95 The test will confirm that there is no unfiltered air bypassing the HEPA filter's seal.

8.96 Each HEPA filter's seal should be scanned to prove that there are no leaks.

8.97 A leak is defined as a significant rise above the background level.

Terminal HEPA filter media leak test

8.98 The test will confirm that the HEPA filters have not sustained damage while being installed.

8.99 The face of each HEPA filter should be scanned to prove that there are no leaks.

8.100 A leak is defined as a significant rise above the background level.

Vertical UCV terminal air velocity tests

Test set up

8.101 The terminal face diffuser screen should be in place for these tests.

8.102 Take spot readings to establish that the room is within the specified temperature and humidity test conditions.

8.103 Set out the test grid as described previously.

8.104 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to air flow, are perpendicular to the front edge of the test sheet and face the back edge. Any lamp and equipment heads should as far as practicable be outside of the UCV terminal footprint.

Test instrument

8.105 The measuring instrument should be a hot-wire anemometer with a digital read-out. The instrument resolution should be at least 0·01m/s, have a tolerance of ±0·015 m/s or 3% of that reading and be calibrated down to 0·15 m/s or lower. An alternative instrument may be used providing it is of no lesser specification.

Test method

8.106 The instrument should be mounted on a test stand and set to take a mean reading over a ten-second sample interval.

8.107 It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. Alternatively they could be downloaded to a computer or data logger at the end of the test.

8.108 The test stand to be positioned on each test point in turn and the reading taken when the instrument has stabilised.

8.109 When taking a reading the test person should not stand within the same quadrant as the test instrument.

8.110 Readings are to be taken at the test positions with the instrument probe facing the wall housing the surgeon's panel, commencing at the first test position.

Readings are taken working along the row from left to right and back, or for all text positions in one quadrant at a time.

8.111 When all test positions under one half of the terminal have been covered, readings of temperature and humidity are then taken at the specified height in the centre of the terminal. The read-outs on the surgeon's panel should be recorded at the same time.

8.112 Having completed one half of the test grid, the operating lamp arms and any other stem arms should be swung round through 180º and the test stand reversed so that the wall housing the surgeon's panel is behind the test person. Readings are recommenced starting at the right of the test row and working from right to left a quadrant at a time, as above.

UCV high-level discharge velocity test

8.113 Measurements of air velocity are to be taken at every test position 2m above floor level and the results averaged.

8.114 The average of the total readings taken is to be not less than:

0.38 m/s for a partial-wall system;

0.30 m/s for a full-wall system.

The average air velocity for each quadrant should not exceed ±6% of the measured average velocity for the terminal

UCV low-level air velocity test

8.115 Measurements of air velocity are to be taken at each of the inner zone test position 1m above floor level.

8.116 The measured velocity at every test position in the inner (operating) zone shall be not less than 0·2 m/s.

Horizontal UCV terminal air velocity test

Test set up

8.117 Set out the line of test positions as described previously.

8.118 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to air flow and are perpendicular to the line of test positions.

Test instrument

8.119 See that specified for vertical systems (Paragraph 8.105 refers).

Test method

8.120 The instrument should be mounted on a test stand and set to take a mean reading over a ten-second sample interval.

8.121 It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. Alternatively, they could be downloaded to a computer or data-logger at the end of the test.

8.122 The test stand should be positioned on each test point in turn and the reading taken when the instrument has stabilised.

8.123 When taking readings the test person should stand well downstream of the instrument.

8.124 Readings are to be taken at the test positions with the instrument probe facing the UCV terminal, commencing at the first test position on the left and working along the row from left to right at the specified height.

8.125 The instrument should be reset to the next specified height and the test repeated and so on.

8.126 Readings of temperature and humidity should be taken at the specified height in the centre of the terminal. The read-outs on the surgeon's panel should be recorded at the same time.

UCV discharge velocity test

8.127 Measurements of air velocity are to be taken at all test positions at 1m, 1·5m and 2m above floor level.

8.128 The average of the total readings taken should be no less than 0·4 m/s.

UCV entrainment test (Vertical systems only)

Rationale for the entrainment test

8.129 The performance of UCV systems may be compromised by room air being drawn into the ultra-clean airflow, a phenomenon known as "entrainment." Significant levels of entrainment could lead to microbial contamination of items left exposed on instrument trolleys laid out beneath the canopy.

8.130 UCV systems having permanently fitted full sidewalls do not need to be tested, as the sidewalls physically prevent entrainment.

Principle of the test

8.131 A source of particles is produced outside of the UCV terminal and is used to challenge the system. A detector is placed within the ultra-clean airflow and used to determine the percentage penetration of the test particles at predefined

locations under the UCV terminal footprint. The source and detector are moved in tandem around the UCV canopy and pairs of readings taken, from which the percentage penetration at specified locations is calculated. The degree of penetration should be below specified maximum limits if entrainment is to be declared not significant.

8.132 The entrainment test may be carried out using either of the following techniques:

- use DOPs to provide the challenge source at the specified release position and a photometer to measure the entrainment; or
- duct non-HEPA-filtered air to the specified release position and use a DPC to measure the entrainment.

Test set-up

8.133 The terminal face diffuser screen should be in place for these tests.

8.134 The test should be performed without any equipment in place beneath or closely adjacent to the UCV terminal.

8.135 The theatre lights should be moved to a central position beneath the terminal and raised to 2m above floor level, so as not to interfere with the peripheral airflows.

8.136 Take spot readings at the centre of the canopy, one metre from floor level, to establish that the room is within the specified temperature and humidity test conditions.

8.137 Set out the test grid as described previously.

8.138 For either of the following entrainment tests, a measurement of particle penetration through a representative section of the HEPA filter media is to be taken and used as the reference background level.

Test equipment, challenge source, measuring instrument and detector head

8.139 The challenge and detector equipment should be chosen so that:

- the tracer particles are mainly within the size range 0.3 to 5 microns and thus capable of remaining airborne for a substantial time;
- the particles used should not be able to penetrate the terminal filters in sufficient numbers to cause a background count that is more than 0.1% of the challenge count;
- the choice of particle and detector will enable a minimum of a three-logarithm (1,000-fold) range of counts to be recorded between the highest (that is, source) and lowest (that is, background) readings expected. (A concentration of approximately 10^5 particles per cubic metre of source air has been shown to be adequate.)

Source – Dispersed Oil Particles (D.O.P.)

8.140 The DOP generator should be able to produce a cloud of test particles in the form of a visible smoke. The test smoke should be delivered via an aperture so that it flows vertically downward from the lowermost edge of the partial wall, on the outside of the UCV canopy.

8.141 The test smoke is to be delivered via an aperture.

Note 4: To prevent undue contamination of the theatre and filters with deposits of oil, DOP should only be released for the minimum amount of time necessary to complete the test.

Challenge source – natural particles

8.142 The source unit should be a fan/blower or other method that takes non-HEPA-filtered air and expels it via a delivery head at the specified release position to provide the particle challenge. The challenge air should be delivered vertically downwards from the lowermost edge of the partial wall, on the outside of the UCV canopy, parallel to the airflow coming from the diffusers. The challenge air velocity should be the same as the measured average velocity at 2m from the terminal under test.

Note 5: The use of DOP for testing is gradually being phased out and replaced by a natural challenge measured with a DPC. At the time of writing research is under way to define more precisely a challenge source unit for natural particles. It is anticipated that such a unit, together with a matching test methodology, will become available during the life of this Scottish Health Technical Memorandum.

The detector (defined in terms of range and resolution)

8.143 This may be a photometer or a DPC. It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. The instrument should be capable of sampling a minimum a 28.3 litres of air per minute and in the case of the DPC, provide readings for particle size ranges from 0.3 microns to 5.0 microns and greater. The instrument should be compliant with the requirements of BS EN ISO 14644-1. An alternative instrument may be used providing it is of no lesser specification.

Test positions and orientation of source and detector

8.144 The test positions should be at the centre of each test square, as defined for the velocity test.

8.145 For rectangular UCV terminals, measurements of penetration are to be taken at the four corner test squares of the test grid and at intermediate positions along the line of test squares between the corners. The number of intermediate test positions will be as equally spaced as possible around the periphery with no fewer than 3 and no more than 5 complete test squares between test positions.

8.146 A further series of measurements are to be obtained around the periphery of the inner zone. Measurements of penetration are to be taken at the four corner test squares of the inner zone of the test grid and if necessary at intermediate positions along the line of test squares between the corners as equally spaced as possible, with no fewer than 3 and no more than 5 complete test squares between test positions.

8.147 A single measurement should be taken at the geometrical centre of the UCV terminal footprint. The centre measurement will be taken with the detector head mounted vertically upwards 1 metre above floor level.

8.148 The centre of the challenge particle source should be aligned with the centre of the designated test square, with its longer edge against the outer edge of the partial wall and delivering the challenge from the lower edge of the partial wall. The air containing challenge particles is directed vertically downwards from the lower edge of the partial wall, in a plane parallel to the adjacent partial wall. Where there is physical interference due to obstructions such as gas pendants, the source will be moved to the next available non-obstructed test-square location nearest to the stipulated sampling position. The detector should then also be moved to remain opposite the source.

8.149 In the case of non-rectangular terminals, an interpretation of the above strategy should be adopted that will yield a no less searching examination of the unit's ability to control entrainment.

Test method

8.150 The sampling head of the detector instrument is mounted on a test stand with its sampling orifice facing outwards horizontally from the centre of the UCV canopy, 1m above floor level. The sampling head should be orientated at right angles to the partial wall when sampling along the sides of the test grid but will be set to bisect the angle when measuring at the corner test positions (Figure 88 illustrates the challenge and detector orientations when evaluating a 2.8m x 2.8m UCV terminal).

8.151 The test will commence at the first test position, this being designated the leftmost corner of the test grid when facing the wall housing the surgeon's panel. The penetration will also be measured at the corresponding test point on the inner zone commencing at the corner nearest to the first test position. When these tests have been completed, the source and detector equipment should be moved to the next test positions, working around the test grid in a clockwise direction.

8.152 The test stand should be positioned on each test point in turn and a pair of readings (challenge, then penetration) taken when the instrument has stabilised. The detector should be set to take a reading over a 15 second sample interval.

8.153 When taking a reading the test person should stand within the UCV terminal footprint but not in the same quadrant as the detector head.

Analysis and interpretation

8.154 The following standard is to be achieved:

- penetration to be not greater than 10% of the challenge at each test position in the outer zone;
- penetration to be no greater than 1% of the challenge at each test position in the inner zone;
- penetration to be no greater than 0·1% of the challenge at the centre of the test grid.

If a result is close to, or above the given limits, then a further reading must be obtained using a longer time base (1 minute) and the penetration must not exceed the given limit.

Basis of the test

8.155 Whyte W, Shaw BH, Freeman MAR. An evaluation of a partial-walled laminar-flow operating room. *J Hyg Camb* 1974; 73: 61 – 75.

Whyte W, Lidwell OM, Lowbury EJL, Blowers R. Suggested bacteriological standards for air in ultraclean operating rooms. *J Hosp Infect* 1983; 4: 133 – 139.

UCV visualisation

8.156 The use of smoke to gain an understanding of the overall performance of the system may prove useful at this stage in the validation process but cannot be relied on to produce a contractually definitive measure of performance.

UCV noise level

8.157 An industrial-grade sound-level meter to BS EN 61672 Type 2 fitted with a muff should be used to check the noise level. The instrument should be calibrated using a matched sound source prior to each set of readings.

Vertical systems

8.158 The noise level readings should be taken at typical normal listening positions 1·5m above floor level and at least 1m from any surface and not on any line of symmetry. Measurements should be taken under the centre of each quadrant of the UCV terminal and the four readings averaged.

Horizontal systems

8.159 The noise level readings are to be taken at typical normal listening positions 1·5m above floor level on the test line. The width of the unit should be divided

in two and a measurement taken in the centre of each half but avoiding any line of symmetry. The two readings should be averaged.

8.160 Measurements should also be taken in each room of the suite.

8.161 In the event of a contractual deficiency a Type 1 precision-grade sound-level meter complying with BS EN 61672 should be used. Readings should be taken at the positions specified above and in each case the logarithmic mean of the results should be calculated in order to determine the noise level. Further information can be found in SHTM 08-01 (2011).

8.162 For vertical or horizontal systems, the noise level shall not exceed:

- 50NR [55dB(A)] – for UCV operating rooms and spaces without doors that open directly on to it (for example the scrub);
- 40NR [45dB(A)] – for all other peripheral rooms of the suite.

UCV control system checks

Temperature

8.163 The readings of temperature taken under or in front of the UCV unit should be within ±1 K of each other and the read-out on the surgeon's panel.

Humidity

8.164 The readings of humidity taken under or in front of the UCV unit should be within ±5% of each other and the read-out on the surgeon's panel.

Direct-reading differential pressure gauges

8.165 The differential pressure across the terminal filter(s) should be measured to confirm the accuracy of the indicated reading of any gauge.

Control functions

8.166 The operation of all control functions provided on the surgeon's panel should be proved for conformity with the design specification.

8.167 If an auxiliary panel has been fitted then its interlocking with the main surgeon's panel control functions must be proved to conform to the design specification.

Panel indicator lights

8.168 The panel indicator lights should illuminate as appropriate when the control functions are selected or warning levels are reached

BEMS interface

8.169 The operation, monitoring and alarm functions must be proved to conform to those set out in the design specification.

UCV theatre microbiological tests

8.170 There is little value in performing microbiological sampling in a new theatre supplied with ultra-clean ventilation. The foregoing filter challenge tests, air velocity measurements and entrainment test should have proved that the system operates satisfactorily and achieves the contracted level of performance. The HEPA filters will remove bacteria-sized particles from the air supplied through the UCV terminal. Therefore there will be an insignificant number of bacterial and/or fungal CFUs present until the Theatre is actually used.

8.171 Once the theatre has been taken into use, microbial sampling during a surgical procedure should help to confirm the satisfactory performance of the system and discipline of the users. Before commencing bacteriological testing, the room and its ventilation system should have achieved a steady state condition: (see also Paragraph 8.74)

8.172 The installation should be tested during surgical procedure at intervals between the time of the first incision and final closure of the wound. On average, the air sampled within 300mm of the wound should not contain more than 10 CFU/m^3.

UCV validation report

8.173 Following validation a full report detailing the findings should be produced. The report shall conclude with a clear statement as to whether the UCV theatre suite achieved or did not achieve the standard set out above.

8.174 A copy of the report should be lodged with the following groups:

- operating department;
- infection control;
- estates and facilities.

Dirty	Service corridor Disposal room	0 -5 or 0	- -	f 0.41 or 0.10

Table A2

Notes (applicable to Table A2):

a. Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved.

b. An open or semi-open bay is considered to be part of the operating room; provided air movement is satisfactory, no specific extract is required. However if the layout means that air movement is poor, a local extract may be required to control local condensation on the building surfaces, which can result in mould growth.

c. For design purposes, anaesthetic should be assumed to be at 14Pa. When commissioning 10Pa is considered suitable.

d. 15 ac/hr are considered necessary for the control of anaesthetic gas pollution.

e. Supply airflow rate necessary to make up 7 ac/hr after taking into account secondary air from cleaner areas.

f. No dilution requirement. Temperature control requirements only.

Type	Pressure difference - Pa						
	5	10	15	20	25	30	40
Single door (CDB Size 2.4.3.2.6.)	.03	.05	.06	.06	.07	.07	.08
Double door (CDB)	.04	.08	.10	.11	.12	.13	.14
High permanent length of 3mm gap	.004	.008	.010	.011	.012	.012	.013

Table A3: Leakage flows in m^3/s through closed door gaps

Note: CDB = Component Data Base

It should be noted that many doors are now fitted with cold smoke seals as standard. These will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design leakage is factored into the sizing of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air gap whistles and doors being held partially open by air pressure.

Factory-assembled door-sets with a steel frame and pre-hung leaves have become common. There is effectively no leakage across these doors when closed. Therefore, when this type of door assembly is fitted, the door leakage can be ignored and the design airflow into the room reduced accordingly. The design airflow would then become that required either (i) for open door

protection, or (ii) to achieve the specified air-change rate - whichever is the greater.

Room class		Dirty	Transitional	Clean	Sterile
Sterile	Hatch	0.3	0.24	0.18	
	Single door	0.47	0.39	0.28	0 or 0.28 a
	Double door	0.95	0.75	0.57	0 or 0.57 a
Clean	Single door	0.39	0.28	0 or 0.28 a	
	Double door	0.75	0.57	0 or 0.57 a	
Transitional	Single door	0.28	0 or 0.28 a		
	Double door	0.57	0 or 0.57 a		
Dirty	Single door	0	Open single door = 0.80m x 2.01m high		
	Double door	0	Open double door = 1.80m x 2.01m high		

Table A4: Recommended air flow rates in m^3/s through a doorway between rooms of different cleanliness to control cross-contamination

Designer's Notes:

a. The degree of protection required at an open doorway between rooms is dependent upon the degree of difference in cleanliness between them.

b. Flow rate required between rooms within the same class tends to zero as class reduces.

c. If two rooms are of equal cleanliness, no flow is required (in practice there will be an interchange in either direction) and the design of the air movement will assume zero air-flow. In certain cases, however, interchange is not permitted and protection airflow of 0.28 is assumed in the design, for example, in the case of a preparation room used as a "lay up".

		Effect on other rooms	
Door open between	Resultant pressure in these rooms (Pa)	Room	Pressure (Pa)
Operating room and corridor or Scrub bay and corridor	0	Anaesthetic Preparation – lay up Disposal Preparation – sterile pack store	0 12 -6 5
Operating room and anaesthetic room (or other series room with double doors)	17	Preparation – lay up Disposal Preparation – sterile pack store	26 -9 22
Operating room and disposal room or Operating room and preparation room	25	No change	
Anaesthetic room and corridor (or other series room with double doors)	0	Preparation – lay-up Disposal Operating room Preparation – sterile pack store	30 -6 20 25
Preparation room – corridor Disposal room & corridor	0	No change	
Disposal room & outer corridor	0	No change	

Table A5: Typical pressures in an operating suite when a given door is open

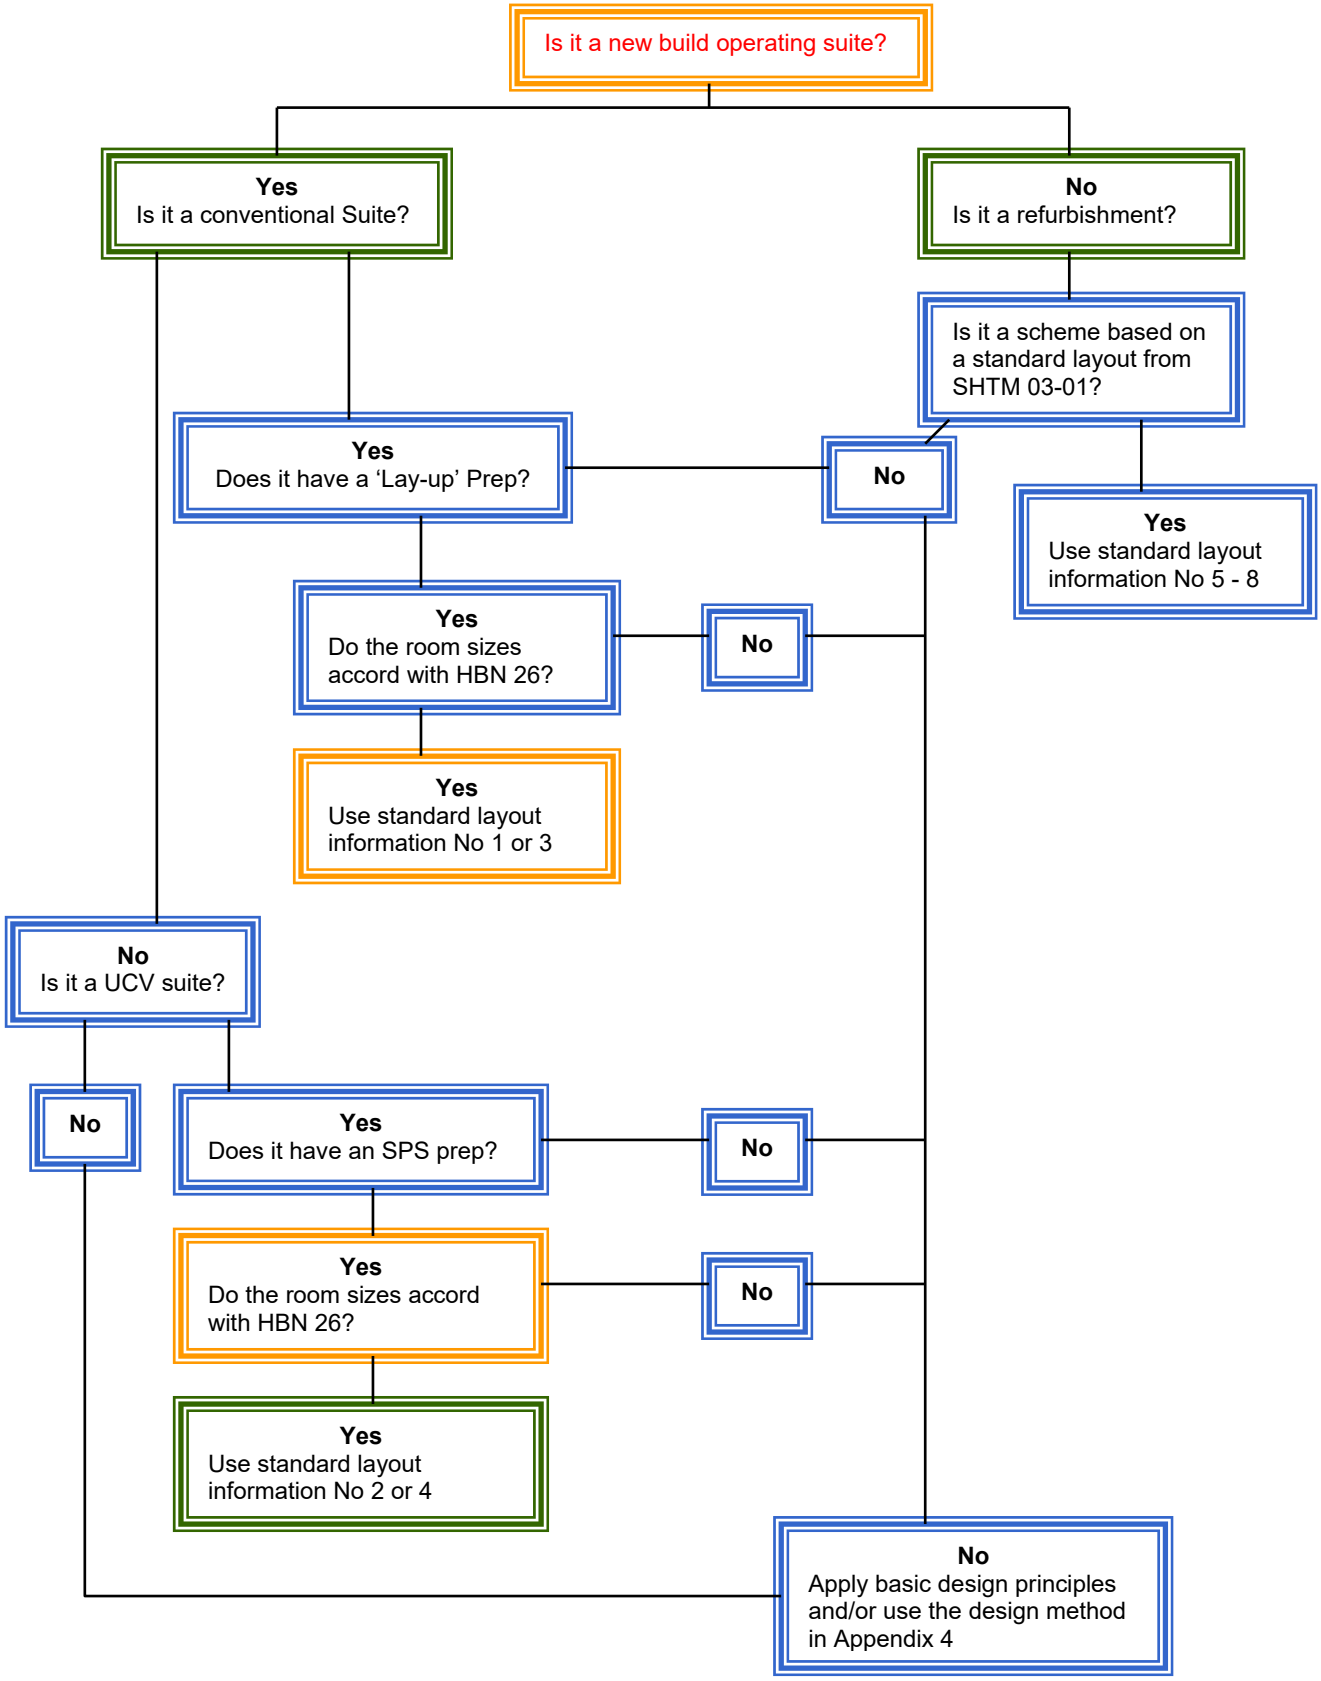
Notes: 1. The room differential pressure protects against reverse flows when the door is closed.

2. The flow of air through a doorway protects against reverse airflow when the door is open.

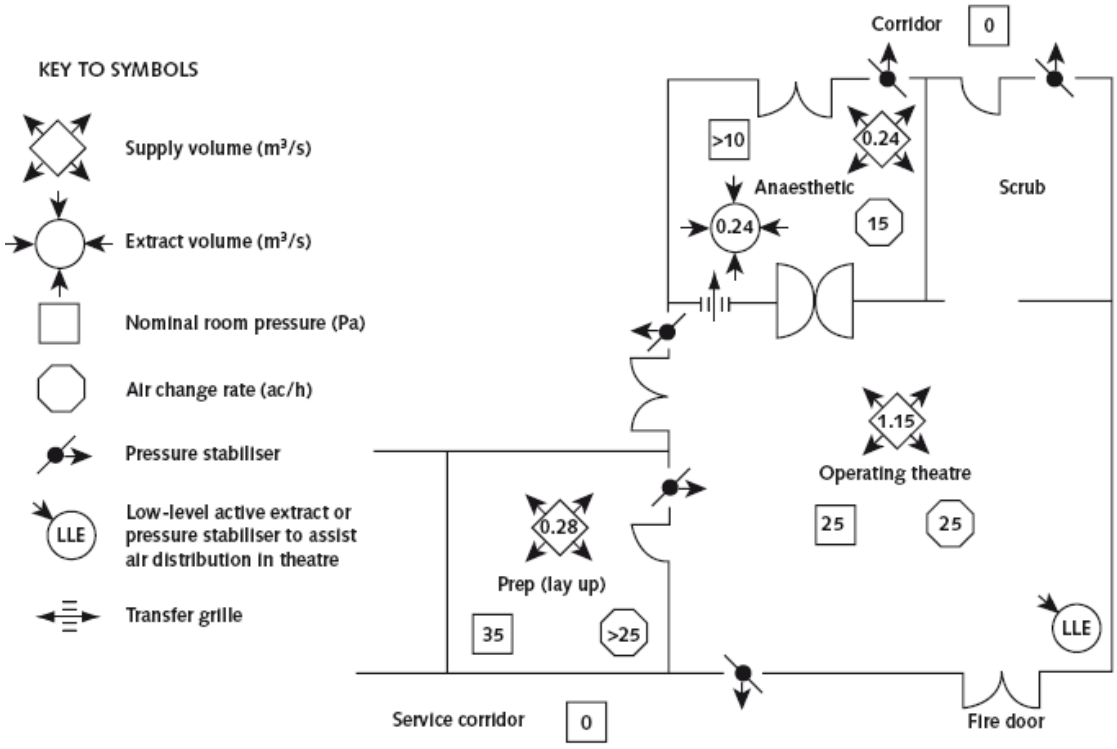
3. Pressure stabilisers control flow and ensure a known air-flow path between rooms when doors are closed and reduce back-flow between rooms when doors to other rooms are open.

A47310563

Appendix 3: Operating suite design logic



New Standard Layout N^{o} 1 - Suitable for a typical conventional theatre suite (Room sizes as specified in HBN 26)



Room	Size m^3 Derived from HBN26	Air-Change Rate per hour	Nominal Pressure Pa	Flowrate m^3/s
Theatre	165	25	25	1.15
Anaesthetic	57	15	>10	0.24
Lay-Up-Prep	36	>25	35	0.28**
Scrub	*	-	25	-

*This is a separate scrub and is not considered as being part of the theatre volume.

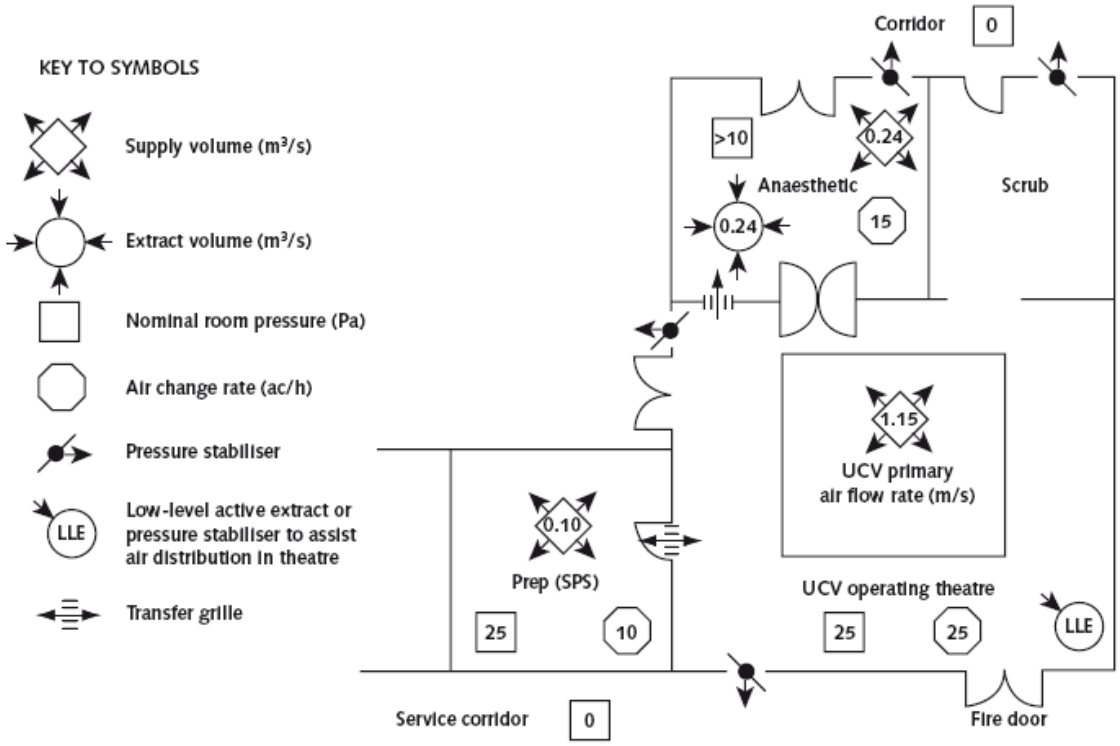
**Interchange is not permitted between the theatre and lay-up prep; therefore an airflow protection of 0.28 + 0.06 closed-door airflow is required as a minimum.

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should be

located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 2 - Suitable for a typical UCV theatre suite (Room sizes as specified in HBN 26)



Room	Size m³ Derived from HBN26	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15**
Anaesthetic	57	15	>10	0.24
Sterile Prep	36	25	25	0.10
Scrub	*	-	25	-

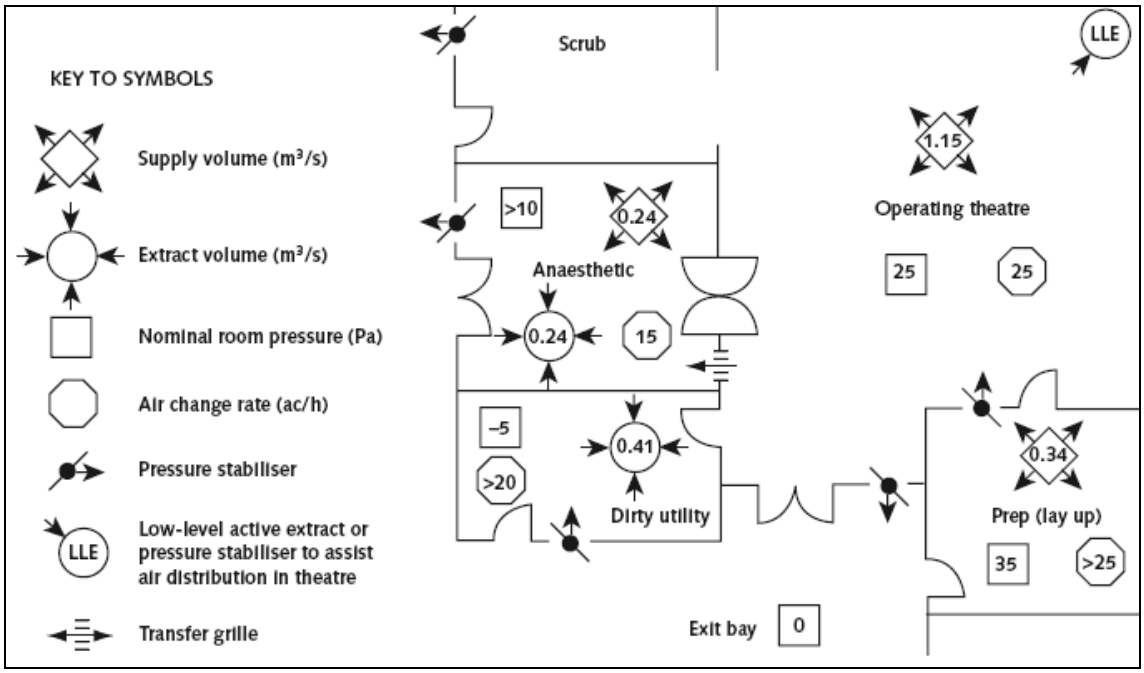
*Separate scrub and not considered as part of theatre volume

**Primary Fresh air Volume Only

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 3 - Suitable for a typical Conventional theatre suite (Layout and room sizes are as illustrated in HBN 26)



Room	Size m³ Derived from HBN26	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15
Anaesthetic	57	15	14	0.24
Lay-Up Prep	36	>25	35	0.34**
Scrub	*	-	25	-
Dirty Utility	36	-	-5	0.41

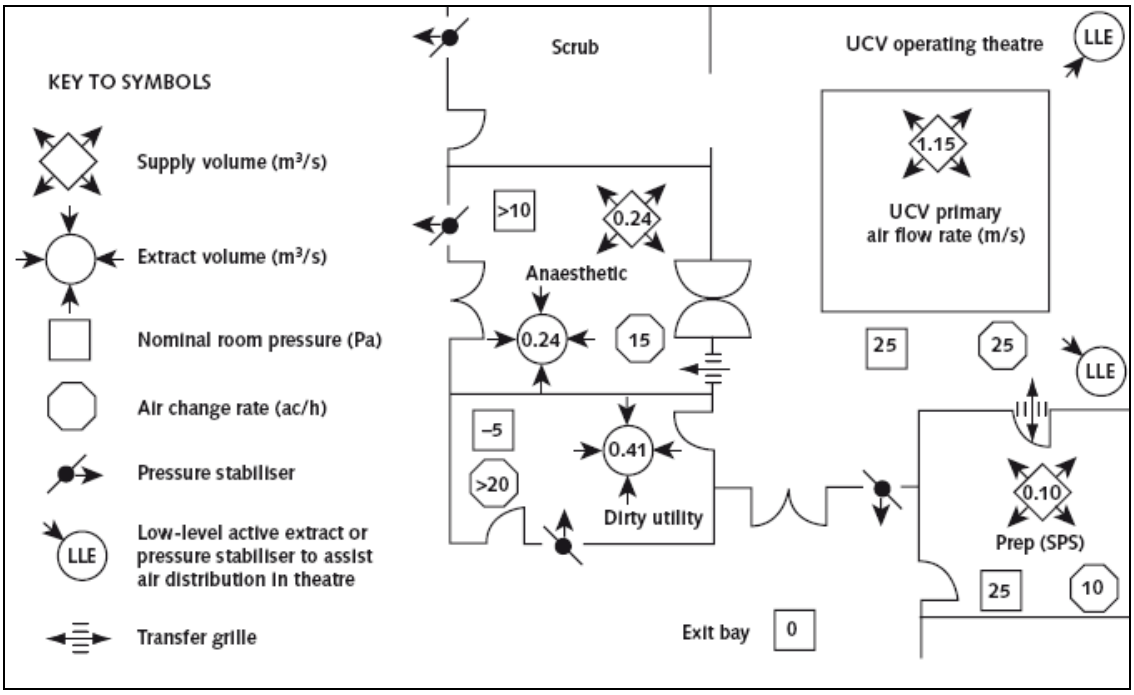
*Separate scrub not considered part of theatre volume.

**Interchange is not permitted between the theatre and lay up prep therefore as Table 4 an airflow protection of 0.28 + 0.06 closed door air flow is required as a minimum.

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 4 - Suitable for a typical UCV theatre suite (Layout and room sizes are as illustrated in HBN 26)



Room	Size m³ Derived from HBN26	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15**
Anaesthetic	57	15	>10	0.24
Sterile Pack Prep	36	10	25	0.10
Scrub	*	-	25	-
Dirty Utility	36	-	-5	0.41

* Separate scrub not considered part of theatre volume

**Primary Fresh air Volume Only

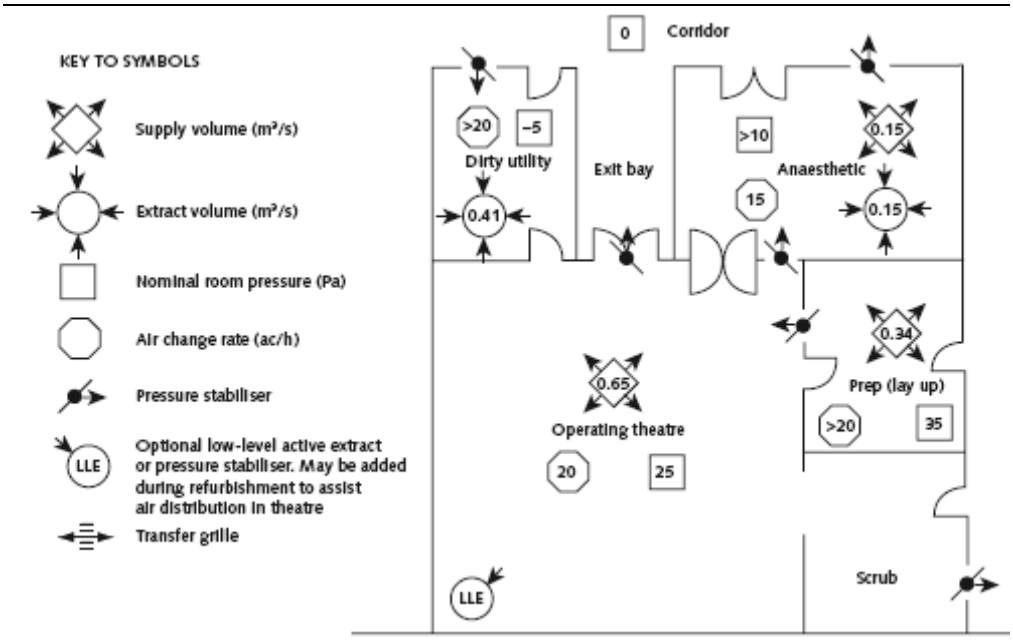
The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

A47310563

New standard layout N° 5 - SHTM 2025 Existing standard plan '1b' typical layout for a conventional theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

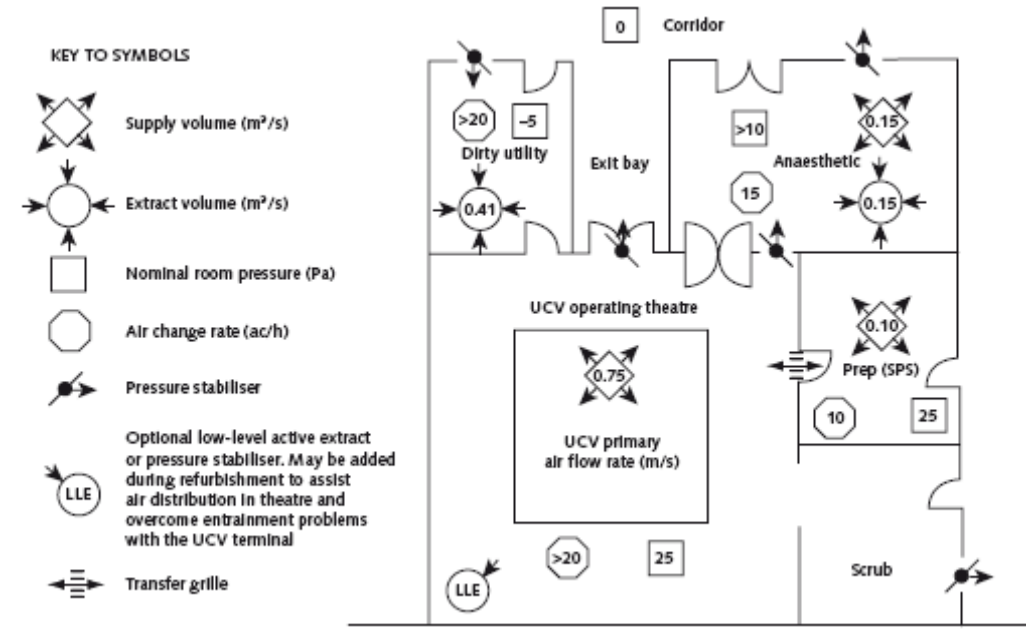


Room	Size m^3	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m^3/s
Theatre	Existing Theatre Suite to Be measured on site	20	25	0.65
Anaesthetic		15	14	0.15
Lay-Up Prep		-	35	0.34
Scrub		-	25	Included within theatre
Disposal		-	-5	0.41

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor.

Standard layout No 6 - SHTM 2025 Existing standard Plan '1a' Typical layout for a UCV theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.



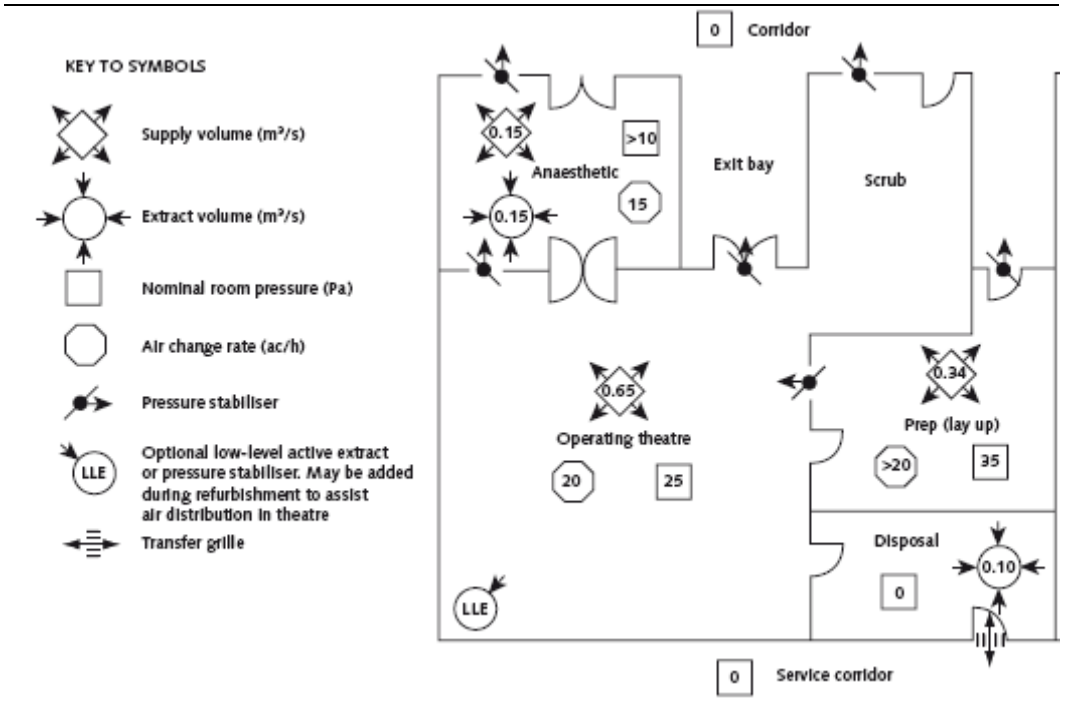
Room	Size m^3	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m^3/s
Theatre	Existing Theatre Suite to be measured on site	20	25	0.75*
Anaesthetic		15	>10	0.15
Sterile Pack Prep		10	25	0.1
Scrub		-	25	Included within theatre
Disposal		-	-5	0.41

*Primary fresh airflow volume

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor.

Standard layout N° 7 - SHTM 2025 Existing standard Plan '5b' Typical layout for a conventional theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

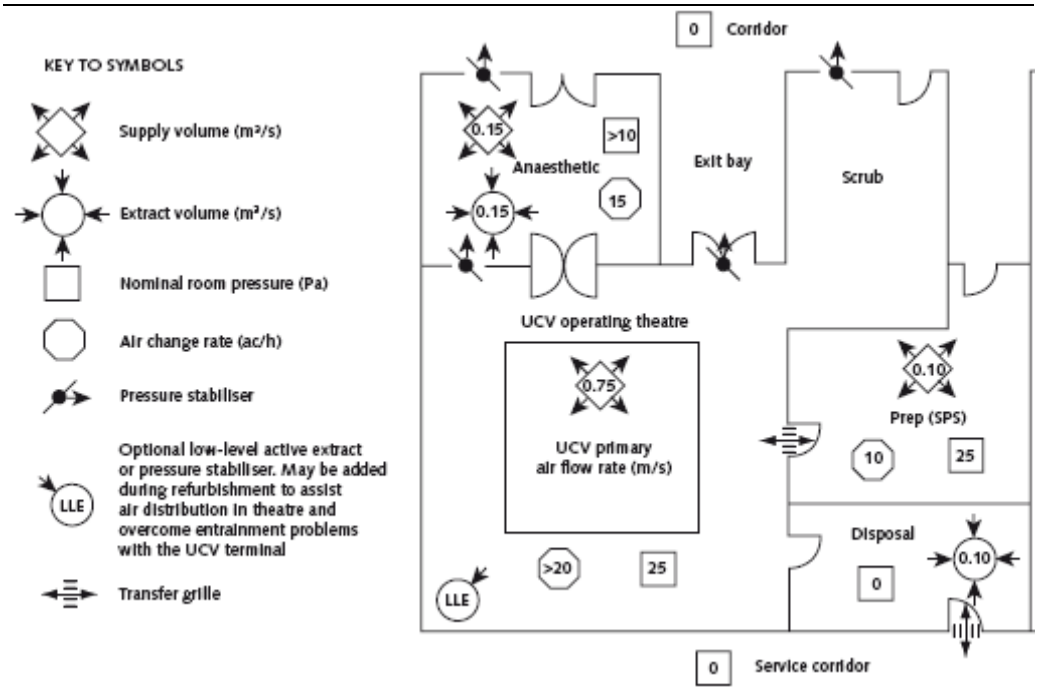


Room	Size m³	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	Existing Theatre Suite to be measured on site	20	25	0.65
Anaesthetic		15	>10	0.15
Lay-Up Prep		>20	35	0.34
Scrub		-	25	Included within theatre
Disposal		-	0	0.1

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor. Alternatively the disposal room could be omitted and replaced with a disposal hatch between the theatre and corridor.

Standard layout N° 8 - SHTM 2025 Existing standard Plan '5a' Typical layout for a UCV theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.



Room	Size m³	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	Existing Theatre Suite to be measured on site	20	25	0.75*
Anaesthetic		15	>10	0.15
Sterile Prep		10	25	0.1
Scrub		-	25	Included within theatre
Disposal		-	0	0.1

*Primary fresh air-flow volume only

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor. Alternatively the disposal room could be omitted and replaced with a disposal hatch between the theatre and corridor.

Appendix 4: Design of air-movement control schemes for operating theatres.

General

A4.1 Standard operating suite design solutions are given in Appendix 3. If these standard solutions cannot be used, the following procedure should be adopted, which will result in an acceptable design. Note that the method employed can equally be used to provide a design solution to a ventilated suite of rooms for any application.

A4.2 The method is concerned with the calculation of airflow rates to ensure that correct air movement occurs between rooms when any one door is open. Under most circumstances, the air quantities required for air-movement control will approximate to those for either temperature control or bacterial contaminant dilution. This flow rate is sufficient to control the effects of any slight reverse flows occurring when a door is opened.

A4.3 The progression through the design procedure is shown in the airflow design procedure chart (Figure A4/3) and is supported by worksheets WS1 to WS7 described in Paragraph A4.4. It is recommended that a plan of the suite and an airflow network be made (Figure A4/2) to collate all information. Flow rates, air-transfer devices etc should be entered as required. The remainder of this Appendix may be treated as reference data to assist in the various steps. The following symbols are used:

S_S – supply airflow rate for summer temperature control;

S_W – supply airflow rate for winter temperature control;

S_D – supply airflow rate for dilution of bacterial contaminants;

S_L – supply airflow rate for heat loss;

S_G – supply airflow rate for heat gain;

E_D – extract airflow rate for dilution of bacterial contaminants;

S_F – final supply airflow rates;

E_F – final extract flow rates;

S_{AMC} – air-supply flow rate for air-movement control;

E_{AMC} – air-extract flow for air-movement control;

L_{OUT} – leakage airflow rate outward;

L_{IN} – leakage airflow rate inward;

$\sum_{OUT}$ – total airflow rate outward;

$\sum_{IN}$ – total airflow rate inward.

A4.4 To simplify the procedure, standard worksheets (WS1 to WS7) have been devised. For each operating suite, a set is required comprising one each of WS1, WS3, WS5, WS6a, WS6b and WS7, one WS4 for each corridor and one WS2 to cover each peripheral room. WS2 has five versions:

- WS2a single flow;
- WS2b parallel/series multi-flow;
- WS2c parallel multi-flow or series multi-flow (unbalanced);
- WS2d series multi-flow (balanced); and
- WS2e bay (semi-open).

Peripheral room type

A4.5 The rooms in the operating suite other than the operating room and corridor are referred to as peripheral rooms. Peripheral rooms have been classified according to the flows in and out. These room classifications are defined below in Paragraphs A4.6 – A4.11.

Single flow

A4.6 This is a room with only one door and a net surplus of supply or extract air.

Parallel multi-flow

A4.7 This is a room with two or more doors through each of which the air-flows either outwards (high-pressure) or inwards (low-pressure) (for example the Prep (lay-up) in standard layout 5).

Parallel/series multi-flow

A4.8 This is a room having a net surplus of supply or extract and with two or more doors. One or more doors will be to an area of equal cleanliness and need not be protected; hence, the flow may vary between inwards and outwards, the remaining door being to an area of greater or lesser cleanliness (for example the Prep (SPS) in standard layout 6).

Series multi-flow (unbalanced)

A4.9 This is a room having a net surplus of supply or extract and with two or more doors. Air flows inwards through one or more doors and outwards through one or more doors.

Series multi-flow (balanced)

A4.10 This is a room as in Paragraph A4.9 above, but having either no mechanical ventilation or no net surplus of supply or extract. (for example an anaesthetic room).

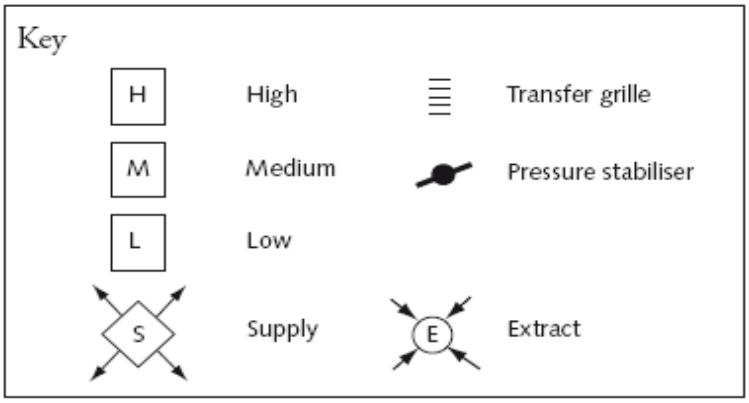
Bay

A4.11 A room that has a permanent opening to the operating room may be considered as a bay off the latter (for example a scrub). Two categories exist:

- open bay – the opening is larger than a normal single door opening. The bay may be considered as part of the main room;
- semi-open bay – the opening is no larger than a normal single door opening. In this case it is possible to protect the bay from the main room by provision of air supply or extract in the bay, or by passing air to or from another area.

Air-movement control in peripheral rooms

A4.12 For the design of air-movement control, two types of air-transfer device are considered. These are transfer grilles and pressure stabilisers. Each has a particular field of application within the design, as described in Paragraphs A4.34 – A4.43. Air movement is controlled in each of the different room types described in Paragraphs A4.13 – A4.31.

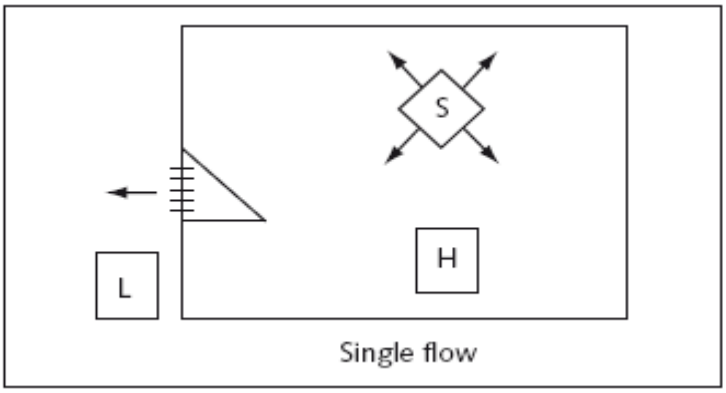


Note: This key applies to each diagram in A4.13 - A4.27.

Single flow rooms

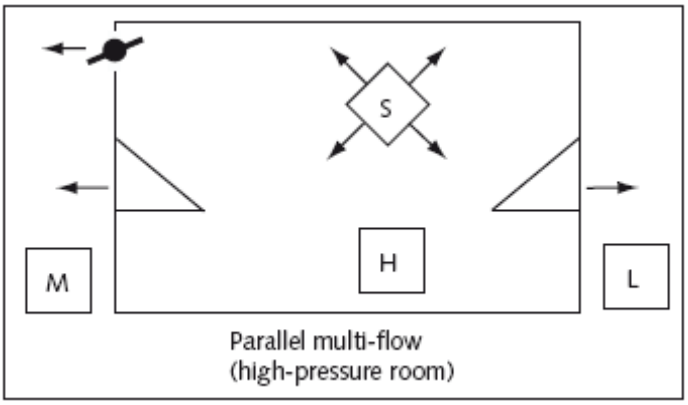
A4.13 An appropriately sized transfer grille should be located in or adjacent to the door of each single flow room to relieve the pressure differences across the door when closed.

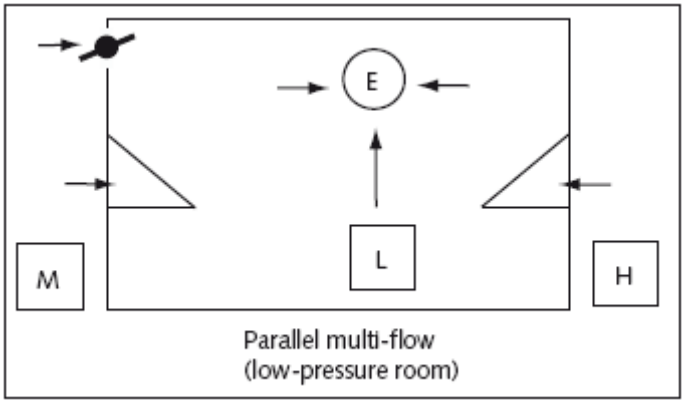
A47310563



Parallel multi-flow rooms

A4.14 The pressure difference across the closed doors must be relieved, but transfer grilles are not appropriate where two doors lead to areas of different pressures, because reverse flow could occur when the other door is open. For this reason, pressure stabilisers are used.





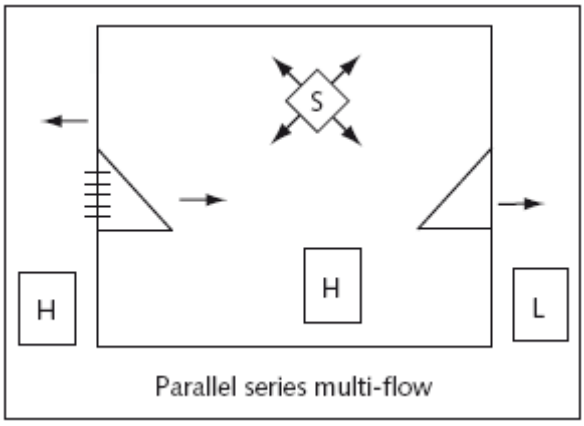
A4.15 These rooms will be either high-pressure or low-pressure with respect to the adjacent areas (see preparation lay-up room and disposal room, respectively, in standard layout 5). The pressure-relief damper is always situated between the room and area, which results in the smaller differential pressure to ensure best use of air.

A4.16 Just as reverse flow can occur if transfer grilles are used, it can similarly occur via door gaps when the other door is opened. It is not possible to avoid this,

except by using air locks, but due to the low flow rates and short durations involved, this is not considered to be of importance.

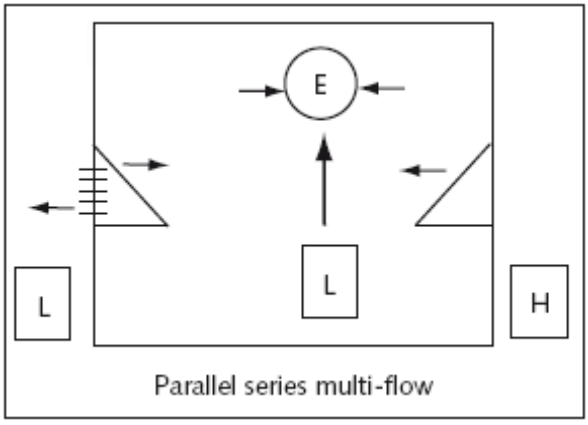
Parallel-series multi-flow rooms

A4.17 These rooms are similar to those in Paragraph A4.14 above, but because the room is of equal cleanliness to one of the adjacent rooms the nominal pressures will be equal and air may flow through the adjoining doorway in either direction. (for example the Prep (SPS) in standard layout 6).



Parallel series multi-flow

A4.18 Where the nominal room pressure equals that of the higher-pressure adjacent room, the best use of air is by supplying air required for bacterial dilution only and allowing this to exhaust via a transfer grille to the area of equal cleanliness. The doorway to the lower pressure area is protected by the combination of the supply air and the air that will flow inwards through the transfer grille from the area of equal cleanliness.

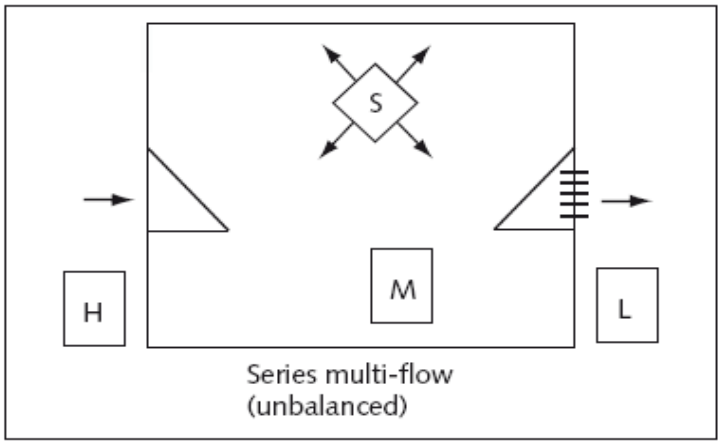


Parallel series multi-flow

A4.19 Conversely, where the nominal pressure equals that of the lower-pressure adjacent room, extract ventilation and a transfer grille to the lower pressure adjacent room should be provided. (for example, the disposal room in standard layout 8).

Series multi-flow (unbalanced)

A4.20 These rooms are somewhat similar to those in Paragraph A4.15 above, but because the pressure lies between that of the rooms on either side, the back-flow problem does not exist.



Series multi-flow (unbalanced)

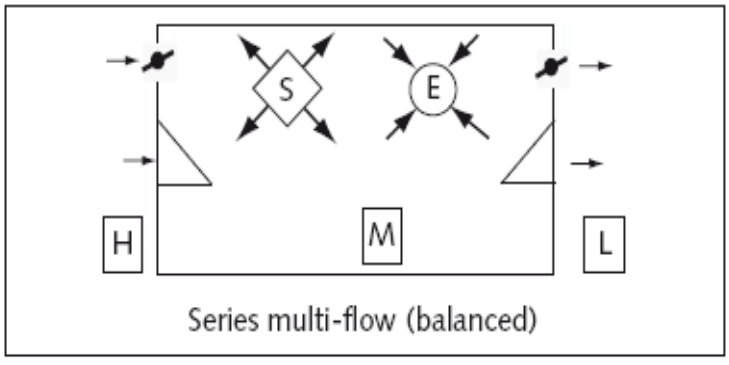
A4.21 Where the room has a net surplus of mechanical supply air, a transfer grille should be located in or adjacent to the door through which air flows outwards, and the mechanical supply flow rate to the room should be chosen to give protection when this door is open.

A4.22 Where the room has a net surplus of mechanical extract air, a transfer grille should be located adjacent to the door through which the air flows inwards, and the mechanical extract flow rate to the room should be chosen to give protection when this door is open.

A4.23 The grille must be sized for the protection requirement of the opposing door when open. When the room on the high-pressure side depressurises, there is a possibility of back-flow through gaps around the door, but this problem may be ignored.

Series multi-flow (balanced)

A4.24 In these rooms, a transfer device adjacent to each doorway is required in order to provide a flow path for the air required to protect the opposing door when opened.



Series multi-flow (balanced)

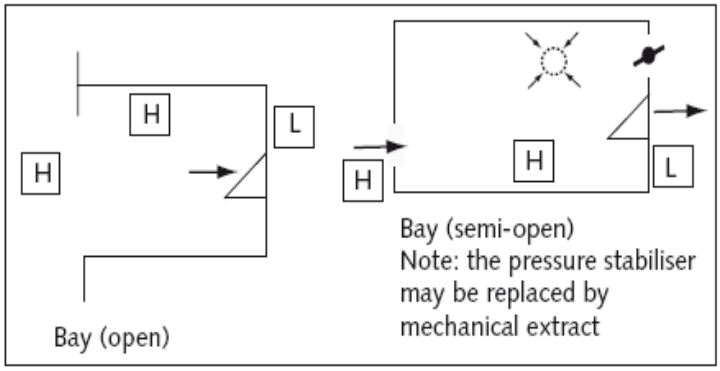
A4.25 These transfer devices will normally be pressure stabilisers, although transfer grilles may be used where a large amount of excess air is to be exhausted from the operating room when all doors are closed. (for example, anaesthetic rooms).

A4.26 The calculation procedure is to assume that pressure stabilisers are being used; then (if there is sufficient excess air) change to transfer grilles as described in Paragraph A4.50.

Bay

Open bay

A4.27 A bay of the open type (for example scrub-up) is considered to be part of the operating room. Provided air movement is satisfactory, no specific extract is required.



Semi-open bay

A4.28 In a bay of the semi-open type, protection of one area from the other is possible. (For example scrub-up).

A4.29 As stated previously, the need for protection between operating room and scrub-room is not very great. Better use of air can therefore be achieved in this case by installing a pressure stabiliser between the scrub-room and clean corridor. This will allow a flow of air through the scrub-room at all times, except when a door is opened elsewhere in the suite. The pressure stabiliser will then close and the air will be diverted to the other door. When it is considered necessary to protect the scrub-room at all times, either a transfer grille to the corridor or mechanical extract in the scrub-room should be provided.

Operating room

A4.30 Once the peripheral rooms have been considered, the operating room requirements may then be decided and the supply flow rate required for air-movement control calculated. This flow rate should be such that, with any one door open, the correct air movement directions are maintained. There will be one door in the suite that will require the largest supply flow rate to the

operating room for protection when open. This is called the “key door” and is discussed separately in Paragraph A4.33. Use of this concept avoids repetitive calculations for each door in turn. Having established the required supply flow rate, a relief route must be provided to the clean corridor for any excess air when the doors are closed. This would be via transfer grilles or pressure stabilisers through a series-flow room or via pressure stabilisers to the clean corridor directly.

Corridors

A4.31 All surplus air from the suite, except that lost through structure leakage and any passing to the outer corridor, will arrive in the patient/staff corridor. Should this air be insufficient to achieve the required air-change rate (see Appendices 1 and 2), some additional air supply should be provided. (The air balance should take account of structural leakage.)

Door opening

A4.32 Whereas the resulting pressures are dependent on ductwork layout, room relationships and characteristics of the fan, the generalisations shown in Appendix 2 can be used to estimate the change in room pressure when a door is opened.

A4.33 The “key door” will be the open double door which leaves the operating room at the highest pressure, and/or requires the largest air flow. This should be determined using the procedure in worksheet WS3.

Transfer grilles

A4.34 These may be used to limit the pressure differences across the closed door of a single-flow room or, in some instances, for protection of a series-flow or parallel-series-flow room. They allow airflow in both directions and may not be suitable for all applications.

A4.35 The free area of a grille is calculated from the following equation:

$$A = \frac{Q}{0.84\sqrt{\Delta P}}$$

where:

A is free area (m^2)

Q is flow rate (m^3/s)

P is pressure difference (Pa).

A4.36 The flow through a grille at a different pressure may be found from the following equation:

$$Q_2 = Q_1\sqrt{\frac{\Delta P_1}{\Delta P_2}}$$

where:

Q_1 and P_1 are original flow and differential pressure

Q_2 and P_2 are new flow and differential pressure.

A4.37 The transfer grille may be replaced by carefully proportioned door undercuts of the equivalent free area.

A4.38 The function of the transfer grille is to provide a means of airflow control by which the volume and pressure loss can be established. If a grille is used, it should have an easily removable core to facilitate cleaning.

Pressure-relief dampers

A4.39 The functions of a pressure-relief damper are now carried out by pressure stabilisers. Accordingly, all further mention of them has been removed from this document.

Pressure stabilisers

A4.40 Pressure stabilisers can be adjusted to hold the pressure constant over a wide range of flow rates. They are used where requirements exist for accurate room-pressure control or rapid shut-off on pressure fall.

A4.41 The installation of a grille or baffle in association with a stabiliser will alter the operating characteristics. It is recommended that a location be chosen to avoid the need for visual screening, for example, at high level. The location should be chosen to minimise the likelihood of damage.

A4.42 The stabilisers used should be virtually silent in operation, adjustable on site, maintenance-free and of a type that cannot be wrongly inserted. They should not be used in external walls or where the pressure difference is less than 5 Pa. The required size of a pressure stabiliser is dependent on the design pressure difference across it and flow rate through it. The manufacturer should provide data relating pressure difference to mean velocity (or flow rate per unit area). From this, the required area can be calculated and then rounded-up to the nearest size manufactured or nearest combination of smaller sizes.

A4.43 It is sometimes possible to arrange for a pressure stabiliser to perform two tasks. In an anaesthetic room, for example, the two pressure stabilisers may be made to pass the open door protection air, and also control the operating and anaesthetic room pressures with the door closed. To achieve this, the

stabilisers are sized for the flow rate required with one of the doors open, but the pressure setting is adjusted to be the value required with the doors closed. This is shown in Figure A4/1.

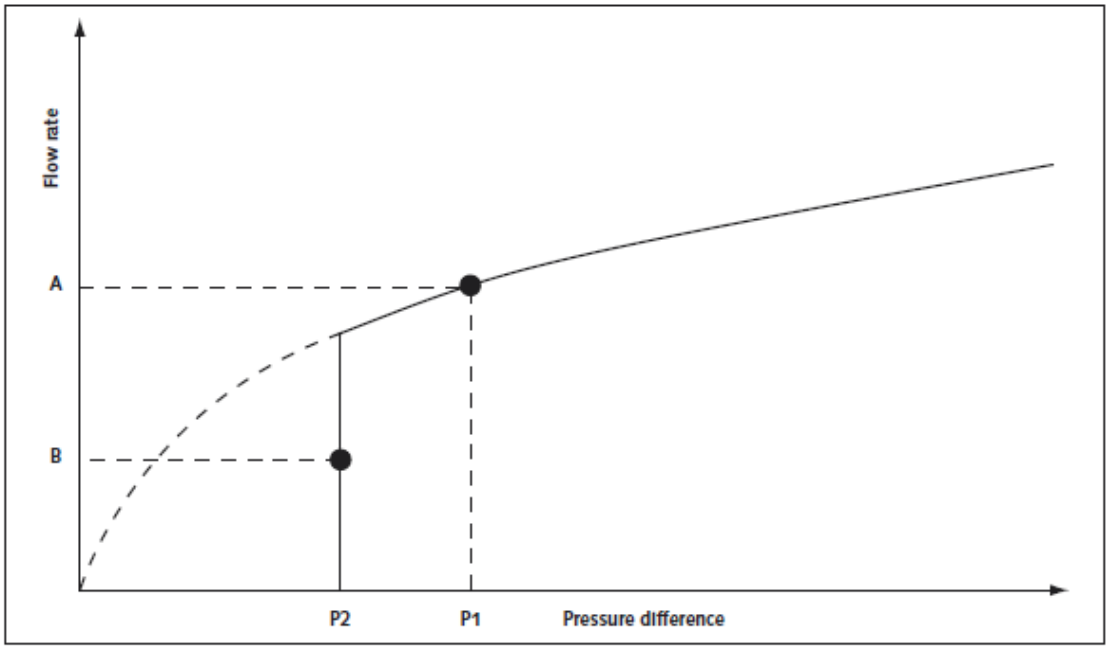


Figure A4/1

Door leakage flows

A4.44 For an air-movement control scheme to work satisfactorily, it is essential that the estimates of door-gap leakage made at the design stage are closely related to those which are achieved in practice. The calculation of gap-flows is complicated by the fact that such flows generally fall into the transition region between laminar and turbulent flow and hence do not follow the normal flow equations. The gaps assumed are 4mm along the bottom, 3mm at the top and sides, and 2mm between double leaves. Doors should not have wider gaps than these. Tighter gaps would result in lower flow-rate requirements and hence lower fan power, but care should be taken to ensure that all doors in the suite have similar gap dimensions. It may be possible to ignore the door leakage and so reduce the airflow requirement (see the notes in Appendix 3).

Room temperature estimation

A4.45 The air-flow rate required to prevent back-flow through an open door is dependent on the temperature difference across the door. The design figures shown in Appendix 3 are based on the temperature differences that will normally occur in practice, assuming heat gains and losses in accordance with Appendix 2.

A4.46 In accordance with the airflow design process, the temperature differences across the doors of all rooms classed as “sterile” is calculated. Worksheet WS6 is recommended for the calculations, using the following criteria:

- assume that the operating room is being controlled at 20°C and calculate the incoming air-supply temperature as shown on worksheet WS6;
- the calculation should be repeated for both summer and winter conditions, with an operation in progress;
- assume all doors are closed;
- use the room supply flow rates from WS1;
- use the inward air flows through air-transfer devices and closed door leakages from WS2a to WS2e;
- the formula used in worksheet WS6 is as follows:

$$T = \frac{(t_1Q_1 + t_2Q_2 + \cdots + t_nQ_n) + 0.828H}{(Q_1 + Q_2 + \cdots Q_n)}$$

where:

Q = flow rate from source (m^3/s)

t = the temperature of source (°C)

H = the room heat gain (kW).

A4.47 If the evaluated temperature differences between rooms do not exceed 2°C, the solution is satisfactory; otherwise proceed as follows:

- check the assumption on which the heat gains are based;
- take steps to reduce the heat gains;
- if the door is to a corridor, the flow through the open door will be larger than the value given in Appendix 2. Calculate on WS3, assuming it is the "key door" with door-flow unknown, and the supply as known;
- if the door leads to a room with mechanical supply, install a trimmer heater in the supply to the room controlled by either a differential thermostat or a thermostat slaved to the operating room thermostat to ensure that T is minimized.
- If the door leads to a room with no mechanical supply, increase the door protection flow as follows:

$$Q_{new} = Q_{old}\left[\frac{\Delta T + 1}{2}\right]$$

A4.48 These options should be considered in the above order, and the first three should be investigated thoroughly before proceeding to the latter two. The mechanical supply may need to be increased in order to achieve the desired air-change rates.

Relief of excess air from operating room when all doors are closed

A4.49 As the mechanical supply to the operating room is sized to provide an appropriate flow outward through any door that is opened, it follows that when all doors are closed, there will be more air supplied to the operating room than can exit from it via leaks etc. This "excess" air can be relieved by either of the two methods described in Paragraphs A4.50 - 4.54.

By transfer devices via the anaesthetic room

A4.50 For door protection, the transfer devices in the anaesthetic room are typically designed to pass 0.47 m^3/s at a differential pressure of 14 Pa. When the doors are closed, the differential pressure will change to 11 Pa between theatre and anaesthetic room, and 14 Pa between anaesthetic room and corridor; the volume of air passed by the transfer devices will be modified as shown in the following formula:

$$Q = Q_1\left(\frac{\Delta P_1}{\Delta P_2}\right)^{1/2}$$

$$= 0.47\left(\frac{11}{14}\right)^{1/2}$$

$$= 0.42\ m^3/s$$

where:

Q = "excess" air to be vented with doors closed;

Q_1 = air-flow required for door protection through transfer device;

ΔP_1 = nominal differential pressure with door to operating room closed and door to corridor closed;

ΔP_2 = nominal differential pressure between either the anaesthetic room and corridor when the operating room door is open, or the anaesthetic room and operating room when the corridor is open. This differential pressure is used when selecting size of both devices.

A4.51 If the "excess" air is less than 0.42 m^3/s, a pressure stabiliser is required to ensure that the correct protection airflow is available to pass through the door.

A4.52 If the "excess" air is greater than 0.42 m^3/s, a transfer grille is acceptable because at all times the airflow will exceed the flow required for door protection.

By pressure stabilisers to the corridor

A4.53 If it is undesirable to pass operating room air through the anaesthetic room, it may be passed directly to a corridor via a separate pressure stabiliser.

A4.54 If there is sufficient "excess" air, the transfer grille solution at Paragraph A4.52 should be adopted, as it provides the simplest solution and, once set up, will require no further maintenance. With less excess air, it is recommended that the air be passed through the anaesthetic room via the pressure stabilisers as at Paragraph A4.51, thus keeping the number of pressure stabilisers to a minimum. Both these solutions increase the air-change rate in the anaesthetic room, but care should be taken to avoid passing excessive amounts through that would cause discomfort to the occupants.

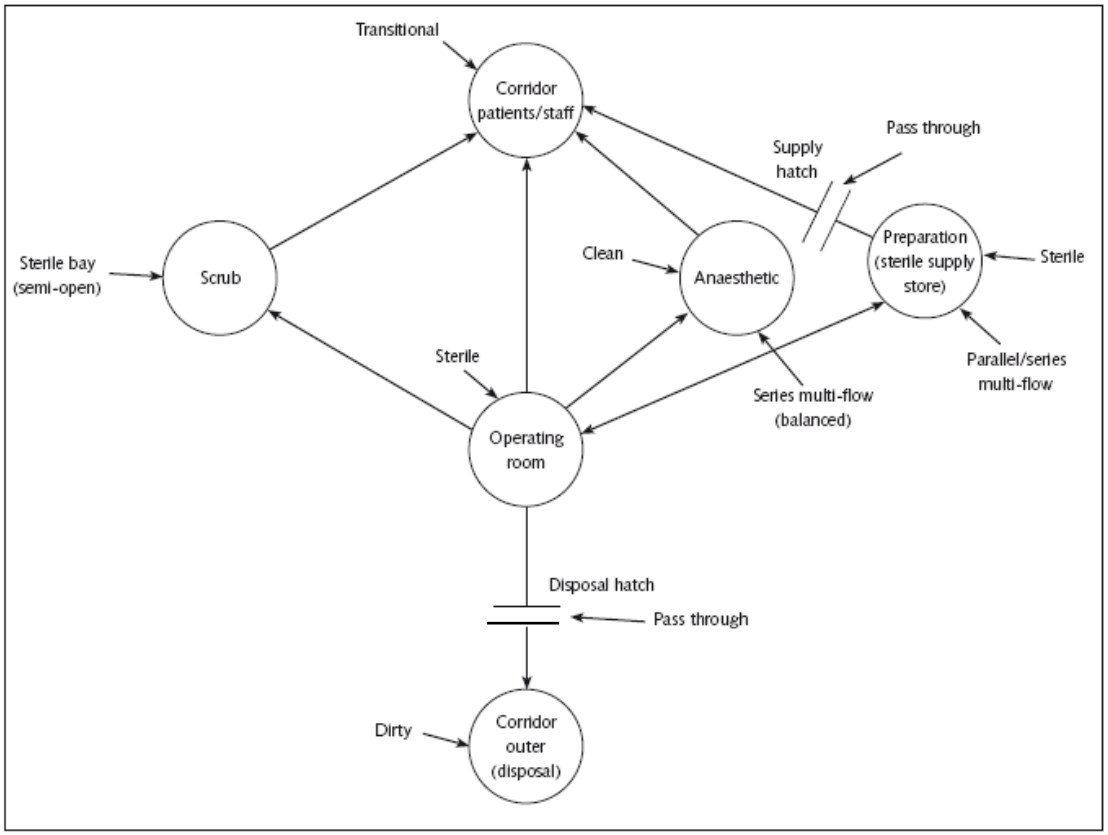

Figure A4/2: An example of an airflow network

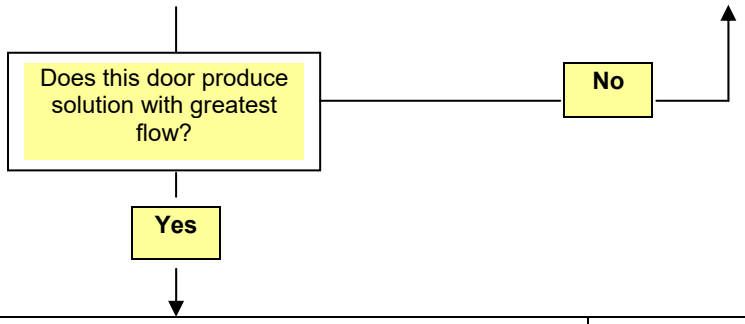
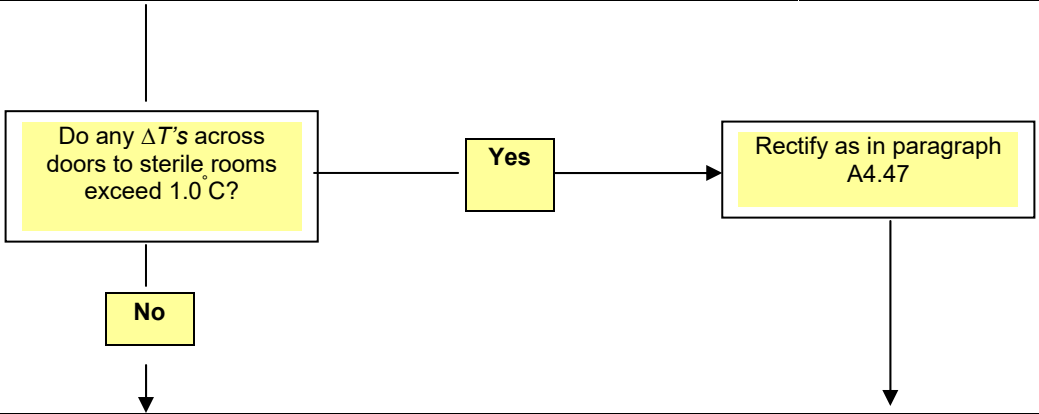
Step	Description	Worksheet
1	Show nominal room pressures and air flow directions on the plan of the theatre suite and WS1	WS1
2	Enter heat/loss/gain data and calculate supply airflow rates for temperature control only. Categorise room types e.g. sterile, clean etc.	WS1
3	Enter airflows required for bacterial contamination control or air change rate whichever is the greater, add supply and extract volumes (S_D, E_D) on the plan.	WS1
4	Define peripheral room types, see paragraphs A4.5 - A4.11, and select appropriate worksheets.	Select from WS2a - WS2e
5	Locate air transfer devices, enter details on worksheets and locate on the plan and Figure A4/2	Selected worksheets from WS2a - WS2e
6	For each peripheral room, determine air flows through doors when open and calculate mechanical supply or extract and transfer device flows	As above
7	Select "Key Door" and calculate air supply for operating room	WS3



8	Transfer to WS1 and select final rate S_F and E_F	WS1. WS3
9	Make provision for relief of excess air with doors closed	Selected Worksheets and WS3
10	Calculate supply and extract flow rates for corridor(s)	WS4, WS5
11	Calculate room temperatures (all doors closed) and ΔT's	WS4, WS5



12	Make summary of flows	WS6a and WS6b
13	Size transfer devices, size ductwork, central plant etc	WS7
14	Design ductwork layout, control plant etc

Subject:	CT AIR CHANGE RATES
Date:	27 September 2016 12:00:24
Importance:	High

All,

In an attermpt to progress this to conclusion we have collectively looked at available current guidance and can conclude that the maximum quoted anywhere for a CT room is 10 ac/hr (SHPN 06, Engineering Requirements Para 7.4) and as such is the maximum that Multiplex can/will design to with available guidance.

If the decision by IPCN is that it must be 15ac/hr, this will need to be submitted as a formal change request that may result in significant cost increase and programme delay, please confirm that you wish me to submit this change request.

Regards

Ronnie

Janice, Fiona and Dorothy thanks for this. I think it would be good to add the context to the scores – i.e. 25 being the worst. It shows that this is a serious risk.

Subject: Risk Assessment re 4 bedded room Ventilation

Dear Both

Please find the clinical risk assessment in relation to the above as requested, which Dorothy, Fiona and I have pulled together.

The issue only really affects Children's Services, but we have discussed with Hester. We consulted with Children's CMT representatives this morning (Fiona Mitchell, Eddie Doyle, Lynda Cowie, Peter Campbell & Sharon Russell) and the risk assessment fully reflects their views. They are clear, as we also are, that we cannot have a new facility that does not give us the option of cohorting patients with air-borne infections. We have suggested an overall compromise position of only some of the 4 bedded rooms in the facility having the ventilation changed (in summary – all in PARU & Medical Inpatients and one of the 4 bedded areas within Critical Care), however the Children's CMT did say that to achieve this, there would be a delay to programme then they questioned whether we should not be changing all of the 4 bedded rooms to allow for future proofing and flexibility.

Infection Control have also confirmed they are happy with our risk assessment.

I am off next week, so Dorothy is around to answer queries ad we are both here tomorrow.

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie, Clinical Director Dorothy Hanley, RHSC Commissioning Lead Fiona Halcrow, Project Manager	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Janice MacKenzie		
Department:	RHSC & DCN Reprovision Project		

Subject of Assessment: Consider Task or Environment.

Bedroom Ventilation design in 4 bedded rooms does not meet the recommendations of SHTM 03-01, as the current design has the 4 bedded rooms as being positive pressure.

To allow cohorting of patients with the same air-borne infections these rooms require to be balanced or negative pressure.

Whilst the Board can rationalise the number of 4 bedded rooms where the ventilation needs to change it should be noted that this does reduce overall flexibility and future-proofing. Given the different patient groups related to specific wards, separate risk assessments have been undertaken (see attached). Individual risk assessments have identified that the need for cohorting of patients is only an issue for the Children's Service.

The risk assessments have been discussed with the Children's CMT and Infection Control & Prevention who have confirmed that not having the ability to cohort patients is not acceptable from a patient safety perspective. In addition the Children's CMT highlighted that if the programme is going to be delayed in order to achieve compliance with the SHTM 03-01 in the 4 bedded rooms then should we not be considering achieving this in all 4 bedded rooms. As opposed to the ones that have been identified to reach a compromise solution which would ensure future proofing and flexibility within the building for service changes and avoid the need to retro-fit.

Step 1: What are the Hazards?

Overall Risks:-

- The inability to cohort patients with air-borne infections in a clinically safe environment
- Clinical risk to isolating babies and children under two years of age with airway compromise i.e RSV
- Need for increased staffing requirements due to the observation and interventions required in this patient group if nursed in singe rooms
- Reduction in overall flexibility and future proofing would be limited if change of use of a ward/s was required
- Reputational risk as one of the key drivers, as outlined in the FBC, is to provide improved modern facilities that overcome the challenges currently faced within the existing facilities that cannot be adapted to provide the best services possible.

See separate risk assessments for inpatient ward/s as the risk rating for each ward/s is different dependent upon the patient group and clinical risk

Step 2: Who might be harmed and how?

See separate risk assessments for specific ward/s

Step 3: What are you already doing? (Existing Precautions)

Generic Precautions

- Isolation rooms have positive pressure lobby which acts as an air curtain and also have a hepa-filter to prevent the transfer of air-borne infection from the corridor into the room or the room into the corridor.
- All single rooms have balanced or slightly negative pressure.
- Increase in the number of single and isolation rooms (See separate risk assessment for the number of isolation and single rooms by ward) from 30% to 62%.
- Within RHCYP wards there will be technology to remotely monitor patient oxygen saturation levels and heart rate

Summary of Risk by Ward/s

Ward/s	Proposed Action	Risk Rating If No Change	Risk Rating if Change Implemented
RHCYP - PARU	All three 4bedded rooms to have ventilation changed	15	4
RHCYP – Medical Inpts	All two 4bedded rooms to have ventilation changed	10	3
RHCYP – Critical Care	One 4 bedded room (B1-063) ventilation changed	9	3
RHCYP – Surgical Wards	No change to ventilation in 4 bedded rooms	3	
RHCYP - Neurosciences	No change to ventilation in 4 bedded rooms	3	
RHCYP – Haematology/Oncology	No change to ventilation in day care	3	
DCN – Inpatient Wards	No change to ventilation in 4 bedded rooms	1	

NB – Risk Scoring range is 1-25 (with 25 indicating an extreme consequence)

Step 4: Action Plan			
What further action is necessary?	**Action By Whom**	**Action by when (dd/mm/yy)**	**Action completed. (dd/mm/yy)**
Clear Guidance in the Building Users Guide as to what 4 bedded rooms can be used to cohort patients with air-borne infections See separate risk assessments for specific actions by ward/s	Jane Campbell	September 2017	

Step 5: Review Table			
Date (dd/mm/yy)	**Reviewer**	**Reasons for review**	**Approved/Not Approved by (dd/mm/yy)**

ID:

NHS Lothian

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project - **RHCYP PARU (A2)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within PARU

Step 1: What are the Hazards?

Significant clinical risk to isolating babies and children under two years of age with airway compromise, some of whom may have co-morbidities where isolation in single room carries additional clinical risk.

If PARU has no cohort areas the hazards are:-

- There is a risk that the 6 shelled beds would require to be opened and additional staffing resource would be required
- Additional staffing would be required to safely care for these patients in single rooms due to the level of observation and intervention required. This has not been accounted for in the agreed workforce plan.
- Reduction in the overall capacity within RHCYP as more single rooms would be required to be used to board patients potentially resulting on the cancellation of elective patients.
- Reliance on remote patient monitoring for oxygen saturation and heart rate to ensure patient safety is increased

The Children's CMT have confirmed that all three of the 4 bedded rooms to have negative/balanced pressure

Step 2: Who might be harmed and how?

Patients: -

- Boarding of patients into other specialities is a recognised clinical risk.
- Patients from whom cohorting may be safest clinical option despite the availability of a single room e.g a child under two years of age with respiratory infection plus co-morbidity (cardiac or neurological) who because of their complex underlying condition need constant observation.

Step 3: What are you already doing? (Existing Precautions)

PARU has 34 beds:-

- 3 x 4 bedded rooms
- I x isolation room
- 21 x single rooms

Increased number of beds in single rooms and 4 bedded rooms as opposed to 6 bedded rooms (in existing hospital).

Procuring a remote monitoring system for oxygen saturation and heart rate to alert staff to a potential deterioration in patient's condition

Level of Risk with no cohort area 15

Level of Risk with cohort area 4

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
Careful selection of patients for boarding	Nursing & Medical Teams	Ongoing	
Use of remote technology to assist with monitoring of patients in single rooms	Nurse in Charge & Consultant	Ongoing	
Clear guidance in the Building Users Guide regarding cohorting of patients with air-borne infections	Jane Campbell	September 2017	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director		
Department:	RHSC & DCN Reprovision Project – **RHCYP Medical Inpatients (C1.1)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Medical Inpatients

Step 1: What are the Hazards?

Despite the fact it is planned that PARU will take all of the acute general admissions, reliance on a cohort area within this ward is only marginally reduced, particularly in times of peak activity when PARU would be unable to accommodate all of the RSV patients.

The Board feel a compromise is not possible in the 4 bedded rooms.

Step 2: Who might be harmed and how?

Patients from whom cohorting may be safest clinical option despite the availability of a single room e.g a child under two years of age with respiratory infection plus co-morbidity (cardiac or neurological).

Step 3: What are you already doing? (Existing Precautions)

Increased number of single and isolation rooms within medical inpatients:-

- 2 x 4 bedded bays
- 4 x Isolation Rooms
- 11 x single rooms

Procuring a remote monitoring system for oxygen saturation and heart rate to alert staff to a potential deterioration in patient's condition

Level of Risk if no change made 10

Level of Risk with Cohort Areas 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
Careful selection of patients for boarding	Nursing & Medical Teams	Ongoing	
Use of remote technology to assist with monitoring of patients in single rooms	Nurse in Charge & Consultant	Ongoing	
Clear guidance in the Building Users Guide regarding cohorting of patients with air-borne infections	Jane Campbell	September 2017	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Fiona Halcrow	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP Critical Care (B1)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Critical Care Unit

Step 1: What are the Hazards?

Clinical risk is still relatively high if no cohort area available and therefore operationally to retain the ability to cohort within B1-063 (low acuity HDU) would be clinically and operationally highly advantageous.

Step 2: Who might be harmed and how?

Patients through spread of infection.
Potential cancellation of elective surgical cases as staff group will be required to deliver 1:1 care who potentially could be cared for within a cohort area

Step 3: What are you already doing? (Existing Precautions)

Critical Care (B1) – 24 beds

- 3 x 4 bedded rooms (intensive care, high acuity & low acuity)
- 1 x 3 bedded room (surgical neonates)
- 4 x isolation rooms
- 5 x single rooms

The increased number of single rooms and a higher nurse to patient ratio within the Critical Care Unit will help mitigate the risk of nursing patients in single rooms

Level of Risk if no cohort area 9

Level of Risk if cohort retained 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that two 4 bedded rooms (ITU & high acuity high dependency) and one three bedded room (surgical neonates) cannot be used to cohort patients with air-borne infections	Jane Campbell	September 2017	
Careful placement of patients within the designated areas	Senior Nurse in Charge & Consultant	Ongoing	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Fiona Halcrow	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP – Surgical Wards (C1.2 & C1.8)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients with air-borne infections within the Surgical Wards

Step 1: What are the Hazards?

- Clinical risk is low as increased number of single rooms within Medical wards reduces the need to board patients into the surgical wards from the medical wards
- Compromise possible in not altering ventilation in the 4 bedded rooms but reduces flexibility and future proofing

Step 2: Who might be harmed and how?

N/A

Step 3: What are you already doing? (Existing Precautions)

There are two surgical wards:-

Surgical Short Stay has 14 beds:-

- 2 x 4 bedded rooms
- 6 x single rooms

Surgical Long Stay has 15 beds:-

- 2 x 4 bedded rooms
- 7 x single rooms

Increased number of beds within PARU and medical inpatients to reduce the need to board patients

Level of Risk 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	September 2017	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP – Neurosciences (C1.3)**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients within Neurosciences Ward

Step 1: What are the Hazards?

- Clinical risk is low as increased number of single rooms within Medical wards reduces the need to board patients into the neuroscience ward from the medical wards
- Compromise possible in not altering ventilation in the 4 bedded rooms but reduces flexibility and future proofing

Step 2: Who might be harmed and how?

N/A

Step 3: What are you already doing? (Existing Precautions)

The Neurosciences Ward has 12 beds

- 2 x 4 bedded rooms
- 1 x isolation room
- 3 x single rooms

Increased number of single rooms including one isolation room within this ward to allow the ward to care for neurosciences patients with an infection within the ward and not board in other wards which is the case in the existing hospital.

Level of Risk 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	September 2017	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Peter Campbell	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Peter Campbell, Deputy Associate Nurse Director – Children's Services		
Department:	RHSC & DCN Reprovision Project – **RHCYP Haematology/Oncology Ward (C1.4)**		

Subject of Assessment: Consider Task or Environment.

Patient pathway for day care patients with a known infection

Step 1: What are the Hazards?

This is a combined inpatient and day care facility, however the design separates these two areas. Operationally the clinical team have already agreed a compromise where patients with infections coming to day care would be dealt with in the consulting room within day care or the inpatient facility. The Board have previously accepted that they can operationally manage these areas without a change in ventilation to the 2 day care rooms.

Step 2: Who might be harmed and how?

N/A

Step 3: What are you already doing? (Existing Precautions)

Haematology/Oncology Ward has 17 inpatient beds and 9 day care beds/trolleys:-

- 5 x isolation rooms
- 12 x single rooms
- 1 x 6 bedded day care room
- 1 x 3 bedded day care room

Operational policy has been agreed for the management of day care patients with an infection

Level of Risk 3

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state the type of pressure in the Day Care areas	Jane Campbell	September 2017	
Written patient pathway and operational policy for the management of day care patients with an infection	Charge Nurse & Lead Consultant	October 2017	

Step 5: Review Table

Date (dd/mm/yy)	Reviewer	Reasons for review	Approved/Not Approved by (dd/mm/yy)

NHS Lothian

ID:

Record of General Risk Assessment

Name of Assessor(s): Posts Held:	Janice Mackenzie Dorothy Hanley Fiona Halcrow	**Date of Original Assessment:**	05/07/17
Manager Responsible:	Hester Niven, Clinical Nurse Manager DCN		
Department:	RHSC & DCN Reprovision Project – **DCN Wards**		

Subject of Assessment: Consider Task or Environment.

Ability to cohort patients with air-borne infections within DCN wards

Step 1: What are the Hazards?

The Board have previously accepted that they can operationally manage these wards due to the number of single rooms and types of patients and the need for cohorting of infectious patients would be extremely rare

Step 2: Who might be harmed and how?

N/A

Step 3: What are you already doing? (Existing Precautions)

DCN has three wards:-

DCN Acute Care (L1) – 24 beds
- 2 x 4 bedded rooms
- 1 x isolation room
- 15 x single rooms

DCN Inpatients Wards (L2) – 43 beds
- 2 x isolation room
- 41 x single rooms

Significant increase in the number of single rooms as compared to existing facility

Level of Risk 1

Step 4: Action Plan

What further action is necessary?	Action By Whom	Action by when (dd/mm/yy)	Action completed. (dd/mm/yy)
In the Building Users Guide need to state that these 4 bedded rooms cannot be used to cohort patients with air-borne infections	Jane Campbell	September 2017	

Step 5: Review Table

Subject: RE: Independent verification of theatres and isolation room ventilation

Dear Jackie,

Thanks for your e-mails. This is absolutely an issue we need to get right given the recent experiences of my microbiology colleagues in Glasgow with their new children's hospital.

It would be useful for us to use St Johns Theatres 11,12 as a Lothian example of the process we have used as a board before.
You will know that last year theatres 11 (Ultraclean theatre for hand surgery) and 12 (Conventional theatre for eye surgery) were built and put through a validation and verification. Initially there was some confusion regarding what the "validation" and "verification" requirement would be require, particularly for Theatre 11.

The approach we took was as follows.

We insisted that the requirements of SHTM 03-01 were met in that Infection Control required a formal validation summary report (and not a collection of documents with uninterpreted particle count and pressure results which we were initially delivered).
The non-negotiable expectation from SHTM 03-01 is we need evidence of compliance with parts 8.170-8.174 on pages 136-138 of the attached.
So we should be being provided with a validation report as indicated below.

UCV validation report

8.173 Following validation a full report detailing the findings should be produced. The report shall conclude with a clear statement as to whether the UCV theatre suite achieved or did not achieve the standard set out above.
8.174 A copy of the report should be lodged with the following groups:

- operating department;
- infection control;
- estates and facilities.

The validation process, particularly for an ultraclean theatre depends on assessment on a battery of physical and engineering parameters and "microbiological" testing i.e. culturing is not part of that process –air quality being assessed by particle counts using standardised methodology.
Taking this on board, the project manager, involved in the theatre 11, 12 commissioning arranged for a company (which was not involved in the theatre construction) to do the assessment and produce the validation report. I've attached a copy of that report in the e-mail trail attached.

As you can see, it is a concise and easy to read document that clearly states the theatres are fit for use. However you will also see from the e-mails that a number of snagging issues were identified that needed correction first – hence why having the report produced by another company is very useful. So I would very much propose we look for independent verification based on 1. We have done it before at SJH and 2. Glasgow have identified many issues since accepting their building that they are in the process of retrospectively addressing and we should avoid finding ourselves in that position.

I find it a bit perturbing that we are being asked such questions by the builders which are very clearly answered by SHMT 03-01 which they should be very familiar with and working to.

With regards to the isolation rooms, it would seem intuitive to take the same approach of independent verification. Although this does not appear from SHTM 03-01 to be mandatory (as it is in theatres). Crucially important given the discussions we have been having about their design are the air flows, pressures and air changes achieved per hour and I would propose that smoke testing is going to be crucial in assessing that air flows are going in the correct direction (particularly if a door is open). From a verbal discussion with a colleague in Glasgow smoke testing of the isolation rooms in their new building identified that air flows were not as intended. It is a crucial bit of the design that we need evidence is correct.

Multiplex as the builder should be performing a "validation" but that is unlikely to be unbiased and may miss issues that need addressed. More crucially I think we should be asking for independent verification and a clear validation summary report indicating that all aspects of these areas are functioning as intended which is supported by SHTM 03-01.

Please note I am on annual leave next week. Drs Kalima and Henderson are included for information in case their input is required while I am away. I'm back on Sept 3rd.

Best wishes
Donald

Subject: Independent verification of theatres and isolation room ventilation

Dear all, at the commissioning meeting with Multiplex yesterday they asked me what verification we wanted to carry out for theatres and isolation rooms.
They were at great pains to separate out validation from verification.
It appears in Glasgow the same person did both. It also appears that in Dumfries and Galloway they insisted on an independent verification.
Can you advise me what we wish to do?

Also what do we wish to do for the UV canopies? They thought we would wish to do microbiological checks.

I would be grateful for your advice.
Many thanks
Jackie

Subject: RE: Framework to Support Staff Development in the Decontamination of RMDs

Hi All!

I have a serious of questions to pick your collective networked brains about:

1. Education in IC of Doctors _ do you have mandatory training for consultant level ? Is it linked to appraisal? Any success stories?

2. Isolation rooms for source isolation : what do you have in place just now re ventilation parameters and ante rooms etc and can I come to see them ?
3. Isolation for protective isolation : same as above .

Look forward to hearing from you all,
Bw
Christine

Subject: Framework to Support Staff Development in the Decontamination of RMDs

Sent on behalf of Christine Young

For Information

Dear Colleague

Here is the link to the recently published framework to support staff development in the decontamination of RMDs:

http://www.nes.scot.nhs.uk/education-and-training/by-theme-initiative/healthcare-associated-infections/training-resources/framework-to-support-staff-development-in-the-decontamination-of-re-usable-medical-devices.aspx

Flyers to support local promotion of the framework have also been published and we are happy to send copies of these on request. If you would like copies of these, then please contact[redacted] and identify how many you require.

This framework was developed to support staff who undertake, manage or are responsible for decontamination activities in decontamination units throughout Scotland. It aims to help staff to develop their existing knowledge, understanding and skills in the complex area of decontamination. It links with KSF, PDPs and the personal development review process.

The next stage of this project is framework implementation and this involves evaluating the most useful and effective methods for implementation by staff working in decontamination. NES will be looking to establish pilot sites incorporating health boards with diverse decontamination structures. These pilot sites will be the focus of the implementation strategy and evaluation results will be shared across NHSScotland to maximise the benefit to staff when using the framework.

An invitation for health boards to volunteer to be a pilot site for local (dental and podiatry), endoscopy and central decontamination will soon be issued.

I would be grateful if you could share this information as widely as possible to the most relevant persons in your area and apologise if I've inadvertently missed anyone from this circulation list.

Please let me know if you have any queries.

Best wishes.

Christine

NSS Health Facilities Scotland

Managing the Risk of Contamination of Ventilation Systems by Fungi from Bird Droppings

Interim Guidance

March 2019

A47310563

Background

The production of this guidance is prompted by recent experience of infection, and the presence of fungal spores, in areas occupied by immunocompromised patients. Investigations are ongoing and updates may be issued as further evidence emerges. This guidance should be read in conjunction with Scottish Health Technical Memorandum (SHTM) 03-01 - Ventilation for healthcare premises, Scottish Health Facilities Note 30 Part A: Manual - Information for Design Teams, Construction Teams, Estates & Facilities and Infection Prevention & Control Teams and Part B: HAI-SCRIBE - Implementation strategy and assessment process.

Fungi are ubiquitous in the external environment and, whilst generally harmless to healthy people, susceptible patients can be infected by various fungi, not just those associated with bird droppings. For that reason ventilation systems serving areas housing patients susceptible to fungal infection are designed to minimise the risk of transmission of spores into the occupied space by means of appropriate filtration and pressure differentials between relatively clean and less clean environments.

Airborne fungal spores can enter general healthcare environments via opening or poorly sealed windows and doors, apertures in building fabric, supplies, plants and flowers etc. Although the filtration in non specialised ventilation systems is not intended to eliminate fungal spores, keeping plant areas free of vermin and bird droppings is good practice and helps prevent spores entering the occupied space.

Ventilation systems serving general patient and non patient areas are primarily designed to dilute contaminants in the occupied space and maintain comfort conditions. Although the filters used will reduce contamination from external sources, they are not designed to eliminate fungal spores. More detailed information is given in SHTM 03-01. The guidance contained herein is intended to reduce the challenge ventilation systems face from fungi and to reduce the risks, particularly recognising that patients in general hospital environments may have reduced immunity for a number of reasons. It is not intended to make areas served by non-specialised ventilation systems safe for patients who should be accommodated in specialised protective environments but it does recognise that people with increased susceptibility can be present in other areas.

Specialised advice on the management of ventilation systems, including the protection of plant from contamination from bird droppings should be sought as needed from the Board's appointed Authorising Engineer (Ventilation). Boards should satisfy themselves that appropriate vermin control measures have been implemented.

Plantrooms

To minimise the risk of contamination of ventilation systems with fungal sporesi, plant rooms should be maintained clean and free of vermin. Where bird droppings are found, the entry points for birds should be found and blocked and the area cleaned and decontaminated under controlled conditions. This should be done in such a way as to prevent further dispersal of spores and contamination of surrounding clinical environments and taking care not to produce dust or aerosol, and an investigation commenced into the source of the contamination.

External ventilation plant

External plant areas are more difficult to protect and measures should reflect the risks involved. NHS Boards should have records of all external ventilation plant, which should identify the areas and patient groups served. The inspection and maintenance of external ventilation plant should be in accordance with the requirements of SHTM 03-01 and should include steps to reduce the risks from fungal contamination from bird droppings.

Where external plant serves areas where patients are considered to be susceptible to fungal infection, or housing immunocompromised patients, measures to minimise the risk of contamination by fungi from bird droppings should be considered, including bird netting, anti roost devices, partial enclosure combined with bird netting, enclosing the plant in a fabricated housing and/or regular inspection and cleaning as appropriate to the risk. Solutions will need to take account of local conditions such as layout, weather exposure, roof loading and maintainability. The integrity of any solution needs to be taken into account as a poorly designed or maintained solution might increase roosting risk.

Bird dropping contamination at air intakes

Bird droppings, in areas where they might be able to produce airborne fungal spores which might be drawn into the system, should be cleaned and decontaminated under controlled conditions. This should be done in such a way as to prevent further dispersal of fungal spores and contamination of surrounding clinical environments and taking care not to produce dust or aerosol.

Where droppings are not likely to be disturbed and not close to air intakes, they are unlikely to shed spores in greater quantities than that present in outside air. If regular inspection identifies places where contamination repeatedly builds up and needs to be cleaned, then appropriate steps should be taken to deter birds from using that place, such as by placement of anti roosting devices or netting. Prevention of bird dropping contamination is preferred to cleaning and the contents of this guidance should be reflected in pest control policies.

The measures adopted should be determined by risk assessment involving appropriate clinical, microbiology, infection prevention and control and estates disciplines, and should take account of patient placement, patient susceptibility, filtration, location of plant, practicability of protective measures and other issues identified by those undertaking the assessment. HAI-SCRIBE has been developed as a framework for disciplines to work together to identify, manage and mitigate built environment infection prevention and control risks.

Removal of bird droppings

The fungi associated with bird droppings presents a risk to those engaged in its removal and any associated work should only be carried out following an appropriate risk assessment and following a procedure developed to control the risks. The risk assessment should identify the appropriate personal protective equipment (PPE) to be used. Microorganisms such as fungi may be substances hazardous to health as in the Control of Substances Hazardous to Health Regulations 2002 http://www.hse.gov.uk/coshh/. Staff with compromised immune systems should not undertake the work of removing bird droppings.

Whether specialist contractors or in house staff are used to remove bird droppings, they should be appropriately trained and use appropriate methods and equipment, including personal protective equipment as identified in the risk assessment and procedure above. A permit to work system should be used to control the timing, methodology and extent of work. The route to and from the work site should also be considered to ensure fungi are not spread to adjoining clinical areas, and should be collaboratively signed off by estates and infection control. Clothing, equipment and tools should be appropriately decontaminated or disposed of at the end of work in accordance with the risk assessment and procedure. All contaminated waste should be disposed of with due regard to the pathogens present. Further information is available on the HSE web site, http://www.hse.gov.uk/construction/healthrisks/hazardous-substances/harmful-micro-organisms/other-diseases.htm.

Health and safety assessments, records and other documentation should be updated in accordance with decisions made, risk assessments and work procedures.

Bird droppings should be removed using techniques designed to minimise the risk of releasing airborne fungi. As the risk of releasing airborne fungi increases when droppings are dry and can produce dust when disturbed, HEPA filtered vacuuming and/or wet removal techniques are likely to be best. Pressure washing should be avoided as this will aerosolise and spread the droppings. When droppings are being removed, the associated ventilation systems should be off and isolated where practicable and indicated by risk assessment. Chemical inactivation of fungi, once the affected area is physically clean, should be used although this should not be relied on as a substitute for other protective measures.

Bird management

This guidance does not set out to address bird management in general, which is a complex multifactorial issue, although it should be noted that management of the bird population in the vicinity of buildings can affect the accumulation of droppings and the risk of contamination from Fungi should be part of a bird management strategy.

All wild birds in Great Britain are protected under the Wildlife and Countryside Act 1981 (as amended). This includes even common species like pigeons and blackbirds. Further information is available from Scottish Natural Heritage here.

Cryptococcus Briefing for AE(V)'s, AP(V)'s & Estates Professionals

Introduction

Following recent press coverage regarding an incident of two patient deaths at a Glasgow hospital, reported as 'due to infections of cryptococcus', the following information summary has been prepared to provide guidance and proportional advice to estates professionals, regarding any additional actions to consider to minimise or address estates ventilation related issues.

Cryptococcus is a pathogenic yeast fungus whose spores are ubiquitous in the environment, normally found in air (including hospital ventilation systems), soil, decaying plant matter, and bird excrement. This makes it extremely difficult if not impossible to control at the point of source.

- The fungal spores produced by the fungi have an effective diameter of between (1 to 2µm)
- Infection is mainly via inhalation although direct wound contamination is also possible.
- Multiplication and growth are strongest in warm and/or damp environments

Whilst Cryptococcus rarely poses a threat to normal healthy people, it is recognised as a potential cause of severe illness and mortality in highly immunocompromised patients.

Cryptococcosis has a number of identified strains including neoformans, gattii, albidus, and uniguttulatus which have all been identified in cases of human infection, there are also a total of fourteen non-infectious species. For the purposes of this briefing paper it is Cryptococcus neoformans that is referenced, as research suggests that this strain is the primary source for the majority of human infections.

Characteristics

Cryptococcus neoformans is a spherical yeast fungus, 3 µm in diameter when desiccated and 5 to 10µm in diameter when hydrated), that produces a capsule containing glucoronoxylomannan (GXM), extending the overall diameter to 25 µm or more.

The problem is the spores from the Cryptococcus are so small, like many other fungal spores such as 'aspergillus' etc., they can pass through the majority of filter grades with the exception of HEPA filters, and enable the spores to penetrate the alveoli within the lung more efficiently than other yeast organisms.

Mode of Transmission

Humans and animals can get the infection after inhaling the microscopic fungal spores from the environment. Cryptococcus neoformans infections are not contagious (human to human), although some research suggests that people may be exposed to Cryptococcus in the environment when they are children. Most people who breathe it in never get sick from it. However, in people who have weakened immune systems, Cryptococcus can stay hidden in the body and cause infection later when the immune system becomes too weak to fight it off.

Incubation Period

Unknown, Cryptococcus neoformans can colonize in the host respiratory tract for months to years without causing any clinical symptoms

How common are Cryptococcus neoformans infections?

Cryptococcus infections are rare among people who have healthy immune systems; however, Cryptococcus can be a major cause of illness in people with HIV/AIDS or patients who have severely weakened immune systems (transplant/oncology).

Pathology

Infection with Cryptococcus neoformans is termed Cryptococcosis. Most infections with Cryptococcus neoformans occur in the lungs. However, fungal meningitis and encephalitis, especially as a secondary infection for severely immunocompromised patients, are often caused by Cryptococcus, making it a particularly dangerous fungus. Infections with this fungus are rare in those with fully functioning immune systems

Infection starts in lungs, disseminates via blood to meninges and then to other parts of the body. Cryptococcus can cause a systemic infection, including fatal meningitis known as meningoencephalitis in normal, diabetic and immunocompromised hosts. The infection from Cryptococcus neoformans in the brain can be fatal if untreated. CNS (central nervous system) infection may also be present as a brain abscess known as Cryptococcomas, subdural effusion, dementia, isolated cranial nerve lesion, spinal cord lesion, and ischemic stroke. If Cryptococcal meningitis occurs, mortality rate is between 10–30%.

Potential Risk Groups

- Organ Transplants
- Oncology / Caner treatment
- Patients on high dose steroids
- Haematology
- I.C.U. / P.I.C.U.
- S.C.I.D.S. / B.M.T.
- HIV Positive patients
- Laboratory Facilities

Suceptibility to Disinfectants

Cryptococcus neoformans is effectively killed by 70% ethyl alcohol and is susceptible to phenolic compounds, formaldehyde, glutaraldehyde, iodophors, and sodium hypochloride (1%)

Potential Additional Maintenance Precautions

- Ensure all plantrooms and air handling unit air intake areas are clear and secured.
- All air intakes should be clear of debris and where practical the immediate surrounding area should be clear of vegetation and any accumulation of bird faeces should be cleaned at regular intervals.
- In all cases where bird ingress to plant areas is evident, it should be dealt with and cleaned up immediately upon discovery.
- Birds must be prevented from nesting or congregating close to any AHU intake. If anti-roosting netting has been recently installed, birds will be displaced and nest elsewhere, special attention should be given to ensure that they do not nest near AHU air intakes.

- All filters should be subject to routine inspection and changed when indicated by pressure drop.
- All anti-roost netting should be inspected as part of the existing quarterly inspection protocol for all critical ventilation AHU plant.
- The IPC team and estates team should establish a regular review meeting to identify clinical areas where patient susceptibility may be high and immunocompromised patients are treated. In extreme cases of known risk consideration should be given to provision of temporary or permanent HEPA filtered positive pressure ventilation systems, however this is not anticipated to be a routine requirement for the majority of healthcare environments.

For specific issues or concerns the Trust Authorising Engineer (Ventilation) should be contacted to work with all estates and clinical stakeholders to agree additional precautionary measures.

Subject: Air testing MRI intra-operative scanning room

Dear all,

I note that the MRI minutes from the meeting on 23.01.2019 appear to have an ongoing action in relation to air testing within the MRI intra-operative scanning room and Stephen has asked Anna for clarification around this.

Both Anna Munro and Lead IPCN Lindsay Guthrie had a previous discussion with Dr Inverarity Consultant Microbiologist and ICD for NHS Lothian in relation to this question. My understanding was that Anna had discussed this with Jackie whom also requested clarification from myself. Please see Dr Inverarity's advice below:

I have previously been asked about this scenario and advised not to perform microbiological air testing because there are no microbiological parameters by which to interpret the result in this context.
I would not usually advise performing a microbiological test when the result is not interpretable.

In such a scenario, the assessment of the adequacy of the ventilation rests on the visual inspection of the area and confidence that air changes and room pressures are adequate.
Donald.

Dr Inverarity has advised that If it would be helpful and he is available, he would be happy to attend the next meeting to explain theatre microbiological air testing (and its limitations).

Kind regards
Sarah

Subject: RE: Ultraclean laminar flow venitilation in DCN new theatres - new RHSC and DCN Building

Dear Fiona

Many thanks. That's really helpful.

It is reassuring to know that the laminar flow ventilation can be switched to conventional ventilation for cranial procedures. I assume the theatre design and environment and all other issues would be captured in the HAI-Scribe and there would be clear protocols and education around that?

There is an increasing awareness about potential risks of laminar flow ventilation, for instance when patient body temperature is not maintained, which could be the case in prolonged procedures. There is a multicentre trial presently looking at the risks of different warming techniques on infection rates.

I think it would be useful to address all the potential issues and pitfalls that may arise far in advance involving surgeons, theatre staff, anaesthesists and estates to minimize risks and delays.

Happy to discuss further.

Subject: Ultraclean laminar flow venitilation in DCN new theatres - new RHSC and DCN Building

Hi Both

I have read through the emails below with regard to the question being raised by both of you with regard to clinicians in DCN requesting ultraclean laminar flow ventilation in the 4 theatres.

The senior DCN clinician involved in the design of theatres early doors was Mr James Steers. Miss Lynn Myles and Mr Jerard Ross were also involved (Mr Ross does not now work with NHSL)

I have information dating back as early as 2009/2010 on the DCN Theatres specifications which included the need for laminar flows in their theatres. One of the key rationales for DCN theatres have laminar flows is that the majority of surgery undertaken in DCN is spinal related.

The laminar flow specification at the procurement stage was also reviewed by clinicians – Mr Sokol and Mr Demetriades from DCN was involved.

One key element was for the units control system that it permitted the Ultra Clean Ventilation System to be set-back to a reduced speed. *So this would be utilised when cranial surgery is being undertaken. Does this help to address your concerns?*

If you wish to meet up to discuss I am usually down at the WGH on a Friday.

Subject: RE: Ultraclean laminar flow venitilation in DCN new theatres - new RHSC and DCN Building

Hi Fiona,

Apologies, working my through emails.

The policy Donald is referring to sits within the Infection Control page on the Intranet. Staff will also find The National Infection Prevention and Control Manual (NIPCM) via the Infection Control pages - Appendix 11 of this document also provides advice on which patients require Isolation and where an Isolation Suite is required.

Staff should be aware of these/familiarise themselves with both documents and where to locate these on the intranet as these are the documents that they should make reference to for guidance.

I have attached the links below however any hard copies of these documents should not be printed and kept as policies/guidance may be updated electronically at any given time.

Hi Fiona,
I think guidance that explains how to work the isolation room and monitor that it is working correctly is really the remit of Facilities. Until the builders or facilities explain and demonstrate how it works to us I don't think anyone in the IPCT would be in a position to write anything useful. I also think ownership of such a document really should be through involvement with the clinical teams who will occupy those areas and using the rooms.

All the best

There is an NHS Lothian policy document that outlines which types of patient require isolation but the design of the isolation rooms in the new building are unique in NHS Lothian with positive pressure HEPA filtered anterooms separating the room from corridor and I suspect we would need to write a protocol regarding how staff would know that they are working correctly once occupied.

McMahon, Alex [redacted]
Subject: RE: Theatre Validation

Hi Ronnie,

The Multiplex document doesn't indicate what size the theatres are, what the air pressures are in the theatre areas (anaesthetic room, prep area, theatre etc) or what number of air changes per hour are achieved and neither does it mention what, if any, microbiological assessment of air quality has been performed (that box is blank so I'm presuming none has been performed). Although you are being assured that it "conforms" it isn't explicitly stated what standard it "conforms" to –presumably SHTM 03-01 ?
The statement:
"The theatre suite ventilation system has been commissioned and validated in accordance with the required regulations and has achieved the required standard."
might be factually correct but there is nothing to back it up and it tells us absolutely nothing about how the theatre performs at baseline. It is essentially asking us to taking everything on trust that its all okay. That makes me a little uncomfortable in the current political climate of scrutiny. Does it achieve the required standard with a wide safety margin or did it barely achieve it empty without any operations in progress?
At validation the report should tell us at baseline how it actually "performs" so that if there are problems in the future we have some baseline parameters of air pressures and air changes per hour to compare it against.
I see that "all test documentation is located on Zutec." I don't know what Zutec is or whether anyone in NHS Lothian has access to that information so essentially I can't provide any assurance to myself or NHS Lothian by assessing it myself. But in my role as infection control doctor I shouldn't need to go to source documents and extract that information to interrogate and interpret it myself, it should be clearly and explicitly included in the validation report.

Section 8.64 of SHTM 03-01 says:
Ventilation system commissioning/validation report
8.64 Following commissioning and/or validation a full report detailing the findings should be produced. The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

Personally I don't think we are being provided with a "full report" detailing the validation findings and there is not enough detail for me to know if the theatre is," fit for purpose and will only require routine maintenance in order to remain so for its projected life." I don't think the Validation checklist provided fulfils point 8.64 of SHTM 03-01 whereas the validation reports we were issued when the SJH theatres were commissioned did and were very easy to read and be assured by.

I'm happy to be over-ruled but, for me, I'm not assured by this checklist that theatre 30 is fit for purpose because the information I would be looking for to allow me to have that assurance is not provided and not accessible by me. I'm happy to hear other views.
Thanks.
All the best.
Donald

Subject: RE: Theatre Validation

Hi Ronnie,

The Multiplex document doesn't indicate what size the theatres are, what the air pressures are in the theatre areas (anaesthetic room, prep area, theatre etc) or what number of air changes per hour are achieved and neither does it mention what, if any, microbiological assessment of air quality has been performed (that box is blank so I'm presuming none has been performed). Although you are being assured that it "conforms" it isn't explicitly stated what standard it "conforms" to –presumably SHTM 03-01 ?
The statement:
"The theatre suite ventilation system has been commissioned and validated in accordance with the required regulations and has achieved the required standard."
might be factually correct but there is nothing to back it up and it tells us absolutely nothing about how the theatre performs at baseline. It is essentially asking us to taking everything on trust that its all okay. That makes me a little uncomfortable in the current political climate of scrutiny. Does it achieve the required standard with a wide safety margin or did it barely achieve it empty without any operations in progress?

At validation the report should tell us at baseline how it actually "performs" so that if there are problems in the future we have some baseline parameters of air pressures and air changes per hour to compare it against.
I see that "all test documentation is located on Zutec." I don't know what Zutec is or whether anyone in NHS Lothian has access to that information so essentially I can't provide any assurance to myself or NHS Lothian by assessing it myself. But in my role as infection control doctor I shouldn't need to go to source documents and extract that information to interrogate and interpret it myself, it should be clearly and explicitly included in the validation report.

Section 8.64 of SHTM 03-01 says:
Ventilation system commissioning/validation report
8.64 Following commissioning and/or validation a full report detailing the findings should be produced. The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

Personally I don't think we are being provided with a "full report" detailing the validation findings and there is not enough detail for me to know if the theatre is," fit for purpose and will only require routine maintenance in order to remain so for its projected life." I don't think the Validation checklist provided fulfils point 8.64 of SHTM 03-01 whereas the validation reports we were issued when the SJH theatres were commissioned did and were very easy to read and be assured by.

I'm happy to be over-ruled but, for me, I'm not assured by this checklist that theatre 30 is fit for purpose because the information I would be looking for to allow me to have that assurance is not provided and not accessible by me. I'm happy to hear other views.
Thanks.
All the best.
Donald

Subject: Theatre Validation

Hi Donald,

Multiplex have provided us with their validation report for Theatre 30 as an example of what they intend to provide for each individual theatre. You will note it differs from the example you sent from St Johns although there is a declaration that it conforms. I can confirm that these have been reviewed and signed off by the independent tester which provides us with reassurance of compliance. If however you have any doubts or concerns, happy to discuss with a view to appointing someone from outwith the project to give an additional layer of assurance if required.

Regards

Ronnie

Subject: RE: THEATRES NEW BUILD

Dear Ashley
I had a lovely Christmas thank you hope you did too.

Air sampling will have to be done at commissioning before you let staff go in and out putting in equipment etc. As this will be part of the assurance protocol that the air handling units are working. As for frequency after that prior to the theatres actually becoming functional I will have to look up and get back to you,
Regards

Subject: THEATRES NEW BUILD

Good Morning Janette

Hope you had a rest over Christmas. I take it you have been busy.

Just a quick question in relation to air sampling new theatres.

My thoughts are :

The plan is to move RHSC first and then DCN .

When would the appropriate time to air sample these theatres . I am proposing that all staff start to wear scrubs as from January 1st 2018.

I do not want to find issues a few days before the move and find that the move would be delayed. So when do you advise us to start remembering that we want no delays and would DCN be completed at the same time. All the

equipment should be in before Christmas 2017 .Only the transfer equipment to follow. Which is not as much as you think except for instrument trays, microscopes , stacks etc.

My other plan is that there is one delivery point DCN recovery this will allow us to control traffic as DCN will be the last in to theatres.

The plan for critical care is once the building clean is completed. Our domestics will start to clean them on a regular basis i.e. daily.

Kind Regards

Ashley

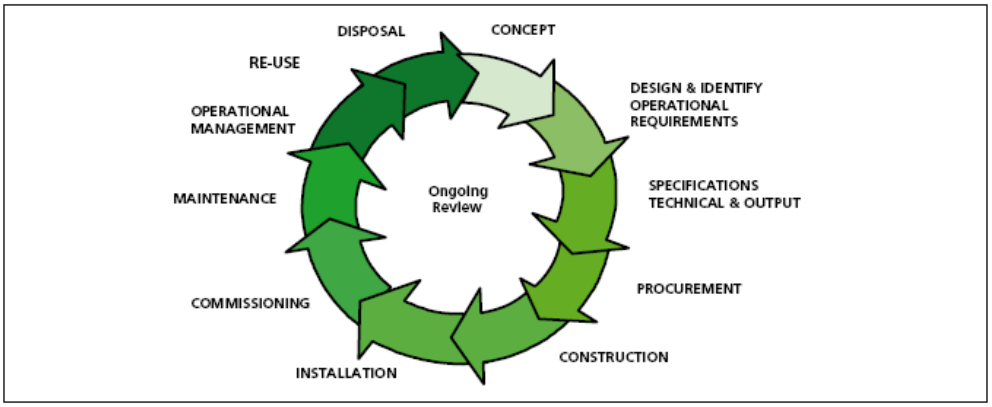
Preface

About Scottish Health Technical Memoranda

Scottish Engineering Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of Scottish Health Technical Memorandum guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle.



Healthcare building life-cycle

Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Scottish Engineering Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;

- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance will ultimately contain a suite of eight core subjects pending a re-assessment of Firecode SHTMs 81-86.

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Health Technical Memoranda in this series)

Scottish Health Technical Memorandum 01: Decontamination

Scottish Health Technical Memorandum 02: Medical gases

Scottish Health Technical Memorandum 03: Heating and ventilation systems

Scottish Health Technical Memorandum 04: Water systems

Scottish Health Technical Memorandum 05: Reserved for future use.

Scottish Health Technical Memorandum 06: Electrical services

Scottish Health Technical Memorandum 07: Environment and sustainability

Scottish Health Technical Memorandum 08: Specialist services

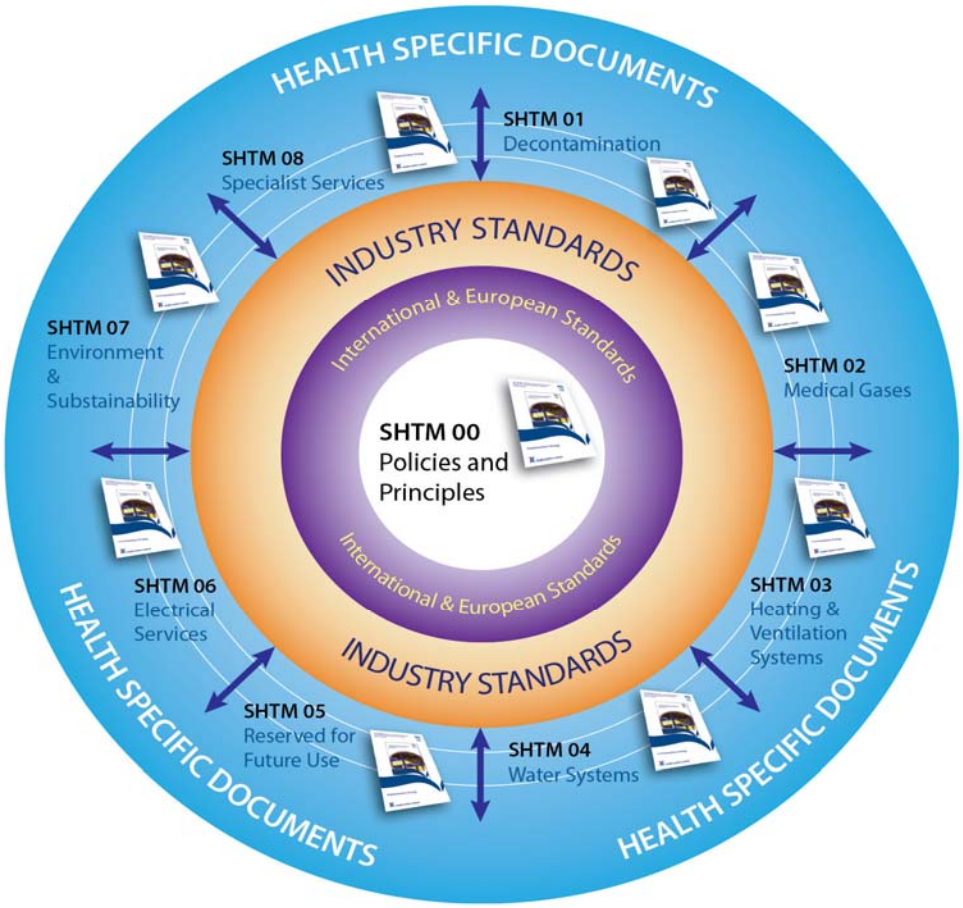
Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent Electrical Services – Electrical safety guidance for low voltage systems.

In a similar way Scottish Health Technical Memorandum 07-02 will simply represent Environment and Sustainability - EnCO_2de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.



Engineering guidance

Health Facilities Scotland

NHS National Services Scotland

Executive summary

Scottish Health Technical Memorandum 03-01: 'Ventilation in healthcare premises' is published in two parts. Part A deals with the design and installation of ventilation systems; Part B covers operational management.

The document gives comprehensive advice and guidance on the legal requirements, design implications, maintenance and operation of specialised ventilation in all types of healthcare premises.

The guidance contained in this Scottish Health Technical Memorandum applies to new installations and major refurbishments of existing installations.

Scottish Health Technical Memorandum 03-01 supersedes all previous versions of Scottish Health Technical Memorandum 2025: 'Ventilation in healthcare premises'.

Who should use this guidance?

This document is aimed at healthcare management, estates managers and operations managers.

Main recommendations

- all ventilation plant should meet a minimum requirement in terms of the control of *Legionella* and safe access for inspection and maintenance;
- all ventilation plant should be inspected annually;
- the performance of all critical ventilation systems (such as those servicing operating suites) should be verified annually.

1. Introduction

1.1 Scottish Health Technical Memorandum 03-01: 'Ventilation in healthcare premises' is published in two parts. Part A deals with design and validation of general and specialised ventilation; Part B covers operational management.

1.2 The document gives comprehensive advice and guidance to healthcare management, design engineers, estates managers and operations managers on the legal requirements, design implications, maintenance and operation of specialised ventilation in all types of healthcare premises.

1.3 The guidance contained in this Scottish Health Technical Memorandum applies to new installations and major refurbishments of existing installations.

1.4 Scottish Health Technical Memorandum 03-01 supersedes all previous versions of Scottish Health Technical Memorandum 2025: 'Ventilation in healthcare premises'.

Ventilation in healthcare premises

1.5 Ventilation is used extensively in all types of healthcare premises to provide a safe and comfortable environment for patients and staff. More specialised ventilation is provided in areas such as operating departments, critical care areas and isolation facilities for primary patient treatment.

1.6 It is also installed:

- to ensure compliance with the quality assurance requirements of items processed in pharmacies and sterile services departments;
- to protect staff from harmful organisms and toxic substances (for example in laboratories).

Statutory requirements

1.7 Increased health risks to patients will occur if ventilation systems do not achieve and maintain the required standards. The link between surgical site infection and theatre air quality has been well established.

If the ventilation plant has been installed to dilute or contain harmful substances, its failure may expose people to unacceptable levels of contamination. Proven breaches of the statutory requirements can result in prosecution and may also give rise to a civil suit against the operators.

Health and Safety at Work etc Act 1974

1.8 The Health and Safety at Work etc Act 1974 is the core legislation that applies to ventilation installations. As these installations are intended to prevent

contamination, control closely the environment, dilute contaminants or contain hazards, their very presence indicates that potential risks to health have been identified.

COSHH

1.9 The Control of Substances Hazardous to Health (COSHH) Regulations 2002 place upon management an obligation to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and microbiological safety cabinets.

1.10 Where specialised ventilation plant is provided as part of the protection measures, there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of COSHH requires that the system be examined and tested at least every 14 months by a competent person and that management maintain comprehensive records of its performance, repair and maintenance.

1.11 Certain substances have workplace exposure limits (WELs) set out in the Health and Safety Executive's Guidance Note EH40 – 'Workplace exposure limits: containing the list of workplace exposure limits for use with the Control of Substances Hazardous to Health Regulations 2002 (as amended)'. If specialised ventilation systems are provided in order to achieve these standards, they will be subject to the COSHH Regulations as above.

Fire regulations

1.12 The Fire Regulations require that if ventilation ductwork penetrates the fabric of a building, it should be designed and installed so as to contain the spread of fire (see Firecode: SHTM 81: 'Fire Precautions in New Hospitals, Version 3' and the requirements of the Scottish Technical Handbooks, Non-Domestic, Section 2: Fire, published by the Scottish Building Standards Agency).

1.13 It is management's responsibility to ensure that the standards applied during the design and installation are not reduced during the subsequent operation and maintenance of the equipment.

Plants installed in units manufacturing medicinal products

1.14 Plants installed in units manufacturing medicinal products to the standards set out in the current European guide to good manufacturing practice (http://ec.europa.eu/enterprise/pharmaceuticals/ eudralex/homev4.htm) may also be subject to particular legislation with regard to their operation and maintenance.

1.15 There are specific requirements under the Medicines Act 1968 to maintain accurate records of plant performance, room conditions and maintenance

events. Such records would need to be preserved for up to 35 years as part of a quality assurance audit trail.

Plants installed in laboratories

1.16 Specialised ventilation plants installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified organisms, may be subject to particular legislation with regard to their operation in addition to that mentioned above.

Codes of practice and guidance

1.17 All ventilation systems should conform to the principles set out in the Health and Safety Commission's Approved Code of Practice and guidance document 'Legionnaires' disease: the control of *Legionella* bacteria in water systems' (commonly known as L8), and Scottish Health Technical Memorandum 04-01: 'The control of *Legionella*, hygiene, 'safe' hot water, cold water and drinking water systems'.

1.18 Scottish Health Facilities Note 30: 'Infection Control in the Built Environment, Design and planning' guides and stimulates thinking on the planning of and execution of new construction and refurbishment works in all types of healthcare facilities. Ventilation systems (covered in this guidance) play an important role in reducing the risk of Healthcare Associated Infection.

Management responsibilities – general

1.19 It is a management responsibility to ensure that inspection, service and maintenance activities are carried out safely without hazard to staff, patients or members of the public.

1.20 Those required to monitor and/or maintain ventilation equipment will need to show that they are competent to do so (see Section 2).

1.21 Maintenance procedures should be reviewed periodically to ensure that they remain appropriate.

System information

1.22 When new ventilation systems are accepted for use, full information as to their designed mode of operation together with recommended maintenance procedures should be provided as part of the handover procedure.

1.23 In many existing systems, original design and commissioning information will not be available. It will therefore be necessary to determine a suitable level of system performance based on the function, purpose and age of the installation.

1.24 Part A of this Scottish Health Technical Memorandum gives design parameters for new installations.

1.25 Section 3 of this document sets out the minimum standards for all air-handling units (AHUs) and their air distribution systems.

1.26 Ventilation system records and logbooks should be kept of the commissioning information, operational management routine, monitoring and maintenance. The Health and Safety Executive and other interested bodies have a statutory right to inspect them at any time. All records should be kept for at least five years.

Note 1: In the event of a reportable incident connected with ventilation equipment or the area that it serves; all records and plant logbooks will need to be collected as evidence.

1.27 A set of specimen maintenance checklists is given in Appendix 1.

Frequency of inspections and verifications

1.28 All ventilation systems should be subject to, at least, a simple visual inspection annually.

1.29 Ventilation systems serving critical care areas should be inspected quarterly and their performance measured and verified annually. The quarterly inspection should be a simple visual check; the annual verification will be a more detailed inspection of the system together with the measurement of its actual performance.

1.30 The LEV section of the COSHH Regulations contains a statutory requirement that systems installed to contain or control hazardous substances be examined and tested at least every 14 months by a competent person.

1.31 Regular tests, at intervals agreed with the local fire prevention officer, will need to be carried out in order to demonstrate the continuing efficiency of the fire detection and containment systems. These may be in addition to the inspections detailed above. Records of these tests should be kept.

Implications of PPP/PFI Procurement

1.32 While the ultimate responsibilities as set out in this SHTM in terms of overall management remain with NHS Boards, when a new or recent hospital has been procured via the Public-Private Partnership (PPP) or Private Finance Initiative (PFI) routes, there are changes in the chain of responsibilities.

1.33 More often than not, the operator of the facility will subcontract or enter into partnership with a Facilities Management (FM) Provider who will maintain and operate mechanical and electrical installations, including ventilation systems. It is not unknown for the FM provider to be the NHS Board's own estates staff. Whichever organisation carries out the functions set out in this SHTM, it will be

necessary for the same practice and procedures to be carried out, records maintained and reports prepared to maintain an audit trail. These have to be submitted to the NHS Board for which the hospital has been established. The NHS Board will retain in-house estates staff and/or technical advisers to monitor these records and reports, having the right to comment where performance standards are not being achieved, inspect installations, and seek to ensure that remedial measures are put in hand and monitored as to their effect.

In the event that a civil suit is served on a NHS Board, they would seek redress from the operator of the Hospital, where appropriate.

1.34 Issues related to control of infection where mechanical ventilation systems are implicated will be the remit of the NHS Board's control of infection teams set up for the purpose and representation should be arranged for estates staff or the FM Provider so that any remedial action agreed can be can be set in motion without delay.

Health Facilities Scotland

NHS National Services Scotland

2. Functional responsibilities

Management responsibilities

2.1 Clear lines of managerial responsibility should be in place so that no doubt exists as to who is responsible for the safe operation and maintenance of the equipment.

2.2 A periodic review of management systems should take place in order to ensure that the agreed standards are being maintained.

2.3 Those required to inspect, verify or maintain ventilation equipment will need to show that they are competent to do so. As a minimum they should have sufficient knowledge of its correct operation to be able to recognise faults.

2.4 It is anticipated that training in the validation and verification of specialised healthcare ventilation systems for Authorised Persons and Competent Persons will become available during the life of this Scottish Health Technical Memorandum.

Designated staff functions

2.5 A person intending to fulfil any of the staff functions specified below should be able to prove that they possess sufficient skills, knowledge and experience to be able to perform safely the designated tasks.

Management

2.6 Management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the safe operation of premises.

Designated Person

2.7 This person provides the essential senior management link between the organisation and professional support. The Designated Person should also provide an informed position at board level.

Authorising Engineer (Ventilation) (AE(V))

2.8 The AE(V) is defined as a person designated by Management to provide independent auditing and advice on ventilation systems and to review and witness documentation on validation.

Authorised Person (Ventilation) (AP(V))

2.9 The AP(V) will be an individual possessing adequate technical knowledge and having received appropriate training, appointed in writing by the Designated Person (in conjunction with the advice provided by the AE(V)), who is responsible for the practical implementation and operation of Management's safety policy and procedures relating to the engineering aspects of ventilation systems.

Competent Person (Ventilation) (CP(V))

2.10 The CP(V) is defined as a person designated by Management to carry out maintenance, validation and periodic testing of ventilation systems.

Infection Control Officer

2.11 The Infection Control Officer (or consultant microbiologist if not the same person) is the person nominated by management to advise on monitoring the infection control policy and microbiological performance of the systems.

2.12 Major policy decisions should be made through an infection control committee. The infection control committee should include representatives of the user department and estates and facilities or their nominated representative (that is, the Authorised Person).

Plant Operator

2.13 The Plant Operator is any person who operates a ventilation installation.

User

2.14 The User is the person responsible for the management of the unit in which the ventilation system is installed (for example head of department, operating theatre manager, head of laboratory, production pharmacist, head of research or other responsible person).

Contractor

2.15 The Contractor is the person or organisation responsible for the supply of the ventilation equipment, its installation, commissioning or validation. This person may be a representative of a specialist ventilation organisation or a member of the general manager/chief executive's staff.

Records

2.16 A record should be kept of those appointed to carry out the functions listed above. The record should clearly state the extent of the postholder's duties and responsibilities, and to whom they are to report.

2.17 Substitute or replacement staff should be designated in order to cover for sickness, holidays and staff transfers.

Training

2.18 Routine inspection and maintenance procedures can cause risks to the health of staff carrying out the work and those receiving air from the plant. All those involved should be made aware of the risks, and safe systems of work should be agreed. Suitable safety equipment should be provided as necessary, and training in its use should be given.

2.19 Any training given should be recorded, together with the date of delivery and topics covered.

2.20 Training in the use of safety equipment and a safe system of work will need to be repeated periodically in order to cater for changes in staff.

Specific health and safety aspects

2.21 Staff engaged in the service and maintenance of extract ventilation systems from pathology departments, mortuaries, laboratories, source-protective isolation facilities and other areas containing a chemical, biological or radiation hazard may be particularly at risk. In these cases, the risk should be identified and assessed.

2.22 The means by which the system can be rendered safe to work on should be determined, and a permit-to-work on the system implemented.

2.23 Training in the exact procedures should be given to all staff involved.

2.24 Some healthcare facilities may contain specialised units that are subject to access restrictions (for example pharmacy aseptic suites). Estates or contract staff requiring access may need additional training or to be accompanied when entering the unit.

Note 2: See also the following guidance published by the Health and Safety Commission's Health Services Advisory Committee:

- 'Safe working and the prevention of infection in clinical laboratories and similar facilities';
- 'The management, design and operation of microbiological containment laboratories';
- 'Safe working and prevention of infection in the mortuary and post-mortem room'.

Health Facilities Scotland

NHS National Services Scotland

3. Ventilation systems – minimum requirements

General requirements

3.1 All ventilation systems should be inspected annually to ensure conformity with minimum requirements, which are designed to:

- ensure safe access when carrying out routine service and maintenance activities;
- prevent or control risks associated with *Legionella* and other potential hazardous organisms;
- check that the system remains fit for purpose;
- maintain records of outcomes.

3.2 Every effort should be made to ensure that all AHUs achieve the minimum requirement set out below.

Location and access

3.3 AHUs should be secured from unauthorised access.

3.4 Units located on roofs must have a safe and permanent means of access. Suitable precautions must be in place to prevent personnel or equipment from falling during maintenance activities.

3.5 Units located outside at ground level should be secured within a compound to prevent unauthorised access. Vehicles should be excluded from the vicinity to ensure that exhaust fumes will not be drawn into intakes.

3.6 All parts of the AHU should be easily and safely accessible for routine inspection and service.

3.7 The area around an AHU within a building should be tanked to prevent water penetration to adjacent areas, and should be adequately drained.

3.8 Fire precautions should be in accordance with Firecode.

3.9 Combustion equipment must not be located in a fire compartment that houses air-handling equipment.

3.10 Plantrooms that house AHUs must not be used for general storage. Care should be taken to ensure that combustible material is not kept in the plantroom.

Basic requirements

3.11 The plant must not contain any material or substance that could support the growth of microorganisms.

3.12 The plant must not contain any material or substance that could cause or support combustion.

3.13 Access to items that require routine service, such as filters, coils and chiller batteries, should be via hinged doors.

3.14 Items requiring infrequent access such as attenuators may be via clipped or bolted-on lift-off panels.

3.15 All doors and panels should be close-fitting and without leaks.

3.16 Every effort should be made to ensure that access is via fixed ladders and platforms or pulpit-style movable steps.

3.17 Electrical and mechanical services should not restrict or impede access to those parts of the AHU that require inspection.

3.18 Viewing ports and internal illumination should be fitted in order to inspect filters and drainage trays.

3.19 Internal illumination should be provided by fittings to at least IP55 rating. Fittings should be positioned so that they provide both illumination for inspection and task lighting.

3.20 A single switch should operate all of the lights in a unit.

AHU intakes and discharges

3.21 Intake and discharge points should not be situated where they will cause vitiated air to be drawn into a system (see paragraphs 3.61-3.71) in Part A, which give detailed information). In existing systems, it may be necessary to extend the intake or discharge point to a suitable position.

3.22 Each intake and discharge point should be fitted with corrosion-resistant weatherproof louvres or cowls to protect the system from driving rain. The inside of the louvres should be fitted with a mesh of not less than 6mm and not more than 12mm to prevent infestation by vermin and prevent leaves being drawn in.

3.23 The duct behind a louvre should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system. Cleaning access must be provided either from the outside via hinged louvres or by access doors in the plenum behind the louvre. Where a common plenum is provided, cleaning access should be via a walk-in door.

AHU drainage system

3.24 All items of plant that could produce moisture must be provided with a drainage system. The system will comprise a drip-tray, glass trap, air break and associated drainage pipework.

3.25 Some existing units may not have been mounted far enough above the floor to permit the correct installation of a drainage system. If the AHU cannot be raised to an adequate height, an alternative arrangement (such as a pump-out system) must be provided.

3.26 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent 'pooling', it is essential that the drain connection should not have an upstand and that a slope of approximately 1 in 20 in all directions should be incorporated to the drain outlet position. The tray must be completely accessible or, for smaller units, easily removable for inspection and cleaning.

3.27 Each drip-tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed, thus giving an early indication of corrosion, biological activity or contamination within the duct (Part A, Section 4, paragraphs 4.20-4.25 refer and paragraph 3.29 of this Part B).

3.28 The trap should have a means for filling and should incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting it to the drainage tray should have a continuous fall of not less than 1 in 20.

3.29 Traps fitted to plant located outside or in unheated plantrooms may need to be trace-heated in winter. The trace heating should be checked for operation and must not raise the temperature of water in the trap above 5°C.

3.30 Water from each trap must discharge via a clear air gap of at least 15mm above the unrestricted spill-over level of either an open tundish connected to a drainage stack via a second trap, or a floor gully (or channel). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish, providing each has its own air break.

3.31 Drainage pipework may be thermoplastic, copper or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22mm and have a fall of at least 1 in 60 in the direction of flow. It should be well supported, and located so as not to inhibit access to the AHU.

Dampers

3.32 AHUs serving critical areas and those areas that are shut down out of hours should be fitted with motorised low-leak shut-off dampers located immediately behind the intake and discharge of each supply and extract system.

Fan drives

3.33 Fan-drive trains, whether supply or extract, should be easily visible without the need to remove access covers. Protecting the drive train with a mesh guard is the preferred option. For weatherproof units designed to be located outside, the fan drive should be enclosed. It should be easily visible through a viewing port with internal illumination and be accessed via a lockable, hinged door.

3.34 The motor windings of induction-drive 'plug' motor arrangements and in-line axial fans having a pod motor within the air stream must be protected from over-temperature by a thermistor and lockout relay.

3.35 It is necessary to ensure that – should the computer control system or its software develop a fault – the fan can be switched to a direct start with fixed speed and manual operation. This is particularly important for critical care systems serving operating suites, high dependency care units of any type, isolation facilities, laboratories and pharmaceutical production suites.

Heater & Frost batteries

3.36 Access for cleaning must be provided to both sides of frost batteries and heater-batteries.

3.37 Where auxiliary wet heater-batteries are located in false ceilings, they should be fitted with a catch tray and leak alarm. The catch tray should be installed under both the battery and the control valve assembly to protect the ceiling from leaks. A moisture sensor and alarm should be fitted in the tray. Placing wet heater batteries in ceiling voids should be avoided if at all possible.

Cooling coils

3.38 Each cooling coil – whether within the AHU or within a branch duct – must be fitted with its own independent drainage system as specified above. A baffle or similar device must be provided in the drip-tray to prevent air bypassing the coil, and the tray should be large enough to capture the moisture from the eliminator, bends and headers.

3.39 The cooling-coil control valve should close upon selection of low speed, system shutdown, low air-flow or fan failure.

3.40 Where auxiliary wet-cooling coils are located in false ceilings, they should be fitted with a catch tray and leak alarm. The catch tray should be installed under both the battery and the control valve assembly to protect the ceiling from leaks. A moisture sensor and alarm should be fitted in the tray.

Humidifiers

3.41 Humidifiers are not generally required. Where they are fitted, but have been out of use for a significant period of time, they should be removed. All associated pipework should also be removed back to its junction with the running main.

3.42 Where humidifiers are fitted and their use is still required, they should fully conform to the installation standard set out in Section 4 of Part A.

3.43 The section of ductwork containing the humidifier may need to be periodically decontaminated. Hinged access doors with viewing ports and internal illumination should be provided.

3.44 All humidifiers must be fitted with their own independent drainage system as detailed above.

3.45 Only steam-injection humidifiers, whether mains fed or locally generated, are suitable for use in air-conditioning systems within healthcare facilities. Water humidifiers, if fitted, should be removed.

3.46 Self- and locally-generated steam humidifiers must be supplied with potable water. The installation should be capable of being isolated, drained and cleaned. Section 4 in Part A of this Scottish Health Technical Memorandum gives further details.

3.47 Some steam generators are of a type that requires regular cleaning and descaling. The installation should enable them to be physically isolated from the air duct in order to prevent contamination of the air supply by cleaning agents.

3.48 The humidifier control system should fully conform to the standard set out in Sections 4 and 6 of Part A.

Filtration

3.49 Filters must be securely housed and sealed in well-fitting frames that minimise air bypass. Air bypass significantly reduces filter efficiency: the higher the filter grade, the greater the effect. Mounting frames should be designed so that the air flow pushes the filter into its housing to help minimise air bypass.

3.50 All filters should be of the dry type. Panel filters are generally used as pre-filters and should be positioned on the inlet side of the supply fan, downstream of the frost battery. Where required, secondary filters (these will be bags or pleated paper) should be on the positive-pressure side of the fan.

3.51 The filter installation should provide easy access to filter media for cleaning, removal or replacement; therefore, a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.

3.52 All filters should be provided with a means of checking the differential pressure across them. Direct-reading dial-type gauges marked with clean and dirty sectors are preferred.

High-efficiency filters – HEPA and ULPA

3.53 Where fitted, HEPA filters should be of the replaceable-panel type with leak-proof seals. Their installation should permit the validation of the filter and its housing.

3.54 HEPA filters are sometimes used in extract systems for the containment of hazardous substances or organisms. They may be fitted with pre-filters to extend their service life.

3.55 When used for the containment of hazardous substances, the installation should incorporate design provision for the subsequent safe removal and handling of contaminated filters by maintenance staff.

Energy recovery

3.56 Energy recovery, where fitted, will require cleaning access to both sides of the device.

3.57 Whichever type of energy recovery device is fitted, the extract side should be protected by a G3 filter and provided with a drainage system to remove condensate.

3.58 The heat-recovery device should be controlled in sequence with the main heater-battery, and may need to incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the plant's required set point.

Attenuation

3.59 Cleaning access should be provided at both ends of any attenuator unit.

Identification and labelling

3.60 All supply and extract ventilation systems should be clearly labelled. The label should identify both the AHU and the area that it serves. The lettering should be at least 50mm high and be mounted in an easily visible place near the fan of the unit. Any sub-systems and the principal branch ducts should be similarly labelled.

3.61 The direction of air-flow should be clearly marked on all main and branch ducts.

3.62 All air-flow test-points should be clearly identified and the size of the duct given.

Pressure stabilisers

3.63 Pressure stabilisers should be unobstructed and silent in operation.

4. Annual inspection and verification requirements

Ventilation systems inspection

4.1 All ventilation systems should be subject to at least a simple visual inspection annually.

4.2 The purpose of the inspection is to establish that:

- the system is still required;
- the AHU conforms to the minimum standard (see Section 3);
- the fire containment has not been breached;
- the general condition of the system is adequate for purpose;
- the system overall is operating in a satisfactory manner.

4.3 It is recommended that a simple check sheet be used to record the result of the inspection. Examples are given in Appendices 1 and 2.

Critical ventilation systems

4.4 All critical ventilation systems should be inspected quarterly and verified at least annually. In some circumstances the verification may need to be carried out more frequently.

4.5 The quarterly inspection should be as detailed in paragraphs 4.1 – 4.3.

4.6 The purpose of the annual verification will be to ensure additionally that the system:

- achieves minimum standards specific to the application;
- is operating to an acceptable performance level;
- remains fit for purpose.

Definition of a critical system

4.7 Ventilation systems serving the following are considered critical:

- operating theatres of any type, including rooms used for investigations (for example catheter laboratories);
- patient isolation facility of any type;
- critical care, intensive treatment or high-dependency unit;
- neonatal unit;

- Category 3 or 4 laboratory or room;
- pharmacy aseptic suite;
- inspection and packing room in a sterile services department;
- MRI, CAT and other types of emerging imaging technologies that require particularly stable environmental conditions to remain within calibration;
- any system classified as an LEV system under the COSHH Regulations;
- any other system that clearly meets the definition.

4.8 The loss of service from such a system would seriously degrade the ability of the premises to deliver optimal healthcare.

Annual verification

4.9 The annual verification is intended to establish that:

- the system is still required;
- the AHU conforms to the minimum standard (see Section 3);
- the fire containment has not been breached;
- the general condition of the ventilation system is adequate;
- the fabric of the area served is satisfactory;
- the system performance is adequate with respect to the functional requirement – this will require:
  - a full measure of the supply and extract air-flow rates;
  - the calculation of room air-change rates if applicable;
  - the measurement of room differential pressures if applicable;
  - the measurement of room noise levels;
  - air-quality checks if appropriate;
  - a check on the control functions.

4.10 An assessment should then be made as to whether the system overall is fit for purpose and operating in a satisfactory manner.

Fabric of the area served

4.11 The building elements in the room or rooms served by a critical ventilation system should also be suitable for the function. As an example, in a suite of rooms comprising an operating theatre complex, the following elements should be checked:

- the ceiling should be complete and, if tiled, all tiles should be clipped down and sealed;

- the walls and floors should be free from significant construction and finish defects;
- windows and their trickle vents should be sealed and locked shut;
- the doors should close completely and the door closers should be correctly adjusted to hold them against the room pressure;
- all service penetrations and access panels should be sealed to prevent uncontrolled air flow between rooms and service voids;
- steps should have been taken (if necessary) to prevent portable equipment and stock items from obstructing low-level supply, transfer or extract airflow paths.

4.12 Failure to achieve a suitable standard will render even the most sophisticated ventilation system ineffective.

4.13 All fire dampers should be tested as part of the annual verification.

4.14 LEV systems will be subject to an examination and test by a competent person at least every 14 months.

4.15 Table 1 overleaf provides a model for the verification of critical ventilation systems.

Critical ventilation systems – verification standards

4.16 Unless otherwise specified below, the ventilation system should achieve not less than 75% of the design air-change rate given in Appendix 1 of Part A, or its original design parameters.

4.17 The pressure regime should achieve not less than 75% of the design value given in Appendix 1 of Part A, or its original design parameters; and the pressure gradient relationships with regards to surrounding areas must be maintained.

4.18 The sound levels given in Table 2 overleaf are maximum permissible levels and should not be exceeded. Measurements should be made using at least a Type 2 sound meter fitted with a muff. Its accuracy should be checked using a calibration sound source before use.

Step	Question	Information/standard required	Comment
1	Is the system still required?	Why was it installed?	Is that function still required?
2	Does the AHU achieve the minimum standard?	Health and safety aspects Intake/discharge positions Inspection access *Legionella* control and drainage Fire and electrical safety Leaks, cleanliness and insulation Filtration	Inspect to ascertain compliance with minimum standards set out in Section 3 Part B of this SHTM
3	Is the air distribution system satisfactory?	Access Fire dampers Cleanliness Insulation Identification Room terminals Pressure stabilisers	Inspect to ascertain continued fitness for purpose
4	Does the measured system performance still accord with the design intent and achieve a minimum acceptable standard?	Design air velocities Design air-flow rates Room air-change rates Pressure differentials Noise levels Air quality	Establish the design values Measure the system output to verify its performance
5	Does the control system function correctly?	Desired environmental conditions Control sequence logic Run; set back, off philosophy	Establish the design requirement Inspect/test to verify performance
6	Having regard to the foregoing, is the system 'fit for purpose' and will it only require routine maintenance in order to remain so until the next scheduled verification?		Yes or No
7	What routine service and maintenance will be required for the system to remain fit for purpose and function correctly until the next scheduled verification?	Filter changes System cleaning Performance indication Performance monitoring Performance measurement	Decide inspection frequency and maintenance schedule

Table 1: Operational management and routine verification process model

Location	Design sound level (NR)	Measured sound level (dB (A))
Ultra-clean operating room	50	55
Conventional operating room	40	45
All other non-specified rooms	40	45
Corridors	40	45
Recovery room	35	40
Ward areas, sleeping areas	30	35

Table 2: Maximum sound levels (service noise only)

Vertical ultra-clean operating theatres

4.19 The following additional measurements should be taken:

- the average air velocity at the 2m level under the canopy: it should achieve a minimum average of 0.38 m/s for a partial wall system and 0.3 m/s for a full wall system;
- the air velocity within the inner zone at the 1m level: every reading should achieve a minimum velocity of 0.2 m/s.

4.20 The air velocity measurements are to be taken using the equipment, test grid and method set out in Section 8 of Part A.

Note 3: There is no requirement to carry out filter scanning or entrainment tests at the annual verification unless the HEPA filters or recirculating air fans are changed, or the system is in some other significant way disturbed or altered. Changing the filters in the AHU or recirculating air filters does not constitute a significant disturbance to the ultra-clean ventilation (UCV) unit.

4.21 Should the UCV terminal fail to achieve a suitable standard, resulting in the need to disturb or replace the HEPA filters or recirculating air fans, the unit should be revalidated using the procedure given in Section 8 of Part A.

Note 4: Scottish Health Technical Memorandum 08-01 (2011) gives detailed guidance on acoustics and the measurement of sound.

Horizontal ultra-clean operating theatres

4.22 The following additional measurements should be taken:

- the discharge velocity test at 1m, 1.5m and 2m in front of the terminal: the average velocity should be not less than 0.4 m/s.

4.23 The measurements are to be taken using the equipment, test grid and method set out in Section 8 of Part A.

4.24 Should the UCV terminal fail to achieve a suitable standard, resulting in the need to disturb or replace the HEPA filters or recirculating air fans, the unit should be revalidated using the procedure given in Section 8 of Part A.

Category 3 and 4 laboratories and rooms

4.25 These areas should conform to the requirements of current information published by the Advisory Committee on Dangerous Pathogens and the Health and Safety Executive:

- 'The management, design and operation of microbiological containment laboratories';
- 'Biological agents: managing the risks in laboratories and healthcare premises'; and
- 'Biological agents: the principles, design and operation of Containment Level 4 facilities'.

Pharmacy aseptic suites

4.26 Pharmacy aseptic suites should conform to the requirements of the European guide to good manufacturing practice (http://ec.europa.eu/enterprise/pharmaceuticals/eudralex/homev4.htm) and the requirements of the Medicine Inspectorate if a licensed manufacturing unit.

Sterile services department – inspection and packing rooms

4.27 Inspection and packing rooms should conform to the requirements of BS EN ISO 14644 and any additional requirements for the processing of medical devices, if applicable (see also Scottish Health Planning Note 13: 'Sterile services department').

LEV systems

4.28 LEV systems should conform to the Health and Safety Executive's 'The maintenance, examination and testing of local exhaust ventilation'.

Critical system verification failure

4.29 Should a critical system be unable to achieve the standard set out above, it should be taken out of service. If healthcare provision needs prevent the system being taken out of service, the senior manager of the user department should be informed in writing that the system performance is suboptimal. A copy of the notice should be sent to the infection control committee.

4.30 If a critical system is refurbished in order to bring it to a suitable standard, it should be subject to the full validation procedure set out in Section 8 of Part A or other application-specific guidance as appropriate.

5. Inspection and maintenance

General

5.1 Inspection and maintenance activities should be assessed to ensure that they do not create a hazard for those who undertake the work or for those who could be affected by it.

5.2 The degree and frequency of maintenance should relate to the function of the system, its location, its general condition and the consequence of failure.

5.3 Specimen inspection and maintenance checklists are given in Appendices 1 and 2.

Inspection and maintenance of critical systems

5.4 The loss of service of these systems would seriously degrade the ability of the premises to deliver optimal healthcare. In order to ensure reliable service provision, it is essential to inspect, verify and maintain these systems at appropriate intervals.

5.5 For many of these systems a permit-to-work will need to be completed to ensure that taking the ventilation system out of service does not compromise the activities of the user department. In any event, it will be necessary to liaise with the user department when switching the system off to carry out routine inspection and maintenance.

AHU drainage

5.6 AHU drainage systems comprise a drainage tray, glass trap, connecting pipework and an air break. The system should be inspected to ensure that it is clean and operating correctly. The cleanliness of the drainage tray and colour of the water in the trap will give an indication of a fault condition (see Table 3 overleaf).

Colour of water	Probable cause and comment
Normal	Satisfactory.
Green	Copper corrosion of pipework Possible leak in battery tubing.
White	Aluminium corrosion of battery fins.
Black	General dirt Filter faulty allowing air bypass System is overdue for a thorough clean Urgent action required.
Brown/red	Iron corrosion (rust) within the duct May indicate a specific *Legionella* hazard Immediate action required.
Bubbly/slimy	Microbiological activity within the duct May indicate a specific *Legionella* hazard Immediate action required.

Table 3: Colour of water in glass trap

Filter changing

5.7 Dirty supply air filters may pose a general dust hazard when being changed.

5.8 Dirty extract- and return-air filters may pose an increased level of hazard. This will relate to the particular contamination within the air that they have filtered. Filters handling extract air from general areas are unlikely to present a significantly greater hazard than that posed by dirty supply air filters.

5.9 Care should be taken to protect staff from inhaling the dust. If there is a need to enter the duct when changing filters, a dust mask should be worn.

5.10 Dirty filters should be carefully removed and placed in the box that contained the replacement filters or in a plastic bag. On completion of the work, the dirty filters should be removed from the plantroom and disposed of appropriately.

5.11 The duct in the area of the filter housing should be carefully vacuumed before fitting the replacement filters. This will prevent particles (that is, those that are shed when the dirty filters are disturbed) being blown into the system downstream.

5.12 It is important to ensure that replacement filters are fitted the right way round. Most panel filters are manufactured with a membrane or wire support mesh on their downstream side. Alternatively they may be colour-coded. The manufacturer's instructions regarding fitting should be followed.

5.13 Bag filters should be fitted with the pockets vertical. Care should be taken to remove any transit tapes and to ensure that the individual pockets are separate and free to inflate.

Changing extract filters containing hazardous substances

5.14 Filters handling extract air from an LEV system will obviously present a hazard and should be subject to a safe system of work.

5.15 Filters used in an extract system for the containment of hazardous substances or organisms should incorporate design provision for their safe removal when so contaminated. This may be achieved by:

- sealing the hazardous substance into the filter before it is removed;
- a system to fumigate the filter to kill any organisms;
- housing it in a 'safe change' unit that permits the filter to be ejected into a bag and sealed without staff having to come into direct contact with it.

5.16 The method chosen should reflect the nature of the hazard.

5.17 Filters fitted to remove hazardous substances from extract air are classed as hazardous waste and should be handled and disposed of accordingly.

Ventilation system cleaning

5.18 The intake section of a ventilation system should be vacuumed-out as necessary to remove visible particles.

5.19 AHUs should be vacuumed-out and/or washed down internally as necessary to remove obvious dust and dirt.

5.20 Chiller batteries, humidifier units, energy-recovery batteries or plates and their drainage systems should be washed down with hot water annually to remove visible contamination.

5.21 Supply air distribution ductwork conveys air that has been filtered. It will require internal cleaning only when it becomes contaminated with visible dirt. The frequency of cleaning will depend on the age of the system and grade of the AHU final filter but will typically be in excess of ten years. There is no requirement to clean ductwork annually. A rapid build-up of visible dirt within a supply duct is an indication of a failure of the filtration or its housing.

5.22 Extract air systems handle unfiltered air. They should be cleaned as frequently as necessary in order to maintain their operating efficiency. Room extract terminals, particularly those sited at low level in critical care areas, will need regular cleaning.

5.23 On completion of cleaning, the ductwork should not be 'fogged' with chemicals. This treatment has no lasting biocidal effect and is responsible for initiating the breakdown of the galvanised coating of ductwork. This will result in accelerated corrosion of the inside of the duct, with the products of corrosion being shed into the air stream. It will also significantly shorten service life.

5.24 Following duct cleaning, all service hatches should be checked to ensure that they have been correctly replaced and do not leak.

5.25 Duct-cleaning equipment that uses rotating brushes or a vacuum unit can easily damage flexible sections of ductwork. On completion of cleaning, all flexible duct sections should be checked for rips and tears. The straps that secure them to rigid duct sections and air terminals should also be checked to ensure that there is no air leakage.

Chilled beams

5.26 The efficiency of these units will rapidly decline if they become blocked with fluff/lint. They should be inspected every six months and cleaned as appropriate.

Split and cassette cooling units

5.27 These units incorporate internal recirculation air filters and a drainage system to remove condensate from the cooling coil. The systems should be inspected and cleaned every three months.

Portable room cooling units

5.28 Portable units are sometimes kept in store or hired-in to cope with temporary local situations giving rise to excessive temperatures. They typically incorporate internal recirculation air filters and a drainage system to remove condensate from the cooling coil. Units employing an internal water reservoir and wick to promote evaporative cooling must not be used in healthcare premises.

5.29 The infection control team must be consulted before these types of unit are deployed.

5.30 The units should be inspected and thoroughly cleaned before being taken into use. Units that are to be used in areas containing immunocompromised patients will, unless new, need to be fumigated before use.

5.31 All portable units should be inspected and cleaned every week that they remain in use.

Self-contained mobile filter and/or ultraviolet (UV) light units

5.32 The efficacy of these units is directly related to their cleanliness. In this respect, the manufacturer's instructions regarding service/maintenance and lamp and filter replacement should be closely followed.

5.33 Units that have been used in isolation rooms or areas containing infective patients will need to be fumigated before being used in other locations, or returned to store or to the hirer.

5.34 Filters fitted to remove hazardous substances from the recirculated room air are classed as hazardous waste and should be handled and disposed of accordingly (see also Scottish Health Technical Note 3: NHS Scotland Waste Management Guidance Parts A-D).

Inspection and maintenance records

5.35 Records of inspection and maintenance activities should be kept for at least five years.

Health Facilities Scotland

NHS National Services Scotland

Appendix 1: Annual inspection of critical ventilation systems – AHU and plantroom equipment

Definition of terms used on survey form

General condition

End of useful life
This should be clear from the condition of the AHU and its associated services and plant. The main indicators will be: • extensive internal and/or external corrosion of the AHU casing; • failure of filter housings to prevent air bypass; • general corrosion of heater and cooling battery fins, attenuator surfaces etc; • significant failure to meet minimum standards; • associated plant services and control elements in a poor condition or not able to fulfil their purpose; • AHU aged 20 years or more.
Action: **Urgent replacement indicated.**

Poor
Should be fairly apparent but should include an assessment of the degree of corrosion; • cleanliness of coils and batteries; • quality of filter mountings and their ability to prevent air bypass; • fan and drive train condition; • the control system elements' ability to fulfil their function; • condition of the access doors and inspection covers. The age of the AHU is generally less important.
Action: **Extensive refurbishment or prolonged replacement indicated**.

Average
Some faults but generally free of significant corrosion, clean internally and conforming to minimum standards.
Action: Faults capable of correction at next maintenance period.

Good
Conforming to the minimum standards, obviously cared for and subject to routine maintenance.
Action: Routine maintenance will preserve standard of equipment.

Compliance with minimum standards (questions 2 to 23, 32 and 33)

Poor
More than three answers are negative.
Action: Management action require by estates/facilities department.

Average
No more than 3 answers are negative.
Action: **Maintenance action required**.

Good
No answers are negative, full compliance.
Action: None.

Maintenance quality (questions 5, 12, 26 to 31 and 34 to 40)

Poor
More than three answers are negative.
Action: Management action required by estates/facilities department.

Average
No more than three answers are negative.
Action: Maintenance action required.

Good
No answers are negative.
Action: None.

(Questions 5, 12, 26 to 31, 34 to 40)

No	Survey question	Yes	No	Comments
1	Plant running?			
2	Are the unit and its associate plant secure from unauthorised access?			
3	Is the unit safely accessible for inspection and maintenance?			
4	Is the air intake positioned to avoid short-circuiting with extract or foul air from other sources such as gas scavenging outlets?			
5	Are all inspection lights operating?			
6	Are motorised dampers fitted to the intake and discharge?			
7	Are the fan motor(s) outside of the air stream?			

No	Survey question	Yes	No	Comments
8	Is the fan drive train visible without removing covers?			
9	Is the cooling coil located on the discharge side of the fan?			
10	Is an energy-recovery system fitted (state type)?			
11	Are condensate drainage systems fitted to all energy recovery systems, cooling coils and humidifiers in accordance of Section 3 of Scottish Health Technical Memorandum 03-01, Part B?			
12	Are drainage traps clean and filled with water? (see Table 3 in SHTM 03-01, Part B)			
13	Is the drain trap air break at least 15mm?			
14	If a humidifier is fitted, state the type			
15	Is the humidifier capable of operation?			
16	Is there space to safely change the filters safely?			
17	Are there test holes in the principal ducts?			
18	Are the test holes capped?			
19	What is the general condition of the exterior of the AHU?			
20	Are the principal ducts lagged?			
21	What is the general condition of the associated control valves and pipework?			
22	Is the pipework adequately lagged?			
23	Is the system clearly labelled?			
24	Record prefilter differential pressure.			
25	Record main filter differential pressure.			

Switch plant off. Fit padlock to isolator.

No	Survey question	Yes	No	Comments
26	Did the motorised dampers close on plant shutdown?			
27	Is the vermin/insect screen clean?			
28	Is the intake section including the fog coil clean?			
29	Are the pre-filters correctly fitted with no air by-pass?			
30	Are all drive belts correctly aligned and tensioned?			
31	Is the cooling-coil matrix cleaned?			
32	Are all drip trays fully accessible or capable of being removed for cleaning and have a fall to drain?			
33	Are the drainage trays stainless?			
34	Are the drainage trays clean?			
35	Are the drainage traps free of water?			
36	Is the matrix clean for each heater-battery?			
37	Have the main filters been correctly fitted with no air by-pass?			
38	Are AHU and its associated main ductwork clean internally?			
Remove padlock and Re-start plant.				
39	Did unit restart satisfactorily?			
Test automatic fan-motor change-over, if fitted				
40	Did automatic changeover operate satisfactorily?			

Additional comments
(For example: air leaks from access doors; control valves leaking or passing; general cleanliness of the area around the unit; or any other items of concern.)

Appendix 2: Operating suite annual verification

Definition of terms used on survey form

Assessment of compliance with Scottish Health Technical Memorandum 03-01 (all questions relevant to the type of theatre)

Poor
• air volumes and hence air-change rates is less than 75% of the design; • room pressure differentials do not ensure a flow from clean to less clean areas; • supply or extract air diffusers are not clean; • pressure stabilisers not clean and/or not operating correctly; • significant faults or failures of indicators on surgeon's panel; • visible faults in the fabric of the suite; • doors unable to close completely; • general air of neglect.
Action: Urgent management action required

Average
• air pressure and room pressure differentials approximate to the original design values; • supply air diffusers clean but extracts visibly fouled; • most pressure stabilisers clean and operating correctly; • some of the indicators on the surgeon's panel not working; • minor faults in the fabric and décor of the suite.
Action: Maintenance action required

Good
Better than average
Action: None

Maintenance quality (all questions relevant to the type of theatre)

Poor

Subject: RE: Theatres Air sampling

Hi Ashley,

My understanding from SHTM 03-01 Part A - Ventilation Validation (attached) and as per Dr Inverarity's advice below, is that any sampling for theatre commissioning whether particle counting or microbiological air sampling should be carried out by an accredited independent company (to that of the builders) and should be reported within the theatre ventilation validation report. Please note the highlighted area in Dr Inverarity's response below.

As discussed last Friday with Lindsay, following the Stage 4 HAI Scribe review, NHSL would only require to carry out further microbiological air sampling following validation if there were any works carried out which caused disturbance to fabric of the theatre suite and this would not include the 'setting up of theatre' (putting in theatre equipment).

I have copied in relevant parties who may wish to comment on the above, and correct me if I am wrong in my interpretation of the guidance..

Kind regards
Sarah

Subject: RE: Air Sampling Theatres

Hi Ashley,

Commissioning of ultraclean theatres is done by particle counting and there is no role for microbiological air culture.
Commissioning of conventional theatres is done by microbiological air culture and not particle counting.
For the neurosurgical theatres that may have the laminar flow switched off for some surgeries the commissioning should include both particle counting and microbiological air testing.
These results should feature as part of the theatre validation report and be performed by an accredited company that is independent to the builders.
Hope that clarifies
Donald

Hi Ashley,

I believe that you have spoken with Dr Inverarity in relation to the sampling process.

In regards to cleaning in these areas, (and all other areas on completion of work) the contractors should carry out a builders clean then the domestic services should carry out a 'terminal clean' using Chlorclean.

It is important following the terminal clean, and before samples are obtained that the project team carry out a visual inspection of the rooms to ensure that the level of cleaning is optimal and there is no dust/debris remaining , particularly in high reach areas such as pendants etc as this would potentially affect sample results.

Kind regards
Sarah

Good Afternoon
Please can I have clarification for cleaning theatres ,imaging(MRI'S) and isolation rooms.
We are having an independent tester next week. I understand that we carry out both for ultra clean theatres.

My question is what type of clean will our own domestics need to carry before the independent tester arrives next week.
Following the independent tester will NHS Lothian carry out their own.
Kind Regards
Ashley

Janice MacKenzie	Project Clinical Director
Ronnie Henderson	Project Hard FM Commissioning Manager
Donald Inverarity	Consultant Microbiologist
Carol Calder	IPCN
William Evans	IPCN
Pota Kalima	Consultant Microbiologist
Catherine McDougall	Medical Consultant

We discussed the current proposals for improving the critical care ventilation to ensure that it is compliant with SHTM 03-01 with 10 air changes and 10 Pa positive pressure in the single rooms and 4 bedded bays. We also reviewed the ventilation requirements in the 4 bedded bays to allow you to cohort patients with the same infections.

<u>Current Proposal for Critical Care Ventilation Improvements</u>
We visited the Unit, specifically 1-B1-031 which will be impacted on with one of the proposals to review the bed space.
Ronnie updated as follows
Of the 5 initial proposals considered, only two now being considered:-

1. Utilise existing plant or replace in existing location, upsize fans and upsize ducting in critical care – Design team assessing but unlikely to be possible
2. Install new plant external and duct in via window in 4 bed bay, connect ducting to serve approx 50% of critical care
   Note – in both options isolation rooms are unaffected

See attached marked up drawing for the space affected:-

- One window would be blocked to allow the duct work to come in and it would be boxed out no further than the start of the vision panel at the side to the adjoining room.
- We placed the pendants in the positions they would be in and considered the equipment that would be at the top of the bed and confirmed that there would be sufficient circulating space. Ronnie took some photos of the pendant positions and he will pass these onto MPX
- We noted that no further windows in the bay could be affected as this would then affect the natural light coming into the area

- The additional plant would be on the grass roof area outside the window. Once size of the unit and orientation is known need to ensure that it does not adversely affect the light coming into the area.
- The Critical Care team asked that both the boxed out area within the bay and the plant would have some form of enhancement to make it more aesthetically pleasing e.g. graphics

Compliance with SHTM 03- 01

- Currently the 4 bedded rooms and single rooms have 4 air changes and this needs to increase to 10 air changes to ensure compliance with SHTM. It was acknowledged that the SHTM was more focused on adult critical care where the patient profile is different and the need to cohort patients was extremely rare
- It was noted that previously a decision had been made to derogate from the SHTM for the 4 bedded areas to allow patients to be cohorted with the same air-borne infection and following consultation with the clinical team and IPCT at the time the decision was made that these areas should be balanced or slightly negative. The SHTM states that both the 4 bedded areas and single rooms should have 10 air changes and 10Pa (positive pressure)
- It was confirmed that the Isolation Rooms were compliant with SHTM 03-01
- IPCT view was that you could cohort patients with the same air-borne infection in the 4 bedded areas that were 10 air changes and 10Pa and that there is no reason that this would result in an increased risk of spread of infection. A design of balanced or slightly negative pressure approaches the issue of spread of infection from a cohort from a different direction but it was agreed that neither approach increases the risk of infection spread but that the SHTM 03-01 compliant design has additional benefit for neutropenic patients who could be in single rooms at 10Pa positive pressure.
- It was acknowledged that the design of the Unit also provided additional control measures to prevent spread of infection and the barriers to transmission included:-
    - Bed space size
    - Distance between single room doors, isolation room doors and 4 bedded bay doors as range of droplet spread is generally considered to be between 1-3 metres
    - Patients on ventilators less of a risk of generating aerosols from coughing
    - Direction of air flow in corridor space directs any air borne contaminants towards an air extract vent and away from other patient rooms. Extract ventilation may need to be improved in corridor area to take account of increased pressure
    - Turn over of air dilutes any airborne organisms in patient rooms and corridors.
- It was noted that if a patient with an infection was in a 4 bedded bay or single room or a neutropenic patient in a single room the windows should not be opened and increased room cleaning would likely be required
- Confirmed that Isolation Rooms should be used for patients with infections transmitted by aerosols e.g. measles, chicken pox, TB
- Single rooms and cohort areas would be suitable for droplet infections e.g. RSV, Influenza
- Confirmed that the single cubicle in neonatal Unit will have 10Pa and 10 air changes and as it has an en-suite it will need a transfer grille on the en-suite door
- Confirmed the entire neonatal area was at 10Pa and 10 air changes with respect to the corridor.
- Because the single cubicle is within the neonatal unit it was confirmed that the single cubicle is at a balanced pressure or slightly negative with respect to the open neonatal bed bay.
- Confirmed that any 'dirty' rooms e.g. Dirty Utility, toilets have extract and any 'clean' rooms e.g. clean utility have supply and extract
- We discussed the Positive Pressure Ventilation Lobby (PPVL) isolation rooms in relation to ventilation in QEUH, specifically in relation to Multi-Drug Resistant TB, however Donald was very cautious about making any comparisons as the context was different (paediatric critical

care versus adult infectious diseases isolation ward) . It was suggested that this was something that could be discussed further with HFS

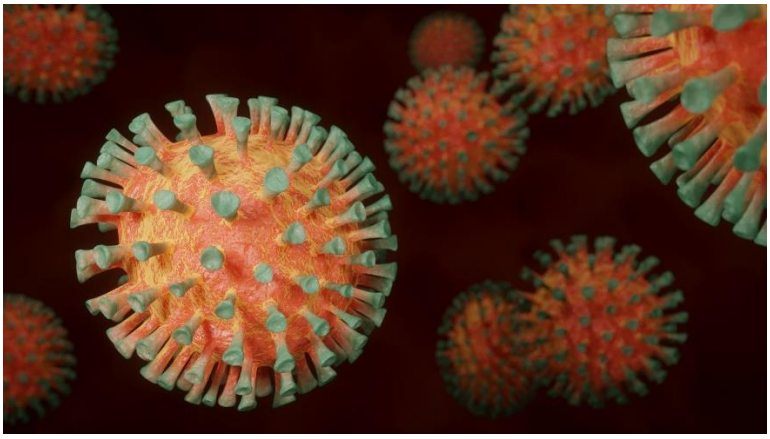
- We discussed a number of different patient groups and scenarios in relation to the use of the Isolation rooms, Single Rooms and 4 bedded bays and in light of these discussions and the points above all agreed that the SHTM 03-01 was a safe design for ventilation within the Paediatric Critical Care Unit in conjunction with the design of the unit and good practice in relation to infection control measures which all worked together as a package to achieve best outcome for patients

We also briefly discussed:-

- Cystic Fibrosis patients and the areas that they would be treated in and whether CF patients with different infections would be treated in the same ward as currently they would be treated in different wards as the existing hospital does not have Isolation Rooms. It was confirmed that Dalhousie ward(Medical Inpatients) have 4 PPVL Isolation room. It was felt by IPCT that provided appropriate measures were in place about the placement of patients within the ward then this could happen. Also Castle Mey (Acute Receiving Unit) has 1 PPVL isolation room. It was noted that currently Dalhouisie Ward is classed as an Augmented Care Area but Castle Mey not. This lead to a discussion about other areas in the hospital where CF patients could be treated, this includes OPD, Cardio Respiratory OPD and Dirleton (Medical Day Care) and therefore whether these areas should also be classed as Augmented Care as far as water sampling is concerned. It was felt that the risk was greater in Inpatient areas. Further discussion to be had with IPCT acknowledging that the water testing regime may need a bit of tweaking when hospital occupied

Specialised Ventilation for Healthcare Society

Updated Briefing & Guidance on Considerations for the Ventilation Aspects of Healthcare Facilities for Coronavirus



Updated 27th April 2020

Document SVHSoc.03-V4.

The Specialised Ventilation for Healthcare Society (SVHSoc.)

The Society was formed in November 2014 with the aim of bringing together those who were practicing or wished to become Authorising Engineers (Ventilation) (AE(V)) or who have a more general interest in Ventilation in the Healthcare setting.

- The SVHSoc. meet several times a year at various locations around the UK.
- Full membership of the Society is open to registered AE(V)'s.
- The Society "Code of Conduct" is issued with all quotations for AE(V) services.
- The Society maintains a register containing details of practicing AE(V)s.
- A set of competencies have been drawn up for prospective AE(V)s.

- Associate membership is open to anyone interested in Ventilation for Healthcare.
- A significant portion of the Society meetings is given over to discussing and clarifying interpretation of HTM03-01 and other healthcare ventilation standards.

Further information concerning the SVHSoc. may be obtained from:-

Malcolm Thomas - President SVHSoc. - [redacted]

Graham Powell – Chair SVHSoc. – [redacted]

John Rayner – Secretary SVHSoc. – [redacted]

The following documents have been issued by SVHSoc. to help clarify Healthcare Ventilation requirements

SVHSoc.01-V3.0 **Operating Theatres - Energy Control Strategies and the Surgeon's panel**

SVHSoc.02-V1.0 **Change in Air Filter Test and Classification standards**

SVHSoc.03-V4.0 **Coronavirus COVID-19 Guidance**

Coronavirus COVID-19

Specialised Ventilation for Healthcare Society

SVHSoc.03-V4.0 (27th April 2020)

Contents

Introduction

Following peer review, recent feedback and experience from SVH Society members, and advice from Public Health England (Peter Hoffman) the briefing and guidance from the SVHSoc has been updated to reflect the current official guidance and to provide a range of options and areas for consideration for healthcare estates professionals to provide enhanced levels of protection for patients, staff, and visitors.

The briefing is intended to provide an overview of the issues and points to consider when assessing the ventilation strategy and options. It has also been updated to provide some initial maintenance considerations and precautions which may need to be considered. It is intended that this briefing and guidance will be subject to regular review and updates as details, information, and the situation continues to develop.

Current guidance on the lifespan of the virus once outside the body is still to be fully established, however current estimates are that it could survive anywhere between a few hours up to 3 to 4 days on hard surfaces and is spread by both primary direct exposure (breathing in droplets expelled from an infected person from coughing or sneezing) and secondary contact by touch (touching a surface which has been contaminated and transferring this contamination by touch to the mouth, nose or eyes). “Coronaviruses are mainly transmitted by large respiratory droplets and direct or indirect contact with infected secretions. They have also been detected in blood, faeces and urine and, under certain circumstances, airborne transmission is thought to have occurred from aerosolised respiratory secretions and faecal material”. That level of airborne transmissibility is specifically associated with certain aerosol generating procedures (AGPs).

That COVID-19 has been termed an airborne infection is an indication that it is capable of transmitting via an airborne route in certain circumstances, not that its mode of spread is primarily airborne nor that any aerosol remains sufficiently concentrated to be infectious over longer distances other than in the immediate vicinity of a dispersing patient.

The PHE guidance is under constant review and updated as necessary. The current guidance can be found at:

https://www.gov.uk/government/publications/wuhan-novel-coronavirus-infection-prevention-and-control

Ventilation can contribute to an isolation or protection strategy to assist in minimising the spread of the virus, however a number of factors need to be considered, not least of all the provision of adequate ventilation to provide dilution of any airborne contamination, with other factors including;

- Area / rooms where isolation can be established
- Physical / fabric of the room construction / air permeability rates (e.g. solid ceilings)
- Surrounding areas of clinical activity
- Room volume and airflow / room pressure differentials (dilution effects)
- Provision and location of ventilation (e.g. ceiling mounted supply with low level extract)

- Point of discharge and filtration of any extracted air
- Levels of isolation and practical considerations
- Decontamination of the area between patients
- Protection of all potentially exposed staff groups (clinical, cleaning, and estates)
- Potential risks associated with oxygen enriched atmospheres

Standards and Technical Specifications

HTM 03-01 sets out the overall guidance for ventilation of healthcare premises with addition specific guidance on isolation facilities being contained within HBN 04-01 Supplement and HBN 04-02 for critical care units (it should be noted that the HBN's can be interpreted as containing some conflicting advice for ventilation strategies, however the objectives are similar). These documents should be used as the basis for all ventilation strategies in conjunction with advice from the Infection Prevention Control (IPC) team, WHO & PHE support. Overall it needs to be an issue where IPC set the room criteria and then estates can look to see how it can be provided.

Note/commentary from PHE - Standards and technical specifications within the UK we are rapidly moving to a position where COVID patients will be cohorted on bays in wards. Beyond specific "aerosol generating procedures" (AGPs) there is not thought to be an airborne risk and staff do not require respirators. This can be seen from the "general ward" guidance for AGPs in the PHE guidance.

Table 1: Transmission based precautions (TBPs): Personal protective equipment (PPE) for care of patients with pandemic COVID-19

	*Entry to cohort area (only if necessary) no patient contact**	*General ward **	*High risk unit ICU/ITU/HDU*	*Aerosol generating procedures (any setting)*
Disposable Gloves	*No*	*Yes*	*Yes*	*Yes*
Disposable Plastic Apron	*No*	*Yes*	*Yes*	*No*
Disposable Gown	*No*	*No*	*No*	*Yes*
Fluid-resistant (Type IIR) surgical mask (FRSM)	*Yes*	*Yes*	*No*	*No*
Filtering face piece (class 3) (FFP3) respirator	*No*	*No*	*Yes*	*Yes*
Disposable Eye protection	*No*	*Risk assessment*	*Risk assessment (always if wearing an FFP3)*	*Yes*

Notwithstanding the above, in the SVHSoc's opinion, a standard for any facility used, should strive to achieve the following performance criteria;

- The room/area should achieve between 6 to 12 air changes per hour. The greater the air changes provided the more effective the dilution effect provided that it does not interfere with other critical elements.
- The room/area ideally should be at least neutral to the surrounding areas (0 to -10 Pa)
- If achievable the room/area should have sufficient air supply and extract to achieve open door protection, however this may not be possible other than in a PPVL room or air-locked facility.
- The room should ideally have a protected lobby (if possible) with barrier or isolation nursing care and PPE worn by all staff
- Immediately outside but adjacent to the room there should be a wash hand basin and an area for de-gowning. If the room has a lobby (PPVL) then de-gowning should take place within the lobby.

Droplet Transmission & Airborne Dilution / Clearance

The PHE have stated that in their opinion there is very little to no risk of any viable virus transfer beyond the immediate clinical area through air gaps in doors or via pressure stabilisers as the water droplets would not survive the distance or routes without very significant dilution and desiccation. This is especially true for a patient who is anesthetised and on a closed breathing circuit. All staff within a critical care environment should be wearing full PPE. There is however emerging anecdotal evidence that the concentration of exposure may have a direct correlation to the severity of any subsequent infection and therefore dilution of aero-microbiological contamination is considered an essential precaution, even where PPE is worn.

Definitive scientific evidence that the infection is not airborne is not yet clear, and on a precautionary principle it should be assumed that it can be airborne on droplet nuclei, until proved otherwise, certainly for short distances within confined or poorly ventilated environments. Droplets expelled during AGP's can be anywhere from 1 µm to 2mm in size with an estimated average size of 50 µm. A droplet of 100 µm will fall to the floor at around 30cm/s and a droplet of 30 µm will fall at a rate of around 3cm/s, so droplets ejected from a patient by coughing/breathing are estimated to travel around 1 – 4 metres and with a downward displacement ventilation system in operation are likely to fall/be pushed to the floor very quickly. Added to this is the fact that patients are in a horizontal position typically 1m above the floor level and if ventilated on a closed breathing circuit making release of droplets less likely.

After any treatment or surgical procedure any residual airborne particles are cleared from a room at a rate of 63% per air change, therefore within 6 air changes 99.8% of any airborne contaminates will have been removed. In an operating department achieving the recommended air change rate of 25 air changes per hour (HTM 03-01 standard) the room will be effectively clear of residual airborne particles within 15 minutes or 20 minutes if achieving 20 air changes per hour (HTM 2025 standard). A similar effect will be achieved within a treatment or CCU space although these will typically achieve between 15-10 ACH and will correspondingly achieve the required 6 air changes within 24-36 minutes.

The practical implication of this guidance is that the current supply and extract ventilation systems offer a significant dilution effect to a facility and should remain in use and are unlikely to offer any risk to building occupants / users.

General Options and Considerations

A negative pressure or PPVL room with lobby is the likely preferred locally achievable option. Extract filtration, provided the air is discharged in an appropriate location, is not likely to be required as it is likely to significantly impact on the airflow performance and it will be necessary to undertake a risk based assessment on the use of extract filtration and consider system upgrades to maintain overall airflow performance. The point of discharge of any extract ventilation system should be assessed to ensure that it does not provide a route of cross contamination.

If however multiple PPVL rooms are not available then a side room with a lobby and its own en-suite is likely to be the next best option. The extract from the en-suite will provide some degree of pressure cascade / regime although it is unlikely to provide open door protection and the point of discharge location will again require to be assessed. If a side room has supply air then this should provide a minimum fresh air rate of at least 6 ACH but ideally be less than the extract air volume to maintain the room at a neutral/negative pressure, whilst not compromising dilution effect.

In most clinical care environments the vast majority of openable windows have security/restrictor arrangements to enhance user safety. In order to improve ventilation, it may be possible to undertake a risk assessed review to enable some windows to open more fully.

If an air scrubber/filtration unit is considered it will not provide any dilution or fresh air supply into the room, but may remove some contamination from the air, however the issue of how to de-contaminate and dispose of the filter unit between patients will need consideration (see maintenance considerations below).

As the spread of the virus has continued hospitals have been required to identify and consider designating entire ward areas or even buildings as isolation facilities. This cohorting of cases has been driven by clinical risk assessment based upon risk of cross contamination (between patients within the isolation space) and the need for clinical support/treatment.

In these circumstances it is likely that the capacity of the electrical and medical gas infrastructure (oxygen, medical air, and vacuum) systems has been the greatest challenge and ventilation has been a secondary issue, however some basic principles should still be considered;

- Wards with single bedrooms with en-suite facilities are likely to offer the best solution.
- Maintaining a good air change rate of between 6 - 12 ACH is considered appropriate to maintain a dilution effect for both patients and staff protection.
- The extract rate should ideally be greater than the supply where practical, to create an appropriate pressure cascade to surrounding areas, ideally with supply in corridors and extract by means of en-suite facilities and dirty extract systems, in all cases ward doors to circulation spaces MUST be kept closed as far as reasonably practical.

- If open plan/multi-bed bay wards are used then a clinical assessment of risk relating to cross contamination will be needed, however areas with low level extract by each bed space are preferable.
- If the ventilation system (AHU) serves more than a single ward then the supply aspect is less critical as the airflow direction provides a level of protection, however an ACR of around 6 ACH should be considered as a minimum. Shared extract systems are less ideal and consideration should be given to separating or closing off non-essential extracts if practical. Extract systems should be inter-locked with supply systems to ensure that if the supply fails the extract continues to operate, however if the extract fails then the supply should also switch off, only as a short term measure until the extract system can be repaired / re-instated. If a failure is likely to be over 1 hour then the supply can be reinstated to provide both thermal comfort and dilution provided that it does not create a cross contamination risk.
- If an area or room is identified as being potentially suitable to be used as a temporary isolation facility it is advisable if possible to undertake a 'room air permeability or leakage test' to ensure air is contained within the room and does not leak to adjacent areas through suspended ceiling or service penetrations, (this may not be practical to achieve, given the urgency of demand).
- Any room used as a temporary holding or isolation facility should be stripped of all non-essential materials and soft furnishings.
- If you can locate an increased extract unit to provide a negative pressure environment then care will be needed when considering the distribution ducting and the exhaust air discharge point. Ducting and extract grilles should be located to ensure an even draw of air from around bed spaces and not rely on a single point at the end of the unit which draws air over adjacent patients and staff. The exhaust discharge however providing it is discharging to a safe external space (ideally at high level 3m above roof level) then HEPA filtration is unlikely to be required. Consider sealing any openable windows in the immediate vicinity (around 4m) of any low level discharges and avoid discharge over pedestrian paths/walkways.

Use of Theatres as CCU's

As the need for critical care beds has increased some hospitals have identified areas which are suitable and have the required engineering and medical services to provide an appropriate and safe clinical environment. In many cases where patient ventilation / life support is required the theatre and associated recovery suites (freed up from elective procedures from mid-April) are considered as ideal. If kept for the exclusive use by non-infected patients the ventilation system is likely to need little modification or adjustment, however consideration may be given to lowering both supply and extract rates to save energy and ensure patient comfort (reducing ACRs to around 10 ACH would be appropriate).

Recovery areas are preferable to theatres in the first instance as the ventilation strategy of these spaces provides a good air change rate (15ACH) with neutral pressure cascade to surrounding areas and bedhead low level extract to provide a clean air path for staff protection.

Typically 2 CCU bed spaces could be provided per theatre with an addition bed located in the anaesthetic room if needed, (medical gases, adequate ventilation and electrical outlets are typically all present in these rooms). Recovery spaces are designed to provide 12-15 ACH and should be neutral to surrounding areas so no modifications to the ventilation system should be needed.

If it is proposed to use theatres as spaces to treat COVID 19 infectious patients then the airflows would need to be very carefully reviewed and adjusted to maintain a safe air change rate and provide an ideally neutral pressure regime to surrounding clinical and staff areas.

Use of Theatres for COVID 19 infected patients Including Emergency Maternity Theatres

The following information reflects the current guidance from the centre for the use of theatres for known or suspected infected (COVID19) patients;

https://www.gov.uk/government/publications/wuhan-novel-coronavirus-infection-prevention-and-control

It is recommended that ventilation in both laminar flow and conventionally ventilated theatres should remain fully on during surgical procedures where patients may have COVID-19 infection. Air passing from operating theatres to adjacent areas will be highly diluted and is not considered by PHE to represent a significant risk.

- Theatres must be informed in advance of a patient transfer of a confirmed or possible COVID-19 positive case, the patient should be transported directly to the operating theatre and should wear a surgical mask if it can be tolerated.
- The patient should be anaesthetised and recovered in the theatre. Staff should wear protective clothing but only those at risk of exposure from aerosol generating procedures, i.e. during intubation need to wear FFP3 respirators and full gowns. Those closest to aerosol generation procedures are most at risk. The rapid dilution of these aerosols by operating theatre ventilation should minimise the exposure to operating room staff.
- Instruments and devices should be decontaminated in the normal manner in accordance with manufacturers' advice
- Both laryngoscope handle and blade should either be single use or reprocessed in the Sterile Supply Department. Video laryngoscope blades should be single use and scope/handle decontaminated as per manufacture instructions.
- Instruments must be transported safely to decontamination, following use.
- The theatre and all associated support areas should be cleaned as per local policy for infected cases, paying particular attention to hand contact points.
- Theatres should not be used by staff or patients for 20 minutes after the patient leaves.
- Possible or confirmed cases of COVID-19 should be placed at the end of the list where feasible

The follow information is provided to support or supplement this initial guidance.

Neutral Pressure Theatres

With the current COVID19 infection issues there may be a requirement for an operating suite to be used for an infected or suspected patient. If airborne micro-organisms liberated from a patient during the surgical procedure are allowed to cascade out into the adjacent corridors, they could contaminate surfaces or infect other patients or the staff within the surrounding operating department. Although air passing from operating theatres to adjacent areas will be highly diluted and this is not considered by PHE to represent a significant risk.

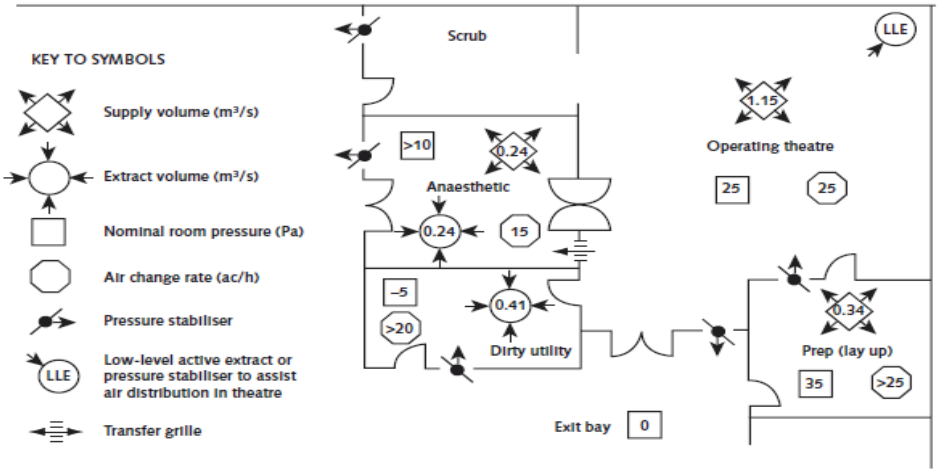
The concept of a neutral pressure or infectious theatre is to maintain an appropriate and safe air change rate to the theatre space but instead of the traditional cascade arrange of air from the theatre suite to the surrounding areas it is based on a balanced air flow of both supply and extract from ideally within the theatre itself or as a minimum within the individual theatre suite.

The room provision and layout will be as for a conventional operating suite with the following variation to the ventilation scheme:

- The operating theatre will have a balanced supply and extract so that it is at the same pressure as the corridor.
- Air should not cascade from the theatre to the surrounding rooms so pressure stabilisers and / or transfer grilles will not be fitted.
- The preparation room could be dispensed with to avoid having stock that could become pre-contaminated. Sterile packs, instruments and consumables would be delivered to the theatre on a case by case basis. If a preparation room is required, then it should be maintained at 10Pa to both the theatre and corridor.
- The anaesthetic room should have a supply in excess of extract so that is maintained at 10Pa above both the corridor and theatre. There should be a pressure stabiliser between the anaesthetic and corridor but no transfer between the anaesthetic and theatre.
- The scrub should have an active extract as for a conventional operating suite but no pressure stabiliser between it and the corridor.
- The utility should be at -5Pa to the theatre and its corridor.
- The corridor extract will be sized to cater for the air leakage from the anaesthetic room only.

Overall the ventilation scheme should ensure that all air supplied to the operating theatre is removed in the theatre suite. The theatre should be neutral (at the same pressure) to the corridor so that when the theatre exit door is open there is effectively no interchange of air between them. Ideally when the preparation or anaesthetic doors are opened airflows from them into the theatre and not the other way.

The traditional theatre suite layout typically as below (or a variation thereof);



If sites are required to endeavour to transform existing positive pressure cascade theatres to create a neutral pressure theatre the following areas will need to be considered.

In line with guidance the patient should be brought into and out of the theatre through the anaesthetic room, but anaesthetised and recovered in theatre. The doors and any pressure stabilisers from the theatre to the corridor should be sealed and not used.

The lay-up prep area should only hold the minimum stock required for the given procedure, however the air cascade from the lay-up prep to theatre should be maintained as a positive differential.

The pressure stabilisers from both the scrub area to the corridor and the anaesthetics room to corridor should be sealed.

The dirty utility room should remain at a negative pressure differential to both the theatre and corridor.

Ideally the anaesthetics room should be positive pressure to the theatre, however this may not be practical, in which case the anaesthetics room should only have all surfaces as clear as practical and all surplus or spare equipment held elsewhere.

A full re-balance of the supply and extract systems will be required and the provision of addition theatre extract is also likely. This will have to be assessed and designed on a theatre by theatre basis.

The same considerations apply to both conventional and UCV theatres. The UCV canopy is a re-circulation canopy and as such should have minimal impact on the theatres pressure regime, however due care should be taken not to disturb the canopies clean airflow area with excessive localised air movement and prevent perturbation of the UCV canopy air pattern.
It may be necessary to consider a relaxation of minimum air change rates to achieve a neutral pressure cascade however these should not be lower than 18ACH and MUST be agreed with clinical and IPC teams based on clinical risk assessment.

All non-essential materials and equipment should be removed from the theatre and surrounding corridor areas to ensure all cleaning can be undertaken as easily as possible. Specific patient and staff procedures and flows will need to be considered and agreed.

An alternative approach may be to designate a suite of theatre suites within a single location (floor or building) as infectious at which point the entire theatre complex could be isolated from any surrounding clinical areas and used exclusively for only infectious patients. In this case provided the extracted air was discharged to a safe location and all staff wear PPE whenever within the theatre area no or limited modification to ventilation strategies would be necessary.

NHS Nightingale Units - Potential Viral load risk and test methodologies

One of the founding principles of healthcare ventilation is the dilution and removal of airborne contaminants from the patient environment with particular requirements for the air change rates, by room volumes (as specified in HTM 03-01 (2007), via clean airflow paths. In addition to the issue of aero-microbiological loading, there is also the additional risk of oxygen enrichment of the general environment due to the potentially high concentration of patients on ventilators or receiving oxygen based therapy/ treatments.

Both of these issues are addressed by the use of good general ventilation through air changes of the occupied volume of the treatment/ patient space.

The spaces being used generally appear to benefit from very high ceiling void spaces and there is likely to be a high degree of thermal air movement from the bed areas into the open void above, where the existing ventilation system will be located.

It is not possible to know what specific ventilation strategy is deployed into any proposed space, however it is likely that the facility will have some degree of forced mechanical ventilation (both supply and extract) and provided that this does not utilise re-circulation airflows, and achieves in excess of 5 air changes per hour (preferably 10-12ach), the space should have sufficient ventilation. However it may not be practical to provide a fully ducted exhaust ventilation by each bedhead. If recirculation of air is used as part of the existing ventilation/energy strategy then this needs to be assessed and where practical adjusted to maximise fresh air supply.

In order to test and certify the effectiveness of the patient environment, it would be ideal if a two stage approach were adopted;

- Stage 1: pre-occupation
- Stage 2: appropriate intervals during the operational phase of the facility.

Stage one (pre-occupation) ventilation test approach.

Active air sampling for microbiological activity will be of little use prior to patient occupation, it is therefore suggested that a simple test of air movement and dilution be completed at a number of sample bed spaces. This would involve:

- Use of cold smoke (Draeger Smoke Test Puffer) to demonstrate the time taken to clear and general direction of airflow paths - ideally this should occur within a few seconds of release.

- Additionally, a Kata Test Thermometer can be used to produce an accurate air velocity performance reading at the bedhead - ideally this should be in excess of 0.2m/s.

A vane or thermal anemometer is unlikely to produce a reliable test reading at these low velocity levels.

Stage two (occupied) ventilation test approach.

Once occupied, a regular air monitoring regime could be employed to establish and monitor both 'oxygen concentration' levels (using a suitably calibrated and certified oxygen monitor, to BS EN 50104:2019), to enable action to be taken if high levels are found and, 'active air sampling' in the form of occupational environmental air sampling (HSE G409 and Monitoring strategies for toxic substances HSG173 (Second edition) HSE Books 2006 ISBN 0 7176 6188 1) of staff to ensure adequate dilution is being achieved in use.

Community Healthcare Ventilation systems

The practical implication of the guidance is that the current supply and extract ventilation systems offer a dilution effect to the facility and should remain in use and are unlikely to offer any risk to building occupants / users.

Recirculating air conditioning units (also known as split systems) should not be used within clinical care environments as they incorporate both air filtration and water / condensation 'open' trays. These units can provide a location where micro-organisms can become concentrated and proliferate. This is not a specific COVID-19 risk but a general consideration for the use and installation of these units.

Environmental cleaning following a possible case
Once a possible case has been transferred from the primary care premises, the room where the patient was placed should not be used, the room door should remain shut, with windows opened and the air conditioning switched off until it has been cleaned with detergent and disinfectant. Once this process has been completed, the room can be put back in use immediately.

Note - The air conditioning referred to is understood to be any room mounted 'split' air conditioning unit which only circulates the air within the space and cools or in some models heats the air. As this does not provide fresh air, nor does it remove air to outside the advice to switch it off is related to it not being used whilst windows are open.

Non ventilation Considerations

In addition to the ventilation issues associated with the current COVID 19 pandemic, other healthcare related engineering services and operational considerations will need to be assessed and considered. These are likely to include;

- Medical gas capacities and flow rates to deliver required clinical treatments (oxygen, medical air & vacuum).
- Number and location of electrical outlets on essential power supplies, for clinical and medical electronics.
- Provision of suitable emergency lighting
- Patient access and egress / transportation routes through other clinical / public areas.
- A minimum separation distance of between 1 – 2 metres should be maintained between beds
- If temporary separation / partition walls or barriers are constructed to create segregated bed spaces, the fire strategy and fire evacuation plans MUST be reviewed to ensure they remain appropriate. This should involve identification of evacuation routes and places to provide both an immediate safe refuge and a place to continue care and treatment.
- Provision of adequate hand washing facilities.
- Waste collection and storage capacities and locations and transfer routes.
- Surrounding clinical services to avoid close proximity to other 'at risk' patient groups.
- Adequate staff welfare and rest areas if staff numbers are increased to meet clinical needs.

Estates staff are recommended to give consideration to all of the above and where considered necessary review the PHE guidance and consult with their appropriate Authorising Engineer for the associated engineering specialty.

Additional guidance is available in the NHS&I – Novel coronavirus (COVID-19) standard operating procedure – Design Note: COVID-19 ward for intubated patients version 1.0 published 22/03/2020 (Publications approval ref 001559).

Ventilation Maintenance Considerations

Ventilation breakdowns and repairs

Any potential contamination risk associated with extract ductwork, fans and filters is likely to be very low. The ventilation system acts to dry out any droplets that are drawn out of a room and if these droplets settle on ductwork or fan surfaces they will very quickly desiccate and are likely to be inactive. Notwithstanding this it is advised that enhanced precautions should be taken by maintenance staff when working on such systems both as a precautionary measure and to provide re-assurance to those undertaking the work.

If a breakdown or internal inspection is required to an extract system from a potentially contaminated area then the following issues should be considered;

- Minimise the tools taken into the area during any period when a system is 'opened up' for maintenance or inspection.
- Following work being completed old or redundant materials / components should be bagged and removed as clinical waste.
- Tools used during the work should be washed / disinfected where practical or wiped down with alcohol based steri-wipes or similar.
- Minimise the number of workers in the immediate area of the work, whilst maintaining safe working conditions and staffing levels (two man working may be necessary if working at height or if moving and handling issues exist).
- All staff should wear appropriate PPE and dress, remove, and dispose of it as detailed below.

Other maintenance activities not directly relating to extract ventilation maintenance such as fire damper drop testing, or ductwork cleanliness inspections will need to be managed so as to ensure that no potential contaminated extract ductwork is opened accidentally. Smoke and fire dampers on extract systems will need to be assessed to ensure routine fire alarm testing does not interrupt or involve extract ductwork ventilation system operation, if being used for isolation protection.

The precautions and method statement detailed above should be adapted / applied to all maintenance staff working in areas where potentially or known infectious patient are or have been located whether working on ventilation systems or any building / estates related element / equipment.

Filter changing

There are two typical types of filters installed in extract ventilation systems, Safe change types in systems designed to handle toxic or contaminated air (LEV's or HCID units) also known as Bag In Bag Out BIBO type filter units and general filtration (primarily designed to protect fan components and heat exchangers).

Safe change filter units as specifically designed to enable removal and replacement without exposing the maintenance worker to direct contact with the dirty filter. The design of these units can vary so the manufacturers' guidance notes and method statements should be followed to ensure safe removal and disposal.

General filters will not be of a grade that is designed to capture all particles, but will capture some and should be treated carefully. Prior to opening up a unit to remove a general filter a disposal bag should be available. The unit should be switched off and any backflow dampers allowed to close (or if manual – closed) prior to opening up the filter access door. The filter should be removed carefully to minimise the release of any dust/contamination on the filter surfaces and placed directly into the disposal bag. The filter frame should be cleaned ideally with a HEPA filter vacuum cleaner or wiped down with and alcohol based steri-wipe, the used wipes should also be disposed of in the filter disposal bag.

Once clean the new replacement filter can be installed, the unit re-assembled and the fan switch on, once any manual dampers have been re-opened.

PPE - Putting on and removing personal protective equipment

Putting on PPE

Before donning, healthcare maintenance workers should, remove all nonessential items and tools from overalls and tool bags, ensure they are hydrated, and perform hand hygiene.
Staff should wear the following PPE, put on in the following order:

- Disposable boiler suit/coveralls
- FFP3 respirator and fit check
- eye protection (goggles or face shield)
- disposable gloves

The order given above is practical but the order for putting on is less critical than the order of removal given below. During donning each item must be adjusted as required to ensure it fits correctly and interfaces well with other PPE items.

Removal of PPE

PPE should be removed in an order that minimises the potential for cross-contamination.
If working within a clinical space after leaving the side room gloves, disposable boiler suit and eye protection should be removed (in that order, where worn) and disposed of as clinical waste. The respirator can be removed and the filters disposed of as clinical waste with the mask being wiped clean with alcohol based steri-wipes or similar.
If working in a plantroom or service area (on remote located ventilation equipment associated with an isolation facility then the PPE should be removed and bagged prior to leaving the plantroom area. Other staff should not be working in the area whilst the maintenance work to extract ventilation systems is being undertaken.
The order of removal of PPE is suggested as follows, consistent with WHO guidance:

- peel off gloves and dispose in clinical waste
- perform hand hygiene
- remove boiler suit by using a peeling motion, fold in on itself and place in clinical waste bin
- remove goggles or visor only by the headband or sides and dispose in clinical waste
- remove respirator from behind and dispose of filters as clinical waste
- Clean respirator mask housing using alcohol based steri-wipes or similar.
- perform hand and face hygiene

For additional guidance see the PHE COVID-19: Guidance for infection prevention and control in healthcare settings. Version 1.0. Appendix 3 – Best Practice - Putting on and taking off PPE.

Endnote

Any healthcare organisation which is undertaking works or modifications to their ventilation systems should seek to obtain specialist advice both internally from the organisations own multi-disciplinary team (estates (AP(V)), IPC, Clinical leads, Decontamination leads, Medical Gas AP(MPGS), etc.…) but also from an appropriately qualified and experienced Authorising Engineer (Ventilation) or other suitable professional design consultant.

Introduction

Following a review and advice from Public Health England (Peter Hoffman) the briefing and guidance from the SVHSoc has been updated to reflect the current official guidance and to provide a range of options and areas for consideration for healthcare estates professionals to provide enhanced levels of protection for patients, staff, and visitors.

The briefing is intended to provide an overview of the issues and points to consider when assessing the ventilation strategy and options. It has also been updated to provide some initial maintenance considerations and precautions which may need to be considered. It is intended that this briefing and guidance will be subject to regular review and updates as details, information, and the situation continues to develop.

Current guidance on the lifespan of the virus once outside the body is still to be fully established, however current estimates are that it could survive anywhere between a few hours up to 3 to 4 days on hard surfaces and is spread by both primary direct exposure (breathing in droplets expelled from an infected person from coughing or sneezing) and secondary contact by touch (touching a surface which has been contaminated and transferring this contamination by touch to the mouth, nose or eyes). Coronaviruses are mainly transmitted by large respiratory droplets and direct or indirect contact with infected secretions. They have also been detected in blood, faeces and urine and, under certain circumstances, airborne transmission is thought to have occurred from aerosolised respiratory secretions and faecal material". That level of airborne transmissibility is specifically associated with certain aerosol generating procedures (AGPs).

That COVID-19 has been termed an airborne infection is an indication that it is capable of transmitting via an airborne route in certain circumstances, not that its mode of spread is primarily airborne nor that any aerosol remains sufficiently concentrated to be infectious over longer distances other than in the immediate vicinity of a dispersing patient.

The PHE guidance is under constant review and updated as necessary. The current guidance can be found at:

https://www.gov.uk/government/publications/wuhan-novel-coronavirus-infection-prevention-and-control/wuhan-novel-coronavirus-wn-cov-infection-prevention-and-control-guidance

Ventilation can contribute to an isolation or protection strategy to assist in minimising the spread of the virus, however a number of factors need to be considered, not least of all the provision of adequate ventilation to provide dilution of any airborne contamination, with other factors including;

- Area / rooms where isolation can be established
- Physical / fabric of the room construction / air permeability rates (e.g. solid ceilings)
- Surrounding areas of clinical activity
- Room volume and airflow / room pressure differentials (dilution effects)
- Provision and location of ventilation (e.g. ceiling mounted supply with low level extract)
- Point of discharge of any extracted air and filtration of same
- Levels of isolation and practical considerations
- Decontamination of the area between patients
- Protection of all potentially exposed staff groups (clinical, cleaning, and estates)

Standards and Technical Specifications

HTM 03-01 sets out the overall guidance for ventilation of healthcare premises with addition specific guidance on isolation facilities being contained within HBN 04-01 Supplement. These documents should be used as the basis for all ventilation strategies in conjunction with advice from the Infection Protection Control (IPC) team, WHO & PHE support. Overall it needs to be an issue where IPC set the room criteria and then estates can look to see how it can be provided.

Note/commentary from PHE - Standards and technical specs; We (PHE) are rapidly moving to a position where COVID patients will be cohorted on bays in wards. Beyond specific "aerosol generating procedures" (AGPs) there is not thought to be an airborne risk and staff do not require respirators. This can be seen from the "general ward" guidance for AGPs in the PHE guidance.

Table 1: Transmission based precautions (TBPs): Personal protective equipment (PPE) for care of patients with pandemic COVID-19

	*Entry to cohort area (only if necessary) no patient contact**	*General ward **	*High risk unit ICU/ITU/HDU*	*Aerosol generating procedures (any setting)*
Disposable Gloves	*No*	*Yes*	*Yes*	*Yes*
Disposable Plastic Apron	*No*	*Yes*	*Yes*	*No*
Disposable Gown	*No*	*No*	*No*	*Yes*
Fluid-resistant (Type IIR) surgical mask (FRSM)	*Yes*	*Yes*	*No*	*No*
Filtering face piece (class 3) (FFP3) respirator	*No*	*No*	*Yes*	*Yes*
Disposable Eye protection	*No*	*Risk assessment*	*Risk assessment (always if wearing an FFP3)*	*Yes*

Notwithstanding the above, in the SVHSoc's opinion, a standard for any facility used, should strive to achieve the following performance criteria;

- The room ideally should be neutral or negative to the surrounding areas (-5 to -10 Pa)
- The room should achieve between 6 to 12 air changes per hour
- If achievable the room should have sufficient air supply and extract to achieve open door protection, however this may not be possible other than in a PPVL room.
- The room should ideally have a protected lobby (if possible) with barrier nursing and PPE worn by all staff
- Immediately outside but adjacent to the room there should be a wash hand basin and an area for de-gowning. If the room has a lobby (PPVL) then de-gowning should take place within the lobby.

General Options and Considerations

A negative pressure or PPVL room with lobby is the likely preferred locally achievable option. Extract filtration is not likely to be required as it is likely to significantly impact on the airflow performance and it will be necessary to undertake a risk based assessment on the use of extract filtration and consider system upgrades to maintain overall airflow performance. The point of discharge of any extract ventilation system should be assessed to ensure that it does not provide a route of cross contamination.

If however multiple PPVL rooms are not available then a side room with a lobby and its own en-suite is likely to be the next best option. The extract from the en-suite will provide some degree of pressure cascade / regime although it is unlikely to provide open door protection and the point of discharge location will again require to be assessed. If a side room has supply air then this should be re-balanced to provide a minimum fresh air rate but be less than the extract air volume to maintain the room at a negative pressure, whilst not compromising dilution effect. Negative pressure units (NPU) are readily available in the asbestos removal industry, they come with DOP test HEPA filters and could be considered to create a negative pressure room on a temporary basis.

If an air scrubber/filtration unit is considered it will not provide any dilution or fresh air supply into the room, but may remove some contamination from the air, however the issue of how to de-contaminate and dispose of the filter unit between patients will need consideration (see maintenance considerations below).

As the spread of the virus continues it is likely that hospitals will be asked to identify and consider designating entire ward areas or even buildings as isolation facilities. This cohorting of cases will be driven by clinical risk assessment based upon risk of cross contamination (between patients within the isolation space) and the need for clinical support/treatment. In these circumstances it is likely that the capacity of the electrical and medical gas infrastructure (oxygen, medical air, and vacuum) systems will be the greatest challenge and ventilation will be a secondary issue, however some basic principles should be considered;

- Wards with single bedrooms with en-suite facilities are likely to offer the best solution.
- The extract rate should be greater than the supply where practical, to create a negative pressure cascade to surrounding areas, ideally with supply in corridors and extract by means of en-suite facilities and dirty extract systems, in all cases ward doors to circulation spaces MUST be kept closed as far as reasonably practical.
- Maintaining a good air change rate of between 6 - 12 ACH is considered appropriate to maintain a dilution effect for both patients and staff protection.

- If open plan/multi-bed bay wards are used then a clinical assessment of risk relating to cross contamination will be needed, however areas with low level extract by each bed space would be preferable.
- If the ventilation system (AHU) serves more than a single ward then the supply aspect is less critical as the airflow direction provides a level of protection, however an ACR of around 6 ACH should be considered as a minimum. Shared extract systems are less ideal and consideration should be given to separating or closing off non-essential extracts if practical. Extract systems should be inter-locked with supply systems to ensure that if the supply fails the extract continues to operate, however if the extract fails then the supply should also switch off, only as a short term measure until the extract system can be repaired / re-instated. If a failure is likely to be over 1 hour then the supply can be reinstated to provide both thermal comfort and dilution provided that it does not create a cross contamination risk.
- If an area or room is identified as being potentially suitable to be used as a temporary isolation facility it is advisable if possible to undertake a 'room air permeability or leakage test' to ensure air is contained within the room and does not leak to adjacent areas through suspended ceiling or service penetrations, (this may not be practical to achieve, given the urgency of demand).
- Any room used as a temporary holding or isolation facility should be stripped of all non-essential materials and soft furnishings.
- If you can locate an increased extract unit to provide a negative pressure environment then care will be needed when considering the distribution ducting and the exhaust air discharge point. Ducting and extract grilles should be located to ensure an even draw of air from around bed spaces and not rely on a single point at the end of the unit which draws air over adjacent patients and staff. The exhaust discharge however providing it is discharging to a safe external space (ideally at high level 3m above roof level) then HEPA filtration is unlikely to be required. Consider sealing any openable windows in the immediate vicinity (around 4m) of any low level discharges and avoid discharge over pedestrian paths/walkways.

Use of Theatres as CCU's

As the need for critical care beds increases hospitals will need to identify areas which are suitable and have the required engineering and medical services to provide an appropriate and safe clinical environment. In many cases where patient ventilation / life support is required the theatre and associated recovery suites (freed up from elective procedures from mid-April) could be considered as ideal. If kept for the exclusive use by non-infected patients the ventilation system is likely to need little modification or adjustment, however consideration may be given to lowering both supply and extract rates to save energy and ensure patient comfort (reducing ACRs to around 10 ACH would be appropriate). Typically 2 CCU bed spaces could be provided per theatre with an addition bed located in the anaesthetic room if needed, (medical gases, adequate ventilation and electrical outlets are typically all present in these rooms). Recovery spaces are designed to provide 12-15 ACH and should be neutral to surrounding areas so no modifications to the ventilation system should be needed.

If it is proposed to use theatres as spaces to treat COVID 19 infectious patients then the airflows would need to be very carefully reviewed and adjusted to maintain a safe air change rate and provide an ideally neutral pressure regime to surrounding clinical and staff areas.

Use of Theatres for COVID 19 infected patients Including Emergency Maternity Theatres

The following information reflects the current guidance from the centre for the use of theatres for known or suspected infected (COVID19) patients;

https://www.gov.uk/government/publications/wuhan-novel-coronavirus-infection-prevention-and-control

18. Theatres

- theatres must be informed in advance of a patient transfer of a confirmed or possible COVID-19 positive case
- the patient should be transported directly to the operating theatre and should wear a surgical mask if it can be tolerated
- the patient should be anaesthetised and recovered in the theatre. Staff should wear protective clothing but only those at risk of exposure from aerosol generating procedures, ie during intubation need to wear FFP3 respirators and full gowns. considerations about the use of respiratory/anaesthetic equipment are addressed in the critical care section above
- instruments and devices should be decontaminated in the normal manner in accordance with manufacturers' advice
- both laryngoscope handle and blade should either be single use or reprocessed in the Sterile Supply Department. Video laryngoscope blades should be single use and scope/handle decontaminated as per manufacture instructions.
- instruments must be transported safely to decontamination, following use
- the theatre should be cleaned as per local policy for infected cases, paying particular attention to hand contact points on the anaesthetic machine
- theatres should not be used by staff or patients for 20 minutes after the patient leaves if conventionally ventilated, or 5 minutes if ultraclean ventilation is used
- possible or confirmed cases of COVID-19 should be placed at the end of the list where feasible

The follow information is provided to support or supplement this initial guidance.

Neutral Pressure Theatres

With the current COVID19 infection issues there may be a requirement for an operating suite to be used for an infected or suspected patient. If airborne micro-organisms liberated from a patient during the surgical procedure are allowed to cascade out into the adjacent corridors, they could contaminate surfaces or infect other patients or the staff within the surrounding operating department.

The concept of a neutral pressure or infectious theatre is to maintain an appropriate and safe air change rate to the theatre space but instead of the tradition cascade arrange of air from the theatre suite to the surrounding areas it is a based on a balanced air flow of both supply and extract from ideally within the theatre itself or as a minimum within the individual theatre suite.

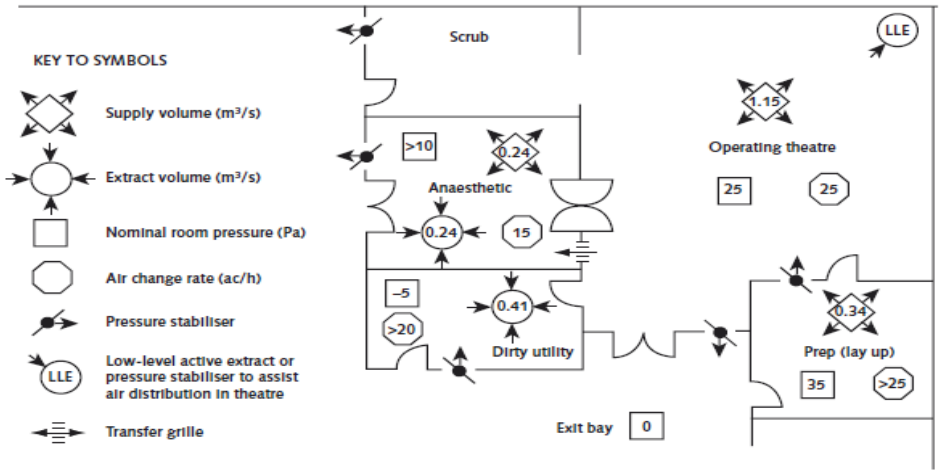
The room provision and layout will be as for a conventional operating suite with the following variation to the ventilation scheme:

- The operating theatre will have a balanced supply and extract so that it is at the same pressure as the corridor.
- Air should not cascade from the theatre to the surrounding rooms so pressure stabilisers and / or transfer grilles will not be fitted.

- The preparation room could be dispensed with to avoid having stock that could become pre-contaminated. Sterile packs, instruments and consumables would be delivered to the theatre on a case by case basis. If a preparation room is required, then it should be maintained at 10Pa to both the theatre and corridor.
- The anaesthetic room should have a supply in excess of extract so that is maintained at 10Pa above both the corridor and theatre. There should be a pressure stabiliser between the anaesthetic and corridor but no transfer between the anaesthetic and theatre.
- The scrub should have an active extract as for a conventional operating suite but no pressure stabiliser between it and the corridor.
- The utility should be at -5Pa to the theatre and its corridor.
- The corridor extract will be sized to cater for the air leakage from the anaesthetic room only.

Overall the ventilation scheme should ensure that all air supplied to the operating theatre is removed in the theatre suite. The theatre should be neutral (at the same pressure) to the corridor so that when the theatre exit door is open there is effectively no interchange of air between them. Ideally when the preparation or anaesthetic doors are opened airflows from them into the theatre and not the other way.

The traditional theatre suite layout typically as below (or a variation thereof);



If sites are required to endeavour to transform existing positive pressure cascade theatres to create a neutral pressure theatre the following areas will need to be considered.

In line with guidance the patient should be brought into and out of the theatre through the anaesthetic room, but anaesthetised and recovered in theatre. The doors and any pressure stabilisers from the theatre to the corridor should be sealed and not used.

The lay-up prep area should only hold the minimum stock required for the given procedure, however the air cascade from the lay-up prep to theatre should be maintained as a positive differential.

The pressure stabilisers from both the scrub area to the corridor and the anaesthetics room to corridor should be sealed.

The dirty utility room should remain at a negative pressure differential to both the theatre and corridor.

Ideally the anaesthetics room should be neural pressure to the theatre, however this may not be practical, in which case the anaesthetics room should only have all surfaces as clear as practical and all surplus or spare equipment held elsewhere.

A full re-balance of the supply and extract systems will be required and the provision of addition theatre extract is also likely. This will have to be assessed and designed on a theatre by theatre basis.

The same considerations apply to both conventional and UCV theatres. The UCV canopy is a re-circulation canopy and as such should have minimal impact on the theatres pressure regime, however due care should be taken not to disturb the canopies clean airflow area with excessive localised air movement and prevent perturbation of the UCV canopy air pattern.

It may be necessary to consider a relaxation of minimum air change rates to achieve a neutral pressure cascade however these should not be lower than 18ACH and MUST be agreed with clinical and IPC teams based on clinical risk assessment.

All non-essential materials and equipment should be removed from the theatre and surrounding corridor areas to ensure all cleaning can be undertaken as easily as possible.

Specific patient and staff procedures and flows will need to be considered and agreed.

An alternative approach may be to designate a suite of theatre suites within a single location (floor or building) as infectious at which point the entire theatre complex could be isolated from any surrounding clinical areas and used exclusively for only infectious patients. In this case provided the extracted air was discharged to a safe location and all staff wear PPE whenever within the theatre area no or limited modification to ventilation strategies would be necessary.

Summary

Any healthcare organisation which is undertaking this assessment or provision should seek to obtain specialist advice both internally from the organisations own multi-disciplinary team (estates (AP(V), IPC, Clinical leads, Decontamination leads, Medical Gas AP(MPGS), etc…) but also from an appropriately qualified and experienced Authorising Engineer (Ventilation) or other suitable professional design consultant.

Non ventilation Considerations

In addition to the ventilation issues associated with the current COVID 19 pandemic, other healthcare related engineering services and operational considerations will need to be assessed and considered. These are likely to include;

- Medical gas capacities and flow rates to deliver required clinical treatments (oxygen, medical air & vacuum).
- Number and location of electrical outlets on essential power supplies, for clinical and medical electronics.
- Provision of suitable emergency lighting
- Patient access and egress / transportation routes through other clinical / public areas.
- A minimum separation distance of between 1 – 2 metres should be maintained between beds
- If temporary separation / partition walls or barriers are constructed to create segregated bed spaces, the fire strategy and fire evacuation plans MUST be reviewed to ensure they remain appropriate. This should involve identification of evacuation routes and places to provide both an immediate safe refuge and a place to continue care and treatment.
- Provision of adequate hand washing facilities.
- Waste collection and storage capacities and locations and transfer routes.
- Surrounding clinical services to avoid close proximity to other 'at risk' patient groups.
- Adequate staff welfare and rest areas if staff numbers are increased to meet clinical needs.

Estates staff are recommended to give consideration to all of the above and where considered necessary review the PHE guidance and consult with their appropriate Authorising Engineer for the associated engineering specialty.

Additional guidance is available in the NHS&I – Novel coronavirus (COVID-19) standard operating procedure – Design Note: COVID-19 ward for intubated patients version 1.0 published 22/03/2020 (Publications approval ref 001559).

Ventilation Maintenance Considerations

Ventilation breakdowns and repairs

Any potential contamination risk associated with extract ductwork, fans and filters is likely to be very low. The ventilation system acts to dry out any droplets that are drawn out of a room and if these droplets settle on ductwork or fan surfaces they will very quickly desiccate and are likely to be inactive. Notwithstanding this it is advised that enhanced precautions should be taken by maintenance staff when working on such systems both as a precautionary measure and to provide re-assurance to those undertaking the work.

If a breakdown or internal inspection is required to an extract system from a potentially contaminated area then the following issues should be considered;

- Minimise the tools taken into the area during any period when a system is 'opened up' for maintenance or inspection.
- Following work being completed old or redundant materials / components should be bagged and removed as clinical waste.
- Tools used during the work should be washed / disinfected where practical or wiped down with alcohol based steri-wipes or similar.
- Minimise the number of workers in the immediate area of the work, whilst maintaining safe working conditions and staffing levels (two man working may be necessary if working at height or if moving and handling issues exist).
- All staff should wear appropriate PPE and dress, remove, and dispose of it as detailed below.

Other maintenance activities not directly relating to extract ventilation maintenance such as fire damper drop testing, or ductwork cleanliness inspections will need to be managed so as to ensure that no potential contaminated extract ductwork is opened accidentally. Smoke and fire dampers on extract systems will need to be assessed to ensure routine fire alarm testing does not interrupt or involve extract ductwork ventilation system operation, if being used for isolation protection.

The precautions and method statement detailed above should be adapted / applied to all maintenance staff working in areas where potentially or known infectious patient are or have been located weather working on ventilation systems or any building / estates related element / equipment.

Filter changing

There are two typical types of filters installed in extract ventilation systems, Safe change types in systems designed to handle toxic or contaminated air (LEV's or HCID units) also known as Bag In Bag Out BIBO type filter units and general filtration (primarily designed to protect fan components and heat exchangers).

Safe change filter units as specifically designed to enable removal and replacement without exposing the maintenance worker to direct contact with the dirty filter. The design of these units can vary so the manufacturers' guidance notes and method statements should be followed to ensure safe removal and disposal.

General filters will not be of a grade that is designed to capture all particles, but will capture some and should be treated carefully. Prior to opening up a unit to remove a general filter a disposal bag should be available. The unit should be switched off and any backflow dampers allowed to close (or if manual – closed) prior to opening up the filter access door. The filter should be removed carefully to minimise the release of any dust/contamination on the filter surfaces and placed directly into the disposal bag.

The filter frame should be cleaned ideally with a HEPA filter vacuum cleaner or wiped down with and alcohol based steri-wipe, the used wipes should also be disposed of in the filter disposal bag.

Once clean the new replacement filter can be installed, the unit re-assembled and the fan switch on, once any manual dampers have been re-opened.

PPE

Putting on and removing personal protective equipment

Putting on PPE

Before donning, healthcare maintenance workers should, remove all nonessential items and tools from overalls and tool bags, ensure they are hydrated, and perform hand hygiene.

Staff should wear the following PPE, put on in the following order:

- Disposable boiler suit/coveralls
- FFP3 respirator and fit check
- eye protection (goggles or face shield)
- disposable gloves

The order given above is practical but the order for putting on is less critical than the order of removal given below. During donning each item must be adjusted as required to ensure it fits correctly and interfaces well with other PPE items.

Removal of PPE

PPE should be removed in an order that minimises the potential for cross-contamination.

If working within a clinical space after leaving the side room gloves, disposable boiler suit and eye protection should be removed (in that order, where worn) and disposed of as clinical waste. The respirator can be removed and the filters disposed of as clinical waste with the mask being wiped clean with alcohol based steri-wipes or similar.

If working in a plantroom or service area (on remote located ventilation equipment associated with an isolation facility then the PPE should be removed and bagged prior to leaving the plantroom area. Other staff should not be working in the area whilst the maintenance work to extract ventilation systems is being undertaken.

The order of removal of PPE is suggested as follows, consistent with WHO guidance:

- peel off gloves and dispose in clinical waste
- perform hand hygiene
- remove boiler suit by using a peeling motion, fold in on itself and place in clinical waste bin
- remove goggles or visor only by the headband or sides and dispose in clinical waste
- remove respirator from behind and dispose of filters as clinical waste
- Clean respirator mask housing using alcohol based steri-wipes or similar.
- perform hand and face hygiene

For additional guidance see the PHE COVID-19: Guidance for infection prevention and control in healthcare settings. Version 1.0. Appendix 3 – Best Practice - Putting on and taking off PPE.

Dear All

Please find attached a summary of our discussions at the two meetings this week along with a marked up drawing showing the 4 bedded bay affected by the proposed ventilation works. Hopefully I have captured the key points but if there is anything I have missed then please let me know

The feedback from these discussions will now be feed into the design meetings currently being held involving HFS which Donald and Ronnie attend.

Kind regards

Janice

Quantity	Code	Description
4	BAS101	BASIN, medium, hospital pattern, vitreous china, no tap holes, no overflow, integral back outlet, 600W 400D
2	BED003	BED; cot, baby; dropside, standard size
2	BED016	BED, COT/IFC, radio translucent lying backrest, two-way tilt, height adjustable (900-600), on castors
4	BED2501	Mobile bed divider 1600W 1350H
4	BIN2503	BIN, sharps disposal
1	BMS999	BMS Sensor
7	CAL035	LAMP repeat call (patient/staff or staff emergency or Cardiac call), ceiling mounted
1	CAL1001	CALL, lamp time unit, ceiling mounted
4	CHA002	CHAIR; height adjustable; medium back, swivel, 5 star base; on castors
8	CHA2512	CHAIR, upright with arms; vinyl plastic; stacking
1	CLO003	CLOCK synchronous with second sweep hand, wall mounted
1	COM038	COMPUTER PRINTER, laser, A4, 250H 350W 385D
4	COM904	CIS CART; with CPU ; screen; keyboard & mouse
4	CON902	Remote monitor control (cabling integrated into the pendant or WiFi)
4	DIS013	DISPENSER, paper towel, wall mounted
4	DIS030	DISPENSER, soap, disposable single cartridge, lever action, wall mounted
4	DIS2500	DISPENSER, dispenser; combined glove/apron,
4	DIS2503	DISPENSER; alcohol gel, disposable single cartridge, wall mounted,
1	EBB001	Equipotential Bonding Busbars
4	HOI005	HOIST PATIENT, with washable slings, electric; 24v; straight track ceiling mounted (Length of the track to suit the individual needs)
9	HOL005	HOLDER, bin, medium, capacity 70 litres, freestanding.
4	HOO002	Hook for suction support. Upper Medirail mounted,
2	MAT005	MATTRESS, ITU/CCU bed, extra care
2	MAT901	MATTRESS, reliever
4	MON904	MONITOR, High end multi-functionality for ITU/Theatre/High Acuity
4	MON909	MONITOR; Transport monitor for ITU/Theatre/High Acuity
4	OUT004	OUTLET cable, fused, 13 amp, ceiling mounted
4	OUT005	SOCKET outlet, switched, 13amp, single
5	OUT010	SOCKET outlet, switched, 13amp, twin
1	OUT059	CONNECTION UNIT switched 13amp, indicator light
2	OUT121	SOCKET outlet double data/voice; wall/trunking mounted.
8	OUT900	Data Input Box for CIS with 16 input channels (Lantronix): uses 1 plug, 1 data point
4	PEN1000LR	PENDANT; critical care; twin arm; multi movement, with sockets, equipotential sockets, dtd data, oxygen, vacuum, medical air, AGSS, nurse call, light swc, lamp, uplighter, medirails, infusion poles, shelves as detailed in ME-XX-AX-DC-400-002
4	PEN1004	PENDANT, critical care, CIS; single arm with elbow joints; multi movement with 4 sockets & 2 data points as detailed in ME-XX-AX-DC-400-002
4	PRI015	PRINTER, label, portable
2	SUP2500	SUPPORT LEG; for 920 high worktop
4	SUR955	Humidifier. 1 plug, 1 Data (Lantronix) cable
4	SUR965	Docking station with 7 volumetric pumps. 1 plug, 1 Data (Lantronix) cable
4	SUR987	Nebuliser mounted on Medirail . 1 plug
8	SUR989	Alaris volumetric pumps. 2 plugs
4	SUR991	Double oxygen flow meter. Upper Medirail mounted
4	SUR992	Air flow meter. Upper Medirail mounted
4	SUR993	Airway pressure monitor. Upper Medirail mounted
4	SUR999	Enteral feed pump
1	SWC025	SWITCH, light
4	SYR004	SYRINGE pump; anaesthetic use, with diffusor, 115H 400W 180D
4	TAP804	TAP bib, hospital pattern, integral thermostatic mixer, HTM64
4	TEL1000	TELEPHONE, handset,
2	THE005	THERMOSTAT
4	TRA1003	TRACK, curtain, bed/trolley; length and shape as drawn.
3	TRA1004	TRACK, curtain, to internal screens
4	TRA2500	TRACK; curtain; window, length to suit
4	TRO151	TROLLEY, dressing/instrument, stainless steel, buffered, 870H 450W 450D
4	UPS003	Uninterrupted power supply (UPS).
4	WAS100	WASTE, unslotted flush-grated, metal, 1.1/4 in
4	WAS1000	TRAP; concealed waste, for back outlet basins,
1	WKT1003H	WORKTOP; 900 high 600 deep 40mm thick, with 60mm upstand, length as drawn.

Janice MacKenzie	Project Clinical Director
Ronnie Henderson	Project Hard FM Commissioning Manager
Donald Inverarity	Consultant Microbiologist
Carol Calder	IPCN
William Evans	IPCN
Pota Kalima	Consultant Microbiologist
Catherine McDougall	Medical Consultant

We discussed the current proposals for improving the critical care ventilation to ensure that it is compliant with SHTM 03-01 with 10 air changes and 10 Pa positive pressure in the single rooms and 4 bedded bays. We also reviewed the ventilation requirements in the 4 bedded bays to allow you to cohort patients with the same infections.

<u>Current Proposal for Critical Care Ventilation Improvements</u>
We visited the Unit, specifically 1-B1-031 which will be impacted on with one of the proposals to review the bed space.
Ronnie updated as follows
Of the 5 initial proposals considered, only two now being considered:-

1. Utilise existing plant or replace in existing location, upsize fans and upsize ducting in critical care – Design team assessing but unlikely to be possible
2. Install new plant external and duct in via window in 4 bed bay, connect ducting to serve approx 50% of critical care
   Note – in both options isolation rooms are unaffected

See attached marked up drawing for the space affected:-

- One window would be blocked to allow the duct work to come in and it would be boxed out no further than the start of the vision panel at the side to the adjoining room.
- We placed the pendants in the positions they would be in and considered the equipment that would be at the top of the bed and confirmed that there would be sufficient circulating space. Ronnie took some photos of the pendant positions and he will pass these onto MPX
- We noted that no further windows in the bay could be affected as this would then affect the natural light coming into the area

- The additional plant would be on the grass roof area outside the window. Once size of the unit and orientation is known need to ensure that it does not adversely affect the light coming into the area.
- The Critical Care team asked that both the boxed out area within the bay and the plant would have some form of enhancement to make it more aesthetically pleasing e.g. graphics

Compliance with SHTM 03- 01

- Currently the 4 bedded rooms and single rooms have 4 air changes and this needs to increase to 10 air changes to ensure compliance with SHTM. It was acknowledged that the SHTM was more focused on adult critical care where the patient profile is different and the need to cohort patients was extremely rare
- It was noted that previously a decision had been made to derogate from the SHTM for the 4 bedded areas to allow patients to be cohorted with the same air-borne infection and following consultation with the clinical team and IPCT at the time the decision was made that these areas should be balanced or slightly negative. The SHTM states that both the 4 bedded areas and single rooms should have 10 air changes and 10Pa (positive pressure)
- It was confirmed that the Isolation Rooms were compliant with SHTM 03-01
- IPCT view was that you could cohort patients with the same air-borne infection in the 4 bedded areas that were 10 air changes and 10Pa and that there is no reason that this would result in an increased risk of spread of infection. A design of balanced or slightly negative pressure approaches the issue of spread of infection from a cohort from a different direction but it was agreed that neither approach increases the risk of infection spread but that the SHTM 03-01 compliant design has additional benefit for neutropenic patients who could be in single rooms as 10Pa positive pressure.
- It was acknowledged that the design of the Unit also provided additional control measures to prevent spread of infection and the barriers to transmission included:-
    - Bed space size
    - Distance between single room doors, isolation room doors and 4 bedded bay doors as range of droplet spread is generally considered to be between 1-3 metres
    - Patients on ventilators less of a risk of generating aerosols from coughing
    - Direction of air flow in corridor space directs and air borne contaminants towards and air extract vent and away from other patient rooms.
    - Turn over of air dilutes any airborne organisms in patient rooms and corridors.
- It was noted that if a patient with an infection was in a 4 bedded bay or single room or a neutropenic patient in a single room the windows should not be opened and increased room cleaning would likely be required
- Confirmed that Isolation Rooms should be used for patients with infections transmitted by airosols e.g. measles, chicken pox, TB
- Single rooms and cohort areas would be suitable for droplet infections e.g. RSV, Influenza
- Confirmed that the single cubicle in neonatal Unit will have 10Pa and 10 air changes and as it has an en-suite it will need a transfer grille on the en-suite door
- Confirmed that any ‘dirty’ rooms e.g. Dirty Utility, toilets have extract and any ‘clean’ rooms e.g. clean utility have supply and extract
- We discussed the Positive Pressure Ventilation Lobby (PPVL) isolation rooms in relation to ventilation in QEUH, specifically in relation to Multi-Drug Resistant TB, however Donald was very cautious about making any comparisons as the context was different (paediatric critical care versus adult infectious diseases isolation ward) . It was suggested that this was something that could be discussed further with HFS
- We discussed a number of different patient groups and scenarios in relation to the use of the Isolation rooms, Single Rooms and 4 bedded bays and in light of these discussions and the points above all agreed that the SHTM 03-01 was a safe design for ventilation within the

Paediatric Critical Care Unit in conjunction with the design of the unit and good practice in relation to infection control measures which all worked together as a package to achieve best outcome for patients

We also briefly discussed:-

- Cystic Fibrosis patients and the areas that they would be treated in and whether CF patients with different infections would be treated in the same ward as currently they would be treated in different wards as the existing hospital does not have Isolation Rooms. It was confirmed that Dalhousie ward(Medical Inpatients) have 4 PPVL Isolation room. It was felt by IPCT that provided appropriate measures were in place about the placement of patients within the ward then this could happen. Also Castle Mey (Acute Receiving Unit) has 1 PPVL isolation room. It was noted that currently Dalhouisie Ward is classed as an Augmented Care Area but Castle Mey not. This lead to a discussion about other areas in the hospital where CF patients could be treated, this includes OPD, Cardio Respiratory OPD and Dirleton (Medical Day Care) and therefore whether these areas should also be classed as Augmented Care as far as water sampling is concerned. It was felt that the risk was greater in Inpatient areas. Further discussion to be had with IPCT acknowledging that the water testing regime may need a bit of tweaking when hospital occupied

Subject: Re: SHTM 03-01 Critical Care

Hi Donald,

Overall with this one we think its not really an issue. The fact that there is a door that can be closed on the 4 bed room will in itself reduce infection spread by 80%. Changing to a negative pressure facility in that room area will not necessarily add anything. Will look over again later in more detail and get back to you if we think of anything else. Will have an evening session again tonight with Peter where we might be able to ask him some more questions.

I'm sorry you're feeling a little brain fried, but I'm not surprised! We are starting to feel that way too after these 12 hour plus days of learning.

Kind regards,

Jen.

> Any views from Falfield please?
> Essentially Carol and I spent a couple of hours talking through each room of RHCYP ITU/HDU with the critical care medical and nursing team and why the design parameters set in SHTM 03-01 did not put patients at risk outwith a 4 bedded cohort from RSV etc based on air flow to extract in corridor, closed doors, distance to next patient > 3metres, need to overcome 10Pa pressure for aerosol to enter another room.
> Discussion was detailed but crucial to get their agreement for us to have an SHT 03-01 compliant design. The current design of balanced or slightly negative 4 bedded rooms (deviation from SHTM 03-01) seems to have arisen from clinical teams rightly wanting to protect patients outwith a potential cohorted area and so much of this concern is to convince them that this is still possible with an SHTM 03-01 compliant design.

> Dear Janice and Donald,
>
> The bit I am struggling with is the pressures with respect to the single rooms and the 4 bed bays.

Everything on Appendix 1 of SHTM 03-01 that is infectious or a “dirty” area is negative pressure and everything that is “clean” is positive pressure. It is also about flow between areas.

The need to cohort RSV in the 4 bed bays was the reason we went for balanced pressures.

So Questions:

- From the HTM a neutropenic patient or patient awaiting transplant would only require to be in a single room if the pressure was at 10 Pa above the corridor is this correct?
- If the 4 bed bay is at 10Pa above the corridor does this confer any advantageous with respect to balanced pressures in protecting the patients in the bay from each other or not?
- Will the air changes per hour in the critical care corridor circulation space be 10 as well?
- Are our clean and dirty utilities at the correct pressures and air changes?

I will sleep on it and get back to you if I have more questions.

Regards
Julie

Hi Donald

Can you phone me regarding Julie's emails as she has also phoned me and she is now feeling very uncomfortable about this and reversing a decision that was made several years ago in conjunction with Pota and is very keen to meet to discuss further which I think we do need to do as a matter of urgency.

She has said that she is available today and tomorrow (although I appreciate that you are very tied up tomorrow with meetings)

Look forward to hearing from you, if I am not at my desk give me a call on my mobile.

Janice

PROUD HISTORIES | NEW CHAPTERS

www.nhslothian.scot.nhs.uk/proudhistoriesnewchapters

From: Freeman, Julie
Sent: 11 July 2019 09:37
To: Freeman, Julie; Mackenzie, Janice; Inverarity, Donald
Cc: Reilly, Laura; Smith, Pat
Subject: RE: SHTM 03-01 Critical Care

Hi Janice and Donald,

More questions:

- P 92 section 7.6 talks about balanced flow theatres for infectious cases. Is this not the same situation as cohorting patients in our 4 bed bays?
- We will have immunocompromised patients in our cubicles or infectious patient albeit of lower infectivity.
- Does the design with respect to pressure differential (balanced or positive) affect how the increase in air exchanges is engineered?
- Past events described at burn meetings where theatre has been the common location of transmission of acinetobacter between patients makes me nervous and influences the pressure decision.
- Do the single rooms have both supply and extract ventilation as well as the 4 bed bays?
- The SHTM 03-01 for Critical Care has supply ventilation only with the positive pressure in Appendix 1. Is balanced pressure with both supply and extract ventilation not better than that?
- Is the neonatal cubicle balanced pressure? Does it have supply and extract ventilation?
- Does positive or balanced pressures make any difference to whether Option 1 works?

I think it would be helpful to meet to discuss these questions face to face with the same group of people. I know some issues were discussed yesterday but there was a lot of information to take in. I not clear on all aspects of on the current situation is and less clear on the planned solution. Inherently cohorting infectious disease in a positive pressure area does not feel right to me.

I am freely available this week and next and I think now is the time to have further discussion. Ronnie and Carol may also be helpful. I'd rather be sure we are making the right decision rather than a decision based on a table that does not fully describe our position.

Regards
Julie

Subject: SHTM 03-01 Critical Care

Dear Janice and Donald,

The bit I am struggling with is the pressures with respect to the single rooms and the 4 bed bays.

Everything on Appendix 1 of SHTM 03-01 that is infectious or a "dirty" area is negative pressure and everything that is "clean" is positive pressure. It is also about flow between areas.

The need to cohort RSV in the 4 bed bays was the reason we went for balanced pressures.

So Questions:

- From the HTM a neutropenic patient or patient awaiting transplant would only require to be in a single room if the pressure was at 10 Pa above the corridor is this correct?
- If the 4 bed bay is at 10Pa above the corridor does this confer any advantageous with respect to balanced pressures in protecting the patients in the bay from each other or not?
- Will the air changes per hour in the critical care corridor circulation space be 10 as well?
- Are our clean and dirty utilities at the correct pressures and air changes?

I will sleep on it and get back to you if I have more questions.

Regards
Julie

NHSL OUTCOMES EXPECTED FROM AHU RELATED WORKS: AHU 02-06 REVIEW 27/09/19

Numbers in brackets represent corresponding number on IOM issues log, letters in brackets represent items identified communicated during HFS audit walkround

1. (29) Cabling inside AHU's – NHSL preference is for these to be removed in compliance with SHTM 03-01, Part A clause, 4.12. IHSL to demonstrate that any alternative solution meets or betters this requirement.
    - Does any of this work affect or invalidate any warranties
    - Does the containment of the cables produce thermal risk to the insulation of the cables or connectors particularly in the vicinity of the heater battery
    - Electrical safety labelling to be applied to the containment
    - Has electrical testing been carried out with the containment in place
    - What maintenance will be in place to check and repair seals around the edges on a regular/frequent basis
    - Can consistency of workmanship be guaranteed for all units
    - Does the method of sealing present an additional infection risk
    - Is there a potential for condensation to form within the containment
    - Local isolator in difficult to reach location
2. (30) Filter pleat orientation – To be rectified as part of AHU works
    - **CLOSED**
3. (31) Pre filters showing signs of bypass – To be rectified as part of AHU works
    - Provide means to secure pre filters in place that does not allow gaps to form between each column of filters and minimises gap at end of filter tray
4. (39) Motorised dampers take a long time to close – To be rectified as part of AHU works
    - MPX to confirm when this will be done
5. (40) Plant labelling incorrect – To be rectified as part of AHU works
    - **CLOSED**
6. (43) Motors running 95% – MPX to provide report showing actual versus max capacity, if issues arise a new scope of works is required for item.
    - Await report from MPX
7. (50) AHU Pressure controls – With IOM for review, if issues arise a new scope of works is required for item.
    - IOM to issue written feedback, however verbally acknowledged that this item can be **CLOSED**
8. (52) Temperature control – NHSL await temperature log report and confirmation that all passing valves have been repaired or replaced. If issues arise a new scope of works is required for item.
    - Await report from MPX
9. (57) Inverters – NHSL await demonstration of proposal to remove inverters from inside AHU
    - Provide means of local isolation
    - Provide protection against ingress
    - Confirm containment is appropriately bonded and is of a standard equivalent to electrical trunking

10. (58) Dampers (backdraught) – To be rectified as part of AHU works. NHSL require demonstration that fixing method is appropriate given the number of failures
    - One damper damaged during inspection, BYES to consider implications of continued failure of these components
    - Visible dust on blades of damper
11. (60) Cleaning – NHSL await confirmation and evidence that bird droppings have been removed from the surface of AHU's and associated infrastructure (cable trays, pipework etc)
    - No evidence of droppings at this review, BYES to confirm this is complete at the specific location to which this refers
12. (61) Cleaning – NHSL await confirmation and evidence that dead rodent/bird has been removed from AHU inlet
    - No evidence of this issue at this review, BYES to confirm this is complete at the specific location to which this refers
13. (62) Cleaning – NHSL await confirmation that the internals of all AHU's have been cleaned to an appropriate standard
    - Evidence of dust on internal surfaces, ensure all AHU's are cleaned prior to inspection
14. (64) Inlet section – NHSL await confirmation that drains have been fitted to allow self draining.
    - **CLOSED**
15. (A) Air tightness – To be rectified as part of AHU works. All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage
    - Evidence of leakage from various points, please review and rectify
16. (B) AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions
    - **CLOSED**
17. (C) Position of light switches – NHSL require that light switches installed at high level are re-positioned to a convenient height from floor level.
    - MPX have confirmed that they will not move this item, BYES to confirm that they have accepted this
18. (D) Ductwork section changes – NHSL require confirmation that ductwork section changes comply with SHTM 03-01, Part A, paras 5.35 and 5.36
    - Not applicable on this unit, MPX to confirm impact on other units
19. (E) AHU Intake Louvres – NHSL require confirmation that access to intake louvre complies with SHTM 03-01, Part B, para 3.23
    - Not applicable on this unit, MPX to confirm impact on other units
20. (F) AHU Drainage – NHSL require confirmation that the borosilicate traps have been suitable cleaned and that a maintenance regime is in place to inspect and clean
    - **CLOSED**
21. (G) AHU Drainage – NHSL require confirmation that AHU drainage has appropriate fall to drain and that there is a minimum air gap of 15mm
    - Fall OK, air gap should be immediately downstream of trap

22. (H) AHU 04-07 drainage – NHSL require confirmation that brackets and impediments to the appropriate installation of drainage pipework have been removed and that pipe runs have been installed correctly
    - Not applicable on this unit, MPX to confirm work complete on unit referenced
23. (I) Air flow test points – NHSL require confirmation that appropriate and correctly labelled airflow test points are available on major branches to main ducts
    - **CLOSED**

General comment – the foregoing applies to the inspection carried out today only. It is envisaged that the same checklist will apply to each unit.

Please ensure that all future units have all above elements rectified if possible and that they have been cleaned prior to presentation for inspection

Using personal protective equipment (PPE) to control risks at work

2. Managing risk using PPE

As part of your risk assessment you should decide whether PPE is needed. Use the hierarchy of controls to make this decision.

Hierarchy of controls

PPE should be the last resort to protect against risks. Consider controls in the following order, with elimination being the most effective and PPE being the least effective:

- Elimination – physically remove the hazard
- Substitution – replace the hazard
- Engineering controls – isolate people from the hazard
- Administrative controls – change the way people work
- PPE – protect the worker with equipment

You must select equipment carefully. Make sure all workers are trained to use it properly and know how to detect and report any faults.

Queen Elizabeth University Hospital

Isolation Rooms

Report 2016 D 0.05

Ian Storrar

1. Introduction

1. Health Facilities Scotland (HFS) were contacted by Mr D Loudon , Director of Facilities and Capital Planning of NHS Greater Glasgow and Clyde (NHS GGC), to give an opinion on the suitability of the isolation rooms at the isolation rooms at the Queen Elizabeth University Hospital (QEUH) in Glasgow, with reference to the scope noted below.
2. HFS and NHS GGC met at QEUH on 13th June 2016 to discuss the scope of this report and visit an isolation room.
3. The scope was agreed as follows:-
    - Review client briefing information
    - Review design documentation
    - Review as installed information
    - Review commissioning information
    - Engage colleagues from Health Protection Scotland (HPS) as necessary
    - Comment on the isolation room designs with respect to published guidance and the client briefing information
    - Is the ventilation design criteria set out in SHPN 04 supplement 1: Isolation Facilities in Acute Settings As detailed in Table 1: Isolation Suite – Ventilation Parameters and Sheet 2: New build single room with en-suite facilities and bed-access lobby (isolation suite), suitable for safe nursing of patients with the one of the following conditions?
        - Multi Drug Resistant TB (MDRTB)
        - MERS
        - H1N1
4. The two main design guidance documents current at the time of design for isolation rooms are
    - SHPN 04 Supplement 1 dated September 2008
    - HBN 04-01 Supplement 1 dated 2005. (Note: this document is superseded by the 2015 version, specifically the guidance therein that relates to rooms used for source isolation. It does not supersede the guidance on protective isolation). Most of the documents cite HBN 04 Supplement 1 as the design guidance and the 2005 version will be used to check the various aspects of the design and as installed information as this was current at the time of design. It should be noted that Scottish Design Guidance should take precedence over any equivalent English (or other) Design Guidance if it is available.

5. Both HPN 04-01 supplement 1 (2005) and SHPN 04 supplement 1 (2008) advise "This supplement does not describe the specialist facilities required in infectious disease units or on wards where severely immuno-compromised patients are nursed. Guidance for these facilities will follow in a further supplement to HBN 4". The Department of Health (DoH) has not provided this additional documentation to date.
6. To enable this report to be concluded in full some additional information is required from NHS GGC to allow a more comprehensive assessment of the physical and environmental conditions. The suggested additional information is noted in Appendix 2.
7. HPS have provided commentary on this report based on the information received from NHS GGC and the notes contained within this report. To provide expert opinion on the possible use of the isolation rooms for highly infectious patients would require further work by HPS in collaboration with HFS and NHSGGC.

2. Review of Documentation provided by NHS GGC

1. The documents provided by NHS GGC for review are listed in Appendix 1
2. From the information provided there are a combination of single isolation rooms without lobbies and isolation suites with lobbies. Additionally there appears to be rooms noted as isolation rooms which do not have en-suite facilities.
3. The document "NSGACL Critical Care NSG_iss1_rev - Clinical Output Spec" clause 2.1.1 notes that the Intensive Care Unit (ICU) shall have 20 beds in two pods of ten, 2 of which are single rooms with gowning lobbies and the remainder of which (18) are single bed rooms with glass frontage. This clause also notes that the facility will "need to meet all current Scottish Health Planning / Health Building Note on radiological protection issues and Health Board Radiological Protection Officer advice." Clause 2.1.1 also notes that all patient rooms must have access to natural light. Clause 7.2 notes that the Environmental and Services Requirements "should correspond to the relevant SPHNs, HTMs and other technical guidance and the technical output specification for this project." The specific requirements of the isolation rooms from a clinical perspective are outlined in Clause 8. Clause 8.1 notes that for intensive care (level 3) single rooms and lobbies are required for isolation.
4. The room datasheet (RDS) document RDS - NA-SZ-01-RD-400-CCW_B, details the specific requirements for the isolation rooms amongst others. This notes that the mechanical services ventilation provision should be to HBN 04-01 Supplement 1.
5. Considering the drawings provided for the isolation room lobby (NA-SZ-XX-AS-400-126 and NA-SZ-XX-AS-400-126_Z1) against the requirements of HBN 04-01 Supplement 1, it is noted that whilst the majority of items are provided, the following are not:
    - Storage for "other" clean PPE (plastic apron, glove and mask storage provided)
    - Storage for room cleaning equipment
    - Facilities for completing and storing log books
6. Detailed drawings for isolation rooms with en-suites were not provided therefore no comment can be made.
7. Considering the drawings for the isolation rooms which were provided (NA-SZ-XX-AS-400-127-01 and NA-SZ-XX-AS-400-127-01_Z1), they show rooms with no en-suite as part of the design. This arrangement is also shown on schematic ZBP-XX-XX-SC-524-707 B. This

arrangement is not part of HBN 04-01 Supplement 1, which notes that an en-suite is a key consideration and provides a simple cost effective way to provide isolation. It is not clear from the information provided where these rooms are, as those isolation rooms identified in 2.2 above have en-suites.

8. In general, the air handling units serving the isolation rooms supply and extract air from other rooms (non-isolation rooms). A common supply is permissible under the guidance in HBN 04-01 Supplement 1; there is no information provided on the control strategy to ensure that the supply system will deliver constant volume depending on the demand.
9. The ventilation extract from the isolation room en-suites and the isolation rooms themselves are extracted via a separate system which would appear to terminate at a louver on the side of the building. HBN 04-01 Supplement 1 notes that this extract should terminate at roof level at least 3m above the building height. It is not clear from the information provided if all the extract fans are supplied from the "essential" side of the electrical distribution or if they have any safe change housings for changing filters.
10. The recoded magnehelic gauges for the isolation rooms, with the exception of Lobby ID GW3-051 (Bed 16) read 10 Pa or above. The noted unit was recorded as 9.0 Pa. HBN 01 Supplement 1 permits a positive pressure between 8Pa and 12 Pa.
11. The room leakage test carried out and reported by the specialist contractor, RSK Environment Limited, indicate that they meet the leakage parameters set out in HBN 04-Suppliemnt 1.
12. There is no confirmation in the commissioning data provided that the rooms or the en-suites meet the required air change rates.

3. Conclusions and recommendations

1. It is clear that in HBN-04 Supplement 1 that the design of the isolation suits is based on a validated design, which was carried out by BSRIA for DoH. The drawings provided appear to show that the isolation rooms at QEUH do not, in some instances, meet the requirements of the guidance in the following respects :-
    - Some isolation suite extract ventilation would appear to terminate behind louvers on the facade
    - Some extract ventilation would appear to terminate in formed turrets above plant rooms.
    - Isolation suites may have been provided without en-suite facilities.
    - Log books not available in lobbies

Recommendations

2. As stated in both HBN 04-01 Supplement 1 (and SHPN 04 Supplement 1), "this supplement does not describe the specialist facilities required in infectious disease units or on wards where severely immuno-compromised patients are nursed. Guidance for these facilities will follow in a further supplement to HBN 4." The Department of Health (DoH) have confirmed that the additional guidance noted was never produced and there are no plans in place for it to be produced as part of their guidance review. Therefore, to provide a more detailed

response to the safe nursing of patients with certain conditions this additional guidance may be required. In conjunction with colleagues from HPS we are preparing a SBAR and bid to Scottish Antimicrobial Resistance and Healthcare Associated Infection group (SARHAI) to provide advice and guidance for these patients.

3. Without complete information on the isolation rooms to be reviewed it is not possible for HPS to provide a comprehensive response to NHSGGC regarding the suitability of the rooms to care for highly infectious or infectious patients. With the limited information available HPS would recommend;
    - That the isolation rooms with positive pressure lobbies and en-suites are not used for highly infectious/infectious patients. The positive pressures recorded in the lobby meets the parameters laid out in HBN 04-01 Supplement 1. Leak tests also confirmed met the leakage parameters set out in HBN 04-01 Suppliement 1. However no air changes information is available for the room and en-suite itself so we cannot advise if the rooms meet expected or safe standards.
    - That rooms without lobbies are not used for highly infectious/infectious patients. At this time as we do not have air changes information and cannot be confident that the risk of cross transmission of infection from the room via the ventilation system cannot be excluded.
    - That rooms without en-suite facilities are not used for the care of highly infectious/infectious patients as advised within the HBN 04-01 Supplement 1, which notes that an en-suite is a key consideration and provides a simple cost effective way to provide isolation. Using rooms without en-suite facilities risks possible cross transmission of infection as alternative methods for toilet facilities and personal hygiene must be made.
    - That NHSGGC provide the requested information to allow HPS/HFS to provide a more detailed appraisal of the current isolation room facilities and suitability for use, which may include some on-site collaborative working.
    - That HPS and HFS, in line with previous work, visit NHSGGC and review the isolation rooms in question and all associated building and commissioning information to provide an SBAR on the suitability of the rooms as requested by NHSGGC.
    - Caring for highly infectious/infectious patients within the QEUH should be undertaken using a risk assessment for patient placement until a full appraisal of the isolation rooms is complete and recommendations provided.

NICE guideline

Tuberculosis

NICE guideline
Published: 13 January 2016
Last updated: 12 September 2019

www.nice.org.uk/guidance/ng33

Your responsibility

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals and practitioners are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or the people using their service. It is not mandatory to apply the recommendations, and the guideline does not override the responsibility to make decisions appropriate to the circumstances of the individual, in consultation with them and their families and carers or guardian.

All problems (adverse events) related to a medicine or medical device used for treatment or in a procedure should be reported to the Medicines and Healthcare products Regulatory Agency using the Yellow Card Scheme.

Local commissioners and providers of healthcare have a responsibility to enable the guideline to be applied when individual professionals and people using services wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with complying with those duties.

Commissioners and providers have a responsibility to promote an environmentally sustainable health and care system and should assess and reduce the environmental impact of implementing NICE recommendations wherever possible.

Contents

This guideline replaces CG117 and PH37.

This guideline is the basis of QS141.

Overview

This guideline covers preventing, identifying and managing latent and active tuberculosis (TB) in children, young people and adults. It aims to improve ways of finding people who have TB in the community and recommends that everyone under 65 with latent TB should be treated. It describes how TB services should be organised, including the role of the TB control board.

Who is it for?

- Healthcare professionals and TB multidisciplinary teams
- Substance misuse services, prisons and immigration removal centres
- Local government and commissioners
- TB control boards, directors of public health and public health consultants
- Public Health England and NHS England
- Voluntary sector workers
- People with TB and their carers

Recommendations

People have the right to be involved in discussions and make informed decisions about their care, as described in making decisions about your care.

Making decisions using NICE guidelines explains how we use words to show the strength (or certainty) of our recommendations, and has information about prescribing medicines (including off-label use), professional guidelines, standards and laws (including on consent and mental capacity), and safeguarding.

1.1 Preventing TB

1.1.1 Raising and sustaining awareness of TB

Among health professionals and those working with high-risk groups

1.1.1.1 Multidisciplinary TB teams (in collaboration with Public Health England, primary care, the voluntary sector and Health Education England) should identify and support an ongoing TB education programme for local professionals in contact with the general public, and at-risk groups in particular. This includes, for example, staff in emergency departments, GPs and wider primary care staff, people who work in housing support services, staff who support migrants and those working in walk-in centres, hostels, substance misuse projects and prisons. **[2012, amended 2016]**

1.1.1.2 Multidisciplinary TB teams should ensure the education programme increases other professionals' awareness of the possibility of TB and reduces the stigma associated with it. The programme should include detail on:

- causes of TB, how it is transmitted, and the signs and symptoms
- lifestyle factors that may mask symptoms

- local epidemiology, highlighting under-served groups, other high-risk groups and the fact that TB also occurs in people without risk factors
- principles of TB control:
  - early diagnosis and active case-finding
  - how to support treatment (including directly observed therapy)
  - drug resistance
  - awareness of drug interactions (including factors such as effect on contraception efficacy)
  - contact investigation after diagnosing an active case
  - the importance of adhering to treatment
  - treatment for TB is free for everyone (irrespective of eligibility for other NHS care)
  - social and cultural barriers to accessing health services (for example, fear of stigma and staff attitudes)
  - local referral pathways, including details of who to refer and how
  - the role of allied professionals in awareness-raising, identifying cases and helping people complete treatment
  - misinformation that causes fear about TB, including concerns about housing people with the condition
- the best ways to effectively communicate all the above topics with different groups. **[2012, amended 2016]**

1.1.1.3 Statutory, community and voluntary organisations and advocates working with the general public, and under-served and high-risk groups in particular, should share information on TB education and awareness training with all frontline staff. (They should get information on this from the local multidisciplinary TB team.) **[2012, amended 2016]**

1.1.1.4 If possible, statutory, community and voluntary organisations should ensure peers from under-served groups and anyone else with experience

of TB contribute to, or lead, awareness-raising activities. (Peers who lead such activities will need training and support.) **[2012, amended 2016]**

Among high-risk groups

1.1.1.5 Multidisciplinary TB teams should help professionals working in relevant statutory, community and voluntary organisations to raise awareness of TB among under-served and other high-risk groups. These professionals should be able to explain that treatment for TB is free and confidential for everyone (irrespective of eligibility for other NHS care). They should also be able to provide people with details of:

- how to recognise symptoms in adults and children
- how people get TB
- the benefits of diagnosis and treatment (including the fact that TB is treatable and curable)
- location and opening hours of testing services
- referral pathways, including self-referral
- the potential interaction of TB medication with other drugs, for example, oral contraceptives and opioids (especially methadone) and HIV treatment
- TB/HIV co-infection
- how to address the myths about TB infection and treatment (for example, to counter the belief that TB is hereditary)
- how to address the stigma associated with TB
- the risk of migrants from high-incidence countries developing active TB, even if they have already screened negative for it
- contact tracing. **[2012, amended 2016]**

1.1.1.6 Multidisciplinary TB teams and others working with at-risk groups should use high quality material to raise awareness of TB (see section 1.1.2). **[2012, amended 2016]**

1.1.1.7 Multidisciplinary TB teams and others working with the general public, and with under-served and other high-risk groups in particular, should include information on TB with other health-related messages and existing health promotion programmes tailored to the target group. **[2012, amended 2016]**

1.1.1.8 Multidisciplinary TB teams should work in partnership with voluntary organisations and 'community champions' to increase awareness of TB, in particular among under-served groups at risk of infection but also in the general population. If possible, peers who have experience of TB should contribute to awareness-raising activities and support people in treatment. **[2012, amended 2016]**

1.1.2 Providing information for the public about TB

1.1.2.1 National organisations (for example, National Knowledge Service: Tuberculosis, TB Alert, Public Health England, Department of Health and NHS Choices) should work together to develop generic, quality-assured template materials with consistent up-to-date messages. These materials should be made freely available and designed so that they can be adapted to local needs. **[new 2016]**

1.1.2.2 Multidisciplinary TB teams should use these templates for general awareness raising and targeted activities in under-served and other high-risk groups. Involve the target group in developing and piloting the materials. **[new 2016]**

1.1.2.3 The content of any materials should:

- be up-to-date and attractively designed, including pictures and colour if possible
- be culturally appropriate, taking into account the language, actions, customs, beliefs and values of the group they are aimed at
- be tailored to the target population's needs
- include risks and benefits of treatment, and how to access services, advice and support

- dispel myths
- show that, by deciding to be tested and treated for TB, a person can be empowered to take responsibility for their own health
- use language that encourages the person to believe that they can change their behaviour
- be simple and succinct. **[new 2016]**

1.1.2.4 Make the material available in a range of formats such as written, braille, text messages, electronic, audio (including podcasts), pictorial and video. Make them freely available in a variety of ways, for example, online, as print materials or on memory sticks. **[new 2016]**

1.1.2.5 Disseminate materials in ways likely to reach target groups, for example, via culturally specific radio or TV stations, at shelters, and at community, commercial or religious venues that target groups attend regularly. **[new 2016]**

1.1.3 BCG vaccination

1.1.3.1 To improve the uptake of BCG vaccination, identify eligible groups (in line with the Department of Health's Green Book) opportunistically through several routes, for example:

- new registrations in primary care and with antenatal services, or other points of contact with secondary or tertiary care
- people entering education, including university
- links with statutory and voluntary groups working with new entrants and looked-after children and young people
- during contact investigations. **[new 2016]**

1.1.3.2 When BCG vaccination is being recommended, discuss the benefits and risks of vaccination or remaining unvaccinated with the person (or, if a child, with the parents), so that they can make an informed decision. Tailor this discussion to the person, use appropriate language, and take into account cultural sensitivities and stigma. **[2006]**

1.1.3.3 If people identified for BCG vaccination through occupational health, contact tracing or new entrant screening are also considered to be at increased risk of being HIV-positive, offer them HIV testing before BCG vaccination. **[2006]**

BCG vaccination in neonates (0 to 4 weeks)

1.1.3.4 Identify babies eligible for vaccination (in line with the Green Book) before birth, ideally through antenatal services. **[new 2016]**

1.1.3.5 Discuss neonatal BCG vaccination for any baby at increased risk of TB with the parents or legal guardian. **[2006]**

1.1.3.6 Preferably vaccinate babies at increased risk of TB before discharge from hospital or before handover from midwifery to primary care. Otherwise, vaccinate as soon as possible afterwards, for example, at the 6-week postnatal check. **[new 2016]**

1.1.3.7 Incorporate computer reminders into maternity service (obstetrics) IT systems for staff, to identify and offer BCG vaccination to babies eligible for vaccination. **[new 2016]**

1.1.3.8 Provide education and training for postnatal ward staff, midwives, health visitors and other clinicians on identifying babies eligible for vaccination, local service information and providing BCG vaccination, including:

- case definition for at-risk groups to be offered vaccination
- information about the local BCG vaccination policy that can be given verbally, in writing or in any other appropriate format (see sections 1.1.1 and 1.1.2) to parents and carers at the routine examination of the baby before discharge
- local service information about BCG vaccination, such as pre-discharge availability of neonatal vaccination, local BCG clinics and referral for BCG vaccination if this is not available in maternity services
- administration of BCG vaccination and contraindications. **[new 2016]**

1.1.3.9 Primary care organisations with a high incidence of TB should consider vaccinating all neonates soon after birth. **[2006]**

1.1.3.10 In areas with a low incidence of TB (see Public Health England's TB rate bands, published in their annual tuberculosis report), primary care organisations should offer BCG vaccination to selected neonates who:

- were born in an area with a high incidence of TB **or**
- have 1 or more parents or grandparents who were born in a high-incidence country **or**
- have a family history of TB in the past 5 years. **[2006, amended 2016]**

BCG vaccination for infants (0 to 5 years) and older children (6 to 15 years)

1.1.3.11 Routine BCG vaccination is not recommended for children aged 10 to 14 years.

- Healthcare professionals should opportunistically identify unvaccinated children older than 4 weeks and younger than 16 years at increased risk of TB who would have qualified for neonatal BCG (see recommendation 1.1.3.4) and provide Mantoux testing (see the section on diagnosing latent TB in children and young people) and BCG vaccination (if Mantoux-negative).

  At the time of publication (January 2016) the BNF states: 'The Mantoux test is recommended for tuberculin skin testing, but no licensed preparation is currently available.' For further guidance, see immunisation against infectious disease (the Green book).

- This opportunistic vaccination should be in line with the Green Book. **[2006, amended 2016]**

1.1.3.12 Mantoux testing should not be done routinely before BCG vaccination in children younger than 6 years unless they have a history of residence or prolonged stay (more than 1 month) in a country with a high incidence of TB. **[2006]**

BCG vaccination for new entrants from high-incidence areas

1.1.3.13 Offer BCG vaccination to new entrants who are Mantoux-negative who:

- are from high-incidence countries **and**

- are previously unvaccinated (that is, without adequate documentation or a BCG scar) **and**
- are aged:
  - younger than 16 years **or**
- 16 to 35 years from sub-Saharan Africa or a country with a TB incidence of 500 per 100,000 or more. **[2006, amended 2016]**

Encouraging uptake among infants, older children and new entrants

1.1.3.14 Deliver the following interventions in primary care settings to improve uptake of BCG vaccination in people from eligible groups (as outlined in the Green Book):

- education and support for practice staff, including:
  - raising awareness of relevant guidelines and case definition for at-risk groups
  - promoting BCG and TB testing in eligible groups
- incorporating reminders for staff (prompts about eligibility for BCG) on practice computers (for example, embedded in medical records)
- consider financial incentives for practices for identifying eligible groups for BCG and TB testing
- reminders ('immunisations due') and recall ('immunisations overdue') for people who are eligible for vaccination or for parents of infants and children who are eligible, as outlined in the Green Book. (This could include written reminders, telephone calls from a member of staff or a computerised auto dialler, text messages or a combination of these approaches.) **[new 2016]**

1.1.3.15 Use home visits to give information and advice to people who are disadvantaged on the importance of immunisation. This should be delivered by trained lay health workers, community-based healthcare staff or nurses. **[new 2016]**

BCG vaccination for healthcare workers

1.1.3.16 Offer BCG vaccination to healthcare workers and other NHS employees as advised in the Green Book. **[2006, amended 2016]**

BCG vaccination for contacts of people with active TB

1.1.3.17 Offer BCG vaccination to Mantoux-negative contacts of people with pulmonary and laryngeal TB (see the section on diagnosing latent TB in all age groups) if they:

- have not been vaccinated previously (that is, there is no adequate documentation or a BCG scar) **and**
- are aged 35 years or younger **or**
- are aged 36 years and older and a healthcare or laboratory worker who has contact with patients or clinical materials. **[2006, amended 2016]**

BCG vaccination for other groups

1.1.3.18 Offer BCG vaccination to previously unvaccinated, Mantoux-negative people aged 35 years or younger in the following groups at increased risk of exposure to TB, in accordance with the Green Book:

- veterinary and other staff such as abattoir workers who handle animal species known to be susceptible to TB, such as simians
- prison staff working directly with prisoners
- staff of care homes for older people
- staff of hostels for people who are homeless and facilities accommodating refugees and asylum seekers
- people going to live or work with local people for more than 3 months in a high-incidence country. **[2006, amended 2016]**

1.1.4 Preventing infection in specific settings

Healthcare environments: new NHS employees

1.1.4.1 Employees new to the NHS who will be working with patients or clinical specimens should not start work until they have completed a TB screen or health check, or documentary evidence is provided of such screening having taken place within the preceding 12 months. **[2006]**

1.1.4.2 Employees new to the NHS who will not have contact with patients or clinical specimens should not start work if they have signs or symptoms of TB. **[2006]**

1.1.4.3 Health checks for employees new to the NHS who will have contact with patients or clinical materials should include:

- assessment of personal or family history of TB
- asking about symptoms and signs, possibly by questionnaire
- documentary evidence of TB skin (or interferon-gamma release assay) testing within the past 5 years and/or BCG scar check by an occupational health professional, not relying on the applicant's personal assessment. **[2006]**

1.1.4.4 See the section on healthcare workers for screening new NHS employees for latent TB. **[2006, amended 2011]**

1.1.4.5 Employees who will be working with patients or clinical specimens and who are Mantoux- or interferon-gamma release assay-negative (see section 1.2.1) should have an individual risk assessment for HIV infection before BCG vaccination is given. **[2006, amended 2016]**

1.1.4.6 Offer BCG vaccination to employees of any age who are new to the NHS and are from countries of high TB incidence, or who have had contact with patients in settings with a high TB prevalence, and who are Mantoux-negative. **[2006, amended 2011]**

1.1.4.7 If a new employee from the UK or other low-incidence setting, who has not had a BCG vaccination, has a positive Mantoux test and a positive

interferon-gamma release assay, they should have a medical assessment and a chest X-ray. They should be referred to a TB clinic to determine whether they need TB treatment if the chest X-ray is abnormal, or to determine whether they need treatment of latent TB infection if the chest X-ray is normal. **[2006, amended 2011, amended 2016]**

1.1.4.8 If a prospective or current healthcare worker who is Mantoux-negative (see the section on healthcare workers) declines BCG vaccination, explain the risks and supplement the oral explanation with written advice. If the person still declines BCG vaccination, he or she should not work where there is a risk of exposure to TB. The employer will need to consider each case individually, taking account of employment and health and safety obligations. **[2006, amended 2016]**

1.1.4.9 Screen clinical students, agency and locum staff and contract ancillary workers who have contact with patients or clinical materials for TB to the same standard as new employees in healthcare environments, according to the recommendations set out above. Seek documentary evidence of screening to this standard from locum agencies and contractors who carry out their own screening. **[2006]**

1.1.4.10 NHS trusts arranging care for NHS patients in non-NHS settings should ensure that healthcare workers who have contact with patients or clinical materials in these settings have been screened for TB to the same standard as new employees in NHS settings. **[2006]**

Healthcare environments: occupational health

1.1.4.11 Include reminders of the symptoms of TB, and the need for prompt reporting of such symptoms, with annual reminders about occupational health for staff who:

- are in regular contact with TB patients or clinical materials **or**
- have worked in a high-risk clinical setting for 4 weeks or longer.

Give one-off reminders after a TB incident on a ward. **[2006]**

1.1.4.12 If no documentary evidence of previous screening is available, screen

staff in contact with patients or clinical material who are transferring jobs within the NHS as for new employees (see recommendations 1.2.1.5 to 1.2.1.7 in the section on healthcare workers). **[2006]**

1.1.4.13 Assess the risk of TB for a new healthcare worker who knows he or she is HIV-positive at the time of recruitment as part of the occupational health checks. **[2006]**

1.1.4.14 The employer, through the occupational health department, should be aware of the settings with increased risk of exposure to TB, and that these pose increased risks to HIV-positive healthcare workers. **[2006]**

1.1.4.15 Healthcare workers who are found to be HIV-positive during employment should have medical and occupational assessments of TB risk, and may need to modify their work to reduce exposure. **[2006]**

1.2 Latent TB

1.2.1 Diagnosing latent TB in adults

1.2.1.1 Offer Mantoux testing to diagnose latent TB in adults aged 18 to 65 who are close contacts of a person with pulmonary or laryngeal TB.

- If the Mantoux test is inconclusive, refer the person to a TB specialist.
- If the Mantoux test is positive (an induration of 5 mm or larger, regardless of BCG history) assess for active TB (see the sections on diagnosing active TB in all age groups, diagnosing pulmonary (including laryngeal) TB in all age groups, diagnosing pulmonary (including laryngeal) TB in adults and diagnosing extrapulmonary TB in all age groups).
- If the Mantoux test is positive but a diagnosis of active TB is excluded, consider an interferon gamma release assay if more evidence of infection is needed to decide on treatment. This could be, for example, if the person needs enhanced case management or if there could be adverse events from treatment.

- If the Mantoux is positive, and if an IGRA was done and that is also positive, offer them treatment for latent TB infection (see the sections on managing latent TB in all age groups and managing latent TB in adults).

  At the time of publication (January 2016) the BNF states: 'The Mantoux test is recommended for tuberculin skin testing, but no licensed preparation is currently available.' For further guidance, see immunisation against infectious disease (the Green book).**[2011, amended 2016]**

Adults who are immunocompromised

1.2.1.2 In adults who are anticipated to be or are currently immunocompromised, do a risk assessment to establish whether testing should be offered, taking into account their:

- risk of progression to active TB based on how severely they are immunocompromised and for how long they have been immunocompromised
- risk factors for TB infection, such as country of birth or recent contact with an index case with suspected infectious or confirmed pulmonary or laryngeal TB. **[new 2016]**

1.2.1.3 For adults who are severely immunocompromised, such as those with HIV and CD4 counts of fewer than 200 cells/mm^3, or after solid organ or allogeneic stem cell transplant, offer an interferon-gamma release assay and a concurrent Mantoux test.

- If either test is positive (for Mantoux, this is an induration of 5 mm or larger, regardless of BCG history), assess for active TB.
- If this assessment is negative, offer them treatment for latent TB infection. **[new 2016]**

1.2.1.4 For other adults who are immunocompromised, consider an interferon-gamma release assay alone or an interferon-gamma release assay with a concurrent Mantoux test.

- If either test is positive (for Mantoux, this is an induration of 5 mm or larger, regardless of BCG history), assess for active TB.

- If this assessment is negative, offer them treatment for latent TB infection. **[new 2016]**

Healthcare workers

1.2.1.5 Offer a Mantoux test to new NHS employees who will be in contact with patients or clinical materials, if the employees:

- are not new entrants from high-incidence countries **and**
- have not had BCG vaccination (for example, they are without a BCG scar, other documentation or a reliable history).

  If the Mantoux test is positive, offer an interferon-gamma release assay. If this is positive, assess for active TB; if this assessment is negative, offer them treatment for latent TB infection. **[2011, amended 2016]**

1.2.1.6 Offer a Mantoux test to new NHS employees who are from a high-incidence country.

- If the Mantoux test is positive (5 mm or larger, regardless of BCG history), assess for active TB; if this assessment is negative, offer them treatment for latent TB infection.
- If Mantoux testing is unavailable, offer an interferon-gamma release assay. **[new 2016]**

1.2.1.7 Offer an interferon-gamma release assay to new NHS employees who have had contact with patients in settings where TB is highly prevalent:

- If the interferon-gamma release assay is positive, assess for active TB **and**
- if this assessment is negative, offer them treatment for latent TB infection. **[2011, amended 2016]**

1.2.1.8 Healthcare workers who are immunocompromised should be screened in the same way as other people who are immunocompromised (see recommendations 1.2.1.2 to 1.2.1.4). **[2011]**

1.2.2 Diagnosing latent TB in children and young people

1.2.2.1 Only consider using interferon-gamma release assays alone in children and young people if Mantoux testing is not available or is impractical. This includes for example, situations in which large numbers need to be tested (see the section on incident and outbreak response and recommendation 1.2.3.2). **[new 2016]**

1.2.2.2 Refer children younger than 2 years and in close contact with people with smear-negative pulmonary or laryngeal TB to a specialist to determine what testing strategy for latent TB should be done. This should be a paediatrician with experience and training in TB, or a general paediatrician with advice from a specialised clinician. **[new 2016]**

1.2.2.3 If a neonate has been in close contact with people with smear-positive pulmonary or laryngeal TB who have not had at least 2 weeks of anti-TB treatment:

- Assess for active TB (see the sections on diagnosing active TB in all age groups, diagnosing pulmonary (including laryngeal) TB in all age groups and diagnosing pulmonary (including laryngeal) TB in children and young people).
- Start isoniazid (with pyridoxine).
- Carry out a Mantoux test after 6 weeks of treatment.
- If the Mantoux test is inconclusive, refer the child to a TB specialist.
- If the Mantoux test is positive (5 mm or larger, regardless of BCG history), reassess for active TB; if this assessment is negative, continue isoniazid (with pyridoxine) for a total of 6 months.
- If the Mantoux test is negative, reassess for active TB and consider an interferon-gamma release assay:
  - if the interferon-gamma release assay is negative then stop isoniazid (and pyridoxine) and give a BCG vaccination
  - if the interferon-gamma release assay is positive, reassess for active TB; if this assessment for active TB is negative, continue isoniazid (with pyridoxine) for a total of 6 months. **[new 2016]**

1.2.2.4 If a child aged between 4 weeks and 2 years has been in close contact with people with smear-positive pulmonary or laryngeal TB who have not had at least 2 weeks of anti-TB treatment:

- Assess for active TB.
- Start treatment for latent TB (see the sections on managing latent TB in all age groups and managing latent TB in children and young people) and carry out a Mantoux test.
- If the Mantoux test is inconclusive, refer the child to a TB specialist.
- If the Mantoux test is positive (5 mm or larger, regardless of BCG history), reassess for active TB; if this assessment is negative, complete treatment for latent TB.
- If the Mantoux test is negative, continue treatment for latent TB, reassess for active TB after 6 weeks and repeat the Mantoux test:
  - if the Mantoux test is negative, consider an interferon-gamma release assay
  - if the interferon-gamma release assay is negative, treatment for latent TB may be stopped; give a BCG vaccination if the child has not already had one
  - if either test is positive, reassess for active TB; if this assessment is negative, complete treatment for latent TB. **[new 2016]**

1.2.2.5 If a child or young person aged between 2 and 17 years has been in close contact with people with pulmonary or laryngeal TB:

- Offer Mantoux testing.
- If the Mantoux test is inconclusive, refer the child or young person to a TB specialist.
- If the Mantoux test is positive (5 mm or larger, regardless of BCG history), assess for active TB; if this assessment is negative, offer them treatment for latent TB infection.

- If the initial Mantoux test is negative, offer an interferon-gamma release assay after 6 weeks and repeat the Mantoux test. **[new 2016]**

Immunocompromised children and young people

1.2.2.6 If latent TB is suspected in children and young people who are anticipated to be or are currently immunocompromised (for example, if they are from a high incidence country or have been in close contact with people with suspected infectious or confirmed pulmonary or laryngeal TB), refer to a TB specialist. **[2016]**

1.2.3 Diagnosing latent TB in all age groups

New entrants from high-incidence countries

1.2.3.1 Offer Mantoux testing as the initial diagnostic test for latent TB infection in people who have recently arrived from a high-incidence country who present to healthcare services. If the Mantoux test is positive (5 mm or larger, regardless of BCG history):

- assess for active TB (see recommendations 1.3.1 to 1.3.5 in the section on active TB) **and**
- if this assessment is negative, offer them treatment for latent TB infection (see the section on managing latent TB in all age groups to the section on managing latent TB in children and young people).

  If Mantoux testing is unavailable, offer an interferon-gamma release assay. **[new 2016]**

Contacts: incident situation

1.2.3.2 In an incident situation when large numbers of people may need to be screened, consider a single interferon-gamma release assay for people aged 18 to 65 years. For children and young people, follow the recommendations in the sections on diagnosing latent TB in children and young people and immunocompromised children and young people. **[2011, amended 2016]**

Under-served groups

1.2.3.3 Offer people younger than 65 years from under-served groups a single interferon-gamma release assay. **[2011, amended 2016]**

1.2.3.4 Substance misuse services with access to an interferon-gamma release assay should provide testing for people younger than 65 years who misuse substances if they:

- live in a high incidence area
- are likely to be involved with substance misuse services or other support services on a regular basis (for example, for opioid substitution therapy), when support should be available for directly observed preventive therapy. **[2012, amended 2016]**

1.2.3.5 In high incidence areas (and at prisons that receive prisoners from high incidence areas), prison health services should offer an interferon-gamma release assay for TB to inmates younger than 65 years who are in regular contact with substance misuse services or other support services. This is provided arrangements have been made for this support to continue after release. **[2012, amended 2016]**

1.2.3.6 Substance misuse services and prison health services should incorporate interferon-gamma release assay testing with screening for hepatitis B and C, and HIV testing. They should refer prisoners and people who misuse substances with positive interferon-gamma release assays to local multidisciplinary TB teams for further clinical investigations. For prisoners, these investigations should be done in the prison if practically possible. **[2012, amended 2016]**

1.2.3.7 If the interferon-gamma release assay is positive, assess for active TB (see the sections on diagnosing active TB in all age groups to diagnosing extrapulmonary TB in all age groups); if this assessment is negative, offer them treatment for latent TB infection (see sections on managing latent TB in all age groups to managing latent TB in children and young people). **[new 2016]**

1.2.4 Managing latent TB in all age groups

1.2.4.1 Be aware that certain groups of people with latent TB are at increased risk of going on to develop active TB, including people who:

- are HIV-positive
- are younger than 5 years
- have excessive alcohol intake
- are injecting drug users
- have had solid organ transplantation
- have a haematological malignancy
- are having chemotherapy
- have had a jejunoileal bypass
- have diabetes
- have chronic kidney disease or receive haemodialysis
- have had a gastrectomy
- are having treatment with anti-tumour necrosis factor-alpha or other biologic agents
- have silicosis. **[new 2016]**

1.2.4.2 For people, including those with HIV, aged younger than 65 years with evidence of latent TB who have been in close contact with people who have suspected infectious or confirmed active pulmonary or laryngeal drug-sensitive TB, offer either of the following drug treatments:

- 3 months of isoniazid (with pyridoxine) and rifampicin **or**
- 6 months of isoniazid (with pyridoxine). **[new 2016]**

1.2.4.3 Base the choice of regimen on the person's clinical circumstances. Offer:

- 3 months of isoniazid (with pyridoxine) and rifampicin to people younger than 35 years if hepatotoxicity is a concern after an assessment of both liver function (including transaminase levels) and risk factors
- 6 months of isoniazid (with pyridoxine) if interactions with rifamycins are a concern, for example, in people with HIV or who have had a transplant. **[new 2016]**

1.2.4.4 Clearly explain the risks and potential benefits of each treatment regimen. In discussion with the person, select a suitable regimen if they wish to proceed with preventive treatment. **[new 2016]**

1.2.4.5 If a person also has severe liver disease, for example, Child-Pugh level B or C, work with a specialist multidisciplinary team with experience of managing TB and liver disease. **[new 2016]**

1.2.4.6 Manage treatment with caution, ensuring careful monitoring of liver function, in:

- people with non-severe liver disease
- people with abnormal liver function (including abnormal transaminase levels) before starting treatment for latent TB infection
- people who misuse alcohol or drugs. **[new 2016]**

1.2.4.7 Ensure people having treatment for latent TB who also have social risk factors, such as misusing alcohol or drugs or being homeless, are linked to support services. They should also have an assessment of social needs and stability, including potential barriers to adherence or treatment completion (see the section on adherence, treatment completion and follow-up). **[new 2016]**

1.2.4.8 People in the groups listed in recommendation 1.2.4.1 who do not have treatment for latent TB, as specified in recommendations 1.2.4.2 to 1.2.4.8, for any reason should be advised of the risks and symptoms of TB (on the basis of an individual risk assessment), usually in a standard letter of the type referred to as 'Inform and advise' information (see section 1.1.2). **[new 2016]**

1.2.5 Managing latent TB in adults

1.2.5.1 For adults between the ages of 35 and 65 years, offer drug treatments only if hepatotoxicity is not a concern. **[new 2016]**

1.2.5.2 Offer testing for HIV before starting treatment for latent TB. See the NICE guidelines on increasing the uptake of HIV testing among black Africans in England and increasing the uptake of HIV testing among men who have sex with men. **[new 2016]**

1.2.5.3 Offer adults testing for hepatitis B and C before starting treatment for latent TB. See the NICE guidelines on hepatitis B and C: ways to promote and offer testing to people at increased risk of infection and hepatitis B (chronic): diagnosis and management of chronic hepatitis B in children, young people and adults. **[new 2016]**

1.2.6 Managing latent TB in children and young people

1.2.6.1 Consider testing children and young people for hepatitis B and C before starting treatment for latent TB. See the NICE guidelines on hepatitis B and C: ways to promote and offer testing to people at increased risk of infection and hepatitis B (chronic): diagnosis and management of chronic hepatitis B in children, young people and adults. **[new 2016]**

1.3 Active TB

1.3.1 Diagnosing active TB in all age groups

1.3.1.1 If TB is a possibility, microbiology staff should consider carrying out TB culture on samples (see recommendations 1.3.2.2 and 1.3.2.3), even if it is not requested. **[2006, amended 2016]**

1.3.1.2 If there are clinical signs and symptoms consistent with a diagnosis of TB, start treatment without waiting for culture results. **[2006]**

1.3.1.3 Consider completing the standard recommended regimen (see recommendations 1.3.7.2 and 1.3.7.3 in the section on standard

treatment), even if subsequent culture results are negative. **[2006, amended 2016]**

1.3.2 Diagnosing pulmonary (including laryngeal) TB in all age groups

1.3.2.1 Take a chest X-ray; do further diagnostic investigations (as detailed below and summarised in table 1) if chest X-ray appearances suggest TB. **[2016]**

1.3.2.2 Send multiple respiratory samples (3 deep cough sputum samples, preferably including 1 early morning sample) for TB microscopy and culture. **[2016]**

- This should be before starting treatment if possible or, failing that, within 7 days of starting treatment in people with life-threatening disease. **[2006, amended 2016]**
- Obtain spontaneously-produced, deep cough sputum samples if possible, otherwise use:
  - 3 gastric lavages or 3 inductions of sputum in children and young people (see recommendation 1.5.1.10 in the section on infection control in healthcare settings) **[new 2016] or**
  - induction of sputum or bronchoscopy and lavage in adults. **[2006, amended 2016]**
- Laboratory practices should be in accordance with the UK's Standards for Microbiology Investigations. **[new 2016]**

1.3.2.3 Send samples for TB culture from autopsy samples if pulmonary or laryngeal TB is a possibility. **[2006, amended 2016]**

1.3.3 Diagnosing pulmonary (including laryngeal) TB in adults

1.3.3.1 Request rapid diagnostic nucleic acid amplification tests for the *M. tuberculosis* complex (*M. tuberculosis*, *M. bovis*, *M. africanum*) on primary specimens (listed in table 1) if there is clinical suspicion of TB

disease, and:

- the person has HIV **or**
- rapid information about mycobacterial species would alter the person's care **or**
- the need for a large contact-tracing initiative is being explored. **[new 2016]**

1.3.4 Diagnosing pulmonary (including laryngeal) TB in children and young people

1.3.4.1 In children aged 15 years or younger with suspected pulmonary TB, offer rapid diagnostic nucleic acid amplification tests for the *M. tuberculosis* complex (*M. tuberculosis*, *M. bovis*, *M. africanum*). Usually only 1 nucleic acid amplification test is needed per specimen type (for example, spontaneous sputum, induced sputum or gastric lavage; see table 1). **[new 2016]**

1.3.4.2 In young people aged 16 to 18 years use the same criteria as in adults to decide whether to request rapid diagnostic nucleic acid amplification tests (see table 1). **[new 2016]**

Table 1 Diagnostic investigations for pulmonary TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests (if it would alter management)
Pulmonary (adult)	X-ray (Routine test, see recommendation 1.3.2.1.) CT thorax Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	3 respiratory samples: • preferably spontaneously-produced, deep cough sputum samples, otherwise induced sputum or bronchoscopy and lavage • preferably 1 early morning sample	Microscopy Culture Histology	Nucleic acid amplification test
Pulmonary (young people aged 16 to 17 years)	X-ray (Routine test, see recommendation 1.3.2.1.) CT thorax Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	3 respiratory samples: • preferably spontaneously-produced, deep cough sputum samples, otherwise induced sputum or gastric lavage • preferably 1 early morning sample	Microscopy Culture Histology	Nucleic acid amplification test

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests (if it would alter management)
Pulmonary (children aged 15 years or younger)	X-ray (Routine test, see recommendation 1.3.2.1.) CT thorax Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	3 respiratory samples: • preferably spontaneously-produced, deep cough sputum samples, otherwise induced sputum or gastric lavage • preferably 1 early morning sample	Microscopy Culture Histology Nucleic acid amplification tests (1 per specimen type)	Interferon-gamma release assay and/or tuberculin skin test (with expert input)

1.3.4.3 Either a paediatrician with experience and training in TB or a general paediatrician with advice from a specialised clinician should investigate and manage TB in children and young people. **[new 2016]**

1.3.4.4 An expert in paediatric TB may request interferon-gamma release assays and tuberculin skin tests. Interpret these together with other diagnostic tools (such as history taking, clinical examination and imaging). **[new 2016]**

1.3.5 Diagnosing extrapulmonary TB in all age groups

1.3.5.1 Discuss the advantages and disadvantages of both biopsy and needle aspiration with the patient, with the aim of obtaining adequate material for diagnosis. **[2006]**

1.3.5.2 Do not place part or all of any of the samples in formalin (or other fixative agent) when sending for TB culture. **[2006, amended 2016]**

1.3.5.3 Think about a diagnosis of extrapulmonary TB even if rapid diagnostic tests in, for example, cerebrospinal fluid, pleural fluid or ascitic fluid are negative. **[new 2016]**

1.3.5.4 Offer all patients presenting with extrapulmonary TB a chest X-ray and, if possible, culture of a spontaneously-produced respiratory sample to exclude or confirm coexisting pulmonary TB (see recommendations 1.3.1 to 1.3.3 in the section on active TB). Also, consider site-specific tests as described below to exclude or confirm additional sites of TB. **[new 2016]**

1.3.5.5 Refer to an expert for sites not listed here, including TB of the eye and other rare sites of disease. **[new 2016]**

Pleural TB

1.3.5.6 Use the site-specific investigations listed in table 2 to diagnose and assess pleural TB.

Table 2 Site-specific investigations for pleural TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Pleural	X-ray Bronchoscopy Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	3 respiratory samples: • preferably spontaneously-produced, deep cough sputum samples, otherwise induced sputum or gastric lavage • preferably 1 early morning sample Pleural biopsy	Microscopy Culture Histology	-
Pleural	X-ray Bronchoscopy Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Pleural fluid	Microscopy Culture Cytology	Adenosine deaminase assay

[new 2016]

Central nervous system TB

1.3.5.7 Use the site-specific investigations listed in table 3 to diagnose and assess central nervous system TB.

Table 3 Site-specific investigations for central nervous system TB

Suspected site of disease	Possible imaging techniques[a]	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Central nervous system	CT (Routine test, see recommendation 1.3.5.8) MRI (Routine test, see recommendation 1.3.5.8) Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Biopsy of suspected tuberculoma	Microscopy Culture Histology	-
Central nervous system	CT (Routine test, see recommendation 1.3.5.8) MRI (Routine test, see recommendation 1.3.5.8) Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Cerebrospinal fluid	Microscopy Culture Cytology	Adenosine deaminase assay

Suspected site of disease	Possible imaging techniques[a]	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Meningeal	CT (Routine test, see recommendation 1.3.5.8) MRI (Routine test, see recommendation 1.3.5.8) Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Cerebrospinal fluid	Microscopy Culture Cytology	Nucleic acid amplification test Adenosine deaminase assay

[new 2016]

1.3.5.8 Offer a CT or MRI scan to people in whom central nervous system involvement is suspected. **[2016]**

1.3.5.9 Offer treatment for TB meningitis if clinical signs and other laboratory findings are consistent with the diagnosis, even if a rapid diagnostic test is negative. **[new 2016]**

Lymph node TB (including intrathoracic mediastinal adenopathy)

1.3.5.10 Use the site-specific investigations listed in table 4 to diagnose and assess lymph node TB (including intrathoracic mediastinal adenopathy).

Table 4 Site-specific investigations for lymph node TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Lymph node (including intrathoracic mediastinal adenopathy)	Ultrasound CT MRI Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Biopsy	Microscopy Culture Histology	Nucleic acid amplification test
		Aspirate	Microscopy Culture Cytology	Nucleic acid amplification test

[new 2016]

Pericardial TB

1.3.5.11 Use the site-specific investigations listed in table 5 to diagnose and assess pericardial TB.

Table 5 Site-specific investigations for pericardial TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Pericardial	Echocardiogram Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Biopsy of pericardium	Microscopy Culture Histology	-
Pericardial	Echocardiogram Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Pericardial fluid	Microscopy Culture Cytology	Nucleic acid amplification test Adenosine deaminase assay

[new 2016]

Gastrointestinal TB

1.3.5.12 Use the site-specific investigations listed in table 6 to diagnose and assess gastrointestinal TB.

Table 6 Site-specific investigations for gastrointestinal TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Gastrointestinal	Ultrasound CT Laparoscopy Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Biopsy of omentum Biopsy of bowel Biopsy of liver	Microscopy Culture Histology	-
Gastrointestinal	Ultrasound CT Laparoscopy Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Ascitic fluid	Microscopy Culture Cytology	Adenosine deaminase assay

[new 2016]

Genitourinary TB

1.3.5.13 Use the site-specific investigations listed in table 7 to diagnose and assess genitourinary TB.

Table 7 Site-specific investigations for genitourinary TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Genitourinary	Ultrasound Intravenous urography Laparoscopy Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Early morning urine	Culture	-
Genitourinary	Ultrasound Intravenous urography Laparoscopy Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Biopsy from site of disease, such as endometrial curettings or renal biopsy	Microscopy Culture Histology	-

[new 2016]

Bone and joint TB

1.3.5.14 Use the site-specific investigations listed in table 8 to diagnose and assess bone and joint TB.

Table 8 Site-specific investigations for bone and joint TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional test on primary specimen (if it would alter management)
Bone or joint TB	X-ray CT MRI Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment	Biopsy or aspirate of paraspinal abscess Biopsy of joint Aspiration of joint fluid	Culture	-

[new 2016]

Disseminated TB

1.3.5.15 Use the site-specific investigations listed in table 9 to diagnose and assess disseminated TB.

Table 9 Site-specific investigations for disseminated TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Disseminated	CT of the thorax and head MRI Ultrasound of the abdomen Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Biopsy of site of disease, including lung, liver and bone marrow	Microscopy Culture Histology	Additional tests appropriate to site
Disseminated	CT of the thorax and head MRI Ultrasound of the abdomen Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Aspirate bone marrow Bronchial wash Cerebrospinal fluid	Microscopy (if sample available) Culture Cytology	Additional tests appropriate to site
Disseminated	CT of the thorax and head MRI Ultrasound of the abdomen Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment.	Blood	Culture	Additional tests appropriate to site

[new 2016]

Skin TB

1.3.5.16 Use the site-specific investigations listed in table 10 to diagnose and assess skin TB.

Table 10: Site-specific investigations for skin TB

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Skin	-	Biopsy	Microscopy Culture Histology	-

[2016]

Localised tuberculous abscess

1.3.5.17 Use the site-specific investigations listed in table 11 to diagnose and assess TB in a localised, tuberculous abscess at a site other than a lymph node.

Table 11: Site-specific investigations for localised tuberculous abscess

Suspected site of disease	Possible imaging techniques	Specimen	Routine test	Additional tests on primary specimen (if it would alter management)
Abscess outside of the lymph nodes	Ultrasound or other appropriate imaging Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment	Aspirate	Microscopy Culture Cytology	-
Abscess outside of the lymph nodes	Ultrasound or other appropriate imaging Taking into account, for example, the exact site of suspected disease and the availability of the test at the time of assessment	Biopsy	Microscopy Culture Histology	-

[2016]

1.3.6 Rapid-access radiology and other investigation results: referral to multidisciplinary TB team process

1.3.6.1 Local hospitals, clinical commissioning groups and the local multidisciplinary team should consider developing a local pathway for people with imaging highly suggestive of active TB. The pathway should enable them to be referred by the radiology department by the next working day to multidisciplinary TB teams. Consider including the following in the pathway:

- Agreed standardised radiology codes to identify imaging investigations highly suggestive of active TB.

- Regular liaison between multidisciplinary TB teams and the radiology department (for example, weekly) to ensure all patients have been referred to the multidisciplinary team for triage using the agreed local mechanism or pathway. **[new 2016]**

1.3.6.2 Report results of all pathology or other diagnostic results suggesting TB to the multidisciplinary TB team and clinicians who ask for them. **[new 2016]**

Direct referral from emergency departments to multidisciplinary TB teams

1.3.6.3 Commissioners and multidisciplinary teams should consider working with emergency departments to develop direct referral pathways for people with suspected active TB so that:

- the local multidisciplinary team is informed of all suspected cases of TB using the appropriate process

- referral is accepted from any appropriate healthcare professional, for example an on-call radiologist. **[new 2016]**

1.3.6.4 Emergency department clinicians should ensure first-line diagnostic tests for TB are performed on anyone presenting with suspected TB (see table 1 on diagnostic investigations for pulmonary TB). **[new 2016]**

1.3.6.5 Emergency departments should consider carrying out audits of their direct referrals because of suspected active TB and the outcomes of diagnosis. **[new 2016]**

1.3.6.6 Multidisciplinary TB teams should consider training emergency department staff in:

- using approaches that do not stigmatise people with TB

- giving people with TB appropriate advice (see recommendations 1.1.1 and 1.1.2 in the section on raising and sustaining awareness of TB and the section on infection control). **[new 2016]**

1.3.7 Managing active TB in all age groups

Standard treatment

1.3.7.1 Once a diagnosis of active TB is made:

- the clinician responsible for care should refer the person with TB to a clinician with training in, and experience of, the specialised care of people with TB
- the TB service should include specialised nurses and health visitors
- active TB in children should be managed by a TB specialist (see recommendation 1.3.4.3 in the section on diagnosing pulmonary (including laryngeal) TB in children and young people), and by paediatric trained nursing staff, where possible.

  If these arrangements are not possible, seek advice from more specialised colleagues throughout the treatment period. **[2016]**

1.3.7.2 For people with active TB without central nervous system involvement, offer:

- isoniazid (with pyridoxine), rifampicin, pyrazinamide and ethambutol for 2 months **then**
- isoniazid (with pyridoxine) and rifampicin for a further 4 months.

  Modify the treatment regimen according to drug susceptibility testing. **[2016]**

1.3.7.3 For people with active TB of the central nervous system, offer:

- isoniazid (with pyridoxine), rifampicin, pyrazinamide and ethambutol for 2 months **then**
- isoniazid (with pyridoxine) and rifampicin for a further 10 months.

  Modify the treatment regimen according to drug susceptibility testing. **[2016]**

1.3.7.4 Test people with active spinal TB who have neurological signs or symptoms for central nervous system involvement (see recommendation

1.3.5.8 in the section on central nervous system TB). Manage direct spinal cord involvement (for example, a spinal cord tuberculoma) as TB of the central nervous system. **[2016]**

1.3.7.5 For people with active spinal TB without central nervous system involvement, do not extend treatment beyond 6 months for residual effects (for example, persistent bending of the spine or vertebral loss). **[2016]**

1.3.7.6 Test people with disseminated (including miliary) TB who have neurological signs or symptoms for central nervous system involvement. If there is evidence of central nervous system involvement, treat as for TB of the central nervous system. **[2016]**

1.3.7.7 Treat active peripheral lymph node TB in people who have had an affected gland surgically removed with the standard recommended regimen. **[new 2016]**

1.3.7.8 For people with active TB of the lymph nodes, do not routinely extend treatment beyond 6 months for newly enlarged lymph nodes or sinus formation, or for residual enlargement of the lymph nodes or sinuses. **[new 2016]**

Dosing of regimens

1.3.7.9 Use fixed-dose combination tablets as part of any TB treatment regimen. **[2006]**

1.3.7.10 Do not offer anti-TB treatment dosing regimens of fewer than 3 times per week. **[2006, amended 2016]**

1.3.7.11 Offer a daily dosing schedule to people with active pulmonary TB. **[2006, amended 2016]**

1.3.7.12 Consider a daily dosing schedule as first choice in people with active extrapulmonary TB. **[2006, amended 2016]**

1.3.7.13 Consider 3 times weekly dosing for people with active TB only if:

- a risk assessment identifies a need for directly observed therapy and enhanced case management (see section on adherence, treatment completion and follow-up) **and**
- daily directly observed therapy is not possible. **[2006, amended 2016]**

People with comorbidities or coexisting conditions

1.3.7.14 If the person has a comorbidity or coexisting condition such as:

- HIV **or**
- severe liver disease, for example, Child-Pugh level B or C **or**
- stage 4 or 5 chronic kidney disease (a glomerular filtration rate of <30 ml/minute/1.73m^2) **or**
- diabetes **or**
- eye disease or impaired vision **or**
- pregnancy or breastfeeding **or**
- a history of alcohol or substance misuse

work with a specialist multidisciplinary team with experience of managing TB and the comorbidity or coexisting condition. **[new 2016]**

1.3.7.15 For people with HIV and active TB without central nervous system involvement, do not routinely extend treatment beyond 6 months. **[new 2016]**

1.3.7.16 For people with HIV and active TB with central nervous system involvement, do not routinely extend treatment beyond 12 months. **[new 2016]**

1.3.7.17 Take into account drug-to-drug interactions when co-prescribing antiretroviral and anti-TB drugs. **[new 2016]**

Adjunctive corticosteroids

Central nervous system TB

1.3.7.18 At the start of an anti-TB treatment regimen, offer people with active TB of the central nervous system dexamethasone or prednisolone, initially at a high dose with gradual withdrawal over 4 to 8 weeks. An example of a suitable regimen is listed in table 12.

Table 12 Example of suitable corticosteroid regimen for adults

Dose of dexamethasone by week	Stage 1	Stage 2 or 3
Week 1	0.3 mg/kg/day (intravenous)	0.4 mg/kg/day (intravenous)
Week 2	0.2 mg/kg/day (intravenous)	0.3 mg/kg/day (intravenous)
Week 3	0.1 mg/kg/day (oral)	0.2 mg/kg/day (intravenous)
Week 4	3 mg/day (oral)	0.1 mg/kg/day (intravenous)
Week 5	2 mg/day (oral)	4 mg/day (oral)
Week 6	1 mg/day (oral)	3 mg/day (oral)
Week 7	-	2 mg/day (oral)
Week 8	-	1 mg/day (oral)

According to the modified British Medical Research Council criteria for disease severity:

Stage 1: Glasgow coma score of 15 without focal neurological deficits; alert and oriented.

Stage 2: Glasgow coma score of 14 to 11 or 15 with focal neurological deficits.

Stage 3: Glasgow coma score of 10 or less, with or without focal neurological deficits.

[new 2016]

1.3.7.19 At the start of an anti-TB treatment regimen, offer children and young people with active TB of the central nervous system dexamethasone or prednisolone. This should initially be at a high dose with gradual withdrawal over 4 to 8 weeks in line with the British National Formulary for Children. **[new 2016]**

Pericardial TB

1.3.7.20 At the start of an anti-TB treatment regimen, offer adults with active pericardial TB oral prednisolone at a starting dose of 60 mg/day, gradually withdrawing it 2 to 3 weeks after starting treatment. **[2016]**

1.3.7.21 At the start of an anti-TB treatment regimen, offer children and young people with active pericardial TB oral prednisolone in line with the British National Formulary for Children. Gradually withdraw prednisolone 2 to 3 weeks after starting treatment. **[2016]**

Adjunctive surgery

1.3.7.22 If surgery is indicated, the surgeon should fully explain what is involved to the person, either with or after consulting a TB specialist. Discuss the possible benefits and risks with the person and their family members or carers, as appropriate, so that they can make an informed decision. **[new 2016]**

Central nervous system TB

1.3.7.23 Consider referring people with TB of the central nervous system for surgery as a therapeutic intervention only if there is evidence of raised intracranial pressure. **[new 2016]**

Spinal TB

1.3.7.24 Do not routinely refer people with spinal TB for surgery to eradicate the disease. **[new 2016]**

1.3.7.25 Consider referring people with spinal TB for surgery if there is spinal instability or evidence of spinal cord compression. **[new 2016]**

1.4 Drug resistant TB

1.4.1 Multidrug-resistant TB

1.4.1.1 For people with clinically suspected TB, a TB specialist should request rapid diagnostic nucleic acid amplification tests for rifampicin resistance on primary specimens if a risk assessment for multidrug resistance identifies any of the following risk factors:

- history of previous TB drug treatment, particularly if there was known to be poor adherence to that treatment
- contact with a known case of multidrug-resistant TB
- birth or residence in a country in which the World Health Organization reports that a high proportion (5% or more) of new TB cases are multidrug-resistant.

Start infection control measures (see section 1.5). **[new 2016]**

1.4.1.2 If the rapid diagnostic nucleic acid amplification test for rifampicin resistance is positive:

- continue infection control measures until pulmonary or laryngeal disease has been excluded
- manage treatment along with a multidisciplinary team with experience of managing multidrug-resistant TB (see the section on service organisation)
- offer a treatment regimen involving at least 6 drugs to which the mycobacterium is likely to be sensitive
- test for resistance to second-line drugs. **[new 2016]**

1.4.1.3 If the rapid diagnostic nucleic acid amplification test for the *M. tuberculosis* complex is positive but rifampicin resistance is not detected, treat as drug-susceptible TB with the standard regimen (see the section on managing active TB in all age groups). **[new 2016]**

1.4.1.4 If the rapid diagnostic nucleic acid amplification test for the *M. tuberculosis* complex is negative in a person at high risk of

multidrug-resistant TB:

- obtain further specimens for nucleic acid amplification testing and culture, if possible
- use rapid rifampicin resistance detection on cultures that become positive for the *M. tuberculosis* complex
- consider waiting for the results of further tests before starting treatment if the person is well
- if urgent treatment is needed, consider managing as multidrug-resistant TB until sensitivity results are available. **[new 2016]**

1.4.1.5 When definitive phenotypic susceptibility results are available, modify treatment as needed (see sections on managing active TB in all age groups and drug-resistant TB). **[new 2016]**

1.4.1.6 Consider more intensive clinical follow-up for people with multidrug-resistant TB. This includes people having directly observed therapy (see the section on adherence, treatment completion and follow-up) throughout treatment because of the complexity of treatment and risk of adverse events. **[new 2016]**

1.4.1.7 Discuss the options for organising care for people with multidrug-resistant TB with clinicians who specialise in this. Seek the person's views and take them into account, and consider shared care (see the section on service organisation). **[2006]**

1.4.1.8 Consider surgery as a therapeutic intervention in people with potentially resectable multidrug-resistant disease if:

- optimal medical therapy under direct observation has not worked **or**
- medical therapy is likely to fail because of extensively drug-resistant TB. **[new 2016]**

1.4.2 Drug-resistant TB (excluding multidrug- and extensively drug-resistant TB)

1.4.2.1 For people with TB, without central nervous system involvement, that is resistant to just 1 drug consider the treatments in table 13.

Table 13 Treatment regimen for people with TB that is resistant to 1 drug

Drug resistance	First 2 months (initial phase)	Continue with (continuation phase)
Isoniazid	Rifampicin, pyrazinamide and ethambutol	Rifampicin and ethambutol for 7 months (up to 10 months for extensive disease)
Pyrazinamide	Rifampicin, isoniazid (with pyridoxine) and ethambutol	Rifampicin and isoniazid (with pyridoxine) for 7 months
Ethambutol	Rifampicin, isoniazid (with pyridoxine) and pyrazinamide	Rifampicin and isoniazid (with pyridoxine) for 4 months
Rifampicin	As for multidrug-resistant TB	As for multidrug-resistant TB

[new 2016]

1.4.2.2 For people with drug-resistant TB and central nervous system involvement, involve a TB specialist with experience in managing drug-resistant TB in decisions about the most appropriate regimen and the duration of treatment. **[new 2016]**

1.5 Infection control

NICE has also produced general guidelines on the prevention and control of healthcare-associated infections in primary and community care, and the prevention and control of healthcare-associated infections.

1.5.1 Healthcare settings

1.5.1.1 Ensure healthcare settings can promptly identify people with suspected infectious or confirmed pulmonary or laryngeal TB before or at

presentation. Ensure people working in the settings follow the recommendations about testing and treatments (see the sections on latent TB, active TB and drug resistant TB*).* **[new 2016]**

1.5.1.2 Put people with suspected infectious or confirmed pulmonary or laryngeal TB who will remain in a hospital setting (including emergency, outpatients or inpatient care) in a single room. If this is not possible, keep the person's waiting times to a minimum. This may involve prioritising their care above that of other patients. **[new 2016]**

1.5.1.3 Minimise the number and duration of visits a person with TB makes to an outpatient department while they are still infectious. To minimise the risk of infection, people with infectious TB should be seen at times or in places away from other people. **[new 2016]**

1.5.1.4 In hospital settings, risk assess people with suspected infectious or confirmed pulmonary TB for multidrug-resistant TB *(*see the section on multidrug-resistant TB). Care for people deemed to be at low risk in a single room, as a minimum. For people deemed to be at high risk:

- provide care in a negative pressure room **and**
- have specimens sent for rapid diagnostic tests, such as nucleic acid amplification tests. **[new 2016]**

1.5.1.5 Unless there is a clear clinical or public health need, such as homelessness, people with suspected infectious or confirmed pulmonary TB should not be admitted to hospital for diagnostic tests or for care. **[2006, amended 2016]**

1.5.1.6 Do not admit people with suspected infectious or confirmed pulmonary TB to a ward containing people who are immunocompromised, such as transplant recipients, people with HIV and those on anti-tumour necrosis factor alpha or other biologics, unless they can be cared for in a negative pressure room on the same ward. **[new 2016]**

1.5.1.7 Assess any visitors to a child with suspected active TB in hospital for symptoms of infectious TB, and keep them separate from other people until they have been excluded as a source of infection (see

recommendations 1.2.1 to 1.2.3 in the section on latent TB and the section on contact tracing). **[new 2016]**

1.5.1.8 Care for people with a continuing clinical or public health need for admission with pulmonary TB in a single room (as a minimum) until they have completed 2 weeks of the standard treatment regimen (see the section on managing active TB in all age groups) if they:

- are unlikely to be rifampicin resistant (that is, do not have risk factors for multidrug-resistant TB) **or**
- have negative rifampicin resistance on nucleic acid amplification test or culture. **[new 2016]**

1.5.1.9 Consider de-escalating isolation after 2 weeks of treatment, taking into account the risks and benefits, if:

- the person is showing tolerance to the prescribed treatment
- there is agreement to adhere to treatment
- there is resolution of cough
- there is definite clinical improvement on treatment; for example, remaining afebrile for a week
- there are not immunocompromised people, such as transplant recipients, people with HIV and those on anti-tumour necrosis factor alpha or other biologics, in the same accommodation
- the person's initial smear grade was not high; for example, 2 or less
- there is not extensive pulmonary involvement, including cavitation
- there is no laryngeal TB. **[new 2016]**

1.5.1.10 In people who may have TB, only carry out aerosol-generating procedures such as bronchoscopy, sputum induction or nebuliser treatment in an appropriately engineered and ventilated area (ideally a negative pressure room). **[new 2016]**

1.5.1.11 Consider discharging from hospital people:

- who do not have a continuing clinical or public health need for admission with pulmonary TB **and**
- who are unlikely to be rifampicin resistant (that is, do not have risk factors for multidrug-resistant TB) **or**
- who have negative rifampicin resistance on nucleic acid amplification test or culture.

If discharged, the person should avoid congregate settings for the first 2 weeks of their treatment. **[new 2016]**

1.5.1.12 Explain to inpatients with suspected infectious or confirmed pulmonary or laryngeal TB that they will need to wear a surgical mask in the hospital whenever they leave their room. Ask them to continue wearing it until they have had at least 2 weeks of treatment. **[2016]**

1.5.1.13 Offer people advice on simple respiratory hygiene measures. **[new 2016]**

1.5.2 Non-healthcare settings

1.5.2.1 In non-healthcare settings catering for large numbers of people and populations at high risk of TB (such as detention settings, residential hostels and day centres):

- promote simple respiratory hygiene
- ensure awareness of symptoms of potentially infectious TB to enable prompt healthcare referral
- work with the local public health team and the local authority to ensure accommodation for people with TB
- ensure adequate ventilation. **[new 2016]**

1.5.2.2 In prisons or immigration removal centres, everyone with X-ray changes indicative of active TB, as well as those with symptoms who are awaiting X-ray, should be isolated in an adequately ventilated individual room or cell. Prisoners and detainees should be retained on medical hold until they have:

- proven smear-negative and had an X-ray that does not suggest active TB **or**
- had a negative risk assessment for multidrug-resistant TB and completed 2 weeks of the standard treatment regimen. **[2012, amended 2016]**

1.5.3 Multidrug-resistant TB

1.5.3.1 If people with suspected or known infectious multidrug-resistant TB are admitted to hospital, admit them to a negative pressure room. If none is available locally, transfer them to a hospital that has these facilities and a clinician experienced in managing complex drug-resistant cases. Carry out care in a negative pressure room for people with:

- suspected multidrug-resistant TB, until non-resistance is confirmed
- confirmed multidrug-resistant TB, until they have 3 negative smears at weekly intervals and ideally have a negative culture. **[new 2016]**

1.5.3.2 As soon as possible, explore options to reduce the psychosocial impact of prolonged isolation. For example, through providing free access to internet, telephone and television, and accompanied walks in the open air. **[new 2016]**

1.5.3.3 Consider earlier discharge for people with confirmed multidrug-resistant TB, if there are suitable facilities for home isolation and the person will adhere to the care plan. **[new 2016]**

1.5.3.4 For people with confirmed multidrug-resistant TB whose symptoms have improved and who are unable to produce sputum, discharge decisions should be taken by the multidisciplinary team and the health protection team. **[new 2016]**

1.5.3.5 Staff and visitors should wear filtering face piece (FFP3) masks during contact with a person with suspected or known multidrug-resistant TB while the person is thought to be infectious. **[2016]**

1.5.3.6 Before deciding to discharge a person with suspected or known multidrug-resistant TB from hospital, agree with the person and their carers secure arrangements for supervising and administering all anti-TB

therapy. **[2016]**

1.5.3.7 Discuss the decision to discharge a person with suspected or known multidrug-resistant TB with:

- the infection control team **and**
- the local microbiologist **and**
- the local TB service **and**
- the health protection team. **[2016]**

1.5.3.8 Ensure negative pressure rooms used for infection control in multidrug-resistant TB meet the standards of the Interdepartmental Working Group on Tuberculosis, and are clearly identified for staff, for example by a standard sign. Keep such signs up to date. **[2016]**

1.6 Case finding

1.6.1 Contact tracing

Human to human transmission

1.6.1.1 Once a person has been diagnosed with active TB, the diagnosing physician should inform relevant colleagues so that the need for contact tracing can be assessed without delay. Contact tracing should not be delayed until notification. **[2006]**

1.6.1.2 Offer screening to the close contacts of any person with pulmonary or laryngeal TB. **[2006, amended 2016]**

1.6.1.3 Assess symptomatic close contacts for active TB (see recommendations 1.3.1 to 1.3.4 in the section on active TB). **[new 2016]**

1.6.1.4 In asymptomatic close contacts younger than 65 years, consider standard testing for latent TB (see recommendations 1.2.1 to 1.2.3 in the section on latent TB), followed by consideration of BCG vaccination in

line with the section on BCG vaccination or treatment for latent TB infection (see recommendations 1.2.4 to 1.2.6 in the section on latent TB) once active TB has been ruled out for people who:

- are previously unvaccinated **and**
- are contacts of a person with smear-positive pulmonary or laryngeal TB **and**
- are Mantoux-negative.

  At the time of publication (January 2016) the BNF states: 'The Mantoux test is recommended for tuberculin skin testing, but no licensed preparation is currently available.' For further guidance, see immunisation against infectious disease (the Green book). **[2006, amended 2016]**

1.6.1.5 In asymptomatic close contacts older than 65 years, consider a chest X-ray (if there are no contraindications), possibly leading to further investigation for active TB. **[2006, amended 2016]**

1.6.1.6 Do not routinely assess social contacts of people with TB, who will include most workplace contacts. **[2006, amended 2016]**

1.6.1.7 Assess the need for tracing social contacts of people with pulmonary or laryngeal TB if:

- the index case is judged to be particularly infectious (for example, evidenced by transmission to close contacts) **or**
- any social contacts are known to possess features that put them at high risk of going on to develop active TB. **[2006, amended 2016]**

1.6.1.8 Offer 'inform and advise' information to close and social contacts of people with smear-positive TB (see section on providing information for the public about TB). **[2006]**

Cases on an aircraft

1.6.1.9 After diagnosis of TB in an aircraft traveller, do not routinely carry out contact tracing of fellow passengers. **[2006, amended 2016]**

1.6.1.10 The notifying clinician should inform the relevant consultant in communicable disease control or health protection if:

- less than 3 months has elapsed since the flight and the flight was longer than 8 hours **and**
- the index case is smear-positive **and either**
  - the index case has multidrug-resistant TB **or**
  - the index case coughed frequently during the flight. **[2006]**

1.6.1.11 The consultant in communicable disease control or health protection should provide the airline with 'inform and advise' information to send to passengers seated in the same part of the aircraft as the index case. **[2006, amended 2016]**

1.6.1.12 If the TB index case is an aircraft crew member, contact tracing of passengers should not routinely take place. **[2006]**

1.6.1.13 If the TB index case is an aircraft crew member, contact tracing of other members of staff is appropriate, in accordance with the usual principles for screening workplace colleagues. **[2006]**

Cases in schools

1.6.1.14 After diagnosis of TB in a school pupil or member of staff, the consultant in communicable disease control or health protection should be prepared to explain the prevention and control procedures to staff, parents and the press. Advice on managing these incidents and their public relations is available from the Public Health England health protection team and the local authority. **[2006, amended 2016]**

1.6.1.15 If a school pupil is diagnosed with smear-positive TB, carry out a risk assessment of the need to test the rest of his or her class (if there is a single class group), or the rest of the year group who share classes, as part of contact tracing. **[2006]**

1.6.1.16 If a teacher has smear-positive TB, assess the pupils in his or her classes during the preceding 3 months as part of contact tracing. **[2006]**

1.6.1.17 Consider extending contact tracing in schools to include children and teachers involved in extracurricular activities, and non-teaching staff, on the basis of:

- the degree of infectivity of the index case
- the length of time the index case was in contact with others
- whether contacts are unusually susceptible to infection
- the proximity of contact. **[2006, amended 2016]**

1.6.1.18 Treat secondary cases of smear-positive TB as index cases for contact tracing. **[2006]**

1.6.1.19 If the index case of a school pupil's TB infection is not found, and the child is not in a high-risk group for TB, contact tracing and screening (by either symptom enquiry or chest X-ray) should be considered for all relevant members of staff at the school. **[2006]**

Cases in community childcare

1.6.1.20 When an adult who works in childcare (including people who provide childcare informally) is diagnosed with smear-positive TB, follow recommendations 1.6.1.1 to 1.6.1.8. **[2006, amended 2016]**

Cases in hospital inpatients

1.6.1.21 If TB is diagnosed in a hospital inpatient, do a risk assessment. This should take into account:

- the degree of infectivity of the index case
- the length of time before the infectious patient was isolated
- whether other patients are unusually susceptible to infection
- the proximity of contact. **[2006, amended 2016]**

1.6.1.22 Carry out contact tracing and testing only for patients for whom the risk is regarded as significant. **[2006]**

1.6.1.23 Regard patients as at risk of infection if they spent more than 8 hours in the same bay as an inpatient with smear-positive TB who had a cough. Document the risk in the contact's clinical notes, for the attention of the contact's consultant. Give the contact 'inform and advise' information, and inform their GP. **[2006]**

1.6.1.24 If patients were exposed to a patient with smear-positive TB for long enough to be equivalent to close contacts (as determined by the risk assessment), or an exposed patient is known to be particularly susceptible to infection, manage their TB risk in the same way as close contacts. **[2006, amended 2016]**

1.6.1.25 If an inpatient with smear-positive TB is found to have multidrug-resistant TB, or if exposed patients are HIV positive, trace contacts following the Interdepartmental Working Group on Tuberculosis guidelines. **[2006]**

1.6.1.26 In cases of doubt when planning contact tracing after diagnosing smear-positive TB in an inpatient, seek further advice from the local or national Public Health England or Wales unit or people experienced in the field. **[2006, amended 2016]**

1.6.2 Opportunistic case finding

New entrants from high incidence countries

1.6.2.1 Assess and manage TB in new entrants from high incidence countries who present to healthcare services as follows:

- assess risk of HIV, including HIV prevalence rates in the country of origin, and take this into account when deciding whether to give a BCG vaccination
- offer testing for latent TB (see recommendations 1.2.1 to 1.2.3 in the section on latent TB)
- assess for active TB if the test for latent TB is positive (see recommendations 1.3.1 to 1.3.5 in the section on active TB)

- offer treatment to people aged 65 years or younger in whom active TB has been excluded but who have a positive Mantoux test or a positive interferon-gamma release assay for latent TB infection (see recommendations 1.2.4 to 1.2.6 in the section on latent TB)

- consider offering BCG for unvaccinated people who are Mantoux- or interferon-gamma release assay-negative (see the section on BCG vaccination)

- give 'inform and advise' information to people who do not have active TB and are not being offered BCG or treatment for latent TB infection (see the section on providing information for the public about TB). **[2006, amended 2011 and 2016]**

1.6.2.2 Primary care services should support local, community-based and voluntary organisations that work with vulnerable migrants to ensure they:

- register with a primary care provider

- know how to use NHS services (emergency or primary care). **[2012]**

1.6.2.3 Healthcare professionals, including primary care staff, responsible for testing new entrants should test all vulnerable migrants who have not previously been checked. This is regardless of when they arrived in England. People born in countries with an incidence of more than 150 per 100,000 per year should be made a priority for latent TB testing when they arrive here. **[2012, amended 2016]**

People using homeless or substance misuse services

1.6.2.4 In areas of identified need (see the section on local needs assessment), including major urban centres with a high incidence of TB, commissioners should:

- ensure there is a programme of active case-finding using mobile X-ray in places where homeless people and people who misuse substances congregate (this includes: homeless day centres, rolling shelters, hostels and temporary shelters established as part of cold weather initiatives and venues housing needle and syringe programmes)

- base the frequency of screening at any 1 location on population turnover
- where local demand does not warrant a mobile X-ray team, consider commissioning mobile X-ray capacity from another area. **[2006, amended 2012]**

1.6.2.5 Multidisciplinary TB teams should consider using simple incentives, such as providing hot drinks and snacks, to encourage people to attend for testing. **[2006, amended 2012, amended 2016]**

1.6.2.6 Commissioners of TB prevention and control programmes should consider offering people who are homeless and people who misuse substances other health interventions when they are screened for TB at a mobile X-ray unit. (Examples may include blood-borne virus screening, dentistry and podiatry services.) **[2012]**

1.6.2.7 Multidisciplinary TB teams should work closely with mobile X-ray teams and frontline staff in hostels and day centres to promote TB screening and to ensure appropriate onward referrals and follow-up. **[2012]**

1.6.2.8 Multidisciplinary TB teams should consider using peer educators to promote the uptake of TB screening in hostels and day centres. **[2012]**

1.6.2.9 Multidisciplinary TB teams should provide routine data to TB control boards on: screening uptake, referrals and the number of active TB cases identified. **[2012]**

People in prisons or immigration removal centres

1.6.2.10 Healthcare professionals in prisons and immigration removal centres should ensure prisoners and detainees are screened for TB within 48 hours of arrival. **[2012]**

1.6.2.11 Prisons with Department of Health-funded static digital X-ray facilities for TB screening should X-ray all new prisoners and detainees (including those being transferred from other establishments) if they have not had a chest X-ray in the past 6 months. This should take place within 48 hours of arrival. **[2012]**

1.6.2.12 Prison and immigration removal centre health staff should report all suspected and confirmed TB cases to the local multidisciplinary TB team within 1 working day. **[2012]**

1.6.2.13 Multidisciplinary TB staff should visit every confirmed TB case in a prison or immigration removal centre in their locality within 5 working days. **[2012]**

1.6.2.14 If a case of active TB is identified, the local Public Health England unit, in conjunction with the multidisciplinary TB team, should plan a contact investigations exercise. They should also consider using mobile X-ray to check for further cases. **[2012]**

1.6.3 Active case finding in under-served groups

1.6.3.1 Multidisciplinary TB teams should follow NICE recommendations on contact tracing (see the section on contact tracing).They should coordinate contact investigations at places where the person with TB spends significant amounts of time. Examples could include pubs, crack houses, parks and community centres. The aim is to help identify people who have been living with them and people they frequently socialise with. **[2012]**

1.6.3.2 Multidisciplinary TB teams dealing with someone from an under-served group should work alongside health and social care professionals known to them to help trace relevant contacts. They should also work in partnership with voluntary, community and statutory organisations to conduct outreach contact investigations. **[2012]**

1.6.3.3 Multidisciplinary TB teams should, if available and appropriate, encourage peer educators or TB programme support workers to help with contact investigations involving under-served people who have complex social networks. **[2012]**

1.6.3.4 Multidisciplinary TB teams in discussion with local Public Health England health protection teams should consider using digital mobile X-ray for active case-finding in settings identified by looking at social networks as places where under-served people at risk congregate. They should also

provide the necessary support so that multidisciplinary TB teams can use strain-typing and social network analysis to ascertain where transmission is occurring in the community. (Examples of transmission sites may include pubs, crack houses, hostels and day centres.) They should focus on active case-finding in the settings identified. **[2012, amended 2016]**

1.6.4 Incident and outbreak response

1.6.4.1 Multidisciplinary TB teams should coordinate incident or outbreak contact investigations at places where the person with active TB spends significant amounts of time. Examples include workplaces, schools, colleges, universities, childcare settings. Identify people that the person with TB frequently spends substantial time with, as outlined in the section on contact tracing. **[new 2016]**

1.6.4.2 Multidisciplinary TB teams should refer any incident in a congregate setting to the local Public Health England health protection team for risk assessment within 5 working days of suspicion of a potential incident. **[new 2016]**

1.6.4.3 TB control boards working with local health protection teams should, through local arrangements, mobilise existing staff or have access to an incident team that will:

- undertake an incident risk assessment and provide advice
- support or undertake contact investigations
- provide information and communication support to the multidisciplinary TB team, the local director of public health, the setting in which the incident has occurred and the people affected including:
  - written advice, printed or by email
  - question and answer sessions
  - telephone advice
  - media engagement

- gather and collate data, and report on outcomes to measure the effectiveness of the investigation (for example, offering testing to all people identified at risk and monitoring uptake)

- report back to TB control boards at appropriate times. This includes when outcomes of initial investigation of people classified as close contacts are available. It also includes when a decision is made to broaden the investigation to the next stage using the concentric circle method for risk assessment. **[new 2016]**

1.6.4.4 When incidents have been identified, multidisciplinary TB teams in discussion with local Public Health England health protection teams should consider providing support for strain-typing and other analysis to ascertain where transmission is occurring. (Examples of transmission sites may include workplaces, schools, colleges, universities, childcare settings.) **[new 2016]**

1.6.4.5 In all types of contact investigation scenarios (active case finding, incident or outbreak investigations) multidisciplinary TB teams should investigate all people who have been in contact with children who have pulmonary or extrapulmonary TB to identify the primary source of infection. If necessary, they should look beyond immediate close contacts to find the source. **[2012, amended 2016]**

1.7 Adherence, treatment completion and follow-up

1.7.1 Improving adherence: case management including directly observed therapy

1.7.1.1 Allocate a named TB case manager to everyone with active TB as soon as possible after diagnosis (and within 5 days). The clinical team should tell each person who their named TB case manager is and provide contact details. **[2006, 2012 amended 2016]**

1.7.1.2 The TB case managers should work with the person diagnosed with TB to develop a health and social care plan, and support them to complete

therapy successfully. The TB case manager should:

- offer a risk assessment to every person with TB, to identify their needs and whether they should have enhanced case management including directly observed therapy
- educate the person about TB and the treatment
- develop an individual care plan after discussion with the person
- gain the person's consent to the plan and agree a review date (for example, when moving from initiation to maintenance, or at each contact to ensure the person's needs are being met)
- coordinate discharge planning, especially for people on directly observed therapy
- involve representatives from other allied professions and key workers from all organisations who work with the person, if appropriate
- explore appropriate ways that peers and voluntary organisations can provide support. **[2006, 2012, amended 2016]**

1.7.1.3 Offer directly observed therapy as part of enhanced case management in people who:

- do not adhere to treatment (or have not in the past)
- have been treated previously for TB
- have a history of homelessness, drug or alcohol misuse
- are currently in prison, or have been in the past 5 years
- have a major psychiatric, memory or cognitive disorder
- are in denial of the TB diagnosis
- have multidrug-resistant TB
- request directly observed therapy after discussion with the clinical team
- are too ill to administer the treatment themselves. **[2012, amended 2016]**

1.7.1.4 In children whose parents are members of any of the above groups, offer directly observed therapy as part of enhanced case management and include advice and support for parents to assist with treatment completion. **[2016]**

1.7.1.5 Re-evaluate the need for directly observed therapy throughout the course of TB treatment whenever the person's (or in the case of children, parents') circumstances change. **[new 2016]**

1.7.1.6 TB case managers should ensure the health and social care plan (particularly if directly observed therapy is needed) identifies why a person may not attend for diagnostic testing or follow a treatment plan, and how they can be encouraged to do so. It should also include ways to address issues such as fear of stigmatisation, support needs and/or cultural beliefs, and may include information on:

- demographics (for example, age, nationality, place of birth, length of time in UK)
- all current prescribing regimens
- housing needs and living situation, including looked-after children
- substance misuse (drugs or alcohol)
- any contact with the criminal justice system
- the need for hepatitis B and C or HIV testing (see recommendations 1.2.5.2 and 1.2.5.3 in the section on managing latent TB in adults and recommendation 1.2.6.1 in the section on managing latent TB in children and young people)
- HIV status
- other health conditions (physical or mental)
- communication factors (for example, language and literacy levels)
- ability to access treatment (mobility and transport needs)
- employment or entitlement to benefits

- legal or immigration status (including risk of removal or relocation within the UK)
- any enablers or incentives to overcome anything that is stopping diagnosis or treatment. **[2012, amended 2016]**

1.7.1.7 The health and social care plan should:

- state who will be observing treatment and where (if the person is having directly observed therapy this should be provided at a location that is convenient and accessible to them, for example, at a methadone clinic) **[2012, amended 2016]**
- include actions to take if contact with the person is lost (for example, keeping details of people who might be able to help re-establish contact) **[2012]**
- refer to, and be coordinated with, any other care plan already established for the person **[2012]**
- define the support needed to address any unmet health and social care needs (for example, support to gain housing or other benefits, or to help them access other health or social care services) **[2012, amended 2016]**
- include a commitment from the person to complete their TB treatment **[2012, amended 2016]**
- be supported by frequent contact with any key workers who work with the person. **[2006 amended 2011, amended 2016]**

1.7.1.8 Multidisciplinary TB teams should aim to find people with active TB who are lost to follow-up, or who stop using services before completing diagnostic investigations. They should report all those lost to follow-up to local Public Health England teams, GPs, the referring organisation and specialist outreach teams. **[2012]**

1.7.2 Other strategies to encourage people to follow their treatment plan

1.7.2.1 To encourage people to follow their treatment plan, involve people in treatment decisions for active or latent TB from the start. Emphasise the importance of following the treatment plan when agreeing the regimen.

[2016]

1.7.2.2 Multidisciplinary TB teams should implement strategies for active and latent TB to encourage people to follow the treatment plan and prevent people stopping treatment early. These could include:

- reminder letters, printed information, telephone calls, texts and apps using an appropriate language **[2006, amended 2016]**
- health education counselling and patient-centred interviews **[2006, amended 2016]**
- tailored health education booklets from quality sources (see section on providing information for the public about TB) **[2006, amended 2016]**
- home visits **[2006]**
- random urine tests and other monitoring (for example, pill counts) **[2006]**
- access to free TB treatment for everyone (irrespective of eligibility for other NHS care) and information about help with paying for prescriptions **[2006, 2012, amended 2016]**
- social and psychological support (including cultural case management and broader social support) **[new 2016]**
- advice and support for parents and carers **[new 2016]**
- incentives and enablers to help people follow their treatment regimen. **[new 2016]**

1.7.2.3 TB control boards should ensure services take into account the barriers facing vulnerable migrants who may need treatment, and in particular the stigma they may face. Other issues include the location of services (both geographically and in terms of opening times) and people's language and cultural needs, in terms of the format of advice and the type of information given. **[2012, amended 2016]**

1.7.3 Strategies in prisons or immigration removal centres

1.7.3.1 On arrival at a prison or immigration removal centre, healthcare

professionals should ask all prisoners and detainees (including those being transferred from other establishments) if they are taking TB medication, to ensure continuity of treatment. **[2012]**

1.7.3.2 All prisoners and immigration removal centre detainees having treatment for active TB should have a named TB case manager. The case manager should be responsible for contingency planning for discharge from prison or detention. **[2012]**

1.7.3.3 Prisons and immigration removal centres should ensure multidisciplinary TB staff have access to prisoners and detainees who need treatment (for example, by being given security clearance). **[2012]**

1.7.3.4 All prisoners having treatment for active TB should have directly observed therapy. **[2012]**

1.7.3.5 Prison health services should have contingency, liaison and handover arrangements to ensure continuity of care before any prisoner on TB treatment is transferred between prisons or released. In addition, other agencies working with prisoners or detainees should also be involved in this planning. **[2012]**

1.7.3.6 Prison and immigration removal centre healthcare services should liaise with the named TB case manager (from the multidisciplinary TB team) to ensure contingency plans for continuation of treatment are drawn up for prisoners and immigration removal centre detainees with TB. **[2012]**

1.7.3.7 Multidisciplinary TB teams should ensure accommodation is available for the duration of TB treatment after the prisoner or detainee's release (see section on Identifying and managing active TB in prisons, custody suites or immigration removal centres: organisational factors). **[2012]**

1.7.3.8 Multidisciplinary TB teams should ensure directly observed therapy is arranged for prisoners or detainees being treated for TB after their release. This should be available close to where they will live in the community. **[2012]**

1.7.4 Re-establishing treatment for active or latent TB after

interruptions because of adverse events

1.7.4.1 In people who have experienced a treatment interruption because of drug-induced hepatotoxicity:

- investigate other causes of acute liver reactions **and**
- wait until aspartate or alanine transaminase levels fall below twice the upper limit of normal, bilirubin levels return to the normal range and hepatotoxic symptoms have resolved **then**
- sequentially reintroduce each of the anti-TB drugs at full dose over a period of no more than 10 days, starting with ethambutol and either isoniazid (with pyridoxine) or rifampicin. **[new 2016]**

1.7.4.2 In people with severe or highly infectious TB who need to interrupt standard therapy because of a reaction, consider continuing treatment:

- for hepatotoxicity, a combination of at least 2 anti-TB drugs of low hepatotoxicity (such as ethambutol and streptomycin, with or without a fluoroquinolone antibiotic, such as levofloxacin or moxifloxacin) and monitor with a liver specialist for further reactions

  See MHRA advice for restrictions and precautions for using fluoroquinolone antibiotics due to very rare reports of disabling and potentially long-lasting or irreversible side effects affecting musculoskeletal and nervous systems. Warnings include: stopping treatment at first signs of a serious adverse reaction (such as tendonitis), prescribing with special caution in people over 60 years and avoiding coadministration with a corticosteroid (March 2019).

  Not licensed for tuberculosis, so use would be off label. The prescriber should follow relevant professional guidance, taking full responsibility for the decision. Informed consent should be obtained and documented. See the General Medical Council's Good practice in prescribing and managing medicines and devices for further information.

- for a cutaneous reaction, a combination of at least 2 anti-TB drugs with a low risk of cutaneous reactions (such as ethambutol and streptomycin) and monitor with a dermatologist for further reactions. **[new 2016, amended 2019]**

1.7.4.3 If another reaction of a similar or greater severity occurs because of reintroducing a particular drug, do not give that drug in future regimens and consider extending the total regimen accordingly. **[new 2016]**

1.7.5 Follow-up after treatment completion

1.7.5.1 Follow-up clinic visits should not be conducted routinely after treatment completion. **[2006]**

1.7.5.2 Tell patients to watch for symptoms of relapse and how to contact the TB service rapidly through primary care or a TB clinic. Key workers should ensure that patients at increased risk of relapse are particularly well informed about symptoms. **[2006]**

1.7.5.3 Patients who have had drug-resistant TB should be considered for follow-up for 12 months after completing treatment. Patients who have had multidrug-resistant TB should be considered for prolonged follow-up. **[2006]**

1.8 Service organisation

When using the recommendations in this section with under served groups, also check sections 1.1.1 on raising and sustaining awareness, 1.1.2 on providing information for the public, 1.6.2 on opportunistic case finding, 1.6.3 on active case finding in under served groups and 1.7 on adherence, treatment completion and follow up. See also, recommendations on under served groups in section 1.2.3 on diagnosing latent TB in all age groups.

1.8.1 Strategic oversight and commissioning of TB prevention and control activities

1.8.1.1 Public Health England, in partnership with NHS England, should take responsibility for national oversight of TB prevention and control activities. This includes setting up TB control boards (see section 1.8.2). **[2012, amended 2016]**

1.8.1.2 Public Health England and NHS England should consider working together to establish control boards in agreed geographical areas and employ appropriate staff (see recommendation 1.8.2.3). **[new 2016]**

1.8.1.3 Clinical commissioning groups and local authority public health teams working in partnership with Public Health England and NHS England should consider collaborative commissioning arrangements through TB control boards. This could, for example, include working with 1 or more clinical commissioning groups to cover a major metropolitan district, region or TB control board area taking into account:

- local TB incidence
- local at-risk populations and their movements across different geographical areas
- existing service configurations for organisations involved in TB prevention and control
- the need to share services, such as mobile X-ray facilities, and outreach incident teams across different geographical areas. **[2012, amended 2016]**

1.8.1.4 TB control boards should develop TB prevention and control programmes working with commissioners, Public Health England and NHS England. The board could include clinical, commissioning (from clinical commissioning groups, local government and the voluntary sector) and public health leaders and people with TB or groups who advocate on their behalf from across the control board area. This may include identifying a lead clinical commissioning group, which could be led by an executive director of that commissioning group working with the board. Feedback mechanisms between local commissioning groups and the TB control board should be developed. **[new 2016]**

1.8.1.5 An executive director of local commissioning groups, working with the local director of public health or another nominated public health consultant, should lead implementation of the programme in their locality. The lead should ensure a comprehensive prevention and control programme is commissioned to support the level of need (see section on local needs assessment) and that they work with the control board regularly. **[2012, amended 2016]**

1.8.1.6 Working together through TB control boards and local networks, commissioners, local government and Public Health England should ensure TB prevention and control programmes set up multidisciplinary TB teams to provide all TB services (see section on commissioning multidisciplinary TB support). They should ensure that local strategy and service commissioning focuses on an end-to-end pathway. **[2012, amended 2016]**

1.8.1.7 Working together through TB control boards, commissioners and Public Health England should ensure the TB prevention and control programme is informed by relevant NICE guidance and developed in collaboration with clinical services. It should also be informed by the standard minimum data set collected through local needs assessment and service audit. **[2012, amended 2016]**

1.8.1.8 Working together through TB control boards, commissioners and Public Health England should ensure the TB prevention and control programme targets all ages, including children, and covers all aspects of TB prevention and control (see recommendations 1.8.2.1 and 1.8.2.2), including but not limited to:

- active case finding (contact investigations and identifying latent TB in high-risk groups)
- awareness-raising activities
- standard and enhanced case management (including providing directly observed therapy and free treatment)
- finding people lost to follow-up and encouraging them back into treatment
- incident and outbreak control
- monitoring, evaluating and gathering surveillance and outcome data. **[2012, amended 2016]**

1.8.1.9 Working together through TB control boards, commissioners, Public Health England and the voluntary sector should ensure TB prevention and control programmes take account of the need to work with other programmes targeting specific high-risk groups, such as those who are

under-served. Examples include programmes focused on the health of asylum seekers and refugees, under-served children, homelessness and housing, offenders and people who misuse substances. **[2012, amended 2016]**

1.8.1.10 TB control boards should consider integrating TB and HIV services, joint clinics and training opportunities. **[new 2016]**

1.8.1.11 Commissioners should consider commissioning support and advice to all groups diagnosed with TB irrespective of whether they are under-served. **[new 2016]**

1.8.2 Developing the TB prevention and control programme

1.8.2.1 TB control boards should be responsible for developing a TB prevention and control programme based on the national strategy and evidence-based models. **[new 2016]**

1.8.2.2 TB control boards should plan, oversee, support and monitor local TB control, including clinical and public health services and workforce planning. **[new 2016]**

1.8.2.3 TB control boards should assess services in their area, identify gaps in provision and develop plans to meet these, including:

- undertaking a workforce review to support local or regional commissioning of TB services to meet the needs of their population (see sections on local needs assessment and cohort review)
- supporting development of appropriate services and pathways to improve access and early diagnosis (see the sections on rapid-access radiology and other investigation results: referral to multidisciplinary TB team process, non-clinical roles including TB support workers and rapid-access TB services)
- negotiating arrangements to cover the cost of additional services to address specific gaps in current TB control arrangements. **[new 2016]**

1.8.2.4 TB control boards should ensure cohort review is undertaken at least quarterly, and the results are fed back to local clinical and TB networks.

These should be agreed by accountable bodies such as clinical commissioning groups, trust management, regional Public Health England and centre directors and local authority directors of public health as agreed, all of whom should make sure appropriate action is taken. **[new 2016]**

1.8.2.5 TB control boards should enable full and consistent use of national guidelines including:

- ensuring the needs of all people with TB, particularly under-served populations, are addressed
- ensuring contact tracing arrangements are appropriate to the needs of the population (see the section on case finding)
- assuring themselves that TB control in low-incidence areas is established and delivered appropriately (see the section on rural services: organisational and support factors)
- assuring themselves that multidrug-resistant TB is managed appropriately (see the section on multidrug-resistant TB) and mechanisms are in place to ensure:
  - there is sufficient clinical expertise available to manage cases
  - regional multidrug-resistant TB networks take account of expert advice (see section 1.8.3). **[new 2016]**

1.8.2.6 TB control boards should develop links and partnerships and establish agreed relationships and lines of accountability between TB control boards and local clinical and TB networks. This includes engaging with other key stakeholders to ensure universal coverage of TB control efforts. **[new 2016]**

1.8.2.7 TB control boards should collaborate with their local and regional partners. They should agree and establish regular monitoring, surveillance and reporting arrangements with all partners to support needs assessment (see the section on local needs assessment) and regular audit and evaluation. **[new 2016]**

1.8.2.8 TB control board staff should have clearly defined roles and

responsibilities. Their roles and responsibilities could include:

- Establishing the links, partnerships and relationships between all aspects of the control board area within their remit (if necessary across usual geographical commissioning boundaries).
- Developing and supporting adoption and implementation of evidence-based model service specifications for the clinical and public health actions needed to control TB including:
  - improving access and early diagnosis (see the sections on raising and sustaining awareness of TB, providing information for the public about TB, rapid-access radiology and other investigation results: referral to multidisciplinary TB team process and non-clinical roles including TB support workers)
  - diagnostics, treatment and care services (see the sections on latent TB and active TB)
  - contact investigations and tracing (see the sections on diagnosing latent TB in adults and case finding)
  - cohort review
  - vaccination (see the section on BCG vaccination)
  - drug resistance (see the section on multidrug-resistant TB)
  - tackling TB in under-served populations
  - surveillance, monitoring and quality assurance
  - workforce development and commissioning (see the sections on commissioning multidisciplinary TB support and non-clinical roles including TB support workers). **[new 2016]**

1.8.2.9 TB control boards should ensure there is sufficient capacity available to them to manage a sudden increase in demand such as:

- TB contact investigations, (such as incidents in congregate settings)

- large scale active case-finding initiatives in under-served groups in the community
- outbreaks in a variety of settings or sites where transmission risk may be high, including but not limited to schools, workplaces, hostels and prisons. **[new 2016]**

1.8.2.10 To set up, monitor and evaluate a TB control programme, TB control boards should:

- agree plans within their partnerships to assess local services against the service specifications
- develop plans and quality standards to secure improvements
- establish quality assurance mechanisms and regular audits including, but not limited to, cohort review for all aspects of the TB control board partnership plans. **[new 2016]**

Coordinating local TB networks

1.8.2.11 TB control boards should (in collaboration with commissioners) consider the need for a TB network local coordinator, particularly if working across multiple clinical commissioning group areas (see recommendation 1.8.1.3). **[new 2016]**

1.8.2.12 The coordinator should work in close collaboration with clinicians and all relevant multidisciplinary TB teams to develop the network and be responsible for:

- setting up the network and developing it based on needs, reporting back to the TB control board regularly
- establishing the links, partnerships and relationships across their local network (if necessary across usual geographical commissioning boundaries). **[new 2016]**

1.8.3 Regional multidrug-resistant TB network

1.8.3.1 TB control boards should consider setting up a regional multidisciplinary

TB network to oversee management of multidrug-resistant TB. This could:

- Identify and designate regional expert centres.
- Ensure all healthcare professionals who suspect or treat a case of multidrug-resistant TB are informed about and have access to specialist advisory services for multidrug-resistant TB. This includes the designated expert centre in their regional network and may also include the national advisory service for multidrug-resistant TB (currently provided by the British Thoracic Society).
- Ensure all cases of multidrug-resistant TB are discussed at the regional multidisciplinary TB team meeting in the local clinical network.
- Formally consider and record the advice from the specialist advisory services for multidrug-resistant TB provided by the designated regional expert centre or the national advisory service for multidrug-resistant TB. **[new 2016]**

1.8.4 Rural services: organisational and support factors

1.8.4.1 Commissioners in rural areas (working with the TB control board) should consider collaborative approaches to deliver and manage TB services. They could, for example, set up a network including areas with high and low incidence of TB. **[new 2016]**

1.8.5 Local needs assessment

1.8.5.1 Directors of public health, in discussion with local health protection teams, should ensure that TB is part of the joint strategic needs assessment. **[2012, amended 2016]**

1.8.5.2 Directors of public health should provide commissioners of TB prevention and control programmes and TB control boards with local needs assessment information annually using data provided by Public Health England. **[2012, amended 2016]**

1.8.5.3 Commissioners of TB prevention and control programmes should ensure services reflect the needs of their area, identified by needs assessment.

Health and wellbeing boards should ensure that local TB services have been commissioned based on local needs identified through needs assessment. **[2012, amended 2016]**

1.8.5.4 Directors of public health and TB control boards should use cohort review (see section 1.8.6) and other methods to collect data on the following, to inform local needs assessment:

- Number of annual notified TB cases (see Public Health England's enhanced TB surveillance data and annual 'suite of indicators').
- Size, composition (for example, age and ethnicity) and distribution of local at-risk groups.
- Indices of social deprivation.
- Local statutory and non-statutory services working with these groups.
- Organisation of local TB services, including the composition and capacity of the local multidisciplinary TB team(see the results of local audit) and location of services. This may also include data to support evaluating the need for integrated TB/HIV services including joint clinics.
- Numbers needing enhanced case management (see the section on adherence, treatment completion and follow-up).
- Numbers receiving directly observed therapy from the start of, or at any point during, treatment (see Public Health England's enhanced TB surveillance data).
- Evidence of recent transmission (for example, using DNA fingerprinting or surrogate markers such as number of cases in children under 5 years (see UK TB national strain-typing database and local incident and outbreak reports).
- Completeness and yield of contact investigations. This includes: proportion of smear-positive cases with 0, 5 or more contacts identified; proportion of identified contacts clinically assessed; and proportion of contacts with latent TB infection who successfully complete treatment.
- Active case-finding initiatives, incident contact investigations and identification of latent TB infection in high-risk groups.

- Treatment outcomes for everyone grouped according to social risk factors and by the use of directly observed therapy (including rates of loss to follow-up and treatment interruptions, see Public Health England's enhanced TB surveillance data).
- Local education and awareness-raising programmes for under-served groups, professionals and practitioners working with them.
- Views and experiences of people with TB, carers and the services working with them. **[2012, amended 2016]**

1.8.5.5 Local needs assessments should also be equity proofed to assess the potential effect of planning, commissioning and policy decisions on health inequalities (see planning and commissioning services in NICE's local government briefing on health inequalities and population health). **[new 2016]**

1.8.6 Cohort review

1.8.6.1 TB control boards and prevention and control programme leads should initiate, audit and evaluate cohort reviews in their commissioning area. Quarterly cohort review meetings should take place in the area covered by the programme. Combine these meetings with others if possible, or use technology to make it easier for clinicians and case managers to attend. **[2012, amended 2016]**

1.8.6.2 TB case managers should present standardised information on each case, including: demographic information, HIV test results, pre-treatment and ongoing status (clinical, laboratory, radiology), adherence to treatment and the results of contact investigations. **[2012, amended 2016]**

1.8.6.3 TB case managers and key allied professionals from the TB prevention and control programme should attend cohort review meetings. This could include the lead clinician (who may or may not be the case manager). Either a paediatrician with experience and training in the treatment of TB or a general paediatrician with advice from a specialised clinician should be present when cases of children with TB are presented. **[2012, amended 2016]**

1.8.6.4 The chair of the cohort review should not work for any of the TB services included in the review. Examples of possible chairs include a public health consultant, a specialist physician or a senior TB nurse, preferably from a different geographical area. Alternatively the chair could be a representative from the local Public Health England health protection team or the TB control board. **[2012, amended 2016]**

1.8.6.5 Multidisciplinary TB teams, in conjunction with Public Health England units, should collate and present cohort review data on TB treatment and the outcome of contact investigations at the review meetings. In addition, progress towards national, regional and local service targets should be presented. **[2012, amended 2016]**

1.8.6.6 TB control boards, directors of public health and local public health consultants should ensure outputs from the cohort review feed into the needs assessment for TB services. TB control board directors should attend the cohort review at least once a year. **[2012, amended 2016]**

1.8.6.7 TB case managers should feed back promptly to multidisciplinary TB teams on issues identified as a result of cohort review. The results of the cohort review should be collated locally and agreed by the chair before being fed back to TB control boards, commissioners and health and wellbeing boards regularly and via needs assessment. **[2012, amended 2016]**

1.8.6.8 People participating in a cohort review should review the results and evaluate local services (for example, auditing adverse outcomes, rates of culture confirmation, treatment completion rates or time to diagnosis). **[2012, amended 2016]**

1.8.7 Commissioning multidisciplinary TB support

1.8.7.1 Commissioners should ensure multidisciplinary TB teams:

- Have the skills and resources to manage the care of people with active TB who are not from under-served groups. **[2012, amended 2016]**

- Include at least 1 TB case manager with responsibility for planning and coordinating the care of under-served people and those with active TB who receive enhanced case management. **[2012, amended 2016]**
- Have the resources to manage latent TB care in under-served groups and the wider population. **[new 2016]**
- Include a range of clinical specialties in the multidisciplinary TB team, including paediatrics, infection control and respiratory medicine. **[2012]**
- Have regular attendance at these multidisciplinary team and cohort review meetings for all team members included as a programmed activity as part of their work planning. **[new 2016]**
- Have the skills and resources necessary to manage the care of people with complex social and clinical needs (either directly or via an established route). This includes the ability to provide prompt access (or if necessary, referral) to skilled outreach and advocacy workers who can draw on the services of allied practitioners. The aim is to address people's housing, asylum, immigration, welfare, substance dependency and other health and social care needs. (The allied practitioner support should include both a specified housing officer and a social worker.) **[2012]**
- Can provide rapid access TB clinics for all cases, including under-served groups. **[2012]**
- Consider providing administration support for TB nurses and case managers so they have capacity for clinical and case management work. This could include giving TB nurses access to computer hardware and software. **[new 2016]**
- Have the resources to provide a continuous service throughout the year, ensuring the TB service accounts for the following to manage continuity of care:
  - planned absence (for example, professional development, mandatory training, annual, maternity or paternity leave)
  - unplanned absence (such as sickness absence). **[2012, amended 2016]**
- Can provide prompt access to a professional who has training and experience in assessing and protecting children and vulnerable adults at risk of abuse or neglect. **[2012]**

- Have access to funds through local government and clinical commissioning groups that can be used flexibly to improve adherence to treatment among under-served groups. For example, funds could be used to provide transport to clinics, to provide support or enablers for treatment, or for paying outreach workers or community services to support directly observed therapy. Funds may also be used to provide accommodation during treatment. **[2012, amended 2016]**

- Have the resources to provide ongoing TB awareness-raising activities for professional, community and voluntary (including advocacy) groups that work with populations at high risk of TB (see the section on raising and sustaining awareness of TB). These resources could be financed by local government or clinical commissioning groups. **[2012, amended 2016]**

1.8.7.2 Commissioners should ensure NHS England's safe staffing principles are applied when commissioning TB services.

The staffing ratios used in Public Health England and NHS England's collaborative tuberculosis strategy for England (published in 2015) came from NICE's guideline on tuberculosis: identification and management in under-served groups (published in 2012) which has been replaced by this guideline.

NICE's 2012 guideline on tuberculosis: identification and management in under-served groups recommended 1 WTE case manager per 40 incident cases needing standard management and 1 WTE case manager per 20 incident cases needing enhanced case management. **[new 2016]**

1.8.8 Non-clinical roles including TB support workers

1.8.8.1 TB control boards and local TB services should consider employing trained, non-clinically qualified professionals to work alongside clinical teams to agreed protocols, and to contribute to a variety of activities. Examples of this may include awareness raising and supporting people to attend appointments (including other health and social care appointments). They could also help with collecting samples, contact tracing, case management including directly observed therapy and cohort review, or any other aspect of the service if:

- they are trained to deliver the intervention or processes effectively
- they are supported, mentored and supervised by a named case manager, such as a TB nurse
- they have the skills to monitor, evaluate and report on their work practices and outcomes to maintain a process of ongoing evaluation and service improvement in relation to cohort review (see the section on cohort review). **[new 2016]**

1.8.8.2 TB control boards should ensure that people working in the TB service have the right knowledge, engagement, advocacy and communication skills to meet the needs (for example, language, cultural or other requirements) of all the groups they may work with. **[new 2016]**

1.8.8.3 Commissioners should consider taking into account different needs across traditional geographical and organisational boundaries. Put agreements in place so that staff can work across these boundaries, covering the whole service or TB control board area if appropriate. **[new 2016]**

1.8.8.4 Commissioners and TB control boards should ensure they put in place appropriate governance (including clear lines of accountability and extension of scope of practice) and data sharing practices and agreements. This includes ensuring they are part of service level agreements between NHS and non-NHS services, for example, the third sector or local government, and appropriate training has been completed. **[new 2016]**

1.8.9 Rapid-access TB services

1.8.9.1 Multidisciplinary TB teams should establish relationships with statutory, community and voluntary organisations that work with people at risk of TB to develop appropriate TB referral pathways. They should ensure these organisations know how to refer people to local TB services. **[2012]**

1.8.9.2 Multidisciplinary TB teams should accept referrals from healthcare providers and allied organisations working in the community with

under-served groups. This includes voluntary and statutory organisations (for example, mobile X-ray teams or community organisations or outreach workers working with vulnerable migrants). **[2012]**

1.8.9.3 Multidisciplinary TB teams should accept self-referrals to TB clinics by people who suspect they have TB or have recently been in contact with someone with TB. **[2012, amended 2016]**

1.8.9.4 Multidisciplinary TB teams should consider accepting direct referrals from emergency departments (see the section on rapid-access radiology and other investigation results: referral to multidisciplinary TB team process). **[new 2016]**

1.8.9.5 Healthcare professionals should consider urgent referral to TB clinics for people with suspected active TB. They should also ensure the results from first-line diagnostic tests (including a sputum smear and chest X-ray) are available before the person sees a specialist. (Note: this should not delay the referral.) **[2012, amended 2016]**

1.8.9.6 Multidisciplinary TB teams should have pathways to triage referrals, start investigations and collect clinical information before the person is seen by a physician. **[new 2016]**

1.8.9.7 While triaging, multidisciplinary TB teams should ensure everyone is given information about TB as part of the process (see the section on providing information for the public about TB). This should include who the person should contact if they have any questions and how to access advice or information from support groups, national charities such as TB Alert and other sources such as local government (for example, public health or social care teams). **[2016]**

1.8.9.8 Multidisciplinary TB teams should ensure people who have a smear-positive result or imaging features highly suggestive of smear-positive TB (for example, evidence of cavitation on chest X-ray) are assessed the next working day. This is so that case management and infection control procedures start promptly. **[2012, amended 2016]**

1.8.9.9 The multidisciplinary TB team should assess people who are not

smear-positive but have imaging that suggests pulmonary or laryngeal TB as soon as possible. This should be no later than 5 working days after a referral. **[2012, amended 2016]**

1.8.9.10 Multidisciplinary TB teams should, where necessary, be able to provide or arrange outreach services to ensure sputum samples or other assessments such as contact investigations can be arranged in the community. **[2016]**

1.8.10 Identifying and managing active TB in prisons, custody suites or immigration removal centres: organisational factors

1.8.10.1 Multidisciplinary TB teams, prisons, custody suites and immigration removal centre healthcare services should have named TB liaison leads to ensure they can communicate effectively with each other. **[2012, amended 2016]**

1.8.10.2 Prison, custody suites and immigration removal centre healthcare services should develop a TB policy by working with the TB control board and multidisciplinary TB team and the local Public Health England health protection team. **[2012, amended 2016]**

1.8.10.3 Multidisciplinary TB teams, in conjunction with prisons, custody suites and immigration removal centre healthcare services, should agree a care pathway for TB. This is to ensure that any suspected or confirmed cases are reported to, and managed by, the multidisciplinary TB team. **[2012, amended 2016]**

1.8.10.4 Multidisciplinary TB teams, in liaison with prisons, custody suites or immigration removal centre healthcare providers, should manage all cases of active TB. Investigations and follow-up should be undertaken within the prison or immigration removal centre if possible. **[2012, amended 2016]**

1.8.11 Accommodation during treatment

1.8.11.1 Multidisciplinary TB teams should assess the living circumstances of people with TB. Where there is a housing need they should work with

allied agencies to ensure that all those who are entitled to state-funded accommodation receive it as early as possible during their treatment, for example, as a result of a statutory homelessness review and identified need. **[2012, amended 2016]**

1.8.11.2 Multidisciplinary TB teams, commissioners, local authority housing lead officers and other social landlords, providers of hostel accommodation, hospital discharge teams, Public Health England and the Local Government Association should work together to agree a process for identifying and providing accommodation for homeless people diagnosed with active pulmonary TB who are otherwise ineligible for state-funded accommodation. This includes people who are not sleeping rough but do not have access to housing or recourse to public funds. The process should detail the person's eligibility and ensure they are given accommodation for the duration of their TB treatment. **[2012, amended 2016]**

1.8.11.3 Local government and clinical commissioning groups should fund accommodation for homeless people diagnosed with active TB who are otherwise ineligible for state-funded accommodation. Use health and public health resources, in line with the Care Act 2014. **[2012, amended 2016]**

1.8.11.4 Multidisciplinary TB teams should make people who would not otherwise be entitled to state-funded accommodation aware that they may lose this accommodation if they do not comply with treatment. They should ensure plans are made to continue housing people once their TB treatment is completed. **[2012]**

1.8.11.5 Public Health England, working with the Local Government Association and their special interest groups, should consider working with national housing organisations such as the Chartered Institute of Housing, Homeless Link, Sitra and the National Housing Federation to raise the profile of TB. This is to ensure people with TB are considered a priority for housing. **[new 2016]**

1.8.11.6 Consider training housing commissioners and frontline staff on TB and the need for housing support, so that they understand that a stable

home life is a prerequisite to successful TB treatment. **[new 2016]**

Terms used in this guideline

Active case-finding

Systematically identifying people with active or latent TB using tests, examinations or other procedures.

Adherence

The term adherence refers to the person's ability or willingness to keep to a treatment regimen as directed.

Adults

People aged 18 or older.

Case management

Case management involves follow-up of a person suspected or confirmed to have TB. It needs a collaborative, multidisciplinary approach and should start as soon as possible after a suspected case is discovered.

Case manager

Standard and enhanced case management is overseen by a case manager who will usually be a specialist TB nurse or (in low-incidence areas) a nurse with responsibilities that include TB. Depending on the person's circumstances and needs, case management can also be provided by appropriately trained and supported non-clinical members of the TB multidisciplinary team.

Children

People aged 15 or younger.

Children and young people

People aged 17 or younger.

Close contacts

'Close contacts' are people who have had prolonged, frequent or intense contact with a person with infectious TB. For example, these could include 'household contacts', those who share a bedroom, kitchen, bathroom or sitting room with the index case. Close contacts may also include boyfriends or girlfriends and frequent visitors to the home of the index case. Depending in the circumstances, occasionally coworkers are classed as 'close contacts although they are more usually classed as 'social contacts'.

Cohort review

Cohort review is a systematic quarterly audit of the management and treatment of all TB patients and their contacts. The 'cohort' is a group of cases counted over a specific time, usually 3 months. Brief details of the management and outcomes of each case are reviewed in a group setting. The case manager presents the cases they are responsible for, giving the opportunity to discuss problems and difficulties in case management, service strengths and weaknesses, and staff training needs.

Congregate setting

A place where people congregate or an institutional setting such as a workplace, prison, hostel, or childcare or educational setting, where social contacts might have had significant exposure to TB.

Contact

A person who has spent time with someone with infectious TB. See also 'close contact' and 'social contact'.

Contact investigation

Clinical investigations (diagnostic testing) of people identified as having had significant exposure to a case of TB, including tests to diagnose latent or active TB. The aims of

contact investigations are to:

- detect active TB earlier to offer treatment and prevent further transmission
- detect latent TB that may benefit from drug treatment
- detect people not infected but for whom BCG vaccination might be appropriate.

Contact tracing

Identifying people who may have come into contact with a person with infectious TB and assessing them for risk of significant exposure to TB. The aim is to find associated cases, to detect people with latent TB and to identify those not infected but for whom BCG vaccination might be appropriate.

Disseminated TB

Blood-borne spread of TB that may or may not be accompanied by chest X-ray or high resolution CT changes.

Enablers

Methods of helping someone to overcome barriers to completing diagnostic investigations and TB treatment. Examples of barriers include: transport, housing, nutrition and immigration status.

Enhanced case management

Management of TB for someone with clinically or socially complex needs. It starts as soon as TB is suspected. As part of enhanced case management, the need for directly observed treatment is considered, along with a package of supportive care tailored to the person's needs.

Equity proofed

Tools such as health equity audit and health impact assessment have been used systematically to assess the potential effect of all policies, programmes and activities (including those without an explicit health focus) on health inequalities. Equity proofing

helps ensure all policies and programmes address the social determinants of health and health inequalities. Including a health equity audit as part of the joint strategic needs assessment can help local authorities and their partners to:

- develop strategy and plans according to need
- identify and work with community and health partners
- commission activities based on the best available evidence
- implement interventions to tackle inequity.

End-to-end pathway

The pathway from awareness raising and primary prevention, through diagnosis to treatment completion, incorporating all aspects such as contact tracing and other infection control mechanisms, for example, access to isolation facilities. This includes governance and commissioning considerations so that a comprehensive clinical and public health service is developed and delivered across any agreed geographical footprint.

Extrapulmonary TB

Active TB disease in any site other than the lungs or tracheobronchial tree.

Extensively drug-resistant TB

Resistance to at least isoniazid and rifampicin, 1 injectable agent (capreomycin, kanamycin or amikacin) and 1 fluoroquinolone.

High incidence

A high-incidence country or area has more than 40 cases of TB per 100,000 people per year. Public Health England lists high-incidence countries and areas of the UK on its website.

High-risk groups

The term 'high-risk groups' is used in this guideline to mean adults, young people and

children from any ethnic background, regardless of migration status, who are at increased risk of having or contracting TB. This includes people classified as under-served, people identified as contacts according to the case finding recommendations, new entrants from high-incidence countries and people who are immunocompromised.

Homelessness

For the purposes of TB control, a broad and inclusive definition of homelessness has been adopted that incorporates overcrowded and substandard accommodation. It includes people:

- who share an enclosed air space with people at high risk of undetected active pulmonary TB (that is, people with a history of rough sleeping, hostel residence or substance misuse)
- without the means to securely store prescribed medication
- without private space in which to self-administer TB treatment
- without secure accommodation in which to rest and recuperate in safety and dignity for the full duration of planned treatment.

Immigration removal centres

Immigration removal centres are private or prison-run holding centres for migrants waiting to be accepted by, or deported from, the UK. Immigration removal centres are also known as immigration detention centres and pre-departure accommodation.

Immunocompromised

In this guideline, immunocompromised refers to a person who has a significantly impaired immune system. For instance, this may be because of prolonged corticosteroid use, tumour necrosis factor-alpha antagonists, antirejection therapy, immunosuppression-causing medication or comorbid states that affect the immune system, for example, HIV, chronic renal disease, many haematological and solid cancers, and diabetes.

Incident risk assessment

Assessment of risk of exposure to TB in a congregate setting to decide on the need for and extent of contact investigation. The risk assessment would take into consideration factors such as infectiousness of the index case, vulnerability of contacts to TB infection, length of contact with or exposure to an infectious case and the built environment (for example, size of the rooms, ventilation and overcrowding).

Index case

The initial person found to have TB, whose contacts are screened. The source of their infection may be found to be 1 of the contacts, but the person who presents first is regarded as the index case.

Induration

The firm skin reaction occurring after a tuberculin skin test to diagnose latent TB infection. It is measured, and the result used to determine whether the test result is classified as positive or negative. This guideline recommends a threshold of 5 mm for tuberculin skin test positivity.

Infectious TB

Active smear-positive pulmonary TB, that is with acid fast bacilli visible on microscopy. Active TB affecting other parts of the respiratory tract or oral cavity, though rare, is also considered infectious.

Isolation

An infection control measure in which people with infectious TB are kept away from others who may be at risk of infection. This guideline deals with 3 levels of isolation for infection control in hospital settings:

- negative pressure rooms, which have air pressure continuously or automatically measured, as defined by NHS Property Services
- single rooms that are not negative pressure but are vented to the outside of the building

- beds on a ward, for which no particular engineering standards are needed.

Lost to follow-up

People are defined as 'lost to follow-up' if they cannot be contacted within 10 working days of:

- their first missed outpatient appointment (if they are on self-administered treatment)
- their first missed directly observed therapy appointment (if they are on directly observed therapy).

Multidisciplinary TB teams

A team of professionals with a mix of skills to meet the needs of someone with TB who also has complex physical and psychosocial issues (that is, someone who is under-served). Team members will include a social worker, voluntary sector and local housing representatives, TB lead physician and nurse, a case manager, a pharmacist, an infectious disease doctor or consultant in communicable disease control or health protection, a peer supporter or advocate and a psychiatrist.

Multidrug-resistant TB

TB resistant to isoniazid and rifampicin, with or without any other resistance.

Negative pressure room

Used to isolate some patients known or suspected to have infectious TB. A negative pressure room is one where the air from the room is sucked out into dedicated ducting through a filter and into the outside air, at a distance from all other air intakes. The pressure should be 10 pascals below the ambient air pressure.

Neonates

Children aged 4 weeks or younger.

New entrant

Anyone coming to work or settle in the UK. This includes immigrants, refugees, asylum seekers, students and people on work permits. It also includes UK-born people, or UK citizens, re-entering the country after a prolonged stay in a high-incidence country.

Opportunistic case-finding

Opportunistic identification of people with active or latent TB using tests, examinations or other procedures in the course of existing appointments or interactions, rather than identification through formal screening programmes.

Outbreak

There is no robust, widely accepted threshold for an outbreak of a disease, but in practical terms an outbreak is the occurrence of an unusually high number of cases in associated people, in a small geographical area, or in a relatively short period of time.

Peers

Peers are people who may have experienced TB. They are often in a good position to help convey, with empathy, the need for testing or treatment. They may be recruited from specific populations. With support they can communicate health messages, assist with contact investigations or testing and offer people support while they are being tested or treated.

Prisons

Any state prison establishments, including young offender institutions.

Rapid access

In the context of TB services, rapid access refers to timely support from a specialist team.

Smear grade

The number of bacilli found in a sputum sample, believed to relate to the degree of

infectivity of the person. There are several systems but in general recording goes from no mycobacteria in 100 fields (0 or negative) to more than 10 acid-fast bacilli per field in at least 20 fields (grade 3).

Social contacts

Someone who has had contact with a person with infectious TB but has not been in prolonged, frequent or intense contact.

Substance misuse

Substance misuse is defined as intoxication by, or regular excessive consumption of or dependence on, psychoactive substances, leading to social, psychological, physical or legal problems. It includes problematic use of both legal and illegal drugs.

TB control board

A partnership of mixed professionals and lay people who have experience of leading, commissioning, managing or supporting people with TB. Board members are likely to include the voluntary sector, housing representatives, TB specialists and other clinicians, consultants in communicable disease control or health protection, peer supporter and advocate groups, clinical commissioning groups, executive officers, local government commissioners and an independent chair. This list is not intended to be exhaustive; membership should be determined based on an area's needs, agreements and commissioning arrangements.

Treatment interruption

A break in the prescribed anti-TB regimen for 2 weeks or more in the initial phase, or more than 20% of prescribed doses missed intermittently.

Under-served groups

This term is used in this guideline to mean groups of adults, young people and children from any ethnic background, regardless of migration status. They are 'under-served' if their social circumstances, language, culture or lifestyle (or those of their parents or carers) make it difficult to:

- recognise the clinical onset of TB
- access diagnostic and treatment services
- self-administer treatment (or, in the case of children and young people, have treatment administered by a parent or carer)
- attend regular appointments for clinical follow-up.

The groups classified as under-served in this guideline are:

- people who are homeless
- people who misuse substances
- prisoners
- vulnerable migrants.

Under-served children

Groups of children identified as potentially under served include:

- unaccompanied minors
- children whose parents are under served, including vulnerable migrants
- children whose parents are in prison or who abuse substances
- children from Gypsy and Traveller communities
- looked-after children.

Vulnerable migrants

Vulnerable migrants may include undocumented migrants and those with no recourse to public funds. Some refugees, asylum seekers and new entrants to the country may also fall into this category.

Young people

People aged 16 or 17.

Context

Tuberculosis (TB) is a curable infectious disease caused by a type of bacterium called *Mycobacterium tuberculosis* ('M. tuberculosis' or 'M.Tb'), or other bacterium in the M. tuberculosis complex (that is*, M. bovis* or *M. africanum*). It is spread by droplets containing the bacteria being coughed out by someone with infectious TB, and then being inhaled by other people.

The initial infection clears in over 80% of people but, in a few cases, a defensive barrier is built round the infection and the TB bacteria lie dormant. This is called latent TB; the person is not ill and is not infectious. If the immune system fails to build the defensive barrier, or the barrier fails later, latent TB can spread in the lung (pulmonary TB) or develop in the other parts of the body it has spread to (extrapulmonary TB). Only a small proportion of people with latent TB will develop symptoms ('active TB').

Many cases of TB can be prevented by public health measures and, when clinical disease does occur, most people can be cured if treated properly. Taking medication in the wrong dose or combination, irregularly or for too short a time can lead to drug resistance. Drug-resistant strains of TB are much harder to treat and significantly increase a person's risk of long-term complications or death. If left untreated, 1 person with active pulmonary TB may infect as many as 10 to 15 people every year.

TB incidence in the UK has increased since the early 1990s, but has remained relatively stable since 2005. Despite this, it remains high compared with many other western European countries. Cases tend to cluster in urban areas where populations of at-risk groups are high. These include areas with many people born in countries with a high incidence of TB, areas with a high level of homelessness, poor housing or poverty, and areas with high rates of problem drug use.

The NHS and Public Health England, as well as a local authority public health teams and many third sector organisations, have been working to reduce the harm caused by TB to many individuals and communities. TB is a notifiable disease, meaning that clinicians have a statutory duty to notify local authorities or a local Public Health England centre of suspected cases, and efforts have been made to strengthen services and ensure clear lines of accountability and responsibility. However, a stronger approach to TB control is now needed to build on this work. Indicators of TB incidence and TB treatment outcomes have been included in the Public Health Outcomes Framework. In addition, Public Health

England and NHS England have designed a collaborative tuberculosis strategy for England that brings together best practice in clinical care, social support and public health. Agencies at all levels, including national and local government, clinical commissioning groups and third sector partners, are committed to working in partnership to decrease the incidence of TB, fight the spread of drug-resistant forms of the disease, reduce current health inequality and, ultimately, eliminate TB as a public health problem in England.

Recommendations for research

The guideline committee has made the following recommendations for research. The guideline committee's full set of research recommendations is detailed in the full guideline.

1 Universal compared with risk-based approach to using rapid diagnostic tests

In people with suspected TB, what is the relative clinical and cost effectiveness of universal and risk-based use of rapid nucleic acid amplification tests?

Why this is important

The guideline committee noted that there were 2 possible approaches to using rapid nucleic acid amplification tests for suspected TB. The current approach is to use them only if TB is strongly suspected and rapid information about mycobacterial species would alter the person's care. Another approach is to use them in anyone with a possible diagnosis of TB. There is a trade-off between ensuring that all people with active TB are diagnosed and avoiding a large number of false positives, which leads to unnecessary treatment. This trade-off may lead to differences in the cost effectiveness of each approach. NICE's systematic review of the diagnosis of active TB did not identify any robust evidence on this, nor did the health technology assessment on using nucleic acid amplification tests to detect drug resistance. Cost-effectiveness studies are needed to improve understanding in this area.

2 Diagnosis in children

Apart from culture, what other diagnostic tests or combinations of tests are effective in establishing an accurate diagnosis of active respiratory TB in children and young people with suspected active TB?

Why this is important

The guideline committee noted the lack of evidence on the diagnosis of active TB in children. The disease manifests differently in children than in adults, and more evidence

would have been useful to the committee. Cross-sectional studies are needed to examine the relative accuracy of different tests, and the most appropriate specimen type for these tests, compared with tests currently in use. In particular, the poor accuracy of many tests in children means that diagnostic strategies that is, combinations of tests, should be investigated, including both tests with high sensitivity and tests based on host response.

3 Treating isoniazid-resistant TB

For isoniazid-resistant TB, what is the most effective regimen for reducing mortality and morbidity?

Why this is important

There is little evidence for the treatment of isoniazid resistant TB. This is the most common form of drug resistance in the UK, occurring in 7.5% of TB cases. Currently, treatment is not always successful, even when the recommended drugs are given for the recommended time and there are no adherence issues. It is particularly difficult to treat if there are treatment interruptions or if the central nervous system is involved. Randomised controlled trials are needed to compare different anti-TB regimens for isoniazid-resistant TB, assessing mortality, treatment success or treatment failure, rates of relapse and adverse events.

4 Impact of infection control measures on quality of life

What effects does isolation have on the quality of life of people being treated for TB?

Why this is important

Isolation is known to significantly affect a person's quality of life. Despite this, the guideline committee identified no reliable data on the impact of isolation on quality of life. This information is essential in producing economic models that reflect the real costs of isolation. Data on the impact of isolation on quality of life need to be collected and reported.

5 Treatment interruptions caused by adverse

events (specifically hepatotoxicity)

For people with active, drug susceptible TB who experience treatment interruptions because of adverse events, particularly hepatotoxicity, what approach to re-establishing treatment is most effective in reducing mortality and morbidity?

Why this is important

There is little evidence on re-establishing treatment after interruptions because of adverse events. This is key to ensuring treatment success without relapse or the emergence of drug resistance, but avoiding further adverse events is also important. Randomised controlled trials are needed to compare approaches to re-establishing treatment for active, drug susceptible TB after it is interrupted because of adverse events, particularly hepatotoxicity. These trials should assess mortality, treatment success or failure, rates of relapse, the recurrence of adverse events and the emergence of drug resistance. Approaches evaluated could compare, for example, restarting regimens with lengthening their duration, as well as sequential reintroduction. Approaches should vary depending on the proportion of doses missed and the stage of treatment (initial or continuation phase) in which the interruption occurred. Prospective observational cohort studies with multivariable analyses may also be useful.

Finding more information and committee details

To find NICE guidance on related topics, including guidance in development, see the NICE topic pages on tuberculosis and vulnerable groups.

For full details of the evidence and the guideline committee's discussions, see the full guideline. You can also find information about how the guideline was developed, including details of the committee.

NICE has produced tools and resources to help you put this guideline into practice. For general help and advice on putting our guidelines into practice, see resources to help you put NICE guidance into practice.

Update information

September 2019: Minor wording changes have been made to recommendation 1.7.4.2 and footnotes added to reflect new restrictions and precautions for the use of fluoroquinolone antibiotics. It is labelled **[new 2016, amended 2019]**.

June 2019: Recommendation 1.6.1.8 has been amended to add in more detail about the meaning of contacts.

November 2018: Recommendation 1.1.3.16 on BCG vaccinations for healthcare workers and other NHS employees was updated after a surveillance review.

May 2016: Recommendation 1.2.1.1 was clarified to reflect the sequencing of tests. Reference to IGRA status was removed from recommendations 1.1.3.13; 1.1.3.16-18; 1.1.4.6; 1.1.4.8 and 1.6.1.4.

February 2016: Recommendation 1.1.3.4 has been amended to clarify that the recommendation is about assessing risk for and vaccinating the baby.

January 2016: This guideline was published. It is an update of NICE guideline CG117 (published March 2011) and replaces it. It also incorporates and adapts NICE guideline PH37 (published March 2012).

Through the scoping process we work with stakeholders to identify, prioritise and agree areas of the guideline to update. This means that areas outside the scope were not reviewed during this update and the recommendations may not reflect current practice. Areas that have not been reviewed in this update may be addressed 2 years after publication, when NICE next considers updating this guideline. NICE may undertake an update of discrete areas of the guideline if new and relevant evidence is published.

Recommendations are marked as:

- **[new 2016]** if the evidence has been reviewed and the recommendation has been added or updated
- **[2016]** if the evidence has been reviewed but no change has been made to the recommended action

- **[2006]** if the evidence has not been reviewed since 2006
- **[2006, amended 2011]** or **[2011]** if the evidence has not been reviewed since 2006
- **[2012]** if the evidence has not been reviewed since 2012
- **[2006, amended 2011, amended 2016]** or **[2011, amended 2016]** if the evidence has not been reviewed since 2011, but either changes have been made to the recommendation wording that change the meaning or NICE has made editorial changes to the original wording to clarify the action to be taken (see below).
- **[2006, 2012, amended 2016]** or **[2012, amended 2016]** if the evidence has not been reviewed since 2012, but either changes have been made to the recommendation wording that change the meaning or NICE has made editorial changes to the original wording to clarify the action to be taken (see below).

Recommendations from NICE guideline CG117 that have been amended

Recommendations are labelled **[2011, amended 2016] and [2006, amended 2011, amended 2016]** if the evidence has not been reviewed but either:

- changes have been made to the recommendation wording that change the meaning, or
- NICE has made editorial changes to the original wording to clarify the action to be taken.

Further details of the specific changes to the recommendations during the 2016 update are available on request.

Recommendations from NICE guideline PH37 that have been amended

Recommendations are labelled **[2012, amended 2016]** if:

- The evidence has not been reviewed, but a change has been made to clarify roles or actions in the original recommendation, extrapolate to the whole population, or where system changes such as establishment of TB control boards have been reflected
- NICE has made editorial changes to the wording to clarify the action to be taken, but where there is no change of meaning to the original recommendation.

Further details of the specific changes to the recommendations during the 2016 update are available on request.

Attachments: HVC 107 - Paediatric Critical Care and Haemonc Ventilation_FOR APPROVAL_05_12_19.pdf

Importance: High

Following recent requirements communicated by the Board's Chief Executive and as endorsed by the Executive Steering Board, the attached High Value Change Notice is required to be approved by the parties listed below.

I would be grateful for your response by midday tomorrow, 4th December, 2019, to allow consideration and hopefully final approval by the Oversight Board on Thursday morning of this week.

	Approval Required
Project Manager	*Ronnie Henderson*
Project Technical Adviser	*Mott MacDonald*
Service leads	*Laura Reilly and Julie McGill*
Infection Control	*Lyndsay Guthrie and Donald Inverarity*
Authorising Engineer	*John Rayner*
Project Director	*Brian Currie*
Director of Facilities	*George Curley*
Executive Director	*Tracey Gillies*
HFS	*Eddie McLaughlan and/or Ian Storrar*
HPS	*Laura Imrie*

High Value Change Notice

Project:	RHCYP + DCN – Little France Edinburgh

1 – Issue of Change Notice to Project Co			
Title:	**Paediatric Critical Care and Haematology / Oncology Ventilation**		
Reference No: 0107		**Date: 5th December, 2019**	
Target Cost Capital:	**£4.6m**	**Target Cost Revenue:**	**TBA**

High Value Change Requirements (Schedule Part 16, Section 4, Clause 2.1.3)

Single bedrooms and Multi-bedrooms in Paediatric Critical Care

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems which will deliver **10 air changes/hour at +10pa** as per SHTM 03-01, Appendix 1, Table A1 to the following rooms at the Facilities:

Room Number	Room Type
1-B1-065	*Neo Natal 3 cot area* including 1-B1-022 – *Corridor*, 1-B1-069 – *Staff Base*, 1-B1-066 – *Clean Utility* and 1- B1-071 – *Resus Bay* which are all open to 1-B1-065
1-B1-075	*Single cot cubicle neo natal* including *1-B1-074 en-suite*
1-B1-063	*Open plan bay 4 bed*
1-B1-037	*Single bed cubicle*
1-B1-031	*Open plan bay 4 bed*
1-B1-021	*Single bed cubicle*
1-B1-020	*Single bed cubicle*
1-B1-019	*Single bed cubicle*
1-B1-009	*Open plan bay 4 bed*

Isolation Rooms in Paediatric Critical Care

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems for a positive pressure ventilated lobby PPVL Single Bedroom Isolation Suite with a lobby air supply terminal with a HEPA filter, as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1, to the following rooms at the Facilities.

Project Co may utilise the supply and extract ventilation system description in SHPN 04-01, Supplement 1, Clause 4.5 for a dedicated ventilation system per Suite or SHPN 04-01, Supplement 1, Clause 4.8 for a common ventilation system to multiple Suites as the basis of their design. If Clause 4.8 is selected as the basis of design, a duplicate supply unit is considered necessary. A combination of both methods may be used provided Project Co, as far as is reasonably practical, reuse the existing ventilation installations. Regardless of option chosen, all aspects of the design and installation must be technically compliant with all relevant guidance.

NHSL require to remove or significantly reduce the risk of losing all isolations rooms due to a single point of failure. Ideally each isolation room would benefit from its own supply and extract, however, NHSL appreciate this may not be possible or practical due to other constraints e.g. space. Therefore, Project Co are requested to provide their best practical solution to reduce the risk as low as possible but maintaining guidance criteria as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1.

Room Number	Room Type
1-B1-016	Isolation Bedroom
1-B1-017	Isolation Bedroom
1-B1-026	Isolation Bedroom

1-B1-036	Isolation Bedroom

Single bedrooms and Multi-bedrooms in Haematology and Oncology

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems which will deliver **10 air changes/hour at +10pa** as per SHTM 03-01, Appendix 1, Table A1 and fit Hepa filters (H12 grade) to the air inlets to the following rooms at the Facilities:

Room Number	Room Type
3-C1.4-059	Single Bedroom
3-C1.4-057	Single Bedroom
3-C1.4-055	Single Bedroom
3-C1.4-046	Single Bedroom
3-C1.4-032	Single Bedroom
3-C1.4-018	Single Bedroom
3-C1.4-016	Single Bedroom
3-C1.4-013	Single Bedroom
3-C1.4-010	Single Bedroom
3-C1.4-074	Single Bedroom
3-C1.4-076	Single Bedroom
3-C1.4-078	Single Bedroom
3-C1.4-084	Multi-Bed (3) Day Care
3-C1.4-061	Multi-Bed (6) Day Care

Isolation Rooms in Haematology and Oncology

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems for a positive pressure ventilated lobby PPVL Single Bedroom Isolation Suite with a lobby air supply terminal with a HEPA filter, as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1, to the following rooms at the Facilities.

Project Co may utilise the supply and extract ventilation system description in SHPN 04-01, Supplement 1, Clause 4.5 for a dedicated ventilation system per Suite or SHPN 04-01, Supplement 1, Clause 4.8 for a common ventilation system to multiple Suites as the basis of their design. If Clause 4.8 is selected as the basis of design, a duplicate supply unit is considered necessary. A combination of both methods may be used provided Project Co, as far as is reasonably practical, reuse the existing ventilation installations. Regardless of option chosen, all aspects of the design and installation must be technically compliant with all relevant guidance.

NHSL require to remove or significantly reduce the risk of losing all isolations rooms due to a single point of failure. Ideally each isolation room would benefit from its own supply and extract, however, NHSL appreciate this may not be possible or practical due to other constraints e.g. space. Therefore, Project Co are requested to provide their best practical solution to reduce the risk as low as possible but maintaining guidance criteria as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1.

Room Number	Room Type
3-C1.4-040	Isolation Bedroom
3-C1.4-043	Isolation Bedroom
3-C1.4-049	Isolation Bedroom

3-C1.4-052	Isolation Bedroom
3-C1.4-072	Isolation Bedroom

(the "**Ventilation Works and Services**").

All environmental requirements for all spaces in the Facilities served by or affected by the Ventilation Works and Services systems shall be met and maintained – including but not limited to, temperature and control, lighting levels, noise, and humidity. These should be consistent to the agreed parameters throughout the Facilities to meet the specific clinical and operational needs for each space in the Facilities.

The Ventilation Works and Services shall fully comply with SHTM 03-01 requirements which includes, without limitation, implementation of the Ventilation Works and Services so that the system installation, finishes and maintenance regime shall be in accordance with SHTM 03-01 requirements, together with the clinical and operational constraints identified below:

1. All Ventilation Works and Services shall be carried out and monitored after and with reference to a collaborative full Stage 3 HAI SCRIBE assessment being approved by the Board.
2. The fire strategy and systems agreed for the Facilities will be maintained throughout the Ventilation Works and Services and the Operational Term and such that the ventilation systems will integrate with the fire strategy and systems and all other building management systems comprised in the Facilities.
3. The location of the installation within the rooms, external areas, route across such spaces and the take out of any windows, etc, will enable the current operational functionality and safety policies and procedures to be maintained.
4. The design, layouts, finishes and other details etc for the Ventilation Works and Services, at all stages (including during the design development stages), will require to be agreed with the Board's Representative (and in turn the clinical service and related stakeholders and Project Co recognises that in order to achieve agreement from the Board's Representative's the Board's Representative will seek input from the Board and all appropriate stakeholders.
5. Design must provide resilience in compliance with SHTM 03-01 to ensure performance of ventilation to rooms during maintenance downtime.

The Board will, in consultation with Project Co, continue to review costs as the design develops and at other stages. In order for the Board to assess whether the High Value Change Stage 2 Submission offers it value for money the submission shall include as a minimum the following information:

- A detailed and fully quantified pricing schedule for the construction works
- A detailed breakdown of all Preliminaries and general cost items
- Construction issue drawings and specification
- Proposed, construction and commissioning/testing programme
- Construction phase method statement

Date by which parties are required to meet to review the High Value Change Notice and agree the content for the High Value Change Proposal (Schedule Part 16, Section 4, Clause 2.3.1)	**13th December, 2019**

To: **IHS Lothian**

We require the Change described above.
Please advise when Project Co will submit a High Value Change Proposal for the above.

Signed on behalf of NHS Lothian: ……..

Name of Signatory (type or print): ……Brian Currie – Board Rep – NHS Lothian……

Date: 5th December, 2019 ……..

SBAR assessment: Outpatient and therapy areas: Ventilation Room Review RHCYP DCN

Lindsay Guthrie, Lead IPCN

Dr Donald Inverarity, Consultant Microbiologist and Lead ICD

1. **Situation:**

NHS Lothian are required by the Oversight Board "*to consider its clinical service model in light of the ventilation arrangements in place for general wards and other non critical areas (incorporating literature review and design information not yet available)*".

A clinical risk assessment of ventilation installed has been provided in relation to in patient (ward) areas.

A separate review of all outpatient and therapies areas was undertaken in September 2019 by a clinical lead from the project team (Dorothy Hanley); lead infection prevention and control nurse (Lindsay Guthrie) and lead infection control doctor & consultant microbiologist (Dr Donald Inverarity) with project management support from Kelly Bain & Ross Southwell (Mott McDonald).

2. **Background:**

No specific provision is made within SHTM 03-01 Part A Appendix 1 for the ventilation requirements for outpatient consultation rooms, therefore requirements are calculated using other building standards, which take into account the size of the room, availability of natural ventilation (opening window) and maximum number of people intended to use the space at any given time.

This means that rooms which appear on the matrix or hospital plan to have the same named function may have been designed with different ventilation requirements.

The environmental matrix was reviewed to assess the ventilation design specification for all rooms designated as:

- Treatment rooms
- Consultation rooms
- Clinical rooms
- Therapy rooms
- Investigation rooms

Consideration was then given to the risk profile of patients who would use these rooms, and the type of activity regularly undertaken on an outpatient basis.

The outcome of the preliminary independent verification of commissioning testing by IOM was reviewed to confirm that the system is functioning to the design parameters.

3. **Assessment**

3.1 Overall, there were no significant concerns or issues identified in relation to any impact on factors that would compromise delivery of infection prevention and control procedures and ventilation delivered based on the stated intended clinical use of the space and patient population.

3.2 Where treatment rooms were provided, particularly in areas which will see or treat high susceptibility patients (such as paediatric haematology/oncology) these were confirmed to have been designed and performing to deliver 10 air changes per hour at positive pressure in line with the requirements of SHTM 03-01 Part A Appendix 1.

3.3 It was noted that where some consulting rooms were designed to provide 6 air changes, not all such rooms included an opening window, sometime due to the location of the room within the building.

3.4 A multi bed bay in the clinical research facility was designed as contingency to be 'flexed' up to provide additional inpatient accommodation if required for overnight research studies in the future. The environmental matrix for this area showed the ventilation was designed to provide 3 air changes. Based on SHTM 03-01 Part A Appendix 1 this room should achieve 6 air changes if it is intended to be used for in patient accommodation, and is therefore not compliant with current guidance. Further risk assessment is required if the area is used for in patient use [*Recommendation 4.1*].

3.5 OPD 7 will provide Neurosciences outpatient services. No compliance issues were identified, and a treatment room compliant with SHTM 03-01 is provided in this area for any procedure or intervention common to this specialty.

3.6 OPD 8-11 - General paediatric services and specialist OPD including haematology/oncology. All consultation rooms are designed to provide 3 air changes, with exception of room D1-016 which provides 6 air changes. The treatment room in OPD 8-11 is compliant with SHTM 03-01 Part A Appendix 1 and this room should be used for any invasive or high risk intervention or procedure (as appropriate to an outpatient setting) in children or young people considered in a high susceptibility group (e.g. haematology/oncology) [*Recommendation 4.2*]

3.7 OPD 9- Cardio-Respiratory OPD Rooms GD2005/006/009/014were considered in earlier discussion with clinicians who provide care to children and young people with Cystic Fibrosis. [*Recommendation 4.3*]

3.8 In Crichton ward, 2 consulting rooms are provided (labelled as "treatment rooms" on the plans) which have been designed to provide 4 air changes. These are not suitable for any invasive procedures or interventions. [*Recommendation 4.4*]

3. 9 OPD 10 Dental Services: The dental unit was confirmed as providing 10 air changes (supply and extract) which is compliant with guidance for this type of service.

3. 10 OPD 12 (Dressings Clinic) all treatment rooms provide 10 air changes with positive pressure. These are appropriate for dressing changes and other clinical interventions appropriate to an outpatient setting.

3. 11 The rooms in the 'Acorn suite' (forensic services) are designed to deliver 3 air changes per hour, and we have confirmed that no invasive procedures would be performed in this area.

3.12 No significant issues were identified in the therapies treatment area [*Recommendation 4.5*]

4. Recommendations

4.1 We advise further risk assessment of compliance with ventilation standards is carried out by clinical research teams to ensure appropriate control measures to protect staff and young people are in place to minimise any risk from exposure to aerosolised or airborne pathogens as this requires local knowledge regarding which micro-organisms may be encountered depending on the nature of the research study, as at least one current research project relates to children with respiratory viruses.

4.2 The treatment room in OPD 8-11 should be used for any invasive or high risk intervention or procedure (as appropriate to an outpatient setting) in children or young people considered in a high susceptibility group (e.g. haematology/oncology

4.3 We advise that a clear standard operating procedure is developed to inform the use of these OPD 9outpatient rooms for outpatient review and care of children with CF, and in particular, where a diagnosis with *Mycobacterium abscessus* has been made. This should include consideration of leaving the room 'fallow' after any treatment to allow the full volume of room air to be changed.

4.4 A local SOP should be developed to ensure that no invasive treatment or procedures are carried out in the consultation rooms in Crichton ward.

4.5 In therapies, we advise that in treatment rooms 6, 7 & 16 (identified as physiotherapy rooms) that no cough generating procedures (such as induced sputum, NIPPV) are carried out in these rooms as these provide 10 air changes on supply only – this means room air is extracted to corridor, meaning that other patients and staff could potentially be exposed to respiratory pathogens aerosolised during such procedures.

Dental RHCYP

Walk round on 18/02/2021 of Dental surgeries and Atrium/Pod

Advised that all works are reported to be on schedule.

Dental rooms -

Flooring now completed

Ceiling in the process of completion

Power back on and being tested

Week of 22nd Feb

Dental units being put back in place

Week 1st March

Planned for snagging. Dental to check chairs and renew the water and air lines.

Week 8th March

Planned handover

Atrium

Atrium plasterboard taken back to approximately 1400cm in height

Plaster board and insultation replaced – sanding was in progress area being cleaned prior to painting.

Cabinets and water fountain to be reinstalled – planned date for this area to be handed back is the 01/03/2021.

Hi Donald,

Thank you for this comprehensive response. I have commented below in red at each of the relevant points. I note from today's press that there is a negative news story relating to S. Aureus and although testing for this is mentioned in SHTM 04-01 part G I think the context is that it should only be done if there are high TVC results from sampling, I cannot find explicit requirement for testing for this as part of handover commissioning or routine maintenance, would appreciate input from yourself, Alan, George & Brian.

Alan, would appreciate your views on the below and attached, unfortunately this is very urgent so hope you can help. Please treat as confidential.

Regards

Ronnie

Subject: RE: RHCYP & DCN EDINBURGH - WATER QUALITY
Importance: High
Sensitivity: Confidential

Dear Ronnie,
Thanks for bringing this to my attention. There are a number of things to consider I think with regards to this. Firstly is Brian Douglas as the NHS Lothian Responsible Person for Water and co-chair of the NHS Lothian Water Safety Group aware of the issue? Yes he is I may not have the correct titles but I believe Alan Hambridge is contracted by NHS Lothian to be the Authorising Engineer for Water and I very much think we should be seeking

both Brian and Alan's views on this (particularly as Alan is a UK expert in this area). I think it's also useful to have their views as we had similar issues at the new buildings on the Royal Edinburgh site that required rectifying before hand over that were being discussed at the Water Safety Group. I have copied Alan into this response along with the original attachments

My own views are:

Water testing in an unoccupied building may not necessarily represent what you would see in an occupied building where there is much more flow through storage tanks and pipes/taps/toilets etc. When there is more water flowing through pipes there is less chance for biofilm to develop or bacterial counts to be raised. Agree, issue is should we have any concerns given the results and that the building will not be fully functional until July

Do we have assurance that the correct methodology was used for water sampling? Yes The methodology is different if you are looking for Pseudomonas aeruginosa compared to when you are looking for Legionella species. Pseudomonas aeruginosa testing methodology is very clearly explained in HTM 04-01 Part C but SHTM 04-01 Part C is not explicit about the testing methodology for Pseduomonas aeruginosa and really only deals with the testing method for Legionella slightly confused about this sentence, I think on reading part C that the results and actions are defined for Legionella but not pseudomonas aeruginosa. The preflush and post flush sampling at a time when the pipe has not been used much is crucial for getting representative samples. All agree that the sampling carried out on 15/2 was done correctly, no way of verifying if the sampling on 6/2 & 11/2 was.

Although it is correct that any species of Pseudomonas or Legionella could cause infection, the risk of this happening is not uniform. It depends very much on whether the patient is in an "at risk" category and whether the area sampled is in a "high risk" area. Within the new building there will definitely be "at risk" patients i.e. paediatric immunocompromised cancer patients but there are also high and low risk areas i.e. a public toilet tap would likely be lower risk that a tap in an ensuite isolation room. Its difficult to interpret the overall significance of the lab results without knowing where in the building was sampled and what the intended purpose of that area will be. Think the test results give description of location, none of which were in augmented care areas. **Main issue is do high TVC and P. species counts directly link to an increased risk of the presence of Pseudomonas Aeuriginosa.**

However I would be extremely uncomfortable knowing there is any Legionella species in the water pre-handover as generally it will form biofilm and will come back over time despite corrective measures like flushing and chemical/thermal disnifection and would need continual monitoring in order to know that it stays low and doesn't cause disease.Legionella counts were well below action levels, however I agree this is a concern in a system so young, action has already been taken on this and re-sampling took place yesterday. As you know, the legal consequences to NHS Lothian and its employees from non compliance with L8 are enormous. Agree Inevitably I suspect the pipework in such areas would end up needing replaced. Cause and extent of contamination yet to be established although as I say well below normal action levels.

With regards to Pseudomonas aeurginosa it was my understanding that "augmented care areas" e.g. intensive care or high dependency etc must have water that is free of Pseudomonas aeruginosa and this may be achieved once the throughput of regular flushing has begun. But I really would value the views and knowledge of Alan Hambridge for his informed opinion if that was possible to be arranged within the need for confidentiality etc. It looks like you have evidence of there being no P aeuginosa in the repeat sampling waters so it looks like you have achieved that although I don't know the intended clinical purpose of the areas that have been sampled and thats quite important to put them in context. As previous none are in augmented care areas.

Please see the recent documents from Health Protection Scotland that are relevant to this problem. We have these documents already and we will ask the FM provider to adopt them fully in the operational phase.

I hope that helps.

All the best

Donald

Subject: FW: RHCYP & DCN EDINBURGH - WATER QUALITY
Importance: High
Sensitivity: Confidential

Hi Donald,

In light of significant issues elsewhere in the NHS Scotland Estate I thought I would bring the attached to your attention.

To give you a bit of background the FM provider (Bouygues) decided to carry out some water sampling ahead of handover, this took place on the 6th of February. Preliminary results indicated high CFU counts and there were positives for Pseudomonas species and Legionella. The main contractor disputed the method of test and the need to test for Pseudomonas species. As a result all 'fails' from the sampling on the 6th were re-sampled on 15th Feb specifically for Pseudomonas Aeruginosa and these are the first attached results shown in the Zip file, the remaining results are confirmation of the results from the 6th Feb.

To give the issue proper context there are two letters attached from Bouygues to IHSL explaining their concerns, please treat these as confidential for the time being.

I would appreciate it if you could give us your opinion on the infection control and microbiology implications of these results.

If you need to discuss please feel free to call or equally happy to meet.

Regards

Ronnie

Wallace,

Further to the correspondence earlier from Mark Griffiths, please find attached the Laboratory final results for all of the sample tests that were performed on site by the BYES contractor Hydro-X.
So that both Arcadis and the NHSL board have all of the correspondence from Bouygues I have also attached our initial letter on this matter.

In the meantime, should you require any further information or to discuss further then please advise.

Kind Regards

David,

Legionella	MW28	G	Not Detected	cfu/1000ml	

Grade Key: 'G' = within specification.

Microbiologically Acceptable - PASS

Results presented above are a measure of the quality of the water sample received (as is) by Eurofins. These results may not be a true measure of the quality of the sample at point of origin if prescribed sampling and transportation protocols have not been adhered to.
The lower limit of detection (LOD) for legionella is 25cfu per volume or swab tested, apart from the centrifuge method for which there is an LOD of 3cfu/150ml.

All tests are carried out according to our schedule of accreditation unless marked.
Tests marked * are not accredited. Tests marked ‡ were sub contracted and are not accredited. Tests marked † were sub contracted and are accredited according to their schedule.

Comments, opinions, grades and interpretations expressed herein are outside this current scope of UKAS accreditation.

This report amends and supersedes Certificate No 2948957 of 10/02/2019 which is now withdrawn

Results presented above are a measure of the quality of the water sample received (as is) by Eurofins. These results may not be a true measure of the quality of the sample at point of origin if prescribed sampling and transportation protocols have not been adhered to.
The lower limit of detection (LOD) for legionella is 25cfu per volume or swab tested, apart from the centrifuge method for which there is an LOD of 3cfu/150ml.

All tests are carried out according to our schedule of accreditation unless marked.
Tests marked * are not accredited. Tests marked ‡ were sub contracted and are not accredited. Tests marked † were sub contracted and are accredited according to their schedule.

Comments, opinions, grades and interpretations expressed herein are outside this current scope of UKAS accreditation.

19 February 2019

By-Hand & e-mail

Dear Wallace,

RHCYP & DCN EDINBURGH - WATER QUALITY

Further to the recent communications from David Wilson of Multiplex and subsequent correspondence from Darren Pike, we do not agree with the Multiplex assessment in their letter of 15th February 2019 and can confirm that all of the samples taken on site on 06th February 2019 were indeed in accordance with the guidance laid out in SHTM-04-01.

Multiplex did not have a representative available for the sampling and instead requested that a Mercury representative attend to witness and assist. Bouygues E&S FM (BYES) supply chain member Hydro-X were therefore joined in the sampling by both the BYES & Mercury Supervisors where all were satisfied with the manner in which the readings were taken and that correct hand hygiene was in place at all times. It is surprising that no response or concerns were received from Mutiplex or their supply chain until after the preliminary results had identified concerns of contaminants within the building water systems.

BYES have already issued the presumptive readings for Pseudomonas Spp, TVC and Legionella to IHSL between 12th February 2019 and 13th February 2019 and have now issued the final results for all readings on 19th February 2019 (including additional sampling for Pseudomonas Aeruginosa which were taken on 15th February 2019).

These results represent a selection of locations that were sampled for a range of pathogens, to provide BYES confidence in the systems in advance of the completion of sampling by Multiplex in keeping with *'Scottish Health Technical Memorandum 04-01: Water safety for healthcare premises Part G: Operational procedures and Exemplar Written Scheme' Section 23.8.* However, these samples have identified some concerns which we have communicated to Multiplex.

BOUYGUES ENERGIES & SERVICES

Our energies for a **Better Life**

Pseudomonas Spp has been found at the nearest (Sample No. 19-02562) and furthest (Sample No. 19-02563) MCW outlets. Whereas these are not a defined check within SHTM04, they do represent concern for potential system contamination, and a potential established biofilm risk. It is strongly recommended that these are investigated further and retested to determine local or systemic colonisation, and system risk.

A low reading for Legionella (25 CFU/L) has also been detected at the nearest (Sample No. 19-02548) MCW outlet; this does not require to be retested in keeping with Scottish Health Technical Memorandum 04-01 Water safety for healthcare premises Part B: Operational management but is of concern when considered in conjunction with the Pseudomonas Spp Sample No. 19-02562.

TVC samples were recorded to be high at a variety of locations. TVC samples do not specify the bacteria / particles, they represent the total content which may represent a risk to the system. These locations should be retested to determine the breakdown of the high results and the risk to the system or outlets as applicable.

With consideration to 'Scottish Health Technical Memorandum 04-01: Water safety for healthcare premises Part G: Operational procedures and Exemplar Written Scheme', Section this denotes the circumstances under which samples are taken, which includes specific reference to 'as part of commissioning process, prior to handover of a new building or introduction of a (altered, refurbished or new) water system into use;'.

These samples are defined within the document and refer to SHTM 04-01 Section C, and detail the types and locations to be tested. Bacteria to be sampled includes:

- Coliforms
- Legionella
- Escherichia coli
- Salmonella
- Pseudomonas aeruginosa
- Campylobacter
- Aerobic Colony Counts
- E.coli O157
- Environmental Mycobacteria
- Staphylococcus aureus

The locations are detailed within 23.13 as '....initial water system sampling take a Post-Flush sample (as defined in BS 7592: 2008) at sentinel points without disinfection.....'. And we await these results to provide us with the assurance the system is safe and in control.
It is also of note, these samples are not limited to drinking water, they are applicable to 'hot & cold water systems' which include the Cat 5 supplies which have been disputed as being applicable by Multiplex. This requirement is also supported in a related British Standard BS 8554:2015 Code of practice for the sampling and monitoring of hot and cold water services in buildings; as a commissioning requirement.

BOUYGUES ENERGIES & SERVICES

Our energies for a Better Life

BYES would also like to note that we also requested on 23rd November 2018 detailed evidence on the water system maintenance being carried out by Multiplex, and in particular the following which has yet to be provided.

Recorded Temperature recordings of the outlets during testing and flushing
TMV commissioning certificates

We would therefore re-iterate the concerns outlined within our recent communications and request that Multiplex address these urgently and would welcome any input / feedback from the NHS Lothian (Board) Head of Infection Control. We therefore once again give notice in accordance with Clause 30 of the PA that we will be seeking full relief until the above concerns have been addressed.

Kind Regards.

13th February 2019

By-Hand & e-mail

For the attention of Mr. Wallace Weir

RE: RHCYP & DCN Edinburgh - Water Quality

Dear Wallace,

We refer to our previous email correspondence from our David Gordon in relation to water quality sampling prior to the RHCYP going live on Thursday 7th February 2019. The Go-Live subsequently did not happen however the planned water sampling did go ahead.

We now have had a presumptive report from our specialist advising that the sampling for water quality at RHCYP & DCN Edinburgh, is indicating counts of Pseudomonas spp and Legionella have been identified in varying concentrations at defined locations. In addition to this, the total aerobic count samples have been found to exceed industry expectations at a small number of other locations.

There have been some suggestion from the Principal Contractor / Principal Designer Multiplex that Pseudomonas Aeruginosa is the only pseudomonas bacteria that requires action as a clinical risk, and whilst it is most certainly the most well studied, the presence of all Pseudomonas bacteria species require action in a healthcare environment. SHTM 04-01 part A Design, Installation and testing identifies that not only Pseudomonas Aeruginosa is of interest, but also specifically makes reference to Pseudomonas spp; and, where practicable, it should be managed/designed out of a system.

Bouygues E&S FM (BYES) are concerned with the presumptive presence of Pseudomonas spp and Legionella at this stage in the process of construction hand over, as all Pseudomonas bacteria species have the ability to create biofilms and establish themselves in such a way that they can be very difficult to eradicate thus causing major infection control concerns.

The presence of biofilm and Legionella in a system is extremely undesirable, as they will create an environment that promotes the proliferation of other potentially pathogenic bacteria, protecting them from excessive temperature, and to a certain extent, chemical disinfection.

BOUYGUES ENERGIES & SERVICES

Shared **innovation**

Bouygues E&S FM (BYES) are recording their concern that the Water Systems at RHCYP & DCN Edinburgh are “Out of Control” on the basis of these presumptive reports along with the fact that there has been no management of the water systems in accordance with SHTM 04.

Should the presumptive reporting be followed with firm laboratory reports confirming this position we will therefore not be in a position to accept the building with existing issues with Pseudomonas; and/or Legionella; and/or high TVC which would compromise our ability to operate the system within safe parameters using “normal maintenance activities” thus increasing our risk profile and increased management costs. Furthermore we give notice in accordance with Clause 30 of the PA that we will be seeking full Relief should the laboratory reporting confirm the above concerns.

Kind Regards.

Rapid Review of Healthcare Associated Infection Risks and Outbreaks Associated with Healthcare Water Systems

Version: 0.4

Author: Infection Control Team

Publication Date:

Contents

Abbreviation list:

CVC: Central venous catheter

EPDM: Ethylene propylene diene monomer

HAI: Healthcare Associated Infection

HFS: Health Facilities Scotland

HPC: Heterotrophic Plate Count

HPS: Health Protection Scotland

HTM: Health Technical Memorandum

ICU: Intensive care unit

NIPCM: National Infection Prevention & Control Manual

NNU: Neonatal unit

NTM: Non-tuberculous mycobacteria

POU: Point-of-Use

Background

Water distribution systems and the associated fixtures and fittings can act as reservoirs for waterborne pathogens in healthcare facilities. Microorganisms often identified within water systems include heterotrophic plate count (HPC) bacteria, *Legionella* spp. and nontuberculosis mycobacteria.[1] These organisms are able to persist by forming biofilms which coat structures within water systems, allowing survival, replication and resistance against disinfection.[2] Experimental studies have demonstrated biofilm resistance to biocides such as chlorine, sodium hypochlorite, glutaraldehyde and quaternary ammonium compounds compared to planktonic cells.[3]

Normally these organisms do not infect healthy individuals. However, they do pose a particular risk to susceptible patients, such as those who are severely immunocompromised; have a breach in dermal integrity; or who are cared for within intensive care units.[4] The cumulative effect of direct contact with colonised water, susceptibility of patients, poor water system management, and non-compliance with infection control practices can lead to HAIs and outbreaks.[5]

Aim

To provide a rapid review of the scientific evidence base on HAI risks and outbreaks associated with healthcare water systems.

Objectives

Objectives for the rapid review were as follows:

- To assess the microorganisms associated with outbreaks due to healthcare water delivery systems.
- To assess the clinical settings and patient populations which may be affected by contaminated healthcare water delivery systems.
- To assess the potential sources of outbreaks linked to healthcare water delivery systems.
- To assess the routes of transmission of waterborne outbreaks linked to healthcare water delivery systems.
- To assess the control measures to put in place to minimise risk of waterborne outbreaks within healthcare facilities.

Search Strategy

Academic databases were searched to identify relevant academic and grey literature from 1998-2019 (see Appendix 1).

Results

The literature search identified 871 articles. After screening 104 articles were included and following additional hand searching and expert recommendation a further 34 papers identified, providing 138 articles for the review. Of the 138 articles, the papers included outbreak reports, case-control studies, pseudo-outbreak reports, and intervention studies in both outbreak and endemic situations linked to water systems. Additional guidance documents were retrieved from Health Protection Scotland (HPS),[6, 7] Health Facilities Scotland (HFS),[2, 6, 8] the UK Department of Health[4, 9] and legislative guidance from the UK Health and Safety Executive[10] on water system safety within healthcare facilities. A report produced by HPS was also included.[11]

Research Questions

What organisms are associated with HAI outbreaks due to healthcare water systems?

A broad range of microorganisms are associated with water system contamination which can lead to healthcare outbreaks or endemic situations. Table 1 displays the organisms most frequently isolated from hospital water delivery systems and includes: 53 articles on *Pseudomonas aeruginosa*;[11-62] 24 articles on *Legionella pneumophila*;[61, 63-84] 19 articles on nontuberculosis mycobacteria (NTM);[61, 85-102] 11 articles on *Klebsiella pneumoniae* studies;[11, 60, 103-110] and 6 articles on *Acinetobacter baummannii*.[111-115]

Table 1. Most frequently cited microorganisms, identified during the rapid review, linked to healthcare water delivery system contamination.

Type of Microorganism	Microorganism Identified
Gram negative bacteria	*Pseudomonas aeruginosa* *Legionella pneumophila* *Klebsiella pneumoniae* *Acinetobacter baumannii*
Mycobacteria	Nontuberculosis mycobacteria (NTM)

Other causative organisms (Table 2) included *Achromobacter* spp.,[116] *Acinetobacter junii,*[117] *Acinetobacter ursingii,*[11] *Burkholderia* spp.,[118-120] *Chryseomonas indologenes,*[11] *Citrobacter freundii*,[121] *Cupriavidus pauculus,*[11] *Elizabethkinga meningoseptica*,[122, 123] *Enterobacter cloacae*,[11, 60, 124-126] *Enterobacter hormaachei spp.,*[127] *Klebsiella oxytoca*,[11, 128-130] *Klebsiella pneumoniae carbamenepase* (KPC)- producing *Enterobacteriae,*[131] KPC-producing *Escherichia coli,*[132] *Pantoea agglomerans*[133], *Pseudomonas fluorescens,*[11, 134] *Pseudomonas putida,*[11, 59, 135] *Staphylococcus aureus,*[132] *Serratia marcescens* [11, 110, 136] and *Stenotrophomonas maltophilia.*[11, 137-139] Fungi including *Candida parapsilosis,*[140] *Candida metapsilosis,*[140] *Aspergillus* spp.,[141] *Fusarium* spp., [142, 143] *Exophiala jeanselmei,*[144] *and Rhizomucor* spp.[141] were additionally identified as the cause of HAI outbreaks, as well as viruses such as Norovirus and an unidentified small round structured virus which were isolated in two studies. [145, 146]

Table 2. Other microorganisms, identified during the rapid review, linked to healthcare water delivery system contamination.

Type of Microorganism	Microorganism Identified

Gram negative bacteria	*Achromobacter* spp *Acinetobacter junii* *Burkholderia* spp. *Citrobacter freundii* *Elizabethkinga meningoseptica* *Enterobacter cloacae* *Klebsiella oxytoca* *Pantoea agglomerans* *Pseudomonas fluorescens* *Pseudomonas putida* *Serratia marcescens* *Stenotrophomonas maltophilia*
Gram positive bacteria	*Staphylococcus aureus*
Fungi	*Aspergillus* spp. *Fusarium* spp. *Exophiala jeanselmei* *Rhizomucor* spp. *Candida parapsilosis* *Candida metapsilosis*
Virus	Norovirus Small round structured virus

The fact that *P. aeruginosa* and *L. pneumophila* were the organisms most commonly associated with outbreaks is reflected in the available guidance on healthcare water systems within the UK. The Department of Health HTM 04-01[4] states that there is a risk of *P. aeruginosa* in patients within augmented care settings. These patients are also at risk of other waterborne pathogens such as *S. maltophilia, B. cepacia* and atypical mycobacteria.[4] Current UK guidance also mentions that *Legionella* spp. are also frequently found to cause infection within healthcare settings following water exposure.[4, 9, 10]

What clinical settings and patient populations are affected?

There is no established definition for augmented care areas. However, the Department of Health[4] defines augmented care areas as those in which medical and nursing procedures performed put patients at risk of infection from environmental and opportunistic pathogens. These high-risk patients include the following:[2, 4, 6]

- Those who are severely immunosuppressed because of disease or treatment;
- Those cared for in intensive care units (ICUs);
- Those with breaches in dermal integrity such as those with extensive burn injuries;
- Patients within neonatal units (NNUs);

- Adult and paediatric ICUs;
- Patients with cancer;
- Patients in transplant or renal wards.

Augmented care settings were most frequently affected with waterborne outbreaks - one of the most common being haematology and oncology units,[12, 13, 18, 28, 30, 35, 37, 43, 59, 63, 75, 84, 88, 93-95, 101, 116, 117, 124, 128, 141-144] with additional outbreaks involving patients within bone marrow and stem cell transplant wards.[33, 35, 39, 60, 66, 71, 73, 82, 83, 86, 88, 95, 100, 134, 144] This was followed by outbreaks within adult and paediatric ICUs[17, 20, 21, 23, 27, 29, 38, 42, 45, 52-54, 56, 62, 66, 70, 73, 74, 84, 103, 106, 107, 109, 114, 115, 125, 136, 138] and NNUs.[14, 15, 23, 31, 32, 48, 50, 51, 57, 72, 123, 139]

Haematology-Oncology Units

Colonisation or infection of patients within haematology and oncology wards was frequently demonstrated within the retrieved literature,[11-13, 18, 28-30, 35, 37, 40, 43, 59, 63, 75, 77, 84, 88, 93-95, 101, 116, 117, 124, 128, 141-144] with 9 of these involving paediatric patients.[30, 59, 93-95, 116, 117, 141, 142] The organisms implicated included Gram negative bacteria: *Achromobacter* spp.,[116] *A. junii,*[117] *E. cloacae,*[124] *P. aeruginosa,*[12, 13, 28-30, 37, 40, 43, 59] *P. putida,*[59] *K. oxytoca,*[128] *and L. pneumophila;*[63, 75, 77, 84] nontuberculosis mycobacteria including *M. mucogenicum;*[93, 94, 101] and fungi such as *Aspergillus* spp.,[141] *E. jeanselmei,*[144] *F. oxysporum,*[142] *F. solani,*[142, 143] and *Rhizomucor* spp.[141]

The underlying medical conditions of the immunocompromised patients who became colonised or infected included: bone marrow or blood cancer such as active leukaemia,[63] acute lymphocytic leukaemia,[30, 37, 59, 93, 94, 116, 141, 142] acute myeloid leukaemia,[28, 37, 77, 93, 101, 116, 128, 142, 143] juvenile myelomonocytic leukaemia,[116] myelodysplastic syndrome,[28, 128] and non-hodgkin lymphoma;[101, 128] organ associated cancer such as hepatoblastoma,[59] medulloblastoma,[30, 117] nephroblastoma,[59] retinoblastoma;[59, 117] other cancer including neuroblastoma,[96, 119] and rhabdomyosarcoma;[30, 94] blood or bone marrow disorder and disease such as aplastic anaemia,[94] autoimmune haemolytic anaemia,[116] idiopathic medullary aplasia,[59] neutropenia;[29, 43, 143, 144] and other undisclosed haematological diseases and malignancies.[43, 124, 144]

In two further studies, haematology and oncology outpatients acquired a waterborne HAI. Outpatients with malignant tumours acquired infections with *P. agglomerans*[133] and patients with sickle cell disease developed infection with *M. mucogenicum*[96] following infusions or flushes of implanted ports respectively, using liquids which had come into contact with contaminated with sink water. In one outbreak not only patients, but a visitor with a history of lung transplant and chronic neutropenia, contracted the outbreak strain of Legionella from a haematology-oncology ward.[63]

Several additional cases of nosocomial infection occurred in patients assumed to be undergoing bone marrow or stem cell transplantation or preparatory conditioning procedures.[33, 35, 39, 60, 66, 71, 73, 82, 83, 86, 88, 95, 100, 134, 144] Infection and/or colonisation was associated with *E. cloacae,*[60] *E. jeanselmei,*[144] *F . solani,*[143] *P. fluorescens,*[134] *P. aeruginosa,*[33, 35, 39, 60] *K. pneumoniae,*[60] *L. pneumoniae,*[66, 71, 73, 82, 83] or NTM.[86, 100] The underlying conditions of these immunosuppressed patients included: acute lymphatic leukemia,[76, 102, 136] acute myeloid leukemia,[33 100, 134] adrenoleukodystrophy,[102] anemia,[39, 102] anaplastic lymphoma,[100] chronic myeloid leukaemia,[40, 82, 134, 143] hemophagocytic lymphohistiocytosis,[100] hodgkin lymphoma,[100, 134] leukemia,[71] mantle cell lymphoma,[40] multiple

myeloma,[33, 82, 134] multiple sclerosis,[33] myelodysplastic syndrome,[100, 134] non-hodgkin lymphoma,[33] neuroblastoma,[100] and osteoporosis.[100]

Multivariate analysis identified neutropenia,[144] long duration of hospital stays,[144] and use of corticosteroids[83, 144] as risk factors for patient acquisition of outbreak pathogens within haematology and bone marrow transplant units. Additionally, during an outbreak of *B. cepacia*, patients with cancer were found to be at a significant risk of acquisition.[119]

Importantly, many of the outbreaks of infection within adult and paediatric haematology and oncology wards were associated with central venous catheters (CVCs) becoming contaminated during patient bathing.[12, 30, 59, 93, 94, 101, 116]

Intensive Care Units (ICUs)

The second most common clinical setting in which waterborne outbreaks occurred was the ICU. This included colonisation and/or infection of patients within general ICUs,[29, 62, 66, 70, 73, 74, 84, 131] surgical ICUs,[20, 21, 38, 42, 54, 56, 106, 115, 136, 138] neurosurgical ICUs,[45, 103, 107] burns ICUs,[17, 52, 112] cardiac ICUs,[27, 125] and paediatric ICUs.[70, 109, 114]

Gram negative organisms were implicated including *A. baumannii,*[112, 114, 115] *P. aeruginosa,*[17, 20, 21, 27, 29, 38, 42, 45, 52, 54, 56, 62] *K. pneumoniae,*[103, 106, 107, 109] *K. oxytoca*,[125] *L. pneumophila,*[66, 70, 74] *S. marcescens,*[136] and *S. maltophilia.*[138]

Patients within ICUs had an array of underlying medical conditions prior to colonisation and/or infection, which included: bacterial infections,[19] bacterial meningitis,[104] burns,[17, 19, 52, 112] cancer,[42, 45, 122] cardiac disease or failure,[19, 27, 55, 110] cystic fibrosis,[19, 27] haemorrhagic events,[45, 103] head or spine injury or trauma,[45, 103] idiopathic pulmonary fibrosis,[27] primary pulmonary hypertension,[26] neurological illness,[136] pneumonia,[104, 110] sarcoidosis,[27] sepsis,[110] stroke,[110] or ulcers.[19]

The characteristics of patients at risk of colonisation and/or infection with pathogens associated with waterborne outbreaks within healthcare facilities were analysed in several case-control studies. Significant risks factors ($p \leq 0.05$) for patients included: undergoing dialysis or haemodialysis,[20, 55] longer stays within ICU,[55, 56, 112] surgery prior or during ICU stay,[26, 56] mechanical ventilation,[56, 136] central lines,[136] length of time with a CVC,[26, 56] arterial catheterisation,[56, 138] urinary catheterisation,[56] warming up with warm air blanket,[26] antibiotic use during admission,[26, 55] preceding infection,[55] frequency of bronchial lavage,[26] intracranial pressure cathetarisation,[136] nebulisation therapy,[136] peripheral nutrition solution/number of days receiving solution,[56, 136] medication received orally,[136] and receiving multiple doses of medication.[136]

Neonatal Units (NNUs)

Neonatal units were also regularly host to outbreaks associated with water systems in healthcare facilities.[14, 15, 23, 31, 32, 48, 50, 52, 57, 72, 123, 139, 140] The majority of outbreaks discussed (75%) were caused by *P. aeruginosa*[14, 15, 23, 31, 32, 48, 50, 51, 57] however, there were also cases of infection in neonates due to *E. meningoseptica,*[123] *L. pneumophila*[72], *S. maltophilia*[139], *Candida parapsilosis* and *Candida metapsilosis.*[140]

Clinical conditions in neonates who were colonised and/or infected included; congenital anomalies, hypoplasia, intraventricular haemorrhage, laryngeal anomalies, oesophageal atresisa, patent ductus arteriosis, pulmonary disease, and respiratory stress disorder.[14, 31]

Case-control studies identified the gestational age and mean birth weight as risk factors, with those with a lower birth weight[14, 48] and lower gestational age[14] at a higher risk of colonisation and/or infection. Additionally case patients were more likely to have exposure to a peripherally inserted catheter or invasive ventilation or respiratory support.[14, 48] These clinical risks factors were noted in additional outbreak reports with at least half of neonates colonised/infected with extremely low birth weight (<1000g),[32, 50] pre-term (<37 weeks),[32, 139] and ventilated or requiring respiratory support.[31, 139] Additionally, neonates who had received blood transfusions were found to be at a higher risk of infection, however, this was found ultimately to be due to the use of a contaminated water bath used to heat transfusion products.[51]

Other Clinical Settings

Less frequently, waterborne colonisation and infection of high-risk patients occurred in other clinical settings. This included surgical units: cardiothoracic[88, 89], general,[64] neurosurgical[81] and paediatric,[41] and transplant units (including lung, liver and kidney)[27, 61, 63, 69, 88, 147] as well as a pacemaker implantation unit.[87]

Additional specialised clinical locations implicated in outbreaks were a bronchoscopy suite,[79] burns units,[24, 135] cardiac wards,[64, 74, 75, 77, 83, 132] an ear, nose throat department,[22] a HIV unit,[92] nephrology wards,[36, 58, 76] and respiratory wards.[64, 76] Other clinical care settings included private or military hospitals,[85, 97] long term care facilities,[80, 102] and a re-education facility.[145]

It was also noted that water system contamination could result in outbreaks across different clinical settings[18, 21, 27, 29, 35, 42, 44, 53, 64, 66-68, 70, 73-77, 83, 84, 88, 91, 95, 98, 119, 143, 146, 147] and between two or more geographically distinct hospitals.[57, 65, 105, 106, 108] In one study, an outbreak of *L. pneumophila* not only affected patients within multiple wards such as chest and general surgery wards but also hospital staff such as those within the chest department and laboratory.[64] Furthermore in one study, a contaminated decorative fountain in a hospital lobby, caused legionella infections in visitors who came into contract with it.[78]

What are the potential sources of waterborne outbreaks?

According to the British Department of Health,[9] healthcare water systems the incoming water supply is reported to be the usual source of *Legionella* spp. with problems arising when measures such as water treatment or temperature controls fail. Additional sources described include water supplied from storage and distribution systems and waste water systems, or system components which have been retrogradely contaminated.

Alongside this, *Legionella* spp. can colonise water fittings, pipework and materials within water systems.[2] The presence of sludge, sediment, scale, organic matter and rust can favour growth and water stagnation encourages this colonisation and biofilm formation.[2] Stagnation arises due to poor water flow, areas with dead-legs, and rises and falls in water temperature.[2] The biofilms formed allow bacterial growth and survival within water systems, and provide protection from control measures such as heat and chlorine.[2] This is highlighted within the UK Health and Safety Executive guidance, which states that 'any water system that has the right environmental conditions could potentially be a source for legionella bacteria growth'.[10]

The hospital water delivery system is a potential source of *P. aeruginosa* infection within augmented care settings.[4] Contributing risks include water system features with oversized water storage tanks, flexible hoses, long branch pipes and dead-legs, with stagnant water and poor temperature control also implicated.[4] Infrequently used water outlets with low water throughput, complex internal tap designs, clinical hand wash basins and waste-water drain outlets are also at risk of contamination with *P. aeruginosa*.[4]

HTM 04-01[9] details that taps and tap water, sinks and sink traps, showers, hydrotherapy pools, ice-makers, disinfectant solutions, haemodialysers, nebuliser chambers, humidifier reservoirs, bronchoscopes and ventilator circuits can become colonised with *Stenotrophomonas* spp.. Additionally, water-based heater-cooler units used during cardiothoracic surgery have been linked to outbreaks of *M. chimaera*.

The studies included within the review, demonstrated many different sources of outbreaks linked to healthcare water systems, however, in some cases no single source was identified.[13, 15, 99, 146] It was not always clear how these sources initially became contaminated. This may have been due to low levels of intrinsic microorganisms within the potable water supply or, as several studies suggested, may be due to contamination following contact with initial index case patient, or hands of healthcare workers treating index patient.[16, 32, 34, 37, 80, 106, 128, 130, 135] Fixtures may also become contaminated due to the improper disposal of bodily fluids, such as emptying the contents of dialysis bags into sinks also used for hand hygiene.[20, 46, 62, 106, 107, 110, 120, 121, 128, 129]

Water Distribution Systems

Water distribution systems within healthcare facilities were the most frequently cited source of outbreaks. Colonisation and/or infection of patients was often due to direct contact with contaminated tap water, or through exposure to equipment, fluids and infusates which had been contaminated with non-sterile tap water supplied by the water system.[14, 25, 33, 43, 58-61, 63-68, 70, 73-77, 80-85, 87, 88, 93-95, 97, 98, 100-102, 108, 116, 118, 119, 142, 143, 145, 147, 148] Water tanks and reservoirs were frequently implicated[85, 87, 101, 142] with contamination associated with sediment and stagnation,[85, 101] which likely attributed to biofilm formation.

Several studies detailed environmental risk factors which may have led to the microbial contamination of water systems such as favourable water temperatures for microbial growth (45-50°C);[63, 74, 75, 147] inadequate disinfectant levels (i.e. low residual chlorine, <1 ppm);[63, 67, 75, 87, 88, 94, 101, 102] contamination of the public water supply;[88, 95, 97] reduced water usage;[68, 88, 102] slow delivery or low flow rates water to outlets;[88, 102] and dead-leg pipes.[66, 68, 74] In one study there was no disinfection programme for the hospital water system which led to an outbreak of *L. pneumophila.*[64] Whilst others had used disinfection systems incorporating ultraviolet light[58] or copper-silver ionization[67] but had failed to prevent water system contamination.

The recent construction of a new build hospital, long term care facility, or specialised unit water system was implicated in subsequent outbreaks of *L. pneumophila* and *P. aeruginosa.*[14, 63, 80, 82] This was hypothesised to have occurred due to water stagnation and biofilm formation for several months before the building was completed and opened.[14, 63, 82] Recent interruption or renovation of water systems was also implicated during outbreaks[25, 66, 73] which may have disrupted established biofilms within older sections of pipe work or caused an increase in the number of dead-legs. An

outbreak of *Fusarium* spp. occurred after reintroduction of the maintenance of water reservoirs in one report, which had been neglected for several years prior.[142]

Additionally, waste water systems were implicated in two hospital outbreaks. In the first hospital discussed, a leaking waste pipe was thought to have caused environmental contamination of a haematology unit.[29] Whilst in another facility, slow drainage and blocked drains resulted in backflow of dirty water into toilets and showers which were improperly cleaned, leading to contamination of environment.[29] Additionally, an unsealed floor drain in a cystoscopy suite used to drain fluids from patients was also indentified as a source, which due to its design allowed blood and urine to float back up to floor level.[36]

Taps and Aerators

Taps (faucets) and aerators (flow-straighteners) of water outlets were also cited in 27 studies as the source of waterborne outbreak within healthcare facilities.[12, 16, 17, 23, 26, 31, 34, 38, 41, 45, 47, 49, 53-56, 96, 103, 111, 117, 122, 123, 125, 136, 138, 139] In many reports it was likely that water faucets had acted as long-term environmental reservoirs, and use had resulted in the subsequent transmission to patients, staff and medical infusions.[12, 16, 17, 26, 34, 38, 41, 45, 47, 53-56, 96, 122, 123, 125, 136] Importantly aerators within taps were also implicated,[23, 103, 117, 122, 138, 139] with organic matter and debris collecting on the wire mesh of these components, resulting in water stagnation and contamination via low levels of microorganisms within potable water.[23, 117, 138] In 5 cases automatic sensor taps where linked to outbreaks[31, 49, 57, 94, 111] with microorganisms isolated from the complex internal structures including aerators, filters, metal support collars and tap bodies,[57, 111] with no or significantly less growth on the equivalent hand operated taps.[31, 57, 94]

Sinks (Basins, Drains and Siphons)

Sinks and associated structures were also associated with waterborne HAI. Sink units, siphons (sink traps), and drains were thought to be implicated in 38 studies,[11, 18, 20, 21, 24, 27, 28, 30, 32, 35, 39, 40, 42, 44-46, 48, 53, 62, 103-107, 109, 110, 112-115, 120, 121, 124, 125, 128-133, 139] as well as a soap dispenser in another.[33] These fixtures and fittings were often one of several environmental reservoirs.[21, 24, 27, 39, 40, 104, 105, 112, 113, 125] Positive cultures of outbreak strains were isolated from sinks units, drains and siphons located in: patient rooms or care environments,[18, 20, 27, 30, 32, 35, 39, 42, 44, 46, 53, 103, 104, 106, 107, 114, 115, 120, 121, 125, 131, 139] outside patient rooms,[129] pharmacy clean rooms,[133] a medicine preparation room,[128] a nurses station,[45] staff bathrooms,[39, 133] examination rooms,[133] infusion rooms,[133] and shower rooms.[112]

Poor design, which allowed splashing, aerosol formation and inadequate infection control, was frequently cited as the reason as to why sinks became the source of waterborne outbreaks. These design features included small and/or shallow sinks;[109, 110, 114] short taps;[30] taps directing water over drains;[110, 124] location of sinks close to countertops used for medical preparations or patient care products;[120, 133] sinks located in close proximity to patients;[42] drainage systems which impaired adequate drainage;[129, 130] improperly sealed joints between walls and sinks;[70] grouted tiles surrounding sinks;[48] poor quality sinks with damaged porcelain.[110] The shallow design of a sink and high water pressure in one study led to staff to place towels around the sink to prevent a damp environment, which resulted in the sink and towels becoming an environmental reservoir and preventing adequate hand hygiene.[114] Additionally, in two outbreaks of *P. aeruginosa* reusable hair washing basins were implicated as additional sources of transmission during outbreaks.[21, 26]

Wash Rooms and Hydrotherapy Rooms

Patient wash rooms and hydrotherapy rooms have been implicated in waterborne outbreaks within healthcare facilities. Shower heads used for patient cleansing have been implicated in several studies, colonised with NTM, *A. baumannii*, *P. aeruginosa* and *S. aureus.*[39, 41, 52, 59, 90, 95, 112, 135] Reports within burns units have documented that shower heads are one of several environmental reservoirs within patient washing facilities and hydrotherapy rooms, with other sources including sinks,[112] showering platforms,[112] bathing stretchers,[135] or patient trolleys.[52] Additionally an adult burns hydrotherapy room was found to harbour *P. aeruginosa* in floor traps, shower trolleys and shower drains, which not only resulted in infection in adult burns patients but in a paediatric burns patient who visited the hydrotherapy room.[19] Other fixtures and fittings within shower rooms which have been identified as potential sources during outbreaks includes shower drains,[27, 52] shower traps,[105] and shower fittings.[146] A whirlpool bath was also implicated in one outbreak, with the bath water becoming contaminated when the tub was filled. Contamination of the bath water occurred in the 2.5 cm long space between the strainer and drain, with the patients who bathed in this contaminated water acquiring *P. aeruginosa* infections.[37]

An unusual case of Mucormycosis infection occurred in two paediatric patients within an oncology unit. This was due to a leaking shower, which caused water damage to plaster in the shower room and linen store. This resulted in a source of infectious moulds, such as *Aspergillus* spp. and *Rhizomucor* spp., which infected the severely immunocompromised patients.[141]

Drinking Water and Ice Dispensers

Drinking water and ice dispensing machines have been identified as sources of infection. Contaminated water and ice have been found to cause infections with NTM and *P. fluorescens* in immunocompromised patients within bone marrow and stem cell units.[86, 134] Additionally an undersink drinking water cooling unit, caused *S. maltophilia* infection within an ICU.[137] Although this system had a carbon filter there were multiple biofilms found in the flexible tube from the carbon filter to the chiller, and from the chiller to tap at the kitchen sink, with the carbon filter found to remove chlorine dioxide from water and accumulate organics allowing microbial multiplication.[137]

Additionally three pseudo-outbreaks were associated with ice machines, with two studies detailing patient colonisation with *M. fortuitum* following consumption of contaminated ice.[91, 92] Ice was implicated in the third pseudo-outbreak when it was used to cool syringes of saline solution used during bronchoscopy, and resulted in patient colonisation with *L. pneumophila.*[79]

Decorative drinking water fountains have also been implicated in cases of legionnaires disease, with one case associated with foam material above the fountain trough causing infection in 8 visitors to a hospital.[78] The second case of infection involved two patients within a radiation oncology suite and was due to stagnation of water for 4 months within the pipes that supplied and re-circulated water to the fountain.[71] Another drinking fountain was implicated in an outbreak of *P. aeruginosa* amongst oncology patients in an ear, nose and throat department.[22]

Water-Based Equipment and Other Sources

In several cases the outbreak source was thought to be water-based medical equipment such as: heart-lung machines and associated heater-cooler units used during cardiothoracic surgery contaminated with *Mycobacterium abscessus,*[88] *Mycobacterium chimaera,*[89] *and Mycobacterium*

wolinsky,[99] water baths contaminated with *P. aeruginosa* used to heat feeding bottles[50] and blood transfusion products[50] within NNUs; humidifiers contaminated with *L. pneumophila* used for oxygen therapy and drug delivery in pnuemology and nephrology units;[76] air humidifiers contaminated with *L. pneumophila* used within NNUs[72] and a bone marrow transplant unit.[82] The initial contamination of this equipment is likely due to use of tap water containing microorganisms.

What are the potential transmission routes for waterborne outbreaks?

Available guidance from Health Protection Scotland and Health Facilities Scotland states that transmission of waterborne *P. aeruginosa* can occur via environment to patient through direct contact with contaminated water, splashes from water outlets, or through indirect contact involving contaminated hands, objects and equipment.[6] Additionally, the guidance states that this organism can be transmitted from patient to patient or patient to environment through clinical procedures which produce aerosols.[6] Health Facilities Scotland and the Department of Health also state that transmission of *Legionella* spp. is through inhalation of aerosols into the lungs.[2] Aerosols can be generated from the process of water splashing on to wash-hand basins, sinks, and baths, in shower cubicles and when flushing toilets.[2] Aspiration of contaminated drinking water in the airways is also a possible route and is a particular risk for patients with nasogastric tubes, stroke patients, those taking sedatives and narcotics and those with motor neurone disease.[2]

In the waterborne outbreak reports retrieved, there were often multiple, complex transmission routes identified or hypothesized. Frequently, transmission was thought to be due to patient exposure to water which was contaminated from within the water system or via water outlets.[17, 25, 26, 34, 60, 61, 63-65, 67, 68, 75, 77, 78, 80, 81, 84, 98, 142, 145, 147] Patient exposure to contaminated water may have occurred during: hand washing, oral hygiene or showering;[13, 28, 54, 59, 93-95, 97, 101, 102, 124, 143] consumption of contaminated water and ice;[86, 91, 92, 100, 134, 136] during nursing care practices using tap water, such as grooming and tube feeding;[14, 22, 23, 38, 41, 88, 102, 118, 137-139] or treatment in hydrotherapy rooms.[19, 52]

Water splashing from sinks was another common route of transmission. This was generally due to the poor design of sinks, with water flowing directly into drains. As a result aerosols were generated and splashing occurred, which contaminated not only the sink basin and water outlet, but the surrounding environment, patients and patient care products in close proximity.[21, 29, 30, 42, 43, 74, 76, 103, 107, 113-115, 120, 121, 123, 126, 128, 130, 143] Additionally, aerosols may have been inhaled by patients when generated from hot water taps,[76] during showering[83, 143] and from water fountains.[71]

Often clinical procedures associated with splash risk included intravenous preparations carried on contaminated trays;[12, 116] infusates prepared near sinks;[133] saline bags used for port flushes contaminated with tap water aerosols;[96] and transfusion products heated in contaminated water baths.[51]

Contaminated tap water was used to prepare disinfectants or antiseptics, which were then used at the site of IV catheters or before venous punctures, allowing inoculation in patient blood stream.[59, 116, 119] Additionally, contaminated deionized water was also implicated in an outbreak of *E. jeanselmei* when used to make antiseptic solutions within a hospital pharmacy.[144]

Transmission was also associated with water-based equipment. This included heart-lung machines and associated heater-cooler units used during cardiac surgery,[88, 89, 99] humidifiers within oxygen therapy and drug delivery equipment,[76] as well as air humidifiers,[72, 82] and carpet cleaners.[83] This

equipment produced aerosols containing opportunistic organisms which could then be inhaled by susceptible patients. Other equipment included bronchoscopes which were flushed with saline which had been chilled using contaminated ice[79] and ureteroscopes which were used alongside inadequately disinfected water during patient procedures.[58]

Furthermore, rinsing patient equipment with tap water was implicated in transmission. This included using tap water to rinse a decontaminated surgical device used on multiple patients,[85] nebuliser cups (which were also stored wet),[120] suction apparatus for ventilated patients,[107] and aspiration tubes for neonates.[108] Patient feeding items were linked to transmission due to contamination with tap water, including containers for nutrition solutions,[45] tube feeding bags and bottles,[59, 73, 118] and milk bottles.[23] Other vectors of transmission included reusable hair wash basins[21, 26] and operating tables and equipment which had been cleaned with contaminated water.[87]

In several of the outbreak studies, it was suggested that transmission was also interlinked with healthcare workers. Contaminated hands were thought to have led to transfer of pathogens during patient care.[13, 32, 45, 113, 120, 125, 126, 128, 131, 138, 146] This may have been due to hand washing or splash-back with contaminated water,[14, 16, 39, 41, 103, 109, 124, 125, 139] the use of sinks which had previously been used for bodily fluid disposal or cleaning of medical instruments,[20, 46, 53, 106, 110, 121, 122, 129, 137] or touching contaminated environmental surfaces such as sinks or drains.[14, 125, 131]

Horizontal patient-patient transmission,[20, 46, 53, 108, 112, 123, 124, 133, 139] was also implicated as an additional route of transmission, with staff thought to facilitate this transfer.[26, 40, 55] Further, colonised, asymptomatic patients were frequently thought to have contributed to the persistence of an outbreak.[36, 45, 145] It was noted in several studies that the movement of patients and staff between wards and hospitals likely encouraged further cross transmission between patients and contamination of environmental structures.[18, 40, 105, 108]

What control measures can be implemented to stop waterborne outbreaks?

Water specific controls for Legionella include shutting down any processors capable of generating waterborne droplets and aerosols, until sampling, remedial work and cleaning has been performed.[9] Additional controls during outbreak situations are advocated. These include cleaning and disinfection of part of, or the entire water system.[10]

Control strategies differed between the studies included in this rapid review and were generally composed of several elements including both infection control precautions and specific measures used to target the environmental source of waterborne infection. It was noted that the replacement of fixtures and fittings[11, 31, 49, 60, 105, 114, 121, 132] or installation of point of use filters (POU) filters[11, 15, 17, 43, 88, 102, 142] was commonly required as a final measure to cease outbreaks. Several studies carried out replacements with less complex structures to prevent water stagnation and biofilm formation, which included aerators without wire meshes,[117] easier to clean sinks and plumbing,[121] rimless toilets to prevent splashing,[29] siphons without grooves,[28] strainers with larger holes to prevent spashing,[129] sinks with deeper basins,[109] sinks without overflow drains,[62] automatic taps replaced with simpler manual taps,[31, 49, 57, 94] taps with altered lengths,[16, 30] and self disinfecting sink siphons.[30, 126] The materials used for replacement of water system piping, fixtures and fittings should be carefully considered to prevent microbial colonisation and corrosion.[8]

The control methods used within the included articles highlights the complexity of outbreaks associated with water systems and the requirement multi-faceted approaches to ensure outbreak resolution, with limited evidence to support a particular strategy bundle.

Infection Control Measures

The National Infection Prevention and Control Manual provides clear guidance on standard infection control and transmission based precautions to minimise risk of healthcare associated infection.[7]

Infection control precautions and hygiene practices were reinforced during water system related outbreaks. The transmission based precautions implemented include: cessation of admissions;[15, 77] transfer of patients to other wards;[15, 101, 141] cohorting or isolation of patients colonised or infected;[15, 32, 38, 42, 45, 48, 50, 113-115, 128] contact precautions;[31, 38, 42, 50, 113, 114, 117, 122, 128, 129, 136, 145] reinforcing hand hygiene awareness and compliance;[15, 39, 48, 50, 114, 115, 117, 122, 128, 129, 131, 136, 139, 145] use of alcohol based hand-rub as part of hand hygiene procedures;[16, 23, 31, 49, 63, 123, 139] education of staff;[20, 29, 32, 39, 49, 50, 62, 95, 96, 114, 115, 121, 130, 131, 140] and enhanced cleaning and decontamination of the hospital environmental and environmental reservoirs.[15, 29, 44, 99, 103, 104, 113, 128, 130, 141, 145, 146] Screening of patients[32, 48, 82, 107, 123, 129, 130] and the environment[32, 33, 65, 81, 83, 87, 103, 107, 113] was often implemented as a result of outbreaks and included monthly bacteriologic surveillance of water supplies in the affected clinical areas.[41, 45, 77]

Water Distribution Systems

Water distribution systems were implicated in the colonisation and/or infection of patients due to the provision of microbiologically contaminated water. Control measures related to water systems included the implementation of water restrictions,[63, 82, 83, 86, 114, 136, 145] with showering avoided or limited to prevent patient exposure to tap water.[21, 77, 83] In many cases patients were provided with bottled water for drinking,[11, 22, 63, 83, 86, 100, 134] and this was also used for care procedures.[34, 67, 136] Sterile water was used frequently for high-risk and immunocompromised patients during care activities such as bathing, oral care and nasogastric feeding.[13, 15, 23, 38, 41, 73, 83, 102, 122, 123, 139] Waterless care techniques were also implemented in several reports, with waterless oral care[111] and use of disposable sponges or wash cloths implemented.[20, 38, 143]

POU filters, including 0.2 µm/PALL filters, were regularly fitted to water outlets during outbreaks, including sinks and shower heads, to protect patients from circulating pathogens.[12, 14, 15, 17, 25, 33, 43, 56, 59-61, 63, 67, 101, 102, 142] Four intervention studies using POU filters, found that rates of patient colonisation and infection significantly decreased following implementation.[25, 56, 60, 61] However in one of these studies sampling of filtered water 7 and 14 days after installation recovered HPC bacteria, although none of these were identified as the organisms which had previously caused patient colonisation and infection.[61] The positive samples were thought to be due to retrograde contamination via water splashing from the basin or contamination through hands and clothes.[61] Another study isolated *P. aeruginosa* and HPC bacteria from taps following POU filter use, again linked to retrograde contamination.[110] However, Scottish guidance currently states that POU filters should not be used as a first line control for outbreaks in high-risk settings.[6] Filters do not eradicate the organism but prevent its discharge into the environment from the filtered outlets, and due to this retention within water system it may be able to multiply and contaminate other parts of the water system.[8] The SHTM 04-01[8] states that filters should only be considered as part of control strategy when the most vulnerable patients are to be treated.

Decontamination of the water system and fixtures and fittings usually included superheating (heat-shock) and flushing (≥60°C),[64, 70, 76, 81, 84, 147] hyperchlorination,[14, 33, 34, 41, 54, 66, 73, 98, 102] or both such measures.[14, 63, 67, 75, 77, 82, 145] However, in several studies these techniques were inadequate with further patient infections of positive environmental samples.[64, 69, 73, 102] The subsequent measures were varied: one study repeated superheating and flushing using water at an increased temperature of 70°C; one study installed POU filters after chlorination failed,[102] another disconnected the hot water supply and used electric showers;[69] whilst in two others complete eradication of the outbreak organism failed even after installation of continuous chlorine units[73] or heat shock units.[70]

Other control measures for water distribution systems included: immediate shut down of water systems;[67] cleaning of water tanks and associated fittings;[15, 75, 87, 101] removal or capping of dead-legs;[77, 83, 133] monitoring and/or increasing chlorine to ensure adequate levels;[63, 87, 94, 98, 133] introduction of continuous, in-line, chlorine dioxide dosing of the water systems;[14, 67, 73, 77, 83, 87, 142] increasing chloramine levels;[88] increasing temperature of water heaters;[75, 84] increasing temperature of circulating hot water temperature;[15, 147] testing of temperature and flow;[14] and engineering controls to improve flow rates, water delivery and system pressure and the initiation of regular maintenance and flushing plans.[16, 75, 87, 88, 101, 133] Further control strategies included installation of heat shock units;[70, 81] UV light systems,[64] silver-copper ionization systems,[75, 80] in-line filters,[58, 142] and a water loop producing microbiologically controlled water.[59]

Taps and Aerators

When taps and aerators were identified as the environmental reservoir of outbreaks, several different control measures were put in place including: restricting the use of sinks;[44, 111, 122, 139] removal of mineral deposits on taps and aerators;[14, 45, 83, 125] cleaning, decontamination or sterilization of taps and aerators;[14, 34, 54, 122, 125] flushing of taps;[76, 83] removal of aerators;[14, 96, 120] replacement of aerators[117, 122, 138, 139] and taps;[16, 29-31, 33, 41, 49, 57, 62, 94, 103, 111, 123, 125, 136] and replacement or installation of mixing valves to ensure correct temperatures at water outlets.[111, 123] Additionally, regular flushing[16] and cleaning of taps[34, 38, 111] and detachable aerators;[34, 56, 117] was implemented.

Sinks (Basins, Drains and Siphons)

Similar control measures were enforced when sinks and associated plumbing were found to be the source of waterborne outbreaks. These measures included: decommissioning or removal of sinks, siphons and overflow holes;[49, 106, 129, 133] removal of mineral deposits[14] and biofilms;[124] cleaning, disinfection, decontamination or sterilization of sinks,[14, 44, 104, 105, 128, 133] siphons[19, 46, 105] and drain pipes;[28, 40-42, 44, 46, 106, 115, 125, 131] replacement of sinks,[18, 28, 29, 45, 62, 106, 107, 109, 111, 114, 121, 128] siphons,[20, 30, 103, 105, 106, 121, 126] and drainage pipes;[18, 23, 107, 121, 129] and implementation of regular cleaning and disinfection of sinks,[28, 48, 101, 109, 114] siphons[45, 101, 121] and drains.[18, 29, 124, 130] Several studies improved sink hygiene practices by implementing dedicated clean sinks,[38, 121] ensuring staff did not using patient sinks for bodily fluid disposal,[20, 56, 62, 107, 131] and storing patient care items away from the sink area.[29, 120] Other measures included addition of shut-off valves in drains,[130] closing floor drains,[36] and fixing or replacing splash backs.[48]

Wash Rooms and Hydrotherapy Rooms

To help control outbreaks related to patient wash rooms, measures put in place included: cleaning of shower heads with sodium hypochlorite;[105] replacement of shower heads and hoses;[59, 83, 95, 101] removal of shower curtains and treatment of room as a wet rooms;[101] ensuring hoses hung straight

to prevent stagnation;[95] and ensuring showers were run before use.[39, 100, 101] The lining of shower hoses as well as those which connect pipe work to fixtures and fittings may be composed materials such as ethylene propylene diene monomer (EPDM) rubber which can allow colonisation with organisms such as *Legionella* spp. and *Pseudomonas* spp.[8] New lining materials are available and should be considered for hoses in used in areas housing high risk patients.[8]

The use of hydrotherapy rooms was ceased in one study[135] whilst another revised disinfectant protocol disinfectants and ensured areas were not persistently wet within the hydrotherapy room to control the outbreak.[19] Additionally, in the case of a whirlpool bath in which bath water had become contaminated due to the space between the drain and strainer, the subsequent control measure was to use baths which had drains which sealed at the top preventing water contamination.[37]

Drinking Water and Ice Dispensers

Water dispensers including drinking fountains and cooling units which acted as environmental reservoirs in the included studies were generally removed from use within the healthcare,[71, 78, 134, 137] however in one case the unit was replaced with one which performed terminal UV treatment.[22] In the case of ice machines, consumption of ice and water from the machine was banned and replaced with bottled water,[86] with machines disconnected, cleaned and disinfected[91, 92] and filters installed,[92, 102] or machines completely removed from service.[91] In one study, ice machines were replaced with smaller models, reducing the potential for water stagnation and continuous drains were installed to allow for daily flushing.[86] In the case of ice baths used for medical syringes, immersing syringes of saline into ice was discontinued and replaced by a practice of immersing the bottle of saline in ice and drawing aliquots of saline from the bottle using sterile technique to avoid contact with the ice.[79]

Water-based Equipment

In the case of heart-lung machines and associated heater-cooler units, this equipment was replaced and sterile or filtered water used for these new devices[88, 89, 99] with regular disinfection and drainage implemented.[88, 99] Sterile water was also used for humidified respiratory equipment,[76] whilst air humidifiers were no longer used.[82] In the case of contaminated water baths, these were either replaced with dry heating incubators[51] or refilled using sterilised water.[50]

Other Control Methods

Several other control measures were used during water associated outbreaks in healthcare facilities. Firstly, sterile water was used for cleaning of reusable patient equipment such as surgical[85] and respiratory equipment[73, 76] and to prepare antiseptic solutions.[116]

Control strategies for patient care during outbreaks included the removal of CVCs[101, 116] or covering CVCs when bathing to prevent contact with non-sterile water.[93-95] Antibiotics were also prescribed for prophylaxis or treatment patients during outbreaks.[82, 96, 101, 116, 141]

Often policies and guidance regarding the aforementioned measures, as well as those on hygiene and other medical procedures such as hydrotherapy and respiratory care, were introduced, reviewed or changed in a bid to prevent further outbreaks.[38, 40, 41, 62, 83, 95, 112, 120, 130, 135, 136]

In several cases, major renovation works were undertaken to stop outbreaks, such as renovations of patient rooms[42] and bathrooms,[142] and reconditioning of water systems.[65, 147] Other significant

measures included ward relocation[27] and, in one case, the complete rebuild of the ward due to the age of the water system.[13]

Discussion and Implications for Future Research

This rapid review highlights the range of microorganisms which can be associated with waterborne outbreaks within healthcare facilities. In the studies retrieved, outbreaks were largely due to Gram negative organisms, with the most frequently cited being *P. aeruginosa*, *L. pneumophila, K. pneumoniae* and *A. baumannii*. NTM were also regularly identified as the causative organisms. A small number of outbreaks within healthcare facilities were due to fungi and viruses causing water system contamination.

In respect of the clinical settings and patients affected, it is clear that immunocompromised patients within haematology-oncology wards, ICUs and NNUs are at particular risk, with others at risk within surgical and transplant units. These high-risk patient groups within such high-risk settings are detailed within current guidance from Health Protection Scotland and Health Facilities Scotland and the Department of Health.[2, 4, 6, 9]

The origins of waterborne outbreaks vary, with contaminated water being the most frequently identified source. Contamination generally occurred within water distribution systems or as a result of contaminated fixtures and fittings. Design of water systems, fitting and fixtures was repeatedly associated with water outbreak. It is therefore clear that the design of both the water distribution system and associated fixtures and fittings can impact the likelihood of bacterial contamination and potential biofilm formation.

This review has also highlighted that installation and renovation of water systems can have a substantial impact on the likelihood of HAI outbreaks. This was demonstrated through several outbreaks which occurred due to water stagnation and biofilm formation prior to the occupation of new buildings and clinical areas[14, 63, 82] even when commissioning and testing had been performed prior to patient occupancy.[80] This should be reviewed in further detail to identify relevant guidance and literature regarding the installation of water systems to identify methods to prevent water stagnation and biofilm formation in the period before hospital facilities are in use.

From the studies included it was also clear that there is a lack of a standardised control measures used during outbreak situations, with only two studies stating their control measures were in line with national guidance.[17, 62] In several cases POU filters were used to control outbreaks[11, 15, 17, 43, 88, 102, 142] however Scottish guidance currently states that these should not be used as a primary control measure during an outbreak.[6] Therefore, further analysis is required to determine the current guidance available on suitable control measures for healthcare outbreaks linked to water systems to ensure suitable and effective resolution through standardised implementation.

Finally, it was noted that water system control measures already in place did not prevent outbreaks.[67, 78, 84] Other studies implemented regular maintenance, cleaning and testing procedures following the outbreak.[16, 18, 28, 29, 34, 38, 45, 48, 56, 75, 86-88, 101, 109, 111, 114, 117, 121, 124, 130, 133] However, these operational, cleaning, and maintenance measures differed in technique and frequency between studies. It would therefore be important to perform further scrutiny of control measures within healthcare facilities to identify current guidance and literature to analyse if these measures are

sufficient to prevent or reduce the number of waterborne outbreaks occurring, or if such measures are being applied in line with existing guidance.

The results of our rapid review are similar to those found by other similar literature reviews.[149, 150] Indeed, both studies concluded that design features promote sink-related infections; by promoting biofilm formation and by disruption of biofilm with subsequent aerosolization, splashing and contamination of surfaces.[149, 150]

Recommendations:

- Further analysis of the available guidance and literature is required to: i) understand the best possible design to ensure waterborne outbreaks are prevented, ii) identify the requirements for the installation of water systems, iii) identify effective infection control measures in case of an outbreak and for maintenance of the water system.

Appendix 1

Search Strategy

Ovid MEDLINE, Embase and Maternity and Infant Care (MIDIRS) were searched on 27/06/2018. Results were limited to English language, human subjects, 1998-Current and following deduplication 798 results were retrieved. Papers were then screened and excluded if they were not a study focussing on outbreaks within healthcare facilities due to water systems, resulting in the selection of 98 articles. Additional hand searching and expert recommendation resulted in the inclusion of an extra 34 papers which met the criteria for inclusion. In total 132 articles were included in the final literature review. Additionally using the Google search engine guidance documents were retrieved from relevant websites for Health Protection Scotland, Health Facilities Scotland, the UK Department of Health and the UK Health and Safety Executive.

A new search was carried out on 01/04/2019 in the abovementioned databases. Results were limited to English language, human subjects, 2018-current and following deduplication 73 results were retrieved. Papers were then screened and excluded if they were not a study focussing on outbreaks within healthcare facilities due to water systems, resulting in the selection of seven articles.

The search strategy used was as follows:

1. exp *water/
2. water system*.mp.
3. (tap* or faucet*).mp.
4. (basin* or sink*).mp.
5. drain*.mp.
6. shower*.mp.
7. outbreak*.mp.
8. exp disease outbreaks/
9. nosocomial infection*.mp.
10. waterborne infection*.mp.
11. hospital*.mp.
12. healthcare facility.mp.
13. healthcare setting*.mp.
14. 1 or 2 or 3 or 4 or 5 or 6
15. 7 or 8 or 9 or 10
16. 11 or 12 or 13
17. 14 and 15 and 16
18. limit 17 to English language
19. limit 18 to human
20. limit 19 to yr=”1998-Current”
21. remove duplicates from 20

Health Protection Scotland

NHS National Services Scotland

Summary of Incident and Findings of the NHS Greater Glasgow and Clyde: Queen Elizabeth University Hospital/Royal Hospital for Children water contamination incident and recommendations for NHSScotland

Date: 20/12/18

Status: Final v2

Contents

Executive summary

NHS Greater Glasgow and Clyde (NHSGGC) are currently investigating and managing a contaminated water system across the Queen Elizabeth University Hospital (QEUH) and Royal Hospital for Children (RHC) with probable linked cases of bloodstream infections associated with wards 2A/2B RHC.

Wards 2A/2B RHC is a haemato-oncology unit, also known as Schiehallion, and houses the National Bone Marrow Transplant Unit. In 2016 a patient within ward 2A RHC was identified as having a blood stream infection (BSI) as a result of *Cupriavidus pauculus*. NHSGGC investigations included water samples from outlets within the aseptic suite of the pharmacy department where the parenteral nutrition received by the child was prepared. *Cupriavidus pauculus* was isolated from water samples taken from a tap on a wash hand basin within this area. The wash hand basin was subsequently removed as a result. A further single case of *Cupriavidus pauculus* was identified in September 2017 however no environmental or water sampling was undertaken at this time.

Between the period of 29th January and 26th September 2018, 23 cases of blood stream infections (11 different organisms) with organisms potentially linked to water contamination were identified. As a result further testing of the water supply was undertaken across both hospital sites early in the investigation. This testing identified widespread contamination of the water system. Control measures implemented included sanitisation of the water supply to ward 2A, installation of the use of point of use filters in wash hand basins and showers in ward 2A/B and other areas where patients were considered high risk. Drain decontamination was undertaken and on 26th September 2018 wards 2A/B were closed and patients decanted to ward 6A QEUH and 4B QEUH. There have been no new linked cases identified since the decant of the patients.

NHSGGC requested support from Health Protection Scotland (HPS) with this incident on 16th March 2018 and Scottish Government invoked the national support framework on 20th March 2018 which requires HPS to lead an investigation and provide board support. This report is a summary of the findings from this ongoing investigation for the period of 29th January 2018 – 26th September 2018. Further technical work is being undertaken for NHSGGC by Health Facilities Scotland (HFS).

Background

Health Protection Scotland

HPS plan and deliver effective and specialist national services which co-ordinate, strengthen and support activities aimed at protecting the people of Scotland from infectious and environmental hazards.

They do this by providing advice, support and information to health professionals, national and local government, the general public and a number of other bodies that play a part in protecting health.

HPS is a division of NHS National Services Scotland which works at the very heart of the health service across Scotland, delivering services critical to frontline patient care and supporting the efficient and effective operation of NHS Scotland. The specialist group involved in supporting NHSGGC in this investigation is the antimicrobial resistance and healthcare associated infection (ARHAI) group. The lead from HPS in this investigation and author of this report is a Consultant Nurse in Infection Prevention and Control with a specialist qualification in water and ventilation and is also the national HAI built environment and decontamination lead. HPS have been supporting NHSGGC with this incident since 16th March 2018. This report has been produced with full support from colleagues across NSS.

National Support Framework

The National Support Framework[1] is a structure that sets out the roles and responsibilities of organisations in the event that a healthcare infection outbreak/incident, is deemed to require additional expert support. The National Support Framework may be invoked by the Scottish Government HAI/AMR Policy Unit or by the NHS Board to optimise patient safety during or following any healthcare incident/outbreak(s)/data exceedance or Healthcare Environment Inspectorate (HEI) visit/report. Scottish Government invoked the national support framework[1] on 20th March 2018

NHS Greater Glasgow and Clyde

NHSGGC is the largest health board in Scotland serving a population of approximately 1.2 million people and employ circa 38,000 staff. The main hospital sites covered by this NHS Board are:

- Inverclyde hospitals campus
- Royal Alexandra campus
- Gartnavel campus
- West Glasgow ambulatory care Campus
- Glasgow Royal Campus
- New Victoria Hospital
- Stobhill campus
- Vale of Leven
- Queen Elizabeth University Hospitals Campus

Queen Elizabeth University Hospital (QEUH)/Royal Hospital for Children (RHC)

NHS Greater Glasgow and Clyde's (NHSGGC) Queen Elizabeth University hospital (QEUH) is a 1109 bedded hospital with 100% ensuite single side room. Construction commenced on the £842 million hospital in 2011 which was handed over to the Board on 26th January 2015 with patient migration commencing from 24th April 2015 until 7th June 2015. The adjoining Royal Hospital for Children (RHC) is a 256 bedded childrens hospital which was handed over to the Board on 26th January 2015 with migration of patients occurring between 10th and 14th June 2015. The QEUH and RHC were both fully occupied from 15th June 2015. There are a number of additional healthcare facilities in the surrounding grounds including the maternity unit, neurosurgical unit, elderly care unit and the national spinal injuries unit. The QEUH/RHC is Scotland's largest hospital and replaced a number of existing hospitals from the NHSGGC area including:

- Southern General Hospital
- Victoria Infirmary
- Mansionhouse Unit
- Western Infirmary
- Royal Hospital for Sick Children (Yorkhill)

Introduction

NHS Greater Glasgow and Clyde (NHSGGC) are currently investigating and managing a contaminated water system across the Queen Elizabeth University Hospital (QEUH) and Royal Hospital for Children (RHC) with 23 probable linked cases of bloodstream infections associated with wards 2A /2B RHC. NHSGGC requested support from HPS with this incident on 16th March 2018 and Scottish Government invoked the national support framework[1] on 20th March 2018 which requires HPS to lead an investigation and provide NHS board support. It is recognised that this investigation and remedial action is still underway and may be ongoing for a considerable period, therefore this report is a summary of the findings from this investigation and includes cases and findings for the period 29th January – 26th September 2018.

An initial report was produced by HPS and submitted to Scottish Government (SG) and NHSGGC on 31st May 2018. Due to the ongoing and complex nature of this incident and investigation a further report was requested. This report is a summary overview of this investigation however due to the large volume of data and complexities associated with this incident further technical work is being undertaken by HFS. HPS worked with the support of HFS as the technical engineering experts to support this investigation and report production. In addition the HAI Policy Unit Scottish Government (HAIPU) has requested a separate detailed review of wards 2A/B to be undertaken. This is currently underway and will form a separate report for HAIPU and NHSGGC.

Summary of clinical cases associated with this incident

Case definition

The case definition in place since January 2018 is:

"*any child linked to wards 2A/B RHC with a blood stream infection (BSI) caused by a gram negative bacillus that had been identified from organisms identified within the water system"*

Ward 2A RHC is a haemato-oncology unit, also known as Schiehallion, and houses the National Bone Marrow Transplant Unit and teenage cancer trust. Ward 2B is the day care component of ward 2A. In total there have been 23 cases identified during the period 29th January and 26th September 2018.

2016-2017

In February 2016 a patient within ward 2A RHC was identified as having a bloodstream infection (BSI) as a result of *Cupriavidus pauculus*. NHSGGC investigations included water samples from outlets within the aseptic suite of the pharmacy department where the parenteral nutrition was made that the child had received. *Cupriavidus pauculus* was isolated from water samples taken from a tap on a wash hand basin within this area. Typing by Colindale reference laboratory confirmed the isolate from the washhand basin and the patient were the same. The wash hand basin was subsequently removed as a result. A further single case of *Cupriavidus pauculus* was identified in September 2017. NHSGGC reported that a second hand hygiene sink was found to be positive but following assessment was unable to be removed. Silver hydrogen peroxide treatment was undertaken and repeat testing resulted in zero total viable counts from this outlet.

2018

On 29th January 2018 *Cupriavidus pauculus* was again identified from a bloodstream infection (BSI) in a patient in ward 2A. Following identification of this case a series of investigations were undertaken including water sampling from outlets within the ward area. On 21st February *Pseudomonas fluorescens* was identified from a BSI and between 11th and 16th March 2018, 3 cases of *Stenotrophomonas maltophilia* were identified from patients in ward 2A. On 7th April a further case of *Stenotrophomonas maltophilia* was identified. *Cupriavidas*, *pseudomonas* and *stenotrophomonas* (amongst other gram negative bacillus and fungi) were identified from water samples obtained within wards 2A/B and therefore all cases considered to be linked to the water system. No further cases were reported until April, when between April and June, a further 10 cases were reported: 5 *Enterobacter cloacae*, 3 mixed gram negative bacilli, 2 S*tenotrophomonas maltophilia*. This cluster of mixed organisms, which were present from drain samples prompted the investigation in to the drains within ward 2A/B. Following drain sanitisation and environmental decontamination using hydrogen peroxide vapour, no further cases were reported until 2nd August and between the period 2nd August and 20th September 6 further cases were identified: 1 *Chryseomonas indologenes/Stenotrophomonas maltophilia*, 1 *Serratia marsescens*, 1 *Klebsiella oxytoca*, 2 S*tenotrophomonas maltophilia,* 1 *Enterobacter cloacae.* This latest cluster resulted in immediate further drain decontamination and a temporary decant facility for wards 2A/B being identified, with the patients transferred to wards 6A and 4B on 26th September to allow for investigative and remedial works to be undertaken in wards 2A/B.

In total there have been 23 patient cases identified. A number of patients have multiple organisms so the organism total is greater than the case number.

The organisms linked to cases include:

- *Cupriavidus pauculus* (1)
- *Pseudomonas fluorescens (1)*
- *Pseudomonas aeruginosa* (3)
- *Stenotrophomonas maltophilia* (12)
- *Acinetobacter ursingii* (2)
- *Enterobacter cloacae* (7)
- *Klebsiella oxytoca* (1)
- *Serratia marcescens* (1)
- *Pseudomonas putida* (1)
- *Pantoea sp* (1)
- *Klebsiella pneumonia* (1)
- *Chryseomonas indologenes*(1)

In addition to the organisms detailed above there is evidence of fungal growth in the water system however there have been no associated clinical cases reported.

A timeline of cases is detailed in Appendix 1. This incident has resulted in a number of children requiring additional intervention and some delays in chemotherapy treatment, however, there has been no associated mortality. There have been no associated cases since the temporary closure of wards 2A/B and the decant of the patients to ward 6A QEUH on 26th September 2018.

The clinical component of this incident is considered as occurring within two phases:

- Phase one relates to the water contamination and the clinical cases associated at that time relating to the water system. Following installation of point of use filters, the water system was acknowledged as being of suitable quality for use by patients and staff. Whilst work was ongoing to investigate and manage the water contamination incident the clinical component of this phase was considered over with a debrief held on 15th May 2018

- Phase two relates to the environmental contamination and subsequent associated clinical cases occurring as a result of the contaminated drains and the impact caused by the fitting of point of use filters. Phase two is currently ongoing and will remain open until wards 2A/B have re-opened

Summary of initial findings

Following identification of the potentially contaminated water system in wards 2A/B and the resultant possible linked cases in March 2018, NHSGGC considered the decant of these 2 wards to allow for a full investigation of the source of water contamination in wards 2A/B and consider remedial action. At that time ward 4B QEUH was being prepared for the transfer of adult BMT patients from the Beatson oncology unit. Water sampling was undertaken in this ward prior to decant as a precautionary measure. Results identified the presence of *Cupriavidus pauculus* (and other gram negative bacilli) in water outlets within this ward and was the initial suggestion that there may be widespread contamination of the water system that serves both QEUH and RHC. Further testing across the site provided confirmation of this, with positive samples being identified in a number of areas across both sites at both outlet level and within the water system in the basement level (risers). Within the same timeframe staff within wards 2A/B also reported they had witnessed “black effluent” around the rim of the drain in some wash hand basins. Following visual inspection and laboratory testing, this was considered to be biofilm and sampling identified significant contamination of the drains with microorganisms and fungi. Drain contamination is not unexpected however the level of biofilm evident was not in keeping with a water system of less than four years old.

In an attempt to establish the extent of the water system contamination and any causative factor NHSGGC, supported by HFS and HPS initiated a detailed investigation into the contaminated water system within QEUH/RHC. Support was also requested from a number of external companies experienced in water incident management: These included Leegionella, Public Health England (PHE), water solutions group and Makin & Makin. The detailed investigations led by NHSGGC and supported by HFS/HPS included reviewing commission, installation and maintenance records provided by the contractor. This proved to be challenging due to the archiving of data and there were very few members of the initial project team available who are technically qualified to retrieve data and provide verbal clarification. The detailed findings from these records are included within the technical review.

Results from ongoing water testing were reviewed on a weekly basis and highlighted there was evidence of regressional seeding of contamination which supported NHSGGCs view that a whole system remedial approach was required.

Commissioning and design of the hospital water system

As part of the normal water system commissioning water samples were obtained. Initial preliminary findings have identified that prior to handover from the contractor there were a number of water samples taken that produced results with high level of total viable counts (TVCs). TVCs are indicators that there are hygiene issues within the water system and are quantified as a generic indicator for microbial contamination. Specific microorganisms which can be tested for include: Coliforms, *Escherichia coli (*including O157), *Pseudomonas aeruginosa, Salmonella spp*, *Campylobacter spp* and Environmental Mycobacteria. Testing for these is not conducted as standard within current guidance and typically occurs in response to a suspected or confirmed outbreak, or due to identification of a series of sequential cases.

In response to the high levels of TVCs found as part of the pre handover commissioning sanitisation of the water supply was undertaken by the contractor, with some impact and a reduction in TVCs in most areas, however there are a number of reports which indicate that

there may still have been a number of areas with higher than normally acceptable levels of TVCs.

Design and installation of taps and clinical wash hand basins

The design and construct of wash hand basins, showers and taps in these hospitals were agreed with NHSGGC in line with the Scottish Health Technical Memorandum (SHTM) in place at the point the hospitals were designed (commencing 2009), this included the installation of taps with flow regulators. HFS and HPS were involved in this decision making process as were NHSGGC Infection Control team. The SHTM (SHTM 04-01)[2] was revised in 2015 and no longer supports the use of flow regulators in clinical wash hand basins.

Biofilm formation in flow regulators has been identified in a previously published outbreak.[3] The manufacturers of the taps/flow regulators in place across the QEUH/RHC recommend regular removal of the flow regulators for cleaning/decontamination however do not offer more specific guidance on frequency of decontamination of the flow regulators. The flow regulators in use have a number of components and potentially create ideal conditions for the development of biofilm.

NHSGGC provided an external company (Intertek) with some flow regulators to carry out microbiological testing. This confirmed that flow regulators have the ability to harbour a significant number of micro-organisms with the presence of biofilm being detected on all flow regulators tested and 50% showing high levels of contamination. It is also worthy of note that biofilm was present on some flow regulators which was not immediately obvious on visual inspection.

The taps in place across all clinical wash hand basins in both hospitals are also reported to be non compatible with silver hydrogen peroxide, a product which was used during commission stage to sanitise the water system in view of the high TVC results. It is unclear whether this has caused any degradation of the taps. A tap was deconstructed by NHSGGC and examined for the presence of biofilm, in addition to microbiological sampling. Several components of the tap exhibited microbiological contamination.

The presence of high levels of gram negative bacteria and fungus in the water system may indicate that temperature control required has not always been achieved. Temperature control is included as part of the wider technical review being undertaken for NHSGGC by HFS.

Other aspects discussed in the detailed technical review include:

- Flushing
- Contract/project team
- Roles/responsibilities
- Design and construction
- Guidance and specifications
- Specification of water system
- Flexible hoses
- System description

- Pipe work
- Post handover and maintenance

There are a number of local and national recommendations within this review for both NHSGGC and Nationally. The key NHSGGC and National recommendations from the technical review are included within the recommendation section of this report.

Infection Control at design commissioning and handover

HAI-SCRIBE

Healthcare Associated Infection System for Controlling Risk in the Built Environment (HAI-SCRIBE) [4], reference has been designed as an effective tool for the identification and assessment of potential hazards in the built environment and the management of these risks. HAI-SCRIBE (2007) was in place during the construction and handover of both buildings.

Implementation of HAI-SCRIBE should be the responsibility of a multidisciplinary team of specialists with appropriate skills.

Compliance with HAI-SCRIBE requires an accurate record of the process of hazard assessment and risk management which is essential ‘due diligence’ information.

Evidence has been reviewed in relation to the infection control sign-off of results and the system at commissioning/handover. Whilst there is evidence of involvement with initial results and sanitisation there is no evidence of ongoing input or sign off from the Infection Prevention and Control Team (IPCT). It is noted that there is lack of clarity in current national guidance relating to roles and responsibilities of the IPCT in the commissioning, design and handover of new or refurbished builds. Water was first placed on the Infection prevention and control (IPCT) risk register in 2018. The IPC risk register is reviewed on an annual basis with risks considered and prioritised using a risk scoring system. Water safety was added to the risk register in 2018 in response to the emerging evidence of potential issues associated with this incident. Prior to 2018 water safety did not feature in the IPC risk priorities when scored.

NHSGGC employed a robust approach to the design stage of the hospital project by means of a dedicated Infection Prevention and Control Nurse (IPCN) seconded as part of the project team to support the IPCT aspect of the design stage, commissioning and handover stage.

Whilst there was dedicated resource allocated to the project team, there is no documented evidence of NHSGGC Infection Prevention and Control Team involvement in the commissioning or handover process of the project. However NHSGGC has provided a statement from the Lead Infection Control doctor at the time to confirm that they were involved in reviewing some aspects of the initial water testing methodology and the results for QEUH and RHC during commissioning and handover. The Lead ICD has confirmed being involved in:

- Quality assurance of the water testing methodology used by the commissioning engineers.
- Liaising with Facilities Colleagues in reviewing the water testing results supplied by the commissioning engineers.

- Recommending further actions (dosing), for a small number of outlets with TVCs above the acceptable limits.

In addition to a nurse consultant being seconded as a dedicated resource to the project team with involvement in design, commissioning and handover, the project team were supported by the IPCT. This support included regular review of the new builds hospital project at the infection control committee and senior IPC meetings. NHSGGC reported that both the infection control manager and associate director of nursing (infection control) liaised regularly with the project associate nurse director and ensured the numerous commissioning groups established were supported by a member of the IPCT. In addition all wards were reviewed by a member of the IPCT prior to occupation by patients.

Current management of situation/Control measures

In addition to holding regular incident management IMT meetings (IMT) NHSGGC established a multi disciplinary water technical group which is a sub group of the incident management team. This group is supported by HFS, HPS, with monthly representation from water solutions group and Makin & Makin.

A number of control measures have been instigated during this incident and in particular in wards 2A/B. These included parent and staff education sessions, daily visits to the ward from members of the infection prevention and control team (IPCT), increased domestic hours, environmental monitoring by means of audit, including Standard infection control precautions (SICPs) audits.

Limiting access to water

In the initial investigation the use of water within wards 2A/B was limited with portable wash hand basins being supplied for hand washing. Patients were requested not to use wash hand basins or showers and wipes were provide as an alternative. Drinking water was provided by means of bottled water. Access to water was re-established once point of use filters were in place in showers and wash hand basins/sinks. BMT patients continue to receive sterile water.

Point of Use filters.

Following the identification that the water contamination was widespread across both RHC and QEUH an additional control measure of point of use (POU) filters for high risk areas was implemented to ensure a safe water supply at the point of use. In addition if a high risk patient was being nursed in an area deemed to be of low risk, a point of use filter was fitted to water outlets in their room. POU filters require to be changed every 30 days and are a costly approach, however in the interim until the water contamination can be addressed, is considered the only feasible approach to ensure safe delivery of water. A number of studies found that installation of point of use filters reduced either infection rates in associated healthcare settings[5;6] or pathogen counts within tested water samples.[7]

Once the POU filters were in place the restrictions on access to water within wards 2A/B was removed and patients were able to access washhand basins and showers. It was noted that following the fitting of the POU filters there was a greater splash evident from the wash hand basins as the point of entry of the water from the outlet was closer the basin. This splash was noted more from clinical wash hand basins than ensuite wash hand basins and trough sinks.

Drain Sanitisation

Following the identification of the second phase of cases associated with this incident and the hypothesis that the cases may be related to drain contamination, the drains were inspected by the IPCT. Once the drains were identified as being visibly contaminated with what was thought to be biofilm, a programme of drain sanitisation was undertaken across high risk areas commencing with wards 2A/B.

Environmental decontamination

Prior to and following completion of the first drain decontamination process in wards 2A/B, a terminal clean of all areas using hydrogen peroxide vapour was carried out.

Water treatment

It is well recognised that drinking water distribution systems contain a diverse range of microorganisms.[8-10] The presence of microorganisms is affected by various factors including; the disinfection processes employed, the location and age of the system as well as pipe material.[11]

There were a number of options explored for longer term water treatment by NHSGGC. These options included:

Chlorine dioxide

A number of studies were identified which utilised chlorine dioxide systems within hospital settings, and use of these was found to reduce bacterial numbers.[10,12,13] Various advantages and limitations associated with use of chlorine dioxide are known, with the most relevant summarised below.[14,15]

Advantages**:** Known to be effective against a wide range of bacteria, viruses and some protozoa including Giardia.

Limitations: Production of disinfection by-products (DBP's). Although potential production of DBP's always needs to be considered, the efficacy of water disinfection should not be compromised in trying to eliminate these.[16]

UV light

A number of drinking-water treatment technologies are available which employ UV light radiation to inactivate microorganisms.[15] As with chlorine dioxide, various advantages and limitations associated with use UV are known, with the most relevant summarised below.[14-16]

Advantages: Bacteria, fungi and protozoa (considered to be more effective at killing Cryptosporidium than chlorine dioxide) are readily inactivated at low UV doses, with higher doses required for virus inactivation. In addition, UV disinfection does not result in the formation of DBP's like chlorine dioxide.

Limitations: UV disinfection does not leave any residual compound in treated water and therefore does not offer protection against possible microbial re-growth in distribution pipe-work.

Thermal disinfection

Very limited information was identified in the published literature in relation to advantages and limitations of thermal disinfection. One study found that heat shock treatment at 80˚C reduced Gram negative bacteria in a hospital water system but did not lead to complete eradication.[17] Copper silver ionisation was also considered however this was discounted due to pH levels.

Preferred solution

The NHSGGC preferred method of choice for water treatment was continual dosing chlorine dioxide. This was supported by HFS and HPS. Shock dosing of the system was considered and it was agreed that due to safety issues and the potential impact on both hospitals ability to function during the process, this was not the most appropriate approach. It was also recognised that in the absence of initial shock dosing it may take up to two years for the process to be effective from tank to tap level. The procurement process is well underway and installation expected to commence November 2018.

Temporary closure of wards 2A/B

A recommendation was made by the IMT to pursue the temporary decant of wards 2A/B to allow investigative and remedial work to be undertaken. A number of options were explored resulting in the transfer of patients from wards 2A/B to ward 6A of the QEUH. Adult patients within ward 6A QEUH were transferred to Gartnavel General. Three rooms within the adult BMT (4B) were identified and allocated to the paediatric BMT unit. The patients were transferred on 26th September 2018. It is anticipated that the decant facility will remain in place until mid/late December.

Remedial work/Investigations wards 2A/B

The planned investigations/remedial works planned during the decant period include:

- Drain Survey
- Ventilation review
- Replacement of clinical wash hand basins
- Replacement of taps (with no flow regulator)
- Review of any little used water outlets with a view to remove
- Replacement of sections of pipework where biofilm noted
- Review of toilet cisterns and adaptation to reduce potential toilet plume effect.

Hypothesis

There are a number of workable hypotheses being explored; it is currently considered the most likely cause of the widespread contamination is a combination of hypothesis B and C

A: Ingress contamination

A small low level number of micro-organisms may have been present in the water supply at the point of entry. Lack of temperature or chemical control may have enabled biofilm formation. Due to the increasing biofilm throughout the system this may have allowed any subsequent micro-organisms present at point of entry an opportunity to flourish and cause widespread

contamination of the system.

B: Regressional contamination

This may have occurred due to contamination occurring at the taps/outlets or flow straighteners and contamination has regressed backwards throughout the system causing widespread contamination. The widespread positive results and array of bacteria point to contaminated outlets at installation or contamination of high risk components in the tap from ingress as opposed to the patient contact route.

C: Contamination at installation/commissioning

Contamination may have occurred due to presence of contaminated pipework or outlets. Prior to handover the system required to be sanitised due to high TVC counts. It is unclear if a robust flushing regime was in place from installation to handover and from handover to occupancy to prevent contamination.

Secondary Hypothesis

It is recognised that in many situations control measures or actions taken in an attempt to minimise the risk of HAI there can be unintended consequences. In this scenario the secondary hypothesis is linked to the unintended consequence of the point of use filter use:

POU filters.

In an attempt to provide water of a safe microbiological quality NHSGGC applied point of use filters to all clinical and patient wash hand basins in high risk areas and areas where high risk patients were being treated. These filters meant the exit point of the water from the taps was closer to the washhand basin and as a result caused more splash which may also lead to disruption of any drain biofilm as well as potential environmental contamination. (Pictures 1, 2). At the time of fitting the filters, the issue of biofilm within the drains and the associated risk or the resultant splashing that was being caused had not been identified and therefore the subsequent increased risk of environmental contamination and potential exposure of the children was not recognised.

Picture 1

Picture 2

Additional potential considerations to minimise impact

Ensuite single side rooms/hand hygiene practice

Since 2008 it is recommended that all new build hospitals have 100% en suite single side rooms.[18] As a result this has substantially increased the number of wash hand basins and therefore the frequency with which a wash hand basin is used and the water volume in each basin reduced when compared to multi occupancy wards with a single wash hand basin. Since the introduction and widespread use of alcohol gel, the need for hand washing as a first approach has greatly decreased, as alcohol gel may be used on hands that are not visibly soiled. This requires further exploration and consideration and review of flushing regimes and number of wash hand basins required.

Disposal to drain

A number of drain samples were sent to Intertek for analysis. A report has highlighted that in addition to the general presence of biofilm, there was biofilm noted around the aluminium spigots. There was also some occlusion reported as a result of adhesive and pooling noted between the back of the sink and the pipework. All aluminium spigots in wash hand basins in wards 2A/B were replaced with PVC spigots. In addition a number of foreign objects were identified within the drains. It was also reported that there was evidence of a yellow fluid present suggestive of urine being disposed to the drain. The biofilm has a mustard yellow colour and an odour of ammonia was detected. There was a small amount of yellow liquid in the base of the bowl trap which when removed and looked at in isolation also had an ammonia smell. Parents, families and clinicians are advised that hand wash basins are for hand washing only and additional activities such as fluids being disposed of to drain via a handwash basin should not occur. Staff are aware that this is not acceptable practice however the positioning of a wash hand basin in every ensuite single side room may encourage patients or visitors to expel fluids such as contents of a drink bottle. Items such as coffee, sweet drinks encourage the growth of

bio film and microorganisms within a drain. The large open horizontal drain may also encourage the accidental disposal of foreign items.

Summary

There have been no new reported cases since the decant of patients to ward 6A on 26th September 2018. The IMT will continue to meet regularly until the patients have been transferred back to wards 2A/B. The water subgroup will continue to meet until early/mid 2019 and will be supported by HFS/HPS. It has been evident to HPS that since the identification of this widespread incident and clinical impact on wards 2A/B, patient safety has been paramount with NHSGGC clinicians, facilities, IPCT and management team. A significant financial investment has been made to minimise ongoing risks including widespread use of point of use filters in addition to remedial work planned. A number of lessons can be taken from this incident for NHSGGC and NHSScotland as a whole in relation to water safety and commission, handover and maintenance of buildings. The national work and learning for NHSScotland will be driven via the HAI built environment steering group which is widely represented and chaired by the associate director of facilities (NHSGGC) and deputy chair is the lead ICD (NHSGGC).

Recommendations

A number of local and national recommendations have been made based on the investigation to date. This includes recommendations for NHSGGC which have been identified from a detailed HFS technical review. NHSGGC/HPS/HFS will produce an action plan based on the recommendations as follows:

1. NHSGGC

- To produce a detailed action plan addressing ALL points identified within the HFS technical review and should cover as a minimum:
  - Decontamination
  - The management of the water systems
  - All required rectification work
  - Management of recording systems
  - Routine and reactive maintenance schedules

2. All NHS Boards

- All NHS boards should ensure facilities teams are adequately resourced to ensure maintenance of all aspects of the water system are maintained in accordance with policies and guidance.
- All maintenance undertaken should be recorded and maintenance records should be reviewed regularly to ensure all aspects of the water system are maintained in accordance with policies and guidance

3. HPS/HFS

HPS (supported by HFS) to undertake an urgent national water review of all healthcare premises built since 2013 to provide assurance that a similar incident has not and is not likely to occur elsewhere.

HPS (supported by HFS) to establish a national expert group to:

- Review NHSScotland current approach to water safety including as a minimum:
  - Review NHSScotland current approach to water testing in healthcare settings.
  - Review NHSScotland current surveillance and reporting of potentially linked water related HAI cases.
  - Based on findings develop risk based guidance on water testing protocols, results interpretation roles and responsibilities and remedial steps to be considered.
- Give consideration to the development of a best practice built environment manual which will be evidence based and cover as a minimum current and emerging evidence

and the technical requirements from a clinical, patient safety and HAI perspective that will be adopted by all NHS boards. This will include as a minimum:

- Review existing national and international guidance relating to water safety.
- Develop robust requirements/guidance for all aspects of water safety.
- Develop robust handover requirements in relation to water systems.
- Review of the role of the IPCT into the built environment, and produce clear guidance on roles and responsibilities.
- Establish a risk based approach to water testing and any remedial action required, including roles and responsibilities that NHS boards will adopt.
- Review the requirement for 100% ensuite single side rooms the number of clinical wash hand basins per patient/bed.
- Review the use of flow regulators across NHS Scotland and identify and associated risks and recommend any remedial actions required.

- HPS/HFS will continue to provide support to NHSGGC relating to the current water incident and provide input into the weekly meetings until mid 2019 (and reviewed thereafter).
- Further develop the existing Scottish expertise in the built environment programme (mainly water and ventilation) at national level.

HFS (supported by HPS) to:

- Review all relevant water technical guidance to ensure all aspects are covered within the guidance including as a minimum:
  - Thermal disinfection in sections of water distribution systems
  - Handover checklists
  - Contract management procedures
  - Design guides to eliminate thermal pickup in cold water systems
  - Update advantages and disadvantages of chemical disinfection techniques
  - The organisms Boards should test for and action to take on defined levels
  - Drain cleaning regimes
  - Biofilm growth in drainage systems

.

Appendix : 1 Timeline of cases

The epi-curve demonstrates that only one case of *Cupriavidus pauculus* was reported from 26th January 2018, with the other associated cases being *Stenotrophomonas maltophilia* and/or *Pseudomonas aeruginosa* positive between 21st February 2018 and 5th April 2018.

Glossary

Alcohol gel	A gel, foam or liquid containing one or more types of alcohol that is rubbed into the hands to inactivate microorganisms and/or temporarily suppress their growth.
Aseptic Suite	An ultra clean environment within a department, (for example pharmacy) where sterile solutions are prepared such as chemotherapy under strict measures.
Bacteria	Microscopic organisms (germs).
Bib taps	A tap or stop cock which has a nozzle bent downwards.
Biofilm	Collective of one or more types of microorganisms, including bacteria, fungi and protists, that stick together and can become embedded on a surface.
Blood stream infection	The presence of bacteria in the bloodstream.
Chemotherapy	A cancer treatment where medication is used to kill cancer cells.
Chlorine dioxide	A chemical compound used for a variety of antimicrobial uses, including the disinfection of drinking water.
Clinical wash hand basins	A sink designated for hand washing in clinical areas
Cluster	A group of similar things located around the same location
Copper silver ionisation	A disinfection process where positively charged copper and silver ions are added into the water system. It is primarily used to control control Legionella, the bacteria responsible for Legionnaires' disease.
Decant	Temporarily transferring people to another location.
Decontamination	Removing, or killing pathogens on an item or surface to make it safe for handling, re-use or disposal, by cleaning, disinfection and/or sterilisation.
Drain	A fixture that provides an exit-point for waste water or water that is to be re-circulated.
Ensuite single side room	A room with space for one patient and containing a bed; locker/wardrobe, clinical wash-hand basin, en-suite shower, WC and wash-hand basin.
Flexible hoses	A flexible hollow tube designed to carry fluids from one location to another and are used to connect taps to the water supply
Flow regulators	Point of use regulators designed to provide constant and maximum flow rates at taps and showers etc. irrespective of changes in demand or water pressure

Flushing	The process of cleaning or "scouring" the interior of water distribution mains (pipes) by sending a rapid flow of water through the mains.
Gram negative bacilli	Gram-negative bacteria are bacteria that do not retain the crystal violet stain used in the gram-staining method of bacterial differentiation; examples include E.coli, and Pseudomonas aeruginosa.
Hydrogen Peroxide Vapour	Vaporized hydrogen peroxide is an airborne disinfectant and infection control measure that can be used for room decontamination after patient use.
Ingress	The act of entering.
Microbiological sampling	Sampling for harmful bacteria, parasites, fungi and viruses including those in water, environment and equipment.
Micro-organism	Any living thing (organism) that is too small to be seen by the naked eye. Bacteria, viruses and some parasites are microorganisms.
Organism:	Any living thing that can grow and reproduce, such as a plant, animal, fungus or bacterium.
Parenteral nutrition:	The giving of special liquid feeding products to a person using an intravenous catheter and bypassing the normal digestion process of the stomach and bowel.
Pathogen:	Any disease-producing infectious agent
Point of use filters:	A device that incorporates an integral filter with a maximal pore size of 0.2 µm applied at the outlet, which removes bacteria from the water flow therefore protecting the end user from exposure to harmful waterborne pathogens.
Portable wash hand basins	A sink that is not connected to the mains water supply but connects to a water tank which is filled locally.
Regressional seeding	Where micro-organisms from contaminated water outlets/biofilm regress 'back' through the water system and seed other areas (pipes/tanks/outlets). The microorganisms embed themselves and multiply contaminating other areas of the system.
Sanitisation	Use of antimicrobial agent on objects, surfaces or living tissue to reduce the number of disease-causing organisms to non-threatening levels.
Shock dosing	The use of large quantities of chemicals to the water supply to break down organic waste and get rid of bacteria and contamination.
Silver hydrogen peroxide	A solution of stabilised silver in hydrogen peroxide that is used for surface and water decontamination.

Sterile water	Water free of all microorganisms – bacteria, viruses, fungi.
Terminal clean	Cleaning/decontamination of the environment following transfer/discharge of a patient, or when they are no longer considered infectious, to ensure the environment is safe for the next patient or for the same patient on return.
Thermal disinfection	The use of water and heat for the disinfection process for example washer-disinfectors.
Toilet plume effect	The dispersal of microscopic particles as a result of flushing a toilet.
Total viable counts	A quantitative estimate of the concentration of microorganisms such as bacteria, yeast or mould spores in a sample.
Trough sinks	A long, narrow basin designed for communal handwashing with water delivered at hand-washing temperature via mixer taps in conjunction with a thermostatic mixing valve. Usually used for surgical scrubbing.
UV light	A disinfection method that uses short-wavelength ultraviolet (UV-C) light to kill or inactivate microorganisms.
Water outlets	Any hole or opening where water is released for example taps, showerheads.
Water sampling	The analysing of the water supply for harmful bacteria, parasites, and viruses.
Water system	A system of engineered hydrolic and hydraulic components to supply water.
Spigots	A short cylindrical pipe which connects the Clinical Wash Hand basin to the main pipework.
Occlusion	Obstruction or blockage

Subject: RE: Important -response required:RE: Confidential: HAI SCRIBE RHCYP Risks and Mitigations

Hi

I don't have anything to add except to stress that we should have the opportunity to comment on the continuity plan for items 4&5. During winter, PARU will be our main RSV cohort area and could present a wider issue for the site if it was to close in the event of a sump issue.

Kind regards

Anna Munro

Subject: Important -response required:RE: Confidential: HAI SCRIBE RHCYP Risks and Mitigations
Importance: High

Hi all
I believe Jim Crombie is looking for a (very) rapid response from IPCT in relation to the meeting held last week.

I agree with the other points Sarah has highlighted, and in general terms of documentation/evidence required – this would include 1) a summary report for both water and ventilation which highlights any fails/exceptions, the clinical location/specialty and remedial actions taken; 2) a clear water plan which is visible to IPCT and clinical management teams – presumably via the Water Safety Group and Ventilation group; and 3) that the 4 proposed strategic groups from George C's governance paper will all hold a topic specific risk register.

As I wasn't able to attend the meeting, and having had limited input into the planning/construction phase, I also have the following questions from the risk register:

Risk 4 & 5: sump issues -states there is a risk of loss of sanitary appliances in clinical areas and flooding in the basement – 'mitigation' has been provided and there is a continuity plan –suggest that the continuity plan is provided so that IPC can comment on this element to ensure that toilet/hand washing/waste water disposal is

appropriately managed. I am not clear why the residual risk is YELLOW for the basement sump AMBER for the garden pump failure with further mitigation in place?

Risk 7: previous leak (water joint failure) – risk of recurrence – do we know which clinical areas were affected by this issue – and are any of them augmented care/high risk areas. Monitoring is noted as a future mitigation – so would want confirmation of this monitoring activity (and outcomes) to be summarised for the RHSC infection control committee and the proposed 'Group 3 Environment' committee proposed in the new Facilities governance structure.

Risk 9: movement joints – noting that these are in clinical areas (including some high risk areas) it would be good to have written confirmation of compatibility for up to 10, 00ppm av chlorine solutions and routine cleaning methods/products – this was discussed at walkround but haven't seen written confirmation

Risk 10: Basement sump – noting adjacency to kitchen/food prep area – highlights odour and pest control as an issue. Would be good to see and agree an HAI scribe for routine access and maintenance. Would be good to see an update/monitoring/exception report provided in relation to this risk – possibly at the 'Group 3 environment' meeting as outlined above? Not being an expert in sumps or plumbing I also have a question in relation to air egress if odour is an issue is there a risk of aerosol/backflow of contaminant which would be relevant to food safety and kitchen hygiene??

Risk 12: don't fully understand the statement about extract ventilation and reduced capacity to a minimum of 10%- or indeed what (if any)impact there would be for IPC – which 4 bed areas are affected by this? I also note that even with mitigation, the residual risk remains AMBER (likely to occur)

Risk 23: location of helipad and 'odour' ingress for RIE/RHSC – would be good to have confirmation of additional filter visualisation/checks affecting theatre air handling units via the quarterly ventilation group (proposed in the Facilities governance paper) - assume this group will have a risk register for ventilation issues across Lothian?

Would appreciate a response ASAP – and no later than end of day Thurs 13th please,
Thanks
Lindsay

Subject: RE: Confidential: HAI SCRIBE RHCYP Risks and Mitigations
Importance: High

Dear All,

As requested, I have reviewed the Risk register circulated from Janice on Wednesday and would be grateful if you could check over the response from an IPCT perspective. Please add/delete or amend as appropriate. Please comment or clarify if suggestions in red should be considered/initiated from an IPC view before I reply to Ronnie, Janice and Jim Crombie et al. Please also identify if you feel any of the 24 residual risks identified are IPC related which I have missed! Jim is looking for a response ASAP.

Following review of the risk register for residual risks, the following evidence is required by the IPCT in order to provide assurance that mitigation measures undertaken result in healthcare system components being fit for purpose and evidence that patient safety issues have been addressed with view to signing off HAI Scribe Stage 4:

Risk 1: Ventilation: Validation of ventilation systems (as per requirements in SHTM 03-01) to include air sampling results from theatres inclusive of particle counts for those that are Laminar flow theatres. The reports should be provided in a format which facilitates easy reading and assessment. (G.Curley (G.C) advised he would like an asset list for critical ventilation systems).

Due to rooms only having 4 air changes per hour opposed to 6, G.C advised that maintenance must be rigorous due to decrease in a/c capacity and IPCT would support this.

Risk 2: Water contamination: Validation of water quality results to be presented on an Excel spreadsheet for ease of reading and assessment. This is currently being undertaken and will be provided by the by project team in due course. IPCT have directly requested with those compiling this information, that the spreadsheet indicates the clinical area/speciality where the water outlet is located in order to assess risk. (G.Curley suggested that a further independent water sampling regime could be undertaken by Westfield Caledonia - ? if required and ? if being taken forward by facilities – Fiona correct me if I misinterpreted this)
G.C has also requested a more specific Water Management Plan from Authorising Engineer as the current plan is 187 pages. Assurance is required that Hard Facilities Management carry out water sampling in line with guidance HTM 04-01.

Risk 6: Mould and Fungus: Mitigation undertaken included the removal of plasterboard, replacement of flooring and fixtures and fittings. A walk round review was carried out by IPCT following flood and damage (Dr Inverarity and Janette Rae). (G.Curley suggested that for further assurance to ascertain that there is no residual damp, particularly as there is often foil coverings within wall cavities - Further review of wall /cavity by removing and visualising area - out with theatre environment ? required).

Risk 14: Access hatches: Where access hatches remain in theatre and these are accessed for maintenance or other, a domestic clean and air sampling/particle counts should be carried out prior to theatre being put back into use. These hatches should feature within the Hard FM maintenance plans.

Risk 20: Entrance matting: Where matting is available/not available at external entrances assurance must be given that an increase in domestic cleaning will be in place as required to ensure that dirt and debris from outdoor footwear is not trailed through the hospital corridors.

Kind regards
Sarah

Subject: Confidential: HAI SCRIBE RHCYP Risks and Mitigations

What Jim has asked is can we go through the list and

1. confirm which items are IPC related
2. advise what evidence is required against the items to provide the assurance to progress

They are aware that the ventilation and water evidence needs to be formatted to facilitate the group ease of reading and assessing , they are currently working on this

Dear All

Further to our meeting today please find attached an electronic version of the Residual Risk Register, please can you treat as confidential.
<< File: 080519 RHCYP DCN Residual Risks.xlsx >>
As agreed at the meeting if you can get back to us if you require any further information/evidence in relation to any of the residual risks

Kind regards

Janice

All,

Please find agenda for tomorrow's meeting below:

1. '86' Item List
2. Residual Risk register
3. Water Safety
    - Current Status
    - Sampling & Analysis Results
    - AE's Meeting
4. Ventilation
    - Current Status
    - Independent Validation
5. HAI SCRIBE Stage 4
6. AOCB

Regards

Ronnie

Subject: HAI SCRIBE RHCYP Risks and Mitigations
When: 05 June 2019 12:30-14:00 (UTC+00:00) Dublin, Edinburgh, Lisbon, London.
Where: MacKinlay Room RHCYP

<< File: Updated Directions to Site 150398.pdf >>
Dear Jennifer,

I've booked the MacKinlay room for you.

Please go to the "Turnstiles" (shown on map) where the Security team will let you in and then go to the RHCYP Entrance (shown on map) where the Main Reception is. Please sign in at the reception desk.

I'd be grateful if you could send me a list of people attending the meeting so that we can add them to the visitors list to allow them through the security turnstiles.

Many thanks.

With kind regards,

Mashoodha Shah

HPS Water report

Dated 20/12/18 but only made available to NHS Lothian via Scottish Microbiology and Virology Network on 20/8/19.

Page	Comment	Response	Themes?
3	Water system contamination – are they including drainage as part of the system?		
	Water samples taken for Cupriavidus pauculus from aseptic pharmacy – were these also taken from the ward at this time?	If Cupriavidus pauculus has caused several cases of bloodstream infection at RHC (and is described elsewhere e.g. Ohio, why do none of the recommendations about water testing for Scotland cover testing water for it or other Burkholderiaceae?	Was a microbiologist involved in writing the report?
	Water sampled where patients deemed 'high risk' – what definition are they applying and is it the same as for augmented care areas in the HPS interim guidance?		
	"Drain decontamination was undertaken"	This seems to be through vaporised hydrogen peroxide(p7) but this is known not to be an effective method for sink drain decontamination.	
	Report states 'widespread contamination of the water system' – but unclear what sampling was undertaken in wards 6A and 4B after transfer of haem/onc patients out of ward 2A/B. Control measures outlined are local controls?	Is there a way to determine if a ward (e.g. 6A or 4B) is safe?	
4	The author of this report is a Nurse Consultant in Infection Prevention and Control	Would it not be more helpful to have multidisciplinary involvement e.g. have input from engineering and microbiology and water management background?	
5	QEUH is a 1109 bedded hospital with 100% ensuite single rooms	There are no other facilities in Scotland of this size and likely none with such a demand on plumbing or volume of water outlets so are the	Is this an unintended consequence of 100% single rooms. i.e. are these water quality issues present at Golden Jubilee but not causing

		water findings and issues from QEUH directly transferable to other Scottish hospitals which are smaller with less complex plumbing?	infection because different patient risk or seen at Birmingham QEH where there is a Pseudomonas aeruginosa water quality issue in critical care?
6	'further review of wards 2A/B to be undertaken' – review of what? Environment? Practice?		
7	Case definition is weak. How do you define a patient 'linked' to wards 2A/B? Subsequently lists 23 cases but unclear if some of these are confirmed cases, probable cases of possible cases. It's lacking precision.	Agree on p6 it states there are 23 probable cases of bloodstream infection but there is no definition of "probable "case.	
	23 cases in a period of 8months – would be helpful to have some kind of background incidence rate of Gram negative bloodstream infection from the unit at Yorkhill?		
	A second hand hygiene sink (should be wash hand basin not sink)was found to be positive	Positive from water from the outlet or culture of a drain? Why can you not remove a wash hand basin?	
	Silver H202 treatment of drains – this cannot be in line with the manufacturers stated used and methodology – will not penetrate organic matter?		
	States repeat testing- is this water and drain, or just drain? How did they sample, and how many consecutive samples were obtained?		
	Why were the cases of Stenotrophomonas BSI attributed to water. Was the role of antimicrobial selection considered (exposure to meropenem to which Steno is inherently resistant is common in bone marrow transplant units)?		
	Did the clinical and environmental isolates of Steno and Pseudomonas undergo typing to look		

	for a match with environmental isolates? Were these quantified cultures and if so how much was present in the water?		
	Between April and June there were 10 cases – not clear if these were 10 cases of BSI. If so why were these attributed to being from water? Drains may be positive due to hand decontamination after touching colonised patients rather than drains being the source of infection. Were there any other patients with Gram negative bacteraemia that wasn't attributed to hospital water during this time frame?		
	Drain samples – methodology for sampling unclear		
	Question – do Glasgow domestics routinely use Chlorine for all sanitary items (including sinks...) and have they done so since the building was occupied? Was sink cleaning methodology reviewed as this isn't clear from the report anywhere?		
	When further drain decontamination undertaken, did they also take further water samples, or was the focus only drains??		
	Did they sample the water supply intake to the hospital? What is the background rate of these organisms in the overall supply?		
	Have Glasgow (or another paediatric bone marrow transplant unit) ever audited the range of pathogens that they recovered from blood cultures? How does this list compare ?		

P8	Were all of the organisms associated with cases isolated from water samples? If not, does this not mean that some would be probable cases (likely to be linked to water source in the ward but no micro evidence?) rather than lumping them all as confirmed cases??	Agree it looks like a mix of apples and pears. Enterobacter, Serratia and Klebsiella is more likely coming from a patient source. The high incidence of Stenotrophomonas may be resulting from meropenem exposure and selection not burden in water.	
	What is the total bed base for wards 2A/B?		
	Unclear of the relevance of statement "there is evidence of fungal growth in the water but no associated clinical cases" - also assume they looked at all clinical isolates for the hospital and not just within ward 2A/B	Do they genuinely mean there was fungal "growth" in the water or do they mean that fungi were detected from the water. This does not appear to translate into clinical infection in their experience "no clinical cases" so why is it raised as a risk? Has there been comparison with other Scottish hospital water? Is it accurate to expect that hospital water is free of fungi? Taken to a logical extreme should they not also be looking for water borne parasites to which immunosuppressed patients are susceptible too e.g. cryptosporidium, cyclospora, giardia?	
	No further cases since decant of ward 2A/B – unclear what sampling is in place for 6A – were the outlets here always negative (water and drains) and what control measures did they apply in the decant setting (if any).		
	Unclear about the statement that there is evidence of widespread contamination of the water supply as the report only details contamination in wards 2A/B and the aseptic pharmacy (which is never mentioned again in the report after page 3 despite one case being linked to this location??)		

	Phase 1 – the water system was acknowledged as being of a suitable quality for use	How as this established? By culture? For what purposes was the water being used?	
	Phase 2 – the association is made to contaminated drains and not the water system? Limited information (positive or negative) about impact of POU. Don't really understand what the last bullet point on page 8 actually means?	At any point was there audit of how clinical waste water was being disposed in this unit? Was bathing water being disposed of down clinical wash hand basins? If the aseptic unit was the source do patients outwith 2A/B receive any IV products from the aseptic unit (particularly TPN) and have they had Gram negative BSI? Were such aseptic products ever disposed of down clinical wash hand basins to contaminate them?	
	The report states no further cases between decant (Sept 18) and I assume the report publication in December 18. Have there been any further cases between Jan19 and Aug 19 – and what control measures remain in place? What has further water sampling (any drain sampling??) shown in this period – I think this is a question for HPS as will inform what we do at RHCYP?	Did they use stand alone wash hand basins? If so were they assessed as a possible source?	
9	Narrative describes ' water sampling' – is this supply water as it then goes onto describe/discuss biofilm and drains. Also unclear if the Cuprivadus was only found in water supply or if focus was only on drains based on the descriptions before page 9		
	Now using the term "possible linked case" but there is no case definition for a "possible"		
	Was it established if there was contamination in the water tanks or is it only risers and outlets affected? Would be helpful to know what the pipes are made from – e.g. plastic or copper?		

	Black effluent/mould inside drains is not an unusual finding and would be present in all drains??		
	Leegionella – is this a typo or the company name?	Its a company.	
	Para 2 last sentence – “there were very few members of the initial project team available who are technically qualified to retrieve data and provide verbal clarification” – what does this mean and verbal clarification of what??		
	Results from ongoing water testing were reviewed weekly – what testing, assume weekly frequency? Who was reviewing the results (did this include HPS?)		
	What action is being advised in light of statement –evidence of regression seeding and whole system remedial approach advised – this is not clear to me from the remainder of the report		
	Report suggest testing for coliforms is not standard – but its required for identifying whether the water is of a potable standard.	SHTM 04-01 Part A states: 17.9 After disinfection, microbiological tests for bacteria colony counts at 37°C and coliform bacteria, including *Escherichia coli*, should be carried out under the supervision of the infection prevention control team to establish that the work has been satisfactorily completed. Water samples should be taken from selected areas within the distribution system. The system should not be brought into service until the infection control team certifies that the water is of potable quality.	

	Report suggests pre handover sanitisation was performed because of high TVCs	Wouldn't this have been indicated prior to 30 days of occupation regardless of TVCs. What was it sanitised with?	
P10	There are a number of areas with higher than normally acceptable levels of TVCs	What normal range of TVCs are they using? Where are the areas with residual high TVC counts in the building?	
	Now using terminology clinical wash hand basins rather than sinks		
	Unclear what the action relating to flow regulators is. Was it a recommendation for future builds or expectation of universal removal?		
	50% of flow regulators were "contaminated" at "high levels" but unclear how this was quantified or what they were contaminated with. If the contamination isn't visible what is the method for detecting it?		
	What concentration of silver hydrogen peroxide was used? Was incompatibility established prior to use?		
	Water temperature control is raised as an issue but no indication if records of this from the building management system were scrutinised to establish whether there were deviations in temperature control. What is meant by "high levels" of Gram negative bacteria and fungus in water – what were the organisms present and what were the counts per 100ml water?		
	Unclear whether the focus is on water quality or contamination of drains as a source. Unclear where drains sit in the technical review e.g. part of the water system.		

P 11	In the description of the HAI Scribe process it is unclear if there was anything which would reasonably have been assessed as a hazard or require an action or whether hind sight bias is influencing what would now be considered in a HAI Scribe.		
	There is no evidence of "sign off" from the IPCT. Unclear what this sign off would involve. Water quality assessment is a bigger responsibility than that of the IPCT.	SHTM 04-01 indicates that water quality is only the responsibility of the infection control doctor once it has left the tap.	
	Unclear why water quality should be on IPCT risk register. Should this not be on the corporate risk register or site risk register as a site (or health board) clinical risk?	Presumably prior to 2018 water was not on the IPCT risk register because the outbreak was identified in 2018.	
	In the absence of clinical cases the actions of ICD and IPCT in commissioning, design and handover appears compliant with SHTM 04-01 Part A	17.9 After disinfection, microbiological tests for bacteria colony counts at 37°C and coliform bacteria, including *Escherichia coli*, should be carried out under the supervision of the infection prevention control team to establish that the work has been satisfactorily completed. Water samples should be taken from selected areas within the distribution system. The system should not be brought into service until the infection control team certifies that the water is of potable quality.	
P12	That actions of the IPCT appear to have been consistent with what was required as stated in SHTM 04-01 and HAI Scribe (SHFN 30)		
	The control measures listed are vague and very unclear what specifically was introduced to specifically address a water related hazard or what was being monitored in the environment.		

	We presume the education sessions related to best practice regarding disposal of clinical waste water? Who was reviewing flushing methodlogy or records? Who reviewed tap and WHB cleaning methodology? How was water temp being monitored and deviations acted on? Was correct disposal of clinical waste water enforced?		
	Portable WHB can introduce a risk – how were they filled, was tap or sterile water used, how were they stored and cleaned? Were they a source of micro-organisms?		
	How was the source of contamination in aseptic pharmacy addressed?		
	Unclear what the purpose of the sterile water being given to BMT patients is – was this for drinking or washing?		
	Point of Use Filters – what is meant by high risk areas? Is that patient susceptibility or burden or contamination within the water system? These do not address risk more proximal to water outlet e.g. riser and may not address risk from aseptic product contamination.		
	Splashing from POU filters – was water pressure adjusted. How was the “greater splash” determined		
P13	Why were the drains inspected by IPCT and not estates? What were the IPCT looking for? If a substance was “thought to be biofilm” how as it established what it actually is?		
	The method used for environmental (hydrogen peroxide vapour) decontamination is known not to decontaminate sink drains. Was the terminal		

	clean initially quality assured prior to hydrogen peroxide. What was the terminal clean methodology – was a chlorine based product used?		
	The section on water treatment infers that all hospital water should be of a potable standard. Unclear whether water in QEUH met the quality standard of drinking water or not. The nature of the pipe material is highlighted as important but the report doesn't tell us what the pipes of QEUH and RHC are made from.		
	There should be recognition that the method of water treatment used may have unintended consequences (slightly different to advantages and disadvantages) compatibility with component parts of the plumbing needs to be established first before exposure		
P14	Preferred solution. How was continual dosing chlorine dioxide identified as the preferred option. Does this not create a new patient risk in an occupied building?		
	1. One of the control measures was to move paed BMT patients to ward 4B but the report says there was Gram negative bacilli in water in that area (p9) so how was it risk assessed and considered to be a safe move? 2. What water quality monitoring is being performed in 2A/B while unoccupied? 3. Have patients moved back to 2A and 2B?		

	4. If there is widespread water contamination what is the ongoing testing regimen for water in 4B and 6A? 5. What other local controls are in place e.g. POU filters?		
	It is unclear how the cases, investigation and potential source link to some of the proposed remedial works or the rationale for others (e.g. toilet plume)		
	Hypothesis This section is difficult to follow. Each hypothesis is speculative and unclear what evidence is used to support or discount these.		
P15	There is a statement that splashing risk from POU was not recognised with potential exposure of children. The exposure is not proven .		
P16	The disposal to drain section is very speculative.		
P18	Recommendation 1 We have no access to the action plan described but the bullet point items seems vague e.g. decontamination of what? What aspect of water management system - flushing, temp control?		
	Recommendation 2 Very vague. What policies and what guidance are being referred to? Is water sampling included in the maintenance records? Who in the organisation is responsible – responsible person for water?		
	Recommendation 3 Why is the start date of the urgent water review 2013? Most recommendation seem to be for HFS and HPS.	There are only two points in 2 pages of recommendation relevant to other boards: All NHS boards should ensure facilities teams are adequately resourced to ensure	

		maintenance of all aspects of the water system are maintained in accordance with policies and guidance. ˜ All maintenance undertaken should be recorded and maintenance records should be reviewed regularly to ensure all aspects of the water system are maintained in accordance with policies and guidance

Dear all

To note the reports as promised from HFS/ HPS.

Ronnie can these be shared with the water quality group for next Wed's meeting.

Ian L and Carol C in Lindsay and Donald's absence can you review with others? Could we have an initial analysis of what the reports say and any actions for Thursdays IMT?

Jacqui is keen that we agree the actions with HFS/ HPS for the Governance Oversight Group so I would hope that the reports, our review than any agreed actions could be taken in a paper to the next meeting of the group on the 22nd Aug.

Alex

Subject: Draft water and ventilation reports

Dear colleagues
I understand you have asked for sight of the specialist reports on water and ventilation and I have attached them to this email. They are not yet complete or checked for accuracy and we have not considered, nor taken a view on, any recommendations made therein. They are supplied purely in the interests of openness, so you are sighted on the information we have been given. Further drafts will be produced in due course, and as each issue is considered and added (or not) to our report, we will be in a position to discuss any implications. The next draft of our report will be forwarded when available.
Regards

AUTHORISING ENGINEER (VENTILATION)

REPORT

FOR

NON-CRITICAL VENTILATION SYSTEMS

AT THE

Royal Hospital for Children and Young People, Edinburgh

9 August 2019

Introduction

1. I was asked by Health Facilities Scotland (HFS) to prepare a report on the non-critical Ventilation systems at the new Royal Hospital for Children & Young People, Edinburgh (RHCYP) on 18 Jul 19. The requirement was to produce an initial Red/Amber/Green feedback for specific questions on this situation by 5 Aug, and a more full report by 26 Aug 19. Both of these time frames were subsequently shortened by HFS to 1 & 12 Aug respectively.

2. I agreed to visit the site over the period 1 – 2 Aug 19. I was sent copies of various papers and reports, including the draft Validation Summary from IOM and two schedules of ventilation plant (one for each plant room) dated 25 May 16. I was able to start assembling the data for site wide Air Handling Unit (AHU) Register before arriving on site. This data was later updated with help from Bouygues, and a full list is attached. I concluded that there are a total of 18 non-critical AHUs at the RHCYP.

3. I gave a verbal de-brief on my findings to Ian Storrar on Thu 1 Aug and then submitted an initial Red/Amber/Green (RAG) report by e-mail in the early morning of Fri 2 Aug. This RAG report was later updated that same day in one area following further discussions and on-site visits.

Executive Summary

4. There are a number of design and installation errors in the non-critical ventilation systems which do not generally impede the occupation of the RHCYP Hospital non-critical areas by staff, patients or the general public.

5. However, it is strongly recommended that the issues identified in this report are corrected in a reasonable time frame.

6. Clinicians should be made aware of the physical limits of the suitability of non-critical area use due to the limited ventilation systems provided. The clinicians should include the provision of suitable ventilation in all decisions regarding the temporary and longer term placement of patients, staff and general public.

Investigation Findings

7. Design Information. The final tender for the design for the new RHSC was dated December 2013. It was subsequently updated and incorporated an unknown series of comments and it was republished in August 2014. NHS Lothian assembled an on-site team to liaise with the main contractors. They held a short series of meetings in the summer months of 2016 concerning the Ventilation discipline.

8. It is unclear when and by whom the derogation of ventilation requirements laid down in SHTM 03-01, Appendix 1, Table A1: “Recommended air-change rates.” was agreed. Of particular relevance to this report is that the requirement for General Wards was reportedly reduced from 6 air changes/hour to 4 air changes/hour. The latter figure was used as the design standard for these areas by the organisation carrying out the re-validation tests carried out by IOM.

9. The lack of clarity regarding this derogation process is a major concern. HFS is strongly advised to develop a system for formally agreeing derogations from the standards required by the relevant SHTM or other ruling document. A written proposal by any agency should be screened by an independent Chartered Engineer who has relevant experience in the field of Engineering in question (possibly the Board Authorising Engineer for that discipline). The screening Engineer should then produce a written report to support or deny the request for derogation. This report should be retained by all parties concerned.

10. In addition, the clinicians should be made aware of any ventilation derogations as this factor should be included in their Risk Assessments for positioning vulnerable patients.

11. Commissioning Information. The re-validation of the systems was being undertaken by IOM at the time of my visit. This work included measurements taken from over 2,000 ventilation grilles and the subsequent calculations of the air changes/hour achieved.

12. Initial findings reportedly indicate that some areas failed to achieve the derogated design requirements. The output of the AHUs supplying these areas will probably need to be enhanced to meet these minimum requirements. It is considered preferable to exceed them to approach the standards originally required in SHTM 03-01.

13. I was told that there are no Local Exhaust Ventilation units to be considered for this site. The on-site fume cupboards are subject to an independent inspection and maintenance regime and were not examined.

14. Equipment. I examined several AHUs in both plant rooms and noted that there are some common deficiencies in their design and installation against the requirements of SHTM 03-01.

15. I did not check the operation of the AHUs as this task is included in the current work being undertaken by IOM. It is understood that the detailed control of the ventilation systems is exercised by the BMS system. This was not examined during my site visit.

16. AHU Airtightness. SHTM 03-01, Part A, para 4.13 requires AHUs to have a high degree of air-tightness. The AHU penetrations by water pipes for heating and cooling batteries were often poorly made and left unsealed. AHU 04-03 and 04-07 were noted to be performing poorly against this requirement. All pipe penetrations of AHU surfaces should be checked and leakages sealed.

17. AHU Electrical services. SHTM 03-01, Part A, para 4.17 requires that services are not installed in positions that will reduce or impede access. The AHU major components have been fabricated off-site and installed on-site. The control cabling joints have been made by plug-in units which are then allowed to dangle in the airstream, causing some turbulence as well as unnecessary fatigue on the fittings themselves. These connections should be secured so that they do not impede the airstream.

18. SHTM 03-01, Part A, para 4.17 requires that services are not installed in positions that will reduce or impede access. AHU 04-05 access door is obstructed by an electrical conduit. All access doors in the AHUs should open unimpeded by other installations and fittings.

All AHU doors should be checked for full opening and corrective work instigated where necessary.

19. AHU Internal Lighting. SHTM 03-01, Part A, para 4.18 requires viewing ports to be at a convenient height. This has not been possible with the "double-deck" AHUs used on this site. Pulpit ladders have been provided in each plant room to allow easy access to the top deck of inspection windows. This is considered a reasonable way ahead.

20. SHTM 03-01, Part A, para 4.18 requires that all the lights in a unit should be operated by a single switch. This has been achieved, but these switches are sometimes positioned at about 3m above floor level – i.e., AHU 04-03. It is recommended that such switches are re-positioned to a convenient height from floor level as most inspection hatches are at the lower level.

21. Duct Changes in Section. SHTM 03-01, Part A, paras 5.35 and 5.36 define the allowable changes in duct section. It was noted that several AHU intake duct sections included severe changes in cross-section. All AHU ductwork section changes should be checked to ensure that they are within the allowable limits.

22. AHU Intake Louvres. SHTM 03-01, Part B, para 3.23 requires cleaning access to be provided by hinged louvres or by access doors behind the louvre. The current louvres are not hinged. There is a small hatch in the intake section, but this is not large enough to admit a person to inspect and clean the anti-vermin screen. It is recommended that the louvres are re-configured to include at least a door sized hinged section.

23. SHTM 03-01, Part B, para 3.23 requires the duct behind the louvre to be self-draining, or to be tanked and provided with a drainage system. None of the AHUs that I visited had this facility. This should be provided.

24. AHU Drainage. SHTM 03-01, Part B, paras 3.27 requires drain traps to be the clear (borosilicate) glass type. These were observed to be in use, but several were dirty or contained particulate matter. These traps should all be kept in a "sparkling clean" condition.

25. SHTM 03-01, Part B, para 3.30 requires that AHU drainage systems must have a discharge air gap of at least 15mm above the drainage receptor. The top surface of a grill situated above a floor drain should be taken as the lower reference for this measurement as the grill could support trash that would interrupt the waste water flow. Several air gaps were significantly less than this distance. These systems require critical examination and re-fitting.

26. SHTM 03-01, Part B, para 3.31 requires drainage pipework to have a fall of at least 1 in 60 in the direction of flow. Several drainage lengths were observed to be running parallel to the floor for significant distances. These drains should be carefully checked to ensure that the correct fall is maintained.

27. The drainage system installation for AHU 04-07 was poorly installed. In addition some supports were broken. This system should be replaced.

28. Duct Measurement Points. SHTM 03-01, Part B, para 3.62 requires all air-flow test-points to be clearly identified and size of the duct given. All the test-points found were well capped, but not labelled in any way. This situation should be corrected.

29. Some major branches to the main ducts did not appear to have air-flow test-points inserted. It is recommended that the positioning of all air-flow test-points is re-examined by an independent organisation.

30. In addition to the above, the ventilation system balance appears to be incorrect in places. This was noted particularly on Floor 1 where the corridors seem to be at a higher pressure than the surrounding rooms. This lack of compliance with the SHTM needs to be quantified and corrected. It is strongly recommended that all of the ventilation systems that have been re-balanced should now be re-commissioned.

31. Safe System of Work. I was briefed that Bouygues have started to set up a sound SSoW that utilises an in-house Permit-to-work system for intrusive works and an Authority-for-access system for non-intrusive work on ventilation systems. All plant rooms and AHUs have logbooks. This is considered sound practice.

32. Bouygues have engaged a reputable AE and plan to have at least two APs and two CPs to provide 24/7 cover. A third AP & CP will additionally be trained and appointed to provide cover for the duty personnel when they are on leave or sick. The training of the individuals has been hampered by an unusually high turnover of manpower during the initial months of this contract. Suitable individuals have now been identified to fill all of these requirements. The individuals are currently named as follows:

    a. AE: Paul Crothers.
    b. APs: David Allan, Paul Crothers (until a second AP is trained and appointed), Jonathan Reynolds (requires training and appointment), Bill Whiteman (requires training and appointment).
    c. CPs: Alan Herkes, Garry Ferguson, James Taylor (requires training and appointment).

33. A training and appointment regime should continue to be followed to ensure that adequate skilled manning levels are maintained.

34. Inspection & Maintenance. Bouygues reported that there is a site-wide system for planning downtime for the AHUs to allow for routine inspection and maintenance work. This system requires a 3-month notice period.

35. Bouygues reported that their current PPM system includes daily, weekly and monthly visual checks of the AHUs. They are planning to mark up the differential pressure gauges with green/red sectors to facilitate this process in conjunction with the current work of contractors who are calibrating the ventilation systems.

Recommendations

36. The following actions should be carried out to ensure optimum compliance of the non-critical ventilation systems with SHTM 03-01. They are not in any particular order, but have been SCART prioritised using the following agreed scale.

SCART Risk Grades	
5	Very High
4	High
3	Medium
2	Low
1	Very Low

Ser	Rating	Reference	Action Required
1	5	190809/01	A robust and accountable derogation process should be established and used.
2	5	190809/02	Clinicians should include any ventilation derogation levels when they are Risk Assessing the placement of their patients.
3	4	190809/03	All pipe penetrations of AHU surfaces should be checked and sealed to prevent air losses.
4	5	190809/04	Internal AHU control cabling joints should be removed from the airstream in a secure fashion.
5	5	190809/05	All AHU door openings should not be impeded by other service obstructions.
6	2	190809/06	All AHU lighting switches should be positioned to be easily accessible from ground level.
7	3	190809/07	Changes in duct section should be checked to ensure that they are within allowable limits.
8	5	190809/08	AHU intake louvres should be re-configured to allow easy access to the intake section of the plant ductwork.
9	5	190809/09	All AHU intake sections should be provided with drainage.
10	3	190809/10	Borosilicate drainage traps should be kept clean.
11	4	190809/11	AHU drainage pipes should discharge with the correct air-gap clearance from the receptor.
12	5	190809/12	The drainage installation for AHU 04-07 should be replaced.
13	5	190809/13	All air-flow test-points should be clearly labelled with the information required by SHTM 03-01, Part B, para 3.62.
14	4	190809/14	The provision of air-flow test-points should be analysed by an independent organisation. Additional test-points should be inserted where necessary.
15	5	190809/15	All non-critical ventilation systems that have been re-balanced should now be re-commissioned.

Conclusions

37. There are a number of design and installation omissions in the ventilation systems designated for the non-critical areas of the hospital. These are not considered to generally impede the occupation of the RHCYP Hospital non-critical areas by staff, patients or the general public.

38. However, it is strongly recommended that the issues identified above are corrected in a reasonable time frame.

39. Clinicians should be made aware of the physical limits of the suitability of area use due to the limited ventilation systems provided. The clinicians should include the provision of suitable ventilation in all decisions regarding the temporary and longer term placement of patients, staff and general public.

40. Bouygues have set up a sound inspection, maintenance and repair system to support the non-critical ventilation systems.

27 July 2019

Dear Ian,

Children's Hospital, Edinburgh
Site Visit 25 July 2019

I visited site on 25 July to gain an appreciation of the ventilation system as installed. The Hospital is new and yet to be taken into use.

General

Overall first impressions were that the ventilation plant installation overall was average but that there were many minor air leaks, faults and niggles. Most of these will be straightforward to rectify but what was alarming was that even though the Hospital opening had been delayed they still remained to be resolved. The report from IOM highlighted similar issues and it was evident that the system when offered for validation was not ready.

I was concerned to read about the length and configuration of flexible ductwork above the ceilings. The HTM is quite clear that flexible ductwork should be as straight and short as possible, not exceed 1m in length and never be used in lieu of a bend.

Air Handling Units

A major non compliance arises with the ability to change the supply and extract fans in the major Air Handling Units (AHU). They are buried within the AHU with no obvious way to access or remove them. HTM03-03 requires that all elements of an AHU be accessible for maintenance and that over the life of the unit they may need to be removed or replaced. This will not be possible without major disruption with the units as installed. Given the large areas that the individual AHU's serve, changing fans will take a significant amount of time and render the section of the hospital that they serve unavailable.

It was also noted that there is a large amount of loose wiring and plug connectors inside the units and the IOM report also highlighted this issue.

Helicopter Landing Pad

I am unhappy with the location of the helicopter landing pad. There are open courtyards below and various air supply intakes and extract discharges in the vicinity. The downdraft from the helicopter when using the pad will have an adverse effect on the performance of these systems and may result in reverse air flows into the hospital.

I note that there is a ground level helicopter pad adjacent to the neighboring building and within easy reach of the children's hospital and wonder why this facility is not considered adequate. I understand the desire to have a short transfer route for a patient arriving by helicopter but there are also the needs of all the patients in the hospital to consider.

Operating Theatres

UCV Theatres

The "Clean zone" under the Ultra Clean Ventilation terminal is only delineated by a thin line on the floor. Good practice in a new installation such as this is to delineate the entire floor zone in a contracting colour to that of the surrounding floor area. In that way it is immediately obvious when personnel or instrument trolleys stray or get nudged out of the zone. From the comments in the IOM report the line is a late addition so the contractor evidently did not intend to meet the HTM requirement when the flooring was originally laid.

Conventional Theatres - Preparation room

Noted that all the preparation rooms are designed as "Sterile Pack Store" (SPS) rooms. This is normal for Ultra Clean Ventilated (UCV) theatres where good practice recommends that lay up of instruments takes place under the UCV terminal. In Conventional Operating suites instrument packs are normally opened and prepared in "Lay up" preparation room as this cuts down the time between cases. The Preparation room in the conventional theatre in this development is a SPS Prep. It is important that staff using the facility are made aware of this.

Scrub areas

The scrub rooms are effectively an open corridor off the operating room so their volume does not need to be included in the total volume of the operating room. The scrub areas do however need a good air flow from the operating room, down the length of the scrub and out at the far end. The existing ceiling level extract terminal is only designed to extract 100L/s which given that the approximate average volume of the scrub is $33m^3$ only gives 11 air changes per hour to this area. I recommend providing an additional low level extract terminal in the corner adjacent to the far end of the scrub trough. This terminal to extract 100L/s which together with the existing ceiling terminal will result in approximately 20 air changes per hour from the scrub area. Corner duct to be formed with plaster board and fitted with a pull off face extract terminal for ease of cleaning.

Anaesthetic rooms

Supply and extract in Anaesthetic rooms should provide a clean air flow path for the staff to reduce the possibility of them being casually exposed to leaking and /or exhaled Anaesthetic agents. Most rooms are satisfactory but Anaesthetic rooms 31 and 34 need the ceiling supply terminal moving to the opposite side of the room and in Anaesthetic room 30 the ceiling supply terminal is too close to the door and should be relocated towards the middle or further end of the room. (See attached information)

Shared Utility rooms

The extract for the utility rooms is shared between two air handling units. If one AHU is shut down or put into "set back" then there will not be sufficient air extract in the utility. Rather than installing complicated constant volume boxes it would be simpler to fit a small auxiliary extract fan that is controlled by room pressure.

Recovery areas

Satisfactory as these are ventilated with high level supply down the center of the room and low level extract at the head end of the beds.

Isolation rooms

There is an obvious problem of resilience and routine maintenance as up to five isolation rooms are fed from a single AHU which, to make matters worse also serves the critical care unit and some general areas. All the eggs are in one basket! There is an emergency bypass that will allow the load to be taken by another AHU during routine maintenance or breakdown but the operation of this has yet to be proved.

I understand that there is an intention to split the load in two, an approach that I endorse. I have left information about cabinet AHU's with Ian Brodie of Mott Macdonald as these may offer a simpler solution to splitting the load than just adding a single conventional AHU.

Conclusions

Taken overall the design and provision of ventilation in this development has I consider made insufficient allowance for the routine operation and maintenance of the systems. As a consequence resilience is very poor. Breakdowns and unforeseen stoppages will result in significant portions of the hospital without active ventilation. It should be remembered that ventilation is provide in critical areas such as theatres, isolation rooms and critical care in order to reduce the possibility of infection by the airborne route.

The ventilation installation itself is below the standard that would be expected with many outstanding issues that are yet to be resolved. I recommend a full snagging inspection of each systems from its supply intake right through to the discharge position. This should be followed by "cause and effect" testing to prove the control and indication functions.

The fire dampers also need to have their operation proved. Note that in many locations inspection access panels have not been installed so the action of the fire dampers cannot be directly observed. This needs to be rectified.

It is evident that much remains to be done before the hospital can accept patients.

1.0 Assurance Statement

The headings in the following table reflect those from the Health and Safety Executive's Approved Code of Practice L8 (4th edition) published in 2013: Legionnaires Disease; the control of legionella bacteria in water systems. This gives indicators for audit and assurance purposes.

Compliance Actions	Status at audit (S, P/S, U/S)
Appoint a person to be managerially responsible	
Records of appraisal of Responsible Persons & Deputy Responsible Persons by the Authorising Engineer	
Records of appointment of Responsible Persons & Deputy Responsible Persons	
Training records for Responsible Persons & Deputy Responsible Persons	
Identification and assessment of sources of risk	
Risk Assessment programme in place	
Fit for Purpose Risk Assessment reports	
Written scheme of Control	
Risk minimisation scheme, based on outcome of risk assessments	
Policy	
Procedures	
Management, implementation and monitoring of written scheme of control	
Implementation of risk assessment findings	
Monitoring results and suitable remedial actions	
Audit report	
Records	
System of records	

S – Evidence of satisfactory system in place and effective	**P/S** – Partially satisfactory system in place improvement required	**U/S** – system missing or ineffective

Water Solutions Group

2.0 Executive Summary

The Royal Hospital for Children and Young People is a new development in Edinburgh's Bio Quarter Campus adjacent to the Royal Infirmary of Edinburgh.

Questions have been raised at governmental level regarding the suitability of this facility for occupation by patients and staff. The Scottish government have enlisted assistance from Health Facilities Scotland and Health Protection Scotland to determine that the domestic water systems within the building are fit for purpose given the profile of patients undergoing treatment.

A number of specialists have been asked to assist Health Facilities Scotland and H2O Solutions (Europe) LLP, an operating subsidiary of the Water Solutions Group has been enlisted for specialist technical and analytical support, based on their work at the Queen Elizabeth University Hospital, Glasgow.

H2O Solutions (Europe) LLP are supported by the Intertek Group, who are providing in-depth microbiological assistance and specialist analytical services as deemed appropriate (UKAS 4065).

Assessing the results of the sampling undertaken by H2O Solutions (Europe) LLP against the Water Supply Regulations, Private Water Supply Regulations and ACOP L8 (HSG 274 Part 2), the results comply with all of these regulations.

All samples tested for Legionella species achieved results of less than 50 cfu/l - not detected (the laboratory's limit of detection). The total viable count results for both 22C and 37C are not covered in the regulations. There were guidance levels supplied in previous versions of such regulations but have since been removed. The Total Viable Count results do show some areas with slightly elevated levels, but these would not be considered excessive in this case.

As the building is not yet open, it must be considered that as the building is not in use, that there will be a considerable reduction in the movement of water around the system. Because of this, the ambient water temperature in the system would be expected to be higher than normal. These two factors would allow the background

Water Solutions Group

bacteria in the system to multiply, and is the possible reason for the slightly elevated Total Bacteria Counts observed.

Given this, we would expect the Total Bacteria levels of the water to reduce when the building is fully operational. It should also be noted that reduced movement of water in the system over a prolonged period of time could have a negative impact on the ongoing water quality in the system.

When comparing H2O Solutions (Europe) LLP's set of sample results with the guidance parameters, there is no indication from the microbiological results to suggest that the water system is not fit for use.

However, when we widen the microbiological scope to include other organisms identified at QEUH Glasgow, then currently the results are inconclusive and awaiting further investigation.

Water Solutions Group

3.0. Audit Summaries & Governance Assurance

Rating	Comment
	• As yet to be evidenced - training levels • As yet to be evidenced - formal appointments
	• Poor asset knowledge and management • As yet to be evidenced standard operating procedures • Poor log book keeping and management information • As yet to be evidenced contingency measures • Poor levels of experience of some key personnel
	• Lack of agreed and approved documentation including water safety policy, water safety plan, written scheme - as yet to be evidenced • Lack of agreed KPI's • Lack of fault escalation process • Lack of contractor supervision

Rating	Definition
	No assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitability designed and applied effectively. Action is required to address the whole control framework in this area with high impact on residual risk exposure until resolved.
	Limited assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitably designed and applied effectively. More significant matters require management attention with moderate impact on residual risk exposure until resolved.
	Substantial assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitably designed and applied effectively. Few matters require attention and are compliant or advisory in nature with low impact on residual risk exposure.

Water Solutions Group

4.0. Scope

Following an initial discussion with Ian Storrar (HFS) and meeting on site with Ronnie Henderson the following initial scope was agreed:

1) As a result of HPS guidance issued in August 2018, and the belief held by NHS Lothian IPC team that the presence of Pseudomonas aeruginosa at outlets in augmented care areas presents a significant risk of HAIs to undertake random sampling across the facility. This involved retrieving a single, pre-flush sample together with a post flush sample from a variety of outlets and submission for specific analysis for the organism Pseudomonas aeruginosa.

2) The testing protocol was extended to include other potential organisms identified at QEUH Glasgow and not yet considered at RHCYP Edinburgh. These are: gram negatives, mould, fungi, cupriavidus and atypical mycobacteria. Additional sampling for Legionella and TVC 22 and 37 was also part of the sampling remit.

3) As part of the overall bacteriological load on the water system, a number of strainers and tap filters to be removed for inspection. This to be focused on high risk patient areas.

4) To undertake a review of already compiled documentation from third parties, together with design criteria with a view to making recommendations as to the pathway forward based on current guidance and lessons learned at QEUH Glasgow.

Scope Limitations

This report has to be mindful on the information obtained as part of the investigation, which may include third party reports and practices operated by the current FM provider Bouygues. Many of these aspects should be addressed by the water risk assessment carried out in accordance with BS8580-1:2019.

In respect of microbiological analysis, this is undertaken by the Intertek Group, UKAS accreditation 4065, supported by the Maldi-tof Buker Library.

Water Solutions Group

5.0. Observations

5.1. The microbiological analysis presents a very different picture to samples so far derived by others:

a) Of the 60 pre/post samples taken for the identification of Pseudomonas aeruginosa - all results have returned negative (all clear).

b) In respect of Legionella, all samples have returned negative (all clear).

c) Some Mould and Fungi positive results have been identified, and these are currently undergoing morphology identification.

d) In respect of gram negatives, there has been some identification and these are currently undergoing investigation.

e) Atypical mycobacteria is a long testing cycle - the results of which will not be known until late August 2019 (estimated 23rd).

f) TVC's at 22 and 37 demonstrated some activity. However, this is not surprising given the under utilisation of the water system.

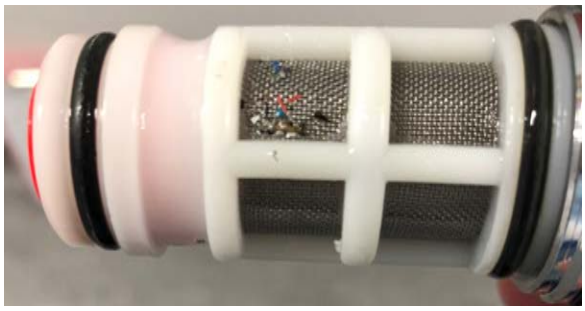
g) An extension of the sampling (based on Glasgow experience) was an evaluation of the drains at wash hand basins within Neonatal. To this end, the drain outlets were swabbed and sent for culture and analysis. Other than an elevated TVC count, nothing else was identified.

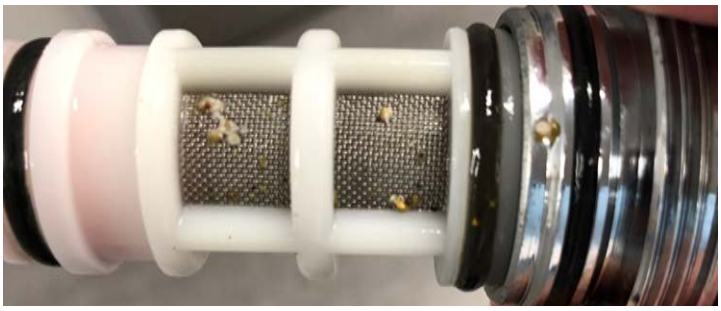
h) In respect of Pseudomonas aeruginosa, there appears to be a degree of variance between the sample results undertaken by various parties over the previous months. Our sampling results did not identify Pseudomonas aeruginosa, whereas sampling by others produced positive results. This has the potential to bring into question the sampling methodology. The actual taking of samples for Pseudomonas aeruginosa is very clearly defined within SHTM and PHE guidance. However, where we have seen variance in results, this has been attributed to a) transportation and b) time at laboratory awaiting processing. The samples (as per the guidance) were taken by ourselves at first water and prior to any flushing. These were then immediately transferred into a temperature

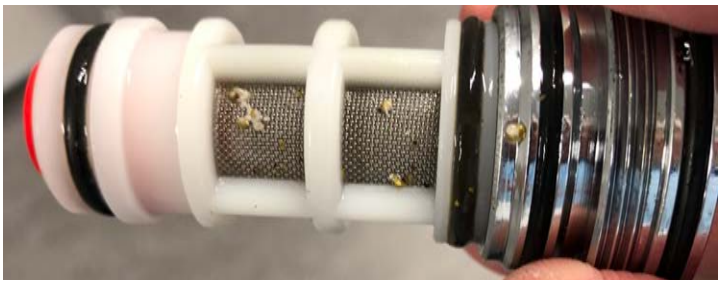
Water Solutions Group

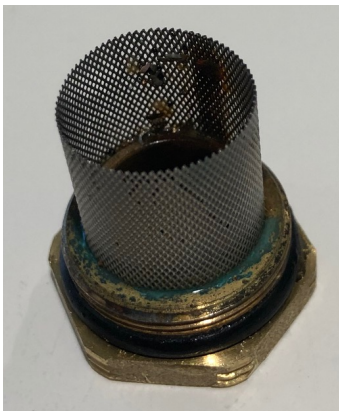
controlled vehicle by 10am and were being processed in the laboratory by 2pm. This means there was minimal delay in the processing of the samples. It is a well established fact that delay can influence the results.

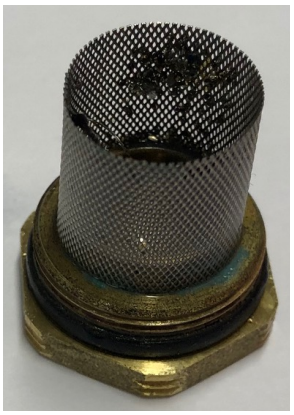
5.2. A number of strainers from wash hand basins were removed for examination. The results identified metal filings and general debris.











Based on these findings, all strainers on all outlets must be either removed, cleaned and disinfected or replaced with new strainers.

Water Solutions Group

6.0. Risk Assessments

Rating	Definition
	Limited assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitably designed and applied effectively. More significant matters require management attention with moderate impact on residual risk exposure until resolved.

A Legionella risk assessment and water hygiene survey report was undertaken on behalf of Bouygues E&S FM UK by Clira water hygiene specialists on 18th-21st February 2019. A further compliance audit was undertaken by Callidus in May 2019. It is disturbing to identify from both of these reports that the risk rating overall for the site was high. Within the risk assessment, there are a large number of identified remedial actions. To date, a large number of them have yet to be completed.

Within this report are some “quick wins”. However, there are more fundamental issues such as the management chain, documentation, training, written scheme, plan - all of which need to be addressed.

We have been advised by Bouygues that much of this has been completed. However, documentary evidence remains outstanding.

Water Solutions Group

7.0. Recommendations and Actions

Item	Description	Action
1	Tap Strainers and Filters	All filters and strainers to be either removed, cleaned and disinfected or replaced with new. This should be done at the same time as tap cartridge replacement.
2	Flushing	Until occupation of the building has been completed and little used outlets identified, a daily robust flushing regime must be maintained of at least 4 minutes, 3 times a day. All outlets to have temperature measured at start and end of flushing and the information suitably recorded. This action is for all outlets including showers.
3	Zoning	In the event that the hospital is allowed to open, but on a selected area basis, any areas unoccupied should be zoned and if the delay is going to be for some considerable time (e.g. greater than 6 months) then consideration should be given to draining the zone and purging with nitrogen.
4	Training	It was interesting speaking to the Bouygues “Responsible Person” as (at that point in time) they had not been appointed in writing or undertaken an accredited RP course (to the best of his knowledge). Likewise, it was very evident that the support team had very little knowledge or understanding of the water systems within the building and in particular, the Kemper system. More in-depth site training of hot and cold water systems, together with Kemper management system to be undertaken.
5	Risk Assessment Actions	The risk assessment of Feb 2019 needs to be completed and updated by Bouygues and all actions signed off as completed or mitigated.
6	System Disinfection	At this stage, we believe that a shock system disinfection may do more harm than good as it may not completely remove biofilm build up and simply expose further issues that it does not resolve. Our recommendation is to implement a continuous dosing regime based upon Chlorine Dioxide, which can provide both elevated (where applicable) and continuous dosing as an on-going strategy.

Water Solutions Group

7	Chlorine Dioxide Treatment Regime	Based upon experiences at many healthcare facilties, there is a need for a tried and tested secondary control measure - Chlorine Dioxide. This should be implemented prior to occupation on the cold water storage tanks to treat at 0.5mg/l - Drinking Water Inspectorate Approved Levels. An indicative budgetary figure is £60,000, with a 2-3 week implementation programme.
8	Expansion Vessel Bladder and Component Investigation	Based upon findings at QEUH Glasgow, it is evident that expansion vessel bladders can be high source of biofilm and nutrients to aid microbial growth and can lead to system contamination. There is little evidence in respect of flow through vessels that this is any different and given that the majority of bladders are made from EDPM, a known nutrient source for micro-organisms, further investigation work is essential to determine the current status at Edinburgh.
9	Incoming Water Filtration	As evidenced at QEUH Glasgow, there is a high risk of microbiological contamination build up on the micro filtration plants. It is recommended that Chlorine Dioxide backwash water dosing is implemented without delay. A budgetary figure for both filtration units is £16,000.
10	Tertiary Loop Temperature Measurement	To obtain a better understanding of the temperature profile across the building, particularly at tertiary loops. It is recommended that an automatic measurement and data download system is installed in order that continuous temperature management can be achieved.
11	Drains	Based on the experience at QEUH Glasgow, all wash hand basin drains (or all drains) should be dosed with hysan biocide treatment at intervals to be agreed. However, it would be prudent to implement weekly drain dosing during period prior to occupation.
12	Fire Water Tank	The fire water tank has a large capacity of stagnating water. We would support the Bouygues proposal to install a UV recirculating loop to prevent stagnation and provide a degree of disinfection. The PPM requires review.

Water Solutions Group

13	Rain Water Harvesting	The words “Rain Water Harvesting” and “Healthcare” do not go together. It is important that a testing regime for the rainwater tank is put in place, which must include organisms related to Ornithological Faecal Matter (e.g. Cryptococcus). A review of disinfection strategy needs to be undertaken.
14	PPM Schedules	The current invisibility of a meaningful water safety plan, SOPs and PPM programme brings into doubt the regime being operated on this site pre and post occupation. It is essential this document is received for review and comment.
15	Shower Heads and Hoses	Currently all shower heads have the capability of reaching the floor drain and toilet. All shower hoses to be replaced to a length preventing the shower head touching the floor. The use of shower head insert replacement (colour coded) should be considered (medi-shower).

	• As yet to be evidenced - training levels • As yet to be evidenced - formal appointments
	• Poor asset knowledge and management • As yet to be evidenced standard operating procedures • Poor log book keeping and management information • As yet to be evidenced contingency measures • Poor levels of experience of some key personnel
	• Lack of agreed and approved documentation including water safety policy, water safety plan, written scheme - as yet to be evidenced • Lack of agreed KPI's • Lack of fault escalation process • Lack of contractor supervision

Rating	Definition
	No assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitability designed and applied effectively. Action is required to address the whole control framework in this area with high impact on residual risk exposure until resolved.
	Limited assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitably designed and applied effectively. More significant matters require management attention with moderate impact on residual risk exposure until resolved.
	Substantial assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitably designed and applied effectively. Few matters require attention and are compliant or advisory in nature with low impact on residual risk exposure.

Water Solutions Group

4.0. Scope

Following an initial discussion with Ian Storrar (HFS) and meeting on site with Ronnie Henderson the following initial scope was agreed:

1) As a result of HPS guidance issued in August 2018, and the belief held by NHS Lothian IPC team that the presence of Pseudomonas aeruginosa at outlets in augmented care areas presents a significant risk of HAIs to undertake random sampling across the facility. This involved retrieving a single, pre-flush sample together with a post flush sample from a variety of outlets and submission for specific analysis for the organism Pseudomonas aeruginosa.

2) The testing protocol was extended to include other potential organisms identified at QEUH Glasgow and not yet considered at RHCYP Edinburgh. These are: gram negatives, mould, fungi, cupriavidus and atypical mycobacteria. Additional sampling for Legionella and TVC 22 and 37 was also part of the sampling remit.

3) As part of the overall bacteriological load on the water system, a number of strainers and tap filters to be removed for inspection. This to be focused on high risk patient areas.

4) To undertake a review of already compiled documentation from third parties, together with design criteria with a view to making recommendations as to the pathway forward based on current guidance and lessons learned at QEUH Glasgow.

Scope Limitations

This report has to be mindful on the information obtained as part of the investigation, which may include third party reports and practices operated by the current FM provider Bouygues. Many of these aspects should be addressed by the water risk assessment carried out in accordance with BS8580-1:2019.

In respect of microbiological analysis, this is undertaken by the Intertek Group, UKAS accreditation 4065, supported by the Maldi-tof Buker Library.

Water Solutions Group

5.0. Observations

5.1. The microbiological analysis presents a very different picture to samples so far derived by others:

a) Of the 60 pre/post samples taken for the identification of Pseudomonas aeruginosa - all results have returned negative (all clear).

b) In respect of Legionella, all samples have returned negative (all clear).

c) Some Mould and Fungi positive results have been identified, and these are currently undergoing morphology identification.

d) In respect of gram negatives, there has been some identification and these are currently undergoing investigation.

e) Atypical mycobacteria is a long testing cycle - the results of which will not be known until late August 2019 (estimated 23rd).

f) TVC's at 22 and 37 demonstrated some activity. However, this is not surprising given the under utilisation of the water system.

g) An extension of the sampling (based on Glasgow experience) was an evaluation of the drains at wash hand basins within Neonatal. To this end, the drain outlets were swabbed and sent for culture and analysis. Other than an elevated TVC count, nothing else was identified.

h) In respect of Pseudomonas aeruginosa, there appears to be a degree of variance between the sample results undertaken by various parties over the previous months. Our sampling results did not identify Pseudomonas aeruginosa, whereas sampling by others produced positive results. This has the potential to bring into question the sampling methodology. The actual taking of samples for Pseudomonas aeruginosa is very clearly defined within SHTM and PHE guidance. However, where we have seen variance in results, this has been attributed to a) transportation and b) time at laboratory awaiting processing. The samples (as per the guidance) were taken by ourselves at first water and prior to any flushing. These were then immediately transferred into a temperature

Water Solutions Group

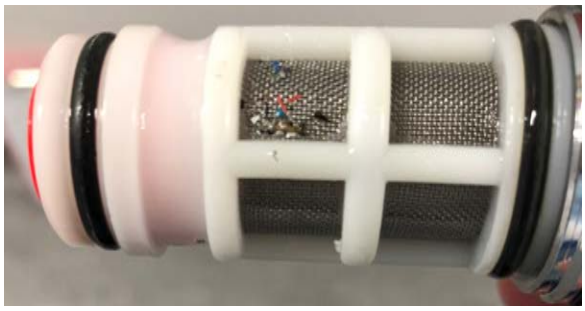
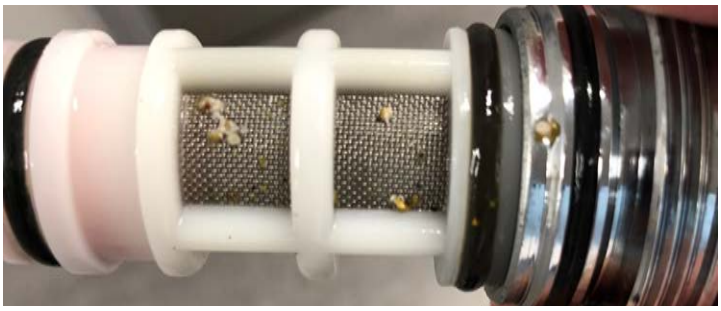
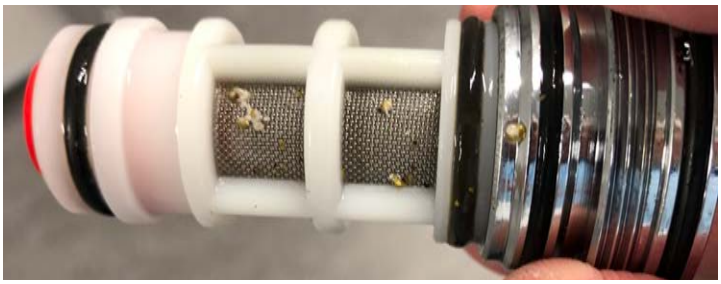
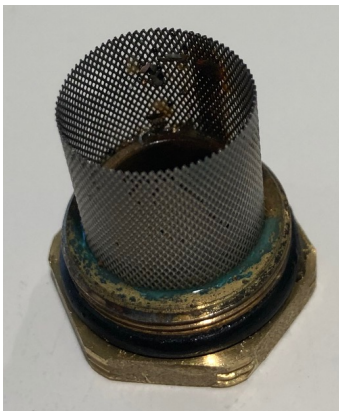
controlled vehicle by 10am and were being processed in the laboratory by 2pm. This means there was minimal delay in the processing of the samples. It is a well established fact that delay can influence the results.

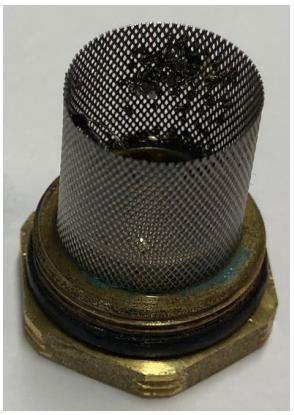
5.2. A number of strainers from wash hand basins were removed for examination. The results identified metal filings and general debris.











Based on these findings, all strainers on all outlets must be either removed, cleaned and disinfected or replaced with new strainers.

Water Solutions Group

6.0. Risk Assessments

Rating	Definition
	Limited assurance that arrangements to secure governance, risk management and internal control, within those areas under review, are suitably designed and applied effectively. More significant matters require management attention with moderate impact on residual risk exposure until resolved.

A Legionella risk assessment and water hygiene survey report was undertaken on behalf of Bouygues E&S FM UK by Clira water hygiene specialists on 18th-21st February 2019. A further compliance audit was undertaken by Callidus in May 2019. It is disturbing to identify from both of these reports that the risk rating overall for the site was high. Within the risk assessment, there are a large number of identified remedial actions. To date, a large number of them have yet to be completed.

Within this report are some “quick wins”. However, there are more fundamental issues such as the management chain, documentation, training, written scheme, plan - all of which need to be addressed.

We have been advised by Bouygues that much of this has been completed. However, documentary evidence remains outstanding.

Water Solutions Group

7.0. Recommendations and Actions

Item	Description	Action
1	Tap Strainers and Filters	All filters and strainers to be either removed, cleaned and disinfected or replaced with new. This should be done at the same time as tap cartridge replacement.
2	Flushing	Until occupation of the building has been completed and little used outlets identified, a daily robust flushing regime must be maintained of at least 4 minutes, 3 times a day. All outlets to have temperature measured at start and end of flushing and the information suitably recorded. This action is for all outlets including showers.
3	Zoning	In the event that the hospital is allowed to open, but on a selected area basis, any areas unoccupied should be zoned and if the delay is going to be for some considerable time (e.g. greater than 6 months) then consideration should be given to draining the zone and purging with nitrogen.
4	Training	It was interesting speaking to the Bouygues “Responsible Person” as (at that point in time) they had not been appointed in writing or undertaken an accredited RP course (to the best of his knowledge). Likewise, it was very evident that the support team had very little knowledge or understanding of the water systems within the building and in particular, the Kemper system. More in-depth site training of hot and cold water systems, together with Kemper management system to be undertaken.
5	Risk Assessment Actions	The risk assessment of Feb 2019 needs to be completed and updated by Bouygues and all actions signed off as completed or mitigated.
6	System Disinfection	At this stage, we believe that a shock system disinfection may do more harm than good as it may not completely remove biofilm build up and simply expose further issues that it does not resolve. Our recommendation is to implement a continuous dosing regime based upon Chlorine Dioxide, which can provide both elevated (where applicable) and continuous dosing as an on-going strategy.

Water Solutions Group

7	Chlorine Dioxide Treatment Regime	Based upon experiences at many healthcare facilties, there is a need for a tried and tested secondary control measure - Chlorine Dioxide. This should be implemented prior to occupation on the cold water storage tanks to treat at 0.5mg/l - Drinking Water Inspectorate Approved Levels. An indicative budgetary figure is £60,000, with a 2-3 week implementation programme.
8	Expansion Vessel Bladder and Component Investigation	Based upon findings at QEUH Glasgow, it is evident that expansion vessel bladders can be high source of biofilm and nutrients to aid microbial growth and can lead to system contamination. There is little evidence in respect of flow through vessels that this is any different and given that the majority of bladders are made from EDPM, a known nutrient source for micro-organisms, further investigation work is essential to determine the current status at Edinburgh.
9	Incoming Water Filtration	As evidenced at QEUH Glasgow, there is a high risk of microbiological contamination build up on the micro filtration plants. It is recommended that Chlorine Dioxide backwash water dosing is implemented without delay. A budgetary figure for both filtration units is £16,000.
10	Tertiary Loop Temperature Measurement	To obtain a better understanding of the temperature profile across the building, particularly at tertiary loops. It is recommended that an automatic measurement and data download system is installed in order that continuous temperature management can be achieved.
11	Drains	Based on the experience at QEUH Glasgow, all wash hand basin drains (or all drains) should be dosed with hysan biocide treatment at intervals to be agreed. However, it would be prudent to implement weekly drain dosing during period prior to occupation.
12	Fire Water Tank	The fire water tank has a large capacity of stagnating water. We would support the Bouygues proposal to install a UV recirculating loop to prevent stagnation and provide a degree of disinfection. The PPM requires review.

Water Solutions Group

13	Rain Water Harvesting	The words “Rain Water Harvesting” and “Healthcare” do not go together. It is important that a testing regime for the rainwater tank is put in place, which must include organisms related to Ornithological Faecal Matter (e.g. Cryptococcus). A review of disinfection strategy needs to be undertaken.
14	PPM Schedules	The current invisibility of a meaningful water safety plan, SOPs and PPM programme brings into doubt the regime being operated on this site pre and post occupation. It is essential this document is received for review and comment.
15	Shower Heads and Hoses	Currently all shower heads have the capability of reaching the floor drain and toilet. All shower hoses to be replaced to a length preventing the shower head touching the floor. The use of shower head insert replacement (colour coded) should be considered (medi-shower).

Water Solutions Group

8.0. Disclaimer

This assessment has been based upon information provided by the client. H2O Solutions (Europe) LLP cannot accept any responsibility for any errors or omissions appertaining to the data, records and information provided by the client.

Every reasonable endeavour has been taken by the auditor to ensure the findings and recommendations contained in this report are representative of the issues that require addressing in order to improve current practice.

Royal Hospital for Children and Young People and Department of Clinical Neurosciences

NHS Lothian response to actions identified in the

NSS National Services Scotland – Review of: Water, Ventilation, Drainage and Plumbing Systems

September 2019
Version 2.0

Introduction

Following the decision to delay moving to the new Royal Hospital for Children and Young People & Department of Clinical Neurosciences in July 2019, NHS National Services Scotland (NSS) were commissioned by Scottish Government to undertake a series of checks to ensure that the relevant technical specifications and guidance applicable to the new hospital had been followed and were being implemented.

Health Facilities Scotland (HFS) and Health Protection Scotland (HPS) have provided their report to Scottish Government on whether the relevant technical specifications and guidance applicable to the RHCYP & DCN are being followed and implemented. The report provides an assessment of actions required where relevant technical specifications and guidance have not been met.

NHS Lothian engaged with NSS throughout the review and addressing follow-up actions. Updates on each action identified in the NSS Review are provided in this response.

Glossary

AHU	Air handling unit
Board	refers to NHS Lothian
HFS	Health Facilities Scotland
HPS	Health Protection Scotland
IHSL	IHS Lothian Limited
IPCT	Infection Prevention and Control Team
NSS	National Services Scotland
SHPN	Scottish Health Planning Note
SHTM	Scottish Health Technical Memorandum
TMT	Thermostatic mixing taps
TMV	Thermostatic mixing valves

Management and Assurance

NSS Review: *Omissions identified in key roles within the management structure, ease of access to information.*

NHS Lothian response: Management roles and responsibilities and will be identified and the responsibility matrix will be reviewed on a regular basis. Archiving of information will be revised in line with guidance and contract requirements

through NHS Lothian's Corporate Management Team.

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
Structures and processes	*Structures and processes are not fully in place to assure the Board that the facility is being operated in compliance with contract requirements. These should be in place from the point where the building services referred to in this report are put into use.*	*NHS Lothian and IHSL should adopt the management and reporting processes as described in SHTM 00 – Best Practice Guidance for Healthcare Engineering and the SHTMs for each critical engineering service.*	**AGREED** Contract management arrangements will follow SHTM 00.
Contract requirements	*Some of the records and documents necessary for the effective and safe operation of the hospital could not be found. The document management system appears to lack a logical structure which will impact on the ability to readily find necessary information. Some of the sections contain none, or only part, of the documentation they should have as required by the Construction (Design and Management) Regulations 2015.*	*The Board should require IHSL to rectify the filing structure of the documentation and verify that the information contained is both complete and accurate as required by the Construction (Design and Management) Regulations 2015.*	**AGREED** A review and demonstration of completeness has been requested from IHSL and additional information has been provided by them.
Alarms	*The alarms for the building are reportedly un-prioritised, resulting in a very large number of alarms potentially masking critical alarms.*	*Prioritise alarms to make most critical failures visible and manageable. Until alarms are prioritised, have procedures and staff in place to ensure critical alarms are not missed as per SHTM 08-05 - Specialist services building management systems.*	**AGREED** NHS Lothian has requested a programme to confirm this in place by the end of September.

Ventilation

NSS Review: *Remedial action is required within both general and theatre ventilation systems. Augmented care redesign was already being considered separately by the Board. Haematology / Oncology is also being reviewed as a result of the review as specific risks were identified. Risk assessments are underway as part of the ward by ward risk assessments being done locally requested as part of the review.*

NHS Lothian response: The required remedial actions are underway with expert input from the engineers. Two Board changes have been progressed for the areas to be redesigned. Discussion with clinical staff and the Infection Prevention and Control Team (IPCT) will guide patient placement in line with documented risk assessments.

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
General ventilation systems 1	*Provision for maintenance or plant failure in the ventilation systems has not been validated in accordance with SHTM 03-01 Ventilation for Healthcare Premises. The bypass arrangements and functioning of ward ventilation in the event of plant failure remains to be demonstrated.*	*Demonstrate efficacy of approach of utilising adjacent air handling unit to supply areas not served by failed plant.* *Commission and validate isolation rooms and general ward spaces in the event of supply by adjacent air handling unit.* *Engage clinical leads and Infection Prevention and Control colleagues in developing service provision strategies in the event of air handling plant failure.* *Confirm damper operation and compliance with fire requirements in bypass mode.*	The date for the demonstration of bypass arrangements is to be confirmed by 13 September 2019. **AGREED** Patient safety in the event of a reduction of air exchange, for any reason, will be managed through infection prevention and control guidance and clinical risk assessment. Work is ongoing with contractors to ensure damper operation is compliant. The programme of works is to be provided by IHSL by 13 September 2019

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
General ventilation systems 2	*Air handling units and ductwork contain numerous deviations from contract requirements (SHTM 03-01) and were found not to be clean despite having been presented for validation. Deviations include: loose internal cabling in the airflow, cable routes allowing air to bypass filters, air leakage at penetrations and possible fan replacement difficulties which need to be corrected.*	*The ventilation systems throughout the hospital should be subject to a full snagging exercise and all defects rectified following which air handling units and ventilation systems are cleaned. All deficiencies identified in validation and specialist Consultant Engineer reports should be addressed as part of this.*	We are working closely with IHSL to ensure all the issues identified in the reports have been rectified. A specimen AHU with all the deficiencies rectified will be made available to NHS Lothian for inspection by HFS and our engineers in September 2019.
General ventilation systems 3	*The general ward ventilation design is based on four air changes per hour mechanical ventilation plus a component of natural ventilation. With a few exceptions, the mechanical component has been validated. However, design and validation information for the natural component has not been proven.*	*Confirm that all areas served by this arrangement are suitable for categorisation as general ward areas or single rooms as listed in SHTM 03-01 Part a, Appendix 1.* *Undertake an IPCT risk assessment ward by ward/ speciality specific in relation to the guidance.*	A risk assessment undertaken by IPCT and clinical teams will be completed by 13 September to ensure that patient placement recognises the general ward ventilation provision.
General ventilation systems 4	*The pressure regimen detailed in the design, and reflecting the environmental matrix, will be affected by opening windows and the pressure between the room and the corridor, and therefore direction of air flow, cannot be relied upon when windows are open.*	*A full assessment of the services and patient population should be carried out and mechanisms for monitoring established.*	**AGREED** Ward level risk assessments will recognise the contribution of open windows to the ventilation provided mechanically.
General ventilation systems 5	*External doors to plant rooms*	*Ensure that excessive gaps are removed and appropriate anti vermin measures are applied to all the doors and screens as per SHTM 03-01 and HFS Interim Guidance - Managing the Risk of Contamination of Ventilation Systems by Fungi from Bird Droppings – February 2019.*	**AGREED** This will be addressed by the end of September. All doors will then comply with the guidance.
General ventilation	*Fire dampers in some locations cannot be adequately tested as duct access has not been*	*Provide access so all fire dampers can be readily visually inspected to verify operation.*	**AGREED** Access to fire dampers will be

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
systems 6	*provided. Also, locations of fire dampers and fire rated ductwork has been questioned in relation to the requirements of SHTM 03-01 and confirmation of compliant provision is awaited.*	*Review fire damper provision and fire rated ductwork and confirm appropriate provision*	corrected as part of the work to air handling units.
General ventilation systems 7	*Air intake location - Air intakes and opening windows are sited in the courtyard below the helipad and at the adjacent RIE. Information has not been provided on the impact of downdraft on air flows and pressures or entrainment of contaminants as per SHTM 03- 01.*	*Demonstrate the effect of helicopter landing on air flows in ventilation systems with intakes below through measurement when test flights take place or through modelling. This should include the air intakes of the RIE adjacent.*	Modelling information has been shared with NSS. The effects of test flights on air flows will be measured in September/ October 2019.
Theatre ventilation systems 1	*Scrub areas which are narrow and deep are unlikely to be scavenged effectively by theatre air changes and require e alternative means of achieving removal of contaminants as per SHTM 03-01. The efficacy of the high level extract to achieve sufficient dilution of contaminants or entrainment of heavier than air water droplets is not in accordance with the requirements of SHTM 03-01and has not demonstrated as equivalent.*	*The ability of the single high level extract provided in deep plan scrub areas to effectively prevent contaminants being dispersed into theatres should be demonstrated and/or additional low level ventilation provided.*	**AGREED** Evidence to confirm the adequate dispersal of contaminants has been requested. If this not satisfactory then a Board change will be instructed to provide low level ventilation.
Theatre ventilation systems 2	*Anaesthetic rooms 31 and 34 do not demonstrate a clean air flow path to reduce exposure of staff to gasses as per SHTM 03-01. Move ceiling supply to opposite side of room from extract. In room 30, move supply away from door.*	*Move ceiling supply to opposite side of room from extract. In room 30, move supply away from door.*	Demonstration of a clean air path has been requested by 13 September 2019; otherwise the supply will be moved.
Theatre ventilation systems 3	*Theatre utility rooms Extract ventilation means theatres have to be used in pairs and taking a theatre out of service may reduce the extract in utility room below the levels as per SHTM 03-01.*	*Add supplementary extract ventilation to allow for one theatre being out of service or plan for service impact following the loss of a pair of theatres.* *NHS Lothian has advised that the appropriate pressure differentials are maintained when only one theatre is operation. Validation*	IHSL have provided evidence that this arrangement meets the standard. Final checks on this are being completed.

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
		evidence is to be provided.	
Isolation room ventilations systems	*Isolation rooms are not served by a single ventilation system for each room as recommended in SHPN4 Supplement 1. The arrangement provided, where ventilation systems serve an area of the building including contained isolation rooms, has not yet been proven in the event of failure of an air handling unit and the implications for service impact are not yet understood.*	*Prove that bypass connections to adjacent ventilation systems will allow safe operation of both areas and / or explain service provision strategy for loss of each area including isolation rooms. Also include assurance on operational effectiveness e.g. the pressure differentials and air flows being maintained.* *Develop clinical service provision strategy to reflect the potential loss of up to 5 of the 19 isolation rooms on the failure of an air handling unit and confirm impact on service continuity.*	The date for the demonstration of bypass arrangements is to be confirmed by 13 September 2019. Detailed advice from the infection control team to allow bespoke risk assessments would be followed in such circumstances.

Water

NSS Review: *Independent testing identified no widespread contamination of the water systems, however, remedial action is required on a number of water system areas as well as system wide disinfection prior to occupation.*

NHS Lothian response: Remedial actions are underway and will be complete prior to occupation. Changes to the regime to maintain water quality have been made to address the findings of this review. System-wide disinfection will take place in the required timeframe prior to occupation.

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
Water services augmented care	*Pseudomonas found in taps, in Paediatric Medical Inpatients and DCN Inpatients . (SHTM 04-01 Part A published in July 2014)*	*All taps (not just TMT/TMV4) to be disinfected and retested. Inspect and replace, as appropriate, taps, tap components and pipework. Replace tap strainers and cartridges in affected TMT taps.*	**AGREED** All taps found positive for pseudomonas prior to occupation will be disinfected and retested using an agreed method statement. To be completed by the end of September 2019.
Water services non-augmented care	*Swarf and biofilm found in tap strainers, contrary to SHTM 04- 01 Water safety for healthcare premises.*	*Replace tap strainers in all areas.*	**AGREED** All tap strainers will be cleaned and replaced if necessary. To be complete by the end of October 2019.
Showers	*Shower hose lengths do not comply with Scottish Water by-laws and guidance in SHTM 04-01 Water safety for healthcare premises.*	*Shorten hose length, or add retaining ring, to ensure that shower head cannot reach WC or drain.* *Disinfect showers, hose and drain after rectification.*	**AGREED** Shower hoses will be rectified by addition of a retaining ring. These have been ordered and will be fitted by end of September.
Water General 1	*Testing has found some fungal / mould contamination and high total viable counts.*	*Given a number of indicators the water system should be disinfected and re-tested.*	**AGREED** The water system will be disinfected and tested prior to occupation.
Water General 2	*Legionella risk assessment actions not recorded as required by HSE Approved Code of Practice and*	*The Legionella Risk assessment Feb 2019 identified a range of actions. The Action Tracker*	**AGREED** Changes to the water

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
	Guidance L8 - Legionnaires' disease. The control of Legionella bacteria in water systems. Legionella risk assessment insufficient to reflect system contamination in general. Those responsible for the system have a responsibility under the Control of Substances Hazardous to Health Regulations 2002 (COSHH) to prevent exposure to microorganisms.	*does not demonstrate that the issues raised have been resolved or a timeline provided for resolution. Record rectification of actions. The risk assessment is heavily focussed on Legionella and not taking into account other organisms in line with patient type that will occupy the building. Broaden to reflect system contamination in general. Develop analysis categorisation of patient type and consideration to susceptibility for each area.*	management plan have been made to reflect this.
Water General 3	*Designated roles and responsibility as per SHTM 00 Best practice guidance for healthcare engineering.*	*The current Responsible Person (RP) has not been appointed in writing and uncertain as to whether received RP training. Additionally, has no previous experience of healthcare.*	**AGREED** The name of the responsible person has been confirmed; their qualifications will be provided.
Water General 4	*Water tanks as per SHTM 04-01 Water safety for healthcare premises.*	*To be inspected. The Raw Water and Filtrate water tanks are interconnected at the drain. These must be separated.*	**AGREED** This work will be complete by the end of September 2019.
Water General 5	*Hot and cold water temperatures / flushing. SHTM 04-01 Water safety for healthcare premises*	*There was an issue with raised cold water temperatures during the boiler outage – this requires investigation.*	**AGREED** Regular monitoring of hot and cold water temperatures is part of the water maintenance plan.
Water General 6	*Filtration Plants*	*From lessons learned by NSS in recent work, microbiological growth potential was identified as part of the Backwash cycle. Consideration should be given to Chlorine dioxide addition to backwash water tank to counter microbiological and biofilms development on filters.*	**CLOSED** NHS Lothian will consider new advice as it is produced and incorporate this into the water management plan as necessary.
Water General 7	*Instant Boil Taps and Rise and Fall Baths*	*These were found to be contaminated and need to be disinfected and tested t demonstrate safe water delivery as per SHTM 04-01 Water safety for healthcare premises.*	**AGREED** This action is underway in conjunction with the manufacturers.

Drainage and Plumbing

NSS Review: *The drainage system has multiple redundancies in place, however, active monitoring is required. Elements of plumbing require disinfection.*

NHS Lothian Response: Monitoring arrangements for drainage are incorporated into the building maintenance schedule. All necessary disinfection of plumbing will be incorporated into the maintenance schedules.

Issue	*NSS Review*	*NSS Action Assessment*	NHS Lothian action
Drainage and plumbing 1	Sinks drains	*Initial testing indicates that these are not significantly contaminated, however the horizontal drain and protruding seal means they retain stagnant water and they need to be disinfected periodically prior to and post occupancy to maintain their condition. From lessons learned, there should be a system of inspection and appropriate remedial action taken.*	**CLOSED** This will be incorporated into the water management plan prior to occupation of the building.
Drainage and plumbing	Bottle traps	*There would appear to be an inconsistency of installation and potential of back-feed from trap to drain. This requires review and rectification.*	**CLOSED** Disinfection of the bottle traps will be incorporated into the regular maintenance regime.
Drainage and plumbing 3	Pumped drainage	*The internal pumped sewage drainage system presents the potential for sewage to back up through basement drains on pump failure and will require active monitoring.*	**CLOSED** The monitoring of pumped drainage is in place and is on the critical alarm list.

NHS National Services Scotland

NHS Lothian - Royal Hospital for Children and Young People & Department of Clinical Neurosciences

NHS National Services Scotland – Review of: Water, Ventilation, Drainage and Plumbing Systems

September 2019
Version D0.20

Contents

1. Executive Summary

1.1 Overview

A decision was taken on 2 July 2019 to delay moving to the new Royal Hospital for Children and Young People & Department of Clinical Neurosciences (RHCYP & DCN) on 9 July. This followed an inspection of the facility which raised concerns regarding the ventilation arrangements for critical care beds and other areas of the hospital. NHS National Services Scotland (NSS) received a commission from Scottish Government to undertake an external series of checks, led by Health Facilities Scotland (HFS) and Health Protection Scotland (HPS), to ensure that the relevant technical specifications and guidance applicable to the new hospital have been followed and are being implemented.

The objectives of the review in relation to RHCYP & DCN were:

- To provide a report by September 2019 to Scottish Government on whether the relevant technical specifications and guidance applicable to the RHCYP & DCN are being followed and implemented.
- Where relevant technical specifications and guidance have not been followed, identify necessary remedial actions.

Given the specific focus on the control of Healthcare Associated Infections (HAI), the review concentrated on a system wide approach for ventilation, water and drainage systems. The process involved site visits, sample inspections and a targeted review of available documentation.

From an early stage of the review process, it was apparent that elements of the Critical Care Unit (CCU) ventilation system required redesign and modification to ensure compliance with guidance. Additionally, Haematology / Oncology is also being reviewed as a result of the review as specific risks were identified. NSS provided advice relating to the design instruction for elements of the CCU ventilation system and similar advice will be provided in relation to Haematology / Oncology.

The review commenced on the 9th July 2019 with this final report published in September 2019 for consideration by the established RHCYP & DCN Oversight Board.

1.2 Summary of findings

The findings have been collated based on information provided by NHS Lothian and on-site reviews of the RHCYP & DCN. Expert advice was sought within the key focus areas of ventilation, water and drainage systems and their overarching management and assurance processes. The following table outlines the status of key findings:

Review	Summary Assessment	No. of Issues per priority				
		1 (H)	2	3	4	5 (L)
Management & Assurance	Omissions identified in key roles within the management structure, ease of access to information and prioritisation of building system alarms.	-	-	1	2	-
Ventilation Systems	Remedial action is required within both general and theatre ventilation systems. Critical Care redesign was already being considered separately by the Board. Haematology / Oncology is also being reviewed as a result of the review as specific risks were identified. Risk assessments are underway as part of the general ward risk assessments being done locally requested as part of the review.	-	1	2	1	-
Water Systems	Independent testing identified no widespread contamination of the water systems, however, remedial action is required on a number of water system areas as well as system wide disinfection prior to occupation.	-	1	2	-	-
Drainage & Plumbing	The drainage system has multiple redundancies in place; active monitoring is required. Elements of plumbing require monitoring and routine disinfection.	-	-	-	1	-

The following definitions were used to categorise the findings:

Priority	Definition
1	Significant – Concerns requiring immediate attention, no adherence with guidance
2	Major – Absence of key controls, major deviations from guidance
3	Moderate – Not all control procedures working effectively, elements of noncompliance with guidance
4	Minor – Minor control procedures lacking or improvement identified based on emerging practice
5	Observation and improvement activity

Overall remedial action is required to be undertaken within the ventilation and water systems prior to the occupation. Following acceptance of this report, the review team are ready to assist the NHS Lothian team in developing a programme of activity and remedial actions to allow a timeline to be constructed which could inform the decision to migrate towards occupancy on a phased basis.

2. Review methodology

2.1 Review process

2.1.1 The review process initially took place between 9th July and 30th August 2019. For this report no further information has been considered after 30th August 2019.

2.1.2 The approach taken was to gather information relating to the services detailed in section 1.2 in drawing, specification, report and oral form and to compare these to the standards and guidance appropriate for the building type, drawing conclusions on whether what is provided matches the requirements. In addition to existing standards and guidance, learning generated from recent experience and national and international guidance and expertise was also used to inform the review. This learning will also inform future guidance development in Scotland.

2.1.3 The review has included

- Establishing a brief.
- Establishing the baseline data to allow the brief to be met.
- Preparation of several question sets to get a greater understanding of the project.
- Preparation and management of detailed question sets and information requests.
- Commissioning UK topic experts to review certain aspects of the project.
- Several site visits.
- Several meetings.
- Analysis of data.
- Analysis of microbiology results related to the hot and cold water systems.
- A rapid review of the literature and international guidance on ventilation systems.

2.2 Standards and Guidance

2.2.1 HFS currently provides a range of advisory and delivery services across a wide variety of topics from a portfolio which covers the built estate, engineering and environment and facilities management. With some exceptions these services are largely advisory in nature, identifying best practice and developing national guidance and standards.

2.2.2 HPS currently provides advice and guidance on all aspects of health protection nationally in Scotland, inclusive of expert advice and guidance on the topic of Healthcare Associated Infections (HAI) and antimicrobial resistance. It maintains and continues to develop a practice guide (National Infection Prevention and Control Manual – NIPCM) as well as a HAI Compendium of all extant guidance and policy appropriate for use in NHSScotland. Like HFS, these services are largely advisory in nature, identifying best practice and developing national guidance and standards. The NHSScotland NIPCM was first published on 13 January 2012 as mandatory guidance, by the Chief Nursing Officer (CNO (2012)1), and updated on 17 May 2012

(CNO(2012)01-update). The NIPCM provides guidance for all those involved in care provision and should be adopted for infection, prevention and control practices and procedures. The NIPCM is mandatory policy for NHSScotland.

The authority of guidance produced by NSS and other national organisations e.g. Healthcare Improvement Scotland is best described by the definitions outlined below (SHMT 00 – Best practice guidelines for healthcare engineering):

Regulations are law, approved by Parliament. These are usually made under the Health and Safety at Work etc Act following proposals from the Health & Safety Commission. Regulations identify certain risks and set out specific actions which must be taken.

Approved Codes of Practice give advice on how to comply with the law by offering practical examples of best practice. If employers follow the advice, they will be doing enough to comply with the law.

Approved Codes of Practice have a special legal status. If employers are prosecuted for a breach of health and safety law, and it is proved that they did not follow the relevant provisions of an Approved Code of Practice, they will need to show that they have complied with the law in some other way, or a court will find them at fault.

Standards (British or European), institutional guides and industry best practice play a large part in how things should be done. They have no direct legal status (unless specified by Regulations). However, should there be an accident; the applied safety practices at the place of work would be examined against existing British or European Standards. It would be difficult to argue in favour of an organisation where safety was not to the described level.

Guidance is issued in some cases to indicate the best way to comply with Regulations, but the guidance has no legal enforcement status.

2.2.3 Whilst guidance is deemed not compulsory by HSE (not legally enforceable), where compliance with guidance is specified in a contract, it becomes a contractual requirement. Therefore, any permitted deviation from it would be expected to follow a formal process with input from all relevant parties with clarity around how the outcome was reached, including risk assessments where appropriate and sign off by all those authorised to approve it.

2.2.4 The terms of standards and guidance are used in the report to refer to the publications setting out the expectations about the level of service to be provided, including legislation, approved codes of practice and guidance. Compliance with guidance is reported on, regardless of whether this implies a contractual requirement, as contract compliance is out with the scope of this report. For the avoidance of doubt we have not considered the project agreement and contractual compliance in accordance with its terms as this is subject to a separate review commissioned by Scottish Government.

2.2.5 The contract model for this project is known as a Non Profit Distribution (NPD) model, which amongst other things is intended to deliver benefits such as:

- Single delivery mechanism.
- Whole life costing.
- Design efficiencies.
- Lifecycle maintenance.
- Improved service provision.

Based on the Board's Construction Requirements (BCRs), including which guidance is to be followed and other parameters, the Special Purpose Vehicle (SPV) develops the design and agrees operational (clinical) functionality with the Board before construction commences and during the Reviewable Design Data process (RDD). It is usual to have an Independent Tester (IT) involved in the project. The IT is a joint appointment to the SPV and the Board. The IT role is to certify the completion of the building as referenced in the project agreement and completion criteria of the contract.

2.3 Reporting methodology

2.3.1 For clarity this report organises issues with each of the systems considered into a priority rating, identifying the importance of deviations from what would be expected based on the standards and guidance. The distinction between the categories is based on NSS judgement of the degree of non-compliance and the implications of that non-compliance. The criteria used are described below.

Priority	Definition
1	Significant – Concerns requiring immediate attention, no adherence with guidance
2	Major – Absence of key controls, major deviations from guidance
3	Moderate – Not all control procedures working effectively, elements of noncompliance with guidance
4	Minor – Minor control procedures lacking or improvement identified based on emerging practice
5	Observation and improvement activity

3. Analysis of information provided

3.1 Information provided

3.1.1 The support of the NHS Lothian project team in responding to questions and accessing data is gratefully acknowledged.

3.1.2 At the time of writing the majority of the information required had been received and whilst the timescale for the review means a selective targeted review of documentation was necessary, the main themes appear clear. However, some information remains outstanding, particularly information requested from Integrated Health Solutions Lothian (IHSL)[1], and NHS Lothian colleagues continue to pursue a response.

3.1.3 The Special Purpose Vehicle (SPV), Contractor, sub-contractors, Facilities Management Contractor and Independent Tester were not directly involved in the production of this report, nor were they requested to verify its contents and they may have additional information not considered here. It is acknowledged that some of the information provided by NHS Lothian came directly from these sources.

Ventilation systems

3.1.4 Prior to this review NHS Lothian commissioned a specialist contractor to validate the performance of ventilation systems within the facility and their report identified that elements of the ventilation system in CCU was not in accordance with current guidance (SHTM 03-01). Whilst this report notes that finding and NSS has been asked to support NHS Lothian in achieving a solution in compliance with guidance, this report focuses primarily on other ventilation issues.

3.1.5 Awaited is the explanation and validation of the ventilation strategy whereby areas with air handling units out of service for whatever reason are served by an adjacent air handling unit, which also continues to serve its own area.

3.1.6 The theatre ventilation appears not to have been installed in accordance with current guidance in respect to required pressure cascades in corridors and removal of contaminants from scrub areas. The Board has sought demonstration of compliance from IHSL in relation to issues identified.

Water systems

3.1.7 Whilst elements of the water testing carried out as part of this review are not detailed in current guidance, and NHS Lothian could not have been expected to be aware, lessons learned recently across health systems suggest that any potential pathogenic contamination found should be eradicated before patients and staff move in. Water test results in RHCYP & DCN indicate some fungi in the water, mainly at taps, as well as higher than anticipated total viable counts (TVC). The latter may be related to the fact that the building is unoccupied with only maintenance processes in place to ensure water turnover. In augmented care areas there is evidence of *Pseudomonas aeruginosa* found in some taps. There would appear to be no systemic contamination of the hot and cold water systems, rather, contamination has

[1] IHSL are the Special Purpose Vehicle (SPV)

been found at outlets, and particularly outlets with complex interstices and organic components which can make them more susceptible to persistent contamination.

Drainage and plumbing systems

3.1.8 The drainage for the hospital utilises one gravity system and two pumped systems. The pumped systems are used to overcome gravity as they are installed below the local water table and level of the external drains. The main concern is the pumped system in the basement in the location of the kitchen. This system has multiple pump backups as well as alternative power supplies. The risk is that if these fail the kitchen drains will back up requiring the kitchen to close, which would have an impact on the services to the hospital. At this stage in the process there appears to be no alternative to locating the drainage system sump in the basement, at least without major structural alterations to the basement and courtyard. It appears that extensive use of standby equipment and power supplies is in place, such that multiple failures would need to occur to cause sewage to back up into the basement. Procedures for maintenance and repair have been extensively considered but will need to be tested in operation.

4. Findings

4.1 Management and assurance

Summary

Review	Summary Assessment	No. of Issues per priority				
		1 (H)	2	3	4	5 (L)
Management & Assurance	Omissions identified in key roles within the management structure, ease of access to information and prioritisation of building system alarms.	-	-	1	2	-

Main Findings

Priority	Review	Action Assessment
4	Structures and processes are not fully in place to assure the Board that the facility is being operated in compliance with contract requirements. These should be in place from the point where the building services referred to in this report are put into use.	NHS Lothian and IHSL should adopt the management and reporting processes as described in SHTM 00 - Best Practice Guidance for Healthcare Engineering and the SHTMs for each critical engineering service.
3	Some of the records and documents necessary for the effective and safe operation of the hospital could not be found. The document management system appears to lack a logical structure which will impact on the ability to readily find necessary information. Some of the sections contain none, or only part, of the documentation they should have as required by the Construction (Design and Management) Regulations 2015.	The Board should require IHSL to rectify the filing structure of the documentation and verify that the information contained is both complete and accurate as required by the Construction (Design and Management) Regulations 2015.
4	The alarms for the building are reportedly un-prioritised, resulting in a very large number of alarms potentially masking critical alarms.	Prioritise alarms to make most critical failures visible and manageable. Until alarms are prioritised, have procedures and staff in place to ensure critical alarms are not missed as per SHTM08-05 - Specialist services building management systems.

Detailed Narrative

4.1.1 Healthcare organisations have a duty of care to patients, their workforce and the general public to ensure a safe and appropriate environment. This requirement is identified in a wide range of legislation. At the most senior level within an organisation, the appointed responsible person should have access to a robust structure which delivers governance, assurance and compliance through a formal reporting mechanism.

4.1.2 The review identified that for both IHSL and NHS Lothian, there were omissions in the identification, appointment and definition of key roles in an effective management structure. Additionally, some records which are necessary to demonstrate compliance with appropriate standards and guidance remain outstanding.

4.1.3 The Board cannot pass its responsibilities under health and safety law to a third party. It can pass duties, but the responsibility for ensuring the safety of those accessing its premises remains with the Board. To discharge its duties, the Board should ensure appropriate structures, processes and personnel are in place to ensure that those responsible for operating the facility are doing so in compliance. The structures and processes set out in the Scottish Health Technical Memorandum (SHTM) suite of guidance, Statutory Compliance Audit and Risk Tool (SCART)[2] and Healthcare Associated Infection-System for Controlling Risk in the Built Environment (HAI_SCRIBE) [3] produced by Health Facilities Scotland, should form the core of this. These arrangements should be in place as soon as practicable and prior to occupation of the RHYCP & DCN.

4.2 Ventilation

Summary

Review	Summary Assessment	No. of Issues per priority				
		1 (H)	2	3	4	5 (L)
Ventilation Systems	Remedial action is required within both general and theatre ventilation systems. Critical Care redesign was already being considered separately by the Board. Haematology / Oncology is also being reviewed as a result of the review as specific risks were identified. Risk assessments are underway as part of the general ward risk assessments being done locally requested as part of the review.	-	1	2	-	-

[2] SCART is a risk based tool used by Boards in NHS Scotland to measure their compliance against statutory and non-statutory position.
[3] HAI_SCRIBE provides Built Environment Infection Prevention and Control information for Design Teams, Construction Teams, Infection Prevention and Control Teams and Estates & Facilities Teams, as well as an assessment process allowing the identification and management of infection control risks in the built environment.

Main Findings

Priority	Review	Action Assessment
2	**General Ventilation Systems -** Provision for maintenance or plant failure in the ventilation systems has not been validated in accordance with SHTM 03-01 Ventilation for Healthcare Premises. The bypass arrangements and functioning of ward ventilation in the event of plant failure remains to be demonstrated.	Demonstrate efficacy of approach of utilising adjacent air handling unit to supply areas not served by failed plant. Commission and validate isolation rooms and general ward spaces in the event of supply by adjacent air handling unit. Engage clinical leads and Infection Prevention and Control colleagues in developing service provision strategies in the event of air handling plant failure. Confirm damper operation and compliance with fire requirements in bypass mode.
	Air handling units and ductwork contain numerous deviations from contract requirements (SHTM 03-01) and were found not to be clean despite having been presented for validation. Deviations include: loose internal cabling in the airflow, cable routes allowing air to bypass filters, air leakage at penetrations and possible fan replacement difficulties which need to be corrected	The ventilation systems throughout the hospital should be subject to a full snagging exercise and all defects rectified following which air handling units and ventilation systems are cleaned. All deficiencies identified in validation and specialist Consultant Engineer reports should be addressed as part of this.
	The general ward ventilation design is based on four air changes per hour mechanical ventilation plus a component of natural ventilation. With a few exceptions, the mechanical component has been validated. However, design and validation information for the natural component has not been proven.	Confirm that all areas served by this arrangement are suitable for categorisation as general ward areas or single rooms as listed in SHTM03-01a Appendix 1. Undertake an IPCT risk assessment ward by ward/ speciality specific in relation to the guidance.
	The pressure regimen detailed in the design, and reflecting the environmental matrix, will be affected by opening windows and the pressure between the room and the corridor, and therefore direction of air flow, cannot be relied upon when windows are open.	A full assessment of the services and patient population should be carried out and mechanisms for monitoring established.

	External doors to plant rooms	Ensure that excessive gaps are removed and appropriate anti vermin measures are applied to all the doors and screens as per SHTM 03-01 and HFS Interim Guidance - Managing the Risk of Contamination of Ventilation Systems by Fungi from Bird Droppings – February 2019.
	Fire dampers in some locations cannot be adequately tested as duct access has not been provided. Also, locations of fire dampers and fire rated ductwork has been questioned in relation to the requirements of SHTM 03-01.	Provide access so all fire dampers can be readily visually inspected to verify operation. Review fire damper provision and fire rated ductwork and confirm appropriate provision
	Air intake location - Air intakes and opening windows are sited in the courtyard below the helipad and at the adjacent RIE. Information has not been provided on the impact of downdraft on air flows and pressures or entrainment of contaminants as per SHTM 03-01.	Demonstrate the effect of helicopter landing on air flows in ventilation systems with intakes below through measurement or modelling. This should include the air intakes of the RIE adjacent.
3	**Theatre Ventilation Systems** - Scrub areas which are narrow and deep are unlikely to be scavenged effectively by theatre air changes and require alternative means of achieving removal of contaminants as per SHTM 03-01. The efficacy of the high level extract to achieve sufficient dilution of contaminants or entrainment of heavier than air water droplets is not demonstrated.	The ability of the single high level extract provided in deep plan scrub areas to effectively prevent contaminants being dispersed into theatres should be demonstrated and/or additional low level ventilation provided.
	Anaesthetic rooms 31 and 34 do not demonstrate a clean air flow path to reduce exposure of staff to gasses as per SHTM 03-01.	Move ceiling supply to opposite side of room from extract. In room 30, move supply away from door.
	Theatre utility rooms Extract ventilation means theatres have to be used in pairs and taking a theatre out of service may reduce the extract in utility room below the levels as per SHTM 03-01.	Add supplementary extract ventilation to allow for one theatre being out of service or plan for service impact following the loss of a pair of theatres. *NHS Lothian has advised that the appropriate pressure differentials*

		are maintained when only one theatre is operation. Validation evidence is to be provided.
3	**Isolation Room Ventilation Systems -** are not served by a single ventilation system for each room as recommended in SHPN4 Supplement 1. The arrangement provided, where ventilation systems serve an area of the building including contained isolation rooms, has not yet been proven in the event of failure of an air handling unit and the implications for service impact are not yet understood.	Prove that bypass connections to adjacent ventilation systems will allow safe operation of both areas and / or explain service provision strategy for loss of each area including isolation rooms. Also include assurance on operational effectiveness e.g. the pressure differentials and air flows being maintained. Develop clinical service provision strategy to reflect the potential loss of up to 5 of the 19 isolation rooms on the failure of an air handling unit and confirm impact on service continuity.

Detailed Narrative

4.2.1 The ventilation systems at RHCYP & DCN were considered in relation to legislation, guidance and the lessons learned from other recent similar projects which may have an impact on the patient group.

4.2.2 The principal legislation which is relevant to the ventilation systems is The Control of Substances Hazardous to Health Regulations 2002 (COSHH).

4.2.3 The principal guidance which is relevant to the ventilation systems is: Scottish Health Technical Memorandum (SHTM) 03-01: Ventilation for healthcare premises; and Scottish Health Planning Note 04 Inpatient Accommodation, Supplement 1 Isolation Facilities in Acute Settings.

4.2.4 Elements of the ventilation within Critical Care were identified by NHS Lothian's validation contractor, and verified in this review, to be not in accordance with the requirements of SHTM 03-01. NHS Lothian is working with IHSL to design a suitable solution to provide the conditions required within CCU. NSS has been asked by Scottish Government to support NHS Lothian to ensure that the system delivered is compliant with requirements.

4.2.5 The general ventilation for non-specialist applications, such as single/shared rooms in general wards, was identified by the Board's validation contractor as having lower air change rates than specified in SHTM 03-01, i.e. 4 air changes per hour as opposed to 6. During the review, NHS Lothian supplied information about a natural ventilation component, with some documents referring to a mixed mode ventilation system. However, IHSL advised that natural ventilation is not part of their design. NSS visited the site with specialist ventilation consultants who produced a report on the general ventilation systems and noted non-compliances with air handling unit provision and installation and pressure regimens, including several identified by the Board's validation contractor.

From an infection prevention and control perspective, there is low-quality to no evidence from outbreak reports and current guidance, respectively, to support minimum ventilation requirements. Therefore, it is not possible to make conclusive statements regarding the individual minimum ventilation parameters for inpatient care areas. A rapid review of the literature found limited clinical evidence to directly implicate air change rates alone in having a direct impact on the development of an outbreak or incidence of infection. Therefore, it is reasonable that, in the absence of evidence, healthcare design teams should continue to adhere to current national guidance. In the event of a deviation from the current recommended ventilation parameters, design teams should ensure that air changes per hour are maintained as close as possible to the recommended air changes per hour without compromising other aspects of the ventilation system requirements. In addition a full assessment of the services and patient population should be carried out and mechanisms for monitoring established. Caution is advised in relying on air change rates alone to provide adequate protection from infection; this is only one part of a multifactorial process involved in creating the appropriate airflow patterns with appropriate mixing and dilution of contaminants. Further research is required to look beyond air change rates to examine the effects that other factors such as supply and exhaust location, door position and motion, spatial orientation, surface composition, temperature, humidity, and air distribution patterns have on particle migration in clinical areas.

4.2.6 Theatre ventilation was identified by NHS Lothian's validation contractor as having some deficiencies. NSS visited the site with a specialist Consultant Engineer, who was lead author on the last three iterations of the ventilation HTM guidance. This identified and confirmed several deficiencies, including lack of evidence about the efficacy of the ventilation in the scrub rooms; deviating from the standard models recommended in SHTM 03-01. The current design of the theatre ventilation system is such that maintenance might entail loss of two theatres rather than one. Additionally, there is an overuse of flexible ductwork, potentially causing problems with balancing theatre ventilation. All issues identified are rectifiable, and as such should not prevent the theatres being put into use following remedial action.

4.2.7 The building contains a number of Positive Pressure Ventilated Lobby (PPVL) isolation rooms for which the guidance, SHPN4 supplement 1, recommends that each isolation room should ideally have its own air handling unit, such that if an air handling unit fails, or is offline for maintenance, only one isolation room is out of commission.

The building, as built, has an air handling unit serving each area of the building, including any contained isolation rooms. This means that up to five out of 19 isolation rooms may be out of action in the event of an air handling unit failure. NHS Lothian have advised that the strategy for maintenance is that a bypass duct will be used to feed an area from an adjacent air handling unit. This mode has not yet been proven and the successful operation of isolation rooms and other spaces in the event of use of this bypass strategy has not been demonstrated. NHS Lothian needs to consider in its clinical service model how each isolation room and ward will function in the event of loss of an air handling unit. This will require full design and validation of air change rates, pressure differentials and direction of air flow for each area in this mode, as well as predicted times to rectify any plant failure.

4.2.8 IHSL has advised that the design of the isolation rooms is as per Scottish Health Planning Note (SHPN) 04-01 Supplement 1: In-patient Accommodation: Options for

Choice Supplement 1: Isolation Facilities in Acute Settings. This guidance notes that isolation rooms ideally should have its own air handling unit (AHU) and the ventilation systems should be as robust as possible so that standby fans are not required. The guidance acknowledges that in high rise buildings a common supply and extract may be the only feasible solution with duct branches fitted with spring close gas tight dampers in the event of failure. The height of this building is less than that defined in the Scottish Building Standards Technical Handbook - Non-Domestic, for high rise (18m). The solution at RHCYP & DCN does not include the gas tight dampers at ward level as required by the validated design parameters detailed in SHPN 04-01 Supplement 1.

4.2.9 Additional observations during a site visit by NSS have highlighted potential concerns linked to the location of some high risk wards, including Haematology / Oncology in relation to the helipad. A demonstration of the effect of helicopter landing/take-off on airflows needs to be completed by NHS Lothian.

4.3 Water

Summary

Review	Summary Assessment	No. of Issues per priority				
		1	2	3	4	5
Water Systems	Independent testing identified no widespread contamination of the water systems, however, remedial action is required on a number of water system areas as well as system wide disinfection prior to occupation.	-	1	2	1	-

Main Findings

Priority	Review	Action Assessment
4	**Water Services Critical Care -** Pseudomonas found in taps, in critical care areas. (SHTM 04-01 Part A published in July 2014)	All taps (not just TMT/TMV[4]) to be disinfected and retested. Inspect and replace, as appropriate, taps, tap components and pipework. Replace tap strainers and cartridges in CCU TMT taps.
3	**Water Services Non Critical Care** - Swarf and biofilm found in tap strainers, contrary to SHTM 04-01 Water safety for healthcare premises.	Replace tap strainers in all areas.

[4] TMT – Thermostatic Mixing Taps, TMV – Thermostatic Mixing Values

2	**Showers -** Shower hose lengths do not comply with Scottish Water bye laws and guidance in SHTM 04-01 Water safety for healthcare premises.	Shorten hose length, or add retaining ring, to ensure that shower head cannot reach WC or drain Disinfect showers, hose and drain after rectification.
3	**Water General** - Testing has found some fungal / mould contamination.	The water system should be disinfected and re-tested.
	Legionella risk assessment actions not recorded as required by HSE Approved Code of Practice and Guidance L8 - Legionnaires' disease. The control of *Legionella* bacteria in water systems. *Legionella* risk assessment insufficient to reflect system contamination in general. Those responsible for the system have a responsibility under the Control of Substances Hazardous to Health Regulations 2002 (COSHH) to prevent exposure to microorganisms.	The *Legionella* Risk assessment Feb 2019 identified a range of actions. The Action Tracker does not demonstrate that the issues raised have been resolved or a timeline provided for resolution. Record rectification of actions. The risk assessment is heavily focussed on *Legionella* and not taking into account other organisms in line with patient type that will occupy the building. Broaden to reflect system contamination in general. Develop analysis categorisation of patient type and consideration to susceptibility for each area.
	Designated roles and responsibility as per SHTM 00 Best practice guidance for healthcare engineering.	The current Responsible Person (RP) has not been appointed in writing and uncertain as to whether received RP training. Additionally, has no previous experience of healthcare.
	Water tanks as per SHTM 04-01 Water safety for healthcare premises.	To be inspected. The Raw Water and Filtrate water tanks are interconnected at the drain. These must be separated.
	Hot and cold water temperatures / flushing. SHTM 04-01 Water safety for healthcare premises	There was an issue with raised cold water temperatures during the boiler outage – this requires investigation.
	Filtration Plants	From lessons learned by NSS in recent work, microbiological growth potential was identified as part of the Backwash cycle. Consideration should be given to Chlorine dioxide addition to backwash water tank to counter microbiological and biofilm development on filters.

	Instant Boil Taps and Rise and Fall Baths	These were found to be contaminated and need to be disinfected and tested to demonstrate safe water delivery as per SHTM 04-01 Water safety for healthcare premises.

Detailed Narrative

4.3.1 The domestic hot and cold water services (DHCWS) at RHCYP & DCN were considered in relation to legislation, guidance and the lessons learned from other recent similar projects which may have an impact on the patient group.

4.3.2 The legislation which is relevant to the water system are Public Water Supplies (Scotland) Regulations SSI 2014/364 and The Control of Substances Hazardous to Health Regulations 2002 (COSHH). In relation to COSHH, the Health and Safety Executive (HSE) note that "*Micro-organisms are covered in COSHH by the term biological agents. These are defined as any micro-organism, cell culture, prion or human endoparasite whether or not genetically modified which may cause infection, allergy, toxicity or otherwise create a hazard to human health*."

4.3.3 The guidance which is relevant to the water system are HSE Approved Code of Practice L8: Legionnaires' disease. The control of *Legionella* bacteria in water systems; HSE 274: Legionnaires' disease: Technical guidance; Scottish Healthcare Technical Memorandum (SHTM) 04-01: Water safety for healthcare premises and HPS document: *Pseudomonas aeruginosa* routine water sampling in augmented care areas for NHS Scotland (*published in draft September 2018*).

4.3.4 From initial inspection of the Independent Tester's reports, there is evidence that areas of the pipe work systems were installed without end protection. This may have allowed dust and organic material to enter the pipe system and this may not have been eradicated by the disinfection process.

4.3.5 From the construction commissioning records contained within the electronic operating and maintenance document repository, it is noted that there is no record of leachate flushing of the system.

4.3.6 The Facilities Management (FM) contractor Bouygues FM (BFM) commissioned a *Legionella* risk assessment when they took possession of the site from the construction contractor. This report has yet to be provided and will be reviewed and assessed when presented.

4.3.7 NHS Lothian commissioned a specialist safety consultant in May 2019 to conduct an overall safety audit of the RHCYP & DCN. Contained within their report is a section on the water system. They assessed the risk condition of the system as "high" mainly as a result of BFM's *Legionella* risk assessment, the lack of evidence of flushing across the system, the lack of maintenance on shower heads and outstanding information on the water management responsibilities by BFM.

4.3.8 NHS Lothian separately commissioned water testing from a specialist water safety consultant, on 12th July 2019, which indicated that certain tap outlets within the augmented care areas were positive for *Pseudomonas aeruginosa*. This report also

noted high Total Viable Counts (TVC). In addition, *Pseudomonas aeruginosa* was recorded in the Instant Boil Taps and the rise and fall baths. The consultant concluded that there was no evidence of wide spread contamination of the water system.

4.3.9 As part of the NSS review, a specialist water consultant carried out water tests around the facility on 18th July 2019 to determine if there were any significant issues.

4.3.10 In summary the NSS specialist contractor concluded from their investigations and as a result of the microbiological samples taken by them and others that: -

- There was no indication that the water system (as a whole) was cause for concern referenced to existing guidance.
- There was no atypical mycobacteria found in the 60 samples taken (mainly from neonatal and intensive care areas); however, there was some Gram-negative activity and mould present.
- Concern was expressed regarding the management of the water system given the lack of occupancy and turnover of the water system.
- The management aspects of the water system by IHSL's FM contractor were not satisfactorily demonstrated.
- The system showed signs of biofilm and swarf contamination, particularly at the taps.
- Shower heads and hoses do not meet the required standards with respect to length.
- During the site investigation it was noted that the cold water temperatures were rising and the hot water temperatures decreasing. In discussions with BFM it was discovered that a boiler had tripped, together with the circulating pumps, and the other boilers did not come on as they should have. The result of this was that the temperature of the water for both hot and cold domestic water systems fell into the *Legionella* growth band for approximately a 12 hour period.
- The NSS commissioned consultant engaged noted that at commissioning only 5% sampling of the number of taps across the whole hospital was completed.
- The management strategy for the Kemper system (water temperature regulation system) requires close control to ensure that water is not "dumped" unnecessarily in an effort to control cold water temperatures.

4.3.11 The tests for atypical mycobacteria proved negative. However fungi were identified in 22% of the samples taken in the water system based on a sample size of 60 taps from a population of c2000. These are not required to be tested as part of the current guidance. However, based on NSS experiences at other hospital sites it was considered prudent to have these tests done.

4.3.12 As a direct result of lessons learned by NSS from work undertaken after the construction of RHCYP & DCN, it is recommended that components parts of the water system are replaced and the originals tested, particularly those which have proven to be problematic.

4.4 Drainage and Plumbing

Summary

Review	Summary Assessment	No. of Issues per priority				
		1 (H)	2	3	4	5 (L)
Drainage & Plumbing	The drainage system has multiple redundancies in place, however, active monitoring is required. Elements of plumbing require disinfection.	-	-	-	1	-

Main Findings

Priority	Review	Action Assessment
4	Sinks drains	Initial testing indicates that these are not significantly contaminated, however the horizontal drain and protruding seal means they retain stagnant water and they need to be disinfected periodically prior to and post occupancy to maintain their condition. From lessons learned, there should be a system of periodic testing and disinfection for wash hand basins with particular focus on augmented care areas.
	Bottle traps	There would appear to be an inconsistency of installation and potential of back-feed from trap to drain. This requires review and rectification.
	Trough Sinks	From previous projects, the drains in trough sinks have been identified as high risk potential due to high microbiological activity. This requires review and treatment strategy considered.
	Pumped Drainage	The internal pumped sewage drainage system presents the potential for sewage to back up through basement drains on pump failure and will require active monitoring.

Detailed Narrative

4.4.1 The range of clinical and non-clinical wash hand basins chosen by the SPV are from a recognised manufacturer of healthcare drainage products. There is no facility to

connect the tap on the sink as the taps are panel mounted. The drain connection is at the rear of the sink bowl and there is no overflow, all as per guidance.

4.4.2 The connection on to the wash hand basin from the drain has proven to be an area where water does not drain freely as the connection reduces the diameter of the drainage outlet and creates a dam effect. Lessons learned by NSS from other projects, after commencement of the construction of RHCYP & DCN, have shown that various organisms were grown from this area in some circumstances.

4.4.3 The waste connection from the sink to the main above ground drainage system is via “bottle trap” rather than a conventional “U-bend”. Lessons learned by NSS from other projects, after commencement of the construction of RHCYP & DCN, identify this arrangement as a risk for bacterial growth.

4.4.4 The plumbing system is connected to the main sewage system via three drainage systems. The first is a gravity fed system. The second is a sump pump arrangement in the external courtyard. The third is a sump in the basement area of the hospital. The rationale behind the use of the sumps is that the basement areas are below the water table and any waste material has to be pumped up and out to the sewer.

4.4.5 The Independent Tester has noted in their report of 30th June 2017 that an issue had been raised regarding the capacity of the basement sump. In further investigation this appears to be related to the fact that more areas/floors were connected to this system than NHS Lothian had originally been made aware of.

4.4.6 The main drainage risk lies with the basement sump. It has a resilience system of back-up power supplies, multiple pumps and alarm systems to three different locations. There are two discharge pipes to sewer, reducing the risk of blockage and the consequent risk of sewage backing up into the basement in the proximity of the kitchen. In addition, if a failure occurred or a maintenance activity was to take place, the location of this sump chamber would mean that all traffic flow through the basement corridor would have to be halted to permit a safe operating procedure to be implemented.

4.4.7 The external courtyard sump has a duty/standby pump as well as a spare submersible pump and also has similar alarm arrangements to the basement pumps. In the event of a catastrophic blockage and spillage the court yard would be impacted.

Both, in complete confidence can you review this report and read it in line with the paper that Tracey sent around earlier.

If you could give comment on the RAG report with any evidence to support that would be very helpful for Thursdays oversight group.

Help appreciated.

Enquiries to [redacted]

Dear Christine,

NSS (HFS & HPS) review of the NHS Lothian Royal Hospital for Children and Young People and Department of Neurosciences

As per our project plan, please find enclosed a draft RAG report. This reflects findings to date on the Water, Ventilation and Drainage systems as these relate to the main HAI Built Environment Risks.

We have flagged in our regular updates that information is incomplete at this stage and this is reflected by gaps in the report. We have just concluded a very positive gap analysis meeting with NHS Lothian colleagues today to clarify and seek further information. On receipt and assessment of this it should enable submission of the completed RAG report by 19 August as per the project plan.

The initial RAG report concentrates on those areas where work is required, and therefore only Red and Amber issues are recorded. It is also acknowledged that some of these issues may well be planned, scheduled or confirmed by NHSL, but that this provides the picture as at the date of the report.

The work to assess the determination and impact of the air changes in the general ward areas is progressing well, and I would hope that this can be added to the RAG report within a week, along with updates as these are received.

Additionally, we are working closely with NHSL colleagues on the description and specification of the remedial works in relation to critical care areas.

We met with Susan Goldsmith today and appraised her of the progress. I believe it would be very useful, and could shorten out timelines for NHSL to have sight of this draft report prior to the first oversight group, and would welcome your views if you feel this is appropriate.

Please do not hesitate to contact me if you have any questions.

Yours sincerely,

JIM MILLER

NSS (HPS & HFS) Technical Review of the Royal Hospital for Children and Young People (RHCYP) and Department of Clinical Neurosciences

Draft & In Confidence – RAG Status Report

05th August 2019

Version Draft 0.7

NSS (HFS & HPS) RAG Table for Royal Hospital for Children and Young People and Department of Clinical Neurosciences

Date 5th August 2019, Version Draft.07

The attached initial draft RAG report has been collated based on information provided, on-site reviews of the RHCYP and expert advice sought within the key focus areas of Ventilation, Water and Drainage systems. NSS would like to thank the NHS Lothian project team for their corporation, input and access to the required information.

This report uses a high level RAG status to review each of the components. The following table describes the RAG and Status:

RAG	Description
Red	Unacceptable condition for patients and staff
Amber	Remedial work required
Green	No comment

Summary:

- Work is still progressing on all issues covered in this draft report and views and RAG status may change.
- There are numerous issues not necessarily impacting significantly on the ability to occupy the building but nonetheless requiring rectification for the building to function the way a new building should. These are not included in this report.
- The report focusses on areas where potential problems have been identified and these are rated red or amber and changed to green following verification of remedial work.
- Issues which would have been rated green initially are not included.

Water Systems:

Service	Comment	Remedial work	RAG
Water services (critical care)			**R**
	Pseudomonas found in taps, in critical care areas.	All taps (not just TMT/TMV) to be disinfected and retested. Follow guidance.	**R**
		Replace tap strainers and cartridges in CCU TMT taps.	**R**
		Showers require to be disinfected.	**R**
		Implementation plan required.	**A**
Water services (non- critical care)			**A**
	Swarf and biofilm found in tap strainers.	Replace tap strainers in all areas.	**A**
Showers (all areas)			**R**
	Shower hose lengths do not comply with Scottish Water bye laws and guidance.	Shorted hose length or retaining ring to ensure that head cannot reach WC or drain	**R**
		Disinfect hose and drain after rectification.	**R**
Water (general)			**R**
	Testing has found widespread fungal contamination.	The water system should be disinfected and re-tested.	**R**

Service	Comment	Remedial work	RAG
	Legionella risk assessment.	The Legionella Risk assessment Feb 2019 identified a range of actions. The Action Tracker does not demonstrate that the issued raised have been resolved or a timeline provided for resolution. The risk assessment is too heavily focussed on Legionella and not taking into account other organisms in line with patient type. There is no categorisation of patient type anywhere in what we have been provided and consideration to susceptibility.	R
	Designated roles and responsibility.	It has not been demonstrated that there are authorised persons or competent persons for the water services as defined in SHTM 00 and SHTM 04-01. In addition, a responsibility matrix and interface to NHSL water management group is required. The current Responsible Person has not been appointed in writing and uncertain as to whether received RP training. Additionally, has no previous experience of healthcare.	Information awaited

Service	Comment	Remedial work	RAG
	Water tanks	To be inspected. The Raw Water and Filtrate water tanks are interconnected at the drain. These MUST be separated.	**A**
	Expansion vessels should be checked for susceptibility to bacterial growth.	Bladder from expansion vessels to be inspected.	**A**
	Hot and cold water temperatures / Flushing.	There was an issue with raised cold water temperatures during the boiler outage – this requires investigation.	**A**
	Filtration Plants	From work done at Glasgow micro-biological growth potential was identified as part of the Backwash cycle. Suggest Chlorine dioxide addition to backwash water tank to aid microbiological and biofilm development on filters.	**R**
	ZIP & HYDRO Units	These were found to be contaminated and are required to be disinfected and tested to demonstrate safe water delivery.	**R**

Service	Comment	Remedial Work	RAG
General (no specific topic)			Items individually rated.
	Information missing	Provide missing information as per information request sheet(s). (1) Water Safety Policy (2) Water Safety plan (3) System of Control (4) PPM Schedule (5) Hydro-X sample results with dated timeline (6) Flushing Records (7) Temperature Records (8) Sentinel Temperature Results (9) Kemper System Maintenance schedule and records (10) Flushing records for taps pre June 2019 (11) Expansion Vessel management protocol (12) Arjo bath commissioning records and results	Status may change depending on information provided and review.
	Callidus compliance report, May 2019	This audit has returned a RED status. A schedule, program of completion for each identified item and demonstration mechanism is required.	**R**
	Roof plant room	Water leaks should be traced and appropriate remedial action taken.	A

Drainage:

Service	Comment	Remedial Work	RAG
Drainage			**A**
	Sinks drains	Initial testing indicates that these are not significantly contaminated, however they need to be disinfected periodically prior to and post occupancy to maintain their condition. Suggest utilising the Hysan methodology being employed at QEUH and RCH Glasgow.	**A**
	Bottle traps	There would appear to be an inconsistency of installation and potential of back-feed from trap to drain. This requires review.	**A**
	Trough Sinks	The drains in trough sinks have been identified as high risk potential. This requires review and treatment strategy considered.	**A**
	Pumped Drainage	The Rainwater drainage system presents the potential for flooding on pump failure and requires review.	Information awaited

Ventilation:

Service	Comment	Remedial Work	RAG
Ventilation (general)			Items individually rated.
	Air Handling Units (AHU)	Confirm AHU comply with the requirements of SHTM 03-01, including fan change, filter bypass, air leakage etc.	Information awaited
	External doors to plant rooms	Ensure that excessive gaps are removed and appropriate anti vermin measures are applied to all the doors and screens.	**A**
	Air intake location - Air intakes are sited in the well below the helipad but information has not been provided on the impact of downdraft on air flows and pressures or entrainment of contaminants.	Demonstrate the effect of helicopter landing on air flows through measurement or modelling.	**R**
Ventilation (Isolation rooms and the areas containing them)	Isolation rooms are not served by a single ventilation system for each room as recommended in SHPN4 Supplement 1. The arrangement provided where ventilation systems serve an area of the building including contained isolation rooms has not yet been proven in the event of failure of an air handling unit and the implications for service impact are not yet understood.	Prove that bypass connections to adjacent ventilation systems will allow safe operation of both areas and / or explain service provision strategy for loss of each area including isolation rooms.	**R**

Service	Comment	Remedial Action	RAG
Ventilation Theatres	The ability of the single high level extract of linear scrub rooms should be demonstrated or additional low level ventilation provided.	Show that mixing and extract in scrub rooms effectively prevents contaminants being dispersed into theatres or provide additional extract.	R
	Anaesthetic rooms 31 and 34 do not demonstrate a clean air flow path to reduce exposure of staff to gasses.	Move ceiling supply to opposite side of room from extract. In room 30, move supply away from door.	A
	Theatre utility rooms Extract ventilation means theatres have to be used in pairs and taking a theatre out of service reduces extract in utility room too low.	Add supplementary extract ventilation to allow for one theatre being out of service or demonstrate resilience following the loss of a pair of theatres.	A
	Theatre corridor extract and pressure differentials do not comply with requirements.	Modify theatre corridor ventilation to comply and test and commission.	R
	Provision for maintenance without unnecessarily affecting service appears poor.	For each area, the Board should have the maintenance and failure contingencies mapped and agreement of clinical colleagues for the expected impact on room availability.	A
	Fire dampers in some locations cannot be adequately tested as duct access has not been provided. Also, locations of fire dampers and fire rated ductwork has been questioned.	Provide access so all fire dampers can be readily visually inspected to verify operation. Review fire damper provision and fire rated ductwork and confirm appropriate provision.	A

Service	Comment	Remedial Action	RAG
	On inspection the ventilation systems throughout the building had clearly not been snagged and were not ready for validation or operation.	A full snagging of the ventilation systems should be undertaken and rectification put in place. E.G. air handling unit leaks, filter bypass, dust in AHUs and ductwork, missing duct access, firestopping, fire dampers.	R

Systems not yet tested:

Service	Comment	Remedial Action	RAG
Electrical	Not inspected yet due to priority put on water, ventilation and drainage.		
Fire	Not inspected yet due to priority put on water, ventilation and drainage.		
Medical Gasses	Not inspected yet due to priority put on water, ventilation and drainage.		

END.

The Royal Hospital for Children and Young People and Department of Clinical Neurosciences (RHCYP & DCN) is a new development in Edinburgh's BioQuarter Campus adjacent to the Royal Infirmary of Edinburgh. Construction, commissioning and formal handover to NHS Lothian is complete, but prior to occupancy and commencement of clinical operations, NHS Lothian were keen to confirm the bacteriological safety of the water supplied from the domestic systems within the building. Westfield Caledonian were commissioned therefore to carry out a series of tests, to both quantify the risk of infection specifically from *Pseudomonas aeruginosa* in augmented care areas, and to assess the bacteriological load within the domestic systems generally. These works were carried out between 1st and 12th July 2019, by Westfield Caledonian's John Bryson and Ross Findlay.

From initial discussions with NHS Lothian Director of Estates, Mr George Curley, and subsequent discussions with the NHS Lothian Commissioning Manager and Infection Prevention and Control Team representatives, the following three scopes were agreed;

1. As a result of revised HPS Guidance issued in August 2018, and the belief held by the NHS Lothian IPC Team that the presence of *Pseudomonas aeruginosa* at outlets in augmented care areas presents a significant risk of HAIs, we undertook to carry out the routine sampling described in the HPS Guidance. Specifically, this involved retrieving a single, Pre-flush sample from each outlet in the augmented care areas identified by the IPCT, for subsequent analysis specifically for the organism *Pseudomonas aeruginosa*.

2. To assess the overall bacteriological load on the water within the distribution systems, a schedule of sample locations was derived for sampling and subsequent analyses. The schedule was to be concentrated on un-tempered hot and cold outlets, although a number of thermostatically mixed outlets were to be sampled from to ascertain the impact these components were having on the bacteriological safety of the discharged water.

3. The final component of the scopes was initially open ended, as it was to carry out further investigative sampling and inspection, the extent of which would be dependent on the results deriving from the initial two components.

Scope Limitations

Although any deficiencies or omissions observed are reported in this document, it should be noted that the agreed scopes did not involve the inspection or assessment of any plant items, the assessment of applied operating practices or control strategies, or a review of the currently applied water safety control measures. All these aspects should be addressed by a suitable and sufficient risk assessment carried out in accordance with BS 8580-1:2019 “Water quality. Risk assessments for Legionella control. Code of practice”.

The Scopes were applicable to the domestic systems serving patient care areas. No cognisance of supplementary systems (Laboratory and Irrigation systems) was made.

3.1 Pseudomonas Aeruginosa

A total of 580 outlets were sampled from within the designated augmented care areas, and subsequently analysed specifically for the organism *Pseudomonas aeruginosa*. A total of 56 samples returned positive results for the organism, around 10% of those sampled. However, the vast majority of the positives were returned from two specific locations, namely the Paediatric Medical Inpatients (3-C1.1) and the DCN Inpatients (2-L2) areas. The schedule overleaf summarises the analyses results by sampled location, together with an overview of the type of outlets which returned the positives.

A review of these results, in conjunction with the water distribution drawings, indicated that these two areas were in fact supplied from the same riser (M2) with very little contamination being evident in the outlets supplied from the other risers in the building (which supply the augmented care areas). Whilst this observation may suggest that the riser is a common factor for the areas of contamination, the subsequent "System Condition" testing carried out throughout the building and discussed elsewhere in this report, do not suggest that this riser displays any less satisfactory hygienic characteristics than other parts of the distribution systems.

Whilst a number of shower outlets, and most of the Zip drinking water dispensers and Arjo baths sampled from returned positive *Pseudomonas aeruginosa* results, it was noted that the majority of positives derived from Markwik 21 thermostatic mixing taps. Interestingly, not a single one of the many Contour thermostatic taps sampled from returned positive results. It is clear therefore that where the *Pseudomonas aeruginosa* contamination was present, the Markwik taps seemed to be particularly prone to colonisation.

It was also noted that all the Arjo baths tested, and most of the Zip Hydrotap outlets, returned unsatisfactory results. Both these types of machines are known to be particularly prone to internal bacteriological colonisation, and as such require the implementation of specific and rigorous internal hygienic maintenance activities. It is our experience that Zip Hydrotaps are particularly prone to colonisation by *Pseudomonas aeruginosa.*

Paediatric Medical Inpatients (3-C1.1)
No. of Outlets sampled – 84
Outlets Ps.ae. Positive – 20 (24%), of which,
Showers; 4
Hot via TMV (push-button); 1
Cold (push-button); 1
Markwick 21 taps; 11
Zip Hydrotaps; 1
Arjo Bath; 2 (both outlets same bath)

Neuroscience Outpatients (3-C1.3)
No. of Outlets sampled – 45
Outlets Ps.ae. Positive – 1 of which,
Arjo Bath; 1

Haematology Oncology (3-C1.4)
No. of Outlets sampled – 100
Outlets Ps.ae. Positive – 1 of which,
Arjo Bath; 1

DCN Inpatients (2-L2)
No. of Outlets sampled – 170
Outlets Ps.ae. Positive – 31 (18%), of which,
Showers; 4
Hot via TMV (push-button); 3
Markwick 21 taps; 21
Untempered Hot; 1
Arjo Bath; 2 (both outlets same bath)

Paediatric Intensive Care Unit HDU (1-B1)
No. of Outlets sampled – 72
Outlets Ps.ae. Positive – 0

DCN Acute Care (1-L1)
No. of Outlets sampled – 90
Outlets Ps.ae. Positive – 2 of which,
Pantry Sink Mixer; 1
Zip Hydrotap; 1

Clinical Research – Isolation room(s) (1-H2 rooms 18,21,22,23 &24)
No. of Outlets sampled – 7
Outlets Ps.ae. Positive – 0

Plastic Dressings Clinic (1-D7)
No. of Outlets sampled – 8
Outlets Ps.ae. Positive – 0

CAMHS – Isolation room (G-A2 rooms 72,73.74)
No. of Outlets sampled – 4
Outlets Ps.ae. Positive – 1 of which,
Markwick21 tap; 1

3.2 System Condition Testing

To form a view on the overall microbiological loading within the domestic systems, an outlet sampling schedule was implemented. The cold water distribution systems within these premises is of the venturi flow-splitter circulating type, whose design intent is to ensure cold water flow to as-close-as-practical to the supplied outlet, regardless of outlet usage. To facilitate flow during periods of low usage, or elevated system temperatures, each subordinate distribution component is terminated at a dump valve, whose operation will artificially induce flow through all system pipework sections. Each of these subordinate distribution systems were identified and samples retrieved from as close as possible to the end-of-line dump point. To establish the microbiological load on the distribution systems, without the results being compromised by the thermostatic mixing process, where possible samples were retrieved from un-tempered hot outlets and cold taps. The predominance of thermostatic mixing taps on the site means that un-tempered hot and cold outlets were typically only found in the Dirty Utility Rooms and DSRs, which were not always located near the end of the distribution line. However, it is considered the implemented sampling schedule provided a good indication in respect of the microbiological safety of the water within the distribution systems. Samples were also retrieved from mixed outlets at the end of lines.

A total of 198 samples were retrieved for this purpose, and subsequently analysed for the 2 Day (37°C) and 3 Day (22°C) TVC, coliforms, *E.coli* and *Pseudomonas aeruginosa*. Samples were also retrieved from 33 outlets and specifically analysed for the presence of Legionella. Typically, these were retrieved from end-of-line showers. The observations arising from a review of these results, are summarised overleaf.

- Neither coliforms or *E.coli* were isolated in any of the samples retrieved.

- At the time of writing, none of the Legionella samples returned positive results. (Full results not available until 22nd July 2019).

- All un-tempered hot outlets returned very low TVC results, particularly where Post-flush samples were taken. Given that the vast majority of hot outlets almost immediately discharged water in excess of 60°C, this is unsurprising, and confirms the effectiveness of the thermal control regime applied to the hot water distribution system. Where this observation was not the case, was where unsatisfactorily low hot water supply temperatures were noted, and this is further discussed in Section 3.4 of this report.

- Generally, un-tempered cold outlets returned satisfactory TVC analysis results on Post-flush samples (typically after one minute of flushing), although a notable number of outlets returned very high TVC results where Pre-flush samples were retrieved. This tends to confirm the general bacteriological safety of the water in the distribution systems (including from Riser M2), but suggests there may be elements of system deterioration between the tertiary return point and the outlets themselves.

- All Pre-flush samples from thermostatically mixed outlets returned elevated TVC results, although it should be noted that Pre-flush samples were only retrieved in the augmented care areas. Post-flush TVC levels were generally found to be satisfactory, although a number did return elevated TVC results. Again, this tends to suggest that there is no systemic contamination in the hot and cold supplies to these outlets, but that local contamination, including between the tertiary return points and the outlets themselves, is present.

- TVC analysis results from all tested Zip Hydrotap machines and Arjo baths were very unsatisfactory.

3.1 Investigative Sampling

Given the high number of positives for *Pseudomonas aeruginosa* recovered from the DCN Inpatients and Paediatric Medical Inpatients areas, and the apparent absence of the contamination in the hot and cold distribution systems, further investigative sampling was carried out to confirm this latter assertion and identify consistent possible sources of the contamination. The strategy applied was to select four of the outlets which returned high concentrations of the organism and sequentially sample from the outlet supply, and subsequent locations to the point of discharge.

All tests were carried out with no flushing of the outlet. Firstly, the tertiary return temperatures were measured on both the hot and cold supplies to each outlet. Secondly, the interconnecting pipework between the hot and cold supply service valves and outlets themselves was removed, and samples retrieved from each of the hot and cold supplies, taking care to sanitise "non-system" components of the sample point which the discharged water may come into contact with. The supplying pipework was then reinstated, and the filter/NRV assemblies were removed from each of the hot and cold sides of the Markwik tap. Again, care was taken to sanitise the non-contact components, and samples were retrieved from the hot and cold inlets to the tap. The detachable spout was then removed, and a fifth sample was taken by operating the tap and retrieving the water discharged directly from the thermostatic mixing valve. Finally, the spout was reinstated and an initial discharge sample was retrieved from the outlet.

In respect of the circulating systems, the range of the hot tertiary returns measured was 56.4°C to 60.7°C, and for the cold circulating system, temperatures ranged from 15.9°C to 19.5°C. Although our preference would be to have hot water circulation closer to 60°C, the hot temperatures may be considered satisfactory, and given all cold temperatures were noted to be below 20°C, again, no operational issues were perceived at the four tested outlets.

The sample analysis results for this exercise are given in full in an attachment to this report, but Figure 1 overleaf summarises the results for ease of interpretation. It can be seen that there was no *Pseudomonas aeruginosa* in either the hot or cold water supply systems to the outlet. It can also be seen that the general bacteriological load on the hot water supply was extremely low, which may be expected given the elevated temperatures being circulated to the test points.

However, high TVC results were returned from the samples retrieved from the cold water supply to the outlet, and whilst the temperatures recorded suggest that water circulation was occurring to the test points, a degree of microbiological contamination was evident in the supply system. At the hot inlet barrel to the TMV, no *Pseudomonas* was detected at three of the four tested taps, although a single colony was isolated in the fourth sample. The TVC of bacteria in three of the four samples was slightly elevated, although very low counts were recorded from the first location, which had the hot water return temperature recorded at greater than 60°C. At the cold inlet to the TMV for each tap, high TVCs were returned, which was consistent with the result of the sample taken from the supplying section. There was however evidence of *Pseudomonas aeruginosa* contamination at three of the tested outlets, albeit in fairly low concentrations.

Pseudomonas was detected in all four samples retrieved from the TMV discharge (with spout removed), generally at very high concentrations. Very high TVCs were also recorded confirming a very poor hygienic condition of the components between the inlet to the tap and the TMV outlet. Similarly, *Pseudomonas* was detected in all four samples taken from the Markwik tap once the spout had been reinstated, albeit at slightly lower concentrations. However, this latter observation may purely be a result of the 250ml which had been flushed out to retrieve the previous sample.

These analysis results suggest the following:

- There is no evidence of *Pseudomonas aeruginosa* contamination within the hot or cold distribution system.

- There is however sufficient evidence to suggest an unsatisfactory high microbiological loading on the cold water supply system (all from the M2 riser).

- The thermostatic mixing components of the tap are clearly the source of the *Pseudomonas aeruginosa* colonisation.

- Contaminant (biofilm) creep is beginning to occur from the thermostatic control components back into the hot and cold water supply lines.

3.4 Other Observations

As has been noted in the Scope Limitations section of this report, these works did not include any inspection or assessment of components, reviews of operational practices or control strategies, or of currently applied control measures. However, as part of the investigative works carried out subsequent to the main sampling exercise, a number of observations arose which it is considered will have an impact on the bacteriological safety of the water supplied to the outlets on these premises.

In-line Strainers

In August 2018 Westfield Caledonian were asked to comment on the proposed methodology for carrying out a system disinfection during commissioning of these systems. One of the observations made was that the methodology should include the removal and cleaning of all in-line strainers which are invariably provided to protect the components of thermostatic mixing devices.

All thermostatic mixing valves and Markwik 21 thermostatic taps are provided with integral strainers at both the hot and cold inlets, whilst the Contour thermostatic taps are provided with in-line strainers on the hot and cold supply lines to the outlets. Whilst no shower thermostatic valves or TMVs (difficult access) were accessed, the integral strainers fitted to the four Markwik taps which were subjected to the investigative sampling, and the in-line strainers supplying a number of Contour taps, were accessed and inspected. Some illustrations of the conditions found are given overleaf, and it can be seen that all strainers were found to be subject to some degree of contaminant retention, ranging from very little to substantial. It is considered very unlikely that the observed contaminants have arisen since the commissioning process, and it would appear that either the necessary cleaning and removal was not carried out at the appropriate point of the commissioning process, or the works were ineffective.

Whilst the observed contamination cannot be identified as the cause of the *Pseudomonas aeruginosa* contamination which was evident at a significant number of outlets, it is clear the conditions are not conducive to maintaining the bacteriological safety of the discharged water, and this will require remediation.

Circulating Temperatures

Each cold outlet (and thermostatic control device cold inlet) is supplied by a flow and return arrangement on the cold water distribution system. Flow through the pipework is induced by flow-splitter valves which utilise the venturi effect to induce flow through the tertiary loop, when flow occurs in the main supply line. When turnover through the cold distribution system section is low, and/or temperatures exceed a pre-set value (usually 20°C or less), automatic controls should activate an end-of-line dump valve, which will simulate flow through the all components of the system and dump the water until end-of-line temperatures below the set point are achieved. During these works, the majority of end-of-line cold tertiary loop return temperatures were recorded, and generally found to be below 20°C. There were a number of occasions however when unsatisfactorily high temperatures were noted, with one end-of-line cold outlet discharging water in excess of 25°C for several minutes.

Similarly, un-tempered hot outlets generally discharged water in excess of 60°C, within a few seconds of operation, and always within one minute of flushing. Again however there were a number of un-tempered extremity outlets, or thermostatic tap inlets, where temperatures below 55°C were noted.

Current guidance suggests that hot water return temperatures should be measured and recorded as an ongoing control measure (at varying frequencies for principal, subordinate and tertiary loops) and it is assumed that the current FM provider on the site has such a programme in place for both the hot and cold systems. However, our observations suggest that the frequency, or tested locations, require to be reviewed, as there are clearly a number of areas where unsatisfactory circulation is occurring.

Hot and Cold Inlet Barrels to Markwik Thermostatic Taps Provided With Filter and NRV Cartridges

Hot and Cold Supplies to Contour Taps Provided With In-line Strainers

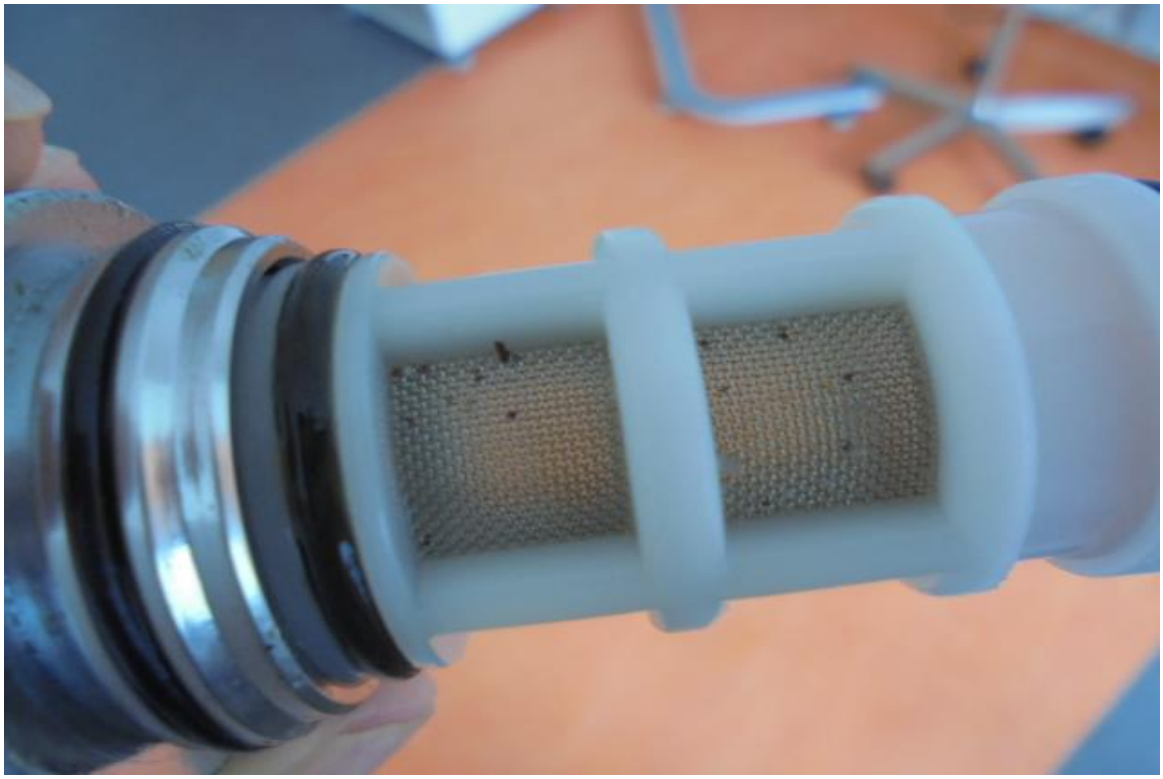

Illustration of Slight Particulate Accumulation on Markwik Inlet Strainer

Further Illustration of Minor Particulate Accumulation on Markwik Inlet Filter

Fairly Extensive Contamination Observed on Markwik Inlet Filter

Installation Debris Accumulation on Markwik Inlet Filter

Minor Accumulation on Contour In-line Strainer

Installation Debris Retained in Contour In-line Strainer

Significant Oxidation Contamination on Contour In-line Strainer

Substantial Debris Accumulation on Contour In-line Strainer

Low Hot Water Supply Temperature to Markwik Inlet

Hot Water Supply from Untempered Outlet Too Low

Elevated Cold Water Supply Temperature Recorded at End-of-Line Outlet

From review of the findings from all three scopes, the following conclusions have been drawn:

1. There is nothing to suggest that *Pseudomonas aeruginosa* contamination is systemic, and that both the hot and cold distribution systems are free from the contamination.

2. General bacteriological contamination of the DHWS distribution system was consistently low, and large sections of the CWS distribution systems also returned satisfactory bacteriological analysis results. However, there is sufficient evidence to suggest that localised general microbiological contamination is present in the CWS distribution system, and that system disinfection would be a prudent pre-occupancy control measure to implement.

3. Where *Pseudomonas aeruginosa* outlet contamination was identified, it was further confirmed that the source of the contamination is specifically the thermostatic mixing components, and that specific remediation activities require to be carried out at all these components. This should include all Markwik 21 taps, all shower thermostatic valves, and all remote thermostatic mixing valves.

4. Appropriate post-commissioning strainer decontamination has not been carried out (effectively) resulting in significant retained contaminants in these components. The above remediation maintenance for all thermostatic outlets should include the removal and cleaning, or replacing where corrosion is evident, of all in-line and integral strainers.

5. End-of-line tertiary return temperature measurements suggest that a number of areas are not achieving satisfactory circulation (both hot and cold).

From the previously described Findings and Conclusions, the following recommendations are made;

5.1 Remedial

- All Markwik 21 taps, shower thermostatic valves, and remote thermostatic mixing valves should be fully serviced and decontaminated. This should include the removal and cleaning of all integral strainers, and decontamination of the Markwik taps by utilisation of the thermal disinfection bypass tappings. The Markwiks can also be autoclaved to kill any microbiological contaminants, but the flushing process has the added benefit of being more effective at dislodging biofilm. In-line strainers on the supplies to all Contour taps should also be removed and cleaned or replaced.

- Although large sections of the CWS distribution system was found to supply bacteriologically safe water, a sufficient number of poor TVC results were returned to suggest that some sections may be hygienically compromised. Furthermore, given it had been in excess of six months since the post-commissioning disinfection of these systems, a pre-occupancy disinfection of all system components would be prudent, and consistent with good practice. It is recommended therefore that, on completion of the above described remediation works, a full system disinfection is carried out, ideally utilising a control agent which is known to be effective against biofilms.

- The Zip Hydrotap and Arjo bath service companies should be advised of the unsatisfactory results, and asked to carry out the appropriate remediation works specific to these machines. The should also be asked provide sanitising procedures and frequencies for approval.

5.2 Control Measures

A review of the currently applied Water Safety Plan should be carried out to ensure the following activities are effectively carried out.

- Six-monthly routine sampling specifically for *Pseudomonas aeruginosa* should be carried out on all outlets within augmented care areas. This testing should be in addition to the return-to-service testing decreed by the current HPS Guidance for outlets where positive results have already occurred.

- A review of return temperature monitoring frequencies and locations should be carried out to ensure that ***all*** hot and cold subordinate and tertiary return loops are tested at the appropriate frequency.

- All thermostatic outlets should be maintained in accordance with the manufacturers' guidance as a minimum, but at least be subjected to annual servicing and decontamination activities. This should include the disinfection (by TMV bypass or autoclaving), of the Markwik taps and the removal of all in-line and integral strainers.

RHCYP & DCN Sampling Locations and Ananlysis Results - 1st July - 11th July 2019

IPCT response to Westfield Caledonian Water Safety Report: 19th July 2019

Lindsay Guthrie (Lead IPCN) Dr Donald Inverarity (Consultant Microbiologist & Lead ICD)

General comment

- NHS Lothian water safety group should be provided with a copy of the Hard FM water management plan for RHCYP as a matter of priority – this will provide further detail and assurance regarding control measures for Legionella.
- The provider should also confirm in this plan their approach to water management in relation to Pseudomonas aeruginosa in augmented care areas – as per HPS interim guidance (2018).
- The scope of the external review is limited only to augmented care areas – which includes Critical care, neonatal unit, haematology oncology, medical ward (Cystic Fibrosis and immunocompromised patients), plastics dressing clinic, and Neurosurgery (local definition adopted by NHS Lothian)
- The recommendations made in the report are specific to augmented care and protecting vulnerable patients. Based on experience from other NHS Boards, it would be prudent to adopt the recommendations to protect the plumbing system from ongoing seeding and compromise future water quality across the site
- It is reassuring that paediatric intensive care, haematology oncology are relatively unaffected by water quality issues
- Some anti-ligature taps are affected by Pseudomonas – need to confirm if these outlets will support use of PAL point of use filters (one of the key control measures going forwards) and explore other options if required
- Shower hose length needs to be reviewed – direct contact between the shower head and floor drain is currently possible (risk of contamination) (identified by HPS on site visit)
- Drainage was not considered within the scope of this review – at this stage, the impact of any drainage issues on the site on water delivery or quality is unknown

Table 1: Water quality issues

Page	Issue identified in report	Infection risk	Other clinical risk	Other organisational risk	NHS Lothian AE(Water) comment
1	The augmented care areas which test positive for Pseudomonas aeruginosa , these are predominantly within Dalhousie Ward (Medical Paediatric In patients) and Ward 231 (Adult Medical Neurology) Positive outlets are linked to the same riser (M2). Issues identified are localised to the outlets, and not the wider water distribution system	Risk of Pseudomonas infection (patients) through exposure to contaminated water if corrective action not taken. **Higher risk associated with Dalhousie ward – Cystic fibrosis patients will be cared for in this area – there is a risk of lung infection with recognised mortality** Risk of recurrent positive water results from these locations.	Whilst outlets test positive, there is an impact on service delivery – these outlets will be taken out of use to complete remedial work and further testing	Clarity required in relation to costs associated with water testing and remedial actions – and who will cover cost. Ongoing costs associated with regular water testing (external provider) and remedial actions to address issues If autoclaving of taps considered – costs associated with external sterilisation service and costs to increase stock of taps to facilitate turnaround time	
1	ARJO baths – all baths tested were positive for Pseudomonas and overall TVC counts were high. This includes the bath in Haematology-Oncology unit	These baths are known to be a Pseudomonas risk. Even with a cleaning and maintenance schedule, our view is these pose an unacceptable risk of invasive Pseudomonas infection to vulnerable patients from this equipment.	Pseudomonas aeruginosa readily becomes resistant to antimicrobials and a persisting environmental source of this organism in a clinical area with high antimicrobial consumption may adversely impact on	Cost pressure associated with replacement or removal of ARJO baths from some/all areas Financial and human cost of an outbreak of Pseudomonas infection	

Page	Issue identified in report	Infection risk	Other clinical risk	Other organisational risk	NHS Lothian AE(Water) comment
		It should be considered that ARJO baths in non augmented care areas (e.g. surgical wards) would pose a similar risk of infection to all patients with wounds or invasive devices	antimicrobial stewardship and treatment efficacy.	Reputational damage and potential for litigation	
1 4	The majority of Zip hydro taps (water for consumption) tested positive for Pseudomonas. This tap is known to be prone to colonisation ZIP taps demonstrated unacceptably high total viable counts (TVC) – i.e. poor drinking water quality	Whilst this does not pose a risk to patients through clinical exposure, there is a risk of retrograde seeding of Pseudomonas to other pipe work and water supply within the building			
4	System condition testing demonstrated that overall the bacteriological quality of water was satisfactory – need clarity from the AE on the statement that there may be system deterioration between	Infection risk from water supply at present is localised to specific areas (Dalhousie, Ward 231, ARJO baths) - in the absence of effective control there is a risk of retrograde seeding of		Impact on service delivery if water outlets removed from use to facilitate decontamination/disinfection	

Page	Issue identified in report	Infection risk	Other clinical risk	Other organisational risk	NHS Lothian AE(Water) comment
	tertiary return point and outlets The overall point being made is contamination is occurring local to the water outlets, not from the wider water system	Pseudomonas to other pipe work and water supply within the building			
6	Unsatisfactory microbiological load on the cold water supply (M2 riser) – this is associated with the presence of Pseudomonas in multiple outlets provided off this riser. There is evidence of biofilm creep back into hot and cold water supply	There is a risk of seeding of bacteria affecting other floors fed by this riser. This may translate into clinical infection through exposure to water as part of clinical care in areas outwith Dalhousie or Ward 231		Impact on service delivery if water outlets removed from use to facilitate decontamination/disinfection	
8	Evidence of particulate contamination in tap strainers	*"Current conditions are not conducive to maintaining the bacteriological safety of the discharged water, and this will require remediation"* Particulate matter will support growth of biofilm within water systems		"*it is considered very unlikely that the observed contamination have arisen since the commissioning process, and* ***it would appear that either the necessary cleaning and removal was not carried out at the appropriate point of the commissioning process****, or the works were ineffective*"	

Page	Issue identified in report	Infection risk	Other clinical risk	Other organisational risk	NHS Lothian AE(Water) comment
9	Issues with water temperature control Cold water temperatures were identified in excess of 20° C Hot water was identified below 55°C	Inadequate temperature control of hot and cold water will facilitate growth of Legionella – this is a risk to patients, staff and the wider public		Non compliance with Risk of litigation from non compliance with HSE (2013) 'The control of Legionella bacteria in water systems approved code of practice ' if a hospital associated case identified	

Compliance Audit

Royal Hospital for Children and Young People, Edinburgh

With Findings and Recommendations

Date: May 2019

Contents

1. Executive Summary

On a project of this size there will always be teething problems and issues that arise, so it is important that stakeholders work in partnership to address any issues that may come to the fore, and it was great to see the close relationship between NHSL site team and the FM provider team. I wish to express my thanks for the cooperation and hospitality shown during my visit by Ronnie Henderson (NHSL), Richard Hair and David Gordon (Bouygues); this was extremely helpful in allowing me to conduct the audit in an effective manner. It is important to note that each of the Bouygues staff the author encountered and interacted with during this site visits were professional and helpful.

This report was compiled following site visits to the Royal Hospital for Children and Young People (RHCYP), Edinburgh on 21st, 22nd March and 25th, 26th April and many of the items identified in the Simple Compliance audit will be repeated here but many wont, and this report is designed to give the client a high-level view of findings on site.

Observations were made during the assessment and walk about in areas of the Hospital and Energy Centre with several comments being made under each relevant section within the report, to ensure that the health and safety responsibilities of Bouygues, as Hard FM Provider and IHSL, as SPV are being discharged adequately and the significant key areas identified which should be addressed. We also carried out an audit whilst on site using our online portal "Simple Compliance" (SC) which records findings against pre-set questions and automatically provides actions to the providers for noncompliance items. The SC audit was published on 27th March. In addition, a summary of recommendations and corrective actions is included at Section 6 of this report.

IHS Lothian Ltd (IHSL) the SPV were invited to attend the initial introductory meeting, site walk round and requested to demonstrate compliance and monitoring information however, whilst they attended the introductory meeting and walk round, they have suggested the interface agreement between Bouygues and Multiplex should be utilised for the provision of information requested from the SPV. The SPV provided access to an online portal to view Multiplex documentation however, this information was a library of PDF files that were numbered and not named so it was difficult to navigate when looking for specific documents and not useful. On publishing the Simple Compliance audit IHSL contacted Callidus and requested face to face meetings to discuss the online audit and the information requested for this report. On several occasions IHSL raised concerns regards the timing of this audit as there were still a large amount of construction works being completed under the "Settlement Agreement". The author felt it was prevalent to discuss the partnership and innovative approach commissioned by NHSL however, the SPV did not agree with the authors view and stated that partnership is always practiced on this Contract.

The FM provider, Bouygues, embraced the audit and whilst supporting requests for information they demonstrated excellent compliance knowledge and as previous, have a very good relationships with the Client, NHSL.

In summary, we found the management arrangements on the contract required development to such a degree to categorise the assessment as RED (as defined below). The contract has

only been live now for a short period of just over two months. It is reported that the site was handed over to NHS Lothian under a “Settlement Agreement” where there are still construction works going on and ownership of areas under health & safety, compliance and maintenance are split between the Hard FM Provider and Construction Co, so not all areas have been passed over to Bouygues. Bouygues demonstrated they are managing the areas handed over to them with a mix of in-house engineers and contractors carrying out maintenance on the site.

	Unsatisfactory, Significant Improvements Needed	Health and safety control measures are not functioning as designed and/or will have a material impact on both statutory compliance and/or contractual obligations. Health and safety control measures are lacking or have degraded since the last audit and is a contributing factor to non-compliance. Immediate management actions need to be taken to address the deficiencies noted, (Project Co & NHSL is currently considered to be at risk).

2. Introduction

The purpose of the assessment visit was to focus on the positive elements of the health and safety management arrangements of the organisation. There was an element of compliance evidence checking however, the main objective was to identify evidence of arrangements underpinning the safety management system and how individuals at all levels within the organisations integrate safety into the day to day operations of the project.

The purpose of the report is to concisely present an overview of the findings of the assessment visit for areas where access was permitted, and evidence demonstrated.

During our visits we reviewed a few examples of management system arrangements and contract documentation. No commercially sensitive (project related) information was taken, although the report may refer to specifics as evidence of industry best practice.

The contents of this report should not be construed as acceptance that the organisation is fully compliant with all existing legislation, as only a representative sample of areas available and evidence was examined.

The following indicates some of the applicable, legislation, standards, guidance and contract documentation which have relevance to the subject areas assessed:

		Applicable areas to NHSL							
		H&S Management	Contractor Management	Statutory Compliance	Fire and Emergency Planning	Legionella	Asbestos	Performance Monitoring	Training
Reference	Project Agreement	●	●	●	●	●		●	●
	Management of Health and Safety at Work Regulations 1999	●	●	●	●			●	●
	COSHH Regulations 2002			●					●
	Electricity at Work Regulations 1989			●					
	Regulatory Reform (Fire Safety) Order 2005				●				●
	LOLER Regulations 1998			●					
	PUWER Regulations 1998			●					
	Work at Height Regulations 2005	●	●	●					
	ACOP (L8) – Control of Legionella in Water Systems			●		●			
	Control of Asbestos Regulations						●		

Note: This is not an exhaustive list of all applicable legislation, guidance etc on the project.

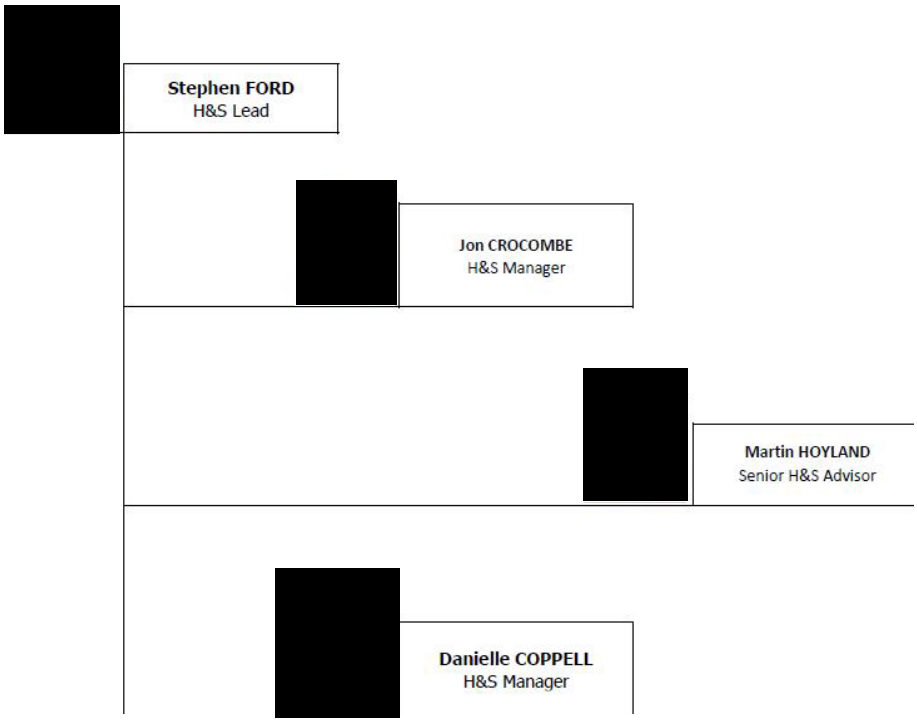
Bouygues FM: Health and Safety (Site Support)



Bouygues: Health and Safety Organogram – Appendix B

4. Review of previous SHE Assessment

This site only handed over to NHSL, under a Settlement Agreement to allow IHSL to complete construction works, in Feb 2019 so there were no previous SHE Assessment's to review.

5. Assessment findings

5.1 Health and Safety Management

Observations:

Health and Safety Management System

The *Royal Hospital for Children and Young People, Edinburgh (RHCYP),* NHSL was handed over on 22nd February 2019 under a Settlement Agreement between *NHS Lothian* and *IHS Lothian Ltd* (SPV), an agreement that allows NHSL take handover of the building whilst construction works and remedials have still to be completed. As a result of ongoing construction works there are areas of building maintenance responsibilities that have not yet been signed off and handed over to the FM provider Bouygues; so much of the Health & Safety information for maintenance visits and first year's defects has still to be done, and for this report information was requested from IHSL and remains outstanding.

We would advise that IHSL have failed to support this audit as we normally expect from an SPV company. Initial requests for information from IHSL were put in writing and IHSL responded asking for face to face meetings. This was discussed at the first available face to face meeting on 25th April where the SPV Deputy General Manager articulated that information should be provided by Multiplex or Bouygues (through their interface agreement) and not through IHSL. Some of the evidence requested was monitoring information however, the SPV representative told the meeting that IHSL do not monitor records. This was discussed during a request that the SPV was monitoring the construction contractor to ensure water flushing was being discharged appropriately but the SPV responded that this would be "duplicating work if they were to monitor". A request was made to IHSL for the following information but to date the SPV has not provided any evidence;

- Assessment of management system documentation
- Review of management structure roles and responsibilities
- Demonstrate how IHSL will ensure SPV Management under the project agreement
- Arrangements identify and address key requirements of the contract
- Assessment of communication and performance monitoring

The Hard FM provider, Bouygues, are still collating their asset list, as packages of work are handed over, and they were able to demonstrate their PPM program covers areas that have been handed over and maintenance works are now in progress. Bouygues report that they will continue to use a number of the construction sub-contractors as specialist maintenance contractors for the first year which will support manufacturers maintenance guidance, awareness and identification of any defects.

Bouygues FM demonstrated excellent evidence of project-specific health and safety management arrangements relating to the activities on site (as required by the Project Agreement). During the audit, we consulted with Bouygues Senior Design Interface & Asset Manager, Richard Hair, who discussed and demonstrated FM health and safety project specific documentation, processes and policy. This was required to be in place upon commencement of the concession period. It is imperative that the health and safety management system is established to provide both the client and FM that on-site arrangements are adequately planned, managed and resourced.

A site walk round with IHSL and Bouygues FM, for familiarisation and visual inspection, highlighted areas for comment and recommendation within this report. These areas were discussed with stakeholders during the walk round.

Areas that were demonstrated included Roles & Responsibilities, Risk Register, General arrangements for managing H&S on the Contract, Competency Matrix for Key Personnel, Control of Contractors, Access to competent H&S advice and arrangements for monitoring and reporting performance and Duty Holder Structure for key activities (Electrical, Water, Fire, Medical Gas, etc), and FM demonstrated compliance for Duty Holder Competence and a very good structure for controlling High Risk Activities (Permit to Work system, AE, AP, CP appointments). Due to the ongoing areas of construction some information e.g. Legionella, was not available, but FM will complete the documentation to meet the compliance structure organogram once the remaining construction areas are completed and signed off.

Once the Compliance Structure is in place, Bouygues FM will have an excellent Management system that will;

- Demonstrate how FM comply with the key requirements of their FM Agreement
- Allow the SPV to monitor performance and provide meaningful reporting to NHSL based on agreed standards
- Allow NHSL to obtain demonstrable evidence of compliance against the Project Agreement
- Provide all parties with reassurance that there is a structure in place which is adequately resourced to manage the risks on site.

Guidance and Documentation

The Bouygues Contract management team demonstrated both H&S qualifications and a very good knowledge of H&S roles and responsibilities on site. They are supported by a central H&S team and Stephen Ford – Health, Safety and Environmental Lead for Bouygues E&S UK Limited, who visits the site monthly and is contactable outside of these planned visits at any time. The FM site team have access to the Bouygues Health and Safety documents on line and have a very good H&S notice board in the main corridor of the FM suite.

The HS&E Team carry out site visits to support staff performance and understanding of H&S documentation and requirements. The Bouygues HS&E team are in regular

contact with site teams to add or improve the H&S information relating to Hard FM activities. Whilst on site we recommend that Bouygues FM refer to specific health sector guidance contained within Scottish Health Technical Memoranda (SHTM) and utilise this guidance when providing FM activities.

Bouygues FM also demonstrated reporting of near misses and use this information to improve processes and information.

It is good to see a process of constant improvement, and whilst the health and safety guidance documentation on site is suitably developed to manage the specific activities undertaken. Guidance had failed to observe there was no provision of rubber matting to the floors at electrical switchgear. (See Appendix E)

Risk Management and Risk Assessment

Bouygues FM demonstrated an excellent library of H&S documentation including Risk Assessments and COSHH Assessments, all relevant to their responsibilities on site.

Bouygues FM demonstrated a proactive approach and documentation to show a good understanding of Risk Assessments and Risk Management. However, due to the Settlement Agreement and the different stakeholders on site there was some confusion regards the quality and risks in the Plant Rooms, who was responsible and the escalation process to drive remedials.

Bouygues FM advised that Plant issues have been raised to IHSL but did not appear to have any progress or completion dates, e.g. requests for Legionella information, Heat Station Plant rooms high temperatures and Heat Station Plant room flooding and humidity.

When discussed IHSL articulated the items identified did not offer any serious risk and reported that Multiplex was working on remedials and reminded that areas of the building were still under construction however, we would recommend that the areas identified do offer a number of risks and the information requested should be made available and shared with NHSL.

We have requested that IHSL support the audit and provide information to demonstrate how IHSL will ensure SPV Management under the project agreement, arrangements to identify and address key requirements of the contract, and assessment of communication and performance monitoring however, IHSL have not provided this information.

Provision of competent advice

Bouygues FM have access to the Bouygues Health, Safety & Environmental Team, a group of competent Advisors, Manager and Director. They are available to the site team by email or phone call and the HS&E Manager visits the site monthly. Through regular communication and programmed site visits they provide a good support structure across the NHS Lothian, (RHCYP) Contract and are delighted to work closely with NHSL and their advisors.

The H&S and compliance information support and feedback from the Bouygues FM site team throughout this audit was very good.

Bouygues FM demonstrated they are supported by external provider's through and were appointed through the procurement process for work tendered by FM.

Corrective Actions Required:

Ref	Findings / Recommendations
5.1.a	HV/LV AE to comment on the lack of rubber matting in electrical Plant areas and offer remedials.
5.1.b	Bouygues FM should report all building issues and self-identified maintenance through the Helpdesk including heat station issues. This provides an excellent tool to demonstrate reporting and provides the client with sight of repairs and issues.
5.1.c	We recommend that IHSL to provide evidence as requested in our Health & Safety Management System paragraphs.
5.1.d	Not used

5.2 Contractor Management

Observations:

Contractor Procurement

Hard FM sub-contractors are Bouygues approved through a strict approval process. A list of sub-contractors is available to the site team and is maintained by the Hard FM procurement team. The site team can request new contractors are added to the list through following the questionnaire process. Any contractors who do not meet the requirements of this process are not taken forward to work for Hard FM.

The contractor's questionnaire is robust with a strict question set that must be met. Contractors are approved through this approval process but also checked by the SHEQ team. The sub-contractor list is with the Hard FM procurement team.

Contractor Control on Site

Hard FM sub-contractors are required to submit RAMS online prior to any works commencing. The RAMS are reviewed by Hard FM staff and sent back to the contractor if not suitable and sufficient, once approved works commence. For PPM works, Bouygues FM informs the client of the works in advance to request access. Bouygues FM reported the client is made aware of who will be completing the works and Bouygues FM control site access, RAMS and any Permits.

Bouygues FM induct all sub-contractor staff before work commences and records are kept in the Hard FM office on site. Contractors are only allowed access to site as controlled by Bouygues FM however, this is complicated by the ongoing construction works.

Under the *Settlement Agreement* IHSL have an agreement where Multiplex are still on-site completing construction works. Although Bouygues FM control Permits for site

areas Multiplex and their contractors were seen to be moving freely around the site. NHSL also have management, Admin and Soft FM staff on site. Requests were made to IHSL for evidence of construction RAMS, Legionella information and how IHSL are performance monitoring but to date no suitable information has been provided.

Permits to Work

Bouygues FM have a Permit office in the FM suite and an excellent library of records to show that Permits are controlled and issued in line with RAMS following a site induction.

Permits are issued to control high risk activities as follows:

- Emergency Light Checks in 2nd floor Plant Room
- Hot Works – Ground floor – floor repairs
- Various others

During the assessment we examined the following Permits to Work.

Ref	Date	Area Covered	Organisation	Comments
006	21/03/19	2nd floor Plant Room	Mercury	Emergency Light Checks
HW005	13/03/19	Hot works - Ground Floor	Xtreme Flooring	Floor repairs

During the assessment, we witnessed the following Contractor Induction Records:

Date	Name	Organisation	Comments
15/03/19	Various	GSS	
11/03/19	Fran Rizzo	Musbury Fabrics	
11/03/19	Gary Ridgewell	RMCH	

Corrective Actions Required:

Ref	Findings / Recommendations
5.2.a	Although areas are controlled through the access control system, we would recommend the site access and control of contractors is tightened up on a daily basis to understand who is on site, where they should be working, what they are doing and timescales for completion, clean work area and checks/signoff.

Ref	Findings / Recommendations
5.2.b	Not used

5.3 Statutory Compliance

Observations:

PPM Systems and Management Arrangements

At present the asset information and PPM process is still being collated as there are areas under the Hard FM Contract that have still to be handed over to the Bouygues FM. This does not yet allow the Hard FM provider to have a complete plan that captures all Statutory, Mandatory, Function Critical and Discretionary assets at the appropriate frequencies however, Bouygues FM were able to demonstrate a good PPM planner that covers the areas they are currently maintaining. This planner is shared with the SPV and client prior to the programme of works commencing. As work packages are agreed, signed off and handed over Bouygues FM will add these to the planner.

Bouygues FM confirmed the PPM planner is still being complied using the asset register following SHTMs and guidance. Bouygues FM acknowledge this is still in progress and is being updated.

The site has only been handed over for a short period so many of the maintenance tasks are planned. During the assessment, the following commissioning records were inspected.

Item	Date	Inspected By	Comments
Gas Booster	15/04/19	Utile	
Passenger Lifts	19/04/19	Zurich	
Damper Control system	31/10/18	Safegard Systems	
Anchor point test	13/06/17	Arjo	
Lightning Protection	19/04/19	PTSG	
Boilers	16/08/18	Bosch	
Generators	26/03/19	Dieselec Thistle	

Corrective Actions Required:

Ref	Findings / Recommendations
5.3.a	We recommend that Bouygues keep NHSL updated as they receive handover of packages and areas of the building regards information, quality and any issues.
5.3.b	Not used

Ref	Findings / Recommendations
5.3.c	Not used

5.4 Fire and Emergency Planning

Observations:

Fire maintenance is part of the Hard FM Contract however, there are areas of ongoing construction works where, its reported, that void detection above bedroom areas was an addition so the Fire maintenance has not yet been fully handed over. Further information was requested from IHSL then again on 25/03/19 from Multiplex but this has still to be provided.

It was observed that the construction contractor is using Energy Centre space to store construction materials. The housekeeping of the construction materials in the boiler house highlighted poor management and several risks including blocking a fire exit, risks from slips trips and falls. (See appendix F)

Fire Risk Strategy and Fire Risk Assessments

*This is a NHS Lothian action and at the time of the audits the Fire Officer (Jim Gardiner) had completed a FRA on 16/07/18 that covered the fit out stage and joint occupancy (commissioning) period. This will be superseded when to Settlement Agreement works are complete and the full building and systems has been handed over ready for patient access.

During the assessment we examined the maintenance records for fire equipment as follows:

Item	Date	Inspected By	Comments
Fire Alarm Quarterly	24/01/19	Boston Networks	
Emergency Lighting	PPM	Bouygues	
Fire Damper (Commissioning)	31/10/18	Safegard Systems	Maintenance by Swegon – to start
Emergency Lighting (Routine)	Monthly PPM	Bouygues	
Fire Extinguisher	Sep 18	Walker Fire	
Fire Door Inspection	PPM	Scotdor	
Fire Strategy	03/09/18	WSP	
Emergency Lighting (Periodic)		NR	

Corrective Actions Required:

Ref	Findings / Recommendations
5.4.a	We recommend that Bouygues keep NHSL updated as they receive handover of the fire detection infrastructure regards information, quality and any issues.

Ref	Findings / Recommendations
5.4.b	NHSL Fire Officer to complete FRA and make available to the SPV and FM provider prior to patient occupation.
5.4.c	Not used
5.4.d	Not used

5.5 Legionella

Observations:

Due to the Settlement Agreement the Legionella completions were still underway and remained with the construction company, Multiplex. A request for information was submitted to IHSL however, no information was provided by IHSL although they did confirm its existence and that Multiplex would supply this information.

Various areas of legionella risk were identified during the site walk round and details recorded later in this report.

In the Simple Compliance audit, all Legionella actions were assigned to the IHSL Project Director, as discussed with the Project Director prior to the audit taking place.

Although water systems have still to be handed over to the Hard FM provider, Bouygues commissioned their specialist contractor, Clira Water Hygiene Specialists, to deliver a Legionella Risk Assessment and Water Hygiene Survey Report which was completed on 21st Feb 19. The survey at that time identifies the overall risk rating for the site as high.

Observations: Main Building

4th Floor Labs

The audit was guided around areas including fourth floor rooms and looked at a section of the Laboratory area. These rooms have flushing sheets present that identify outlets in the room with dates and signatures for flushing however, it was noted that outlets for clinical equipment were not identified on the flushing sheets and were not being flushed. This was discussed with IHSL who advised that as one outlet was on a return loop, the area of "dead leg" was under 100mm and small enough that it did not require being flushed. The author did not agree with this as it was still an outlet and suggested this should be added. In the following room another area of pipework for clinical equipment was identified, this time is was considerably over the 100mm but still was not identified on the flushing sheet. The author suggested this highlighted a risk across this area, and also where outlets for clinical equipment were not being flushed. (See Appendix D)

There are various areas designed as roof courtyards/garden areas where a water supply has been added, during the audit the author requested flushing information for these areas as there was no flushing sheets available in these areas as per the rooms. The author was informed these areas are being flushed and following the meeting on Friday

26th April Multiplex provided evidence of the flushing however, we can report the evidence provided does not follow the same process as the rooms by identifying individual flushing points and we have still not witnessed suitable flushing evidence is available. As Multiplex are unable to provide suitable evidence of flushing to these areas, we recommend this is a non-compliance. We recommend these documents should have been monitored by the IHSL in their role as SPV to ensure compliance.

The author discussed Plant room areas where stand pipes are present and flushing information was not available at the time of the audit. Bouygues FM reported that the construction company have confirmed these areas are being flushed however, evidence has still to be witnessed.

The audit identified that L8 maintenance to shower heads is not currently in practice. IHSL recommend that maintenance of these areas is not required as the "site has been live since 22nd Feb 19 and the maintenance is every six months". We would recommend NHSL request sight of the Multiplex risk assessment we feel the SPV must be referring to as recommended maintenance for showerheads is quarterly. Multiplex articulated that they had disinfected the water system in Sep and Dec 18, then again in Feb 19 so this would negate the need for shower descale, and the SPV agreed with this presumption however, that author does not concur with this as flushing disinfectant through a water system does not meet the required maintenance for descaling showerheads nor does it meet the timescales, but as previous we feel the SPV must be referring to a risk assessment when stating it is a six monthly maintenance and this should be tabled by Multiplex or corrected prior to handover of the water system to the FM provider.

At the time of the audit no access was provided to inspect the internals of water tanks.

IHSL demonstrated multiple copies of testing documentation which they recommend identifies there is currently no water risk. However, we would suggest the flushing regime is not as robust as was first reported and flushing records are not duplicated across all outlets. (See Appendix D)

Scheme of Control

No scheme of control was demonstrated by IHSL.

Bouygues FM demonstrated the named individuals with Legionella Duty Holder responsibilities were: Ian Clark (AE), Alan Herkes (RP), Alan Herkes (CP), David Murphy (CP).

Name	Date Appointed	Duty Holder Role	Letter Issued Y/N
Ian Clark	18/05/18	TA	Certificate
Alan Herkes	04/02/19	AP	Yes
David Murphy	TBC	CP	TBC

During the assessment we requested the following records through IHSL but no documentation has been shared:

Record	Inspected By	Date	Comments
Calorifier Temp Checks			Requested
Water Sampling			Various provided through online portal.
Outlet Flushing		Twice weekly	Rooms have flushing sheets present. Note: some areas were missed e.g. clinical equipment outlets, courtyards, stand pipes.
Shower Descale			Requested, SPV report this is not required.
Outlet Temps			Requested
Quarterly TVC Sampling			Various provided through online portal.
Coliforms Sampling Escherichia coli Sampling			Various provided through online portal.

Corrective Actions Required:

Ref	Findings / Recommendations
5.5.a	IHSL (monitoring Multiplex) to ensure a robust flushing regime that has identified all outlets is in place and reported accurately and reported back to NHSL.
5.5.b	IHSL (managing Construction Co) to demonstrate a safe water system is in place prior to handover of water system maintenance.
5.5.c	IHSL to confirm their duty holder responsibilities for water.
5.5.d	Not used
5.5.e	Not used
5.5.f	Not used

5.6 Building Observations

Observations: Basement Plant Rooms

Heat Station 4

The temperature when entering Heat Station 4 was excessive and we would recommend this is investigated and reported back to NHSL. It was confirmed that air handling to the Plant areas was in operation, so it is unusual to feel the Plant area so hot. The Plant all looked to be insulated and at that time of the audit it was difficult to

identify why the space remained so hot. IHSL were present but did not identify the heat loss as an issue. The heat loss will impact on utility costs.

Heat Station 3

On entering Heat Station 3 we witnessed very hot water discharging from calorifier plant with about 10mm-20mm standing water in the Plant room. There is no mechanical drainage in this Plant room and there has been 100mm holes cored through the block wall to allow water to flow out of the Heat Station Plant room and into the Pneumatic Plant room next door.

We would recommend the design of this Plant room is addressed to identify if a drainage source is required as allowing water to run through a block wall into another Plant area is unacceptable in a new building.
The block wall with the holes cored through it should be investigated to confirm any fire rating has not been compromised. (See Appendix C2)
The Plant room design has the Plant raised off the concrete floor on, what looks like, steel RSJs covered with steel chequered plate. This metal work is showing signs of rusting that would indicate the water has been discharging for considerable time. (See Appendix C1)
During the audit the author was informed by IHSL that Multiplex was “trying to identify” the cause of the water discharging onto the floor and IHSL believe it was because the full building was not in full use however, the author does not agree with this diagnosis and reports it is unacceptable to have this level of flooding in a new building, in an area that has been commissioned.
Due to the heat in this Plant room and the very hot water discharging, the air is humid, and we would recommend that this is a risk as the humid air is drawn through the ducting and Air Handling Plant. We would recommend that IHSL confirm the controls in the Plant room are designed to operate in these conditions for any length of time. We would recommend that these areas are investigated to ascertain what the impact of the humidity is having and what the risks are. (See Appendix C1)

Pneumatic Plant Room

Water was draining through 100mm holes from Heat Station 3 and was ponding on the floor of the Pneumatic Plant room. There is a drainage outlet in this Plant room, but the floor is not raked towards the outlet so the water running from the Heat station must accumulate and pond to a level before water meets the outlet. We would advise that cutting holes through a block wall in a new Plant room to allow water to flow through is unacceptable and we would recommend this is investigated to ascertain why this has happened and what damage the water in the Plant room is causing/has caused. (See Appendix C2)
A computer was sitting to one end of the Plant room on a small desk, the desk was saturated and there was a risk of the moisture meeting the computer. There were also electrical cables behind the desk sitting in water. This was witnessed by all

stakeholders during the walk round. The following day this area was revisited, and as it had not been addressed the author articulated the risks, as there are tradesmen and staff standing in water which is very close to electrical equipment, and the FM Provider moved the PC. (See Appendix C3)

HV/LV Plant Rooms

On inspecting the LV Plant area, it was evident that one of the Transformers in the HV side was generating "load noise" and that it was considerably louder than the other transformers. The author understands that Bouygues AP for HV is monitoring this transformer. We would recommend the manufacturer and installer are asked to advise on the cause and any risk as it is unusual that one of four Transformers is generating such "loud noise".

Rain Water Tank Plant Room

On viewing the rain water tank room is was identified that a waste pipe through the slab from the area above did not appear to have a Fire Collar. Fire Collars were clearly visible to other areas where pipe work was entering through the slab. (See Appendix C4)

Basement Plant Rooms

Many of the basement plant rooms have a small bund wall inside the doorways, prior to accessing plant areas, which also impacts on escape. These walls are not marked up as a hazard to support safe evacuation. As these are the escape routes, we would recommend some form of visual marking is practiced. (See Appendix C5)

Observations: Roof Plant Rooms

Only a small section of roof area plant rooms was inspected with no issues highlighted.

Lifts

It was identified that the condition of the Lifts did not reflect a brand-new building and at the time of the audit the commissioning information was not available for witnessing however, this information was shared at the meeting on Thu 25th April. The SPV articulated that the Lifts were identified for latent defects and were programmed for repair although no completion date for these repairs could be provided.

Observations: Energy Centre

Energy Centre - Boiler Plant Room

The author, with Bouygues FM staff present, identified a strong smell of Gas near the Gas inlet in the Boiler Plant room. Bouygues FM articulated they would follow this up as any smell of Gas is a risk. Bouygues FM later reported that this area was checked with

a Gas sniffer and no leaks were identified. There is Gas Detection is above the boilers (See Appendix G). At the meeting on Fri 26th April we were informed a maintenance visit had identified Gas leaks at each of the boilers which was now being addressed. At that time it was unclear how commissioning and later checks had not identified the Gas leak.

Asbestos

There is a statement by Multiplex to say that there were no materials containing asbestos used in the construction of the site.

Corrective Actions Required:

Ref	Findings / Recommendations
5.6.a	Heat Station 4, recommend heat loss is investigated and reported back to NHSL, by Multiplex
5.6.b	Heat Station 3, recommend discharging water is investigated and rectified with investigation to determine the impact on Plant, gauges and electrical equipment with findings shared with NHSL, by Multiplex
5.6.c	Heat Station 3, recommend the humid air entering the ventilation is investigated and risk assessed and reported back to NHSL by IHSL
5.6.d	Heat Station 3, recommend the Plant Room design and lack of drainage is assessed by Multiplex
5.6.e	IHSL to confirm - Heat Station 3 recommend the cutting of “drainage holes” through the block wall has not impacted on the Fire Rating or integrity of wall.
5.6.f	Heat Station 3, recommend the condition of the Plant base plates is addressed to suit a new Plant Room by Multiplex
5.6.g	Multiplex - recommend HV Plant Room, transformer “load noise” is investigated and report provided to NHSL
5.6.h	Rainwater Tank Plant Room, Fire Collar to be fitted around the white plastic waste pipe by Multiplex
5.6.i	Basement Plant Rooms, Bund Wall to be marked for identification on the escape route by Multiplex
5.6.j	Multiplex - Energy Centre, smell of gas to be investigated and remedials reported back to NHSL.
5.6.k	IHSL to confirm latent defect list and remedial dates for the Lifts
5.6.l	Not used

5.7 Training

Observations:

Training Analysis and Planning

Bouygues FM demonstrated an excellent training matrix and hard copies of certificates. Each member of staff has a training matrix and the level of training and planning is good.

Training Provision, Recording and Relevance of Training Provision

Training can be identified by company policy, line management, SHEQ, at the request of the engineers or as dictated by guidance and it is added to training matrix records.

Roles and responsibilities are clearly defined with support between shift patterns. Ongoing training provision is good, and records are available on site in hard copy and electronically.

Bouygues FM were able to demonstrate that they have a contingency in place to support the site team from engineers in other areas and contractors should support staff ever be required for this contract.

Corrective Actions Required:

Ref	Findings / Recommendations
5.7.a	We would recommend Bouygues share the positive training and contingency information with the Client as it is very positive

5.8 Performance Monitoring

Observations:

Project Level Performance Monitoring

The CAFM System and Helpdesk record performance and this is demonstrated in the client monthly report. Performance monitoring is carried out by the SPV through monthly reporting and monthly meetings but at the time of audit there had been no site audits carried out carried out by the SPV.

Health and Safety Audits

SHEQ have regular visits programmed and are in regular contact with site teams.

At the time of audit there was no SPV audits carried out or programmed.

Director H&S Tours

As these are new sites there has not been a Directors H&S Tour, but this should be programmed and shared with the site.

Ongoing Support from Competent Person

The site teams have ongoing support from the Technical Manager and Line Management above that position.

Other forms of Performance Monitoring

Liaison meetings, Contract Meetings and adhoc meetings take place. The site team are in regular contact with an NHS Lothian point of contact to allow discussions to take place out of programmed dates.

Corrective Actions Required:

Ref	Findings / Recommendations
5.8.a	IHSL should demonstrate that they are discharging their duties as per the Project Agreement
5.8.b	Not used

6. Summary Report

Summary Points

The table below summarises the assessments remedial actions, it is essential that [Service Provider] take these findings and address their legal and contractual obligations in establishing, implementing and maintaining its safety management systems, when identifying hazards, assessing risks and determining controls measures.

Ref	Award	Findings/Recommendations	Target Date	Owner	Closed Date
	Health and Safety Management				
6.1.a		HV/LV AE to comment on the lack of rubber matting in electrical Plant areas and offer remedials.	19/07/ 19	Bouygues	
6.1.b		Bouygues should report all building issues and self-identified maintenance through the Helpdesk including heat station issues. This provides an excellent tool to demonstrate reporting and provides the client with sight of repairs and issues.	31/07/ 19	Bouygues	
6.1.c		We recommend that IHSL to provide evidence as requested in our Health & Safety Management System paragraphs.	31/07/ 19	IHSL	
6.1.d		Not used			
	Contractor Management				
6.2.a		Although areas are controlled through the access control system, we would recommend the site access and control of contractors is	19/07/ 19	Bouygues	

		tightened up on a daily basis to understand who is on site, where they should be working, what they are doing and timescales for completion, clean work area and checks/signoff.			
6.2.b		Not used			

	Statutory Compliance				
6.3.a		We recommend that Bouygues keep NHSL updated as they receive handover of packages and areas of the building regards information, quality and any issues.	Ongoing	Bouygues	
6.3.b		Not used			
6.3.c		Not used			

	Fire and Emergency Planning				
6.4.a		We recommend that Bouygues keep NHSL updated as they receive handover of the fire detection infrastructure regards information, quality and any issues.	Ongoing	Bouygues	
6.4.b		NHSL Fire Officer to complete FRA and make available to the SPV and FM provider prior to patient occupation.	31/07/ 19	NHSL	
6.4.c		Not used			
6.4.d		Not used			

	Legionella				
6.5.a		IHSL (monitoring Multiplex) to ensure a robust flushing regime that has identified all outlets is in place and reported accurately and reported back to NHSL.	July 19	IHSL	
6.5.b		IHSL (monitoring Multiplex) to demonstrate a safe water system is in place prior to handover of water system maintenance and reported back to NHSL.	TBA	IHSL	
6.5.c		IHSL to confirm their duty holder responsibilities for water.	31/07/ 19	IHSL	
6.5.d		Not used			

	Building Observations				
6.6.a		Multiplex - Heat Station 4, recommend heat loss is investigated and reported back to NHSL.	19/07/ 19	Multiplex	
6.6.b		Multiplex - Heat Station 3, recommend discharging water is investigated and rectified with investigation on any damage or impact and findings shared with NHSL.	19/07/ 19	Multiplex	
6.6.c		Multiplex - Heat Station 3, recommend the humid air entering the ventilation is investigated and reported back to NHSL.	19/07/ 19	Multiplex	
6.6.d		Multiplex - Heat Station 3, recommend the Plant Room design and lack of drainage is assessed and reported back to NHSL.	31/07/ 19	Multiplex	
6.6.e		Multiplex to confirm - Heat Station 3 recommend the cutting of “drainage holes” through the block wall has not impacted on the Fire Rating or integrity of wall.	31/07/ 19	Multiplex	
6.6.f		Multiplex - Heat Station 3, recommend the condition of the Plant base plates is addressed to suit a new Plant Room.	31/07/ 19	Multiplex	
6.6.g		Multiplex - recommend HV Plant Room, transformer “load noise” is investigated and report provided to NHSL.	31/07/ 19	Multiplex	
6.6.h		Multiplex - Rainwater Tank Plant Room, investigation why a Fire Collar has not been fitted to waste pipe entering through ceiling slab and any remedials required are completed.	31/07/ 19	Multiplex	
6.6.i		Multiplex - Basement Plant Rooms, Bund Wall is marked up and identified as affecting fire escape route.	31/07/ 19	Multiplex	
6.6.j		Multiplex - Energy Centre, smell of gas to be investigated and remedials reported back to NHSL.	19/07/ 19	Multiplex	
6.6.k		IHSL to confirm latent defect list and remedial dates for the Lifts	31/07/ 19	IHSL	
6.6.l		Not used			

	Training			
6.7.a		We would recommend Bouygues share the positive training and contingency information with the Client as it is very positive	TBA	Bouygues

	Performance Monitoring				
6.8.a		IHSL should demonstrate that they are discharging their duties as per the Project Agreement	31/07/ 19	IHSL	
6.8.b		Not used			
6.8.c		Not used			

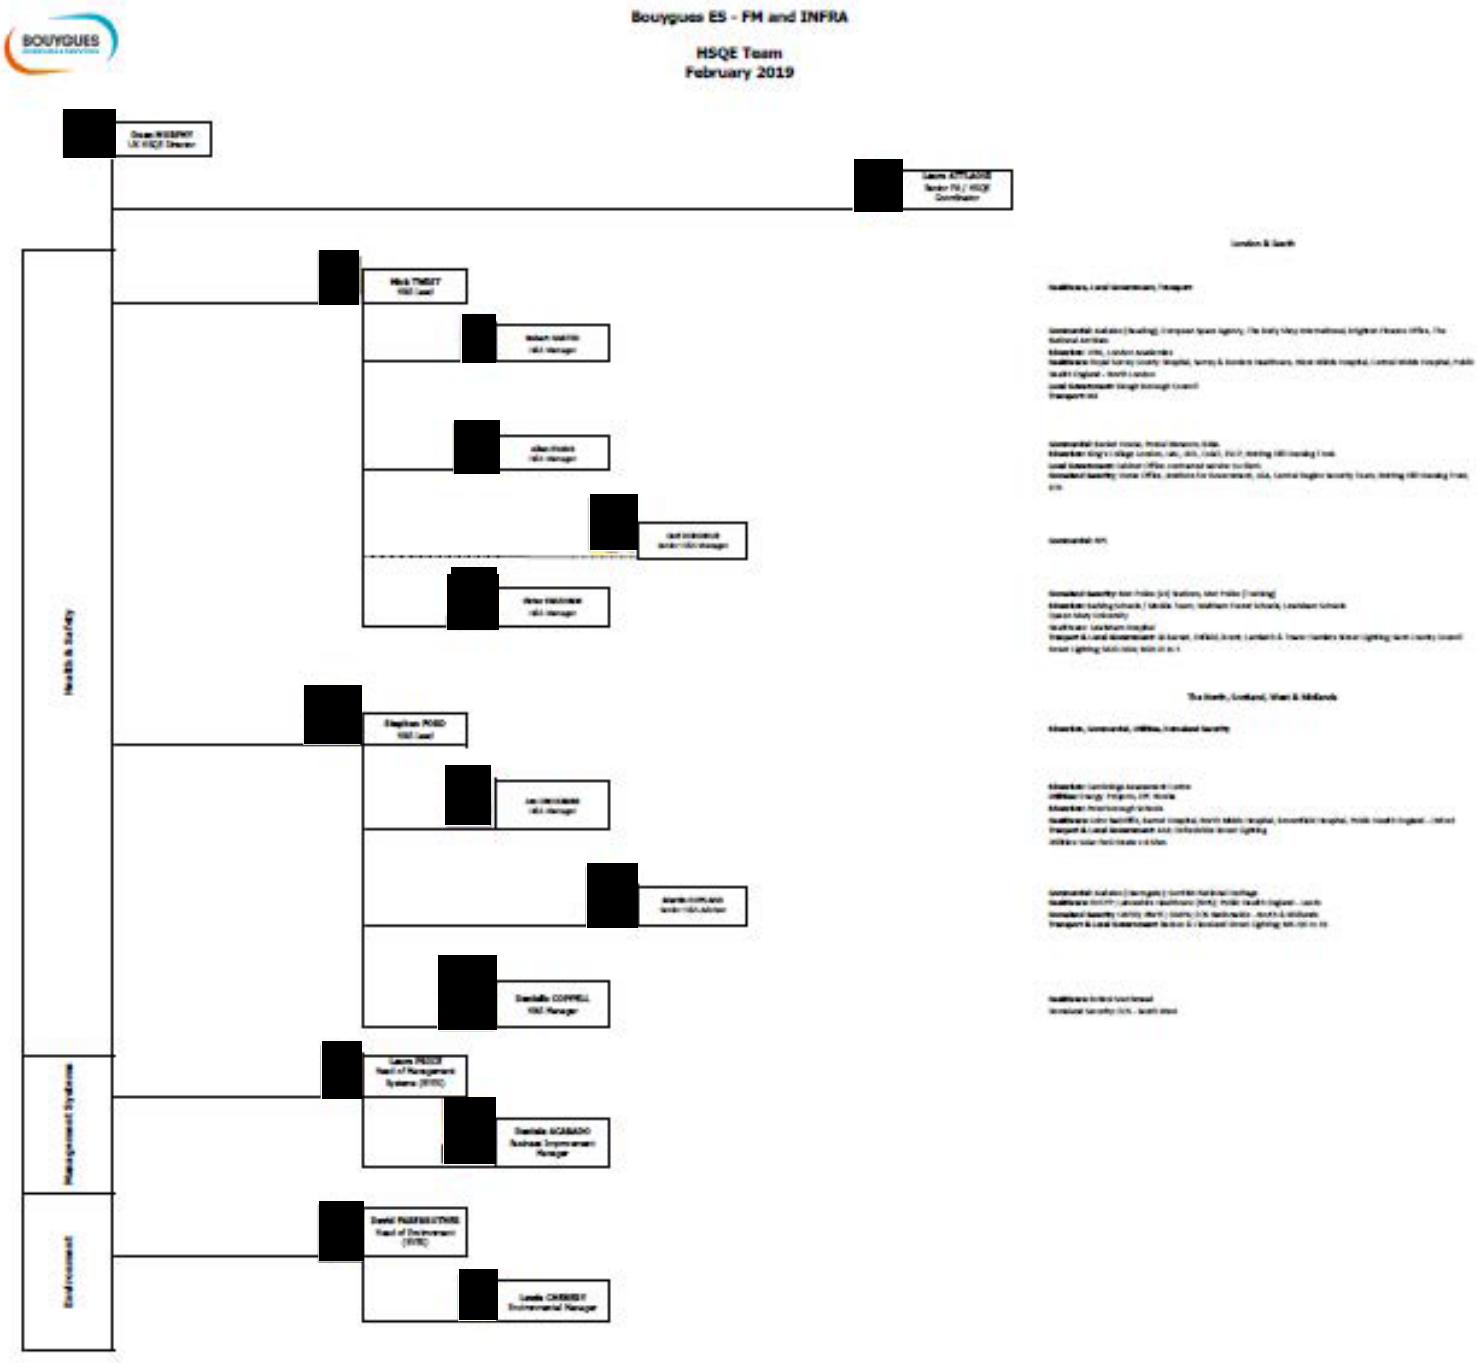
Key to Colour Coding and Timescales for Action	
	A major gap in management arrangements, which directly breaches the requirements of legislation. Project Co is at risk. IMMEDIATE ACTION REQUIRED
	A gap in management arrangements resulting from not fully complying with legislation. Project Co is not considered to be at imminent risk, but corrective action should be implemented within an agreed timescale to remedy the issue. WITHIN 3 MONTHS.
	Opportunity for Improvement. There is no direct breach of compliance, but the existing management arrangements could be improved to provide a more suitable or robust solution. ACTION PLAN TO BE AGREED.

Appendix A – Summary of Assessment Grading Scale

Award	*Audit Rating*	*Definition*
	Controlled, Minor Improvements Needed	All or many of the health and safety control measures are functioning as intended; however, some minor changes may be necessary to make the controlled environment more effective and efficient. Some minor actions may be necessary at this time (Project Co is not considered to be at risk).

	Moderate Improvements Needed	Some of the health and safety control measures are in place and functioning; however, several major issues were noted that could jeopardize statutory compliance or contractual obligations. Actions will be necessary to address the deficiencies noted, (Project Co may be considered at risk in the short to medium term were corrective action not implemented).
	Unsatisfactory, Significant Improvements Needed	Health and safety control measures are not functioning as designed and/or will have a material impact on both statutory compliance and/or contractual obligations. Health and safety control measures are lacking or have degraded since the last audit and is a contributing factor to non-compliance. Immediate management actions need to be taken to address the deficiencies noted, (Project Co is currently considered to be at risk).

Appendix B – Bouygues H&S Organogram

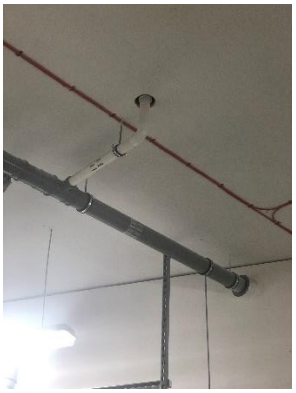


Appendix C – 1 (Heat station 3 – Flooding)

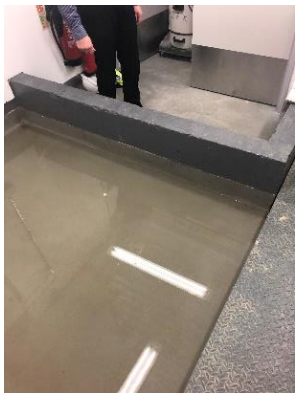
Appendix C – 2 (Pneumatic Plant Room – Flooding, holes through wall and outlet)

Appendix C – 3 (Pneumatic Plant Room – PC risk)

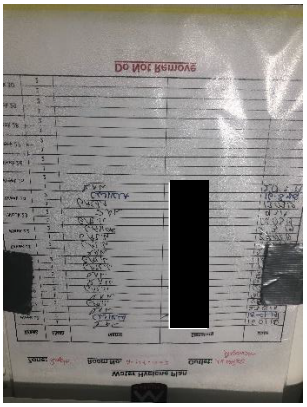
Appendix C – 4 (Fire collar and fire collar missing)

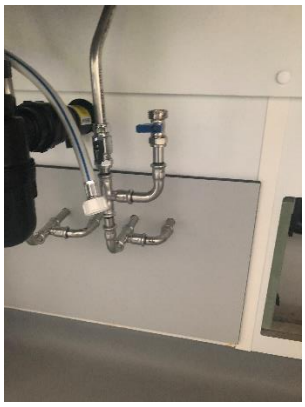


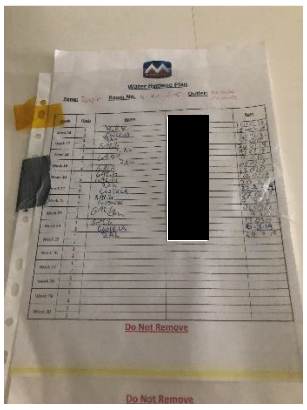
Appendix C – 5 (Bund Walls not marked for fire exit)



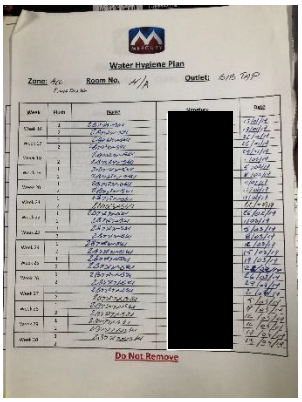
Appendix D – Legionella – (Lab Flushing Points and information)

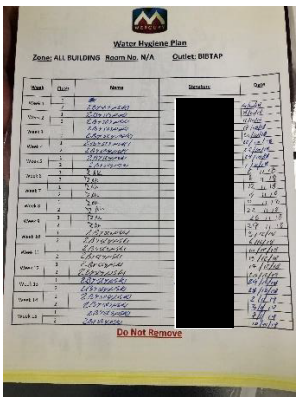






(Courtyard Flushing information)





Appendix E – Missing Electrical Matting

Appendix F – Blocked Fire Exit (Poor storage of construction materials in Energy Centre).

Contents

Preface

Access to safe drinking-water is essential to health, a basic human right and a component of effective policy for health protection.

The importance of water, sanitation and hygiene for health and development has been reflected in the outcomes of a series of international policy forums. This includes, most recently, the adoption of the Sustainable Development Goals by countries, in 2015, which include a target and indicator on safe drinking-water. Further, the United Nations (UN) General Assembly declared in 2010 that safe and clean drinking-water and sanitation is a human right, essential to the full enjoyment of life and all other human rights. These commitments build on a long history of support including the UN Generaly Assembly adopting the Millennium Development Goals in 2000 and declaring the period 2005–2015 as the International Decade for Action, "Water for Life".

Access to safe drinking-water is important as a health and development issue at national, regional and local levels. In some regions, it has been shown that investments in water supply and sanitation can yield a net economic benefit, because the reductions in adverse health effects and health-care costs outweigh the costs of undertaking the interventions. This is true for investments ranging from major water supply infrastructure through to water treatment in the home. Experience has also shown that interventions in improving access to safe water favour the poor in particular, whether in rural or urban areas, and can be an effective part of poverty alleviation strategies.

The World Health Organization (WHO) published four editions of the *Guidelines for drinking-water quality* (in 1983–1984, 1993–1997, 2004, and 2011), as successors to the previous WHO *International standards for drinking water*, which were published in 1958, 1963 and 1971. Since 1995, the Guidelines have been kept up to date through a process of rolling revision, which leads to the regular publication of addenda that may add to or supersede information in previous volumes, as well as expert reviews on key issues in preparation for the revision of the Guidelines.

Leading the process of the development of the fourth edition was the Water, Sanitation, Hygiene and Health Unit within WHO Headquarters. The Chemical Safety Unit and the Risk Assessment and Management Unit provided input on chemical hazards, and the Radiation Programme provided input on radiological hazards. All six WHO regional offices participated in the process, in consultation with Member States.

This version of the Guidelines integrates the fourth edition, which was published in 2011, with the first addendum to the fourth edition published in 2016. It supersedes previous editions of the Guidelines and previous International Standards.

The primary goal of the Guidelines is to protect public health associated with drinking-water quality. The overall objectives of the Guidelines are to:

- provide an authoritative basis for the effective consideration of public health in setting national or regional drinking-water policies and actions;
- provide a comprehensive preventive risk management framework for health protection, from catchment to consumer, that covers policy formulation and standard setting, risk-based management approaches and surveillance;
- emphasize achievable practices and the formulation of sound regulations that are applicable to low-income, middle-income and industrialized countries alike;
- summarize the health implications associated with contaminants in drinking-water, and the role of risk assessment and risk management in disease prevention and control;
- summarize effective options for drinking-water management; and
- provide guidance on hazard identification and risk assessment.

This edition of the Guidelines, incorporating the first addendum, further develops concepts, approaches and information introduced in previous editions, including the comprehensive preventive risk management approach for ensuring drinking-water quality that was introduced in the third edition. This edition considers:

- drinking-water safety, including minimum procedures and specific guideline values, and how these are intended to be used;
- approaches used in deriving the Guidelines, including guideline values;
- microbial hazards, which continue to be the primary concern in both developing and developed countries. Experience has shown the value of a systematic approach to securing microbial safety. This edition builds on the preventive principles introduced in the third edition on ensuring the microbial safety of drinking-water through a multiple-barrier approach, highlighting the importance of source water protection;
- climate change, which results in changing water temperature and rainfall patterns, severe and prolonged drought or increased flooding, and its implications for water quality and water scarcity, recognizing the importance of managing these impacts as part of water management strategies;
- chemical contaminants in drinking-water, including information on chemicals not considered previously (e.g. pesticides used for vector control in drinking-water); revisions of existing chemical fact sheets, taking into account new scientific information; and reduced coverage in the Guidelines in cases where new information suggests a lesser priority;
- key chemicals responsible for large-scale health effects through drinking-water exposure (e.g. arsenic, fluoride, lead, nitrate, selenium and uranium), with the Guidelines providing guidance on identifying local priorities and on management;

- the important roles of many different stakeholders in ensuring drinking-water safety; this edition furthers the discussion introduced in the third edition of the roles and responsibilities of key stakeholders in ensuring drinking-water safety; and
- guidance in situations other than traditional community supplies or managed utilities, such as rainwater harvesting and other non-piped supplies or dual-piped systems.

The Guidelines are accompanied by a series of supporting publications. These include internationally peer-reviewed risk assessments for specific chemicals (see list of chapter 12 background documents in Annex 2) and other publications explaining the scientific basis of the development of the Guidelines and providing guidance on good practice in their implementation (see Annex 1). The publication *Guidelines for drinking-water quality Volume 3—Surveillance and control of community supplies* (1997, revision forthcoming) provides guidance on good practice in surveillance, monitoring and assessment of drinking-water quality in community supplies.

The Guidelines are addressed primarily to water and health regulators, policy-makers and their advisors, to assist in the development of national policies and regulations. The Guidelines and associated documents are also used by many others as a source of information on water quality and health, and on effective management approaches.

The Guidelines are recognized as representing the position of the UN system on issues of drinking-water quality and health by "UN-Water", the body that coordinates among the 24 UN agencies and programmes concerned with water issues.

Acknowledgements

The preparation of the fourth edition of the *Guidelines for drinking-water quality*, the first addendum to the fourth edition and supporting documentation covered a period of more than 10 years. It involved the participation of hundreds of experts from a wide range of developing and developed countries. The contributions of all who participated in the preparation and finalization of the fourth edition and the first addendum to the fourth edition, including those individuals listed in Annex 7, are gratefully acknowledged.

The work of the following working group coordinators and other Drinking-water Quality Committee members was crucial to the development of the fourth edition:

Dr F. Ahmed, Bangladesh University of Engineering and Technology, Bangladesh (*Small systems*)

Dr I. Chorus, Federal Environment Agency, Germany (*Resource and source protection*)

Dr J. Cotruvo, Joseph Cotruvo & Associates/NSF International Collaborating Centre, USA (*Materials and chemicals used in the production and distribution of drinking-water*)

Dr D. Cunliffe, Department of Health, Australia (*Public health*)

Dr A.M. de Roda Husman, National Institute for Public Health and the Environment (RIVM), the Netherlands (*Viruses and risk assessment*)

Dr T. Endo, Ministry of Health, Labour and Welfare, Japan (*Parasites*)

Mr J.K. Fawell, Independent Consultant, United Kingdom (*Naturally occurring and industrial contaminants* and *Pesticides*)

Ms M. Giddings, Health Canada, Canada (*Disinfectants and disinfection by-products*)

Dr G. Howard, British High Commission, India (*Monitoring and assessment*)

Mr P. Jackson, WRc-NSF Ltd, United Kingdom (*Chemicals – Practical aspects*)

Dr S. Kumar, University of Malaya, Malaysia (*Protozoa and risk management*)

Dr S. Kunikane, Institute for Environmental Sciences, Japan (*Operations and Maintenance Network*)

Professor Y. Magara, Hokkaido University, Japan (*Analytical aspects*)

Dr A.V.F. Ngowi, Muhimbili University of Health and Allied Sciences, United Republic of Tanzania (*Pesticides*)

Dr E. Ohanian, Environmental Protection Agency, USA (*Disinfectants and disinfection by-products*)

Dr C.N. Ong, National University of Singapore, Singapore (*Emerging chemical hazards*)

Mr O. Schmoll, Federal Environment Agency, Germany (*Water safety plan capacity building and monitoring*)

Professor M. Sobsey, University of North Carolina, USA (*Risk management*)

The WHO coordinator was Mr B. Gordon, WHO Headquarters, with support from Mr P. Callan from the National Health and Medical Research Council, Australia. Ms C. Vickers and Dr A. Tritscher provided important liaisons with the international chemical risk assessment programmes at WHO Headquarters. Dr M. Perez contributed on behalf of the Radiation and Environmental Health Programme, WHO Headquarters. Dr M. Zaim, Pesticide Evaluation Scheme, WHO Headquarters, provided input on pesticides added to drinking-water for public health purposes. The Coordinator of Water, Sanitation, Hygiene and Health, WHO Headquarters (formerly Jamie Bartram and, since 2009, Robert Bos), provided strategic direction throughout the process.

Ms P. Ward provided invaluable administrative support throughout the review and publication process. Ms M. Sheffer of Ottawa, Canada, was responsible for the scientific editing of the document.

With reference to the addendum, the following experts contributed in the Guideline Development Group or chemical, microbial or protection and control working groups, supporting the development and finalization of this addendum: Dr D. Cunliffe (Chair), Dr S.H. Abedelrahman, Dr R. Bevan, Mrs J. Brown, Mr E. Calderon, Dr I. Chorus, Dr J. Cotruvo, Dr. D'Anglada, Dr A.M. de Roda Husman, Dr A. Eckhardt, Professor J. Fawell, Ms M. Giddings, Dr A. Hirose, Dr P. Hunter, Dr P. Labhasetwar, Professor K. Linden, Dr P. Marsden, Dr Y. Matsui, Dr G. Medema, Dr M.E. Meek, Dr E. Ohanian, Professor C.N. Ong, Dr S. Ramasamy, Professor S. Snyder and Professor M. Sobsey.

The WHO Steering Group for the addendum included: Mr H. Bakir, Mr R. Brown, Ms J. De France, Mr B. Gordon, Ms Payden, Dr M. Perez, Dr A. Pruss-Ustun, Mr O. Schmoll, Dr J. Simon, Dr P. Verger and Dr R. Yadav. The contributions from additional WHO staff are also acknowledged: Dr M. Bagayoko, Dr S. Boisson, Dr N. Hassan, Dr T. Monteiro, Dr A. Tritscher and Ms C. Vickers.

The coordinator for the addendum was Ms J. De France, WHO Headquarters, with support from Mr P. Callan, Australia. Strategic direction was provided by Mr B. Gordon, WHO Headquarters.

Ms P. Ward, Ms L. Robinson and Mr E. Johnson provided administrative support, and Ms M. Sheffer of Canada and Dr H. Cadman of Australia were responsible for the scientific editing of the document.

Many individuals from various countries contributed to the development of the Guidelines. The efforts of all who contributed to the preparation of this document

and in particular those who provided peer or public domain review comments are greatly appreciated.

The generous financial and technical support of the following is gratefully acknowledged: the Australian Department of Foreign Affairs and Trade; Health Canada; the Federal Ministry of Health of Germany; the Ministry of Health, Labour and Welfare of Japan; the Ministry of Environment and Water Resources, Republic of Singapore; the United Kingdom Department for International Development; and the United States Environmental Protection Agency.

Abbreviations used in text

2,4-D	2,4-dichlorophenoxyacetic acid
2,4-DB	2,4-dichlorophenoxybutyric acid
2,4-DP	dichlorprop
2,4,5-T	2,4,5-trichlorophenoxyacetic acid
2,4,5-TP	2,4,5-trichlorophenoxy propionic acid; fenoprop
AAS	atomic absorption spectrometry
Absor	absorptiometry
ADI	acceptable daily intake
AES	atomic emission spectrometry
AIDS	acquired immunodeficiency syndrome
AMPA	aminomethylphosphonic acid
ARfD	acute reference dose
BDCM	bromodichloromethane
BMD	benchmark dose
BMDL	lower confidence limit on the benchmark dose
BMDLx	lower 95% confidence limit on the benchmark dose for an x% response
BTEX	benzene, toluene, ethylbenzene and xylenes
Bti	*Bacillus thuringiensis israelensis*
bw	body weight
CAS	Chemical Abstracts Service
Col	colorimetry
CSAF	chemical-specific adjustment factor
Ct	product of disinfectant concentration and contact time
DAEC	diffusely adherent *E. coli*
DALY	disability-adjusted life year

DBCM	dibromochloromethane
DBCP	1,2-dibromo-3-chloropropane
DBP	disinfection by-product
DCA	dichloroacetic acid
DCB	dichlorobenzene
DCP	dichloropropane
DDT	dichlorodiphenyltrichloroethane
DEHA	di(2-ethylhexyl)adipate
DEHP	di(2-ethylhexyl)phthalate
DNA	deoxyribonucleic acid
DPD	*N*,*N*-diethyl-1,4-phenylenediamine sulfate
EAAS	electrothermal atomic absorption spectrometry
EAEC	enteroaggregative *E. coli*
ECD	electron capture detector
EDTA	ethylenediaminetetraacetic acid; edetic acid
EHEC	enterohaemorrhagic *E. coli*
EIEC	enteroinvasive *E. coli*
ELISA	enzyme-linked immunosorbent assay
EPEC	enteropathogenic *E. coli*
ETEC	enterotoxigenic *E. coli*
F_0	parental generation
F_1	first filial generation
FAAS	flame atomic absorption spectrometry
FAO	Food and Agriculture Organization of the United Nations
FD	fluorescence detector
FID	flame ionization detector
FPD	flame photodiode detector
GAC	granular activated carbon
GC	gas chromatography
GL	guidance level (used for radionuclides in drinking-water)
GV	guideline value
HAA	haloacetic acid
HAV	hepatitis A virus
HCB	hexachlorobenzene
HCBD	hexachlorobutadiene
HCH	hexachlorocyclohexane
HEV	hepatitis E virus
HIV	human immunodeficiency virus

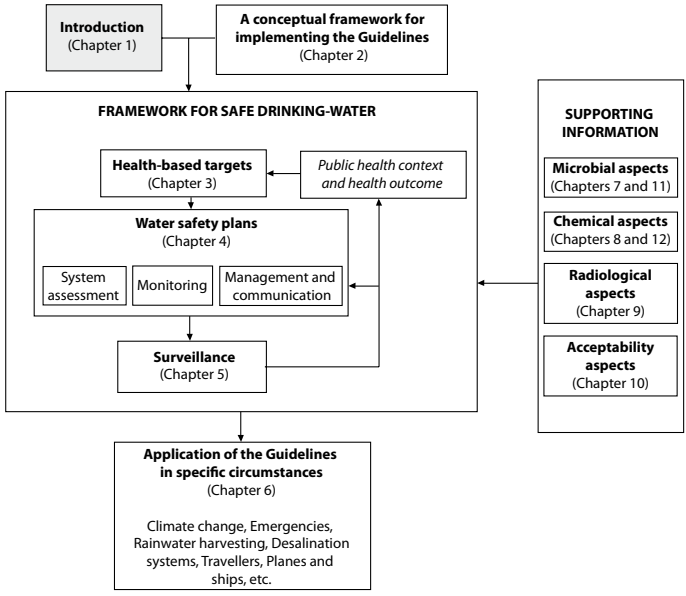
HPC	heterotrophic plate count
HPLC	high-performance liquid chromatography

IARC	International Agency for Research on Cancer
IC	ion chromatography
ICP	inductively coupled plasma
ICRP	International Commission on Radiological Protection
IDC	individual dose criterion
IPCS	International Programme on Chemical Safety
IQ	intelligence quotient
ISO	International Organization for Standardization
JECFA	Joint FAO/WHO Expert Committee on Food Additives
JMPR	Joint FAO/WHO Meeting on Pesticide Residues
LC	liquid chromatography
LOAEL	lowest-observed-adverse-effect level
LRV	$\log_{10}$ reduction value
MCB	monochlorobenzene
MCPA	4-(2-methyl-4-chlorophenoxy)acetic acid
MCPB	2,4-MCPB; 4-(4-chloro-o-tolyloxy)butyric acid; 4-(4-chloro-2-methylphenoxy)butanoic acid
MCPP	2(2-methyl-chlorophenoxy) propionic acid; mecoprop
MDL	method detection limit
MMT	methylcyclopentadienyl manganese tricarbonyl
MS	mass spectrometry
MS/MS	tandem mass spectrometry
MTBE	methyl *tertiary*-butyl ether
MX	3-chloro-4-dichloromethyl-5-hydroxy-2(5H)-furanone
NDMA	*N*-nitrosodimethylamine
NOAEL	no-observed-adverse-effect level
NOEL	no-observed-effect level
NTA	nitrilotriacetic acid
NTP	National Toxicology Program (USA)
NTU	nephelometric turbidity unit
PAC	powdered activated carbon
PAH	polynuclear aromatic hydrocarbon
PCP	pentachlorophenol
PCR	polymerase chain reaction
PD	photoionization detector
PMTDI	provisional maximum tolerable daily intake
PPA	protein phosphatase assay

PT	purge and trap
PTDI	provisional tolerable daily intake

PTMI	provisional tolerable monthly intake
PTWI	provisional tolerable weekly intake
PVC	polyvinyl chloride
QMRA	quantitative microbial risk assessment
RNA	ribonucleic acid
SI	Système international d'unités (International System of Units)
SODIS	solar water disinfection
sp.	species (singular)
spp.	species (plural)
subsp.	subspecies (singular)
TBA	terbuthylazine
TCB	trichlorobenzene
TCU	true colour unit
TD_{05}	tumorigenic dose$_{05}$, the dose associated with a 5% excess incidence of tumours in experimental animal studies
TDI	tolerable daily intake
TDS	total dissolved solids
THM	trihalomethane
TID	thermal ionization detector; total indicative dose
UF	uncertainty factor
UN	United Nations
UNICEF	United Nations Children's Fund
UNSCEAR	United Nations Scientific Committee on the Effects of Atomic Radiation
USA	United States of America
UV	ultraviolet
UVPAD	ultraviolet photodiode array detector
WHO	World Health Organization
WHOPES	World Health Organization Pesticide Evaluation Scheme
WSP	water safety plan
YLD	years of healthy life lost in states of less than full health (i.e. years lived with a disability)
YLL	years of life lost by premature mortality

1 Introduction



The primary purpose of the *Guidelines for drinking-water quality* is the protection of public health. The Guidelines provide the recommendations of the World Health Organization (WHO) for managing the risk from hazards that may compromise the safety of drinking-water. The recommendations should be considered in the context of managing the risk from other sources of exposure to these hazards, such as waste, air, food and consumer products.

1.1 General considerations and principles

Water is essential to sustain life, and a satisfactory (adequate, safe and accessible) supply must be available to all. Improving access to safe drinking-water can result in tangible benefits to health. Every effort should be made to achieve drinking-water that is as safe as practicable.

Safe drinking-water, as defined by the Guidelines, does not represent any significant risk to health over a lifetime of consumption, including different sensitivities that may occur between life stages. Those at greatest risk of waterborne disease are infants and young children, people who are debilitated and the elderly, especially when living

Diseases related to contamination of drinking-water constitute a major burden on human health. Interventions to improve the quality of drinking-water provide significant benefits to health.

under unsanitary conditions. Those who are generally at risk of waterborne illness may need to take additional steps to protect themselves against exposure to waterborne pathogens, such as boiling their drinking-water. Safe drinking-water is required for all usual domestic purposes, including drinking, food preparation and personal hygiene. The Guidelines are applicable to packaged water and ice intended for human consumption. However, water of higher quality may be required for some special purposes, such as renal dialysis and cleaning of contact lenses, or for certain purposes in food production and pharmaceutical use. The Guidelines may not be suitable for the protection of aquatic life or for some industries.

The Guidelines are intended to support the development and implementation of risk management strategies that will ensure the safety of drinking-water supplies through the control of hazardous constituents of water. These strategies may include national or regional standards developed from the scientific basis provided in the Guidelines. The Guidelines describe reasonable minimum requirements of safe practice to protect the health of consumers and derive numerical "guideline values" for constituents of water or indicators of water quality. When defining mandatory limits, it is preferable to consider the Guidelines in the context of local or national environmental, social, economic and cultural conditions. The Guidelines should also be part of an overall health protection strategy that includes sanitation and other strategies, such as managing food contamination. This strategy would also normally be incorporated into a legislative and regulatory framework that adapts the Guidelines to address local requirements and circumstances (see also section 2.6).

The main reason for not promoting the adoption of international standards for drinking-water quality is the advantage provided by the use of a risk–benefit approach (qualitative or quantitative) in the establishment of national standards and regulations. Further, the Guidelines are best used to promote an integrated preventive management framework for safety applied from catchment to consumer. The Guidelines provide a scientific point of departure for national authorities to develop drinking-water regulations and standards appropriate for the national situation. In developing standards and regulations, care should be taken to ensure that scarce resources are not unnecessarily diverted to the development of standards and the monitoring of substances of relatively minor importance to public health. The approach followed in these Guidelines is intended to lead to national standards and regulations that can be readily implemented and enforced and are protective of public health.

The nature and form of drinking-water standards may vary among countries and regions. There is no single approach that is universally applicable. It is essential in the development and implementation of standards that the current or planned legislation relating to water, health and local government is taken into account and that the capacity of regulators in the country is assessed. Approaches that may work in one country or region will not necessarily transfer to other countries or regions. It is essential that each country review its needs and capacities in developing a regulatory framework.

The judgement of safety—or what is an acceptable level of risk in particular circumstances—is a matter in which society as a whole has a role to play. The final judgement as to whether the benefit resulting from the adoption of any of the Guidelines or guideline values as national or local standards justifies the cost is for each country to decide.

Although the Guidelines describe a quality of water that is acceptable for lifelong consumption, the establishment of these Guidelines, including guideline values, should not be regarded as implying that the quality of drinking-water may be degraded to the recommended level. Indeed, a continuous effort should be made to maintain drinking-water quality at the highest possible level.

An important concept in the allocation of resources to improving drinking-water safety is that of incremental improvement towards long-term health-based targets. Priorities set to remedy the most urgent problems (e.g. protection from pathogens; see section 1.1.2) may be linked to long-term targets of further water quality improvements (e.g. improvements in the acceptability of drinking-water in terms of its taste, odour and appearance; see section 1.1.6).

An important concept in the allocation of resources to improving drinking-water safety is that of incremental improvement towards long-term water quality targets.

1.1.1 Framework for safe drinking-water

The basic and essential requirements to ensure the safety of drinking-water are a "framework" for safe drinking-water, comprising health-based targets established by a competent health authority, adequate and properly managed systems (adequate infrastructure, proper monitoring and effective planning and management) and a system of independent surveillance.

A holistic approach to the risk assessment and risk management of a drinking-water supply increases confidence in the safety of the drinking-water. This approach entails systematic assessment of risks throughout a drinking-water supply—from the catchment and its source water through to the consumer—and identification of the ways in which these risks can be managed, including methods to ensure that control measures are working effectively. It incorporates strategies to deal with day-to-day management of water quality, including upsets and failures. In this respect, climate change—in the form of increased and more severe periods of drought or more intense rainfall events leading to flooding—can have an impact on both the quality and the quantity of water and will require planning and management to minimize adverse
