5. Schedule of periodic tests

Introduction

5.1 Periodic tests are carried out at daily, weekly, quarterly and yearly intervals. They are the shared responsibility of the test person and the user.

5.2 The yearly test schedule is identical to that carried out on revalidation (see paragraph 2.39). It contains tests for both recommissioning and performance requalification.

5.3 Tests should be performed on completion of planned maintenance tasks as described in Part 4. The schedules for the tests are set out for each type of clinical sterilizer in Table 4 and for laboratory sterilizers in Table 5. Each test is cross-referenced to a detailed description of the test procedure in a later chapter. The tests should be carried out with the sterilizer at normal working temperature (a warming-up cycle may be needed) and completed in the order shown.

5.4 The calibration of thermometric test equipment should be checked before and after the thermometric tests as described in Chapter 6.

5.5 Where tests on EO sterilizers require EO gas to be in the chamber, sensors should either be removed from the chamber or else disconnected from the recorder and the wires grounded to the body of the sterilizer (see note (d) to Table 4f).

5.6 The results of the tests done by the test person should be kept in the plant history file. The results of the tests done by the user should be kept in the sterilizer process log. (See Part 4 for guidance on record-keeping.)

Weekly safety checks

5.7 The test person should make the following safety checks before starting the sequence of weekly tests:

a. examine the door seal;

b. check the security and performance of door safety devices;

c. check that safety valves, or other pressure-limiting devices, are free to operate;

d. make any other checks required by the competent person in connection with the written scheme of examination for the pressure vessel.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Yearly safety checks

5.8 In order to ensure the safe functioning of the sterilizer, the test person should conduct a sequence of safety checks before starting the yearly tests. The installation checks (Chapter 3) should be used as a basis for these, but it will not be necessary to repeat them all. In selecting which checks to include in the yearly schedule, consideration should be given to conditions which affect safety and to those which may have changed over the course of time. It will not be necessary, for example, to check again that the sterilizer has been supplied in accordance with specification, but it will be necessary to check that the engineering services remain adequate and are connected safely. The authorised person should advise on which checks will need to be included.

6. Test equipment

Introduction

6.1 This chapter discusses the portable test equipment required to carry out the test procedures described in this document. Specifications for instruments fitted permanently to sterilizers are given in the relevant British and European Standards discussed in Part 2 of this SHTM.

6.2 With the rapid advance in instrumentation technology, it is becoming increasingly difficult (and undesirable) to set detailed specifications for the equipment to be used in testing sterilizers. For example, a clear trend is for much of the testing to be under the control of a computer which can automatically take the desired measurements, check that they meet the requirements of the tests in this SHTM, and report the results. The object of this chapter is twofold. First, to ensure that the traditional measurement methods are adequately supported; and second, to make clear the essential requirements for test equipment that apply for old and new technology alike. Where it is proposed to use measurement and recording techniques that are not explicitly covered here, the advice of the authorised person should be sought.

6.3 Access to standard laboratory equipment and supplies is assumed.

Calibration and sources of error

6.4 The errors produced in temperature and pressure measurement will arise from a number of factors. Some are inherent in the design, age and condition of the measuring equipment, and others are due to loose terminals, imperfect plug and socket connections, and the change of environmental temperature around the instrument. Variations in thermocouple alloys, preparation of thermocouple hot junctions, the method of introducing sensors into the chamber, and their location within the load will add to the error in temperature measurement. Temperature fluctuations within pressure-sensing elements will lead to errors in pressure measurement.

6.5 Every effort should be made to eliminate or minimise these errors by attention to detail, location of instruments, effective maintenance, and skill in the application, handling and use of the instruments. Systematic errors can be reduced by careful calibration.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.6 Instruments should be maintained and calibrated as recommended by the manufacturer as part of a planned maintenance programme. Each instrument should be labelled with the calibration date and a reference to its certificate. The calibration of all test instruments should be verified yearly by using reference instruments with a valid certificate of calibration traceable to a national standard. A history record should be kept for each instrument.

6.7 All electronic test instruments should be allowed a period of time to stabilise within the test site environment. They should be located in a position protected from draughts, and should not be subjected to rapid temperature variations. The manufacturer's instructions should be followed.

Recorders

6.8 Test recorders are required to measure temperature and pressure in all types of sterilizer, and humidity in EO sterilizers. They should be designed for use with the appropriate sensors, independent of those fitted to the sterilizer, as described later in this chapter. Most of the tests in this SHTM may be conducted with a single recorder combining temperature and pressure functions, preferably showing both records on the same chart or print-out. For EO sterilizers, a third function, for humidity, is desirable but not essential.

6.9 Twelve temperature channels are sufficient for all the tests on each type of sterilizer in this SHTM, though more may be convenient for determining chamber temperature profiles (see paragraph 7.21). One pressure channel is required for all sterilizers except fluid sterilizers which require up to three. The pressure channel for a dry-heat sterilizer is required to measure the small differential pressure (no more than 10 mbar) across the air filter. Two relative-humidity channels are desirable for EO sterilizers.

6.10 Analogue recorders (conventional pen and chart recorders) should comply with the display requirements of BS 3693. If they use potentiometric techniques, they should comply with BS 5164.

6.11 Digital recorders (data loggers) are rapidly coming into use and have many advantages over traditional pen recorders. They measure the variables electronically and store the values in digital form suitable for computer processing. Data may be presented graphically or as a numerical list, or as a combination of both. Parts of the operating cycle, such as the plateau period, can be expanded and replotted for closer examination. The record should quantify all turning points in the data, and distinguish by colour, print format or separate list, measurements which are within the sterilization temperature band for the operating cycle under test. The recorder should have the facility for downloading data onto tape or disk which can then be removed and kept securely. Software used with digital recorders should be developed under a quality system (such as BS 5750) and validated before use.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

6.12 The detailed specification for a test recorder will depend upon the range of sterilizers with which it is to be used. In all cases the recorder and its sensors should be capable of measuring cycle variables to considerably greater accuracy than the instruments fitted to the sterilizer.

6.13 The accuracy with which a variable can be read from the recorder will be affected not only by the sources of error discussed above (see paragraph 6.4), but also by the precision of the calibration, the scale range selected, the integration time, the sampling interval and the intrinsic accuracy of the recorder itself. Digital recorders will invariably register measurements to a precision greater than the accuracy of the system as a whole, and care should be taken in interpreting such measurements.

6.14 The intrinsic accuracies quoted by recorder manufacturers are measured under controlled reference conditions and do not include errors from temperature, pressure or humidity sensors. Temperature measurement errors due to ambient temperature changes should not exceed 0.04°C per °C rise.

6.15 The scale ranges should include the expected maximum and minimum values of the cycle variables throughout the operating cycle, with sufficient leeway to accommodate any deviations resulting from a malfunctioning sterilizer. (Note that in some sterilizers the temperature in the chamber free space will considerably exceed the upper limit of the sterilization temperature band for a short time at the start of the plateau period.)

6.16 The most critical stage of the operating cycle is the plateau period (the equilibration time plus the holding time, see paragraph 7.11) during which the load becomes exposed to the sterilization conditions. It is during this period that the values of the cycle variables are at their most critical and the recorder should be capable of measuring them to sufficient accuracy to confirm that the sterilization conditions have been attained. The criteria are as follows:

a. for digital recorders, the sampling interval should be short enough for the holding time to contain at least 180 independent measurements in each recording channel. This corresponds to a sampling interval of one second for the shortest holding time (3 minute, high-temperature steam sterilizers) and 40 seconds for the longest (120 minute, dry-heat sterilizers). For pen recorders, the chart speed should be fast enough to allow fluctuations on that scale to be clearly resolved. The duration of the holding time should be measurable to within 1%;

b. the integration time of the recorder (the response time) should be short enough to enable the output to follow significant fluctuations in the cycle variables and to ensure that successive measurements are independent of each other, It should not be longer than the sampling interval;

c. the width of the sterilization temperature band (see paragraph 7.14) varies from 3°C (high-temperature steam sterilizers) to 10°C (dry-heat sterilizers). The recorder must be accurate enough to show clearly whether the measured temperatures are within the band or not. For all

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

the types of sterilizer covered by this SHTM, the repeatability of the recorder should be ± 0.25°C or better, and the limit of error of the complete measurement system (including sensors) should be no more than 0.5°C;

d. for pressure measurement, the limit of error should be no more than 0.5% of the absolute pressure during the plateau period;

e. for humidity measurement, the limiting factor is likely to be the performance of the sensor (see paragraph 6.47).

6.17 A recorder chosen to meet these criteria for the plateau period will have more than enough performance for the preceding and following stages of the operating cycle.

6.18 If a fluid sterilizer is fitted with an F_0 integrating system (see Part 4 for a discussion of the use of F_0 in controlling operating cycles), then the recorder should be capable of computing and printing values of F_0 for each channel with integration times no greater than 2 s (see BS 3970: Part 2).

Temperature measurement

Temperature sensors

6.19 Temperature sensors are required to sense the temperature in locations in the chamber and load as specified in the tests. They may be either platinum resistance elements or thermocouples.

6.20 Platinum resistance elements should comply with Class A of BS EN 60751.

6.21 Thermocouples should conform to BS EN 60584-1 (nickel-chromium/ nickel-aluminium) or Part 5 (copper/constantan). The calibration accuracy should be Tolerance Class 1 as specified in BS EN 60584: Part 2 (formerly BS 4937: Part 20). The tolerance on Part 4 thermocouples (± 1.5°C) is high when compared with that allowed for those in Part 5 (± 0.5°C), and for this reason copper/constantan thermocouples are usually preferred for the test recording system.

6.22 Thermocouple wire is available which is marked to show the limits of variation of the reel from the figures given in the British Standard. The variation will have been established by the manufacturer by testing samples from both ends of the full reel. Selected rather than standard wire should be used. For selected wire this variation is typically (for copper/constantan) of the order of 0.015 mV which is equivalent to 0.4°C at 20°C and 0.3°C at 134°C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.23 The wire should be single-strand, not exceeding 0.7 mm diameter over the covering of one core of a twin cable. Twin-core cable is usually preferred because it is easier to handle and more durable than single-core wire. The width of the cable should not exceed 2 mm. If bulkier cable is used, the tracking of steam along the outside of the cable may invalidate certain tests, such as those which require temperatures to be measured in the centre of a standard test pack (see paragraph 7.27).

6.24 Thermocouples may be argon arc-welded or micro-welded. However, experience has shown that provided the wires are cleaned, they may be satisfactorily twisted together to form the hot junction. Brazing, silver brazing and welding with filler rods may be no more reliable in respect of accuracy than freshly twisted wires. Particular attention should be given to the condition of copper/constantan thermocouples when testing LTSF sterilizers. Thermocouples should not be fitted with a heat sink.

Use of sensors

6.25 A typical method of introducing sensors into a sterilizer chamber is illustrated in Figure 2. Methods which prevent the removal of individual sensors are to be discouraged. In older machines having no dedicated entry port, entry may be made via a tee which can usually be inserted into a service entry pipe to the chamber (for example the steam supply pipe). Sensors should not be introduced through the door seal. The test schedules for sterilizers employing active air removal systems provide for a vacuum leak test to be done after temperature sensors have been introduced into the chamber, and again after they have been removed, to ensure that the chamber remains gas-tight.

6.26 Many of the tests require a temperature sensor to be placed in the active chamber discharge of the sterilizer. This is a drain or vent which permits the controlled flow of air and condensate (a drain) or of air alone (a vent), such that the temperature within the discharge is the same as the chamber temperature.

The preferred locations are as follows:

a. in the drain, if it is active throughout the operating cycle;

b. otherwise in a vent, if it is active throughout the operating cycle;

c. otherwise in the coldest part of the usable chamber space.

6.27 The sensor should be placed in the drain or vent in steam phase boundary conditions in a position where overheat cannot be detected. This will normally require at least 10 mm insertion depth. The sensors connected to the sterilizer temperature indicator and recorder, and to the automatic controller, are normally in this position also. Care should be taken to ensure that the sensor does not touch any metal parts. (Contact between the hot junction and metal surfaces can cause induced electromotive forces (EMFs) leading to inaccurate readings.)

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

6.28 Figure 3 shows several methods for inserting sensors into glass or plastic containers filled with fluid or powders. It is important that the sensor is firmly supported and that the container does not leak. For rigid containers the sensor should be located on the vertical axis and inserted to a depth of 85-5% of the height of the container. For flexible containers, such as plastic bags, the sensor should be located as near as practicable to the centre of the fluid and supported in this position throughout the operating cycle.

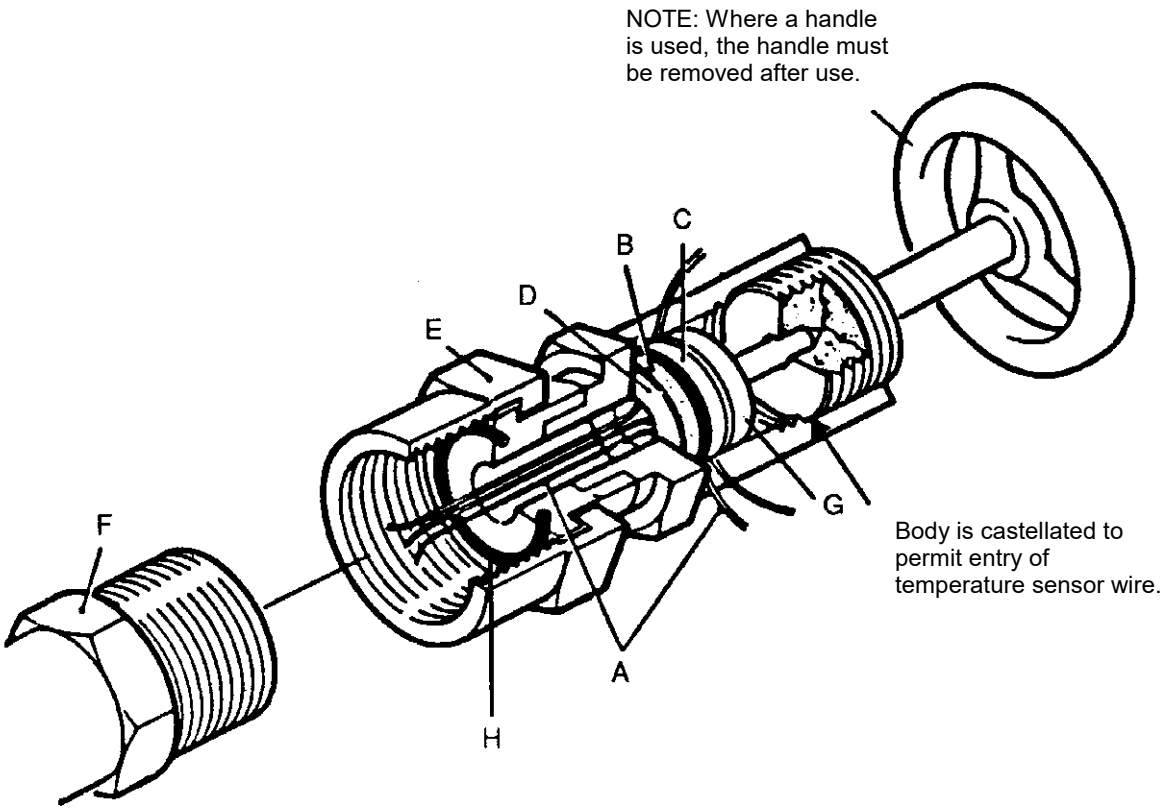
Figure 2: A method of introducing temperature sensors into a sterilizer chamber



A	Temperature sensor wire
B	Silicone rubber washer
C	Silicone rubber disc
D	Metal thrust washer
E	Metal body
F	Adaptor
G	Metal thrust spigot
H	O-ring

The illustration shows a fitting designed for a sterilizing chamber having a male gland and an 'O' ring seal. When the gland is a female thread an adaptor will be required (F). Other methods of introducing temperature sensors into a sterilizer chamber and which guarantee a gas-tight seal are equally acceptable.

6.29 When sensors are used in fluid containers, steam or fluid may be forced along the wire between the core and the sheath. To prevent damage to the recorder, the outer sheath should be either punctured a few centimetres from the end or stripped back for a similar distance to ensure that droplets forming where the sheath has been punctured or terminated fall clear of the recorder.

6.30 If the load item is a solid object, the sensor should be held securely in good thermal contact with the object.

6.31 Where required, sensors may be attached to the chamber walls by means of masking tape.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Verification of calibration

6.32 The recorder should incorporate mechanical or electrical calibration facilities. The manufacturer of the recorder will normally calibrate it without the use of temperature sensors or transducers.

6.33 An independent temperature reference source (a “hot source”) is required, with a pocket to accommodate up to 12 temperature sensors. The temperature gradient within the pocket should not exceed 0.2°C and the control accuracy should be within ± 0.1°C over the relevant sterilization temperature band.

6.34 The temperature of the hot source should be measured either by a mercury-in-glass laboratory thermometer conforming to BS 593 or other temperature measurement system of similar or greater accuracy. The supplier should be asked to provide a certified calibration curve traceable to the national primary standard. Note that all the thermometric measurements required by this SHTM will ultimately depend upon the accuracy of this calibration; an uncertified laboratory thermometer will not be accurate enough to ensure that the sterilizer is working correctly and may give dangerously misleading results. The following types of mercury-in-glass thermometers are suitable:

a. F 75C/100 (24°C to 78°C) for EO sterilizers;
b. F 100C/100 (48°C to 102°C) for LTS disinfectors and LTSF sterilizers;
c. F 150C/100 (98°C to 152°C) for high-temperature steam sterilizers;
d. F 200C/100 (148°C to 202°C) for dry-heat sterilizers.

6.35 Mercury-in-glass thermometers should be used only in the hot source and must never be placed inside a sterilizer chamber. Note that mercury-in-glass thermometers are not permitted to be taken into pharmaceutical production facilities.

6.36 Before a recorder is taken to site, verify the calibration of the system by inserting the test sensors into the hot source at a temperature within the sterilization temperature band. Adjust the recorder in accordance with the manufacturer s instructions until the mean temperature measured by the sensors is the same as the temperature indicated on the thermometer. The calibration is satisfactory if the temperatures measured by individual sensors do not differ from the mean by more than 0.5°C. This test should be carried out at an ambient temperature as close as practicable to that expected at site.

6.37 If the hot source is not to be taken to site, connect a millivolt source to one channel of the recorder, and adjust it until the measured temperature is within 2°C of that obtained with the sensors connected. Note the measured temperature and the voltage indicated on the millivolt source. Also note the ambient air temperature near the source.

6.38 After arriving at site, and before starting any thermometric tests, check the calibration using either the hot source or the millivolt source.

a. If the hot source is used, adjust the temperature to correspond with that used off-site. Check that each sensor is measuring the same temperature as before;

b. If the millivolt source is used, ensure that the ambient temperature is similar to that measured off-site. Connect the millivolt source to the recorder, apply the voltage obtained off-site and check that the same temperature is measured. Bundle all the sensors together, place them in the chamber and expose them to an operating cycle. Check that the temperatures measured during the holding time are consistent with those obtained off-site with the hot source.

6.39 Repeat the check after the tests have been completed.

Pressure measurement

6.40 Pressures are required to be measured over a range from 20 mbar absolute (in vacuum leak testing) to typically 3.8 bar absolute at the working pressure of a high-temperature steam sterilizer and 7 bar absolute at the working pressure of a sterilizer using EO gas diluted with carbon dioxide.

Transducers

6.41 Transducers for use with pressure recorders should conform with BS 6447, be suitable for the purpose, certified and no less accurate than the gauges specified below. The natural frequency of the sensor and connected tubing should not be less than 10Hz, and the time constant for rising pressure (0-63%) should not be greater than 0.04s.

Gauges

6.42 Pressure gauges are required where the pressure recorder is unsuitable or for calibrating pressure instruments fitted to the sterilizer. Four gauges will normally be required to cover the whole pressure range for all sterilizers and these are specified in Table 6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 6 Pressure gauges for test purposes

Scale range [bar]	Mark interval [mbar]	Calibration	Application
0 to 0.160 (abs)	1	Gas	Vacuum leak testing
-1 to 0	10	Gas	LTS, LTSF + pure EO cycles
0 to 4	50	Liquid	High-temp stream, EO + HFC cycles
0 to 10	200	Gas	EO + CO_2 cycles

6.43 Pressure gauges should be temperature-compensated and, except for the absolute gauge, be Bourdon-tube test gauges conforming to BS EN 837-1 of nominal size 150 mm and accuracy class 0.25 (that is, the error should not exceed 0.25% of the maximum scale range). For pressure leak testing on EO sterilizers, gauges should be of accuracy class 1 or, better, over a range within 10% of the gas exposure pressure.

6.44 Gauges not designed for direct connection to steam at 2.8 bar should be connected via a syphon or similar device to ensure that the accuracy of the gauge is maintained over the temperature range associated with changing steam pressure. If the low-pressure gauge used for vacuum leak testing cannot withstand the pressure in the chamber during sterilization an automatic valve should be provided to protect it.

6.45 Gauges should be tested yearly by a recognised testing laboratory as described in BS EN 837-1.

6.46 The very low differential pressure across the air filter in a dry-heat sterilizer can be measured with a water manometer with a range of up to 10 mbar.

Humidity measurement

6.47 Humidity is a critical cycle variable in the control of EO processes. The level of humidity in the chamber and load at the end of the conditioning stage is ideally measured during validation by test instruments calibrated for relative humidity (RH) at atmospheric pressure. The accuracy of measurement should not be less than ±10% RH over the range 30-80% RH.

6.48 In practice, the measurement of relative humidity within the chamber of an EO sterilizer is difficult. Although the new European Standard on EO sterilizers will require RH sensors to be fitted, such sensors are still rare in the UK and the NHS has little experience in their use. If suitable test sensors are not available, then the chamber humidity may be validated by calculation as discussed in Appendix 2.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.49 There is no British Standard for humidity sensors, but it is recommended that test sensors should function at temperatures of 10-60°C and at pressures from vacuum up to 7 bar absolute.

6.50 The sensitivity and accuracy of electrically operated humidity sensors is often compromised by exposure to EO. The tests described in this SHTM require humidity to be measured only during cycles where an inert substitute for EO is used. The measurement can then be extrapolated to production cycles provided the other cycle variables are the same. If it becomes necessary to measure the humidity during cycles using EO gas, sensors should normally be replaced, degassed and recalibrated after each cycle.

Other instruments

Sound level meter

6.51 An integrating-averaging sound level meter is required for the sound pressure test. It should comply with Type 2 of BS EN 60804. Ten microphones are required for a single sterilizer.

Air flow metering device

6.52 A metering device (such as a needle valve) is required to admit air into the sterilizer chamber for the air detector tests, and vacuum and pressure leak tests. The device should be capable of controlling the flow of air into an evacuated chamber. It should be adjustable and have a range which includes a flow of 0-5 ml min^{-1} per litre volume of the sterilizer chamber. The error in repeatability between 10% and 90% of the setting range should not exceed ± 5%. The device is connected to the chamber by a valved port provided by the sterilizer manufacturer.

Balance

6.53 A laboratory balance is required for steam dryness tests, load dryness tests and coolant quality tests. It should be capable of measuring the mass of loads up to 2 kg to an accuracy of 0.1 g (dryness tests), and up to 100 g to an accuracy of 0.1 mg (coolant quality test).

Gas monitoring instrument

6.54 A gas monitoring instrument, such as an infrared spectrophotometer, is required for tests on LTSF and EO sterilizers.

6.55 The formaldehyde instrument should be suitable for measuring formaldehyde concentration in air with an accuracy of ± 10% at 2ppm.

6.56 The ethylene oxide instrument should be suitable for measuring ethylene oxide concentration in air with an accuracy of ± 10% at 15ppm.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.57 The scale ranges should include the appropriate short-term exposure limits specified in Table 1, and extend to at least ten times the exposure limit. The two functions may be combined in one instrument.

Aerosol generator

6.58 An aerosol generator is required for tests on dry-heat sterilizers.

6.59 The device should be capable of generating a polydisperse aerosol with particles having the size distribution shown in Table 7.

Table 7: Particle size distribution for aerosol generator

Particle size [μm]	Fraction by mass [%]
<0.5	>20
<0.7	>50
<1.0	>75

Source: BS 5295: Part 1

Photometer

6.60 A photometer is required for tests on dry-heat sterilizers.

6.61 The device should be suitable for estimation or comparison of mass concentration of airborne particles as defined in Table 7. It should have an accuracy of better than ±5% over the range of a five-expandable, six-decade resolution (that is, 0.01% to 100% of the test cloud) as specified in Appendix C of BS 5295: Part 1.

6.62 The photometer should have a minimum threshold sensitivity of 0.0001μg l^{-l} and should be capable of measuring aerosol concentration in the range 80-120μg l^{-1}

6.63 The sample flow rate should be 0.40 ± 0.05ls^{-1} and sampling should be via a suitable probe device.

7. Testing methods

Introduction

7.1 This chapter discusses general principles and methods that are used in the thermometric and microbiological tests described in this SHTM.

Terminology

7.2 For the purposes of this SHTM the following definitions have been adopted.

Cycle variables

7.3 The **cycle variables** are the physical properties, such as time, temperature, pressure, humidity and sterilant gas concentration, that influence the efficacy of the sterilization process. Most of the tests described in this SHTM require the values of cycle variables to be determined experimentally and then compared with standard values.

7.4 An **indicated** value is that shown by a dial or other visual display fitted permanently to the sterilizer.

7.5 A **recorded** value is that shown on the output of a recording instrument fitted permanently to the sterilizer.

7.6 A **measured** value is that shown on a test instrument, such as a thermometric recorder or a test pressure gauge, attached to the sterilizer for test purposes.

7.7 A **noted** value is that written down by the operator, usually as the result of observing an indicated, recorded or measured value.

Sterilization conditions

7.8 Most operating cycles have a stage in which the load is exposed to the sterilization (or disinfection) conditions for a specified length of time. This period is known as the **holding time**.

7.9 The **sterilization conditions** are the ranges of the cycle variables which may prevail throughout the chamber and load during the holding time.

7.10 The holding time is preceded by a period in which the sterilization conditions are present in the chamber but not yet present throughout the load. This is known as the **equilibration time**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.11 Together, the equilibration time and the holding time constitute the plateau period. While the **plateau period** can always be determined from the recorded chamber temperature, the equilibration and holding times cannot be distinguished unless the temperature in the part of the load that is slowest to reach the sterilization temperature is also being recorded or measured.

7.12 Certain LTSF sterilizers may achieve sterilization by exposing the load to a series of pulses of formaldehyde rather than a single holding time.

7.13 For EO sterilizers the plateau period is equivalent to the **gas exposure time**. The holding time cannot be determined by thermometry and is therefore of no practical interest.

7.14 For steam and dry-heat sterilizers, the sterilization conditions are specified by a **sterilization temperature band**, defined by a minimum acceptable temperature, known as the **sterilization temperature**, and a maximum allowable temperature. A sterilization temperature band can also be quoted for LTSF and EO sterilizers, but since these processes depend primarily upon chemical action such a band is not a complete specification of the sterilization conditions. Bands for the different types of sterilizer are listed in Table 8.

Table 8: Sterlization temperature bands

	High-temperature steam				Dry heat			LTS	LTSF	Ethylene oxide
Sterilization temperature (°C)[a]	115	121	126	134	160	170	180	71[b]	71	30-56
Maximum allowable temperature (°C)	118	124	129	137[c]	170	180	190	80	80	[d]
Minimum holding time (min)	30	15	10	3	120	60	30	10	180[e]	[f]

Notes:

a. The temperature setting on the automatic controller will not generally be the sterilization temperature, but a higher temperature within the sterilization temperature band.

b. Disinfection temperature.

c. British Standards permit 138°C.

d. For EO, the maximum allowable temperature will normally be 4°C above the sterilization temperature.

e. For LTSF, the sterilization conditions may specify either a continuous holding time or the number of pulses for formaldehyde required to achieve sterilization.

f. For EO, the “gas exposure time” is determined for each sterilizer by microbiological methods during commissioning but is typically 2-7 hours depending upon sterilization temperature and gas concentration.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Interpretation of thermometric measurements

7.15 Figure 4 shows in schematic form the kind of data that are typically obtained in a thermometric test using measuring equipment as described in Chapter 6. In practice there may be more or fewer temperature traces depending on the number of sensors used. The detailed behaviour before and after the plateau period is dependent on the nature of the operating cycle and is not shown here.

7.16 The equilibration time begins when the temperature in the coolest part of the chamber (normally the active chamber discharge, see paragraph 6.26) first attains the sterilization temperature. It ends when the holding time begins.

7.17 The holding time begins when the temperature in the part of the load that is the slowest to heat up first attains the sterilization temperature. It ends at the start of the cooling stage, when the temperature in the coolest part of the chamber falls below the sterilization temperature.

7.18 The **fluctuation** in a trace over a given interval is $\pm T$ °C if the difference between the maximum and minimum values is $2T$.

7.19 The **drift** in a trace over a given interval is the change in the mean value of the trace over that interval.

7.20 The **difference** between two traces is the difference in their values at a given instant. A trace is said to be **within** T °C of a given value or another trace if the difference between them at any instant over a given interval is no more than T.

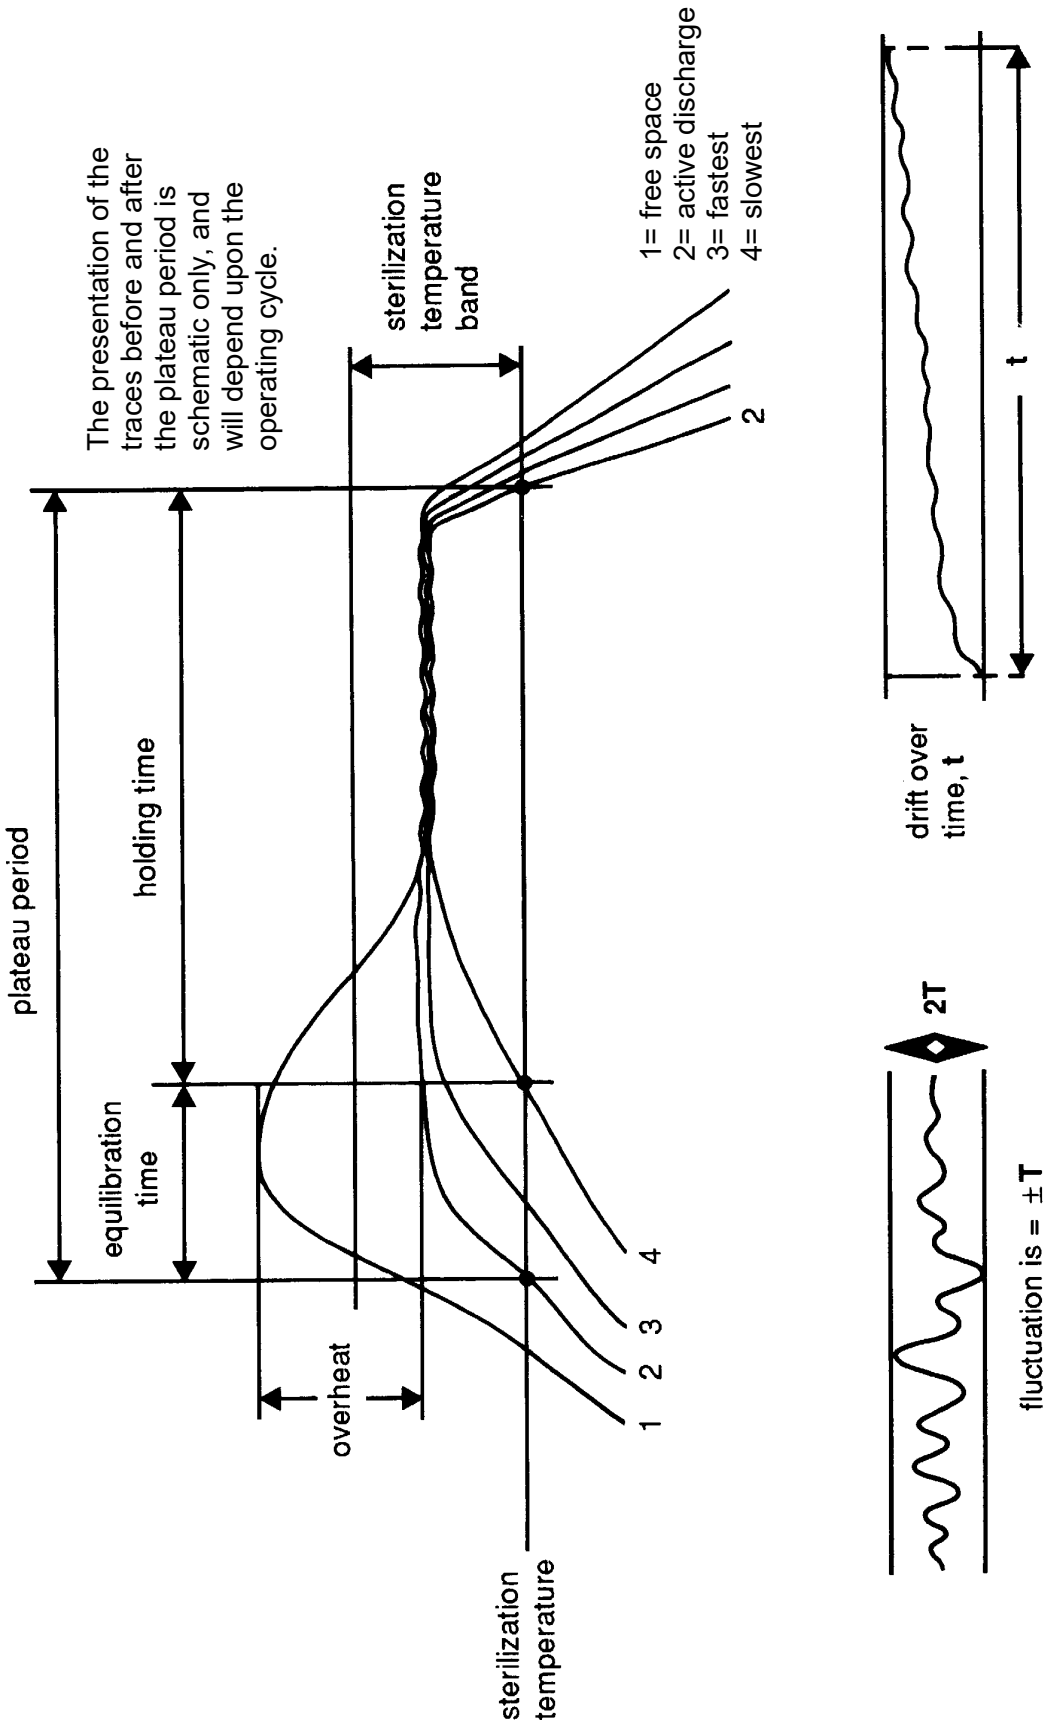
Figure 4: Interpretation of thermometric recording



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chamber temperature profile

7.21 Many of the tests require temperature sensors (or biological or chemical indicators) to be placed in the parts of the load known to be the most difficult to sterilize. To make this assessment, it is necessary to know the hottest and coolest parts of the chamber, and the parts that are the fastest and slowest to attain the sterilization temperature.

7.22 This procedure is not required for porous load sterilizers since compliance with the small-load, full-load and air detector tests ensures that the penetration of steam is effectively instantaneous.

7.23 Place temperature sensors on a grid pattern throughout the usable chamber space. The number of sensors should be at least as many as that specified for the relevant full-load test. If the test recorder has too few channels it will be necessary to run through more than one operating cycle to collect data from a sufficient number of points. If so, at least two sensors should remain in the same positions (including one in an active chamber discharge) to establish the correlation between successive cycles.

7.24 If a choice of operating cycles is available, select the cycle with the highest sterilization temperature. This will normally be 134°C for high-temperature steam sterilizers. Start the cycle.

7.25 At the end of the cycle, examine the measured temperatures and note the following:

a. the parts of the usable chamber space that are the fastest and the slowest to attain the sterilization temperature;

b. the parts of the usable chamber space that are the hottest and the coolest during the sterilization holding time;

c. for sterilizers with a thermal door interlock, the part of the usable chamber space that is the slowest to cool to 80°C.

7.26 Users should be aware that the temperature profile derived in this way is valid only for an empty chamber. The presence of a load will disturb the profile, although the positions determined in paragraph 7.25 will be accurate enough for most practical purposes. However, where the sterilizer is to be used to process medicinal products, the positions will need to be confirmed for each loading condition as part of the performance qualification procedure (see paragraph 8.17).

Standard test pack

7.27 In order to ensure that tests are carried out under repeatable conditions, European Standards require the use of a standard test pack for all sterilizers designed to process porous loads. As well as porous load sterilizers

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

themselves, the standard test pack is used for tests on LTS disinfectors, LTSF sterilizers and laboratory sterilizers with a cycle for the disinfection of fabrics.

7.28 The standard test pack is used to check that, at the levels at which the cycle variables are set, rapid and even penetration of steam into the pack is attained. The pack is chosen to represent the maximum density of porous load material which a sterilizer conforming to British and European Standards should be able to process. It may be used with other materials to form a full load.

7.29 The test pack is composed of plain cotton sheets complying with BS 5815: Part 1, each bleached to a good white and having an approximate size of 90 cm x 120 cm. The number of threads per centimetre in the warp should be 30 ± 6 and in the weft 27 ± 5.

7.30 The sheets should be washed but not subjected to any conditioning agent. (Conditioning agents may affect the characteristics of the fabric and may contain volatile substances which will contribute to the non-condensable gases in the chamber.)

7.31 The sheets should be dried and then aired for at least one hour at a temperature of 15-25ºC and a relative humidity of 30-70%. Failure to observe this protocol can result in the test giving a pass result when it should have been a failure. Sheets which have become excessively dehydrated may cause superheating in the pack, which might also produce misleading results.

7.32 After airing, the sheets should be folded to approximately 22 cm x 30 cm and stacked to a height of approximately 25 cm. After being compressed by hand, the pack should be wrapped in similar fabric and then secured with tape no more than 25 mm wide. The total weight of the pack should be 7.0 ± 0.7 kg. The sheets will become compressed after the pack has been used. If the weight of sheets needed to form a stack 25 cm high exceeds 7.7 kg, the sheets should be discarded.

7.33 Packs which are not used within one hour of preparation may be stored, providing the environmental conditions are maintained within those specified above for airing.

7.34 Non-standard test packs made of different materials (including huckaback towels TL5 or TL6 complying with BS 1781) and of different sizes and weights may be used, provided they comply with BS 7720. These packs may also be useful for small chambers (see paragraph 7.35).

7.35 The standard test pack should not be used where the usable chamber space is less than five times the volume of the pack. In these cases a smaller version of the pack may be constructed. This should be of cubic form with a volume about one-fifth of the usable chamber space, and made of similar materials to the standard test pack.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Use of chemical indicators

7.36 Chemical indicators are designed to show by a change of colour whether specified sterilization conditions have been attained. They should, however, always be regarded as supplementary to definitive thermometric, microbiological or (for EO) hygrometric results. Whenever a cycle variable is outside its specified limits an operating cycle should always be regarded as unsatisfactory, irrespective of the results obtained from any chemical indicators.

7.37 Chemical indicators are manufactured for a range of sterilization processes and cycle variables. They should not be used for any process other than that specified by the manufacturer. The use of an inappropriate indicator may give dangerously misleading results.

7.38 Specifications for chemical indicators for sterilization processes are given in EN 867 which is currently in preparation (1994). Two classes are applicable to the tests covered in SHTM 2010.

7.39 Class A indicators (“process indicators”) are intended for use with individual packs of product to demonstrate that the pack has been exposed to the sterilization process. They have a defined end-point reaction, in which a visible change occurs after exposure to the specified variables at a level equal to or greater than that specified for the indicator. Class A indicators are used alongside biological indicators in tests on LTSF and EO sterilizers to provide an early visual indication of the efficacy of gas penetration. If a chemical indicator shows a failure, then it is normal for the test to be abandoned and the cause investigated. If all chemical indicators are satisfactory, then the biological indicators should be incubated as described in the relevant test. Chemical indicators by themselves are insufficient to demonstrate the efficacy of gaseous sterilization processes. Class A indicators are specified in BS EN 867: Part 2.

7.40 Class B indicators are designed for use in the Bowie-Dick test for steam penetration (see paragraph 13.37). They may have either a defined end-point or a graduated response in which a progressive change occurs on exposure to one or more process variables allowing assessment of the level achieved. Class B indicators are specified in BS EN 867: Part 3.

7.41 Other classes of indicator are available but are not required for the tests in this SHTM.

7.42 The performance of chemical indicators may be affected by the conditions of storage before use, the methods of use and the conditions of storage after exposure to the process. For these reasons the recommendations of the manufacturer for storage and use should be followed precisely. Indicators should not be used beyond any expiry date stated by the manufacturer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Use of biological indicators

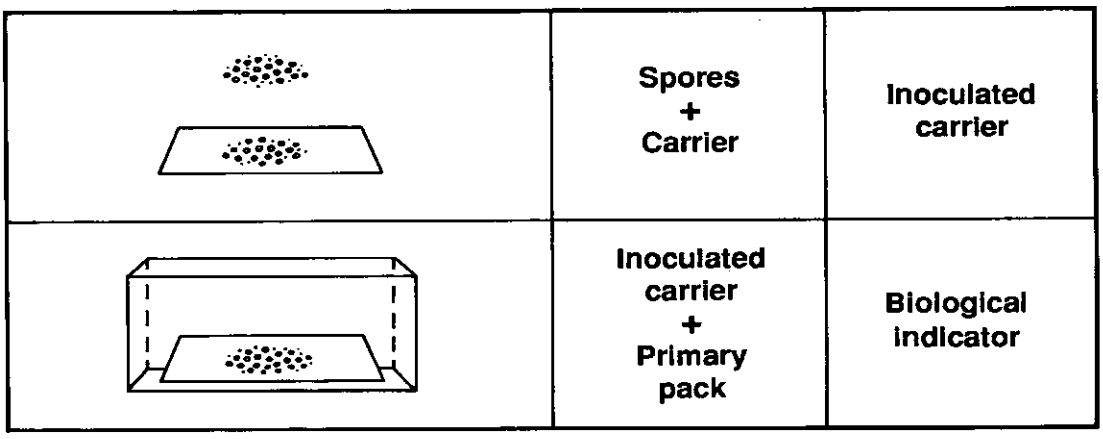
7.43 Biological indicators are designed to show by the survival of test micro-organisms whether specified sterilization conditions have been attained. The absence of growth of a test micro-organism after exposure to a sterilization process demonstrates that a specified level of microbiological inactivation has been delivered. Survival of a test micro-organism subjected to a sterilization process indicates that the process has failed. Biological indicators are required for tests on LTSF and EO sterilizers to confirm that sterilization conditions have been attained. On rare occasions they may be required for PQ tests on other types of sterilizer (see paragraph 8.9).

7.44 Terminology adopted in this SHTM conforms to that given in BS EN 866. An **inoculated carrier** is defined as a piece of supporting material on which a defined number of test organisms has been deposited. A **biological indicator** is defined as an inoculated carrier contained within its primary pack ready for use. The relationship between the components is shown in Figure 5.

7.45 Biological indicators are manufactured for a range of sterilization processes and cycle variables. They should not be used for any process other than that specified by the manufacturer. The use of an inappropriate indicator may give dangerously misleading results.

7.46 The performance of biological indicators may be affected by the conditions of storage before use, the methods of use and the techniques employed after exposure to the process. For these reasons the recommendations of the manufacturer for storage and recovery conditions should be followed. Biological indicators should be transferred to the specified recovery conditions as soon as possible after exposure to the process and in any case within 2 hours of the end of the cycle. Indicators must not be used beyond any expiry date stated by the manufacturer.

Figure 5: Component of a biological indicator



Adapted from BS EN 866: Part 1

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.47 Control of biological indicators should be the responsibility of the microbiologist. Incubation of indicators should be carried out by an accredited laboratory registered with CPA (UK) Ltd (see Appendix 1).

Specifications

7.48 Specifications for biological indicators for sterilization processes are given in the several parts of BS EN 866. The standard draws a distinction between indicators designed for routine monitoring and indicators designed for validation tests. For routine monitoring, BS EN 866 specifies both the minimum number of organisms on the carrier and also a minimum D-value. For validation, no such limits are set. As a consequence, indicators manufactured in accordance with BS EN 866 for routine monitoring will always be suitable for validation, but the reverse will not necessarily be true.

7.49 The following organisms are recommended in BS EN 866 for the microbiological tests specified in this SHTM. Other strains or organisms may be used provided they are demonstrated to be of equivalent performance. Addresses for culture collections may be found in Appendix 1:

a. for LTSF sterilizers, Bacillus stearothermophilus as specified in BS EN 866: Part 5. B stearothermophilus strains NCIMB 8224 and NCTC 10003 have been found to be suitable;

b. for EO sterilizers, Bacillus subtilis var niger as specified in BS EN 866: Part 2. B subtilis var niger strains ATCC 9372, CIP 7718 and NCTC 10073 have been found to be suitable.

7.50 Although not normally required for the tests in this SHTM, the following organisms may be used where the need arises:

a. for high-temperature steam sterilizers, Bacillus stearothermophilus as specified in BS EN 866: Part 3. B stearothermophilus strains ATCC 7953, ATCC 12980, CIP 5281 and NCTC 10003 have been found to be suitable;

b. for dry-heat sterilizers, Bacillus subtilis as specified in BS EN 866: Part 6. B subtilis strains ATCC 9372 and CIP 7718 have been found to be suitable.

Line-Pickerell helix

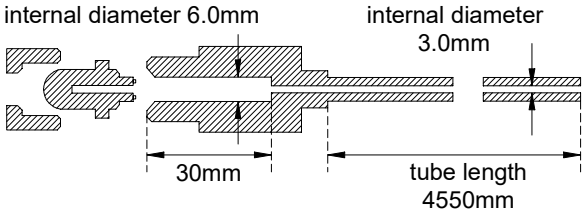
7.51 The Line-Pickerell helix (Line and Pickerell, 1973) is a process challenge device used in microbiological tests on LTSF and EO sterilizers and designed to simulate the worst-case penetration conditions for sterilization by gas. The device is so constructed that an inoculated carrier can be placed within it in a position most difficult for the gas to reach.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

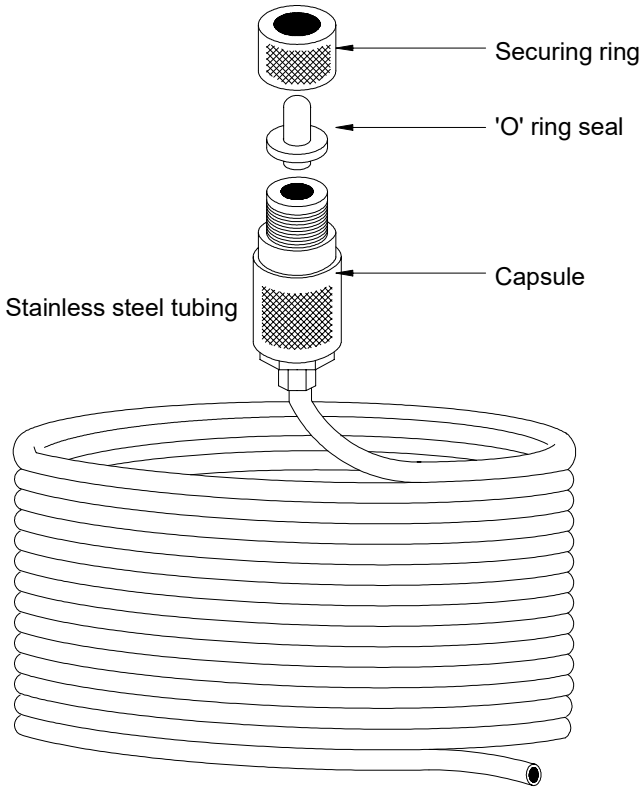
7.52 The device consists of stainless steel tubing with a gas-tight metal capsule for the biological indicator at one end (Figure 6). The capsule is in two parts which fit together against an O-ring seal and are secured by a knurled nut. The capsule body is sealed to the stainless steel tube so that the only entry into the assembled capsule is via the whole length of the tube. The nominal dimensions of the tube are 4.55 m in length and 3.0 mm in internal diameter, presenting a single-ended system with a length-to-bore ratio of approximately 1500:1. The total internal volume of the assembly is approximately 32 ml, of which 0.85 ml comprises the capsule. For compactness, the tube is formed into a helix of nominal 115 mm diameter. The tail of the helix is turned out slightly for ease of connection to air or water services for cleaning.

7.53 Before placing an inoculated carrier in the capsule, ensure that the helix is clear by blowing oil-free compressed air through it. Check the seal for damage or deterioration. Tighten the capsule and test it for leakage by submerging the helix in water and pressurising it with oil-free air at approximately 0.15 bar.

Figure 6: Line-Pickerell helix



Test helix capsule



The test helix

$$\text{Bore/length ratio} = \frac{\text{3mm bore}}{\text{4550mm long}}$$

$$= \frac{1}{1500}$$

Preparation of recovery medium

7.54 The recovery medium should be tryptone soya broth demonstrated as capable of recovering 10-100 viable spores of the test organism. Documentary evidence of performance should be provided by the manufacturer for each batch of dehydrated medium supplied.

7.55 The made-up medium should be prepared in accordance with the producer s recommendation. If no recommendation is available, proceed as follows.

7.56 Each batch should be dispensed in volumes of 15-20 ml in screw-capped bottles of at least 25 ml capacity and sterilized at a sterilization temperature of 121°C. The bottles should be stored at 2-10°C and used within 12 months.

7.57 The microbiologist should test each batch for sterility at each of the incubation temperatures at which it will be used. Select at least 2% of the bottles at random and incubate them for seven days at 52-56°C (for bottles intended for use with *B stearothermophilus*) or 30-32°C (for bottles intended for use with *B subtilis*). The batch should be considered satisfactory for use at that incubation temperature if none of the bottles shows growth. If one or more bottles does show growth, the entire batch should be regarded as not sterile.

7.58 The microbiologist should test each batch for its ability to promote growth. Test organisms which are damaged but not killed in the sterilization process may not outgrow if cultural conditions are not ideal. The following method is recommended.

7.59 Remove the inoculated carriers from two biological indicators of the type to be used with the recovery medium. Place the carriers in 10 ml of quarter-strength Ringer's solution. Agitate to release the test organisms from the carriers; this may be done by ultrasonication, shaking with glass beads, or another appropriate validated method.

NOTE: Ringer's solution (full strength) is made from 9.0g sodium chloride, 0.42g potassium chloride, 0.48g calcium chloride and 0.2g sodium bicarbonate, in 1000ml of distilled water. Source: Bacteriological tests for graded milk (Ministry of Health, 1937).

7.60 Dilute the solution to make a suspension with a count of 500 test organisms per ml.

7.61 Select 20 bottles at random from the sterilized batch of recovery medium. Add 0.1ml of the suspension to each bottle. Incubate the bottles for seven days at 52-56°C (for *B stearothermophilus*) or 30-32°C (for *B subtilis*). Confirm the recovery of the test organism by subculture as described in paragraph 7.71.

7.62 The batch of recovery medium should be considered satisfactory if all 20 bottles show growth. If one or more bottles does not show growth, the entire batch should be discarded.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

General procedure for microbiological tests

7.63 All biological indicators used in any one test should be taken from the same batch.

7.64 Except where specified otherwise (in certain EO tests), all the microbiological tests in this SHTM require biological indicators to be used in the form of unprotected inoculated carriers without their primary packs. They should therefore be handled aseptically to avoid contamination.

7.65 Biological indicators should be positioned as described in the relevant test procedure. If chemical indicators are to be used, they should be placed alongside the biological indicators to form biological/chemical indicator pairs.

7.66 Indicators should be cultured in accordance with the manufacturer s recommendations. The use of an inappropriate recovery system can give dangerously misleading results. If no recommendation is available, proceed as follows.

7.67 Within 2 hours of the end of the cycle, aseptically transfer each inoculated carrier to a bottle of recovery medium at a temperature of 15-25°C. Fit the caps to the bottles loosely (for *B stearothermophilus*) or tightly (for *B subtilis*).

7.68 Prepare control bottles of recovery medium as follows:

a. at least three bottles (for validation tests) or at least one bottle (for periodic tests), each containing an unexposed inoculated carrier, to demonstrate that the indicators are viable;

b. at least three bottles containing recovery medium only, to demonstrate that the medium is not contaminated.

7.69 Incubate the test bottles together with the controls under the conditions shown in Table 9.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 9: Recommended incubation conditions for biological indicators

Organism	*B stearothermophilus*	*B subtils*
Incubation temperature	52-56°C	30-32°C
Incubation time:		
for validation tests (commissioning and performance qualification)	14 days[a]	7 days
for routine tests (production cycles)	7 days	7 days

a. For validation of LTSF cycles it is recommended that biological indicators are incubated for 14 days to allow outgrowth of organisms which may have been damaged but not inactivated by exposure to the process. Once the validation tests have been successfully completed, incubation times of seven days are acceptable for subsequent routine tests.

7.70 Inspect the bottles periodically for signs of growth. After inspection, gently shake the bottles to aerate the medium. Control bottles should be handled in the same way as test bottles.

7.71 As soon as one or more of the test bottles becomes turbid, confirm the isolation of the test organism as follows. Take a sample from each turbid test bottle and from each positive control bottle and streak them on to tryptone soya agar on vented plates. *B stearothermophilus* should be incubated at 52-56°C in an airtight container (such as a plastic bag) to prevent the agar drying out. *B subtilis* should be incubated at 30-32°C. If there is no growth on the test plates after 18-24 hours, the cloudiness is not due to microbial growth. The positive control plate should show characteristic colonies of the test organism as described in *A colour atlas of Bacillus species* (Parry, Turnbull and Gibson, 1983).

7.72 The test should be considered satisfactory if the following requirements are met:

a. chemical indicators show a uniform colour change at the end of the cycle;

b. all bottles containing an inoculated carrier exposed to the sterilization process show no growth at the end of the incubation time;

c. all control bottles containing an unexposed inoculated carrier show growth of the test organism within 24 hours;

d. all control bottles without an inoculated carrier show no growth at the end of the incubation time.

7.73 All culture results should be noted, whether satisfactory or not.

7.74 Where growth has resulted from an organism other than the test organism, the test is inconclusive and should be repeated.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.75 Note the following:

a. as a rough guide, the earlier the growth appears during the incubation period, the less efficacious is the sterilization process;

b. consistent failures in one position in the chamber may indicate problems of gas distribution (for example, stratification);

c. failure in a helix with no failures in the chamber free space may indicate poor gas penetration possibly due to inadequate air removal, excessively wet steam, or (for EO) low humidity;

d. for LTSF sterilizers, failure in the chamber with no failure in a helix may indicate low humidity due to the chamber wall being too hot or the steam being superheated.

8. Performance qualification

Introduction

8.1 Performance qualification (PQ) is defined as the process of obtaining and documenting evidence that the sterilizer, as commissioned, will produce acceptable goods when operated in accordance with the operational instructions. PQ tests are performed as part of the initial validation procedure, as part of any repeat validation procedure, and whenever the user judges that a new loading condition calls for a new PQ test.

8.2 Performance qualification should not be attempted on any sterilizer that falls to meet the requirements of the commissioning tests specified in Chapters 4 and 5.

8.3 Thermometric PQ is required for all sterilizers. Additional microbiological PQ tests, and PQ tests for environmental gas and load degassing times, are required for LTSF and EO sterilizers.

8.4 Information gathered from the PQ test is filed in a PQ report which specifies the standard of performance expected with a particular operating cycle and loading condition (see paragraph 8.7). The report includes a master process record, employed by the user to validate routine production loads, together with thermometric and (where required) microbiological data used for subsequent performance requalification.

8.5 Performance requalification (PRQ) is the process of confirming that the sterilizer continues to meet the performance standards established during performance qualification, and that the working data collected during performance qualification remain valid. It is carried out once a year as part of the yearly test schedule, as part of any revalidation process, or whenever the user requests such confirmation.

8.6 PQ and PRQ tests should normally be preceded by the basic performance tests specified in the commissioning and yearly test schedules.

Loading conditions and reference loads

8.7 A **loading condition** is a specified combination of the nature and number of load items, the items of chamber furniture, and their distribution within the chamber. For example, a load placed on the top shelf of the chamber constitutes a different loading condition from an identical load placed on the bottom shelf. In principle, validation is not complete until a PQ test has been performed for each loading condition that the sterilizer is expected to process. In practice, loading conditions specified in the thermometric tests for small and full loads carried out during commissioning are designed to be representative of

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

the nature of production loads, and to present a greater challenge to the process than most production loads. In these cases PQ data may be taken from the commissioning tests and PQ tests may not be necessary.

8.8 Guidance on the design of loading conditions to achieve efficient sterilization can be found in Part 4 of this SHTM.

8.9 PQ tests are indicated in the following circumstances:

a. where the loading condition presents a greater challenge to the process than that presented by the commissioning tests. For example, while porous load sterilizers rarely need PQ tests, such tests will be required if the density of the porous material exceeds that of the standard test pack (see paragraph 7.27) or if narrow lumens restrict air removal and steam penetration;

b. where the nature of the load is not represented by the commissioning tests. For example, certain loads may be damaged by exposure to the normal sterilization temperature. In these cases, the settings of cycle variables and their permitted tolerances should ensure not only that the load is sterilized, but also that it is not unacceptably degraded by long exposure to high temperatures.

8.10 Where PQ tests are required it is often possible to select a production load that is known to present a greater challenge to the process than any of the others, This **reference load** can then serve as a worst case and allow one PQ test to be valid for a range of less demanding loading conditions.

8.11 A microbiological PQ test is required for LTSF and EO sterilizers in addition to the thermometric test. It may also be required for other sterilizers where air removal and steam penetration are difficult, and a thermometric test does not provide sufficient assurance that the sterilization conditions have been attained throughout the load.

8.12 Responsibility for deciding which loading conditions require PQ tests is exercised as follows in doubtful cases advice should be sought from the authorised person:

a. sterilizers to be used for medicinal products – jointly by the user, the quality controller and the test person;

b. LTSF and EO sterilizers – jointly by the user, the microbiologist and the test person;

c. all other sterilizers - jointly by the user and the test person.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermometric test for performance qualification

8.13 This test is suitable for all steam sterilizers, that is, porous loads, fluids, unwrapped instruments and utensils, LTS, LTSF and laboratory sterilizers. (See Chapter 16 for dry-heat sterilizers, and Chapter 18 for EO sterilizers.)

8.14 The production load under test will normally consist of discrete items such as packs, bottles or other containers. Place temperature sensors in the following positions:

a. one in each of three items known to be the slowest to attain the sterilization temperature;

b. one in each of three items known to be the fastest to attain the sterilization temperature;

c. if the sterilizer has a thermal door interlock, one in each of three items known to be the slowest to cool to 80°C.

8.15 If the load consists of less than six items, then place a sensor in each item.

8.16 The sensors should be in good thermal contact with the fluid or device which they are monitoring, and placed, If possible, in or on the part of the item slowest to heat up. (See Chapter 6 for guidance on the use of temperature sensors.)

8.17 The fastest and slowest items should have been identified as part of the design of the loading condition as described in Part 4. It may be desirable to confirm that the correct items have been selected by placing additional sensors in neighbouring items and running one or more preliminary operating cycles to verify that the selected items are indeed the fastest and slowest.

8.18 Place a sensor either in an active chamber discharge (see paragraph 6.26) or in the coolest part of the chamber. (This will normally be close to the sensor connected to the sterilizer recording instrument.)

8.19 Insert any load temperature probes provided in the chamber into the positions they will normally occupy in the load. If a probe is required to occupy the same position as a sensor, then the sensor should be moved to a neighbouring load item if they cannot both be accommodated in the same load item.

8.20 Note the loading condition and the positions of the sensors and probes in sufficient detail for the test to be replicated on any future occasion.

8.21 If the sterilizer has a pressure instrument, connect a pressure recorder (or test gauge) to the chamber.

8.22 Select the operating cycle that will be used for the production load. Start the cycle.

8.23 Ensure that a batch process record is made by the recording instrument fitted to the sterilizer. This will serve as the basis for a master process record for the

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

loading condition under test (see paragraph 8.58). If the sterilizer does not have a recorder (such as some machines for unwrapped instruments and utensils), note the elapsed time, indicated chamber temperatures and pressures at all significant points of the operating cycle, for example the beginning and end of each stage or sub-stage.

8.24 At the approximate mid-point of the plateau period, note the elapsed time and indicated chamber temperature and pressure.

8.25 For fluid loads, during the cooling stage wait for the temperature in the containers to fall to 90°C (plastic containers) or 80°C (glass). Wearing protective visor and gloves, attempt to open the door. As soon as the cycle is complete, but before opening the door, note the recorded temperature in the containers.

8.26 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. the holding time, as determined from the measured temperatures, is not less than that specified for the appropriate sterilization temperature band in Table 8;

c. during the holding time:

(i) the measured temperatures are within the sterilization temperature band specified for the operating cycle;

(ii) the indicated and recorded chamber temperatures are within 2°C of the temperature measured in the active chamber discharge;

(iii) the temperature measured in each load item does not fluctuate more than ± 1°C, and does not differ from that in other load items by more than 2°C;

(iv) the indicated and recorded chamber pressures are within 0.05 bar of the measured pressure;

d. at the end of the cycle:

(i) the temperature sensors have remained in position;

(ii) the items containing sensors are intact;

(iii) the temperature measured in any fluid containers is not greater than 90°C (plastic) or 80°C (glass).

8.27 If the test is satisfactory, it should be performed two more times to check for reproducibility and to establish permitted tolerances (see paragraph 8.47). A master process record should then be made as described below (see paragraph 8.58).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.28 If, having completed the commissioning tests, the sterilizer fails to meet the above requirements then it is possible that the sterilizer is not capable of processing the load. Advice should be sought from the authorised person.

Microbiological test for performance qualification

8.29 This test is designed to be used in exceptional circumstances as an additional PQ test for steam and dry-heat sterilizers. (See Chapter 17 for LTSF sterilizers, and Chapter 18 for EO sterilizers.)

8.30 The microbiological test should follow a satisfactory thermometric test, and use the identical loading condition and operating cycle. (See Chapter 7 for information on the use of biological and chemical indicators.)

8.31 Put a biological indicator and a chemical indicator together in each of the six load items that carried temperature sensors in the thermometric test. Place the items in as nearly as possible the same positions they occupied in the thermometric test.

8.32 Select and start the operation cycle.

8.33 Ensure that a batch process record is made by the recording instrument fitted to the sterilizer. If the sterilizer does not have a recorder (such as some machines for unwrapped instruments and utensils), observe and note the elapsed time, indicated chamber temperatures and pressures at all significant points of the operating cycle, for example the beginning and end of each stage or sub-stage.

8.34 At the approximate mid-point of the plateau period, note the elapsed time and indicated chamber temperature and pressure.

8.35 At the end of the cycle, remove the indicators from the load items. Check that the chemical indicators show a uniform colour change. If so, place each of the inoculated carriers in a bottle of recovery medium and incubate them with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-75).

8.36 The test should be considered satisfactory if the following requirements are met:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during the thermometric PQ test;

b. the requirements for microbiological tests set out in paragraph 7.72 are met.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Environmental gas test

8.37 This PQ test is designed to determine the concentration of formaldehyde or EO gas discharged into the loading area from the chamber and load at the end of a cycle. The concentration will vary with the type of load, wrapping material and environmental ventilation and temperature.

8.38 This test should follow a satisfactory thermometric PQ test. The loading condition, preconditioning process and operating cycle should be identical. The test may be combined with the microbiological PQ test.

8.39 A gas monitoring instrument as described in Chapter 6 is required.

8.40 Load the chamber as for the microbiological test for performance qualification.

8.41 Select the operating cycle used in the microbiological test. Start the cycle.

8.42 At the end of the cycle, measure the concentration of gas discharged from the chamber into the air when the door starts to open. The sample should be taken 80-120 mm in front of the gap at a height of 1.4-1.6 m. Continue to monitor the gas concentration for the next 15 min.

8.43 Determine the average concentration of gas over the 15 min period.

8.44 The test should be considered satisfactory if the average concentration of gas over the 15 min period does not exceed the short-term exposure limit specified in Table 1.

8.45 The data from the test should be used to establish a permitted upper limit for subsequent performance requalification. This should be as low as reasonably practicable, and in any case lower than the short-term exposure limit (see paragraph 1.28).

Test for degassing time

8.46 Loads from LTSF and EO sterilizers require a further PQ test to determine the minimum degassing time required before a load may be released for clinical use. It is the responsibility of the user to establish this period for the area in which sterilized loads are stored. Procedures for determining the levels of residual EO are described in BS EN 30993: Part 7; a standard for formaldehyde is under development.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Permitted tolerances

8.47 It is the purpose of performance qualification to establish the standard of performance expected with a particular operating cycle and loading condition, so that subsequent production cycles can be judged by that standard. The evidence for this performance is provided by the indicated, recorded and measured cycle variables, and it is necessary to determine how much each variable will be permitted to vary from cycle to cycle while still conforming to that standard.

8.48 A starting point is the limits prescribed for the cycle variables in the commissioning and PQ tests described in this SHTM. Other than in exceptional circumstances, these limits should be regarded as absolute, and a failure to meet them implies a failure of the test and a gross failure of the sterilizer. These limits originate from European and British Standards and from operational experience. They are set to accommodate a wide range of sterilizer models and designs of operating cycles. However, an individual sterilizer should be able to repeat a cycle well within these limits, and the permitted tolerances for PQ purposes should be correspondingly smaller.

8.49 It is important that the tolerances are set with careful consideration of the likely range of variation from cycle to cycle. If set too tight, acceptable production loads may be erroneously rejected as non-sterile, and automatic control and PRQ tests may fail unnecessarily. However, it would be a mistake to set an over-generous tolerance, since that may disguise variations signalling a developing malfunction of the sterilizer. The following paragraphs give guidance on determining the permitted tolerances. The authorised person should be consulted in cases of doubt.

8.50 PQ tests (or commissioning tests providing PQ data) collect indicated, recorded and measured data (see paragraph 7.2-7.20 for an explanation of these terms). The three sets of data serve different purposes and may require different tolerances:

a. **indicated data** are available to the user for production cycles on all types of sterilizer, but cannot be regarded as definitive. Except for sterilizers without a recorder, PQ tests require indicated values to be noted only during the holding time to ensure that they comply with the sterilization conditions;

b. **recorded data** are available to the user for production cycles on most types of sterilizer and can be regarded as definitive for routine production control. The permitted tolerances are normally marked on a master process record (see paragraph 8.58). The user should be aware of any calibration error in the recorder, but since production cycles are validated by direct comparison of the batch process record (BPR) with the master process record (MPR), such errors can be ignored in determining the permitted tolerances;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

c. **measured data** are not available for production cycles and so play no part in routine monitoring. However, they are to be regarded as definitive for the purposes of performance requalification. Measured variables are more reliable than Indicated or recorded values, and the permitted tolerances should reflect this.

8.51 A further consideration is the intended use of the PQ data:

a. **PQ data valid for a single loading condition**: where the PQ data are to be used for one loading condition only, the variation between cycles is essentially random (that is, due to uncontrolled variables or the intrinsic performance limits of the sterilizer) and the permitted tolerances can be tight. This is appropriate, as such cases are often used for loads which would be damaged if the limits were broader. The tolerances should be set by experience of the sterilizer and of the cycle. The three replicate thermometric PQ tests (see paragraph 8.13) will give some indication of what variation to expect;

b. **PQ data valid for a range of loading conditions**: where the PQ data for a single loading condition is judged to be valid for a range of loading conditions, the variation between cycles will contain a systematic variation related to the differing loading conditions and therefore the permitted tolerances will be greater. The choice of loading conditions for which the data is valid should take into account whether this greater tolerance is acceptable;

c. **PQ data obtained from commissioning tests**: for many loads, especially on porous load sterilizers, PQ tests are not normally necessary and data from the thermometric commissioning tests are used to establish performance standards for a wide range of loading conditions. In these cases, data from the small-load and full-load tests can be used to establish the limits of variation for production loads which fall between these two extremes. The permitted tolerances will be broader than either (a) or (b).

8.52 Note that the permitted tolerances during the holding time of an operating cycle will generally be tighter than those allowed during the preceding and following stages. In no circumstances should these tolerances permit the cycle variables to depart from the sterilization conditions specified in Table 8, unless the operating cycle has been designed with that intention.

8.53 Tolerances are normally expressed as a permitted variation either side of a central value, either in absolute terms or as a percentage. In some cases the tolerances may be expressed as an upper or lower limit, with the variables permitted to take any value on the safe side of the limit.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

PQ report

8.54 All the data collected during PQ tests should be filed in a PQ report, a copy of which should be kept with the plant history file. The report should contain or refer to the complete specification for the sterilization process. The specification should be detailed enough to allow the loading condition, the operating cycle and the test itself to be replicated on any future occasion. The report should include the following:

a. a specification of the loading condition, defined either by the nature and number of load items, items of chamber furniture, and their distribution within the chamber, or by a coded reference to a detailed specification held elsewhere;

b. a specification of the operating cycle, defined either by the settings for the cycle variables or by a coded reference to a detailed specification held elsewhere;

c. a specification of any preconditioning, conditioning and degassing process (this is essential for EO sterilizers);

d. all the indicated, recorded and measured data from the test, drawing attention to the values and permitted tolerances of elapsed time and of the indicated, recorded and measured cycle variables at all significant points of the operating cycle, for example at the beginning and end of each stage or sub-stage (the tolerances in recorded variables should also be marked on the master process record);

e. for loads which require the removal of air before sterilization, the method used to verify whether the minimum conditions of steam penetration into the load are attained (for porous load sterilizers, this is by use of the air detector);

f. the original of the master process record derived from the test.

8.55 EO sterilizers require extensive additional data for safety and quality control purposes and these are listed in Table 11.

8.56 Immediately following the PQ tests, the test person should prepare PQ summary sheets (see Appendix 3) and working copies of any necessary master process records. These should be given to the user and kept with the sterilizer process log.

8.57 If PQ tests are not required, the PQ summary sheet should contain data from the thermometric test for a full load and be marked accordingly.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Preparation of a master process record

8.58 A master process record (MPR) is a record of the values and permitted tolerances of cycle variables for a correctly functioning operating cycle against which test and production cycles can be checked. (The term master temperature record was used in previous editions of HTM 10.) It is derived either from the batch process record (BPR) obtained during a thermometric PQ test or, if no PQ test has been deemed necessary, from the BPR obtained from a full-load thermometric test carried out during commissioning. (A further MPR may be required to validate automatic control tests with an empty chamber.) It may be a one-to-one transparent copy of the BPR, a template derived from the BPR, or data stored in a computer control system and compared automatically.

8.59 An MPR is primarily intended for production control on sterilizers used to process medicinal products, but it is also used for test purposes on all types of sterilizer.

8.60 When required for production purposes, a sufficient number and variety of MPRs should be prepared so that there is a suitable MPR for each loading condition or for the appropriate reference load (see paragraph 8.10).

8.61 To prepare an MPR, the appropriate thermometric test should be carried out as described above (see paragraph 8.13). If all three cycles are satisfactory, the BPR showing the shortest holding time should be used for producing the MPR. It should be marked with the following information:

a. an MPR reference number and reference to the PQ report;

b. sufficient information to identify the sterilizer uniquely (by a unique reference number; by the name of the manufacturer, the model of sterilizer and the serial number; or by any sufficient combination of these);

c. a specification of the loading condition as in paragraph 8.54a and other loading conditions for which the MPR is valid;

d. a specification of the operating cycle as in paragraph 8.54b;

e. the permitted tolerances for the cycle variables during each stage of the operating cycle (these are best shown graphically);

f. for fluid loads, the point during the cycle at which the temperature of the fluid in the hottest container falls to 80^{o}C (glass) or 90^{o}C (plastic);

g. date of test;

h. signatures of the test person and the user.

8.62 When the BPR has been annotated it may be endorsed “master process record” and a transparency obtained. An example of an MPR is shown in Figure 7.

8.63 If the BPR is in the form of numerical data, the MPR should be presented in a similar form to the BPR to permit ready comparison. As a minimum

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

requirement, it should list the cycle variables at each turning point of the cycle and contain a plot generated from the data. An example of a digital MPR is shown in Figure 8.

Tests for performance requalification

8.64 PRQ tests are performed once a year to ensure that the sterilization conditions are still met. They should follow the yearly schedule of checks and tests listed in Chapter 5. For a given operating cycle it is normally necessary only to perform the PRQ test for a reference load for which a PQ report exists. The cycle can then be assumed to be effective for less demanding loads also. The need for PRQ tests on other loads should be agreed between the user and the test person.

8.65 The procedure for the PRQ test is similar to that for the PQ test. The operating cycle and the loading condition should be identical to those used for the original PQ test. The test should be considered satisfactory if the values of the measured cycle variables are within the tolerances stated in the PQ report.

8.66 For dry-heat sterilizers, fluid sterilizers and certain fluid cycles on laboratory sterilizers, a simplified PRQ test is required at quarterly intervals, and this is provided for in the schedules (see Tables 4 and 5).

8.67 Results of PRQ tests should be appended to the relevant PQ report.

8.68 Providing the yearly test programme has been completed satisfactorily, the sterilizer should pass the PRQ test. If the PRQ test is not satisfactory, the advice of the authorised person should be sought.

Notes to Figures 7 and 8

Figure 7 shows a typical master process record (MPR) for a fluid sterilizer. This is based on a batch process record made during a performance qualification test at a sterilization temperature of 121°C.

X Temperature recorded in the active chamber discharge.

Y Temperature recorded in the load item slowest to attain the sterilization temperature.

Z Chamber pressure.

A The end of the holding time is taken as the datum point from which intervals are measured.

B Start of the holding time, with permitted tolerance

C Start of the plateau period, with permitted tolerance.

D Temperature in the load item attains 80°C.

E Temperature in the load item falls to 80°C. The door may be opened at this point.

F Sterilization temperature band.

9. Steam quality tests

Introduction

9.1 A continuous supply of saturated steam is required for steam sterilization and for humidification in certain EO sterilizers. Too high a level of non-condensable gases will prevent the attainment of sterilizing conditions; too little moisture carried in suspension may allow the steam to become superheated during expansion into the chamber, while excess moisture may cause damp loads.

9.2 For all these tests, the steam should be sampled from the steam service pipe to each sterilizer. The measurements are taken during a period of maximum steam demand, when steam is first admitted to the sterilizer chamber.

9.3 Silicone rubber tubing is porous to steam and should not be used to carry steam in these tests.

Non-condensable gas test

9.4 This test is used to demonstrate that the level of non-condensable gases in the steam will not prevent the attainment of sterilization conditions in any part of the load. (Possible sources of non-condensable gases are discussed in Part 2 of this SHTM.) The method described should be regarded not as measuring the exact level of non-condensable gas, but a method by which the provision of acceptable steam quality can be demonstrated.

9.5 The apparatus is shown and described in Figure 9. All sizes are nominal.

9.6 Connect the needle valve to the steam service pipe as shown in Figure 9.

9.7 Assemble the apparatus so that condensation will drain freely from the long rubber tube into the sampling pipe. If the tube is too short, copper or stainless steel tubing may also be used.

9.8 Fill the container with cold water until it overflows. Fill the burette and funnel with cold water, invert them and place them in the container. Draw out any air that has collected in the burette.

9.9 With the steam sampling pipe out of the container, open the needle valve and allow steam to purge the air from the pipe. Place the pipe in the container, locate the end within the funnel, and add more cold water until it flows through the overflow pipe.

9.10 Place the empty measuring cylinder under the container overflow.

9.11 Adjust the needle valve to allow a continuous sample of steam into the funnel sufficient to cause a small amount of steam hammer to be heard. Ensure that

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

all the steam is discharged into the funnel and does not bubble out into the container. Note the setting of the needle valve. Close the valve.

9.12 Ensure that the container is topped up with cold water and that the measuring cylinder is empty. Draw out any air present in the burette

Figure 9: Apparatus for non-condensable gas test

h burette stand
i rubber tubing
j thermometer 0-100°C with a minor mark of 1°C
k overflow pipe

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9.13 Ensure that the sterilizer chamber is empty except for the usual chamber furniture. Select and start the operating cycle.

9.14 When the steam supply to the chamber first opens, open the needle valve to the previously noted setting, allowing a continuous sample of steam into the funnel sufficient to cause a small amount of steam hammer to be heard.

9.15 Allow the steam sample to condense in the funnel. Any non-condensable gases will rise to the top of the burette. Overspill formed by the condensate and the water displaced by the gases will collect in the measuring cylinder.

9.16 When the temperature of the water in the container reaches 70-75°C, close the needle valve. Note the volume of gas collected in the burette (V_b) and the volume of water collected in the measuring cylinder (V_c).

9.17 Calculate the fraction of non-condensable gases as a percentage as follows:

$$\text{Fraction of non-condensable gases} = 100 \times (V_b/V_c).$$

9.18 The test should be considered satisfactory if the fraction of non-condensable gases does not exceed 3.5%.

9.19 The test should be done two more times to check consistency. If the results of the three tests differ significantly, then the cause should be investigated before proceeding further.

Superheat test

9.20 This test is used to demonstrate that the amount of moisture in suspension with steam from the service supply is sufficient to prevent the steam from becoming superheated during expansion into the chamber.

9.21 The method described here uses a low-volume sample, continuously taken from the centre of the steam service pipe. The level of superheat determined by this method cannot be regarded as indicative of the true dryness of the steam in the pipe since condensate flowing along the inner surface is not collected. However, devices designed to separate free condensate are incorporated into the steam delivery system to the chamber and therefore the level determined by this method is representative of steam conditions likely to prevail within the chamber during the plateau period.

9.22 This test should normally follow a satisfactory test for non-condensable gases.

9.23 This test, and the subsequent dryness value test, require a pitot tube as shown in Figure 10. The rest of the apparatus is shown and described in Figure 11. All sizes are nominal.

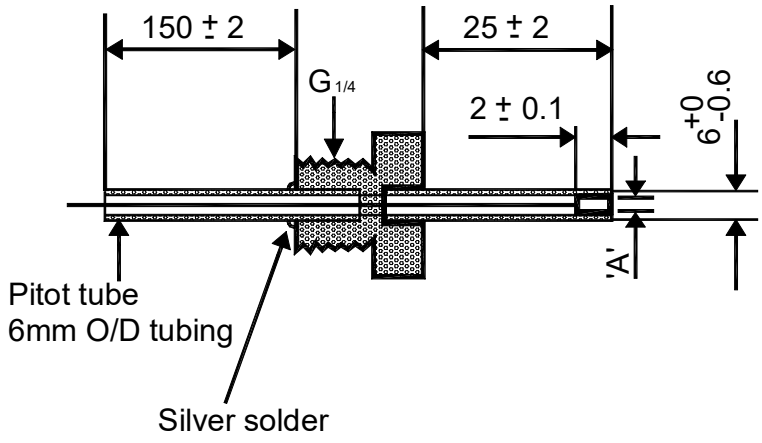
9.24 Fit the pitot tube concentrically within the steam service pipe as shown in Figure 11.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9.25 Fit the sensor entry gland to the steam service pipe. Insert one of the sensors through the gland and position it on the axis of the pipe.

9.26 Insert the second sensor through the gland in the expansion tube and position it on the axis of the pipe. Wrap lagging around the expansion tube. Push the tube on to the pitot.

Figure 10: Pitot tube



Steam pressure bar	Bore 'A' mm ± 0.02
up to 3	0.08
up to 4	0.06
up to 7	0.04

9.27 Ensure that the sterilizer chamber is empty except for the usual chamber furniture. Select and start the operating cycle.

9.28 From the measured temperatures, note the temperature in the steam service pipe (for use in the dryness test) and in the expansion tube (T_e) when the steam supply to the chamber first opens. Calculate the superheat in °C from the following equation:

$$Superheat = T_e - T_o$$

where T_o is the boiling point of water at local atmospheric pressure.

9.29 The test should be considered satisfactory if the superheat measured in the expansion tube does not exceed 25°C.

Dryness test

9.30 The accurate measurement of the percentage of moisture content in the steam is difficult, and the traditional methods where constant steam flow is required are not suitable for sterilizers. This test should be regarded not as measuring the true content of moisture in the steam, but as a method by which the provision of acceptable steam quality can be demonstrated. Possible sources of excess moisture are discussed in Part 2 of this SHTM.

9.31 The test is conveniently carried out immediately after the superheat test.

9.32 This test requires a pitot tube as shown in Figure 10. The apparatus is shown and described in Figure 12. All sizes are nominal. A laboratory balance is also required, capable of weighing a load up to 2 kg with an accuracy of 0.1 g or better.

9.33 If it is not already fitted, fit the pitot tube concentrically within the steam service pipe as shown in Figure 12.

9.34 If it is not already fitted, fit the sensor entry gland to the steam service pipe. Insert a temperature sensor through the gland and position it on the axis of the pipe.

9.35 Connect the rubber tube to the longer of the pipes in the stopper, place the stopper in the neck of the vacuum flask, weigh the whole assembly and note the mass (M_1).

9.36 Remove the stopper and tube assembly and pour 650 ± 50 ml of cold water (below 27°C) into the flask. Replace the stopper and tube assembly, weigh the flask and record the mass (M_2).

9.37 Support the flask close to the pitot, and ensure that the rubber tube and flask are protected from excess heat and draughts. Do not connect it to the pitot tube yet.

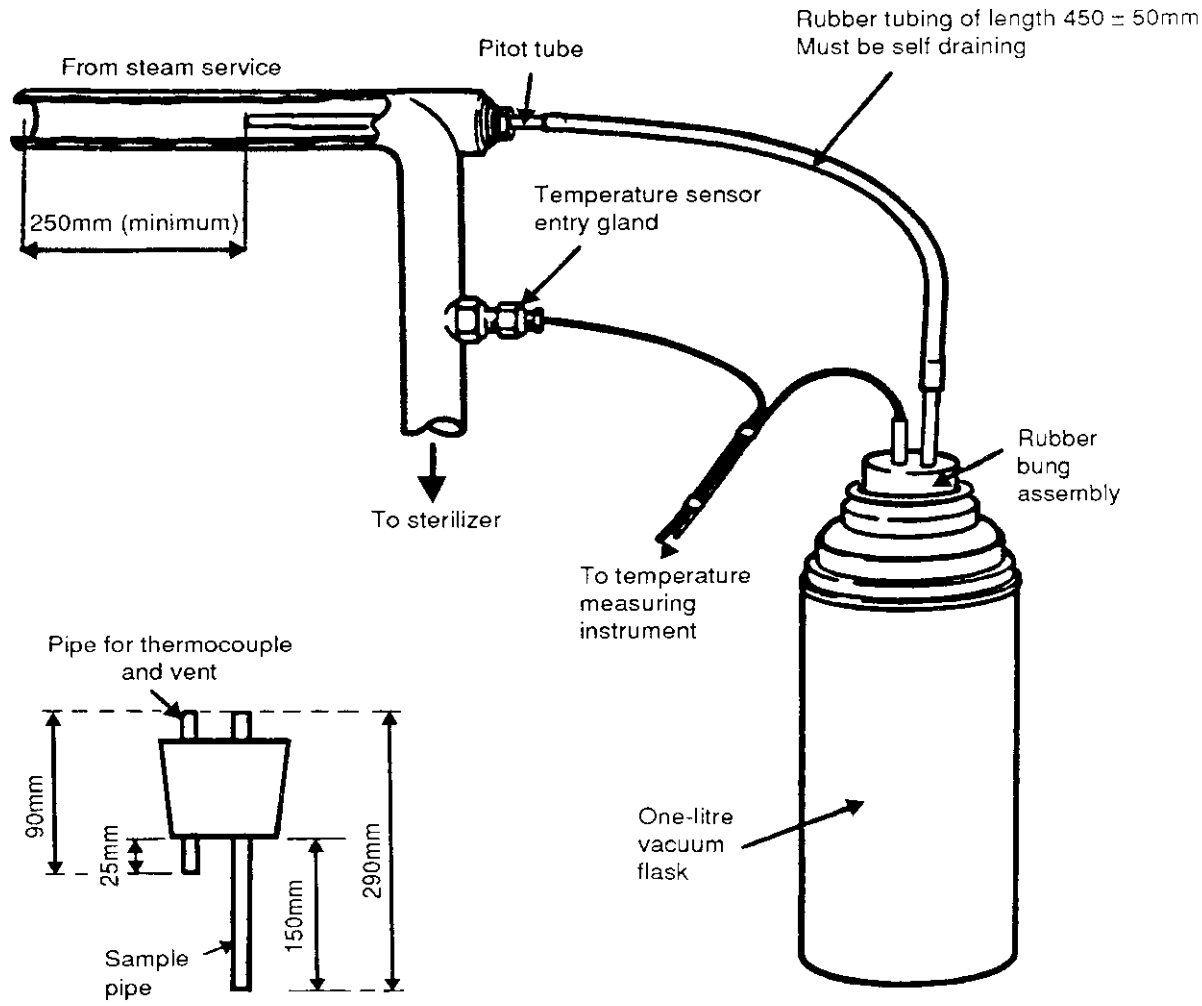
9.38 Introduce the second temperature sensor through the shorter of the two pipes in the stopper and into the water in the flask. Note the temperature of the water in the flask (T_o).

9.39 Ensure that the sterilizer chamber is empty except for the usual chamber furniture. Select and start the operating cycle.

9.40 When the steam supply to the chamber first opens, connect the rubber tube to the pitot discharge and wrap lagging around it. Arrange the rubber tube to permit condensate to drain freely into the flask. Note the temperature in the steam service pipe (T_s).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 12: Apparatus for dryness test



Rubber bung assembly
Glass pipes have 6mm outside diameter

9.41 When the temperature of the water in the flask is approximately 80°C, disconnect the rubber tube from the pitot, agitate the flask so that the contents are thoroughly mixed, and note the temperature of the water (T_1).

9.42 Weigh the flask and stopper assembly and note the mass (M_3).

9.43 The initial mass of water in the flask is given by $M_w = M_2 - M_1$.

9.44 The mass of condensate collected is given by $M_c = M_3 - M_2$.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

9.45 Calculate the dryness value of the steam from the following equation:

$$D = \frac{(T_1 - T_0)(4.18M_W + 0.24)}{LM_C} - \frac{4.18(T_s - T_1)}{L}$$

where :

T_o = initial temperature of the water in the flask (°C);

T_1 = final temperature of the water and condensate in the flask (°C);

T_s = average temperature of the steam delivered to the sterilizer (°C);

M_w = initial mass of water in the flask (kg);

M_c = mass of condensate collected (kg);

L = latent heat of dry saturated steam at temperature T_s (kJ kg^{-1}).

9.46 A derivation of this equation, and a discussion of the assumptions implicit within it, can be found in Appendix 2.

9.47 The test should be considered satisfactory if the following requirements are met:

a. the dryness value is not less than 0.90 (if metal loads are to be processed, the dryness value should not be less than 0.95);

b. throughout the operating cycle, the temperature measured in the steam service pipe is within 3°C of that measured during the superheat test.

10. Sound pressure test

Introduction

10.1 British and European Standards require the manufacturer to carry out a sound power test as a type test for the sterilizer. This test, which measures the total radiated sound power from a sterilizer, must be performed in a suitably equipped test room and it is not necessary or practicable to repeat the test once a sterilizer has been installed.

10.2 Of more practical concern is the perceived level of noise in the immediate vicinity of the sterilizer. This quantity, the A-weighted sound pressure level, depends not only upon the sound power, but also upon the acoustic properties of the environment and other sources of noise. It must therefore be determined on site with the sterilizer installed and working normally. It follows that a failure of the sound pressure test need not imply that the sterilizer is faulty. It is possible that the machine is installed in a room with insufficient sound insulation. Information about sound-reducing measures may be found in Part 2 of this SHTM.

10.3 The sound pressure test described in this chapter should be carried out according to the detailed instructions in BS EN ISO 3746. The additional information given here is by itself not sufficient to permit the test to be completed by personnel unfamiliar with the requirements of this standard.

Test procedure

10.4 A precision sound-level meter is required as described in paragraph 6.51 The sound pressure levels are determined from a number of microphone positions. Where the measuring instrument has insufficient input channels, additional instruments or repeated operating cycles will be required.

10.5 The test determines the A-weighted sound pressure levels using a rectangular measurement surface. For the purpose of this test, the “reference surface” defined in BS EN ISO 3746 is to be drawn as follows:

a. for a single sterilizer, the reference surface is the smallest rectangular box that just encloses the sterilizer, with a width and depth measured from the outside of the vessel lagging, and a height measured from the floor to the top of the vessel lagging. The box does not include pipes and valves used to connect the sterilizer to its services;

b. for a group of sterilizers treated as a single source, the reference surface is the smallest rectangular box that just encloses the reference surfaces of the individual sterilizers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.6 Noise sources which contribute to the sound pressure level in the room in which the sterilizer is installed (including sources in adjacent rooms) should be operating during the test. In particular, all the building services in the area surrounding the room containing the sterilizer should be working normally, under their design conditions.

10.7 Sterilizers should be regarded as “large sound sources” as defined in BS EN ISO 3746. The measurement distance, *d*, should be 1.0 ± 0.1 m or half the distance from the sterilizer to an adjacent wall, whichever is less. It should not be less than 150 mm. Microphones should be placed in the following positions:

a. where a single sterilizer is the only major noise source in the room, place ten microphones as shown in Figure 13a. (If the sterilizer is recessed into a wall or partition, three of these microphones will be in the loading area and the remainder in the plantroom.) The microphone above the sterilizer may be omitted for safety reasons or if preliminary measurements show that its exclusion does not significantly affect the calculated value of the mean sound pressure level;

b. where several sterilizers are installed, they should be treated as a single large source and the reference surface drawn as described in paragraph 10.5b. Place ten microphones as shown in Figure 13b. If any dimension of the reference surface exceeds 5.0 m, intermediate microphone positions will be required as described in BS EN ISO 3746.

10.8 Load the sterilizer with a full load as described in the appropriate chapter of this SHTM.

10.9 If there is a choice of operating cycle, select the cycle with the highest sterilization temperature. Ensure that the pressure and flow from the steam and water services are set to normal working levels. Start the operating cycle.

10.10 Integrate the sound pressure level throughout the operating cycle or, if the cycle exceeds 30 minutes, over a 30-minute period known to contain the loudest sounds.

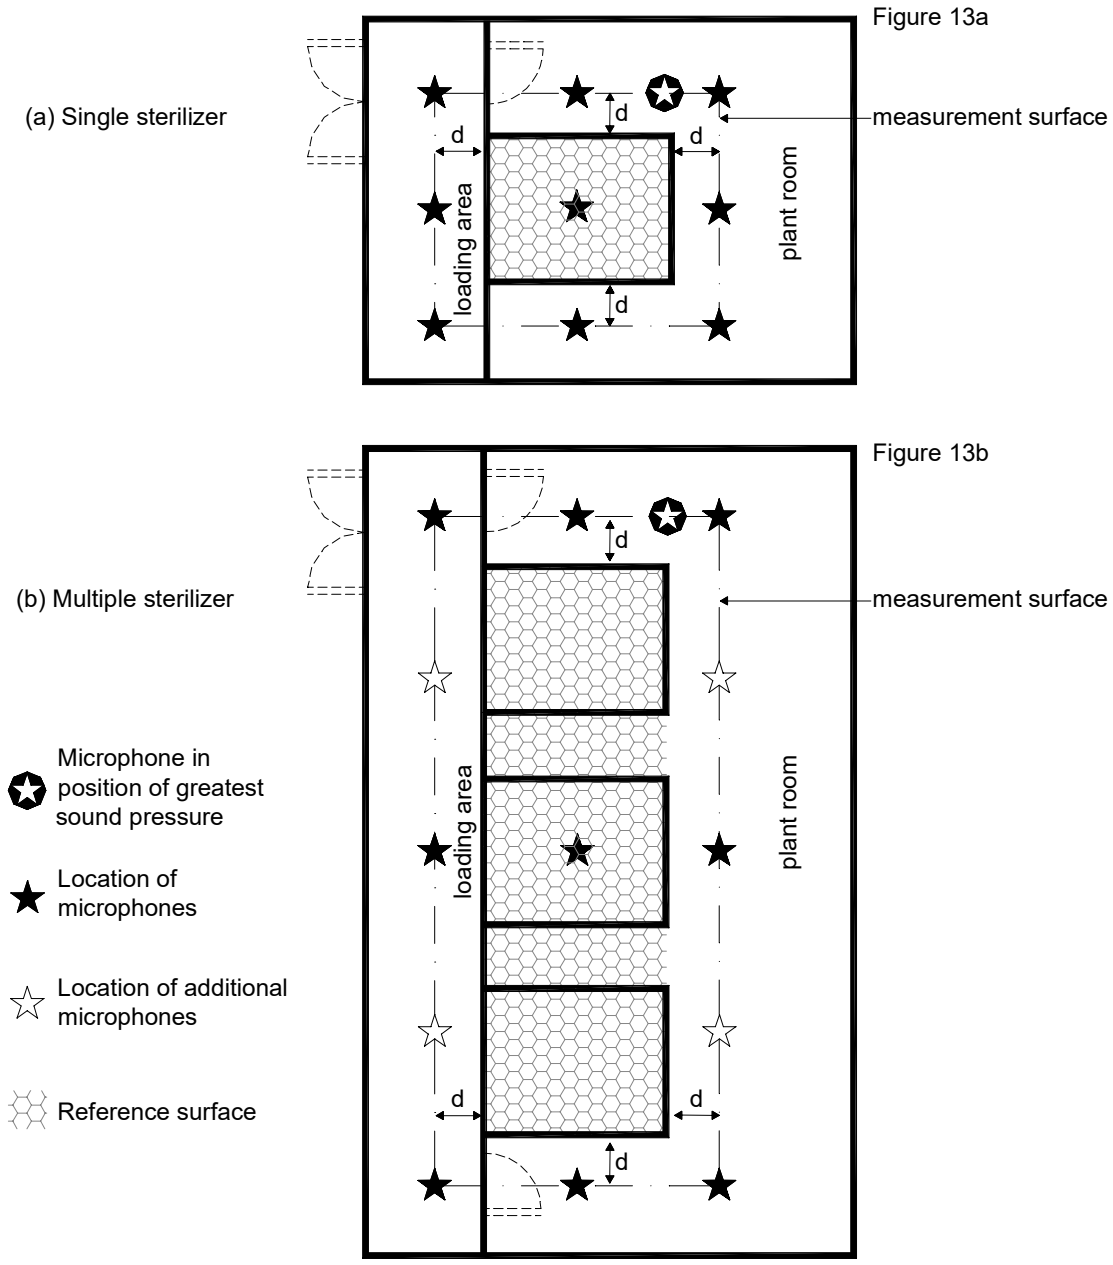
10.11 Using the procedure described in BS EN ISO 3746, for both the plantroom and the loading area, determine the following:

a. the mean A-weighted surface sound pressure level;

b. the peak A-weighted surface sound pressure level.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 13: Location of microphones for sound pressure test



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.12 The test should be considered satisfactory if the following requirements are met:

a. in the loading area, the mean A-weighted surface sound pressure level does not exceed:
   (i) 55 dBA for a sterilizer installed in an operating suite, pharmacy, treatment room or other noise-sensitive area;
   (ii) 70 dBA for a sterilizer installed in a sterile services department;
   (iii) 85 dBA for a sterilizer installed in an area that is not noise-sensitive;
b. in the plantroom, the mean A-weighted surface sound pressure level does not exceed 85 dBA;
c. in both the loading area and the plantroom, the peak A-weighted surface sound pressure level does not exceed the mean A-weighted surface sound pressure level by more than 15 dBA.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11. Chamber integrity tests

Introduction

11.1 These tests are designed to show that the sterilizer chamber does not leak either under vacuum or under pressure, and that the devices used to monitor leakage and the presence of air are functioning correctly.

Vacuum leak test

11.2 The vacuum leak test is applicable to any sterilizer which employs vacuum to remove air from the load, that is, porous load sterilizers, LTS disinfectors, LTSF sterilizers, EO sterilizers and some laboratory sterilizers.

11.3 Leakage of air into the chamber at a rate greater than that specified below (see paragraph 11.15) is unacceptable for three reasons:

a. the presence of air inhibits penetration of the load by the sterilant (steam or gas) and prevents sterilization;

b. air leaking into the chamber during the drying and air admission stages will not have passed through the bacteria-retentive filter, and therefore there is a risk of recontamination of the load;

c. the presence of air may cause an explosive hazard in EO sterilizers

11.4 A vacuum leak test is required to establish that permissible limits are not exceeded.

11.5 The test is performed by measuring the change of vacuum in the chamber when all valves leading to it have been closed and the vacuum source isolated. If the test is conducted as part of a programme including thermometric tests, it will be necessary to repeat it with the temperature sensors and any test pressure gauge in place, and again when they have been removed, to ensure that there is no leakage through the ports. These tests are specified in the appropriate schedules in Chapters 4 and 5.

11.6 The test may either be part of the air removal stage or be performed at the end of the drying stage. It is designed to be carried out either automatically or semi-automatically, and in either case selected by a switch or data entry point located on the front fascia. It should be performed with an empty chamber.

11.7 If the sterilizer is not fitted with a vacuum leak test instrument, connect a 0-160 mbar absolute pressure gauge (Table 6) to the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.8 For the test to be accurate, the chamber temperature should be stable. For example, in a closed vessel at 40 mbar absolute, the pressure changes by approximately 1 mbar for each 10°C change in temperature over the range 20-140°C. At 70 mbar the change is approximately 2 mbar. The test could be compromised if the temperature changes by more than 10°C during the period in which the chamber pressure is monitored. Stabilise the temperature of the chamber by one of the following methods:

a. If the vessel incorporates a heated jacket, carry out an operating cycle with the chamber empty;

b. if there is no heated jacket, ensure that the temperature of the chamber is no greater than 20°C from ambient.

11.9 When the temperature has stabilised, start the vacuum leak test cycle. For automatic systems the following steps are performed automatically, and the vacuum leak rate is displayed as a pressure rise in mbar min^{-1}. For semi-automatic systems, the pressures should be read and noted by the operator.

11.10 When the pressure in the chamber drops below 50 mbar absolute (or the maximum vacuum attained in an EO cycle), close all the valves connected to the chamber and stop the vacuum pump. Note the time and the absolute pressure (P_1).

11.11 Wait for 5 minutes (± 10 s), and then note the pressure again (P_2).

11.12 Wait for a further 10 minutes (± 10 s), and then note the pressure for a third time (P_3).

11.13 Restore the operating cycle, and allow it to proceed normally.

11.14 Calculate the vacuum leak rate for the 10-minute period from:

$$Vacuum\ \ leak\ \ rate = (p_3 - p_2)/10 mbar \min^{-1}$$

11.15 For chambers with a capacity of 250-600 l, the test should be considered satisfactory if the following requirements are met:

a. the absolute pressure (P_2) at the start of the 10-minute period is:
   (i) less than 70 mbar for porous load sterilizers, LTS disinfectors, LTSF sterilizers and laboratory sterilizers;
   (ii) as specified by the manufacturer for EO sterilizers;

b. the vacuum leak rate does not exceed:
   (i) 1.3 mbar min^{-1} for porous load sterilizers and laboratory sterilizers;
   (ii) 0.5 mbar min^{-1} for LTS disinfectors and LTSF sterilizers;
   (iii) 1.0 mbar min^{-1} for EO sterilizers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.16 For chambers outside the range 250-600 l, the test should be considered satisfactory if the pressure P_2 and the vacuum leak rate are as specified by the manufacturer.

11.17 Considerable care must be applied in the interpretation of the results of leak tests. On a typical test on a porous load sterilizer the pressure may rise by 20 mbar or more ($P_2 – P_1$) in the first 5 minutes of the test due to the evaporation of moisture remaining in the chamber and connecting pipework. Such a result does not necessarily indicate a leak.

11.18 A machine which fails to meet the requirements of this test should not be used until the fault has been rectified and the test satisfactorily completed.

Vacuum leak monitor test

11.19 For LTS disinfectors, and LTSF and EO sterilizers, the air removal stage is followed by an automatic check on the leakage of air into the chamber. The vacuum leak monitor test ensures that when the monitoring device is challenged with a specified leak rate the operating cycle is aborted and a fault is indicated.

11.20 Connect an air flow metering device (see paragraph 6.52) to the chamber.

11.21 Follow the procedure for the vacuum leak test, adjusting the metering device to cause a leak rate over the 10-minute test period of:

a. 5.0 ± 0.2 mbar min^{-1} for LTS disinfectors and LTSF sterilizers;

b. 3.0 ± 0.2 mbar min^{-1} for EO sterilizers.

11.22 For LTS disinfectors and LTSF sterilizers, place a standard test pack (see paragraph 7.27) in the chamber. For EO sterilizers, leave the chamber empty. Start the operating cycle.

11.23 The test should be considered satisfactory if the operating cycle is aborted after the air removal stage and a fault is indicated at the end of the cycle.

Pressure leak test

11.24 The pressure leak test is applicable to sterilizers which use EO or EO gas mixtures to sterilize products in chambers pressurised above atmospheric pressure.

11.25 Leakage of EO from the chamber at a rate greater than that specified below (see paragraph 11.35) is unacceptable because the gas is toxic and flammable. The maximum exposure limits are listed in Table 1. A pressure leak test is required to establish that leakage from the sterilizer will not cause these limits to be exceeded.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.26 The test is performed by measuring the change of pressure in the chamber when all valves leading to it have been closed and the pressurising source has been isolated. If the test is conducted as part of a programme which includes thermometric tests, it will be necessary to repeat it with the temperature sensors and any test pressure gauge in place, and again when they have been removed, to ensure that there is no leakage through the ports. These tests are specified in the appropriate schedules in Chapters 4 and 5.

11.27 The test is performed using an inert gas as described in paragraph 1.29 and the measurements taken during the gas exposure stage. The test is designed to be carried out either automatically or semi-automatically, and in either case is selected by a switch or data entry point located on the front fascia. It should be performed with an empty chamber, immediately following a vacuum leak test.

11.28 If the sterilizer is not fitted with a pressure leak test instrument, connect a test gauge to the chamber. Thus should have a accuracy of 1% or better over a range of ± 10% of the gas exposure pressure.

11.29 Start the pressure leak test cycle. This is similar to a normal operating cycle except that an inert gas is used instead of EO. For automatic systems the following steps are performed automatically and the pressure leak rate is displayed as a pressure fall in mbar/min. For semi-automatic systems, the pressures are noted by the operator.

11.30 When the working pressure is attained, the gas will continue to be injected intermittently for a further 5 minutes to allow the pressure and temperature in the chamber to stabilise.

11.31 Close the valves connected to the chamber, and stop the pressure source. Observe and note the time and the pressure (P_1).

11.32 Wait for 60 ±1 minutes and then observe and note the pressure again (P_2).

11.33 Restore the operating cycle, and allow it to proceed normally.

11.34 Calculate the pressure leak rate for the 60-minute period from:

$$\textit{pressure leak rate} = (p_1 - p_2)/60 \ \textit{mbar} \ \text{min}^{-1}$$

11.35 The test should be considered satisfactory if the following requirements are met:

a. for chambers with a capacity of 250-600 l, the pressure leak rate does not exceed 1.0 mbar min^{-1};

b. for chambers outside the range 250-600 l, the pressure leak rate is as specified by the manufacturer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.36 A machine which fails to meet the requirements of this test should not be used until the fault has been rectified.

Air detector tests

11.37 An air detector is fitted to certain sterilizers which employ vacuum as a means of removing air from the load before sterilization. It is currently required for porous load sterilizers and may also be fitted to LTS disinfectors, LTSF sterilizers and some laboratory sterilizers. It is used to determine whether any air or non-condensable gas present in the chamber is sufficient to impair the sterilizing process. The air detector should cause a fault to be indicated if the amount of air or gas in the chamber at the start of the plateau period is sufficient to depress the temperature in the centre of the load more than 2°C below the temperature in the active chamber discharge.

11.38 A correctly adjusted air detector will contribute to product security but should not be regarded as an alternative to effective maintenance.

11.39 The procedure for setting an air detector is lengthy and complex if prior information is not available. The manufacturer will have established the correct settings for the air detector and should supply the following information:

a. the setting of the sensitivity of the air detector;

b. the level of the signal from the air detector (the “trigger point”), which will trigger the automatic controller to abort the cycle and indicate a fault;

c. the vacuum leak rate that will cause this level to be exceeded.

11.40 The three air detector tests are designed to demonstrate compliance with the manufacturer’s specifications. Several operating cycles will be required to complete the tests satisfactorily.

11.41 The three tests - for small load, full load and function - should be performed in sequence after it has been established that the vacuum leak rate of the sterilizer is acceptable.

11.42 Before starting the tests, connect an air-flow metering device (see paragraph 6.52) to the chamber by means of the valved port provided by the sterilizer manufacturer. It will normally be necessary to conduct a sequence of vacuum leak tests to establish the relationship between the setting on the metering device and the induced vacuum leak rate. The relationship should be recorded in the plant history file for each sterilizer.

11.43 If the sterilizer is not fitted with a leak test instrument, connect a 0-160 mbar absolute pressure test gauge (Table 6) to the chamber.

11.44 The two air detector performance tests require temperatures to be recorded by independent measuring equipment as described in Chapter 6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Performance test for a small load

11.45 This test is designed to determine the setting for the air detector so that, with a small load, it will respond to a leak rate sufficient to depress the temperature in the test pack by no more than 2°C.

11.46 The procedure for the small-load test is set out in the flow chart in Figure 14. If the air detector is correctly set, the test should proceed rapidly down the left-hand branch and be complete in two cycles.

11.47 Select the operating cycle with the highest sterilization temperature and standard drying time.

11.48 Place a standard test pack (see paragraph 7.27) in the chamber, with the bottom of the pack supported 100-200 mm above the centre of the chamber base, and two temperature sensors placed in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one at the approximate centre of the test pack (the wire from the sensor should be carefully arranged to prevent steam tracking along it).

11.49 A fresh test pack is required for each cycle. In practice, three test packs will be enough, provided that two are unfolded and left to air while the other is in the chamber.

11.50 At the start of the test ensure that the air detector sensitivity is set to the value recommended by the manufacturer. The detector can be disabled by adjusting the automatic controller so that it will not recognise a fault. This may be done by setting the trigger point, in accordance with the manufacturer s instructions, to a level that will not be attained during normal operation (see paragraph 11.39(b)).

11.51 During the air removal stage, admit air into the chamber by means of the metering device. From the measured temperatures, determine the temperature depression at the start of the plateau period:

Depression, $\Delta T = T_c - T_p$ where:

T_c = temperature measured in the active chamber discharge;

T_p = temperature measured in the centre of the test pack.

11.52 When the small-load test is complete, proceed immediately to the full-load test.

Performance test for a full load

11.53 This test is designed to show that an air detector set to respond correctly during the small-load test will also respond correctly with a full load. It is normally carried out immediately after a satisfactory completion of a small-load test.

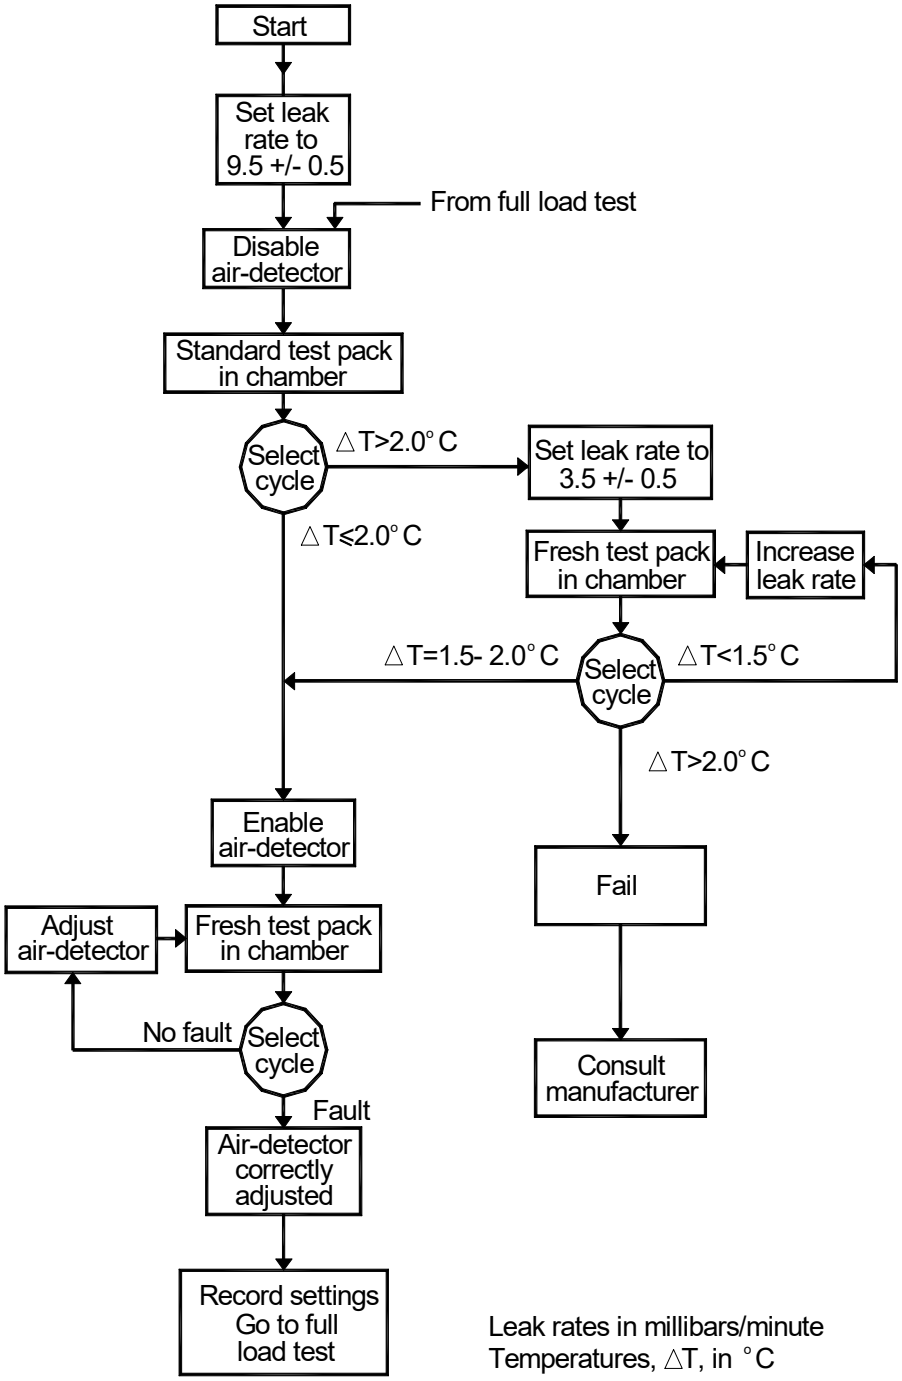
© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.54 The procedure for the full-load test is set out in the flow chart in Figure 15. If the air detector has been correctly set, the test should proceed rapidly down the left-hand branch and be complete in two cycles.

11.55 Select the operating cycle used for the small-load test.

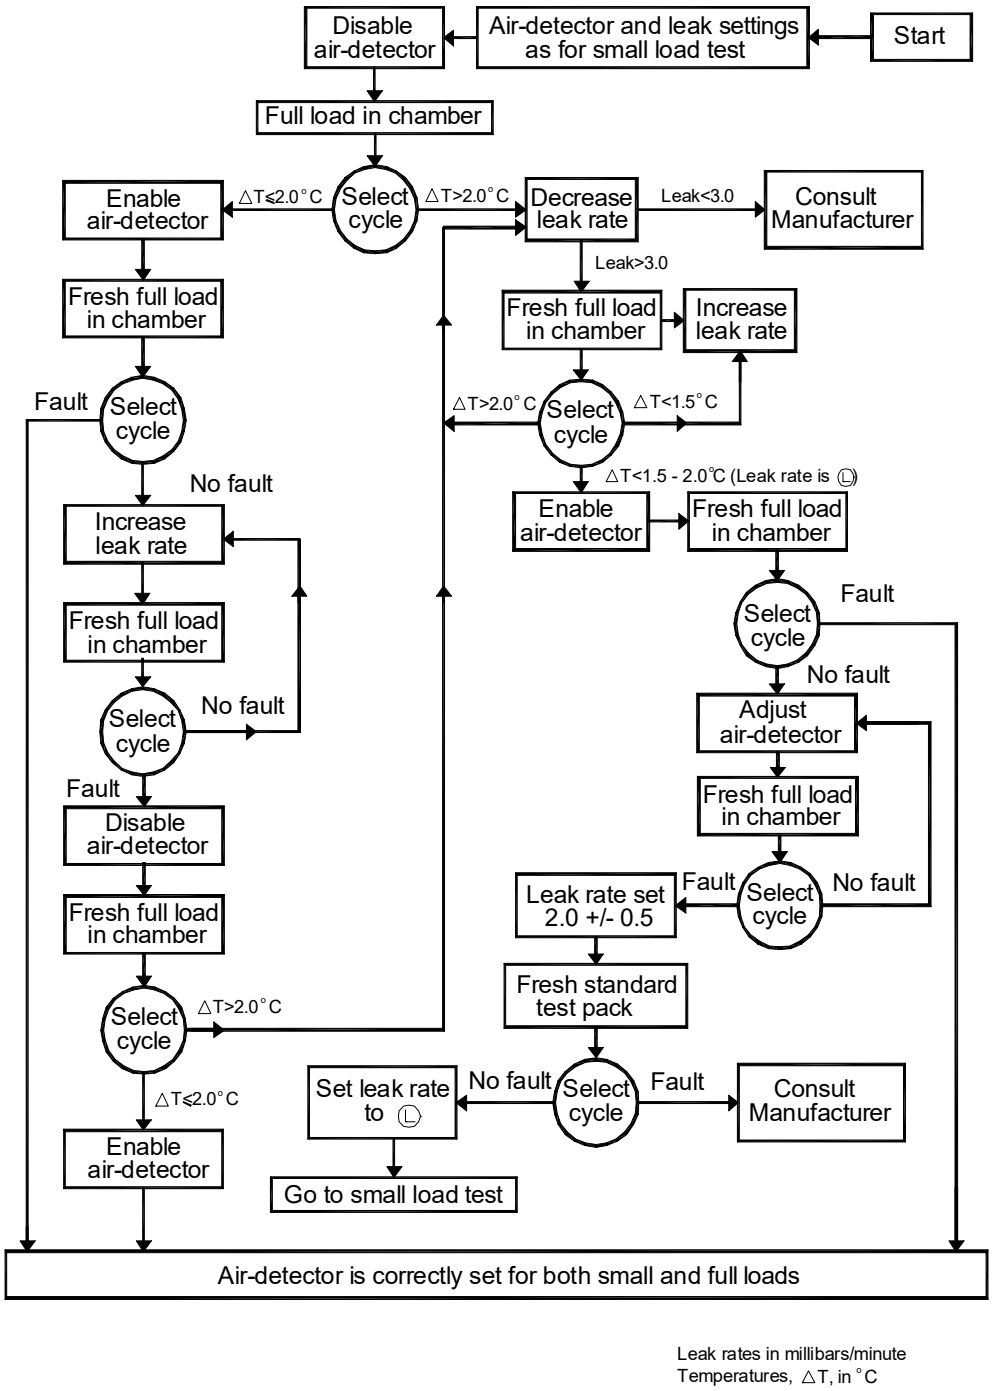
© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 14: Procedure for air detector small-load test



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 15: Procedure for air detector full load



11.56 The load is a standard test pack placed in the chamber in a position identified by the manufacturer as the most difficult to sterilize, with the remaining usable chamber space filled with a full load appropriate to the type of sterilizer under test (see the procedure for the relevant thermometric test for a full load). Place temperature sensors as for the small-load test.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.57 A fresh load is required for each cycle. In practice, three loads will be enough provided that two are unfolded and left to air while the other is in the chamber.

11.58 At the start of the test ensure that the air detector sensitivity and leak rate settings are identical to those established in the small-load test.

11.59 If, during the test, it becomes necessary to readjust the air detector, the procedure requires the small-load test to be repeated from the point indicated in Figure 13.

Function test

11.60 This test is designed to confirm that the air detector is functioning correctly during a normal operating cycle.

11.61 Set the air-flow metering device to the setting established during the small-load test.

11.62 Place a standard test pack in the chamber, with the bottom of the pack supported 100-200 mm above the centre of the chamber base.

11.63 Select and start the operating cycle.

11.64 The test should be considered satisfactory if the operating cycle is aborted and a fault is indicated. If the cycle is not aborted, then the advice of the manufacturer should be sought.

11.65 When the air detector tests are complete, the settings of the air detector sensitivity, the automatic controller trigger point, and the air-flow metering device and induced vacuum leak rate should be noted in the test report.

12. Automatic control test

Introduction

12.1 The automatic control test is designed to show that the operating cycle functions correctly as evidenced by the values of the cycle variables indicated and recorded by the instruments fitted to the sterilizer. It is carried out once a week on most sterilizers, and is the main test for ensuring that the sterilizer continues to function correctly.

12.2 During the commissioning, yearly and quarterly test programmes the temperature and pressure sensors for subsequent thermometric tests will be connected to the chamber during this test. If one sensor is placed in the active chamber discharge (see paragraph 6.26) the calibration of the sterilizer instruments may conveniently be checked during the holding time of the automatic control test.

Test procedure

12.3 For porous load sterilizers, LTS disinfectors and laboratory sterilizers (fabrics cycle), place a standard test pack (see paragraph 7.27) in the chamber, with the bottom of the pack supported 100-200 mm above the centre of the chamber base.

12.4 For sterilizers for unwrapped instruments and utensils, leave the chamber empty except for the usual chamber furniture.

12.5 For fluid, dry-heat, LTSF, EO and laboratory sterilizers:

a. for installation and commissioning tests, leave the chamber empty except for the usual chamber furniture;

b. for periodic tests, load the chamber with a production load of a type for which a record has been established during performance qualification. If the test proves satisfactory, the sterilized load may be released for normal use.

12.6 Sterilizers designed for fluid loads (fluid sterilizers, dry-heat sterilizers and certain laboratory sterilizers) are equipped with one or two probes to record the temperature of the load. If a production load is being processed, insert the probes into the load in the positions they would normally occupy. Otherwise stow the probes on the bracket provided in the chamber. Do not insert probes into discard material to be processed in laboratory make-safe cycles.

12.7 If an LTSF or EO sterilizer is being tested with an empty chamber, ensure that the sterilant is replaced with an inert substitute (see paragraph 1.29).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.8 Select the sterilization temperature for the operating cycle to be tested. As a rule, this should be the highest temperature compatible with the load. If a production load is being used, select the temperature at which it would normally be sterilized. Start the cycle.

12.9 Ensure that a batch process record is made by the recording instrument fitted to the sterilizer. If the sterilizer does not have a recorder (such as some machines for unwrapped instruments and utensils), observe and note the elapsed time, indicated chamber temperatures and pressures at all significant points of the operating cycle, for example the beginning and end of each stage or sub-stage, and the maximum values during the holding time.

12.10 At the approximate mid-point of the plateau period, note the elapsed time and indicated chamber temperature and pressure.

12.11 For fluid loads, during the cooling stage wait for the temperature in the containers to fall to 95°C (plastic containers) or 85°C (glass). Wearing protective visor and gloves, attempt to open the door.

12.12 For fluid loads, as soon as the cycle is complete, but before opening the door, observe and note the recorded temperature in the containers.

12.13 The test should be considered satisfactory if the following requirements are met:

a. a visual display of cycle complete is indicated;

b. during the whole of the cycle the values of the cycle variables as shown on the batch process record are either within the limits established by the manufacturer as giving satisfactory results, or, for production loads, within the permitted tolerances marked on a master process record subsequently established during performance qualification;

c. during the plateau period determined from the recorded chamber temperature:

   (i) the indicated and recorded chamber temperatures are within the appropriate sterilization temperature band specified in Table 8;

   (ii) the difference between the indicated and recorded chamber temperature does not exceed 2°C;

   (iii) the difference between the indicated and recorded chamber pressure does not exceed 0.1 bar;

d. the holding time determined from any load temperature probes is not less than that specified in Table 8;

e. during the holding time, any temperatures recorded in the load are within the appropriate sterilization temperature band specified in Table 8;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

f. the door cannot be opened until the cycle is complete;

g. for fluid loads, at the end of the cycle the temperature recorded in the containers is not greater than 90°C (plastic) or 80°C (glass);

h. the person conducting the test does not observe any mechanical or other anomaly.

13. Porous load sterilizers

Introduction

13.1 This chapter contains detailed procedures for tests specific to sterilizers designed to process porous loads. Schedules prescribing which tests are to be carried out, and when, are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests).

13.2 Unless specified otherwise, all the tests should be performed at each of the sterilization temperatures available on the sterilizer.

Chamber wall temperature test

13.3 This test is designed to show that temperature variations across the chamber walls do not exceed 2°C at the sterilization temperature. Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6. The test is performed with an empty chamber.

13.4 Place 12 temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. five on each of the two chamber side walls (one at the approximate centre and four adjacent to the corner positions of the usable chamber space);

c. one on the plane of the usable chamber space (not on the wall), at a point nearest to the steam inlet port.

13.5 If a jacket is fitted, ensure that it is heated. Select and start the operating cycle.

13.6 The test should be considered satisfactory if, at the start of the plateau period, the measured temperatures are within 2°C of each other.

Thermometric test for a small load

13.7 This test is used to demonstrate that after the air removal stage of the operating cycle, sterilizing conditions are obtained within the chamber and standard test pack. The more air there is to remove, the more exacting will be the test; that is why the pack is used by itself in an otherwise empty chamber.

13.8 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

13.9 Place a standard test pack (see paragraph 7.27) in the chamber with the bottom of the pack supported 100-200 mm above the centre of the chamber base.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13.10 Place three temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one at the approximate centre of the test pack (the wire from the sensor should be carefully arranged to prevent steam tracking along it);

c. one placed in the free space 50 ± 5 mm above the approximate centre of the upper surface of the test pack.

13.11 Connect a pressure recorder (or test gauge) to the chamber.

13.12 Start the operating cycle, with standard drying time, and take readings as described for the automatic control test (see paragraph 12.9).

13.13 If a test gauge is being used, measure the chamber pressure at the approximate mid-point of the holding time.

13.14 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. during the plateau period the temperature measured above the test pack does not exceed the temperature measured in the active chamber discharge by more than 5°C for the first 60 s and 2°C for the remaining period;

c. the equilibration time determined from the measured temperatures does not exceed 15 seconds for chambers up to 800 l and 30 seconds for larger chambers;

d. the holding time determined from the measured temperatures is not less than that specified in Table 8;

e. during the holding time the temperatures measured in the active chamber discharge and in the centre of the test pack:

(i) are within the appropriate sterilization temperature band specified in Table 8;

(ii) do not fluctuate by more than ± 1°C;

(iii) do not differ from one another by more than 2°C;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

f. during the holding time:

   (i) the indicated and recorded chamber temperatures are within 1°C of the temperature measured in the active chamber discharge;

   (ii) the indicated and recorded chamber pressures are within 0.05 bar of the measured pressure;

g. for sterilizers using vacuum as the sole method of drying:

   (i) the duration of the drying stage is not less than 3 minutes;

   (ii) the chamber pressure at the end of the stage does not exceed 40 mbar absolute;

h. at the end of the cycle the sheets are sensibly dry.

Thermometric test for a full load

13.15 The full-load test is designed to demonstrate that, at the levels at which cycle variables are set, rapid and even penetration of steam into the centre of a load occurs, and the sterilizing condition is achieved in a test load of specified maximum mass and of sufficient size to fill the usable chamber space.

13.16 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

13.17 The load is made up of a standard test pack (see paragraph 7.27) and additional folded sheets designed to represent the maximum mass of textiles which may be processed in the sterilizer. Each sheet should contain at least 50% m/m of cotton fibre and have a surface density of approximately 200 g m^{-2}. They should be washed and aired as for the standard test pack (see paragraphs 7.30-31). After airing, the sheets should be folded to approximately 25 cm x 50 cm and laid one on top of the other to form stacks of mass 7.5 ± 0.5 kg.

13.18 Place the standard test pack within the chamber in a position identified by the manufacturer as the most difficult to sterilize. This will normally be in the approximate centre of the chamber.

13.19 Place three temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one at the approximate centre of the test pack (the wire from the sensor should be carefully arranged to prevent steam tracking along it);

c. one below the approximate centre of the top sheet of the test pack.

13.20 Load the rest of the usable chamber space with stacks of sheets. (The mass of fabric in the load should be equivalent to 7.5 ± 0.5 kg for a unit volume 300 mm x 300 mm x 600 mm.)

13.21 Connect a pressure recorder (or test gauge) to the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13.22 Start the operating cycle, with standard drying time, and take readings as described for the automatic control test (see paragraph 12.9).

13.23 If a test gauge is being used, measure the chamber pressure at the approximate mid-point of the holding time.

13.24 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. the equilibration time determined from the measured temperatures does not exceed 15 s for chambers up to 800 l and 30 s for larger chambers;

c. the holding time determined from the measured temperatures is not less than that specified in Table 8;

d. during the holding time:

   (i) the measured temperatures are within the appropriate sterilization temperature band specified in Table 8;

   (ii) the measured temperatures do not fluctuate by more than ± 1°C;

   (iii) the measured temperatures do not differ from one another by more than 2°C;

   (iv) the indicated and recorded chamber temperatures are within 1°C of the temperature measured in the active chamber discharge;

   (v) the indicated and recorded chamber pressures are within 0.05 bar of the measured pressure;

e. the total cycle time is within the performance class stated by the manufacturer;

f. at the end of the cycle the sheets are sensibly dry.

Load dryness test

13.25 This test is used to demonstrate that the operating cycle, without extended drying, will not cause an increase in moisture in a standard test pack sufficient for there to be uncertainty about the dryness of loads routinely processed.

13.26 Three polythene bags, at least 35 cm x 25 cm and of polythene at least 250µm thick, and a balance capable of weighing loads up to 2 kg with an accuracy of 0.1 g or better, are required.

13.27 Allow the sheets which will comprise the standard test pack to air as described in paragraph 7.31.

13.28 Mark three of the sheets and similarly mark each of the polythene bags so that each sheet is identified with a bag.

13.29 Weigh each of the polythene bags and note the mass (M_1).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13.30 Place each sheet in a polythene bag, weigh each bag with its enclosed sheet and note the mass (M_2).

13.31 Remove the sheets from the bags and assemble the standard test pack with one of the sheets in the centre of the pack and one in the second position from each end of the pack.

13.32 Place the test pack in the approximate centre of the sterilizer chamber and start the operating cycle within one minute. (Extended drying should not be used.)

13.33 Not more than one minute after the cycle has finished, remove the test pack from the chamber. Remove the three sheets from the test pack and put them quickly into their marked bags. Seal each bag by turning its open end over several times. This operation should be completed as quickly as possible to reduce evaporation of retained moisture and in any case within three minutes of the end of the cycle.

13.34 Weigh each bag with its enclosed sheet and note the mass (M_3).

13.35 Calculate the percentage gain in mass of each sheet from the formula:

$$\textit{percentage gain in mass} = 100 \times \frac{(M_3 - M_2)}{(M_2 - M_1)}$$

13.36 The test should be considered satisfactory if the average gain in mass of each of the three bagged sheets is not more than 1%.

Hospital load dryness check

13.37 Process a production load which is known to present the greatest challenge to the operating cycle. Extended drying may be required.

13.38 The check should be considered satisfactory if a “cycle complete” indication is obtained and the load is sensibly dry.

Bowie-Dick test for steam penetration

13.39 Sterilization is achieved by the rapid and even penetration of steam into all parts of the load and the maintenance of these conditions for the specified holding time. To ensure this, it is essential to remove air from the chamber and load, and to provide a steam supply which contains a minimal volume of non-condensable gases. Any residual air and non-condensable gases will become concentrated as a bubble in the load and inhibit steam penetration.

13.40 The Bowie-Dick test shows whether or not steam penetration of the test pack is even and rapid, and thus by implication that air or other non-condensable gases are not present. It does not confirm that the sterilization conditions in the load have been achieved.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Principle of the test

13.41 The test, as originally conceived and described in earlier editions of HTM 10 (Bowie, Kelsey and Thomson, 1963), is based on the use of a chemical indicator in the form of an adhesive tape stuck to a piece of suitable paper to form a St Andrew's cross. This indicator paper is placed at the centre of a test pack of folded huckaback towels and then subjected to an operating cycle. The indicator tape shows a change of colour in response to a combination of time, temperature and moisture.

13.42 If no air is present in the chamber, steam will penetrate rapidly and completely, and the indicator will show a uniform colour change. If air is present, it will collect within the pack as a bubble. The indicator in the region of the bubble will be of a different colour than elsewhere on the paper, because of a lower temperature, lower moisture level or both.

13.43 The modern Bowie-Dick test uses a Class B chemical indicator conforming to BS EN 867: Part 3 (see paragraph 7.40) contained within a standard test pack (see paragraph 7.27). The indicator is distributed over an A4 paper sheet in the form of a geometric pattern.

13.44 When used in conjunction with a standard test pack, Class B indicators are designed to show a failure either if, at the start of the holding time, the temperature at the centre of the test pack is 2°C or more below the temperature in the active chamber discharge; or if the indicator is exposed to insufficient moisture. Both conditions are usually caused by the presence of air or other non-condensable gases (see paragraph 13.56). Because of the tolerances necessary in the manufacture of chemical indicators, users should be aware that in order to detect a temperature difference of 2°C the indicator may show signs of failure with a smaller temperature difference.

Test procedure

13.45 The Bowie-Dick test is normally preceded by a warm-up cycle. This cycle is necessary because the effectiveness of air removal may depend on all parts of the sterilizer being at working temperature. A satisfactory sterilizer may give a fail result if this is not done.

13.46 Remove the wrapping from a standard test pack and place the indicator paper in the sheet located nearest to the centre of the pack. Reassemble and secure the pack and replace the wrapping.

13.47 Place the test pack in the chamber with the bottom of the pack supported 100-200 mm above the centre of the chamber base.

13.48 Select the Bowie-Dick test cycle. Ensure that the holding time will not be longer than that specified in Table 10. If this time is exceeded, the indicator may change in such a way as to make it difficult to detect the variations that would indicate a fail condition. Start the operating cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 10: Holding times for the Bowie-Dick test cycle

Sterilization temperature	Holding time	
[°C]	minimum [min]	maximum [min]
134	3.3	3.5
126	10.8	11.0
121	16.8	17.0

13.49 During the holding time, note the reading on the cycle counter, the chamber temperature indicator and the chamber pressure indicator.

13.50 When the cycle is complete, remove the indicator paper from the test pack.

13.51 The test should be considered satisfactory if the following requirements are met:

a. there is a uniform change throughout the indicator;

b. the automatic controller indicates that a Bowie-Dick test cycle has just been completed.

13.52 It is important to compare the colour of the indicator at the corners of the paper with that at the centre so that any difference can be clearly seen. If there is any discernible difference the test should be recorded as failed, and the paper marked accordingly. A large area of unchanged indicator points to a gross failure.

13.53 The indicator paper should be marked with the result and kept for reference for at least three months. The chemical reaction continues during this time and the paper may be discarded when the indicator becomes unreadable. The associated batch process record should be kept for at least 11 years.

13.54 An unsatisfactory test result indicates that the machine should not be used until the fault has been rectified. It is important to realise that if a sterilizer fails to pass the Bowie-Dick test it cannot be made safe simply by increasing the holding time until a uniform colour change is produced. A failed sterilizer is in urgent need of skilled attention.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

13.55 Several factors may inhibit steam penetration and cause the test to fail Common causes of failure include the following:

a. an inefficient air removal stage;

b. an air leak during the air removal stage;

c. the presence of non-condensable gases in the steam supply.

13.56 A subsequent thermometric test for a small load (see paragraph 13.7) will assist in diagnosing the cause of failure:

a. if the test reveals a temperature depression at the centre of the test pack, the problem is likely to be inefficient air removal or an air leak into the chamber. Air remaining in the centre of the test pack is inhibiting the penetration of steam and the correct temperature is not being attained. The sterilizer should not be returned to service until it has been subjected to a vacuum leak test (see paragraph 11.2) and an air detector function test (see paragraph 11.60);

b. if the test fails to reveal a temperature depression, the problem is almost certainly air or other non-condensable gases in the steam supply. In this case the correct temperature is being attained but the steam is diluted, and insufficient moisture is present to change the indicator. The sterilizer should not be returned to service until the steam supply has been tested for the presence of non-condensable gases (see paragraph 9.4).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

14. Fluid sterilizers

Introduction

14.1 This chapter contains detailed procedures for tests specific to sterilizers to process aqueous fluids in sealed containers. Schedules prescribing which tests are to be carried out and when are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests).

14.2 Unless specified otherwise, all the tests should be performed at each of the sterilization temperature available on the sterilizer.

14.3 For the thermometric tests the containers should be filled with the volume of water. The volumes of the fluid in each container should not differ from their mean by more than 5%. At the start of the cycle the temperature of the fluid in each container should be 20 ± 5°C.

Heat exchanger integrity test

14.4 This test is designed to check the integrity of the heat exchanger used to heat and cool the circulating coolant (air or water) in the sterilizer chamber. The circuit which is directly heated is called the primary circuit. Water in the primary circuit must be assumed to be non-sterile. The circuit which exposes coolant to the load is called the secondary circuit. In recent models of fluid sterilizers the secondary circuit is designed to operate at a higher pressure than the primary to prevent leakage of contaminated water into the chamber.

14.5 Where the heat exchanger is designed and constructed in a fail-safe fashion so that the secondary coolant cannot become contaminated under any circumstances, the test is required only for commissioning and yearly tests.

14.6 Attach a pressure recorder (or test gauge) to the primary circuit. The range should include the maximum pressure to which the circuit is to be pressurised.

14.7 Charge the primary circuit with water and pressurise it to either 1.5 times its maximum working pressure or twice the maximum pressure in the secondary circuit, whichever is less. This should be done in accordance with the manufacturer's instructions, and in some cases may require additional ports and valves to be fitted.

14.8 Close the inlet and outlet valves, and allow the pressure to stabilise over a period of 10 min. Observe and note the measured pressure. Wait for a further 10 min. Observe and note the pressure again.

14.9 The test should be considered satisfactory if the measured pressure has not fallen over the 10 min period.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermometric test for a full load

14.10 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

14.11 Load the chamber with one-litre bottles (nominal capacity), each filled with 1 l of water, at the minimum spacing recommended by the manufacturer. The bottles and chamber furniture should fill the usable chamber space. If the sterilizer is not designed to process one-litre bottles, the largest size recommended by the sterilizer manufacturer should be used.

14.12 Place 10 or 11 temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);
b. one in each of the three bottles that are the slowest to attain the sterilization temperature;
c. one in each of the three bottles that are the fastest to attain the sterilization temperature;
d. one in each of the three bottles that are the slowest to cool to 90°C (plastic) or 80°C (glass);
e. one in the coolest part of the coolant spray system (if fitted).

14.13 Insert the load temperature probe into a bottle adjacent to the bottle identified as the slowest to attain the sterilization temperature. If a second probe is provided, insert it into a bottle adjacent to the bottle identified as the fastest to attain the sterilization temperature.

14.14 Connect a pressure recorder (or test gauge) to the chamber and, for sterilizers fitted with a spray pump, to the spray pump discharge. Where the heat exchanger secondary circuit is designed to operate at a higher pressure than the primary circuit, connect a third sensor to measure the differential pressure between the circuits.

14.15 Select and start the operating cycle and take readings as described for the automatic control test (see paragraph 12.9).

14.16 If a test gauge is being used, measure the chamber pressure at the approximate mid-point of the holding time.

14.17 As soon as the cycle is complete, note the measured temperature in the bottles before opening the door.

14.18 If required, collect a sample of coolant for a subsequent coolant quality test (see paragraph 14.32).

14.19 If the coolant is derived from a water or steam service, and is intended to come into contact with the load containers, the operating cycle must expose the coolant to sufficient heat to ensure that it is free of microbial contamination by the end of the holding time. This is checked by calculating an F_0 value (see

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Part 4 for a discussion of the use of F_0) that is equivalent to the time in minutes at a sterilization temperature of 121°C. If the test recorder is not capable of calculating F_0 (see paragraph 6.16), proceed as follows:

a. from the measured temperatures, identify the point during the heat-up time at which the coolant temperature first reaches 108°C. Note the temperature (T°C) at subsequent one-minute intervals until the end of the holding time;

b. for each measurement, calculate the incremental F_0 (ΔF_0) from the following equation:

$$\Delta Fo = log_{10}\left(\frac{T-121}{10}\right) minutes;$$

c. the F_0 value is the sum of all ΔF_0

14.20 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (paragraph 12.13) are met;

b. the holding time is not less than that specified for the appropriate sterilization temperature band in Table 8;

c. during the holding time:

(i) the measured temperatures are within the appropriate sterilization temperature band specified in Table 8;

(ii) the measured temperatures are within 1°C of each other;

(iii) the indicated and recorded chamber temperatures are within 1°C of the temperature measured in the active chamber discharge;

(iv) the indicated and recorded chamber pressures are within 0.05 bar of the measured pressure;

(v) the recorded chamber pressure is within 0.05 bar of saturated steam pressure or, if a partial pressure system is used, as specified by the manufacturer;

d. at the end of the cycle:

(i) the temperature sensors have remained in position;

(ii) the bottles containing sensors have not leaked, burst or broken;

(iii) not more than one of the other bottles (or 1%, whichever is the greater) has burst or broken;

(iv) the temperature measured in the bottles is not greater than 90°C (plastic) or 80°C (glass);

e. throughout the cycle:

(i) the coolant spray pressure complies with the manufacturer's specifications;

(ii) the pressure in the heat exchanger secondary circuit is greater than that in the primary circuit (if appropriate);

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

f. F_0 for the coolant is not less than 8 minutes;

g. the total cycle time is within the performance class stated by the manufacturer.

Thermometric test for a small load

14.21 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

14.22 Place 25 vials or ampoules of 5-ml nominal capacity, each containing 5 ml of water, in each of two wire baskets. Support one basket in the upper rear half of the usable chamber space and the other in the lower front half. Use the upper and lower shelves if provided. If the sterilizer is not designed to process vials or ampoules of this size, the smallest size and number of containers recommended by the sterilizer manufacturer should be used. Where the sterilizer is to be used to process one size of container only, the test load may be a single container of this size, filled with the nominal volume of water and supported in a position known to be the slowest to attain the sterilization temperature.

14.23 Place temperature sensors and load temperature probes as described for the full-load test.

14.24 Connect a pressure recorder (or test gauge) to the chamber and other pressure sensors as described for the full-load test.

14.25 Follow the procedure for the full-load test.

14.26 The test should be considered satisfactory if, except for paragraph 14.20 (g), the requirements of the full-load test (see paragraph 14.20) are met.

Simplified thermometric test for performance requalification

14.27 This test is not a substitute for a full PRQ test, but is used quarterly to check that the sterilization conditions continue to be met. Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

14.28 Prepare a production load known to present the greatest challenge to the operating cycle and for which there is a PQ report. (This will normally be the reference load used in the yearly PRQ tests.)

14.29 Place three or four temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one in a container that is the slowest to attain the sterilization temperature;

c. for chambers of capacity of 800 l and above, one in a container that is the fastest to attain the sterilization temperature;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. one in a container that is the slowest to cool to 80°C (glass) or 90°C (plastic).

14.30 Place the load in the chamber as described in the PQ report. Select and start the operating cycle.

14.31 The test should be considered satisfactory if the requirements listed in the PQ report are met.

Coolant quality test

14.32 This test measures the concentration of particulates and dissolved solids in the coolant. It is carried out after a satisfactory operating cycle, normally at the end of a full-load, small-load or PQ test.

14.33 Rinse a one-litre bottle with purified water BP immediately before use and discard the rinsings.

14.34 Use the bottle to collect a test sample of cooling water from the coolant system immediately after an operating cycle but before the final discharge to waste.

14.35 Take a dish or beaker, made of silica or borosilicate glass, of capacity at least 150 ml. Dry the dish for 2 h in an oven at a temperature of 110 ± 2°C. Put it in a desiccator and allow it to cool to ambient temperature. Weigh it to the nearest 0.1 mg and note the mass (M_1).

14.36 Ensuring that the test sample is well mixed, measure 100 ml of the test sample into the dish and evaporate it over a boiling-water bath until apparently dry.

14.37 Repeat with two further 100 ml of test sample transferred into the same dish.

14.38 Put the dish into the oven and heat at a temperature of 110 ± 2°C for about 2 h. Put it in the desiccator and allow it to cool to ambient temperature. Weigh it to the nearest 0.1 mg and note the mass (M_2).

14.39 Repeat paragraph 14.38 until the difference between two consecutive weighings does not exceed 0.2 mg.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14.40 Calculate the concentration of residue in milligrams per litre of cooling water.

$$Concentration\ of\ residue = \frac{(M_2 - M_1)}{V} mg\,l^{-1}$$

where:

M_1 = mass of dry dish (mg);

M_2 = final mass of dish and residue (mg);

V = volume of sample water evaporated (normally 300 ml).

14.41 The test should be considered satisfactory if the concentration of residue does not exceed 40 mg l^{-1}

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

15. Sterilizers for unwrapped instruments and utensils

Introduction

15.1 This chapter contains detailed procedures for tests specific to sterilizers designed to process unwrapped solid instruments and utensils. Schedules, prescribing which tests are to be carried out and when, are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests). Except where stated otherwise, the tests in this chapter apply equally to fixed and transportable sterilizers.

15.2 Unless specified otherwise, all the tests should be performed at each of the sterilization temperatures available on the sterilizer.

Chamber overheat cut-out test

15.3 This test applies only to sterilizers where the steam is generated within the chamber. The test is done with an empty chamber and with insufficient water charge for a complete cycle. Temperatures should be recorded by independent measuring equipment as described in Chapter 6.

15.4 Attach a temperature sensor to the chamber wall in a position identified by the manufacturer as attaining the highest temperature.

15.5 Select the operating cycle with the highest sterilization temperature. (Only one cycle is normally provided.) Start the cycle.

15.6 The test should be considered satisfactory if the following requirements are met:

a. a boil-dry condition occurs before the end of the cycle;

b. the overheat cut-out operates, and the heaters are isolated from the electricity supply;

c. the chamber wall temperature does not exceed the temperature specified by the manufacturer.

Thermometric test for a small load

15.7 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

15.8 Place a pair of forceps (for example 5-inch artery forceps) in the approximate centre of the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

15.9 Place three temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one trapped between the jaws of the forceps;

c. where steam is supplied from outside the chamber, one in the upper third of the free chamber space;

d. where steam is generated within the chamber, one either in the reservoir or, if water is retained in the chamber, in the water.

15.10 Connect a pressure recorder (or test gauge) to the chamber.

15.11 Select and start the operating cycle.

15.12 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. during the first minute of the plateau period the temperature measured in the chamber free space does not exceed the temperature measured in the active chamber discharge by more than 5°C;

c. after the first minute of the plateau period:

(i) the temperature measured in the chamber free space does not exceed the temperature measured in the active chamber discharge by more than 2°C;

(ii) the temperature measured in the jaws of the forceps is within 1°C of the temperature measured in the active chamber discharge;

d. the holding time determined from the measured temperatures is not less than that specified in Table 8;

e. during the holding time:

(i) the measured temperatures are within the appropriate sterilization temperature band specified in Table 8;

(ii) the indicated and recorded chamber temperatures are within 1°C of the temperature measured in the active chamber discharge;

(iii) the indicated and recorded chamber pressures are within 0.05 bar of the measured chamber pressure;

f. at the end of the cycle the temperature of any water left in the chamber or in the reservoir is less than the boiling point of water at local atmospheric pressure.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermometric test for a full load

15.13 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

15.14 Place a pair of forceps as for the small-load test in the approximate centre of the chamber, and add further instruments and utensils up to the maximum total mass which the sterilizer is designed to process.

15.15 Place four temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one trapped between the jaws of the forceps;

c. where steam is supplied from outside the chamber, one in the free space between the load items;

d. where steam is generated within the chamber, one either in the reservoir or, if water is retained in the chamber, in the water.

15.16 Connect a pressure recorder (or test gauge) to the chamber.

15.17 Select and start the operating cycle.

15.18 The test should be considered satisfactory if the requirements for the small-load test are met, and the total cycle time is within the performance class stated by the manufacturer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

16. Dry-heat sterilizers

Introduction

16.1 This chapter contains detailed procedures for tests specific to dry-heat sterilizers. Schedules, prescribing which tests are to be carried out and when, are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests).

16.2 For these tests it is essential that load items are packaged and positioned in a manner which will permit the circulation of air to all parts of the chamber and pack surfaces.

16.3 Unless specified otherwise, all the tests should be performed at each of the sterilization temperatures available on the sterilizer.

Automatic control test

16.4 Follow the general procedure for the automatic control test given in Chapter 12 with the following amendments.

16.5 Where the chamber is pressurised during the cooling stage, note the differential pressure across the air filter after the start of the cooling stage and shortly before the end.

16.6 As soon as the cycle is complete, and before opening the door, note any recorded temperatures in the load containers.

16.7 The test should be considered satisfactory if the following requirements are met:

a. a visual indication of “cycle complete” is obtained;

b. during the whole of the cycle the values of the cycle variables as shown on the batch process record are either within the limits established by the manufacturer as giving satisfactory results, or within the permitted tolerances marked on a master process record subsequently established during performance qualification;

c. during the plateau period determined from the recorded chamber temperature:

(i) the indicated and recorded chamber temperatures are within the appropriate sterilization temperature band specified in Table 8;

(ii) the difference between the indicated and recorded chamber temperature does not exceed 5°C;

(iii) the recorded chamber temperature does not drift by more than 2°C;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. the holding time determined from any load temperature probes is not less than that specified in Table 8;

e. during the holding time, the recorded temperature in the load containers is within 5°C of the recorded chamber temperature;

f. during the cooling stage, the differential pressure indicated across the air filter is in the range specified by the manufacturer;

g. the door cannot be opened until the cycle is complete;

h. at the end of the cycle the temperature recorded in any load containers is not greater than 90°C;

i. the person conducting the test does not observe any mechanical or other anomaly.

Chamber overheat cut-out test

16.8 This test is designed to show that the thermal cut-out will prevent the temperature in the chamber from exceeding 200°C. The test should be done with an empty chamber. Temperatures should be recorded by independent measuring equipment as described in Chapter 6.

16.9 Place a temperature sensor in the hottest part of the chamber free space.

16.10 Inactivate the chamber temperature control to allow the temperature to rise. This should be done in accordance with the manufacturer's instructions.

16.11 Select and start the operating cycle.

16.12 The test should be considered satisfactory if the measured chamber temperature does not exceed 200°C during the cycle.

Air filter integrity test

16.13 This test is designed to show whether the high-efficiency particulate filter fitted to a dry-heat sterilizer is intact and working correctly. It is based on the test given in Appendix C of BS 5295: Part 1.

16.14 A test aerosol generator and a photometer are required as described in Chapter 6.

16.15 The sterilizer should be at room temperature with the chamber door open. In accordance with the manufacturer s instructions, arrange for the chamber pressurising fan to be drawing air through the filter at its normal rate.

16.16 Set up the aerosol generator outside the chamber so that a uniform concentration of particles is dispersed across the intake of the air filter and its sealing frame. Ensure that this concentration is maintained throughout the test.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

16.17 Using the photometer, measure the concentration of particles as close as possible to the intake of the filter and ideally not more than 150 mm from the filter face. Adjust the photometer (and the aerosol generator if necessary) to give a stable reading of 100%.

16.18 Inside the chamber, use the photometer to scan all of the downstream face of the filter including the sealing device. Hold the sampling probe approximately 25 mm away from the area being tested, and pass it over the entire area in slightly overlapping strokes at a traverse rate of no more than 50 mm s^{-1}. Make separate passes around the entire periphery of the filter, along the bond between the filter pack and the frame, and around the seal between the filter and retaining device.

16.19 Note the location of any steady, repeatable reading of the photometer.

16.20 The test should be considered satisfactory if any steady and repeatable reading does not exceed 0.001%.

16.21 A filter that fails the test should be replaced. It is not possible to repair the high-efficiency filters installed in dry-heat sterilizers.

Thermometric test for performance qualification

16.22 Temperatures should be recorded by independent measuring equipment.

16.23 Follow the procedure for the thermometric test for performance qualification given in Chapter 8 (see paragraph 8.13), but instead of placing a temperature sensor in an active chamber discharge place two sensors as follows:

a. one (sensor A) in thermal contact with the sensor connected to the sterilizer temperature recorder;

b. one (sensor B) in thermal contact with the sensor connected to the sterilizer temperature indicator.

16.24 Where the chamber is pressurised during the cooling stage, connect a pressure recorder to measure the differential pressure across the air filter. Measure the differential pressure during the cooling stage.

16.25 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 16.7) are met;

b. the holding time, as determined from the measured temperatures, is not less than that specified in Table 8;

c. during the holding time:

(i) the measured temperatures are within the appropriate sterilization temperature band specified in Table 8;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

(ii) the indicated chamber temperature is within 1°C of the temperature measured by sensor B;

(iii) the recorded chamber temperature is within 1°C of the temperature measured by sensor A;

(iv) the temperatures measured by each sensor in the load and by sensor B are within 5°C of the temperature measured by sensor A;

(v) the temperature measured by sensor A does not drift more than 2°C;

d. during the cooling stage the differential pressure measured across the air filter is in the range specified by the manufacturer;

e. at the end of the cycle:

(i) the temperature sensors have remained in position;

(ii) the items containing sensors are intact;

(iii) the temperature measured in any item is not greater than 90°C.

Simplified thermometric test for performance requalification

16.26 This test is not a substitute for a full PRQ test, but is used quarterly to check that the sterilization conditions continue to be met. Temperatures should be recorded by independent measuring equipment.

16.27 Prepare a production load known to present the greatest challenge to the operating cycle and for which there is a PQ report. (This will normally be the reference load used in the yearly PRQ tests.)

16.28 Place the load in the chamber as described in the PQ report with temperature sensors in the following positions:

a. one (sensor A) in thermal contact with the sensor connected to the chamber temperature recorder;

b. one (sensor B) in thermal contact with the sensor connected to the chamber temperature indicator;

c. one in the item of the load which is the slowest to attain the sterilization temperature.

16.29 Where the chamber is pressurised during the cooling stage, connect a pressure recorder to measure the differential pressure across the air filter.

16.30 Ensure that the operating cycle corresponds with that used for the performance qualification test for the load. Start the cycle.

16.31 During the cooling stage, measure the differential pressure across the air filter.

16.32 The test should be considered satisfactory if the requirements listed in the PQ report are met.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermometric test for a full load

16.33 This test will have been carried out by the manufacturer as a type test. It need be repeated only if the sterilizer fails to meet the requirements of the thermometric test for performance qualification (see paragraph 16.22).

16.34 The test is adapted from the former BS 3421 (now withdrawn). Temperatures should be recorded by independent measuring equipment as described in Chapter 6. For chambers with more than two shelves, two or more cycles may be required to measure the temperature at all the required points.

16.35 The test load should comprise the largest number of open-topped glass jars, nominally 12 cm high and 6 cm in diameter, which can be placed in the usable chamber space subject to the following conditions:

a. the shelves should be of the type provided for use with the sterilizer. The number of shelves should be the maximum that can be placed in the chamber such that the distances between the top of each layer of jars and the surface above (shelf or roof of chamber) is not less than 3 cm. For the purposes of this test, it is permissible to arrange the shelves on temporary supports;

b. on each shelf the number of jars should be the maximum that can be placed in rows parallel to and at right angles to the front of the chamber with at least 1 cm separating jars in adjacent rows.

16.36 Place 100 ml of a suitable heat-stable, non-volatile liquid in each of the four jars at the corners of each shelf and in the jar nearest to the centre of each shelf. The remaining jars should be empty. Suitable liquids for this purpose are silicone oils which remain liquid under the conditions of the test. Alternative liquids may be used providing they have a similar thermal behaviour.

16.37 Place temperature sensors in the following positions:

a. one (sensor A) in thermal contact with the sensor connected to the chamber temperature recorder;

b. one (sensor B) in thermal contact with the sensor connected to the chamber temperature indicator;

c. one in the centre of the liquid in each of the jars.

16.38 Select a sterilization temperature of 160°C. Adjust the timer to give a holding time of at least 2½h (this is longer than the recommended minimum). Start the cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

16.39 At the end of the cycle, examine the recording of the chamber temperature measured by sensor A:

a. determine the mean temperature during the first 30 min of the holding time. If the temperature at any time before the start of the holding time is higher than this mean, the difference between the maximum temperature attained and this mean is the overheat;

b. determine the mean temperature during a 30-min period commencing 120 min after the start of the holding time. The difference between this mean and the mean determined for the start of the holding time is the temperature drift during a 2h period.

16.40 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 16.7) are met;

b. the temperature overheat does not exceed 2°C;

c. the holding time determined from the measured temperatures is not less than that specified in Table 8;

d. during the holding time:

(i) the measured temperatures are within the appropriate sterilization temperature band specified in Table 8;

(ii) the recorded chamber temperature is within 1°C of the temperature measured by sensor A;

(iii) the indicated chamber temperature is within 1°C of the temperature measured by sensor B;

(iv) the temperatures measured by each sensor in the load are within 5°C of the temperature measured by sensor A;

(v) the temperature measured by sensor A does not drift by more than 2°C over a 2-h period;

(vi) the temperature measured by sensor A does not fluctuate by more than 1°C;

e. the total cycle time is within the performance class stated by the manufacturer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

17. LTS disinfectors and LTSF sterilizers

Introduction

17.1 This chapter contains detailed procedures for tests specific to machines designed to process loads by exposure to low-temperature steam (LTS disinfectors) or low-temperature steam and formaldehyde (LTSF sterilizers). Schedules, prescribing which tests are to be carried out and when, are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests).

17.2 Machines are usually designed for both LTS and LTSF. These processes have similar characteristics and a machine incapable of meeting the LTS requirements will not normally meet the LTSF requirements. Note that some LTSF machines expose the load to a series of pulses of sterilant rather than a continuous holding time.

17.3 Attention is drawn to the safety Information presented in Chapter 1 and the detailed safety precautions discussed in Part 4.

Chamber overheat cut-out test

17.4 This test is designed to show that the overheat cut-out mechanisms for the chamber and jacket will prevent the temperature of the chamber walls and free space from exceeding 80°C. Where two temperature control mechanisms are fitted (for the jacket and the chamber) the test should be done twice, with each mechanism inactivated alternately.

17.5 Temperatures should be recorded by independent measuring equipment as described in Chapter 6. If an LTSF sterilizer is being tested, the LTS cycle should be selected. If an LTS cycle is not available, the primary material for generating formaldehyde should be replaced with an inert substitute (see paragraph 1.29). The chamber should be empty except for the usual chamber furniture.

17.6 Place 12 temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. five on each of the two chamber side walls (one at the approximate centre and four adjacent to the corner positions of the usable chamber space);

c. one on the plane of the usable chamber space (not on the wall) at a point nearest to the steam inlet port.

17.7 Inactivate the chamber or jacket temperature control in accordance with the manufacturer's instructions.

17.8 Select and start the LTS operating cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

17.9 The test should be considered satisfactory if the following requirements are met:

a. the cut-out device operates and causes the heat source to be isolated from the machine and the operating cycle to advance to the drying stage;

b. none of the measured temperatures exceeds 80°C;

c. at the end of the cycle the door remains locked and a fault is indicated.

Chamber wall temperature test

17.10 This test is designed to show that the air removal stage will not start until the chamber walls are heated to within 2°C of the selected operating temperature. If an LTSF sterilizer is being tested, the LTS cycle should be selected. If an LTS cycle is not available, the primary material for generating formaldehyde should be replaced with an inert substitute (see paragraph 1.29).

17.11 Temperatures should be recorded by independent measuring equipment as described in Chapter 6. The chamber should be empty except for the usual chamber furniture.

17.12 Place 12 temperature sensors in the positions described for the chamber overheat cut-out test (see paragraph 17.6).

17.13 Select and start the LTS operating cycle.

17.14 The test should be considered satisfactory if the following requirements are met:

a. the air removal stage of the operating cycle does not start until the temperatures measured by the 10 sensors attached to the chamber side walls are within 2°C of the selected operating temperature;

b. after the first 5 min of the holding time all the temperatures measured in the chamber are within –0°C + 5°C of the temperature measured in the active chamber discharge.

Thermometric test for a small load

17.15 If an LTV sterilizer is being tested, the LTS cycle should be selected. If an LTS cycle is not available, the primary material for generating formaldehyde should be replaced with an inert substitute (see paragraph 1.29).

17.16 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

17.17 Place a standard test pack (see paragraph 7.27) in the chamber with the bottom of the pack supported 100-200 mm above the centre of the chamber base.

17.18 Place three temperature sensors in the following positions:

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

a. one in an active chamber discharge (see paragraph 6.26);

b. one at the approximate centre of the test pack (the wire from the sensor should be carefully arranged to prevent steam tracking along it);

c. one placed 50 ± 5 mm above the approximate centre of the upper surface of the test pack.

17.19 Connect a pressure recorder (or test gauge) to the chamber.

17.20 Select the LTS cycle. Ensure that the process temperature is set to 73°C (corresponding to a sterilization temperature of 71°C). Start the cycle.

17.21 If a test gauge is being used, measure and note the chamber pressure at the approximate mid-point of the holding time.

17.22 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. the holding time, determined from the measured temperatures, is not less than that specified in Table 8;

c. during the holding time:

(i) the measured temperatures are within the temperature band specified in Table 8;

(ii) the temperature measured above the test pack is within 4°C of the temperature measured in the active chamber discharge;

(iii) the temperature measured in the centre of the test pack is within 2°C of the temperature measured in the active chamber discharge;

(iv) the indicated and recorded chamber temperatures are within 1°C of the temperature measured in the active chamber discharge;

(v) the indicated and recorded chamber pressures are within 0.05 bar of the measured pressure;

d. for sterilizers using vacuum as the sole method of drying:

(i) the duration of the drying stage is not less than 3 min;

(ii) the chamber pressure at the end of the stage does not exceed 50 mbar absolute;

e. at the end of the cycle the sheets are sensibly dry.

Thermometric test for a full load

17.23 This test applies to LTS disinfection cycles only. It is not required when the machine is to be used solely with an LTSF sterilization cycle.

17.24 The load is made up of a standard test pack (see paragraph 7.27) and additional folded sheets designed to represent the maximum mass of textiles

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

which may be processed in the machine, and is used to demonstrate that, at the levels at which cycle variables are set, rapid and even penetration of steam into the centre of a load occurs and disinfecting conditions are achieved.

17.25 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

17.26 Place a standard test pack within the chamber in a position identified by the manufacturer as the most difficult to disinfect. This will normally be in the approximate centre of the chamber. Load the rest of the usable chamber space with stacks of sheets as described for porous load sterilizers (see paragraphs 13.17, 13.20).

17.27 Place three temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one at the approximate centre of the test pack (the wire from the sensor should be carefully arranged to prevent steam tracking along it);

c. one below the approximate centre of the top sheet of the test pack.

17.28 Connect a pressure recorder (or test gauge) to the chamber.

17.29 Ensure that the LTS operating cycle is set to an operating temperature of 73°C. Start the cycle.

17.30 If a test gauge is being used, measure and note the chamber pressure at the approximate mid-point of the holding time.

17.31 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. during the holding time:

(i) the measured temperatures are within the temperature band specified in Table 8;

(ii) the temperature measured in the centre of the test pack is within 2°C of the temperature measured in the active chamber discharge;

c. at the end of the test the sheets are sensibly dry;

d. the total cycle time is within the performance class stated by the manufacturer.

Environmental formaldehyde vapour test

17.32 This test is designed to determine the concentration of formaldehyde vapour discharged into the environment from the chamber and test load at the end of an LTSF cycle. A gas monitoring instrument is required as specified in paragraphs 6.54-56.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

17.33 Line two modular cardboard instrument trays (or similar), approximately 600 mm x 300 mm x 50 mm, with a 12- mm thickness of high-density, open-cell polyurethane foam.

17.34 Place two stainless steel rods, each 400 ± 2 mm long by 10 ± 0.5 mm in diameter, in each tray and fit the lids. If the trays are smaller than specified above, the rods may be 250 mm long.

17.35 Place the trays side by side in the centre of the chamber.

17.36 Select the LTSF operating cycle. Ensure that the concentration of formaldehyde used for the test is that to be used for the microbiological test for basic performance. Start the cycle.

17.37 At the end of the cycle, measure the concentration of formaldehyde gas discharged from the chamber when the door starts to open. The sample should be taken 80-120 mm in front of the gap at a height of 1.4-1.6 m. Continue to sample the gas for the next 15 min.

17.38 Determine the average concentration of gas over the 15-min period.

17.39 The test should be considered satisfactory if the atmospheric concentration of formaldehyde gas over the 15-min period does not exceed the short-term exposure limit specified in Table 1.

Microbiological test for basic performance

17.40 Since the efficacy of LTSF sterilization cannot be assured by the measurement of cycle variables, the only definitive performance test currently available for LTSF sterilizers is microbiological. This test is designed to demonstrate the distribution and penetration of formaldehyde gas within the chamber. Chemical indicators are used to give an early indication of the efficacy of gas penetration but by themselves are not sufficient to validate the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators.

17.41 Place 27 inoculated carriers in the chamber arranged on fine thread to the pattern shown in Figure 16. (If the usable chamber space is less than 200 l fewer carriers may be used. The authorised person will advise on this.) Place a chemical indicator alongside each of the inoculated carriers.

17.42 Place an inoculated carrier and a chemical indicator in each of four Line-Pickerill helices (see paragraph 7.51). Double-wrap two of the helices in paper bags (that is, bag in bag) conforming to BS 6257.

17.43 Place the wrapped helices in diametrically opposite corners of the sterilizer chamber; one in the upper rear of the usable chamber space, and the other in the lower front. Place one unwrapped helix in the front half of the usable chamber space and one in the rear half. All these positions are shown in Figure 16.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

17.44 Ensure that the cycle variables are set to the values specified by the manufacturer. The concentration of formaldehyde is normally 15 g m^{-3} of chamber volume per pulse which can be achieved by the vaporisation of 40 ml of formal in per cubic metre of chamber volume. Start the operating cycle.

17.45 At the end of the cycle, remove the inoculated carriers and chemical indicators from the chamber and the helices. Check that the chemical indicators show a uniform colour change. If so, place each of the inoculated carriers in a bottle of recovery medium, and incubate them with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-75).

17.46 If the chemical indicators do not show a uniform colour change, then the test should be abandoned.

17.47 The test should be considered satisfactory if the requirements given in paragraph 7.72 are met.

17.48 The test should be performed two more times to ensure that similar results are obtained.

17.49 The test should be reported in the format shown in Figure 17.

Microbiological test for performance qualification

17.50 This test is designed to follow a thermometric test for performance qualification. The loading condition and operating cycle should be identical. Chemical indicators are used to give an early indication of the efficacy of gas penetration but by themselves are not sufficient to validate the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators.

17.51 Put an inoculated carrier and a chemical indicator together in each of the six load items that carried temperature sensors in the thermometric test. Place the items in as nearly as possible in the same positions they occupied in the thermometric test. Put a biological indicator and a chemical indicator together in a Line-Pickerell helix (see paragraph 7.51) and place the helix in a position known to be the most difficult to sterilize (normally the coolest part of the chamber).

17.52 Select and start the operating cycle.

17.53 Ensure that a batch process record is made by the recording instrument fitted to the sterilizer.

17.54 At the approximate mid-point of the plateau period, note the elapsed time and indicated chamber temperature and pressure.

17.55 At the end of the cycle, remove the indicators from the load items and the helix. Check that the chemical indicators show a uniform colour change. If so, place each of the inoculated carriers in a bottle of recovery medium and incubate

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

them with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-75).

17.56 If the chemical indicators do not show a uniform colour change, then the test should be abandoned.

17.57 The test should be considered satisfactory if the following requirements are met:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during the thermometric PQ test;

b. the requirements for microbiological tests set out in paragraph 7.72 are met.

Routine microbiological test

17.58 A routine microbiological test is required for every production load. Chemical indicators are used to give an early indication of the efficacy of gas penetration but by themselves are not sufficient to monitor the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators. Conditions under which the load may be released as sterile are discussed in Part 4.

17.59 Place an inoculated carrier and a chemical indicator in a Line-Pickerill helix (see paragraph 7.51). Double-wrap the helix in paper bags (that is, bag in bag) conforming to BS 6257. Put it in the chamber with the normal production load.

17.60 Select and start the operating cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

17.61 At the end of the cycle, remove the inoculated carrier and chemical indicator from the helix. Check that the chemical indicator shows a uniform colour change. If so, place the inoculated carrier in a bottle of recovery medium and incubate it with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-75).

17.62 If the chemical indicator does not show a uniform colour change, then the test should be abandoned.

17.63 The test should be considered satisfactory if the requirements for microbiological tests set out in paragraph 7.72 are met.

18. Ethylene oxide sterilizers

Introduction

18.1 This chapter contains detailed procedures for tests specific to sterilizers designed to process loads by exposure to ethylene oxide gas (EO). Schedules, prescribing which tests are to be carried out and when, are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests).

18.2 Attention is drawn to the safety information presented in Chapter 1 and the detailed safety precautions discussed in Part 4.

18.3 Humidity is the most critical cycle variable in EO sterilization but also the most difficult to measure and control. In several of these tests it is necessary to determine the humidity in the sterilizer chamber during the conditioning stage. The ideal method is to use humidity sensors calibrated for RH (see paragraphs 6.47-50), but if these are not available the RH should be calculated using the method given in Appendix 2. Because of the large errors in both methods, and the variation within the chamber, the new EN permits a relatively broad range of 40-85% RH and that is the value given here. Users should aim, however, to attain an ideal true value of 50-60% RH to ensure that no part of the chamber is allowed to reach the dangerous extremes of <30% RH or >95% RH.

Chamber overheat cut-out test

18.4 This test is designed to show that the overheat cut-out mechanisms for the chamber and jacket will prevent the temperature of the chamber free space from exceeding the gas exposure temperature by more than 6°C. Where cycles with different gas exposure temperatures are available, the test should be done for each cycle. Where two temperature control mechanisms are fitted (for the jacket and the chamber) the test should be done with each mechanism inactivated alternately.

18.5 The dimensions of the usable chamber space need to be known for this test. The space is assumed to be a rectangular box. If the usable chamber space is cylindrical, the planes referred to below are those of the smallest box that can contain it (see Figure 18).

18.6 Temperatures should be recorded by independent measuring equipment as described in Chapter 6. The chamber should be empty except for the usual chamber furniture. EO gas should be replaced with an inert substitute (see paragraph 1.29).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

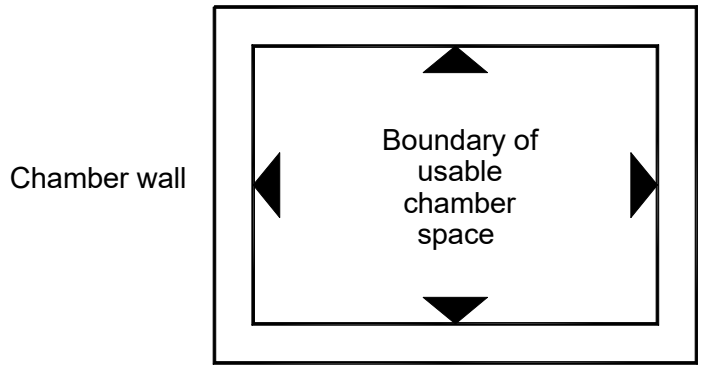
18.7 Place 12 temperature sensors in the following positions:

a. one in thermal contact with the sensor connected to the temperature recorder fitted to the sterilizer;

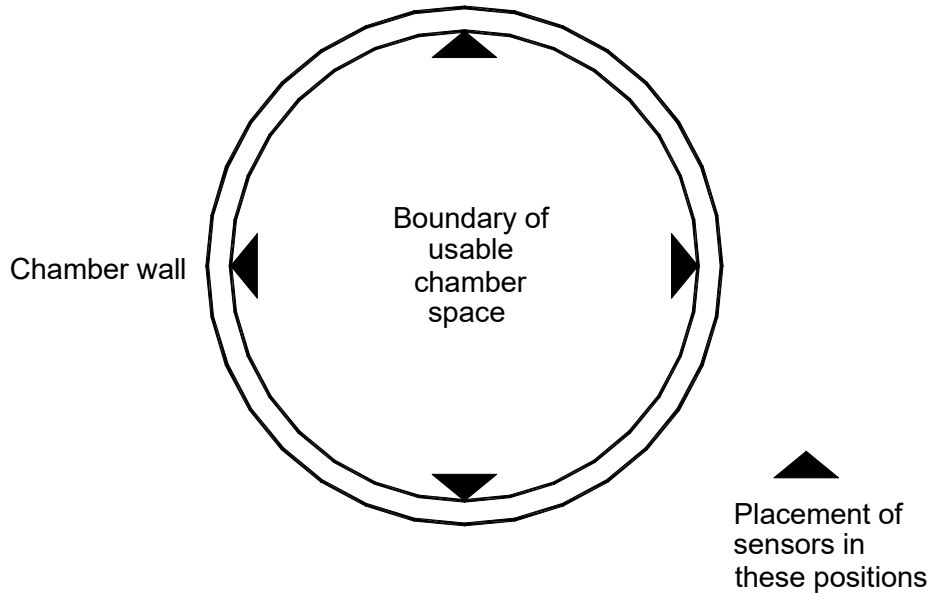
b. two on each of the planes of the usable chamber space, excluding doors (one at the approximate centre of the plane and one in a position known to be the hottest);

c. one on the plane of the usable chamber space at a point nearest to the steam inlet port.

Figure 18: Location of sensors for EO chamber overheat cut-out and chamber space temperature test



(a) Rectangular chamber



(b) Cylindrical chamber

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.8 Inactivate the chamber or jacket temperature control in accordance with the manufacturer's instructions.

18.9 Select and start the operating cycle.

18.10 The test should be considered satisfactory if the following requirements are met:

a. the cut-out device operates and causes the heat source to be isolated from the machine and the operating cycle to advance to the gas removal stage;

b. none of the measured temperatures exceeds the preset gas exposure temperature by more than 6°C;

c. at the end of the cycle a fault is indicated.

Chamber space temperature test

18.11 This test is designed to show that the temperature of the chamber free space is within 2°C of the preset gas exposure temperature at the start of the gas exposure stage.

18.12 Temperatures should be recorded by independent measuring equipment as described in Chapter 6. The chamber should be empty except for the usual chamber furniture. EO gas should be replaced by an inert substitute (see paragraph 1.29).

18.13 Place 12 temperature sensors in the positions described for the chamber overheat cut-out test (see paragraph 18.7).

18.14 Select and start the operating cycle.

18.15 The test should be considered satisfactory if the following requirements are met:

a. at the start of the gas exposure stage the measured temperatures are within 2°C of the preset gas exposure temperature;

b. after the first 5 min of the gas exposure stage the temperatures measured in the chamber are within 2°C of the temperature measured by the sensor adjacent to the temperature recorder sensor.

Chamber wall temperature test

18.16 Temperatures should be recorded by independent measuring equipment as described in Chapter 6. The chamber should be empty except for the usual chamber furniture. EO gas should be replaced by an inert substitute (see paragraph 1.29).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.17 Place 12 temperature sensors in the following positions:

a. one in thermal contact with the sensor connected to the temperature recorder fitted to the sterilizer;

b. two on each of the chamber surfaces, excluding doors (one at the centre of the surface and one in a position known to be the hottest);

c. one on the plane (not on the wall) of the usable chamber space at a point nearest to the steam inlet port.

18.18 Select and start the operating cycle.

18.19 The test should be considered satisfactory if, after the first 5 min of the gas exposure stage, the temperatures measured in the chamber are within 5°C of the temperature measured by the sensor adjacent to the temperature recorder sensor.

Microbiological test for gas exposure time

18.20 Since the efficacy of EO sterilization cannot be assured by the measurement of cycle variables, the only definitive performance test currently available for EO sterilizers is microbiological. This test is designed to demonstrate the penetration of EO gas within the chamber and to determine the duration of the gas exposure stage for routine production. Chemical indicators are used to give an early indication of the efficacy of gas penetration but by themselves are not sufficient to validate the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators.

18.21 During the conditioning stage it will be necessary to determine the relative humidity in the chamber. Humidity may be indicated or recorded by the instrument fitted to the sterilizer, calculated (Appendix 2) or referenced to a test in which an identical loading condition has been tested with an inert gas.

18.22 Place an inoculated carrier and a chemical indicator in each of four Line-Pickerill helices (see paragraph 7.51). Triple-wrap the helices in paper bags (that is, bag in bag in bag) conforming to BS 6257. Seal the bags and allow them to equilibrate in an environment of 20 ± 5°C and 60 ± 20% RH for at least one hour.

18.23 Place two helices towards the front of the usable chamber space and two towards the rear, in positions known to be the slowest to attain the gas exposure temperature.

18.24 Select the operating cycle. The EO concentration in the chamber will normally be 250-1000 mg l^{-1}. The duration of the gas exposure stage should be considerably less than one-third of that anticipated for routine production, and insufficient to inactivate all the biological indicators. The authorised person will advise on what this period should be. Start the cycle.

18.25 At the end of the cycle remove the inoculated carriers and chemical indicators from the helices.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.26 Repeat the cycle several times with fresh inoculated carriers and chemical indicators and the gas exposure time increased in each cycle. The gas exposure time for the final cycle should be sufficient to inactivate all the inoculated carriers. The behaviour of the chemical indicators may be used to estimate when this time is attained. The authorised person will advise on how many cycles are required and the time increment for each one.

18.27 Place each of the inoculated carriers in a bottle of recovery medium and incubate them with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-7.75).

18.28 The test should be considered satisfactory if the following requirements are met:

a. at the end of the conditioning stage of each cycle the humidity in the chamber is in the range 40-85% RH (see paragraph 18.3);

b. at the end of the incubation period:

   (i) one or more of the bottles with inoculated carriers exposed to the EO process shows growth for the shortest gas exposure time, but none shows growth for the longest gas exposure time;

   (ii) control bottles with no inoculated carrier show no growth;

c. control bottles with unexposed inoculated carriers show growth within 24 h.

18.29 Note the shortest gas exposure time for which no growth is observed. Perform the test for a further two cycles at this exposure time. If all three cycles are satisfactory, the gas exposure time determined by this procedure (the critical gas exposure time) should be regarded as one-third of the minimum time required for production loads representing less of a challenge than the load used in this test.

Microbiological test for basic performance

18.30 This test is designed to demonstrate the penetration of EO gas within the chamber and confirm the duration of the gas exposure stage for routine production. Chemical indicators are used to give an early indication of the efficacy of gas penetration, but by themselves are not sufficient to validate the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators.

18.31 Prepare and position four Line-Pickerell helices as described in the microbiological test for gas exposure time (see paragraphs 18.22-18.23).

18.32 Select the operating cycle. Set the duration of the gas exposure stage to the critical gas exposure time determined during commissioning (see paragraph 18.29). Start the cycle.

18.33 At the end of the cycle remove the inoculated carriers and chemical indicators from the helices. Examine the chemical indicators and check whether they

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

show a uniform colour change. If so, place each inoculated carrier in a bottle of recovery medium and incubate them with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-7.75).

18.34 If the chemical indicators do not show a uniform colour change, then the test should be abandoned.

18.35 The test should be considered satisfactory if the following requirements are met:

a. at the end of the conditioning stage the humidity in the chamber is in the range 40-85% RH (see paragraph 18.3);

b. the requirements for microbiological tests set out in paragraph 7.72 are met.

Thermometric test for performance qualification

18.36 The load used for this test should be one of the production loads processed in the sterilizer. To serve as a reference load it should present to the process the greatest challenge on the basis of moisture absorbency, gas absorbency and the attainment of the gas exposure temperature throughout the load. If the load presents a greater challenge than the test load used in the microbiological test for basic performance, then that test will need to be repeated with the new load in order to confirm the gas exposure time.

18.37 Table 11 indicates the information that will need to be noted for the PQ report. See Chapter 8 for general Information about PQ tests and reports.

18.38 Temperatures, pressures and humidities should be recorded by independent measuring equipment as described in Chapter 6. If humidity sensors are not available, humidity should be calculated as described in Appendix 2. EO gas should be replaced with an inert substitute (see paragraph 1.29).

18.39 Package each item of the load in accordance with the procedure to be used for routine production. Note the type of load and method of packaging.

18.40 Ensure that the preconditioning procedure is identical to that which will be used for production. This should normally be for at least 1 h in an environment having a temperature of 15-25°C and a humidity of 40-85% RH.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.41 Place 12 temperature sensors in the following positions:

a. one in thermal contact with the sensor connected to the chamber temperature recorder fitted to the sterilizer (sensor A);
b. one in the gas entry port to the chamber;
c. one in the primary heat source to the gas preheater (if fitted);
d. one in each of five load items known to be the slowest to attain the gas exposure temperature and placed in the coolest part of the chamber;
e. one in a load item in the hottest part of the chamber;
f. one in the coolest part of the chamber free space;
g. one on the hottest part of the chamber;
h. one on the coolest part of the chamber surface.

18.42 If available, place two humidity sensors in the following positions:

a. one alongside the temperature sensor in the load item in the hottest part of the chamber (see paragraph 18.41 (e));
b. one alongside the temperature sensor in the coolest part of the chamber free space (see paragraph 18.41(f)).

18.43 Connect a pressure recorder (or test gauge) to the chamber.

18.44 Select the operating cycle that will be used for the production load. The cycle variables should be set as determined in the microbiological test for gas exposure time, although the duration of the flushing stage may need to be adjusted to satisfy the requirements of the environmental gas test (see paragraph 8.37) and the test for degassing time (see paragraph 8.46). Start the cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 11: Performance qualification data for EO sterilizers

The PQ report for EO sterilizers should include the values and permitted tolerances of the following variables:

1 ***preconditioning*** (in separate areas, if used):

a. time, temperature and humidity;

b. minimum temperature of product permitted to enter preconditioning;

c. maximum elapsed time between removal of the load from preconditioning and the start of the conditioning stage of the operating cycle.

2 ***conditioning*** (in sterilizer chamber):

a. temperature and humidity in the chamber and within the load at the beginning and end of the conditioning stage;

b. if the humidity indicator or recorder is not fitted to the sterilizer, the critical parameters necessary for the attainment of the specified humidity of the load – the parameters chosen will depend on the method used to humidify the load.

3 ***sterilization****:*

a. chamber pressure;

b. chamber temperature;

c. gas exposure time;

d. temperature of the load;

e. EO concentration, estimated from pressure change (see Appendix 2) or (exeptionally) by direct analysis of chamber atmosphere.

4 ***flushing*** (in sterilizer chamber):

a. time, temperature and pressure changes;

b. rate of change of air or other gas;

c. temperature of the load.

5 ***degassing*** (in separate aeration cabinet and/or room):

a. time, temperature and pressure changes;

b. rate of change of air or other gas;

c. temperature of the load.

18.45 Ensure that a batch process record is made by the recording instrument fitted to the sterilizer. This will serve as the basis for a master process record (see paragraph 8.58) for the loading condition under test.

18.46 At the end of the conditioning stage, note the readings from the humidity sensors, including the sterilizer humidity indicator (if fitted).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.47 At the approximate mid-point of the gas exposure stage, note the elapsed time and the indicated chamber temperature and pressure.

18.48 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. after the first 5 min of the gas exposure time the temperatures measured on the chamber walls are within 5°C of the temperature measured by sensor A;

c. after the first 5 min of the gas exposure time, and until its end, all the measured temperatures, except in the gas pre-heater and on the chamber walls, are within 2°C of the temperature measured by sensor A;

d. at the end-of the conditioning stage:

(i) the humidity is in the range 40-85% RH (see paragraph 18.3);

(ii) the difference between the two RH measurements (if made) does not exceed 20% RH;

(iii) the reading on the sterilizer humidity indicator (if fitted) is not less than 40% RH;

e. after the first 15 min of the gas exposure time, and until its end, the peak-to-peak variation in the measured chamber pressure does not exceed 20% for cylinder systems and 25% for cartridge systems;

f. for cylinder systems, throughout the cycle the temperature measured in the primary heat source to the gas pre-heaters does not exceed 70°C.

Microbiological test for performance qualification

18.49 This test is designed to follow a thermometric test for performance qualification. The loading condition, preconditioning process and operating cycle should be identical. Chemical indicators are used to give an early indication of the efficacy of gas penetration but by themselves are not sufficient to validate the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators.

18.50 Assemble 20 biological indicators and 20 chemical indicators to form 20 biological-chemical indicator pairs. Place them in the following positions:

a. one pair in each of the six load items which carried temperature sensors in the thermometric test (see paragraphs 19.41 (d), (e));

b. 14 pairs distributed throughout the remaining load items.

18.51 Select the operating cycle used in the thermometric test. The concentration of EO used for the test should be the same as will be used for production cycles. This is normally 250-1000 mg l^{-1}. Start the cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.52 Ensure that a batch process record is made by the recording instrument fitted to the sterilizer.

18.53 At the end of the conditioning stage, note the indicated chamber temperature, pressure and humidity. Where a humidity instrument is not fitted, RH may be assumed to be the same as that determined during the thermometric test provided that all the cycle variables are identical within the permitted tolerances.

18.54 At the approximate mid-point of the gas exposure stage, note the elapsed time and the indicated chamber temperature, pressure and humidity.

18.55 At the end of the cycle, remove the indicators from the load items. Check whether the chemical indicators show a uniform colour change. If so, place each of the inoculated carriers in a bottle of recovery medium and incubate them with controls as described in the general procedure for microbiological tests (see paragraphs 7.63-7.75).

18.56 If the chemical indicators do not show a uniform colour change, then the test should be abandoned.

18.57 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;
b. the humidity values at the end of the conditioning stage, whether indicated, measured or calculated, are consistent with those obtained during the thermometric test;
c. the requirements for microbiological tests set out in paragraph 7.72 are met.

Routine microbiological test

18.58 A routine microbiological test is required for every production load. Chemical indicators are used to give an early indication of the efficacy of gas penetration but by themselves are not sufficient to monitor the sterilization process. See Chapter 7 for advice on the use of biological and chemical indicators. Conditions under which the load may be released as sterile are discussed in Part 4.

18.59 Assemble ten biological indicators and ten chemical indicators to form ten biological-chemical indicator pairs. Distribute the pairs evenly in the spaces between the load items.

18.60 Select and start the operating cycle.

18.61 At the end of the cycle, remove the indicators from the load. Check that the chemical indicators show a uniform colour change. If so, place each of the inoculated carriers in a bottle of recovery medium and incubate them with

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

controls as described in the general procedure for microbiological tests given in Chapter 7.

18.62 If the chemical indicators do not show a uniform colour change, then the test should be abandoned.

18.63 The test should be considered satisfactory if the requirements for microbiological tests set out in paragraph 7.72 are met.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

19. Laboratory sterilizers

Introduction

19.1 This chapter contains detailed procedures for tests specific to laboratory sterilizers. Schedules, prescribing which tests are to be carried out and when, are set out in Chapter 4 (for validation tests) and Chapter 5 (for periodic tests). The tests in this chapter apply to laboratory sterilizers equipped with one or more of the following operating cycles:

a. make-safe of small plastic discard;

b. make-safe of contained fluid discard;

c. sterilization of culture media (preset or variable cycle);

d. disinfection of fabrics (see paragraph 13.7 for the small-load test);

e. sterilization of glassware and equipment;

f. free steaming;

g. culture media preparator.

19.2 Attention is drawn to the safety information presented in Chapter 1 and the detailed safety precautions discussed in Part 4.

19.3 Unless specified otherwise, all the tests should be performed at each of the sterilization temperatures available on the sterilizer.

Make-safe of small plastic discard

19.4 These tests apply to laboratory sterilizers with an operating cycle designed to make-safe plastic discard material where no one item contains more than 50 ml of aqueous fluid.

19.5 If by agreement with the laboratory safety officer, the user authorises the use of the sterilizer with the thermal door-lock override selected, then these tests should be conducted both with and without the override selected.

NOTE: Information about Hazard Groups may be found in the HSC document Categorisation of pathogens according to hazard and categories of containment (4th edition, 1995) compiled by the Advisory Committee on Dangerous Pathogens.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

19.6 Containers should be held in the discard boxes recommended by the manufacturer. Discard boxes holding containers into which temperature sensors are to be inserted should not contain infected material. Material infected with Hazard Group 2 organisms may be used to make up other boxes in the test load. At no time should any material known to contain Hazard Group 3 or 4 organisms be used.

Thermometric test for a full load

19.7 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

19.8 Prepare sufficient Petri dishes to fill two discard boxes when the dishes are stacked vertically. Each dish should contain approximately 15ml of agar gel.

19.9 Place one temperature sensor in the centre of each of six of the dishes. Put three of these test dishes in each box: one in the centre of the box, one one-third from the bottom and one one-third from the top, supported by the remaining dishes. If only one box will fit in the chamber, put all six test dishes in the box, two at each position.

19.10 Put the two test boxes in opposite corners of the chamber. Load the remaining chamber space with boxes filled with discard material such that the spacing between boxes is in accordance with the minimum recommended by the manufacturer.

19.11 Place a further five temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one in the chamber, alongside the sensing element of the load temperature probe, if it is fitted (the probe should be stowed on its bracket);

c. one in the centre of the free space between the bottom of each test box and its trivet (if fitted). (If the box does not have a trivet, the sensor should be placed in the free space between Petri dishes 15 mm above the centre of the bottom of the box);

d. one in the chamber free space.

19.12 Connect a pressure recorder (or test gauge) to the chamber.

19.13 Select and start the operating cycle.

19.14 If a test gauge is being used, measure the chamber pressure at the approximate mid-point of the holding time.

19.15 The test should be considered satisfactory if the requirements listed in Table 12 are met, and the drain is not blocked with agar.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermometric test for a small load

19.16 This test is not required if the sterilizer is designed to accommodate only one discard box. Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

19.17 Load the chamber with a single discard box filled with Petri dishes as described in the full-load test, with three temperature sensors located in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one in the centre of a dish located one-third from the bottom of the box;

c. one in the centre of a dish located in the approximate centre of the box.

19.18 Follow the procedure for the full-load test.

19.19 The test should be considered satisfactory if all but the cycle time condition of the requirements for the full-load test are met.

Cycles for fluid loads

19.20 These tests apply to laboratory sterilizers with cycles designed to process fluid discard in glass containers and large plastic containers (>50 ml), culture media (preset or variable cycles) and for free steaming.

19.21 Bottles into which temperature sensors are inserted should contain a solution of 10-15g of agar powder dissolved in 1000 ml of distilled water. Other bottles in the loads should be filled with water or water-based culture medium.

19.22 All bottles should be filled to 80% of their nominal capacity. The volumes of the fluid in each bottle should not vary from their mean by more than 5%. At the start of the cycle the temperature of the fluid in each bottle should be 20 ± 5°C and the media preparation in the liquid form.

19.23 The bottles may be either all sealed or all unsealed, according to the practice in the laboratory and the requirements of the schedules in Chapters 4 and 5. Sealed and unsealed bottles should not be mixed in the same load.

Thermometric test for a full load

19.24 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 12 General requirements for the full-load test (laboratory sterilizers)

The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (paragraph 12.13) are met;

b. the holding time, as determined from the measured temperatures, is not less than that specified for the appropriate sterilization temperature band listed in Table 12;

c. during the holding time:

   (i) the measured temperatures are within the appropriate sterilization temperature band listed in Table 12;

   (ii) except for discard cycles, the measured temperatures are within 1°C of each other;

   (iii) the indicated and recorded chamber temperatures are within 1°C of the temperature measured in the active chamber discharge;

   (iv) the indicated and recorded chamber pressures are within 0.05 bar of the measured chamber pressure;

   (v) the measured chamber pressure is within 0.05 bar of saturated steam pressure or, if a partial pressure system is used, as specified by the manufacturer;

d. at the end of the cycle:

   (i) the temperature sensors have remained in position;

   (ii) items holding sensors remain intact;

   (iii) not more than one of the other items (or 1%, whichever is the greater) has burst or broken;

   (iv) the temperature measured in any fluid containers is not greater than 90°C (plastic) or 80°C (glass);

e. the total cycle time is within the performance class stated by the manufacturer.

19.25 Fill nine one-litre bottles with the test liquid as described in paragraph 19.21. Insert a temperature sensor into each one, ensuring that the tops are sealed or unsealed as required. Unsealed bottles should be capped loosely to prevent coolant water entering the bottle.

19.26 If unsealed bottles are used, weigh each of them and note their masses (M_1) to an accuracy of 1g.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

19.27 Place three of the bottles in positions known to be the slowest to attain the sterilization temperature, three in positions known to be the fastest to attain the sterilization temperature, and three in positions known to be the slowest to cool to 80°C.

19.28 Load the remaining chamber space with one-litre bottles, filled either with water or a water-based medium, at the minimum spacing recommended by the manufacturer.

19.29 Place a further temperature sensor in an active chamber discharge (see paragraph 6.26).

19.30 Connect a pressure recorder (or test gauge) to the chamber.

19.31 Select the operating cycle:

a. if a variable culture media cycle is being tested, set the sterilization temperature to 121°C with a minimum holding time of 15 min;

b. if a free steaming cycle is being tested, set the load temperature to 95-98°C for a minimum of 15 min.

19.32 Start the cycle.

19.33 If a test gauge is being used, measure the chamber pressure at the approximate mid-point of the holding time.

19.34 As soon as the cycle is complete, and before opening the door, observe and note the measured temperatures in the bottles.

19.35 Within 5 min of the end of the cycle, weigh any unsealed test bottles again and note their masses (M_2). For each bottle, calculate the percentage loss in mass from:

$$percentage\ \ loss\ in\ mass = 100 \times \frac{(M_1 - M_2)}{M_1}$$

19.36 The test should be considered satisfactory if the requirements listed in Table 12 are met and the loss of fluid in any unsealed bottles does not exceed 2% by mass.

Thermometric test for a small load

19.37 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

19.38 Fill nine 5-ml bijou bottles with 4 ml of test liquid as described in paragraph 19.21. Insert a temperature sensor into each one, ensuring that the tops are sealed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

19.39 Distribute them among two wire baskets, one supported in the upper rear of the usable chamber space and the other in the lower front. Each should contain a total of 25 bijou bottles, so that three test bottles are in positions known to be the slowest to attain the sterilization temperature, three in positions known to be the fastest to attain the sterilization temperature, and three in positions known to be the slowest to cool to 80°C.

19.40 If the sterilizer is not designed to process bottles of this size, the smallest size and number of containers recommended by the sterilizer manufacturer should be used.

19.41 Where the sterilizer is to be used to process one size of container only, the test load may be a single container of this size, filled with the nominal volume of test liquid and supported in a position known to be the slowest to attain the sterilization temperature.

19.42 Place a further temperature sensor in an active chamber discharge (see paragraph 6.26).

19.43 Connect a pressure recorder (or test gauge) to the chamber.

19.44 Follow the procedure for the full-load test.

19.45 The test should be considered satisfactory if, except for the cycle time condition, the requirements listed in Table 12 are met.

Simplified thermometric test for performance requalification

19.46 This test is not a substitute for a full PRQ test, but is used quarterly to check that the sterilization conditions continue to be met. Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

19.47 Prepare a production load known to present the greatest challenge to the operating cycle and for which there is a PQ report. (This will normally be the reference load used in the yearly PRQ tests.) Place temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);

b. one in a container known to be the slowest to attain the sterilization temperature;

c. one in a container known to be slowest to cool to 80°C.

19.48 Place the load in the chamber as described in the PQ report.

19.49 Select the operating cycle as specified in the PQ report. Start the cycle.

19.50 The test should be considered satisfactory if the requirements listed in the PQ report are met.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Sterilization of glassware and equipment

19.51 These tests apply to laboratory sterilizers with a cycle designed to sterilize empty glassware without caps and other non-porous equipment. If caps are fitted, air will not be removed, and the glassware should be classed as disinfected but not sterilized.

Thermometric test for a full load

19.52 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

19.53 Fill four discard boxes with empty glass bijou bottles, without caps, arranged randomly. Place two temperature sensors in each box, one inserted into an inverted bottle in the centre of the box and one in an inverted bottle one-third from the bottom.

19.54 Where the full load is less than four boxes, the maximum load which the sterilizer is designed to process should be used. The eight temperature sensors should be distributed within the load.

19.55 Put these test boxes in the chamber and load the remaining chamber space with boxes of bijou bottles at the minimum spacing recommended by the manufacturer.

19.56 Place three further temperature sensors in the following positions:

a. one in an active chamber discharge (see paragraph 6.26);
b. one in the chamber located alongside the load temperature probe (if fitted);
c. one in the upper chamber free space.

19.57 Connect a test pressure recorder (or a test gauge) to the chamber.

19.58 Select and start the operating cycle.

19.59 If a test gauge is being used, measure the chamber pressure at the approximate mid-point of the holding time.

19.60 The test should be considered satisfactory if the requirements listed in Table 12 are met, and the load is visibly dry.

Thermometric test for a small load

19.61 Fill one discard box with bijou bottles with sensors placed as described for the full-load test and put it in the chamber. Place a further sensor in an active chamber discharge.

19.62 Follow the procedure for the full-load test.

19.63 The test should be considered satisfactory if, except for the cycle time condition, the requirements listed for the full-load test are met.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermal door-lock override test

19.64 A thermal door-lock is fitted to certain laboratory sterilizers to prevent the door from being opened until the temperature in the chamber and load falls below 80°C. The override is intended for use by trained persons who wish to gain access at temperatures above 80°C to loads which will not present an explosive hazard.

19.65 For this test the sterilizer chamber should be empty.

19.66 Select and start the operating cycle to be tested.

19.67 Attempt to select the thermal door-lock override during the heat-up, sterilization (holding time) and cooling stages.

19.68 The test should be considered satisfactory if the following requirements are met:

a. the override operates only during the cooling stage of the cycle and causes the cooling stage to terminate;
b. the override switch resets automatically when released;
c. the thermal door-lock override indicator is Illuminated;
d. at the end of the cycle the door cannot be opened except by means of a key, code or tool which is unique to the sterilizer.

19.69 Where the sterilizer is intended to be used exclusively for make-safe of discard in small containers, compliance with (b) and (d) may be waived by agreement with the laboratory safety officer. In this case, the switch should reset automatically whenever a different operating cycle is selected or whenever the power supply is interrupted.

Culture media preparator

19.70 For these tests, the sterilizer vessel should be filled with the test liquid described in paragraph 19.21 to the nominal capacity specified by the manufacturer.

Thermometric test for a full load

19.71 Temperatures and pressures should be recorded by independent measuring equipment as described in Chapter 6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

19.72 Place two temperature sensors in the following positions:

a. one at the bottom of the chamber in the space occupied by the minimum production volume stated by the manufacturer;

b. one in the approximate centre of the chamber.

19.73 Connect a pressure recorder (or test gauge) to the chamber.

19.74 Select and start the operating cycle.

19.75 If a test gauge is being used, measure the chamber pressure at the beginning, middle and end of the holding time.

19.76 When the cycle is complete, wait for the temperature in the chamber to fall to 85°C. Attempt to open the door safety hood. If the hood does not open, wait for the temperature to fall below 80°C. Attempt to open the hood again.

19.77 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test (see paragraph 12.13) are met;

b. the holding time, as determined from the measured temperatures, is not less than that specified for the appropriate sterilization temperature band listed in Table 13;

c. during the holding time:

(i) the temperatures measured in the medium are both within ± 2°C of the set temperature;

(ii) the indicated and recorded chamber temperatures are within 1°C of the lower of the two temperatures measured in the medium;

(iii) the indicated and recorded chamber pressures are within 0.05 bar of the measured chamber pressure;

d. the door safety hood cannot be opened until the higher of the two temperatures measured in the medium falls below 80°C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 13: Sterilization conditions for laboratory sterilizers

Name of operating cycle	Sterilization temperature [°C]	Maximum temperature [°C]	Minimum holding time [min]
Make safe of small plastic discard.	134 126 121	138 129 124	3 10 15
Make safe of contained fluid discard	134 126 121	138 129 124	3 10 15
Sterilization of culture media (pre-set cycle)	121 115	124 118	15 30
Sterilization of culture media (variable cycle)	102-134 121[a]	 124	Up to 60 15
Disinfection of fabrics	134 126 121	138 129 124	3 10 15
Sterilization of glassware and equipment	134 126 121	138 129 124	3 10 15
Free steaming (variable cycle)	102-104 95[a]	 98	Up to 60 15
Culture media preparator	121 115	124 118	15 30

a. Although the cycle is variable, this temperature band should be used for testing purpose

Reheat and dispensing test

19.78 This test follows immediately after the full-load test, using the same load. Temperature and pressure sensors should be removed.

19.79 Set the sterilizer to reheat the batch to a nominal reheat temperature of 100°C.

19.80 Five minutes after the medium attains the reheat temperature, allow it to cool to a nominal dispensing temperature of 55°C.

19.81 When the indicated chamber temperature reaches 55°C wait 10 min and begin dispensing the medium.

19.82 Note the indicated chamber temperature and pressure at the beginning, middle and end of the dispensing period.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

19.83 The test should be considered satisfactory if the following requirements are met:

a. during dispensing:

(i) the indicated chamber temperature is within ±2°C of the set dispensing temperature;

(ii) the indicated chamber pressure is zero;

(iii) the medium does not solidify;

b. the person conducting the test does not observe any mechanical or other anomaly.

Glossary

The following list of definitions has been adopted in SHTM 2010 and used in Part 2. Certain pressure terms have been modified to comply with the requirements of BS EN 764. Cross references to other terms are shown in bold type.

absolute pressure	Pressure for which the zero value is associated with absolute vacuum.
active chamber discharge	The controlled flow of air, or of air and condensate, from the **chamber**, through either a drain or a vent, such that the temperature of the discharge is at the temperature of the chamber.
aeration	A part of the **sterilization process** during which **sterilant gas** and/or its reaction products desorb from the **load** until predetermined levels are reached. See **degassing** and **flushing**.
air detector	A device used to determine that sufficient air or other **non-condensable gases** have been removed from the **chamber**.
allowable pressure	Of a pressure vessel, a limit to the **operating pressure** specified for safety reasons. See **design pressure**.
automatic controller	A device that, in response to predetermined **cycle variables**, operates the **sterilizer** sequentially through the required stages of the **operating cycle**.
automatic control test	A device that, in response to predetermined **cycle variables**, operates the **sterilizer** sequentially through the required stages of the **operating cycle**.
A-weighted	Of sound level measurements, weighted to the frequency response of the human ear.
batch process record (BPR)	A permanent record of one or more **cycle variables recorded** during a complete **operating cycle** by instruments fitted permanently to the **sterilizer**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

biological indicator	A device, consisting of an **inoculated carrier** contained within a primary pack, designed to test the efficacy of an **operating cycle**.
cartridge	In **EO sterilizers**, a portable, single-use, simple vessel containing **sterilant** gas under pressure from which the gas is delivered by puncturing the cartridge.
chamber	The part of the **sterilizer** in which the **load** is placed.
chamber exhaust ventilation (CEV)	A ventilation system designed to extract gas from the **chamber** of an **EO sterilizer** supplied from a **cartridge**.
chamber furniture	Shelves, pallets, loading trolleys and other fixed or movable parts that support the **load** within the **chamber**.
chamber temperature	The lowest temperature prevailing in the **chamber**.
clinical sterilizer	A **sterilizer** designed to process **medical devices** or **medicinal products** to be used in the clinical care of patients.
commissioning	The process of obtaining and documenting evidence that equipment has been provided and installed in accordance with the equipment specifications and that it functions within predetermined limits when operated in accordance with the operational instructions.
conditioning	In **EO sterilizers**, the treatment of a **load** within the **operating cycle**, but prior to **sterilization**, to attain a predetermined temperature and humidity throughout the load.
contained fluid discard	Discard material held in sealed glass containers or sealed plastic containers of volume greater than 50 ml (see **small plastic discard**).
cooling stage	The period of the **operating cycle**, after the **holding time** has been completed, during which the **load** remains in the **chamber** while the load cools to a safe temperature.
critical gas exposure time	For **EO sterilizers**, the shortest **gas exposure time**, determined during **commissioning**, for which all **biological indicators** are inactivated.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

culture media preparator	A specialised **laboratory sterilizer** designed for the **sterilization** and dispensing of culture media.
cycle complete	Recognition by the **automatic controller** that the preset values for the **cycle variables**, necessary for a successful **operating cycle**, have been attained and that the sterilized **load** is ready for removal from the **chamber**.
cycle variables	The physical properties, for example time, temperature, pressure, humidity and gas concentration, that influence the efficacy of the **operating cycle**.
dedicated steam supply	A supply of steam produced by a generator for the exclusive use of a **sterilizer** or group of sterilizers.
degassing	1. in **LTSF** and **EO sterilizers**, an **aeration** procedure in which **sterilant** gas and its reaction products are desorbed from the **load** by defined treatment outside the **sterilizer** after completion of the **operating cycle**. 2. a pre-heating treatment of boiler feed-water to reduce the amount of **non-condensable gases** in the steam supply.
design pressure	Of a pressure vessel, the pressure chosen for the design calculations. See **operating pressure**, **allowable pressure**.
discard	Laboratory material which is, or may be, infected by micro-organisms and is to be made safe before disposal.
discard bag	A bag, usually of plastic, designed to receive solid **discard** material before being placed in a **discard box** for processing by a **make-safe** cycle.
discard box	A box designed to contain discard material for processing by a make-safe cycle.
disinfection	A process used to reduce the number of viable micro-organisms in a **load** but which may not necessarily inactivate some viruses and bacterial spores.
disinfector	An apparatus designed to achieve **disinfection**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

double-ended sterilizer	A **sterilizer** in which there is a door at each end of the **chamber**.
dry-heat sterilizer	A **clinical sterilizer** designed to sterilise **loads** by exposure to hot dry air near atmospheric pressure.
dryness value	A dimensionless quantity, approximating to the dryness fraction, derived to determine whether steam is of the correct dryness for **sterilization** purposes. A dryness value of 1.0 represents dry **saturated steam**.
D-value	Decimal reduction value (for **biological indicators**). The time in minutes required to secure inactivation of 90% of the test organisms under stated exposure conditions.
EO sterilizer	A **clinical sterilizer** designed to sterilise **loads** by exposure to **ethylene oxide** gas or EO gas mixtures (Chapter 13).
equilibration time	The period which elapses between the attainment of the **sterilization temperature** in the **chamber** and the attainment of the sterilization temperature in all parts of the **load**.
ethylene oxide (EO)	**Sterilant** gas used to sterilise items that would be damaged by exposure to heat or moisture. Chemical formula CH_2CH_2O.
F_O	A quantity, measured in minutes, used to determine the efficacy of an **operating cycle** and equivalent to a continuous period at a temperature of 121°C.
fault	An attribute of **sterilizer** design whereby failure of any component or its associated services does not create a safety hazard.
fail-safe	The recognition by the **automatic controller** that the preset **cycle variables** for the **operating cycle** have not been attained and that **sterilization** or **disinfection** has been jeopardised.
flash sterilizer	A device designed to achieve **sterilization** by exposing the **load** to a very high temperature steam for a few seconds.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

fluid sterilizer	A **clinical sterilizer** designed to sterilise fluids in sealed containers by exposure to **high-temperature steam** under pressure.
flushing	In **LTSF** and **EO sterilizers,** an **aeration** procedure by which remaining **sterilant** gas is removed from the **load** within the **chamber** by the passage of air or other inert gas.
formaldehyde	**Sterilant** gas used in combination with **low-temperature steam** to sterilise items that would be damaged by exposure to **high-temperature steam.** Chemical formula HCHO. Also known as methanal.
formalin	Formaldehyde Solution BP. A 38% aqueous solution of **formaldehyde** stabilised with 10% w/v ethanol, commonly used as the primary material for generating formaldehyde gas.
free steaming	A process, used in **laboratory sterilizers,** in which the **load** is exposed to steam near atmospheric pressure.
free-standing	Of a **sterilizer,** installed in a room which is not separated into a **plantroom** and a **loading area**.
full load	A specified **load,** used in thermometric tests, to represent the maximum size and mass of load which the **sterilizer** is designed to process.
gas exposure time	In **EO sterilizers,** the time for which the **chamber** is maintained at the specified temperature, gas concentration, pressure and humidity.
gauge pressure	Pressure equal to the difference between the **absolute pressure** and local atmospheric pressure.
high-temperature steam	Steam at a temperature above the boiling point of water at local atmospheric pressure.
holding time	The period during which the temperature in all parts of the **chamber, load** and any coolant fluid is held within the **sterilization temperature band.** It follows immediately after the **equilibration time**.
hot-air sterilizer	See dry-heat sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

hot source	A temperature reference used to verify the calibration of a thermometric measurement system.
indicated	An indicated value is that shown by a dial or other visual display fitted permanently to the **sterilizer** (see **recorded** and **measured**).
inoculated carrier	A component of a **biological indicator**, comprising a piece of supporting material on which a defined number of test organisms are deposited.
installation checks	A series of checks performed by the contractor to establish that the **sterilizer** has been provided and installed correctly, is safe to operate, does not interfere with nearby equipment and that all connected services are satisfactory and do not restrict the attainment of conditions for **sterilization**.
installation tests	A series of tests performed by the contractor after the **installation checks** to demonstrate that the **sterilizer** is working satisfactorily.
integral steam supply	A supply of steam produced in a sterilizer **chamber** or in a generator directly connected to it. The pressure in the sterilizer chamber is equal to that in the generator.
Köch steamer	A laboratory apparatus designed to expose a **load** to steam near atmospheric pressure and commonly used for melting solidified agar.
laboratory sterilizer	A **sterilizer** designed to sterilise, disinfect or **make-safe** laboratory materials and equipment.
Line-Pickerell helix	A device containing an **inoculated carrier**, used in microbiological tests on **LTSF** and **EO sterilizers**, and are designed to stimulate the worst-case conditions for **sterilization** by gas.
load	Collectively, all the goods, equipment and materials that are put into a **sterilizer** or **disinfector** at any one time for the purpose of processing it by an **operating cycle**.
load item	One of several discrete containers, packs or other units that together constitute a **load**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

load-temperature probe	A movable temperature sensor fitted within the **sterilizer chamber** and designed to record the temperature inside selected **load items**.
loading area	The room or area in front of the **sterilizer** in which the operator works and from which the sterilizer is loaded and unloaded. It is commonly separated by a fascia panel from the **plantroom**.
loading condition	A specified combination of the nature and number of **load items,** the items of **chamber furniture,** and their distribution within the **chamber**.
loading factor	The average fraction of the **usable chamber space** occupied by a load during normal operation.
local exhaust ventilation (LEV)	A ventilation system designed to extract small amounts **EO** or **formaldehyde** vapour released during normal operation of a **sterilizer** and its ancillary equipment.
low-temperature steam (LTS)	Steam at a temperature below the boiling point of water at local atmospheric pressure.
LTS disinfector	A clinical **disinfector** designed to disinfect **loads** by exposure to **low-temperature steam** at sub-atmospheric pressure.
LTSF sterilizer	A **clinical sterilizer** designed to sterilise **loads** by exposure to **low-temperature steam** and **formaldehyde** gas at sub-atmospheric pressure.
mains steam supply	The supply of steam produced for distribution to a range of steam-consuming equipment by an independent common boiler.
make-safe	A process, used in **laboratory sterilizers,** to reduce the microbial content of contaminated material so that it can be handled and disposed of without causing an infection hazard or environmental contamination.
master process record (MPR)	A **batch process record** obtained from a thermometric **commissioning** or **performance qualification** test and annotated to show the permitted tolerances for **cycle variables** during subsequent testing and routine production.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

measured	A measured value is that shown on a test instrument, such as a thermometric recorder or a test pressure gauge, attached to the **sterilizer** for test purposes **(see indicated** and **recorded)**.
medical device	Any instrument, apparatus, appliance, material or other article, whether used alone or in combination, including the software necessary for its proper application, intended by the manufacturer to be used on human beings for the purpose of: diagnosis, prevention, monitoring, treatment or alleviation of disease; diagnosis, monitoring, treatment, alleviation or compensation for an injury or handicap; investigation, replacement or modification of the anatomy or of a physiological process; control of conception; and which does not achieve its principal intended action in or on the human body by pharmacological, immunological or metabolic means, but which may be assisted in its function by such means. (Source: EU Council Directive 93/42/EEC.)
medicinal product	Any substance or combination of substances presented for treating or preventing disease in human beings or animals. Any substance or combination of substances which may be administered to human beings or animals with a view to making a medical diagnosis or to restoring, correcting or modifying physiological functions in human beings or in animals is likewise considered a medicinal product. (Source: EU Council Directive 65/65/EEC.)
module	A standard unit of **chamber** size being a rectangular box measuring 300 x 300 x 600 mm of volume 54 litres.
non-condensable gases (NCGs)	Gases which cannot be liquefied by compression under the range of conditions of temperature and pressure used during the **operating cycle**.
noted	A noted value is that written down by the operator, usually as the result of observing an **indicated, recorded** or **measured** value.
operating cycle	The set of stages of the **sterilization** or **disinfection** process carried out in sequence and regulated by the **automatic controller.** It is synonymous with the terms “sterilization cycle” for **sterilizers** and “disinfection cycle” for **disinfectors**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

operating pressure	The pressure in the **chamber** during the **plateau period** of an **operating cycle**. See **allowable pressure**, **design pressure**.
override	A system by which the progress of the **operating cycle** can be interrupted or modified as necessary.
performance class	An integer, from 1 to 20, related to the total cycle time for a **sterilizer** with a **full load**.
performance qualification (PQ)	The process of obtaining and documenting evidence that the equipment, as commissioned, will produce acceptable product when operated in accordance with the process specification.
performance requalification (PRQ)	The process of confirming that the evidence obtained during **performance qualification** remains valid.
periodic tests	A series of tests carried out at daily, weekly, quarterly and yearly intervals.
permitted tolerance	A limit, determined during **performance qualification**, on how much a **cycle variable** is permitted to vary from a nominal value.
plant history file	A file containing **validation**, maintenance and other engineering records for each **sterilizer**.
plantroom	The room or area to the rear of the **sterilizer** in which services are connected and which provides access for maintenance. It is commonly separated by a fascia panel from the **loading area**.
plateau period	The **equilibration time** plus the **holding time**.
porous-load sterilizer	A **clinical sterilizer** designed to process, by exposure to **high-temperature steam** under pressure, porous items such as towels, gowns and dressings, and also **medical devices** that are wrapped in porous materials such as paper or fabrics.
PQ report	A report containing the data and results obtained from a **performance qualification** test.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

preconditioning	Treatment of a **load** to attain predetermined conditions, such as temperature and humidity, before the start of an **operating cycle**.
pressure ballasting	A technique used in **fluid sterilizers** by which the pressure in the **chamber** is maintained at or near to the pressure inside the **load** containers during all or part of the **operating cycle**.
pressure vessel	A collective term describing the sterilizer **chamber**, jacket (if fitted), door(s) and components that are in permanent open connection with the chamber.
priming	Of a steam generator, the delivery of steam containing water in suspension due to violent boiling or frothing.
pyrogen	A bacterial toxin that causes a rise in body temperature and which is not destroyed by steam **sterilization**.
recommissioning	A procedure to confirm that operational data established during **commissioning** remain valid.
recorded	A recorded value is that shown on the output of a recording instrument fitted permanently to the **sterilizer** (see **indicated** and measured).
reference load	A specified **load** made up to represent the most difficult combination of items to be sterilized.
repeat validation	A procedure to obtain a new set of **commissioning** and **performance qualification** data to replace the set originally obtained during **validation**.
revalidation	A procedure to confirm an established **validation,** consisting of **recommissioning** followed by **performance requalification**.
safety hazard	A potentially detrimental effect on persons or the surroundings arising directly from either the **sterilizer** or its **load**.
saturated steam	Steam whose temperature, at any given pressure, corresponds to that of the vaporisation curve of water.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

small load	A specified **load,** used in thermometric tests, to represent the minimum size and mass of load which the **sterilizer** is designed to process.
small plastic discard	**Discard** material comprising or held in plastic containers not exceeding 50 ml in volume.
Standard test pack	A pack representing the maximum density of porous material which a **porous load sterilizer** conforming to European Standards should be able to process.
sterilant	An agent used to effect **sterilization,** such as steam, hot air or a sterilising gas**.**
sterile	Condition of a **load item** that is free from viable micro-organisms. See BS EN 556 for the requirements for a **medical device** to be labelled “sterile”.
sterilization	A process undertaken to render a **load sterile**.
sterilization conditions	The ranges of the **cycle variables** which may prevail throughout the **chamber** and **load** during the **holding time**.
sterilization pressure band	The range of pressures which may prevail in the **chamber** during the **holding time**. For a steam **sterilizer**, the sterilization pressure band is directly related to the **sterilization temperature band**.
sterilization process	The complete set of procedures required for **sterilization** of a **load,** including the **operating cycle** and any treatment of the load before or after the operating cycle.
sterilization temperature	Minimum acceptable temperature of the **sterilization temperature band**.
sterilization temperature band	The range of temperatures which may prevail throughout the **load** during the **holding time.** These temperatures are expressed as a minimum acceptable (the **sterilization temperature)** and a maximum allowable and are stated to the nearest degree Celsius.
sterilizer	An apparatus designed to achieve **sterilization**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

superheated steam	Steam whose temperature, at any given pressure, is higher than that indicated by the vaporisation curve of water.
thermal door lock	An interlock fitted to certain **sterilizers** to prevent the door from being opened until the temperature in the **chamber** and **load** falls below a preset value.
transportable	Requiring no permanent connections or installation and capable of being moved manually without mechanical assistance. Synonymous with “bench-top”.
type tests	A series of tests conducted by the manufacturer to establish the working data for a **sterilizer** type.
usable chamber space	The space inside the **chamber** which is not restricted by **chamber furniture** and which is consequently available to accept the **load**.
utilisation factor	The fraction of the open hours for which a sterilizer is available to process loads.
validation	A documented procedure for obtaining, recording and interpreting data required to show that a **sterilization process** will consistently comply with predetermined specifications.
working pressure	The pressure in the **chamber** during the **plateau period** of an **operating cycle**.
works tests	A series of tests to establish the efficacy of each **sterilizer** at the manufacturer’s works.

Appendix 2: Calculations

Derivation of the steam dryness value equation

A2.1 The equation given in Chapter 9 for the steam dryness value can be derived as follows.

A2.2 Steam supplied from the main will contain dry steam with a small amount of moisture carried as droplets in suspension at the same temperature.

The dryness fraction, D, is defined as:

$$D = \frac{M_{dry}}{M_{steam}} = \frac{M_{dry}}{M_{dry} = M_{wet}} \qquad \text{(A2-1)}$$

where a given mass M_{steam} of steam contains a mass M_{dry} of pure dry steam and M_{wet} of moisture. Dry saturated steam has a dryness fraction of 1.0.

A2.3 If dry saturated steam is allowed to condense in cold water, then the temperature rise of the water is related to the amount of latent heat given up by the condensing steam. If the steam contains moisture, then the latent heat (and the temperature rise) will be less than for the same mass of pure dry saturated steam. The dryness fraction may then be estimated (the estimate being known as the dryness value) by equating the heat gained by the water to the heat lost by the steam.

A2.4 At the start of the test the flask contains a mass M_w of water at a temperature of T_0 . At the end of the test the temperature has risen to T_1,

Heat gained by water = $(T_1 - T_0)cM_w$ (A2-2)

where c is the specific heat capacity of water at a representative temperature between T_0 and T_1.

A2.5 The heat lost by the steam is equal to the latent heat of condensation plus the heat lost from the condensate and moisture as they cool from T_s to T_1 .

Heat lost by Steam = $LM_{dry} + (T_s - T_1)cM_c = DLM_C + (T_s - T_1)cM_C$ (A2-3)

where L is the specific latent heat of condensation of steam at temperature T_s and $M_C = M_{steam}$ is the mass of condensate and moisture. Equating (A2-2) and (A2-3) and solving for D gives:

$$D = \frac{(T_1 - T_0)(cM_W + A)}{LM_C} - \frac{(T_S - T_1)c}{L} \qquad \text{(A2-4)}$$

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

where the term *A* represents the effective heat capacity of the flask and other apparatus. For the apparatus specified in Chapter 9, A can be taken as 0.24 kJ K^{-1} (see Table AI). If the apparatus being used differs significantly from Table AI then the effective heat capacity should be recalculated.

A2.6 Example: In a dryness value test the temperature of the water in the flask rises from T_1 = 19°C to T_2 = 81°C. The average steam temperature during this time is T_s = 144°C. The initial mass of water in the flask is M_w = 632 g, and the mass of condensate is M_c = 77 g. From tables c ≈ 4.18 kJ kg^{-1} K^{-1}, and L ≈ 2130 kJ kg^{-1}. Then:

$$D = \frac{(81-19)(4.18\ x\ 0.632 + 0.24)}{2130\ x\ 0.077} - \frac{(144-81)4.18}{2130} = 1.089 - 0.124 = \mathbf{0.96}$$

Table A1 Effective heat capacity for steam dryness apparatus

Component [a]	Mass (g)	Heating factor (b)	Effective heat capacity (kJ K^{-1})
One-litre glass vacuum flask	355	0.5	0.119
Rubber bung	91	0.8	0.116
90-mm glass pipe	2.4	1.0	0.002
290-mm glass pipe	7.8	1.0	0.005
TOTAL			0.242

a. The rubber pipe is not included as it is assumed to be at steam temperature at the start of the test.

b. The heating factor is an estimate of the factor by which the component is heated from T_1 to T_2 during the test.

A2.7 It can be seen that the term for the heat capacity of the apparatus (0.24) contributes approximately 10% to the total dryness value.

Relative humidity in EO sterilizers

A2.8 Due to the difficulty in measuring relative humidity in the chamber of an EO sterilizer, it is usually better to calculate the RH from the measured or recorded rise in pressure as humidifying steam is introduced.

A2.9 At the start of the conditioning stage the chamber contains a small amount of air at pressure P_O and temperature *T*. During the conditioning stage steam is introduced into the chamber and the pressure rises to P_1 while the temperature remains at *T*. From the law of partial pressures we can identify the pressure change, $\Delta P = P_1 - P_0$,with the partial pressure of the water vapour, P_w.

A2.10 Relative humidity is defined as P_w/P_s where P_s is the saturated vapour pressure of water at temperature *T*, which can be obtained from steam tables.

Hence,

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Relative humidity, $RH = \Delta P/P_S$ (A2-5)

A2.11 *Example:* During a conditioning stage at a temperature of 55°C, the chamber pressure rises from P_O = 80 mbar to P_1 = 168 mbar, a rise of ΔP = 88 mbar (8.8 kPa). From the steam tables we find that at 55°C, P_s = 157 mbar. The relative humidity is then 88/157 0.56 = **56%**

Concentration of ethylene oxide

A2.12 The concentration of ethylene oxide (EO) in a sterilizer chamber may be calculated as follows.

A2.13 An ideal gas obeys the equation of state:

$$PV = \frac{Pm}{p} = RT \quad \text{(A2-6)}$$

where:

P = absolute pressure (Pa);

V = molar volume ($m^3\ mol^{-1}$);

m = molecular weight ($kg\ mol^{-1}$);

p = density ($kg\ m^{-3}$);

R = gas constant (8.3 14 $J\ K^{-1} mol^{-1}$);

T = absolute temperature (K).

A2.14 At the end of the conditioning stage, the chamber contains a mixture of air and water vapour at a pressure P_1 and temperature T. During the sterilant gas injection stage the pressure rises to P_2 while the temperature remains at T. From the law of partial pressures the pressure change, $\Delta P = P_2 - P_1$ can be identified with the partial pressure of the EO mixture:

$$\Delta P = P_{EO} + P_{DG} = RT\left(\frac{P_{EO}}{M_{EO}} + \frac{P_{DG}}{M_{DG}}\right) \quad \text{(A2-7)}$$

where the subscript EO refers to ethylene oxide and DG to the diluent gas. Rearranging for the EO density:

$$P_{EO} = M_{EO}\left(\frac{\Delta P}{RT} - \frac{P_{DG}}{M_{DG}}\right) \quad \text{(A2-8)}$$

A2.15 But from equation (A2.6):

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

$$P_{DG} = W_{DGP} = W_{DG}\ \frac{\Delta P \overline{m}}{RT} \qquad \text{(A2-9)}$$

where $\overline{m}$ is the mean molecular weight of the EO mixture and $w_{DG}$is the proportion by mass of diluent gas such that $w_{EO} = w_{DG} = 1$.

A2.16 Inserting equation (A2-9) in equation (A2-8) gives the EO concentration:

$$P_{EO} = \frac{\Delta P}{RT} m_{EO} \left(1 - W_{DG} \frac{\overline{m}}{m_{DG}}\right) \qquad \text{(A2-10)}$$

A2.17 The mean molecular weight of a mixture of two gases, 1 and 2, is defined as:

$$\overline{m} = \frac{n_1 m + n_2 m_{21}}{n_1 + n_2} = \frac{p_1 + p_2}{p_1 / m_1 + p_2 / m_2} = \frac{(p_1 + p_2) m_1 m_2}{p_1 m_2 + p_2 m_1} = \frac{m_1 m_2}{w_1 m_2 + w_2 m_1} \qquad \text{(A2-11)}$$

where n_1 and n_2 are the number of molecules of each gas. Hence, for an EO mixture the mean molecular weight is given by:

$$\overline{m} = \frac{m_{EO} m_{DG}}{w_{EO} m_{DG} + w_{DG} m_{EO}} \qquad \text{(A2-12)}$$

A2.18 Inserting equation (A2-12) in equation (A2-10) and rearranging, the concentration of EO in the chamber is:

$$p_{EO} = \frac{\Delta P}{RT} w_{EO} \overline{m} \qquad \text{(A2-13)}$$

A2.19 *Example:* A sterilizer uses a mixture of 12% EO (molecular weight: 44g mol^{-1}) and 88% dichlorodifluoromethane (molecular weight: 121 g mol^{-1}). From equation (A2-12), the mean molecular weight of the mixture is then:

$$\overline{m} = \frac{44\ x\ 121}{0.12\ x\ 121 + 0.88\ x\ 44} = 100.0 g\ mol^{-1}$$

A2.20 During the gas injection stage the pressure is observed to rise by 1.48bar (1.48 x 10^5Pa) while the temperature remains at 55°C (328 K). From equation (A2-13) the concentration of EO in the chamber, in SI units, is then:

$$P_{EO} = \frac{1.48\ x\ 10^5\ x\ 0.12\ x\ \ 0.100}{8.31\ x\ 328} = 0.652\ kgm^{-3} = \mathbf{0.65\ g\ l^{-1}}$$

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A2.21 *Example:* A sterilizer uses a mixture of 10% EO and 90% carbon dioxide (molecular weight: 44 g mol^{-1}), giving an effective molecular weight of 44 (since both gases have the same molecular weight). During the gas injection stage the pressure rises by 5.16 bar (5.16 x 10^5Pa) while the temperature remains at 37°C (310 K). From equation (A2-13) the concentration of EO in the chamber is then 0.881 kg m^{-3}, or **0.88 g l^{-1}**.

Appendix 3: Summary sheets

Summary sheets

A3.1 The summary sheets for commissioning, performance qualification and yearly or revalidation tests should be completed by the test person and given to the user as described in paragraph 2.30.

A3.2 They cover porous load sterilizers, fluid sterilizers, sterilizers for unwrapped instruments and utensils, dry-heat sterilizers, LTS disinfectors and LTSF sterilizers, EO sterilizers and laboratory sterilizers.

A3.3 The lists of tests are to be regarded as a record of which tests have been done, not a prescription for which tests ought to be done. Detailed schedules are given in Chapters 4 and 5. Tests which do not apply to the sterilizer under test should be marked N/A.

A3.4 Where fluid or dry-heat sterilizers are to be used for the sterilization of medicinal products the sheets should be signed by the quality controller as shown.

A3.5 Common sheets are used for LTS and LTSF machines since most of the tests are identical. The signature of the microbiologist is required only for LTSF sterilizers.

A3.6 The sheets for laboratory sterilizers are designed to be used with any of the following operating cycles: make-safe of small plastic discard, make-safe of contained fluid discard, sterilization of culture media (preset or variable cycle), disinfection of fabrics, sterilization of glassware and equipment, free steaming. They may also be used for a culture media preparator. For commissioning and performance qualification, a separate sheet should be completed for each operating cycle available on the machine, and the name of the cycle written clearly in the space provided.

NOTE: We acknowledge the support of Scottish Healthcare Supplies in providing the Test Forms. Complete Test logbooks containing the Forms are available from Scottish Healthcare Supplies, Trinity Park House, South Trinity Road, Edinburgh EH5 3SH; Telephone 0131 552 6255. Sterilization temperature (ST) selected ……°C
Automatic controller settings for plateau period: Temperature…….°C Time ……min…s

Event	Elapsed time	Chamber	Temperature sensors		
	Min s	Bar	Drain/ Vent °C	Load °C	Free Space °C
SMALL LOAD TEST Start of plateau period Start of holding time End of holding time Maximum values attained Equilibration time Holding time Total cycle time			No…….	No……	No…….
FULL LOAD TEST Start of plateau period Start of holding time End of holding time Maximum values attained Equilibration time Holding time Total cycle time			No……	No…….	No…….

DECLARATION OF TEST PERSON (STERILIZERS)

1. The installation checks and tests have been completed and show that the sterilizer has been provided and installed in accordance with it specification.
2. All test instruments have current calibration certificates.
3. Calibration of the temperature test instruments has been checked before and after the thermometric tests.
4. The commissioning tests have been completed and show that the sterilizer functions correctly when operated in accordance with operational instructions.

Test Person: Name: ……Signature: ……Date:…….

DECLARATION OF USER

The sterilizer is fit for use. The first yearly tests are due no later than:

User: Name: ……Signature: ……Date:…….

Any party making any use thereof or placing any reliance thereon shall do so only upon exercise of that party's own judgement as to the adequacy of the contents in the particular circumstances of its use and application. No warranty is given as to the accuracy of the contents and the Property and Environment Forum Executive, which produced this document on behalf of NHSScotland Property and Environment Forum, will have no responsibility for any errors in or omissions therefrom.

The production of this document was jointly funded by the Scottish Executive Health Department and the NHSScotland Property and Environment Forum.

NHSScotland, P&EFEx, June 2001

Executive summary

SHTM 2010 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of the following types of sterilizer in use in the National Health Service:

a. clinical sterilizers:
   (i) high-temperature steam sterilizers used for processing porous loads (including instruments and utensils wrapped in porous materials);
   (ii) high-temperature steam sterilizers used for processing aqueous fluids in sealed containers;
   (iii) high-temperature steam sterilizers used for processing unwrapped solid instruments and utensils;
   (iv) dry-heat sterilizers (hot-air sterilizers);
   (v) low-temperature steam (LTS) disinfectors and low-temperature steam and formaldehyde (LTSF) sterilizers;
   (vi) ethylene oxide (EO) sterilizers;

NOTE: LTSF sterilizers are considered to be disinfectors.

b. laboratory sterilizers:
   (i) high-temperature steam sterilizers used with one or more specialised operating cycles;
   (ii) culture media preparators.

Users who wish to employ processes not included here bear the responsibility of ensuring that the validation procedures comply with the principles outlined in Part 3 of this SHTM and that the intended operating procedures will ensure an efficacious process for the different types of load.

This SHTM is intended primarily as a guide for technical personnel, whether specialists in sterilizers and sterilization procedures or those responsible for maintenance and testing. It is also intended for those responsible for the day-to-day running of sterilizers, and will also be of interest to microbiologists, infection control officers, supplies officers, architects, estates managers and others in both the public and private sectors.

Detailed information on the planning and design of a sterile services department, including the level of provision of sterilizers, is given in SHPN 13; *Sterile services department*. Guidance for laboratory installations can be found in SHPN 15; *Accommodation for pathology services*.

Although this edition of SHTM 2010 reflects established sterilizer technology, it is recognised that considerable scope exists for the utilisation

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

of emerging technology in the management of sterilizers. This will be kept under review with the aim of introducing recommendations for such technology at the earliest opportunity so that the procedures essential for the efficient, safe and effective operation of sterilizers can be optimised.

The sterilizers described in this SHTM may not be suitable, without modification, for safely processing articles infected with Hazard Group 4 pathogens. Design considerations for sterilizers intended to process articles infected with such organisms are discussed in Part 2.

NOTE: Information about Hazard Groups may be found in the HSC document, 'Categorisation of pathogens according to hazard and categories of containment' (4th edition 1995) compiled by the Advisory Committee on Dangerous Pathogens.

The agents associated with transmissible spongiform encephalopathies (TSEs) are unusually resistant to sterilization and cannot be reliably inactivated by the standard procedures described here. Advice on the sterilization of items contaminated with TSE agents can be found in Appendix 2.

NOTE: Information about TSEs may be found in the HSE document, 'Precautions for work with human and animal Transmissible Spongiform Encephalopathies', compiled by the Advisory Committee on Dangerous Pathogens.

This volume substantially revises previous editions of Part 4.

1. General

Introduction

1.1 This Part of SHTM 2010 covers the maintenance and operation of the various types of sterilizer used in hospitals, laboratories and other healthcare facilities.

1.2 Terminology used in sterilization has long been inconsistent and occasionally ambiguous. This SHTM introduces a set of terms consistent with European Standards (see paragraph 1.18) which, it is hoped, will in time be adopted by sterilization workers in the NHS. The Glossary contains definitions referred to in this Part.

1.3 The Reference section contains full references for all the documents referred to in this Part and for selected documents of which the reader should be aware.

Legal frameworks for sterilization

1.4 There are now two legal frameworks governing the manufacture of sterile products. The long-standing legislation on medicinal products has now joined by new European Union (EU) Directives on medical devices.

1.5 Users should be clear as to whether the load items they intend to process in a sterilizer are classified as medicinal products or medical devices. Definitions for both may be found in the Glossary. While the practical requirements have much in common, their implementation is very different.

1.6 For the guidance given in this SHTM, the various types of sterilizer are presumed to be used primarily as follows (though there are exceptions):

a. for **medicinal products**: fluid sterilizers, dry-heat sterilizers;

b. for **medical devices**: porous load sterilizers, sterilizers for unwrapped instruments and utensils, dry-heat sterilizers, LTS disinfectors, LTSF sterilizers, EO sterilizers.

NOTE: Despite their name, LTSF Sterilizers are disinfectors.

1.7 Where a sterilizer is purchased with the intention of processing both medicinal products and medical devices, users should ensure that the requirements for both types of product are met.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Medicinal products

1.8 The manufacture and supply of medicinal products are controlled by a large body of legislation stemming from the EU Directives on medicinal products and enacted by the UK Medicines Acts and numerous Regulations. Further details can be found in Part 1 of this SHTM.

1.9 The requirements for the manufacture of medicinal products are set out in the 'Guide to good manufacturing practice for medicinal products' published in volume IV of, 'The rules governing medicinal products in the European Community'. This document is referred to as the "GGMP" in this SHTM.

1.10 The GGMP contains an Annex on the 'Manufacture of sterile medicinal products' which has considerable implications for the operation of sterilizers. Users considering using a sterilizer for the processing of medicinal products should consult the GGMP at an early stage.

1.11 Guidance on the application of medicines legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medicines Control Agency (MCA) whose address may be found in Appendix 1.

Medical devices

1.12 he three EU Directives on the manufacture and supply of medical devices, active implantable medical devices and in-vitro diagnostic medical devices. The directives are implemented in the UK by The Active Medical Devices Regulations 1992, The Medical Devices Regulations 1994 and the In Vitro Diagnostic Medical Devices Regulations 2000. General guidance on these directives and regulations may be found in MDA web site www.medical-devices.gov.uk

1.13 Annex I of the Medical Devices Directive lists a number of "essential requirements", among which the following are relevant to sterilization:

a. Section 7.2 requires that devices are "designed, manufactured and packaged in such a way as to minimise the risk posed by contaminants and residues to the persons involved in the transport, storage and use of the devices and to the patients, taking account of the intended purpose of the product." This has implications for the quality of steam used in sterilization processes, and for the efficacy of removal of gas residuals in LTSF and EO sterilization.

b. Sections 8.3 and 8.4 require that devices delivered in a sterile state:

   (i) "must be designed, manufactured and packed in a non-reusable pack and/or according to appropriate procedures to ensure that they are sterile when placed on the market and remain sterile, under the storage and transport conditions laid down, until the protective packaging is damaged or opened";

   (ii) "must have been manufactured and sterilized by an appropriate, validated method".

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

c. Section 8.7 requires that the "packaging and/or label of the device must distinguish between identical or similar products sold in both sterile and non-sterile condition".

d. Section 13.3 sets out the requirements for the labelling of sterile packs.

e. Section 13.6 sets out requirements for the instructions for use which must accompany each device, including instructions in the event of the sterile pack being damaged.

1.14 Requirements for active implantable medical devices are similar, and users should consult the appropriate Directive and Regulations for details.

1.15 It is likely that all or most products for clinical use that are not classified as medicinal products will be classified as medical devices. Whether such medical devices are subject to the Regulations is a complex issue turning on the relationship between the producer and the end-user of the devices and is discussed in MDA Directives Bulletin 18.

1.16 Certain sterilizers used in a "medical environment" are regarded as "accessories" to medical devices, with the consequence that they are to be treated as medical devices in their own right. These machines, which are often (but not necessarily) transportable sterilizers designed for processing unwrapped instruments and utensils, are intended by their manufacturer for use with specific medical devices (such as surgical instruments or endoscopes) in accordance with the manufacturer's instructions for such devices.

1.17 The European Committee for Standardisation (Comité Européen de Normalisation, CEN) has prepared a number of European Standards on the manufacture of medical devices. These are known as "harmonised" standards. Compliance with a harmonised standard is considered to bring with it a legal presumption of compliance with the essential requirements of the Directive it supports. Official notification of European Standards supporting EU Directives is published in the *Official Journal of the European Communities* and in the London, Edinburgh and Belfast Gazettes. European Standards are published in the UK by the British Standards Institution with "BS EN" prefixes.

1.18 Although compliance with a harmonised standard is not the only way of complying with the directives, it is the simplest. Purchasers intending to process sterile medical devices in compliance with the directives should therefore ensure that their processes conform with one of the harmonised standards. The following harmonised standards on the validation and control of sterilization processes are discussed in this Part of this SHTM:

a. EN 556 covering the requirements for a medical device to be labelled "sterile" (BS EN 556);

b. EN 554 covering sterilization by "moist heat" (ie. steam) (BS EN 554);

c. EN 550 covering sterilization by ethylene oxide (BS EN 550).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.19 These standards are themselves supported by the following standards for the specification of sterilizers which are discussed in Part 2 of this SHTM:

a. EN 285 covering “large” porous load sterilizers (BS EN 285);

b. EN 1422 covering ethylene oxide sterilizers (BS EN 1422).

1.20 While the guidance given here is designed to be broadly consistent with the standards, SHTM 2010 should not be regarded as a substitute for the standards themselves when ascertaining compliance with EU Directives and the UK Regulations that implement them.

1.21 Guidance on the application of medical devices legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medical Devices Agency (MDA) whose address may be found in Appendix 1.

Quality systems

1.22 The European Standards referred to in this SHTM may be used alongside a quality system for the supply of sterile medical devices based upon the EN ISO 9000 series:

a. EN ISO 9001 and 9002 describe the basic requirements for a quality system;

b. EN 46001 and 46002 describe particular requirements for the suppliers of medical devices.

1.23 Written procedures for the procurement, validation and management of sterilizers designed to support a quality system for the production of sterile goods will be found in Part 6, which should be obtained from the Stationery Office. Further guidance may be found in the ‘Guide to good manufacturing practice for National Health Service sterile services departments’ published by the Institute of Sterile Services Management and issued to the NHS as EL89(P)136.

Personnel

1.24 The following personnel are referred to in this Part of SHTM 2010. Further information, including qualifications and areas of responsibility, can be found in Part 1.

1.25 **Management** is defined as the person with ultimate management responsibility, including allocation of resources and the appointment of personnel, for the organisation in which the sterilizer is employed.

1.26 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

similar authority. In small, autonomous installations the user may take on this function.

1.27 The **User** is defined as the person designated by Management to be responsible for the management of the sterilizer.

1.28 In a hospital the user could be a sterile services department manager, laboratory manager or theatre manager; in primary care he or she could be a general practitioner, dentist, or other health professional. Where a sterilizer is used to process medicinal products, the user is normally the Production Manager (see paragraph 1.37) in charge of the entire manufacturing process.

1.29 The **Competent Person (Pressure Vessels)** is defined as a person or organisation designated by Management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a sterilizer described in the Pressure Systems Safety Regulations 2000 (see Part 1). The shorter term “Competent Person” is used in this SHTM.

1.30 The **Authorised Person (Sterilizers)** is defined as a person designated by Management to provide independent auditing and advice on sterilizers and sterilization and to review and witness documentation on validation. The shorter term “Authorised Person” is used in this SHTM.

1.31 The Institute of Healthcare Engineering and Estate Management (formerly the Institute of Hospital Engineering) is the registration authority for Authorised Persons. The address is given in Appendix 1.

1.32 Guidance on the appointment of an Authorised Person is given in Appendix 4.

1.33 The **Test Person (Sterilizers)** is defined as a person designated by Management to carry out validation and periodic testing of sterilizers. The shorter term “Test Person” is used in this SHTM.

1.34 The **Maintenance Person (Sterilizers)** is defined as a person designated by Management to carry out maintenance duties on sterilizers. The shorter term “Maintenance Person” is used in this SHTM. See paragraphs 4.5 – 4.8 for more information.

1.35 The **Microbiologist (Sterilizers)** is defined as a person designated by Management to be responsible for advising the user on microbiological aspects of the sterilization of non-medicinal products. The shorter term “Microbiologist” is used in this SHTM.

1.36 The **Production Manager** is defined as a person designated by Management to be responsible for the production of medicinal products.

1.37 The **Quality Controller** is defined as a person designated by Management to be responsible for quality control of medicinal products with authority to

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

establish, verify and implement all quality control and quality assurance procedures. (A similar role may be defined for the manufacture of medical devices, but this is rarely the practice in hospitals.)

1.38 The **Laboratory Safety Officer** is defined as a person designated by Management to be responsible for all aspects of laboratory safety including equipment, personnel and training relating to safety issues, and ensuring compliance with safety legislation and guidelines.

1.39 An **operator** is defined as any person with the authority to operate a sterilizer, including the noting of sterilizer instrument readings and simple housekeeping duties.

1.40 The **manufacturer** is defined as a person or organisation responsible for the manufacture of a sterilizer.

1.41 The **contractor** is defined as a person or organisation designated by Management to be responsible for the supply and installation of the sterilizer, and for the conduct of the installation checks and tests. The contractor is commonly the manufacturer of the sterilizer.

Safety

1.42 Guidance on the safe operation of the various types of sterilizer is given in Chapters 5 to 12. Guidance on safe practices in the testing of sterilizers is given in Part 3 of this SHTM.

1.43 Low-temperature steam and formaldehyde (LTSF) sterilizers and ethylene oxide (EO) sterilizers both use toxic gases in the sterilization process. Occupational exposure to formaldehyde and EO is controlled by the Control of Substances Hazardous to Health Regulations 1999. Maximum exposure limits are set out in the annual Guidance Note EH40, ‘Occupational exposure limits’, published by the Health and Safety Executive (see Reference section). The limits shown in Table 1 are as at 1999. These limits are statutory maxima but should not be regarded as representing a safe working exposure; employers have a legal obligation to ensure that the level of exposure is reduced so far as is reasonably practicable and in any case below the maximum exposure limit.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 1: Maximum exposure limits for atmospheric formaldehyde and ethylene oxide

Gas	Short-term maximum exposure limit		Long-term maximum exposure limit	
	[ppm]	[mg m^{-3}]	[ppm]	[mg m^{-3}]
Formaldehyde	2	2.5	2	2.5
Ethylene oxide	–	–	5	9.2

The short-term maximum exposure limit (STMEL) is the average exposure over any 15-min period.

The long-term maximum exposure limit (LTMEL) is the exposure over any 24-h period expressed as a single uniform exposure over an 8-h period.

COSHH does not specify a STMEL for EO. In the above table the STMEL is deemed to be three times the LTMEL in accordance with the recommendations of the Health and Safety Executive.

Source: COSHH Regulations 1999, HSE Guidance Note EH40 (1999).

1.44 The COSHH Regulations 1999 also introduce new controls on biological agents which are of relevance to users of laboratory sterilizers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2. Operational management – an overview

Introduction

2.1 Quality control and safety of a sterilization process are ultimately dependent upon untiring vigilance. The type of process, and the details of the operating cycle, should be selected with due regard to the nature of the product. Items for sterilization should be properly cleaned, packaged and assembled in accordance with procedures established during performance qualification. Every production cycle should be monitored and carefully documented. Products should not be released until predetermined conditions have been met. The sterilizer itself should be subject to preventative maintenance and periodic testing. In these areas vigilance will necessitate skilful personnel, fully trained in the operation of sterilizers.

2.2 For assurance on these points, responsibility rests ultimately with the user, supported by the Authorised Person, the Competent Person, the Test Person, the Maintenance Person and the Microbiologist.

Maintenance

2.3 BS EN 554 (steam sterilization) and BS EN 550 (EO sterilization) make the following requirements for the maintenance of sterilizers:

a. preventative maintenance shall be planned and performed in accordance with documented procedures;

b. the procedure for each planned task and the frequency at which it is carried out shall be specified and documented;

c. the sterilizer shall not be used to process medical devices until all maintenance tasks have been satisfactorily completed and recorded;

d. records of maintenance shall be retained as specified in 4.16 of BS EN ISO 9001 or in 4.15 of BS EN ISO 9002;

e. the maintenance scheme, maintenance procedures and maintenance records shall be reviewed periodically by persons designated by management.

2.4 The guidance in Chapter 4 puts these requirements into practice.

Safety precautions

2.5 Part 1 of this SHTM discusses the principal health and safety legislation applying to sterilization.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.6 HSE guidance note PM73: 'Safety at autoclaves', applies to steam sterilizers and emphasises the guidance contained in this memorandum.

2.7 Any equipment issued to operators should comply with the Provision and Use of Work Equipment Regulations 1998. Guidance may be found in the HSE document 'Work equipment' (L22).

2.8 Users should note the requirements of The Manual Handling Operations Regulations 1992 with regard to loading and unloading sterilizers. Guidance may be found in the HSE document 'Manual handling' (L23). Reference should also be made to the 'Lifting Operations and Lifting Equipment Regulations 1998 (LOLER)'.

2.9 Access to sterilizer loading areas, plant rooms and equipment should be restricted to those entitled to be there.

Hazards associated with sterilization

2.10 Attention is drawn to the following hazards which may be encountered in the practice of sterilization:

a. the hazard of scalding from escaping steam;
b. the high temperatures (up to 200°C) at which sterilizers are operated;
c. the stored energy hazards associated with the operation of pressure vessels contained within steam and EO sterilizers;
d. the stored energy hazards associated with the pressurised containers in which EO gas is transported;
e. the explosive hazards associated with the sterilization of fluids in sealed glass containers;
f. the toxic properties of formaldehyde gas used in LTSF sterilizers;
g. the toxic and explosive properties of ethylene oxide gas used in EO sterilizers;
h. the infection hazard associated with pathogens that may be handled by personnel using certain laboratory sterilizers;
i. the hazard of infection to patients and staff by the inadvertent release of an unsterile load due to inadequate quality control;
j. the hazard to patients arising from residual ethylene oxide or formaldehyde present in the product;
k. the hazards associated with the handling of heavy and hot loads while loading and unloading sterilizers.

2.11 More detailed information about each process is given in Chapters 5 to 12.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Safety of pressure vessels

2.12 The majority of sterilizers discussed in this SHTM contain pressure vessels that are subject to the Pressure Systems Safety Regulations 2000. Users are reminded of the following safety measures:

a. door interlocking safety devices are designed to prevent:
   (i) the pressurisation of the chamber before the door is secured;
   (ii) the uncontrolled release of chamber contents while the chamber is under pressure;
b. any escape of steam should be reported immediately and appropriate action taken;
c. arrangements for regular systematic inspection and maintenance must be adhered to;
d. all operators must be adequately trained and supervised for their allotted tasks;
e. documented operating procedures must be followed at all times.

Unloading

2.13 During the cooling stage the temperature of the load may be much higher than that in the chamber. Containers of liquid could be pressurised and may explode; liquids spilled on unloading may cause scalding. Users should take note of the following safety measures:

a. thermal door-locks are fitted to sterilizers designed to process fluids, to prevent the door mechanism being released while the temperature of the fluid is too high;
b. a cooling timer may be used in addition to a thermal door-lock;
c. adequate training should ensure that the operator is aware of the nature of the load and any hazards associated with it;
d. operators should wear appropriate personal protective equipment in addition to their normal working clothes (see paragraph 2.14);
e. reaching into a hot sterilizer can be hazardous; consideration should be given to the provision of a load transfer system such as sliding shelves or a carriage and trolley.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Personal protective equipment

2.14 Operators and maintenance personnel should be issued with appropriate personal protective equipment (PPE) complying with the Personal Protective Equipment at Work Regulations 1992 (see Part 1 of this SHTM). The choice of PPE should follow a suitable assessment of risk for each type of sterilizer. Examples of PPE that may be required, in addition to normal working clothes, include:

a. impervious apron to protect against liquid spills;

b. heat-resistant gloves for handling hot loads;

c. protective gloves for handling potentially infected material;

d. safety shoes for use when loading and unloading sterilizers;

e. eye and face protection for use when removing glass containers from a sterilizer;

f. respiratory protective equipment and protective clothing for emergency use with EO sterilizers (see paragraphs A3.35–A3.48).

2.15 PPE should always be regarded as a “last resort” to protect against risks to health and safety; engineering controls and safe systems of work should always be considered first. Guidance on the selection of PPE may be found in ‘Personal protective equipment: guidance on regulations’ (L25) published by HSE.

Compatibility of load and process

2.16 The user should ensure that the load is suitable for the process to which it is to be exposed.

2.17 When selecting a process for a given item, the user should consider the following questions in conjunction with the advice of the manufacturer of the item:

a. *Is sterilization required?* In some cases, where the infection risk is intermediate to low, disinfection or cleaning may be sufficient. The guidance in Table 2 should be followed.

b. *Will the item be damaged by exposure to the process?* Several common items cannot withstand the moisture of steam sterilization or the high temperatures of dry-heat sterilization.

c. *Will the item fail to be sterilized by exposure to the process?* Even if an item can withstand the process it may not be sterilized if, for example, steam cannot penetrate narrow tubing.

d. *Is the process excluded by health and safety considerations?* Some medical devices should not be exposed to formaldehyde or ethylene oxide.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 2: Recommended processes for the decontamination of medical devices according to risk of infection

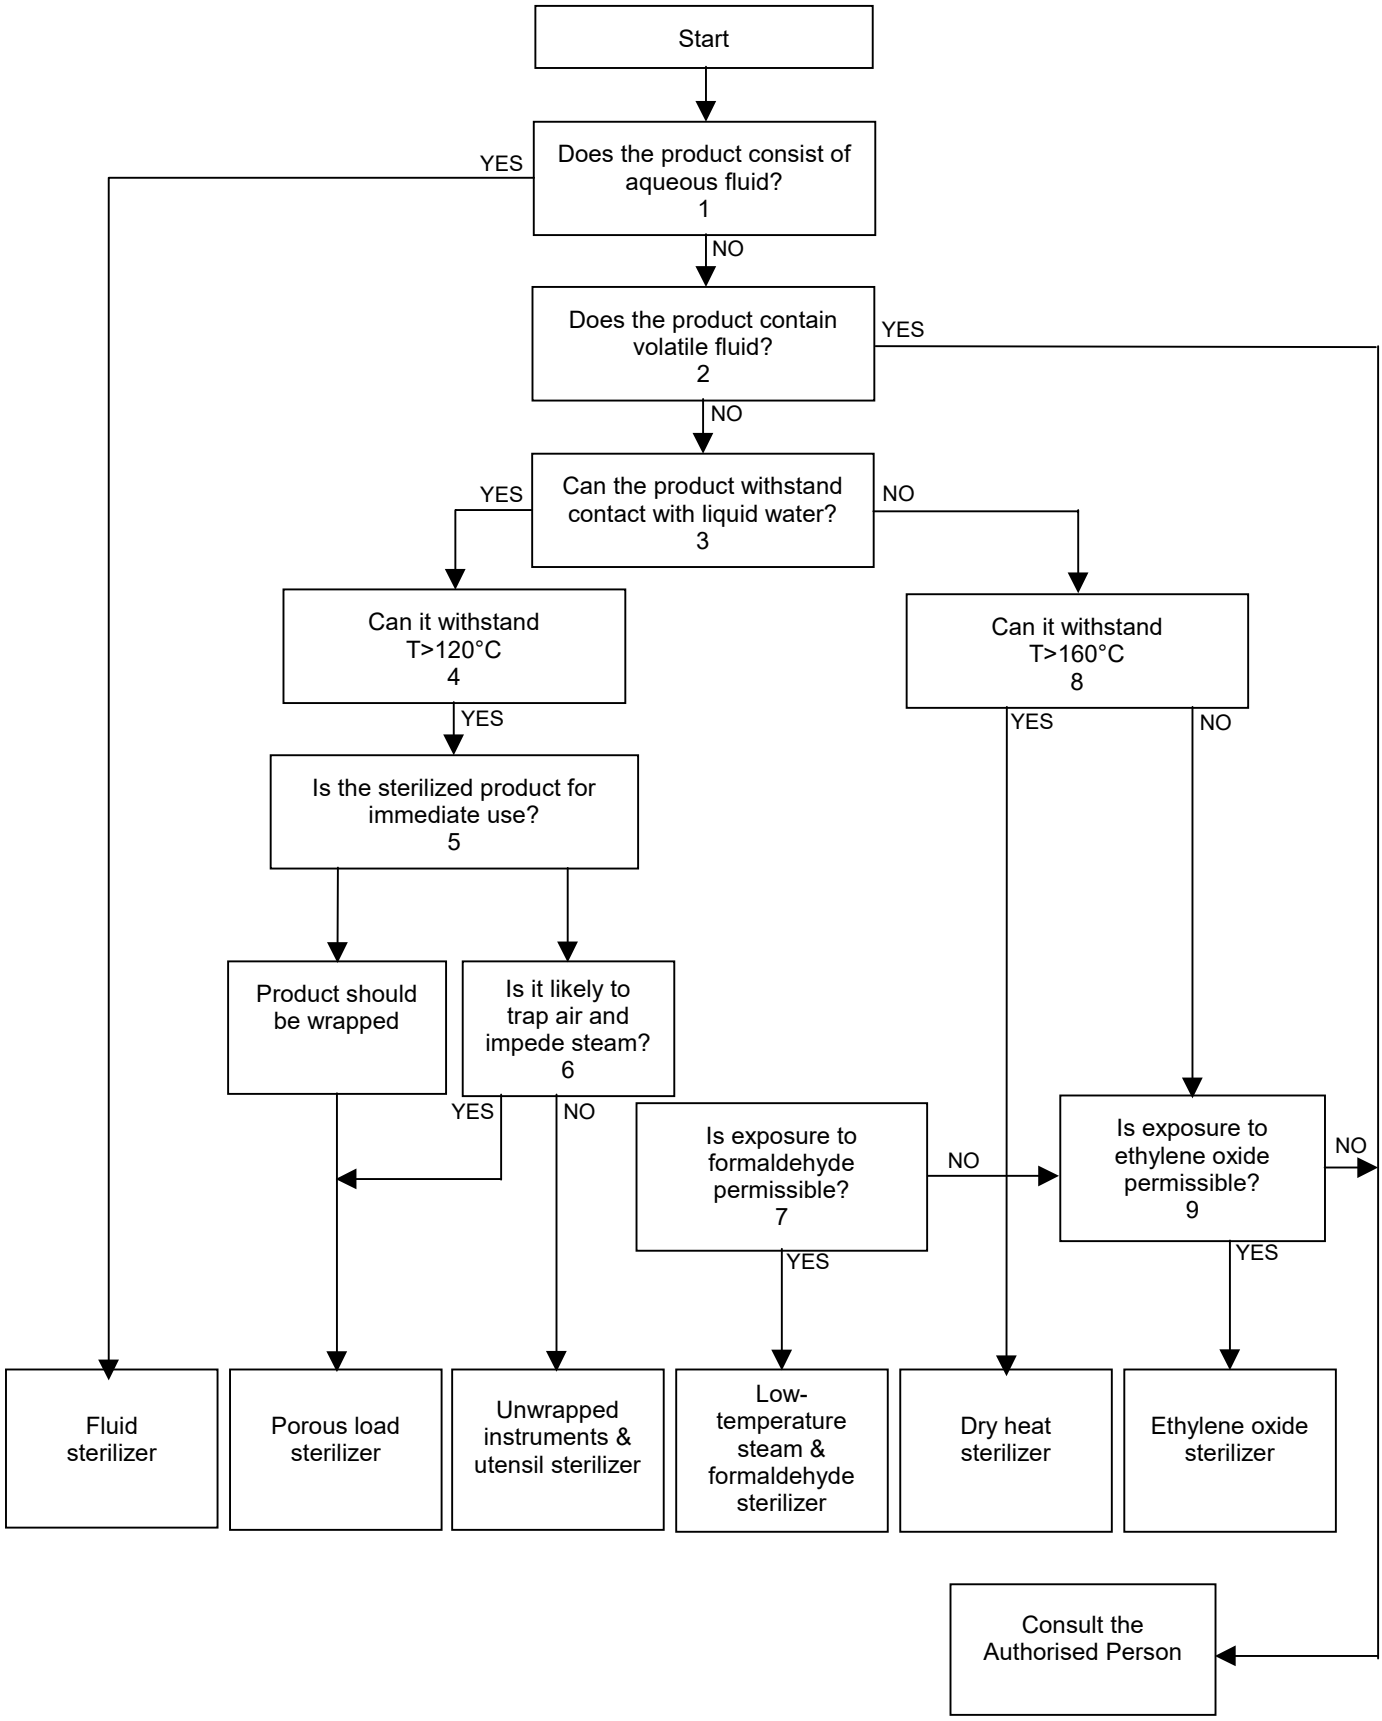
Infection risk	Application	Recommendation
High	Items in close contact with a break in the skin or mucous membrane or introduced into a sterile body area.	Sterilization
Intermediate	Items in contact with intact skin, mucous membranes or body fluids, particularly after use on infected patients or prior to use on immuno-compromised patients.	Sterilization or disinfection. Cleaning may be acceptable in some agreed situations.
Low	Items in contact with healthy skin or mucous membranes or not in contact with patient.	Cleaning

Adapted from: *Sterilization, disinfection and cleaning of medical equipment*, MDA 1993.

2.18 The flow-chart in Figure 1 will assist users in selecting an appropriate sterilization process. The Authorised Person should be consulted in cases of doubt.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 1: A guide for the selection of a sterilization process



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Notes to Figure 1

Figures refer to boxes on the flow chart.

1 *Does the product consist of aqueous fluid?*

If the product is a water solution, then it must be processed in a fluid sterilizer. Bottles or other containers holding aqueous fluids must not be placed in any other kind of sterilizer.

2 *Does the product contain volatile liquid?*

None of the processes discussed in this SHTM are suitable for volatile liquids other than water.

3 *Can the product withstand contact with liquid water?*

All steam sterilizers produce condensate on any surface which is in contact with steam. Water will therefore condense inside hollow items, within unsealed containers and inside porous packaging. Porous packaging is likely to become saturated. Packaging designed for steam sterilizers will not be damaged by such exposure.

4 *Can it withstand temperatures in excess of 120°C?*

High-temperature steam sterilizers operate at sterilization temperatures of 121°C, 126°C or 134°C, with the highest temperature preferred. Most items of glass or metal will withstand such temperatures, but items with plastic components may not. Some items constructed of two or more different metals may distort at these temperatures and some medicinal products may be damaged. In exceptional cases lower temperatures may be used provided the bioburden and the required sterility assurance level are known.

5 *Is the sterilized product for immediate use?*

If the product is to be used in a controlled medical environment immediately after the chamber door has been opened, then it need not be wrapped and a sterilizer for unwrapped instruments and utensils is acceptable. Otherwise the item should be wrapped and processed in a porous load sterilizer.

6 *Is it likely to trap air and impede steam?*

Items which are for immediate use may nevertheless require a porous-load sterilizer if they are likely to trap air and impede the penetration of steam. See paragraph 7.13 for further guidance.

7 *Is exposure to formaldehyde permissible?*

Certain items should not be processed by LTSF for reasons of health and safety. See paragraph 10.29.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8 *Can it withstand temperatures in excess of 160°C?*

Products that cannot withstand contact with liquid water may be processed in a dry-heat sterilizer if they can withstand the high temperatures and prolonged holding times.

9 *Is exposure to ethylene oxide permissible?*

Certain items should not be processed by EO for reasons of health and safety. See paragraph 11.18.

2.19 Processes using toxic gases (LTSF and EO) are a last resort and should not be used for items which could be sterilized or disinfected by another method. Many heat-sensitive items are currently processed by LTSF or EO where LTS disinfection would have been adequate and safer.

Process development

2.20 Once a basic process has been selected, users should consider whether the standard operating cycle needs to be modified to cope with specific load items. For example, delicate items may not be able to withstand the rapid pressure changes that take place in the chamber of a porous load sterilizer and the rate of change of pressure may need to be reduced.

2.21 If the cycle variables are modified from the values used during validation, revalidation (and possibly repeat validation) will be necessary (see Part 3 of this SHTM).

“Single-use” medical devices

2.22 Many medical devices are intended by their manufacturers to be used once only and then discarded. However, it is not uncommon for hospitals to clean, sterilize and reuse the more expensive of these devices (such as cardiac catheters) where it is considered safe and economical to do so.

2.23 Users considering reprocessing single-use items should note the following points:

a. the construction of many such devices, often with long and narrow lumens, makes them difficult to clean with any degree of confidence;

b. if the efficacy of cleaning procedures cannot be assured then neither can the sterilization process;

c. where devices have been sterilized by radiation, subsequent sterilization by EO can lead to structural weakening of certain plastic components;

d. the user will have no redress from the manufacturer for any subsequent failure of the device, whatever the cause.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.24 The MDA gives the following advice on reprocessing.

An organisation that reprocesses a single-use device for reuse against the instructions of the original manufacturer, and then supplies it to other organisations, will be returning the device to the market and it is likely to be regarded as a manufacturer in its own right, with all of the obligations that entails. This is because the organisation is considered to be placing a new device on the market under its own name and must therefore meet the full obligations of the Medical Devices Directive.

If single-use devices are reprocessed for use solely within the organisation, this would not be seen as placement upon the market. Hence the requirements of the Directive, so far as they relate to manufacture, would not apply.

2.25 Further information may be found in MDA web site www.medical-devices.gov.uk

Cleaning

2.26 Cleaning and drying of reusable load items before packaging and sterilization are essential, since the efficacy of the process will be reduced if soiling protects micro-organisms from exposure to the sterilant. All items should therefore be scrupulously clean. Washer-disinfectors are suitable for preparing many such items for sterilization and guidance may be found in SHTM 2030.

2.27 Discard items and materials should not be cleaned.

Packaging

2.28 BS ENs 550 and 554 require the packaging specification to be part of the definition and documentation of the sterilization process. The user should therefore ensure that each load is packaged and assembled in accordance with documented procedures validated during performance qualification.

2.29 When handled in accordance with instructions the packaging should protect the product from physical damage and maintain the sterility of the product up to the point of use.

2.30 The packaging should not inhibit the efficacy of the process by, for example, hindering the removal of air or the penetration of steam, impeding the conduction of heat to the load, outgassing, altering the humidity in the chamber, or absorbing chemical sterilants.

2.31 The packaging should be able to withstand the sterilization process. It may be necessary to carry out preliminary tests on the product and its packaging in order to determine the levels and rates of change of temperature,

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

pressure and other cycle variables which start to cause unacceptable changes in the performance qualities of the product or its packaging.

2.32 Packaging materials should be stored in the conditions recommended by the manufacturer. Packaging material that has become dehydrated, for example, may adversely affect the efficacy of an EO sterilization process.

2.33 Specifications for packaging materials may be found in BS EN 868. Extensive guidance on packaging is given in Part 5 of this SHTM, with a brief summary in Chapters 5 to 12 of this Part.

Performance qualification

2.34 Performance qualification (PQ) is defined as the process of obtaining and documenting evidence that the sterilizer, as commissioned, will produce acceptable goods when operated in accordance with the process specification.

2.35 A loading condition is a specified combination of the nature and number of load items, the items of chamber furniture, and their distribution within the chamber. For example, a load placed on the top shelf of the chamber constitutes a different loading condition from an identical load placed on the bottom shelf. The specification is part of the PQ report for that loading condition. Note that the specification may require load items to be arranged in precise positions or permit them to be placed randomly in the chamber.

2.36 The extent of the PQ required will depend on the type of sterilizer and the nature of the load. All users should adopt the following procedure for every sterilizer.

a. Establish a list of the distinct loading conditions to be processed in the sterilizer. Each production load should correspond to one of the listed loading conditions.

b. Determine whether each loading condition presents a greater or lesser challenge to the process than the small and full loads used in the thermometric tests carried out during commissioning (see Part 3 of this SHTM).

c. Where the loading condition is a lesser challenge than the commissioning loads, the results of the commissioning tests may be used as PQ data.

d. Where the loading condition is a greater challenge than the commissioning loads, PQ tests will be required as specified in Part 3 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.37 The user is responsible for deciding which loading conditions require PQ tests. The user is recommended to seek advice as follows:

a. sterilizers to be used for medicinal products – from the Quality Controller and the Test Person;

b. LTSF and EO sterilizers – from the Microbiologist and the Test Person;

c. all other sterilizers – from the Test Person.

2.38 The flow chart in Figure 2 will assist users in determining whether PQ tests are required or whether data from the commissioning tests will be sufficient. In cases of doubt, advice should be sought from the Authorised Person.

2.39 PQ tests are normally performed as part of the initial validation procedure, as part of any repeat validation procedure, and whenever the user judges that a new loading condition calls for a new PQ test. Detailed instructions for carrying out PQ tests are given in Part 3 of this SHTM.

2.40 In some cases a new load may be adequately represented by one of the existing loading conditions for which a PQ report exists. Further PQ tests will not then be necessary. Where a new load is not covered by an existing PQ report, full PQ tests as specified in Part 3 should be conducted.

2.41 When designing a new loading condition, it is important that the correct packaging is selected and specified along with the load itself. The packaging specification should not then be altered in subsequent production cycles without repeating the PQ procedure unless the loading condition with new packaging can be demonstrated to be equivalent to one covered by an existing PQ report.

Position of PQ sensors

2.42 Temperature sensors should be placed as described in Chapter 8 of Part 3 of this SHTM. In selecting which load items require sensors, the following observations should be noted:

a. small load items will heat up and cool down faster than large items;

b. load items placed near the steam inlet port will heat up faster than those placed further away.

Cycle variables

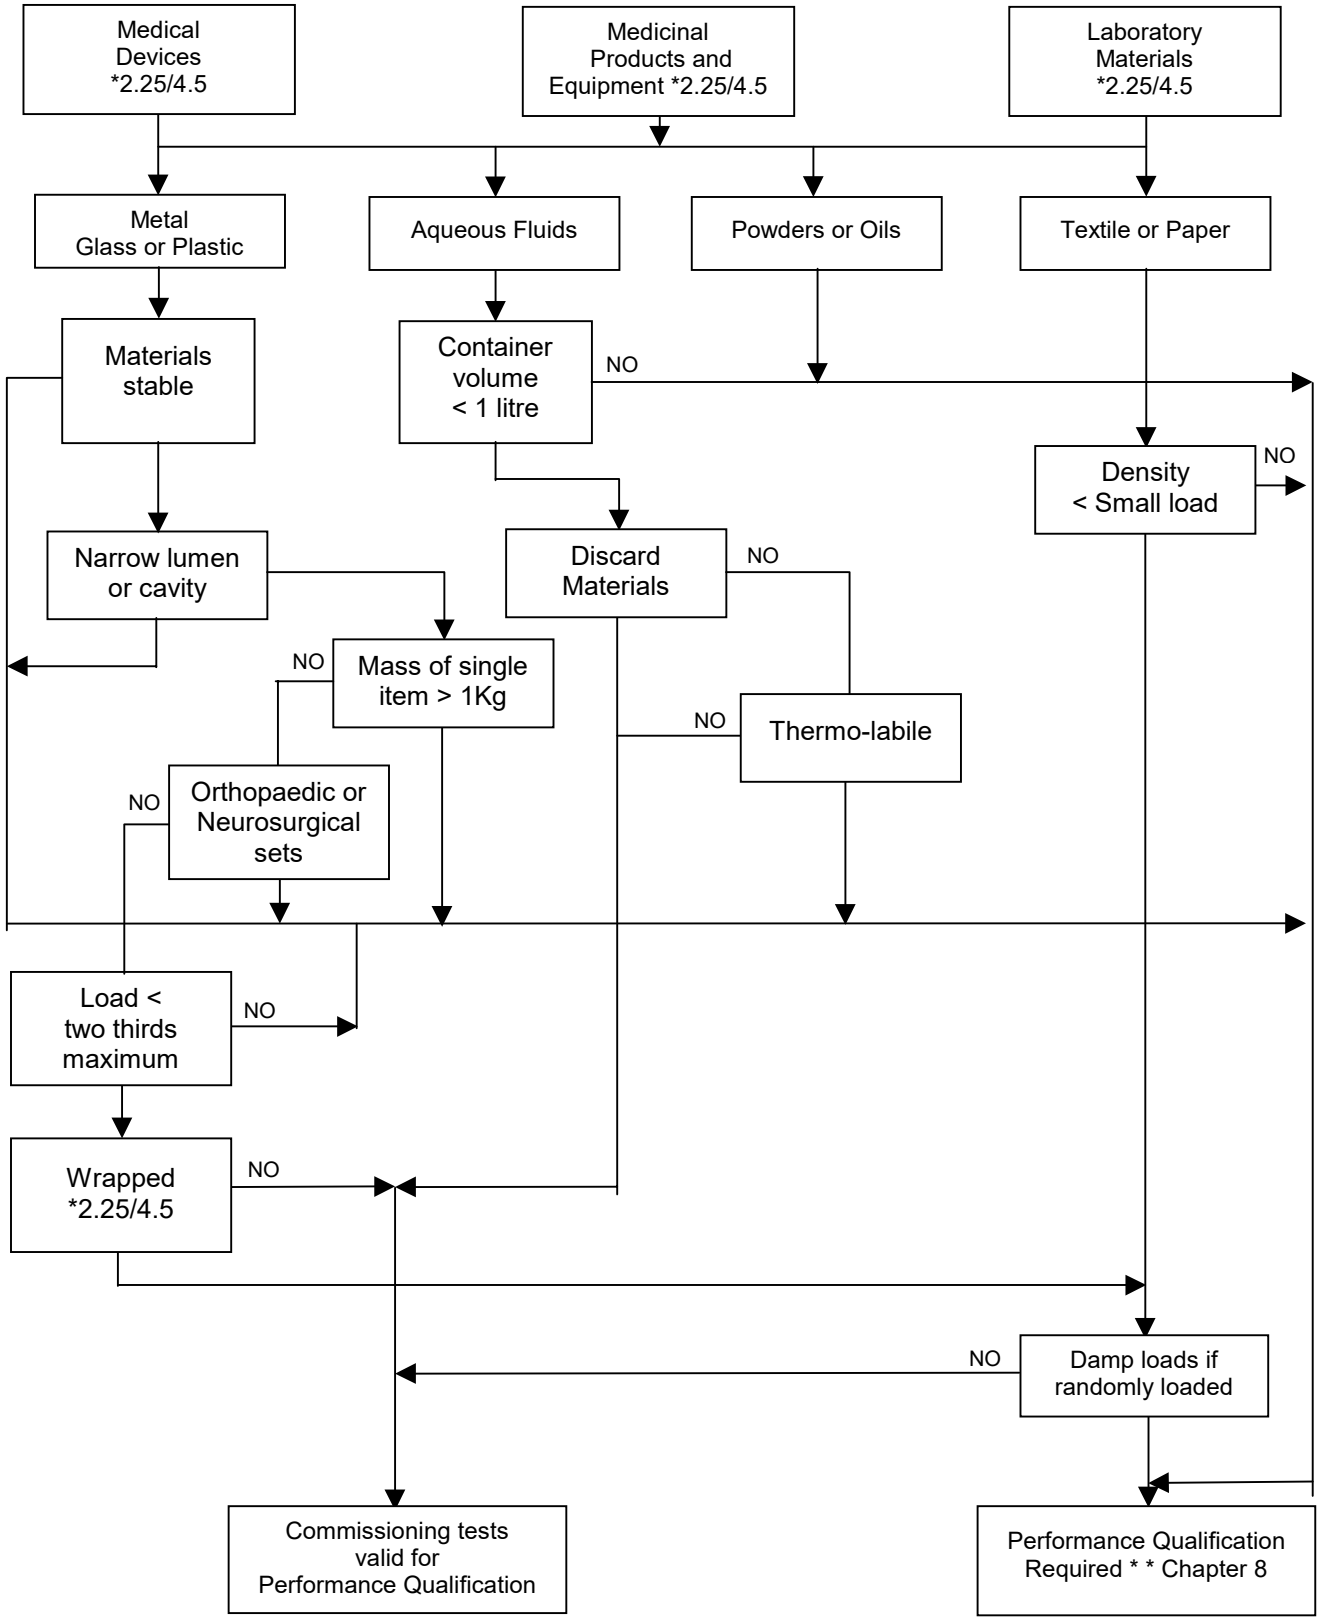
2.43 For the purposes of this SHTM the following definitions have been adopted.

2.44 The **cycle variables** are the physical properties, such as time, temperature, pressure, humidity and sterilant gas concentration, that influence the efficacy of the sterilization process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 2: Performance qualification assessment guide

VALIDATION



***Refer to part 3 for clause references**

**** A PQ for a load with a greater challenge to the process may be used providing product efficacy is not affected**

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.45 Most operating cycles have a stage in which the load is exposed to the sterilization (or disinfection) conditions for a specified length of time. This period is known as the **holding time**.

2.46 The **sterilization conditions** are the ranges of the cycle variables which may prevail throughout the chamber and load during the holding time.

2.47 The holding time is preceded by a period in which the sterilization conditions are present in the chamber but not yet present throughout the load. This is known as the **equilibration time**.

2.48 Together, the equilibration time and the holding time constitute the **plateau period**. While the duration of the plateau period can always be determined from the recorded chamber temperature, the equilibration and holding times cannot be distinguished unless the temperature in the part of the load that is slowest to reach the sterilization temperature is also being recorded or measured.

2.49 Certain LTSF sterilizers may achieve sterilization by exposing the load to a series of pulses of formaldehyde rather than a continuous holding time.

2.50 For EO sterilizers the plateau period is equivalent to the **gas exposure time**. The holding time cannot be determined by thermometry alone.

2.51 For steam and dry-heat sterilizers, the sterilization conditions are specified by a **sterilization temperature band**, defined by a minimum acceptable temperature, known as the **sterilization temperature**, and a maximum allowable temperature. The higher the sterilization temperature the shorter the holding time and the more rapidly the cycle is completed. A sterilization temperature band can also be quoted for LTSF and EO sterilizers, but since these processes depend primarily upon chemical action such a band is only a partial specification of the sterilization conditions. Bands for the different types of process are listed in Table 3. See Table 9 (Chapter 12) for recommendations for laboratory sterilizers.

2.52 Whereas the bands for high-temperature steam are normally 3°C wide, the 134°C band is anomalous in that the maximum allowable temperature may be either 137°C or 138°C. In BS 3970, 138°C is cited both for porous-load sterilizers (Part 3) and transportable sterilizers for unwrapped instruments and utensils (Part 4). At the time of writing these Parts are still current and existing sterilizers are largely designed to operate with a maximum allowable temperature of 138°C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 3: Recommended sterilization temperature bands

	High-temperature steam			Dry heat			LTS	LTSF	Ethylene oxide
Sterilization temperature [°C][a]	121	126	134	160	170	180	71[b]	71[c]	30-56
Maximum allowable temperature [°C]	124	1029	137[d]	170	180	190	80	80	[e]
Minimum holding time [min]	15	10	3	120	60	30	10	180[f]	[g]

a. The temperature setting on the automatic controller will not generally be the sterilization temperature, but a higher temperature within the sterilization temperature band.

b. Disinfection temperature.

c. This temperature is conventional but others may be used.

d. See paragraph 2.52.

e. For EO, the maximum allowable temperature will normally be 4°C above the sterilization temperature.

f. For LTSF, the sterilization conditions may specify either a continuous holding time or the number of pulses of formaldehyde required to achieve sterilization.

g For EO, the "gas exposure time" is determined for each sterilizer by microbiological methods during commissioning but is typically 2-7 hours depending upon sterilization temperature and gas concentration.

2.53 However, BS EN 285, which replaces BS 3970: Part 3, specifies that for "large" porous-load sterilizers all bands should be 3°C wide, implying a maximum allowable temperature of 137°C. This is the temperature adopted in this SHTM. Unfortunately, the proposed EN on "small" sterilizers (essentially transportables) permits a width of 4°C for all bands where unwrapped instruments and utensils are to be processed. The existing and proposed requirements are summarised in Table 4. The recommendation of this SHTM is that a width of 3°C should be adopted for all sterilization bands.

2.54 The 143°C band listed in Table 4 has been rarely used in the NHS because any time advantage offered by the short holding time is outweighed by the longer heating and cooling times.

2.55 Settings for the automatic controller will be determined during performance qualification. Generally these will consist of a chamber temperature within the sterilization temperature band and a plateau period designed to accommodate the equilibration time and the holding time. Guidance on the setting of the cycle variables will be found in Chapters 5 to 12.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 4: Sterilization temperature bands for high-temperature steam specified by British and European Standards

	Maximum allowable temperature						
	Fluids	Porous loads			Unwrapped		
Sterilization temperature [°C]	BS 3970: Part2	BS 3970: Part3	EN 285 ("large")	Proposed type B* ("small")	BS 3970: Part 4	Proposed type N* ("small")	Holding time [min]
115	-	-	-		118	-	30
121	124	124	124	124	124	125	15
126	-	129	129	129	129	130	10
134	-	138	137	137	138	138	3
143	-	-	-	146	-	147	1

* Proposed European Standard under discussion by CEN

Cycle monitoring and documentation

2.56 It is vital that every production cycle is monitored and documented and that records are kept securely. Guidance on record-keeping is given in Chapter 3.

2.57 Except for the simpler processes (specified in the relevant chapter) documentation noted in the sterilizer process log for each sterilized load should include:

a. sufficient information to identify the sterilizer uniquely (by a unique reference number; by the name of the manufacturer, the model of sterilizer and the serial number; or by any sufficient combination of these);

b. a specification of the loading condition (defined either by the nature and number of load items, items of chamber furniture, and their distribution in the chamber, or by a coded reference to a detailed specification held elsewhere);

c. a specification of the operating cycle (defined either by the settings for the cycle variables or by a coded reference to a detailed specification held elsewhere);

d. a reference to the result of any routine pre-production test, such as a Bowie-Dick test;

e. the batch process record from the recorder fitted to the sterilizer marked with the reference number of the master process record used to validate it;

f. any deviations from the PQ specification in terms of loading condition and settings of cycle variables whether or not these result in an acceptable cycle;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

g. the date and time of the start of the operating cycle;

h. the cycle number as indicated on the cycle counter;

i. the name or other identification of the operator;

j. any other records specified in Chapters 5 to 12.

2.58 The batch process record obtained from the sterilizer recorder should be sufficiently detailed to confirm that the requirements for critical parts of the operating cycle are met. This is best achieved by ensuring that a continuous graph is plotted as the cycle progresses and, for a digital system, that the values of all samples are retained for later inspection.

2.59 Biological indicators are not required for monitoring of steam or dry-heat processes, though they may occasionally be necessary for performance qualification of unusual loads (see Part 3 of this SHTM). See Chapters 10 and 11 about the use of biological indicators in LTSF and EO sterilizers.

2.60 If in doubt as to which records are required, the user should consult the Authorised Person. As a rule, it should be possible to trace any sterilized goods from the point of use back through the supply chain to the specific sterilizer and cycle in which they were processed and establish the precise values of the cycle variables throughout the cycle. A bar code attached to each load item is a practical way of keeping track of sterilized goods.

2.61 Cycles abandoned for any reason should be noted in the sterilizer process log along with any remedial action taken. Operators should be encouraged to note and report any observations which suggest that the sterilizer may not be working as it should be.

2.62 Where a load has been reprocessed following the failure of an earlier cycle, records of the original cycle should be readily traceable from the reprocessing records.

2.63 Further guidance on documentation is given in Chapters 5 to 12.

Process indicators

2.64 A foolproof system to differentiate between processed and unprocessed load items should be used to prevent an unprocessed item being mistaken for one that has been sterilized. A convenient method is to use chemical indicators which change colour on exposure to the sterilization process. Such “process indicators” are available in a variety of forms including adhesive tape, labels and preprinted panels on sterilization packaging. Process indicators should conform to the specifications for Class A indicators given in BS EN 867: Part 2.

2.65 Users should note that process indicators demonstrate only that the load item has been exposed to an operating cycle. *They offer no assurance that the load item is sterile and can play no part in the validation and monitoring of the process.*

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Product release

2.66 The user, in consultation with the Authorised Person, should establish and document procedures to ensure that loads are not released for use until the user is satisfied that the operating cycle has been reproduced within the permitted tolerances established during performance qualification.

2.67 For medicinal products, the Quality Controller will establish the procedures for product release.

2.68 The procedures should confirm the following:

a. that the load has been packaged and assembled in accordance with the PQ specification;

b. that the settings for the operating cycle are in accordance with the PQ specification;

c. that the batch process record for the cycle conforms with the relevant master process record within the permitted tolerances (see paragraph 2.71);

d. that any indicated readings required to be noted during the cycle have been noted and are in accordance with the PQ specification;

e. that the sterilized load shows no obvious anomalies, such as damaged packaging or leaking containers, that may suggest a faulty cycle. (If any degree of deterioration is acceptable this should be part of the PQ specification.)

2.69 Loads processed in LTSF or EO sterilizers should not be released until the results of the routine microbiological tests are known (see Chapters 10 and 11).

2.70 Regardless of the above procedure, whenever an operator has cause to suspect that the load may not have been properly sterilized the load must not be released. The user should be informed immediately.

Master process record

2.71 A master process record (MPR) is a record of the values and permitted tolerances of cycle variables (normally time, temperature and pressure) for a correctly functioning operating cycle against which production cycles can be checked. (The term “master temperature record” was used in earlier editions of HTM 10.) It is derived either from the batch process record (BPR) obtained during a thermometric PQ test or, if no PQ test has been deemed necessary, from the BPR obtained from a full-load thermometric test carried out during commissioning. It may be a one-to-one transparent copy of the BPR, a “template” derived from the BPR, or data stored in a computer control system and compared automatically. See Part 3 of this SHTM for further information on MPRs.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.72 Cycle variables recorded on the MPR may include chamber temperature, chamber pressure and the temperature inside one or more load containers as a function of time.

2.73 When a BPR from a production cycle is compared with the appropriate MPR, the value of the cycle variables on the BPR should be contained within the limits shown on the MPR for the entire cycle.

Rejected loads

2.74 Failure to meet any of the product release requirements should lead to the load being placed in quarantine and the cause of the failure investigated. The investigation should be documented and the handling of the product should be in accordance with the procedures for control of non-conforming product required by EN ISO 9001 or 9002.

2.75 Documented procedures for dealing with rejected loads should be agreed between the user and the Authorised Person. There are basically three options:

NOTE: The management of clinical waste and heat treatment processes, published by the Scottish Centre for Infection and Environmental Health, Aug 1994, ISBN 1 873772106, and Scottish Hospital Technical Note 3; *Clinical waste management*, issued by the Property and Environment Forum, should be referred to.

a. the load may be reprocessed; this should only be permitted if the nature of the load and its packaging is such that they will not be unacceptably degraded by a second exposure to the sterilization process;

b. the load may be “reworked”, ie. dismantled, repackaged and then reprocessed;

c. the load may be discarded; in this case, procedures should ensure that load items are permanently marked as rejected, removed from the supply chain and that there is no risk of them being mistaken for correctly processed items.

2.76 Procedures for the disposal of a discarded load should ensure that no hazard is caused either to personnel or to the environment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Storage

2.77 After sterilization and before product release, conditions for product storage and handling should not compromise the qualities of the product.

2.78 Detailed guidance on storage and distribution of sterile goods can be found in Part 5 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3. Record-keeping

Introduction

3.1 The importance of maintaining careful records cannot be stressed too highly. Complete and accurate records are an essential element in ensuring the safe and efficient functioning of sterilizers and compliance with regulatory requirements.

3.2 The following principles, based upon those issued by the World Health Organisation “The collection, fractionation, quality control and uses of blood and blood products (1981)”, for the processing of blood products, apply equally to quality control of sterilization processes. Records should:

a. be original (not a transcription), indelible, legible and dated;

b. be made concurrently with the performance of each operation and test;

c. identify the person recording the data as well as the person checking the data or authorising continuation of processing;

d. be detailed enough to allow a clear reconstruction and understanding of all relevant procedures performed;

e. allow tracing of all successive steps and identify the inter-relationships of dependent procedures, products and waste materials;

f. be maintained in an orderly fashion permitting the retrieval of data for a period consistent with dating periods (shelf life) and legal requirements;

g. indicate that processing and testing were carried out in accordance with procedures established and approved by management;

h. if necessary, allow a prompt and complete recall of any particular batch;

i. show the lot numbers of materials used for making up specified batches of products.

3.3 The requirements for record-keeping in BS ENs 550 and 554 are the same as BS ENs 46001 and 46002, namely that the supplier should retain the quality records for a period of time at least equivalent to the lifetime of the medical device defined by the supplier, but not less that two years from the date of dispatch from the supplier. The supplier should establish a record for each batch of medical devices that provides traceability and identifies the quantity manufactured and quantity released for distribution. The batch record should be verified and the load authorised for release by the user.

3.4 For medicinal products, the record-keeping principles outlined in the GGMP should be followed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.5 The system recommended in this SHTM requires two sets of records to be kept for each sterilizer:

a. a plant history file;

b. a sterilizer process log.

3.6 Both of these are the responsibility of the user. They should be made available to any other personnel who need to use them. This will include the Authorised Person, Test Person, Maintenance Person, Microbiologist, Competent Person and operators.

3.7 In the case of sterilizers used for processing medicinal products, the form of these records should be approved by both the Production Manager and the Quality Controller.

3.8 Log books for recording data obtained from periodic tests are available from Scottish Healthcare Supplies. An example of a log book for a porous load sterilizer is given in Part 6 of this SHTM. The log book is regarded as part of the plant history file.

Plant history file

3.9 The plant history file contains engineering records of the sterilizer installation. It should be kept throughout the life of the sterilizer (see paragraph 3.3). Examples of the information that should be kept in the plant history file include:

- identification of the sterilizer;
- names, addresses and telephone numbers of the sterilizer manufacturer, owner and key personnel (user, Authorised Person, Test Person, Maintenance Person, Competent Person, Microbiologist);
- dates of installation and commissioning;
- validation procedures;
- validation reports (including PQ reports for each loading condition);
- copies of validation summary sheets;
- copy of any maintenance contract;
- planned maintenance programme including detailed procedures for all maintenance tasks;
- records of maintenance, both scheduled and unscheduled, sufficient to show that all examinations, tests and checks have been carried out;
- manuals supplied by the manufacturer;
- documentation for any software used for control or instrumentation (including the name of an agent where the source codes may be obtained should the manufacturer cease trading);
- the written scheme of examination for any pressure vessel;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

- reports by the Competent Person in respect of pressure vessels;
- data from periodic tests carried out by the Test Person or the Maintenance Person;
- copies of data from the periodic tests carried out by the user (kept in the sterilizer process log);
- records of any defects found on the sterilizer and corrective action taken;
- records of any modification made to the sterilizer;
- references to the plant history files for the test instruments used in the validation and periodic tests;
- specifications for the operating cycles.

Sterilizer process log

3.10 The sterilizer process log contains information required for routine operation of the sterilizer and records relevant to each cycle. It should contain the following information:

- identification of the sterilizer;
- names, addresses and telephone numbers of the sterilizer manufacturer, owner and key personnel (user, Authorised Person, Test Person, Maintenance Person, Competent Person, Microbiologist);
- names of authorised operators;
- written procedures for all duties to be carried out by the operators;
- full operating instructions;
- copies of validation summary sheets (see Part 3 of this SHTM);
- data from the periodic tests carried out by the user;
- records of routine housekeeping carried out by the user (see paragraph 4.21);
- specifications for the operating cycles for which the sterilizer has been validated, defined by the settings for the cycle variables;
- specifications for the loading conditions for which the sterilizer has been validated, defined by the nature and number of load items, items of chamber furniture, and their distribution within the chamber.

3.11 The following information should be noted for each batch processed by the sterilizer:

- the name of the operator;
- the date and time of the start of the cycle;
- the cycle number;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

- a reference to the loading condition;
- a reference to the operating cycle;
- a specification of any preconditioning, conditioning or degassing process (this is essential for EO sterilizers);
- reference number of the master process record;
- values of cycle variables required to be observed and noted by the operator during the cycle;
- a signature confirming whether or not the cycle was satisfactory;
- any notes or observations on the cycle.

3.12 The batch process record for each cycle should be filed in such a way that it can be readily retrieved for inspection. Before filing it should be clearly marked with the following:

- sterilizer identification;
- date;
- cycle number;
- batch number;
- reference number of the master process record;
- a signature confirming whether or not the cycle was satisfactory.

3.13 Other requirements for entries in the sterilizer process log may be found in Chapters 5 to 12.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4. Maintenance

Introduction

4.1 Sterilization is a process whose efficacy cannot be verified retrospectively by inspection or testing of the product before use. For this reason sterilization processes have to be validated, the performance of the process routinely monitored, and the equipment maintained.

4.2 Means of assuring that a sterilizer is fit for its intended purpose will include the validation and periodic testing programme specified in Part 3 of this SHTM, and also the programme of planned maintenance (PM) as described in this Chapter.

4.3 The philosophy of maintenance and testing embodies three main principles to ensure that required standards of performance and safety are attained and sustained:

a. all sterilizers are subjected to a carefully planned programme of tests to monitor their performance;

b. all sterilizers are subjected to a planned programme of preventative maintenance irrespective of whether or not a preventative maintenance scheme is being operated on the premises generally;

c. expertise on all aspects of the maintenance of sterilizers should be available at two levels; these are represented by the Authorised Person and the Maintenance Person.

4.4 Testing of sterilizers is dealt with in Part 3 of this SHTM.

Maintenance Person

4.5 As discussed in Part 1 of this SHTM, the Maintenance Person is defined as a person designated by management to carry out maintenance duties on sterilizers.

4.6 The Maintenance Person should be a fitter or an electrician with documentary evidence to demonstrate competence in the maintenance of one or more types of sterilizer. He or she should be in a position to deal with any breakdown in an emergency and have the ability to diagnose faults and carry out repairs or to arrange for repairs to be carried out by others. The Maintenance Person is typically an employee of the organisation operating the sterilizer, an employee of the sterilizer manufacturer, or an employee of an independent contractor.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.7 The principal responsibilities of the Maintenance Person are:

a. to carry out the maintenance tasks outlined in this chapter;

b. to carry out additional maintenance and repair work at the request of the user.

4.8 A Maintenance Person who has a minimum of two years experience in the maintenance of sterilizers and who has obtained a recognised qualification in the testing of sterilizers may perform the duties of the Test Person for the daily, weekly and quarterly tests described in Part 3 of this SHTM.

Planned maintenance programme

4.9 The planned maintenance programme should be designed according to the following principles:

a. all parts of the sterilizer which are vital to correct functioning or safety should be tested at weekly intervals. This is interpreted as follows:

   (i) there is no need to test components individually in those cases where any malfunction will be revealed by the periodic tests prescribed in Part 3 of this SHTM for weekly or more frequent intervals;

   (ii) where the correct functioning of important components is not necessarily verified by the periodic tests prescribed for the sterilizer, those components should be individually tested each week and reference to testing them should be included in the schedules of maintenance tasks. This applies, for example, to door interlocks which may only be required to perform their safety function when presented with an abnormal condition;

b. the maintenance programme should include, at appropriate intervals, those tasks such as lubrication and occasional dismantling of particular components (such as pumps) the need for which is indicated by normal good practice, manufacturer's advice and experience. Apart from those tasks, the maintenance programme should concentrate on verifying the condition of the sterilizer and its components by means of testing and examination without dismantling. Parts which are working correctly should be left alone and not disturbed unnecessarily;

c. maintenance should be carried out under a quality system such as ENISO 9000. Spares fitted to sterilizers constructed under a quality system should be sourced from a similarly approved quality system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Design of a PM programme

4.10 The PM programme supplied by the sterilizer manufacturer should be used where it is available. If no manufacturer's programme can be obtained, a programme should be drawn up in consultation with the Authorised Person and the Maintenance Person.

4.11 Although the sterilizer manufacturer may carry out certain inspection and maintenance procedures under the terms of his guarantee, these may not constitute a full PM programme. The user should therefore ensure that the complete PM programme is carried out by the Maintenance Person (who may be an employee of the manufacturer, see paragraph 4.6) during the guarantee period. The user should also implement any reasonable instructions given by the manufacturer during this period. Failure to carry out maintenance tasks and periodic tests could affect safety. It could also allow a contractor to place some, if not all of his liability on to the management. Where maintenance is carried out under lump sum term contract (see Part 2) such failure is tantamount to breach of contract and can give the contractor cause to terminate the contract if he so wishes.

4.12 A set of procedures should be developed for each sterilizer, containing full instructions for each maintenance task.

4.13 The frequency at which any given task needs to be carried out will depend on how heavily the sterilizer is used. Where there is a two-shift system, for example, it will be necessary to adjust the programme so that work is carried out more frequently than under a single-shift system. Where sterilizers are used infrequently, however, less frequent maintenance is not always acceptable. Infrequent use requires increased maintenance of certain components because of failure of valves, seals, pumps, etc., due to sticking through lack of use. Only when a component is subject to progressive wear in use is the frequency of maintenance related to frequency of use.

4.14 It is important that maintenance is planned so that a sterilizer is out of service for as little time as possible. Maintenance should, where practicable, be scheduled to immediately precede the periodic tests as specified in Part 3 of this SHTM.

Review of the PM programme

4.15 The PM programme, procedures and records should be reviewed at least once a year by the user and the Maintenance Person in association with the Authorised Person. To do this, it is necessary to keep systematic records of all work done, so that judgement can be made in consultation with the manufacturer on what changes, if any, to the PM programme would be desirable.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.16 The review should aim to identify:

a. any emerging defects;

b. any changes required to the maintenance scheme;

c. any changes to any maintenance procedure;

d. any additional training required by personnel concerned with maintenance;

e. whether records have been completed satisfactorily, signed and dated.

Inspection of pressure vessels

4.17 Under the Pressure Systems Safety Regulations 2000, all sterilizers containing pressure vessels are subject to a periodic inspection by a Competent Person (see Part 1 of this SHTM). The Regulations apply to all steam sterilizers, to EO sterilizers operating above 0.5 bar, to dedicated steam generators, to cartridges and cylinders used to supply sterilant or purging gas to EO sterilizers, and to the steam and compressed air services. Pressure vessels include doors and their closing systems. The Authorised Person will advise on the application of the Regulations to any particular installation.

4.18 The Competent Person has three principal duties under the Regulations:

a. advising on the scope of the written scheme of examination for each pressure vessel;

b. drawing up the written scheme of examination or certifying the scheme as being suitable;

c. carrying out examinations in accordance with the written scheme, assessing the results and reviewing the written scheme for its suitability.

4.19 The user should cooperate closely with the Competent Person to ensure that the written scheme of examination is accommodated within the maintenance and testing programmes. The written scheme may require certain examinations to be carried out more frequently than recommended by the manufacturer. Each scheme should include detailed procedures and frequency of examination and be regularly reviewed and updated.

Modifications

4.20 Occasionally, modifications to the sterilizer may be recommended by the manufacturer or by the UK Health Departments for reasons of efficacy and safety. The user should arrange for such modifications to be carried out within a reasonable period, normally coinciding with a scheduled maintenance session.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Routine housekeeping

4.21 Certain simple maintenance tasks may be carried out by the user (or by an operator under the user's supervision) and should be recorded in the sterilizer process log. Examples of such tasks include the following:

a. steam sterilizers: daily, or more often if necessary, clean the strainer fitted in the opening to the chamber discharge line;

b. all sterilizers: daily, wipe the door seal with a clean damp cloth and inspect it for damage. This can normally be done by the operator if the seal is completely exposed when the door is open;

c. all sterilizers: carry out any door safety checks required by the written scheme of examination and which are within the technical competence of the user. (Other door safety checks, normally weekly, will be carried out by the Maintenance Person.)

Maintenance of laboratory sterilizers

4.22 Laboratory sterilizers differ from clinical sterilizers in that they may have cycles expressly designed for the routine making-safe of discard material that is or may be contaminated with pathogenic micro-organisms. Sterilizers without a make-safe cycle may occasionally be used to process infected material if the designated machine is out of service. The user should ensure that a documented procedure is established for the decontamination of a sterilize before it is handed over to maintenance personnel. Such a procedure should comply with the guidelines set out in HSG(93)26, 'Decontamination of equipment prior to inspection, service or repair'.

4.23 Since the contamination status of a sterilizer cannot be established by inspection, all maintenance work should be conducted under a permit-to-work system in which a certificate, signed by the user and the Laboratory Safety Officer, is given to maintenance personnel to indicate that the sterilizer is safe. Where it is not possible to guarantee that a sterilizer is free of contamination (such as where a machine breaks down with a discard load in the chamber), this should be made clear on the permit to work and detailed procedures for safe working should be supplied. This latter option should only be resorted to in exceptional cases and is not an acceptable alternative where decontamination is practicable. A suggested format for the permit to work is given in Figure 3.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 3 Suggested permit to work for laboratory sterilizers

PERMIT TO WORK

This permit relates only to the hazards caused by the possible microbiological or chemical contamination of the sterilizer. The sterilizer is not guaranteed safe against any other source of risk.

Location of sterilizer_____

Manufacturer _____ Serial no:_____

Model _____ Inv. no:_____

- I confirm that the above sterilizer has been decontaminated and cleaned as required to render it safe for maintenance or repair (or)
- It is not possible to guarantee that the sterilizer is free of contamination. Guidance on safe working practices is attached (delete as appropriate).

User: Name: _____ Signature: _____Date:_____ Time: ___

Safety Officer: Name: _____Signature: _____Date _____ Time: ___

RECEIPT (delete as appropriate)

- I accept responsibility for carrying out the work on the above sterilizer.
- I have received the guidance on safe working practices.

Name: _____ Signature: _____Date: ____ Time: ___

HAND-BACK (delete as appropriate)

- The work on the above sterilizer has been completed / suspended.
- The sterilizer may / may not be returned to service.

Name: _____ Signature: _____Date: ____ Time: ____

CANCELLATION

This permit-to-work is now cancelled.

User: Name: _____ Signature: _____Date ____ Time: ____

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.24 Maintenance of laboratory sterilizers should conform with the guidance given in BS 2646: Part 4.

Features requiring special attention

4.25 The following sections provide background information to some of the features requiring special attention in any PM programme.

Stainless steel chambers

4.26 Stainless steel, or mild steel clad with stainless steel, is used in the manufacture of many sterilizer chambers. Over a wide variation in specification, stainless steels, and to a much lesser extent stainless-clad mild steel, are susceptible to cracking from crevice corrosion and stress corrosion initiated by chemical attack. These phenomena occur when the material is subjected to a combination of heat, stress and contact with chemicals, notably chlorides or strong alkalis. The damage resulting from the combined effects occurs at levels far below those which would be of significance if acting separately. Heat and stress are present in all steam sterilizers.

4.27 Material in compression is less susceptible to crevice and stress corrosion than material in stress. Some manufacturers use “shot blasting” (also known as “shot peening”), to convert the tension stresses in the skin of the stainless steel to compression stresses.

4.28 Chemical contact may occur in sterilizers under the following circumstances:

a. in sterilizers processing certain fluids, such as saline solution, a spillage will introduce chloride salts into the chamber;

b. if there is excessive carry-over of boiler water with the steam, this is likely to include significant concentrations of both alkalis and chloride salts;

c. in small electrically heated sterilizers, where steam is generated within the chamber by an immersion heater, a build-up of alkalis and chloride salts may occur if tap water is used to generate steam; this can result in severe pitting corrosion leading to the perforation of the chamber.

4.29 Where cleaning with water is required, only water with a low chloride level, such as distilled water or good quality condensate, should be used.

4.30 Vessels which have not been shot-blasted should be lightly polished by hand. This should be done in accordance with the manufacturer’s instructions and at quarterly intervals on sterilizers used to process fluids. Polishing should only be done using iron-free materials. Household or domestic scouring and polishing compounds should not be used since they often contain chlorine or other corrosive agents which might cause, rather than prevent corrosion. After polishing, the chamber should be thoroughly flushed out with water of low chloride content.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.31 During cleaning and polishing, precautions should be taken to prevent damage to the door seal and the entry of foreign matter into the chamber drain.

Air-tightness of the chamber

4.32 Air-tightness of the chamber is of fundamental importance to the correct functioning of sterilizers. The door seal is the major potential source of leakage and should receive careful attention as advised by the manufacturer. The working life of door seals varies widely and it is essential that all seals are cleaned regularly. Door seals should be renewed with spares approved by the manufacturer at recommended intervals, or when there is any evidence of damage or deterioration.

4.33 Leaks may also occur in the following places:

a. joints in pipework;
b. connections to gauges;
c. blanked-off connections for test gauges;
d. entry points for temperature sensors (whether in use or blanked off);
e. glands and seats of valves;
f. bellows-operated door safety interlocks;
g. cracks in chamber welds or platework.

Door-locking mechanisms

4.34 There have been a number of incidents in which sterilizer door-locking mechanisms have failed during operation.

4.35 Maintenance and inspection of door safety devices and door-locking and chamber sealing systems must be carried out in accordance with the manufacturer's written instructions. Security and settings of door safety switches and door-locking components must be checked weekly and the settings must comply with those provided by the manufacturer.

4.36 Capstan-operated, hinged door-locking mechanisms should be examined for excessive wear on the internal thread sections. Where these are hard to see, thread profile gauges should be used. If there is evidence of excessive wear, then the sterilizer should be removed from service until the capstan wheel assembly can be replaced.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Air detector

4.37 Particular care should be taken when installing, removing or adjusting any part of an air detector. It is preferable not to interfere with it except when necessary. The sensitivity of the air detector should be adjusted in accordance with the manufacturer's instructions and the setting determined during validation as detailed in Part 3 of this SHTM.

4.38 Air detectors work by measuring either temperature or pressure. Certain older temperature-operated air detectors may not fail safe if there is a leak from the detector to the outside. It is crucial that air detectors are carefully checked for air-tightness once a week. A leak too small to be detected by the vacuum leak test given in Part 3 of this SHTM could be large enough to permit the expulsion by steam of any air present in the detector and cause it to indicate falsely that all the air had been removed from the chamber.

4.39 If it has been necessary to adjust the air detector, the Test Person should carry out recommissioning tests as described in Part 3 of this SHTM.

Instruments

4.40 Instruments fitted to sterilizers should be maintained and calibrated in accordance with the manufacturer's instructions. Calibration should be verified at the normal sterilization temperature and pressure and at stable ambient temperatures. Any instrument found to read seriously in error or which is inconsistent, i.e. will not repeat satisfactorily, should be discarded, or repaired by the makers if practical and economical to do so. Instruments which do repeat satisfactorily but read slightly in error should be checked for zero and span and then adjusted to read correctly.

4.41 An instrument case should never be left open; broken glass should be replaced promptly.

4.42 The recorder system is an essential monitor of the general functioning and performance of a sterilizer. Temperature measuring systems are subject to both inherent calibration errors and loss of calibration with use. As a consequence temperatures read from a recorder should be regarded with caution and interpreted from knowledge of the characteristics of the particular recording system, the load and previous records.

4.43 Recording systems which are working correctly should not be interfered with more than is absolutely necessary. Adjustments should be done strictly in accordance with the manufacturer's instructions.

4.44 Persons who change charts, print rolls and other consumables on recording instruments should be trained, made fully aware of the delicate nature of the instruments and authorised by the user.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

Ancillary equipment

4.45 Ancillary equipment used in conjunction with the sterilizer should also be subject to planned maintenance in accordance with manufacturers' instructions.

4.46 Where the maintenance of ancillary equipment is not the responsibility of the user, arrangements should be made to give the user reasonable notice of all periods of maintenance (whether scheduled or not) and of impending modifications to any part of the equipment. The user should also have access to maintenance records.

4.47 Examples of ancillary equipment include:

a. all engineering services to the sterilizer, especially steam;
b. dedicated steam generators (see SHTM 2031 for guidance);
c. room ventilation and local exhaust ventilation (see SHTM 2025 and the HSE document 'The maintenance, examination and testing of local exhaust ventilation' (HS(G)54) for guidance); correct functioning is essential to the safe operation of LTSF and EO sterilizers;
d. personal protective equipment;
e. equipment used to monitor, alarm or protect against exposure to formaldehyde or ethylene oxide.

Returning a sterilizer to service

4.48 The user, with the assistance of the Authorised Person, should prepare an operational procedure for the return to service of a sterilizer after maintenance or testing. The procedure should include safety checks and some or all of the recommissioning (yearly) tests specified in Part 3 of this SHTM.

4.49 The Maintenance Person should certify that the work has been completed and that the sterilizer is safe to use.

4.50 The user should ensure that a sterilizer is not used for production until all required maintenance has been successfully completed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5. Operation of porous load sterilizers

Introduction

5.1 This chapter gives guidance on the routine operation of clinical high-temperature steam sterilizers designed to process wrapped goods and porous loads.

5.2 The guidance given here assumes that the sterilizer is to be used to process medical devices in compliance with the EU Directives discussed in Chapter 1.

The process

5.3 Porous load sterilizers heat load items by direct contact with high-temperature steam at a typical sterilization temperature of 134°C (see Table 5).

5.4 The operating cycle of a porous load sterilizer normally has five stages.

a. Air removal – Sufficient air is removed from the chamber and the load to permit attainment of the sterilization conditions.

b. Steam admission – Steam is admitted to the chamber until the specified sterilization temperature is attained throughout the chamber and load.

c. Holding time – The temperature throughout the chamber and load is maintained within the sterilization temperature band for the appropriate holding time.

d. Drying – Steam is removed from the chamber and the chamber pressure is reduced to permit the evaporation of condensate from the load either by prolonged evacuation or by the injection and extraction of hot air or other gases.

e. Air admission – Air is admitted to the chamber until the chamber pressure approaches atmospheric pressure.

5.5 The complete cycle time for a sterilization temperature of 134°C is typically 35 minutes for a standard full load, but the drying stage may need to be extended for up to a further 20 minutes for loads of high heat capacity, such as trays of instruments, that take longer to dry.

Product compatibility

5.6 A porous load sterilizer is suitable for processing a very wide range of goods and is the method of choice in most cases.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.7 Items to be processed in a porous load sterilizer should have been washed and dried by a validated cleaning process.

5.8 To reduce the possibility of superheating, load items consisting of textiles should be allowed to air for a period of not less than fours hours after laundering (see paragraph 5.50).

Items that should not be processed in a porous load sterilizer

5.9 The following items should not be processed in a porous load sterilizer:

a. items which would be damaged by exposure to moist heat at 121-134°C;
b. items which would be damaged by rapid pressure changes (up to 10 bar min^{-1});
c. aqueous fluids (a fluid sterilizer is required);
d. non-aqueous fluids (a dry-heat sterilizer is required);
e. items in sealed containers (air will not be extracted).

Design of the load

5.10 Items processed in porous load sterilizers will either consist entirely of porous materials (such as dressings) or else comprise wrapped goods, usually of metal (such as surgical instruments).

5.11 The loading condition should be designed with two aims in mind:

a. to permit the rapid removal of air from the load items and the rapid penetration of steam; and
b. to ensure that the condensate formed during the cycle does not result in a wet load.

5.12 With some exceptions, porous load sterilizers may be loaded randomly. It is not necessary to ensure that the loading condition is replicated in detail for each cycle.

Air removal

5.13 The presence of air in the load can impede the penetration of steam and thereby drastically reduce the effectiveness of the sterilization process. Steam will not easily displace air contained in porous materials, such as a paper bag containing an instrument. Any air remaining in the packages before the start of the holding time will occur in random locations and in different volumes. During the holding time it may unpredictably delay or prevent saturated steam from contacting the surfaces over which this air is present. Levels of air will depend on the theoretical dilution rate, the method used for air removal and the air leakage into the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.14 Porous load sterilizers have an active air removal system in which air is replaced with steam by a series of vacuum and pressure changes. Provided it is validated according to the schedule set out in Part 3 of this SHTM, a sterilizer complying with BS EN 285 will be capable of removing sufficient air from packages randomly placed in the chamber and which contain porous material not exceeding the density of the standard test pack.

5.15 Where the density of porous material exceeds that of the standard test pack, or the load consists of components into which steam penetration is not instantaneous, eg. filters and flasks with small orifices, a thermometric performance qualification test is required (see Part 3 of this SHTM).

5.16 As well as air retained in the load, steam penetration may be inhibited if non-condensable gases are liberated from the load as it is heated. This may happen with certain packaging materials, inks, adhesives, labels, etc. Packaging materials should conform to one of standards listed in paragraph 5.27. As a precaution, new non-metallic boxes or trays should be processed in a non-production cycle before being used with production loads.

Handling of condensate

5.17 As in all steam sterilizers, the energy which heats the load is derived almost entirely from the latent heat given up as the steam condenses on the load items. (It is not a simple conduction of heat from hot steam to the cool load.) The more latent heat is given up, the more condensate will be formed. This condensate (hot water) is an essential and unavoidable consequence of steam sterilization.

5.18 The amount of condensate formed will depend on the latent heat required to raise the load to the sterilization temperature. This depends on the heat capacity of the load, which in turn depends on the mass and specific heat capacity of each item. Loads containing metal items have a higher heat capacity than a load of purely porous materials and therefore will produce more condensate. Essentially all of the condensate will be formed before the start of the holding time.

5.19 The process is substantially reversible, however, and by subjecting the chamber to a vacuum during the drying stage, the lowered boiling point of water associated with the reduced pressure enables the heat energy stored in the load item to re-evaporate the condensate and as a consequence the item is both cooled and dried. The re-evaporation process will not occur if the condensate becomes separated from the load items.

5.20 In order to ensure that porous loads are dry at the end of the cycle, it is therefore necessary either to drain the condensate completely clear of the load, or to retain it close to the hot load items where it can be evaporated. With wrapped loads, the latter solution is preferred. No special measures are needed for purely porous loads, but metal items are likely to produce sufficient condensate to saturate their wrapping. The condensate may then spread to other parts of the load from which it may not be evaporated. This

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

migration of condensate may be avoided by including absorbent padding (in addition to the wrapping) suitably positioned inside each pack.

5.21 The optimum amount and arrangement of this extra padding can only be determined by experiment. As a rule, metal items should be well spaced and separated by padding. With preset instrument trays, for example, the instruments should be spaced out across the tray. Unusually heavy items, such as orthopaedic hammers, should be placed away from other instruments and well padded. Loads containing large amounts of metal may require performance qualification tests.

5.22 Holloware, such as bowls and tubes, should be arranged in such a way that condensate will not collect inside them. It may not be practical to ensure that wrapped holloware is always processed inverted and in this case the drainage problem may be overcome by placing absorbent materials inside the holloware.

5.23 Drip deflectors between tiers of instrument trays will ensure that condensate does not drain from one tray to another.

5.24 If a mixed load of porous and wrapped metal items is to be processed, the porous items should be placed above the metal items to ensure that condensate does not drip on to them.

Packaging materials

5.25 Items to be sterilized should use packaging materials which are permeable to air and steam but have an effective maximum pore size which is small enough to exclude microbial contamination under the specified storage and transport conditions.

5.26 Goods are normally double-wrapped; at least one of the layers will usually be a sheet of paper, a paper bag or a plastic pouch. The inner lining may be chosen primarily for its absorbency in order to retain condensate as described above.

5.27 Load items should be wrapped in materials complying with one of the following parts of BS EN 868: Packaging materials for sterilization of wrapped goods:

a. Part 1: General requirements and requirements for the validation of packaging of terminally-sterilized devices;
b. Part 2: Sterilization wrap – requirements and tests;
c. Part 3: Paper for use in the manufacture of paper bags and in the manufacture of pouches and reels;
d. Part 4: Paper bags – requirements and tests;
e. Part 5: Heat-sealable pouches and reel material of paper and plastic film construction – requirements and tests;
f. Part 8: Reusable sterilization containers – requirements and tests.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.28 Extensive guidance on packaging materials and methods is given in Part 5 of this SHTM.

Performance qualification

5.29 PQ tests are not normally required for the majority of loading conditions processed in a porous load sterilizer since they are less of a challenge to the cycle than the full-load and small-load tests carried out during validation.

5.30 PQ tests are required where:

a. the density of any porous load item exceeds the density of the standard test pack (see Part 3 of this SHTM);

b. the mass of any single metal item exceeds 1 kg;

c. the construction of any load item is such that sufficient air may not be removed to ensure the rapid penetration of steam;

d. any cycle variable has been modified from the setting used in validation.

5.31 Two categories of product require special consideration:

a. minimally invasive surgical instruments (such as laparoscopic biopsy forceps) which present particular problems of air removal and steam penetration;

b. barrier fabrics (such as Gore-tex) which have such low porosity to both air and steam that normal air removal stages may be inadequate.

Selection of cycle variables

5.32 The preferred sterilization temperature is 134°C. However, any of the lower sterilization temperature bands in Table 5 may be used where load items would be damaged at 134°C.

Table 5: Sterilization conditions for porous load sterilizers

Sterilization temperature [°C]	Maximum allowable temperature [°C]	Minimum holding time [min]
134	137	3
126	129	10
121	124	15

See paragraphs 2.52-2.53 for comment on maximum allowable temperatures.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Cycle monitoring and documentation

5.33 Users are reminded that a Bowie-Dick test should be carried out at the start of each day as described in Part 3 of this SHTM. Production should not begin until the test has been shown to be satisfactory. Some departments may also require a daily vacuum leak test.

5.34 Documentation as listed in paragraph 2.57 should be recorded. Each cycle should be noted in the sterilizer process log (see paragraph 3.11).

5.35 A batch process record should be generated for each production cycle. The batch process record will contain the following:

a. the temperature (chamber temperature) recorded by a sensor in the active chamber discharge;

b. the pressure (chamber pressure) recorded by a sensor in the chamber.

5.36 It is not necessary to monitor the temperature inside the load.

5.37 In addition to the above information, any cycle aborted due to a fault sensed by the air detector should be noted along with the remedial action taken.

Product release

5.38 The load may be released for use provided that:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. the packaging is undamaged;

c. the load items are visibly dry.

Troubleshooting

Air detector fault

5.39 The air detector is designed to register a fault when the level of air and gas sampled from the chamber is high enough to affect the even and rapid penetration of steam into the load. Possible causes of an air detector fault include:

a. an inefficient air removal stage;

b. an air leak during the air removal stage;

c. non-condensable gases evolved from the packaging;

d. non-condensable gases in the steam supply;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

e. a defective air detector.

5.40 When a cycle has been aborted due to an air detector fault the sterilizer should be taken out of service. If there is no obvious cause for suspicion, such as a change in the loading condition, the sterilizer should be subjected to the weekly tests as described in Part 3 of this SHTM. These will include an air detector function test.

Wet loads

5.41 Any item with wet outer packaging should be rejected since the moisture compromises the protective qualities of the wrapping.

5.42 Wet spots or patches on the packaging show that liquid water has been drawn into the chamber. There are several possible explanations, including:

a. poorly draining steam traps between the sterilizer and boiler (a sudden demand for steam can draw water out of a full trap);

b. severe pressure fluctuations in the main;

c. priming of the boiler leading to carry-over of water in the steam.

5.43 Occasionally, load items with dry outer packaging may be found to be wet inside. While the sterility of the product may be satisfactory, there remains the possibility that the load was wet throughout at some stage and therefore sterility cannot be assured. Since they are invariably discovered by the end-user at the point of need, such wet items do not promote confidence in the sterile supply service.

5.44 Packages that are damp inside are often the result of inadequate packaging and loading (see paragraphs 5.17–5.24), especially when metal objects have been processed. If the precautions outlined above have been followed, however, the cause may be a wet steam supply. This can be confirmed by the steam dryness test described in Part 3 of this SHTM. Users should note that this test will not reliably detect wetness due to sporadic carry-over of water.

5.45 Part 2 of this SHTM describes the engineering requirements for a steam supply of the correct dryness for sterilization. The sudden appearance of wet loads from a loading condition and operating cycle that have been used successfully for a long time may indicate a change in the steam service. For example, there may be a fault somewhere in the system or there may have been engineering modifications to the steam service; new or modified boilers, extensions to the steam main and new equipment installed elsewhere may all affect the dryness of the steam supplied to the sterilizer.

5.46 Another possibility is that operating practice in the boiler room may have changed. For example, it is common in hospitals to shut down all but one boiler for the summer months. When demand increases again in the autumn, the boiler may start to prime (carry over water) before the other boilers are returned to service.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Superheating

5.47 Superheating, arising from steam that is too dry, can cause a failure to sterilize. It is uncommon and can be difficult to identify. A failed process indicator is one sign; charring of wrapping materials is another.

5.48 One possible cause of superheating is an excessive reduction in pressure through a throttling device, such as a pressure reducing system or a partially closed main steam valve. In this case superheating arises from adiabatic expansion. Engineering solutions to this problem are described in Part 2 of this SHTM.

5.49 Superheat can also arise if the steam is admitted into the chamber with excessive velocity. This problem is usually detected and overcome during commissioning, by fitting a throttling device in or over the steam inlet port with some modifications to the baffle plate assembly.

5.50 Another possibility is superheating from exothermic reaction. This may occur during sterilization as a result of rehydration of exceptionally dry hygroscopic material. In these circumstances the superheating may persist for the entire holding time with consequential risk of a failure to sterilize. This phenomenon is usually associated with certain textiles, particularly those incorporating cellulosic materials (such as cotton), which have become excessively dry before sterilization. It may occur during periods of very cold, dry weather especially where the materials to be sterilized are kept in rooms which are heated and mechanically ventilated without humidification.

Spontaneous combustion

5.51 There have been reports of textile loads bursting into flame within the sterilizer chamber. Invariably this is because the load has been allowed to become excessively dry and hot. There are two circumstances in which this may occur:

a. the load is placed in a heated chamber and left for a considerable time before the cycle is started; ignition is believed to occur when the load becomes rehydrated on the introduction of steam to the chamber;

b. the load is left inside the chamber for a long time after the end of the operating cycle; ignition occurs when the door is opened and the load exposed to air. This is most likely to happen where the operating cycle has aborted due to a fault condition and the load is not removed promptly.

5.52 Users should be mindful of this risk and establish operating procedures to ensure that loads are not left in heated chambers for longer than necessary.

6. Operation of fluid sterilizers

Introduction

6.1 This chapter gives guidance on the routine operation of clinical high-temperature steam sterilizers designed to process aqueous fluids in sealed containers.

6.2 The guidance given here assumes that the sterilizer is to be used to process medicinal products in compliance with the EU Directives discussed in Chapter 1. Users should be aware, however, that products in which medicinal products are contained within a delivery system, such as certain irrigations and ophthalmic preparations, may be classified as medical devices as well as medicinal products.

The process

6.3 Fluid sterilizers heat load items by direct contact with high-temperature steam at a typical sterilization temperature of 121°C. Although steam does not penetrate to the product inside the sealed containers, sterilization is effected by the water molecules in the product itself. That is why these sterilizers cannot be used to process non-aqueous fluids.

6.4 A fluid sterilizer will normally have the following operating cycle.

a. *Heat-up*. Steam is admitted to the chamber, heating the load.

b. The *plateau period* starts when the chamber temperature, recorded by a sensor located in the active chamber discharge, reaches the sterilization temperature, which is typically 121°C (see Table 6).

   (i) In the first part of this period, the equilibration time, all parts of the load attain the sterilization temperature. This time depends on the nature and amount of the product, and the material, size and shape of the container.

   (ii) The moment when the temperature in all parts of the load finally attains the sterilization temperature marks the end of the equilibration time and the start of the holding time.

c. *Cooling*. The load is cooled, either by spraying with sterile water (usually chamber condensate) or the circulation of cooled air, until the temperature in the hottest part of the load has fallen below 80°C.

6.5 Heat transfer to the contents is predominantly by conduction through the walls of the containers and by internal convection. A small radiant heat transfer component is also present. During the heat-up phase of the operating cycle, the outside temperature of the load containers quickly approaches that of the chamber space, with a corresponding increase in the temperature of condensate in the active chamber discharge.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Safety precautions

6.6 The main hazard with fluid sterilizers is the high pressure attained inside glass bottles at the sterilization temperature. This pressure may cause weak or damaged containers to burst during sterilization and such explosions may damage other containers in the load.

6.7 A hazard to the operator may result if bottles are removed from the sterilizer before they have cooled to a safe temperature. At a sterilization temperature of 121°C the absolute pressure inside a bottle having a nominal fill of fluid is in the region of 3.6 bar (see Figure 4). If the door were to be opened at this temperature, and the load subject to cold draughts or unintentional impact, the stresses arising in the glass would be sufficient to crack the bottle and cause an explosive breakage. Fluid sterilizers are fitted with a thermal door-lock to ensure that when glass bottles are being processed the door cannot be opened until the temperature inside all the containers has fallen below a safe maximum of 80°C. (Even at this temperature the pressure inside a bottle is approximately 1.8 bar.) Failure to observe this requirement has led to serious accidents resulting from the explosion of glass bottles.

6.8 Operators should be aware that some bottles may break before the end of the cycle and broken glass may need to be removed before the next cycle can begin.

6.9 Operating cycles for plastic containers have the following modifications:

a. pressure ballasting with air is used to prevent pressure differences arising between the inside and the outside of containers sufficient to burst or distort them;

b. the door may be opened when the temperature inside the containers falls below 90°C. This prevents “blooming” of the containers. On no account should these cycles be used with glass containers unless the thermal door lock has been reset to 80°C.

Product compatibility

6.10 Fluid sterilizers may be used to process a wide range of medicinal products in the form of aqueous solutions in sealed containers of either glass or plastic.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Items that should not be processed in a fluid sterilizer

6.11 The following items should not be processed in a fluid sterilizer:

a. fluids in unsealed bottles (the product may be modified by the evaporation of water and the entry of steam and condensate, and will not remain sterile after removal from the chamber);

b. non-aqueous fluids (they will not be sterilized);

c. contaminated fluids intended for discard (discard material should not be processed in clinical sterilizers).

Design of the load

6.12 Items processed in fluid sterilizers will normally consist of large numbers of identical containers such as bottles, bags, ampoules or vials. While the containers are usually made of glass, plastic containers may also be processed. All containers should be sealed to prevent the escape of the contents and the entry of steam or condensate.

6.13 The loading condition should be designed with the aim of permitting the free circulation of steam and coolant over the surfaces of the containers.

Bottles

6.14 Bottles in a load should preferably all be of the same size. Where mixed sizes are unavoidable, the PQ tests should ensure that the largest bottles are monitored to ensure that they attain the required sterilization conditions.

6.15 It is important that steam is allowed to pass freely around the surfaces of bottles. They should be placed in crates or on trays designed to locate each bottle so that it cannot touch its neighbours. Chamber furniture should also allow the free passage of steam and condensate.

6.16 Plastic bottles, particularly those made of polymers which undergo a reduction in tensile strength at the temperatures used for steam sterilization, are often only suitable for use in sterilizers which include air or gas ballasting to increase the pressure throughout the cycle and thus restrain the bottle from bursting.

Plastic bags

6.17 Plastic bags should not be stacked on top of each other. Steam should be allowed to circulate freely around them. Bags may be hung from racks within the chamber or placed on shallow shelves.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Vials and ampoules

6.18 Loads consisting of small containers, such as vials and ampoules, have a large surface-area-to-volume ratio and therefore will cause steam to condense rapidly during the heat-up stage. Where steam is admitted to the chamber through a single inlet, it will first condense on the ampoules nearest to the inlet and these will consequently heat up faster than those further from the inlet. This will produce a large difference in temperature across the chamber and an extended equilibration time. This is acceptable provided that the product can withstand the extended heating experienced by the ampoules near the steam inlet and the ampoules slowest to heat up are correctly identified for the thermometric PQ test.

6.19 Where the product cannot withstand this extended heating, the size of the load should be reduced so that it can be placed further from the steam inlet. A sterilizer with multiple inlets is the preferred solution.

Closure systems

6.20 Containers should have gas-tight seals to prevent evaporation of water from the contents and the entry of steam or condensate. Glass bottles for sterile fluids are commonly sealed with compound closures comprising an elastomeric disc or plug which is secured to the neck of the bottle by means of an aluminium screw cap, an aluminium crimped-on (or turned-on) cap, a cap made of plastic material or a retaining closure embodying both plastic and aluminium parts.

6.21 It is essential that the elastomer is held in tight contact with the neck of the bottle in order to prevent the entry of micro-organisms or other materials which might contaminate the product. It is a characteristic of such containers that when they are charged with the specified volume of the product there remains a substantial air space (sometimes referred to as ullage) above the liquid. The proportion of the total internal volume of a bottle filled with liquid may vary with the design of the bottle but is commonly 80-90 percent, so the ullage may be about 10-20 percent of the internal volume. Such a space is necessary for thermal expansion of the liquid during sterilization.

6.22 When a sealed bottle is sterilized, the pressure inside exceeds that in the sterilizer chamber by a substantial margin. The pressure within the bottle is due to the partial pressures of the air and steam at the sterilization temperature plus an additional factor due to the compression of the air and steam mixture in the ullage by thermal expansion of the liquid in the bottle. Thus at any single temperature the pressure within a bottle under sterilizing conditions will be determined largely by the proportion of the total internal volume filled with liquid since, as this increases, the effect of thermal expansion on the air and steam mixture also increases. Figure 4 shows the internal absolute pressure in a rigid container of water at 121°C as a function of filling factor. This diagram is equally applicable to all sizes of container.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.23 This high internal pressure imposes a stress on the closures which may be distorted or even ruptured as a result. Distortion of closures, especially of aluminium parts, may allow the elastomeric seal to lift or loosen in the bottle neck and allow the escape of some air from the ullage. Should this occur, the bottle on cooling tends to develop a partial internal vacuum. This itself is no danger to the product but may allow the entry into the bottle of spray cooling fluid which will dilute the product and may carry in chemical or microbial contamination. An attempt is made to reduce the risk of product contamination by using retained condensate in the sterilizer (or in some cases filtered gas) as the cooling agent. But since the failure of the seal may not be apparent by visual inspection, an acceptable product requires that the closure of the bottle remains an effective seal throughout the sterilization process.

6.24 Since the above problems arise as a result of the inevitable excess pressure generated within bottles, the security of bottle closures is the responsibility of the user. Thus the user is required to ensure that the closures and containers are suitably designed to withstand the proposed sterilizing conditions. This is best achieved by ensuring that containers and closures comply with a recognised standard. Where containers are reused, the user has to institute a rigid system of inspection after washing to ensure that all bottles with signs of damage, especially of the neck area, are discarded. It is imperative that a bottle is not charged with a volume of fluid greater than the stated nominal volume of the bottle.

6.25 Users are recommended to establish a quality system to ensure that the probability of failure of a closure is low enough that the sterility of the product is not jeopardised. This will generally require the user to identify the parameters of the container and closure system which could lead to a failure and to set limits of acceptance which have been validated to demonstrate closure integrity. Production cycles may require the introduction of a dye into the chamber to identify failed closures. Electronic monitoring systems are also available. Within the NHS it may not be practicable to determine the probability of failure statistically, and in such cases sufficient assurance of sterility may be achieved by ensuring that the steam supplied to the sterilizer, and any coolant water in contact with the load, complies with the “clean steam” purity specification described in SHTM 2031. See also Part 2 of this SHTM for a discussion on the fail-safe design of heat exchangers.

Performance qualification

6.26 PQ tests are not required for loading conditions presenting less of a challenge to the cycle than the full-load and small-load tests carried out during commissioning. Decisions on which loading conditions require PQ tests should be made by the user, in consultation with the Quality Controller and Test Person.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.27 PQ tests are required where:

a. the nominal capacity of any container exceeds 1 litre;

b. the product cannot withstand the equilibration time associated with the commissioning tests (see Part 3 of this SHTM);

c. any cycle variable has been modified from the setting used in validation.

6.28 Users should consider the economic benefits of conducting PQ tests even for stable products, since the heating and cooling times will be generally shorter than that required for the commissioning tests.

Selection of cycle variables

6.29 The sterilizer should be preset to operate in the standard sterilization temperature band shown in Table 6. Other combinations of sterilization temperature and holding time may be used provided that they have been satisfactorily demonstrated to deliver an adequate level of lethality when operated routinely within established tolerances.

Table 6: Sterilization conditions for fluid sterilizers

Sterilization temperature [°C]	Maximum allowable temperature [°C]	Minimum holding time [min]
121	124	15

6.30 The automatic controller should be preset to a plateau period, established during performance qualification, sufficient to include both the minimum holding time and the equilibration time.

Cycle monitoring and documentation

6.31 Documentation as listed in paragraph 2.57 should be recorded. Each cycle should be noted in the sterilizer process log (see paragraph 3.11).

6.32 Where the temperature of the load is to be monitored, the load temperature probe should be inserted into a load item known to be the slowest to attain the sterilization temperature. Where two probes are provided (normally in sterilizers over 600 litres) the second probe should be inserted into the load item known to be the fastest to attain the sterilization temperature. The probe should be located along the geometric axis of the container and inserted to a depth of 85% of the container height.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.33 A batch process record should be generated for each production cycle. he batch process record will contain the following:

a. the temperature (“chamber temperature”) recorded by a sensor in the active chamber discharge;

b. the pressure (“chamber pressure”) recorded by a sensor in the chamber;

c. the temperature (“load temperature”) recorded by the load temperature probe.

6.34 In certain applications the operating cycle may be controlled by measuring the lethality (F_0) delivered to the load as the cycle progresses. An extensive discussion on the applications of the F_0 principle may be found in Part 5 of this SHTM.

Product release

6.35 Documented procedures for release of medicinal products should be established by the Quality Controller.

6.36 The load may be released for use provided that:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. not more than one container (or 1%, whichever is the greater) has burst or broken.

6.37 If the batch process record is unacceptable the load should be rejected. A decision on reprocessing should be based upon a validated procedure which takes account of the chemical and physical stability of the product.

6.38 The load should be examined for damaged containers. The occasional broken bottle or bag may be acceptable provided intact containers have not also been damaged.

6.39 Blooming of plastic containers is a surface effect which normally clears and does not harm the container or the contents. The user and Quality Controller should decide whether blooming is acceptable.

7. Operation of sterilizers for unwrapped instruments and utensils

Introduction

7.1 This chapter gives guidance on the routine operation of clinical sterilizers designed to process unwrapped solid instruments and utensils by exposure to high-temperature steam.

7.2 The guidance given here assumes that the sterilizer is to be used to process medical devices However, these sterilizers do not meet the essential requirements of the EU Directives discussed in Chapter 1, which do not permit the supply of unpackaged sterile medical devices.

The process

7.3 This type of sterilizer is used to process unwrapped surgical instruments and utensils intended for immediate use in a controlled medical environment. Heating is by the direct contact of the product with saturated steam.

7.4 Air is normally removed from the sterilizer by passive displacement, either downward or upward depending on whether steam is supplied externally or generated internally. Active air removal systems of the type found in a porous load sterilizer are rare.

7.5 A few models have a drying stage in which the load is dried by passing filtered air through the chamber, but it is more usual for the load to be partially dried by evaporation after it has been removed from the machine.

7.6 A sterilizer conforming to BS 3970 will have the following operating cycle:

a. *Heating*. The water is heated and steam generated in order to vent the air from the chamber until the sterilization temperature is attained.

b. The *plateau period* starts when the chamber temperature, recorded by a sensor located in the active chamber discharge, reaches the sterilization temperature.

   (i) In the first part of this period, the equilibration time, all parts of the load attain the sterilization temperature.

   (ii) The moment when the temperature in all parts of the load finally attains the sterilization temperature marks the end of the equilibration time and the start of the holding time.

c. *Cooling*. The load is allowed to cool naturally in the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Water supply

7.7 In transportable sterilizers steam is generated by the heating of feedwater within the chamber. The recommendations contained in SHTM 2031 should be followed.

7.8 Users should note that the recommendation for feedwater is designed to facilitate effective sterilization and avoid damage to the machine. Where the steam quality in the chamber is required to meet the specification for pyrogen-free “clean steam” (set out in SHTM 2031), only water complying with Sterilized Water for Injections BP is acceptable.

7.9 A sufficient supply of suitable water should be kept at hand. Operating procedures should ensure that the water level in the sterilizer is checked before every cycle and the reservoir replenished at specified intervals. This is particularly critical for clean steam (see SHTM 2031).

Safety precautions

7.10 As there is no thermal door-lock on the sterilizer, the load may still be very hot (up to 100°C) when it is removed from the chamber. Operators should therefore be issued with heat-resistant gloves.

7.11 Care should be taken not to contaminate load items with the gloves when removing the load from the chamber.

Product compatibility

7.12 These sterilizers are designed to process unwrapped instruments and utensils for immediate use in a controlled medical environment, such as an operating theatre. They should not be used to process items that are wrapped or items intended to be stored or transported before use.

7.13 Because these sterilizers have no active means of extracting air from load items, they should not be used with instruments and utensils whose construction could impede the passive removal of air and the subsequent penetration of steam. In practice, this means that hollow or porous items should not be processed in this type of sterilizer. A sterilizer with an active air removal system, such as a porous load sterilizer, is required in such cases. European standards regard an item as hollow, and therefore unsuitable, if the item possesses a cavity of depth greater than the width of its orifice, or a double-ended hole of length greater than twice its width. This is a conservative criterion, and many borderline items may be safely processed if they are placed correctly in the chamber (see 7.17). However, the risk of incomplete sterilization is a real one, and Users should carefully examine each type of item to be processed to ensure that air removal and steam penetration will be effective. Failure to observe this requirement has led to serious incidents in which patients have become infected by unsterile

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

surgical instruments. The Authorised Person should be consulted in cases of doubt.

Items that should not be processed

7.14 The following items should not be processed in a sterilizer for unwrapped instruments and utensils:

a. medical devices intended to be supplied in compliance with the EU Directives discussed in Chapter 1 (unpackaged devices are not acceptable);

b. medicinal products;

c. wrapped items and other items likely to trap air and impede the penetration of steam (see paragraph 7.13);

d. aqueous fluids (a fluid sterilizer is required);

e. items not for immediate use.

Design of the load

7.15 Load items should be arranged on shelves or trays that permit the free circulation of steam and draining of condensate. Items should not be allowed to rest on the bottom of the chamber.

7.16 Trays or baskets should be constructed of open mesh or with sufficient ventilation holes to ensure that they present no barrier to air removal and steam penetration. BS 3970: Part 4 specifies that any such load containers used in these sterilizers should be perforated such that the total area of the perforations is at least 10% of the surface area of the container. The perforations should be uniformly distributed and each of area 20 mm^2 or more. Draft European standards make the same requirement.

7.17 As far as possible, load items should be arranged to ease the removal of air and the penetration of steam and allow condensate to run directly to the drain, away from the individual objects. Items of the load which could retain air and condensate, such as bowls, should be places on their sides so that air will be displaced and condensate will drain out.

Selection of cycle variables

7.18 Sterilizers conforming to the standards discussed in Part 2 of this SHTM will have a single operating cycle, normally with a sterilization temperature of 134°C and a holding time of at least 3 min. If other cycles are provided (see Table 7), the highest sterilization temperature compatible with the load should be chosen.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.19 It is recognised that users of transportable sterilizers in primary health care units, such as GP and dental practices, where close supervision of the sterilizer is not practicable may wish to operate their machines with a wider margin of safety than would be the case in a hospital SSD staffed by full-time specialist personnel. In such cases the machine's plateau period may be preset to the extended plateau period given in Table 7.

Table 7: Sterilization conditions for sterilizers for unwrapped instruments and utensils

Sterilization temperature [°C]	Maximum allowable temperature [°C][a]	Minimum holding time [min]	Extended plateau period[b] [min]
134	137	3	4
126	129	10	15
121	124	15	20
115[c]	118	30	-

a. See paragraphs 2.52-2.53 for comment on maximum allowable temperatures.

b. See paragraph 7.19.

c. Permitted by BS 3970: Part 4 but not recommended for NHS use.

7.20 Users should note that the "plateau period" here is regarded as beginning when the chamber temperature attains its preset value as signalled by the indicator light. The conventional plateau period (see paragraph 2.48), which starts when the chamber temperature attains the sterilization temperature, cannot normally be defined on these small sterilizers which have no means of detecting when that temperature has been reached.

7.21 The need for regular testing, as specified in Part 3 of this SHTM, is re-emphasised.

Cycle monitoring and documentation

7.22 Each cycle should be noted in the sterilizer process log (see paragraph 3.11).

7.23 Where a recorder is fitted to the sterilizer (as recommended in Part 2 of this SHTM), a batch process record should be generated for each production cycle. The batch process record will contain the following:

a. the temperature ("chamber temperature") recorded by a sensor in the coolest part of the chamber (normally the active chamber discharge);

b. the pressure ("chamber pressure") recorded by a sensor in the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.24 Where a recorder is not fitted, the following records should be made:

a. once a day, note the duration of the plateau period, and the indicated chamber temperatures and pressures at the beginning, middle and end of the plateau period, for a selected production cycle;

b. where practicable, note the indicated chamber temperature and pressure at the approximate mid-point of the plateau period for each production cycle.

7.25 The load may be released for use provided that:

a. *either*, during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. *or*, during the plateau period:

(i) the values of the plateau period and the indicated chamber temperature and pressures as described in paragraph 7.24a are within the permitted tolerances established during performance qualification;

(ii) the values of the indicated chamber temperature and pressures as described in paragraph 7.24b are also within the permitted tolerances established during performance qualification.

7.26 As load items are not wrapped, they are exposed to the air at the end of the cycle and subject to rapid recontamination. They should therefore be used without delay.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8. Operation of dry-heat sterilizers

Introduction

8.1 This chapter gives guidance on the routine operation of clinical sterilizers designed to sterilize load items by exposure to hot, dry air. Such sterilizers are correctly known as “dry-heat sterilizers” and sometimes as “hot-air sterilizers” or “sterilizing ovens”.

8.2 The guidance given here assumes that the sterilizer is to be used to process either medicinal products or medical devices in compliance with the EU Directives discussed in Chapter 1.

The process

8.3 Dry heat sterilizers expose the load to hot, dry gas (normally hot air) at a temperature of 160ºC or greater (see Table 8). The load is heated by conduction from the hot air to the load items. The process is slow and cycle times are several hours.

8.4 A dry-heat sterilizer will typically have the following operating cycle.

a. *Heating-up*. Hot air is heated electrically and circulated through the chamber.

b. The *plateau period* starts when the chamber temperature, recorded by a sensor located in the part of the chamber known to be the slowest to heat up, reaches the sterilization temperature.

   (i) In the first part of this period, the equilibration time, all parts of the load attain the sterilization temperature.

   (ii) The moment when the temperature in all parts of the load finally attains the sterilization temperature marks the end of the equilibration time and the start of the holding time.

c. *Cooling*. The load is cooled by circulating cold, filtered air through the chamber or through a jacket.

Safety precautions

8.5 The main hazard associated with dry-heat sterilizers is the high temperatures at which they operate. The highest sterilization temperature permits the temperature of the load to rise to 190°C (see Table 8). In the event of a control failure, the chamber temperature may rise to 200°C before the thermal cut-out shuts off the heaters.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.6 In normal operation, a thermal door-lock prevents the door being opened until the temperature in all parts of the load has fallen to 80ºC. Nonetheless, operators should take great care in both unloading hot load items from the chamber and reloading a chamber that remains hot from a previous cycle.

Product compatibility

8.7 Dry heat may be used to process a variety of items and materials which would either be damaged by exposure to high-temperature steam or LTSF or would not be sterilized.

8.8 Suitable items include solids, heat-stable powders, waxes, greases, ointments, non-stainless metals, hollow needles, glass syringes and items in sealed containers. Dry heat may also be used for non-aqueous fluids such as white soft paraffin, paraffin gauze dressings, eye ointment bases, oily injections, silicone lubricant and pure glycerol.

Items that should not be processed by dry heat

8.9 The following items should not be processed by dry heat:

a. items that would be damaged by exposure to hot air at 160°C, such as glycerol/water mixtures, rubber, certain plastic or electrical items;
b. aqueous fluids (a fluid sterilizer is required).

8.10 As cycle times can be several hours, items must be able to withstand not only the holding time, but also the relatively slow heating and cooling stages.

Design of the load

8.11 The loading condition should be designed with two aims in mind:

a. to permit air to circulate freely within the chamber and around each item of the load;
b. to allow heat to be transmitted to and within each item of the load.

8.12 The time required for an individual load item to attain the sterilization temperature will depend upon its size, shape and thermal conductivity, and can vary widely. Powders and oils, in particular, take a long time to heat up. Loads should therefore be designed to contain items of similar size and nature.

8.13 If a mixed load cannot be avoided, then great care must be taken during performance qualification to identify the load items that are the slowest to heat up. The duration of the plateau period should be selected to ensure that these items are exposed to the sterilization temperature for the correct time.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load preparation and packaging

8.14 All items must be clean and dry before sterilization.

8.15 Glass or metal syringes should be assembled and hinged instruments should be closed.

8.16 Delicate instruments, such as eye instruments, should be supported to guard against physical damage.

8.17 Good thermal contact between load items and their containers is essential. In the case of a heavy instrument, heat conduction can be improved by supporting the instrument in a metal cradle within its container. Smaller items may be wrapped in heavy or light gauge metal foil or contained in aluminium cans or tubes each of which may be sealed with push-on caps, screw caps, or crimp-on foil caps. Crimp-on foil caps with a pre-printed chemical indicator are also available.

8.18 The packaging does not need to be porous since the heat transfer normally takes place by conduction. However, in sealed packaging the contents of the pack when heated can exert a considerable pressure which may be sufficient to rupture the packaging material or seals. Vented packaging systems that allow pressure equilibration may be suitable for use in sterilizers which operate with a chamber atmosphere which has been filtered through a bacteria-retentive filter. This is particularly important during the cooling stage.

8.19 For items such as laboratory glassware, foil may be used to close the open end of the product to prevent contamination when the load is removed from the sterilizer.

8.20 Kraft paper bags or a simple layer of wrapping material can be used to pack individual items. Plastic bags of the sort sold for roasting meat in domestic ovens may also be suitable.

8.21 An extensive discussion on packaging materials and methods may be found in Part 5 of this SHTM.

Arrangement of load items

8.22 Random loading is not acceptable.

8.23 Load items should be placed in the chamber in such a way that air can circulate freely around them. This requires a space of at least 10 mm between adjacent items. They should therefore not be stacked and should not be allowed to touch each other.

8.24 Shelves and trays should be either perforated or made of wire mesh.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.25 Because of the importance of air circulation, even minor variations in the loading pattern may seriously affect heat distribution and prevent complete sterilization of the load. Purpose-made shelving or spacers should be used to ensure accurate and repeatable positioning of load items.

Performance qualification

8.26 Because of the need for careful design of the load, performance qualification is required for each loading condition to be processed. The full-load test used during commissioning is not an acceptable substitute. The number of different loading conditions should be rationalised by careful design to minimise the number of PQ tests required.

8.27 Decisions on which loading conditions require PQ tests should be made by the user in consultation with the Test Person.

Selection of cycle variables

8.28 The cycle variables should be selected to expose the load to one of the three combinations of sterilization temperature and holding time given in Table 8. The highest sterilization temperature compatible with the load should be chosen.

Table 8: Sterilization conditions for dry-heat sterilizers

Sterilization temperature [°C]	Maximum temperature [°C]	Maximum holding time [min]
160	170	120
170	180	60
180	190	30

8.29 A few heat-sensitive products may require lower temperatures and consequently prolonged holding times. The advice of the Authorised Person should be sought in such cases.

Cycle monitoring and documentation

8.30 The integrity of the air filter should be checked daily or, in the case of medicinal products, during each cycle. This will normally be done by measuring the differential pressure across the filter during the cooling stage and ensuring that the measured value is within the limits specified by the manufacturer. Note that this check is not the same as the air filter integrity test described in Part 3 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.31 Where the temperature of the load is to be monitored, the load temperature probe should be inserted into a load item known to be the slowest to attain the sterilization temperature. Where two probes are provided (normally in sterilizers over 600 litres) the second probe should be inserted into the load item known to be the fastest to attain the sterilization temperature. Sensors sealed into load containers should be located along the geometric axis and inserted to an approximate depth of 50% of the container height.

8.32 Documentation as listed in paragraph 2.57 should be recorded. Each cycle should be noted in the sterilizer process log (see paragraph 3.11).

8.33 The batch process record will contain the following:

a. the temperature (“chamber temperature”) recorded by a sensor in the coolest part of the chamber;

b. for medicinal products, the temperature (“load temperature”) recorded by load temperature probes placed:

(i) in the load item known to be the slowest to reach the sterilization temperature;

(ii) for larger sterilizers, also in the load item known to be the fastest to reach the sterilization temperature.

Product release

8.34 The load may be released for use provided that:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. the packaging is undamaged.

9. Operation of LTS disinfectors

Introduction

9.1 This chapter gives guidance on the routine operation of clinical disinfectors designed to disinfect load items by exposure to low-temperature steam (LTS). See Chapter 10 for guidance on the operation of low-temperature steam and formaldehyde (LTSF) sterilizers.

9.2 The guidance given here assumes that the disinfector is to be used to process medical devices. However, the LTS process does not meet the sterilization requirements of the EU Directives discussed in Chapter 1. LTS should not be used for processing medicinal products.

9.3 LTS disinfectors are occasionally used to decontaminate soiled surgical components to make them safe to handle before they are washed and sterilized (see also paragraph 9.8). In such cases the machine used for initial decontamination should be reserved for that purpose and not be used also for the terminal disinfection of medical devices.

The process

9.4 Disinfection is achieved by direct contact with low-temperature saturated steam at sub-atmospheric pressure at a nominal temperature of 73°C (and not exceeding 80°C) for a minimum holding time of 10 minutes.

9.5 The LTS process kills most vegetative micro-organisms and some heat-sensitive viruses. It disinfects but does not sterilize.

9.6 LTS is free of toxic residues that may occur with chemical disinfection.

9.7 Part 2 of this SHTM specifies that new LTS disinfectors should conform to the requirements of BS 3970. Such a machine will have the following operating cycle.

a. *Preheating*. The walls of the chamber are heated to the preset operating temperature between 71°C and 78°C. This reduces condensation on the walls of the chamber (the door is not normally heated).

b. *Air removal*. Sufficient air is withdrawn from the chamber to permit the attainment of the disinfection conditions. This normally requires an absolute pressure of less than 50 mbar.

c. *Air ingress monitoring*. The chamber is automatically subject to a vacuum leak test before the cycle proceeds any further. If the leak rate is higher than a preset value (normally 5.0 ± 0.2 mbar min^{-1}) the cycle is aborted.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. *Steam admission*. Steam is admitted to the chamber until the temperature attained throughout the load is 73 ± 2°C.

e. *Disinfection*. The temperature throughout the chamber and load is maintained at or above the disinfection temperature (71°C) for a holding time of not less than 10 min.

f. *Drying*. Steam is extracted from the chamber and the chamber pressure is reduced sufficiently to permit the evaporation of condensate from the load, either by prolonged evacuation of the chamber or by the injection and subsequent extraction of heated air or other gases within the chamber.

g. *Air admission*. Air is admitted to the chamber through a filter until the chamber pressure is within 100 mbar of atmospheric pressure.

Safety precautions

9.8 Where LTS disinfectors are used to decontaminate soiled items before cleaning, operators should be aware that the steam may not have penetrated below the surface of the soil and that decontamination may therefore not be complete. Care is required in the subsequent handling of the item before it is cleaned.

Product compatibility

9.9 LTS disinfection is suitable for a wide range of heat-sensitive items capable of withstanding a moist process.

9.10 The process is particularly suitable for the disinfection of respiratory and anaesthetic equipment, external pacemakers and for rigid endoscopes not requiring a sterilization process.

Items which should not be processed by LTS

9.11 The following items should not be processed by LTS:

a. items requiring sterilization;

b. items which may be damaged by the conditions of heat, moisture and pressure during the cycle;

c. items in sealed containers (the steam will not reach them);

d. oily or greasy items (oil or grease will impede the penetration of steam);

e. items likely to be contaminated with bacterial spores or other agents of similar resistance to the disinfection process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Design of the load

9.12 The loading condition should be designed with two aims in mind:

a. to permit the rapid removal of air from the load items and the rapid penetration of steam; and

b. to ensure that the condensate formed during the cycle does not result in a wet load.

Air removal

9.13 The presence of air in the load can impede the penetration of steam and thereby drastically reduce the effectiveness of the disinfection process.

9.14 The principles of ensuring effective air removal for LTS disinfectors are the same as those for porous load sterilizers (see paragraphs 5.13-5.16).

Handling of condensate

9.15 The principles of ensuring that condensate does not result in wet loads are the same as those for porous load sterilizers (see paragraphs 5.17-5.24).

Packaging materials

9.16 Packaging materials for LTS sterilizers should meet the same requirements as those for porous load sterilizers (see paragraphs 5.25-5.28). Any process indicators in the form of printed panels designed for high-temperature steam processes will not, however, reliably respond to the LTS process. Until specific LTS indicators are available, plain bags should be used.

Selection of cycle variables

9.17 The LTS operating cycle is preset by the manufacturer and usually no adjustment is possible.

Cycle monitoring and documentation

9.18 Documentation as listed in paragraph 2.57 should be recorded. Each cycle should be noted in the sterilizer process log (see paragraph 3.11).

9.19 A batch process record should be generated for each production cycle. The batch process record will contain the following:

a. the temperature (“chamber temperature”) recorded by a sensor in the active chamber discharge;

b. the pressure (“chamber pressure”) recorded by a sensor in the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Product release

9.20 The load may be released for use provided that:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. the packaging is undamaged;

c. the load items are visibly dry.

10. Operation of LTSF sterilizers

Introduction

10.1 This chapter gives guidance on the routine operation of clinical sterilizers designed to sterilize load items by exposure to low-temperature steam and formaldehyde (LTSF). See Chapter 9 for guidance on the operation of low-temperature steam (LTS) disinfectors.

NOTE: Despite their name, LTSF sterilizers are disinfectors.

10.2 The guidance given here assumes that the sterilizer is to be used to process medical devices in compliance with the EU Directives discussed in Chapter 1. Due to its toxicity, LTSF should not be used for sterilization of medicinal products.

10.3 LTSF sterilizers are occasionally used to decontaminate soiled surgical components to make them safe to handle before they are washed and sterilized. In such cases the sterilizer used for initial decontamination should be reserved for that purpose and not be used also for the terminal sterilization of medical devices.

10.4 The user should seek advice from the Authorised Person, the Microbiologist or the manufacturer if in any doubt about the operation of LTSF sterilizers.

The process

10.5 Sterilization is achieved by direct contact with a mixture of low-temperature saturated steam and formaldehyde gas at sub-atmospheric pressure at a typical operating temperature of 73°C and not exceeding 80°C.

10.6 LTSF has a broad-spectrum action against vegetative bacteria, bacterial spores, fungi and most viruses.

10.7 Many operating cycles are in use, in which there are variations in the pattern of injection of steam and formaldehyde injection, the depth of vacuum, length of holding stages and the amount of formaldehyde employed. Part 2 of this SHTM specifies that new LTSF sterilizers should conform to the requirements of BS 3970. Such a sterilizer will have the following operating cycle.

a. *Preheating*. The walls of the chamber are heated to the preset operating temperature (typically 73°C, but the standard does not specify this). This reduces condensation on the walls of the chamber (the door is not normally heated).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

b. *Air removal*. Sufficient air is withdrawn from the chamber to permit the attainment of the sterilization conditions. This normally requires an absolute pressure of less than 50 mbar.

c. *Air ingress monitoring*. The chamber is automatically subjected to a vacuum leak test before the cycle proceeds any further. If the leak rate is higher than a preset value (normally 5.0 ± 0.2 mbar min^{-1}) the cycle is aborted.

d. Sterilization.

   (i) Phase 1. The required steam and formaldehyde conditions within the chamber and load are attained.

   (ii) Phase 2. The temperature, humidity and formaldehyde concentration are maintained within specified limits for the holding time.

e. *Gas removal*. Formaldehyde and steam are removed from the chamber and load.

f. *Drying*. Steam is extracted from the chamber and the chamber pressure is reduced sufficiently to permit the evaporation of condensate from the load, either by prolonged evacuation of the chamber or by the injection and subsequent extraction of heated air or other gases within the chamber.

g. Air admission. Air is admitted to the chamber through a filter until the chamber pressure is within 100 mbar of atmospheric pressure.

10.8 Since the sterilization process is ultimately dependent on chemical action, a routine microbiological test is required for each production load to confirm that sterilization conditions have been attained (see paragraph 10.48).

Formaldehyde solution

10.9 Formaldehyde (CH_2O), also known as methanal, is a colourless, toxic gas with a strong, characteristic odour. It is normally produced within the sterilizer by the evaporation of Formaldehyde Solution BP, also known as formalin, containing 34-38% w/w formaldehyde stabilised with methanol.

10.10 Analytical reagent grade formaldehyde solution, also specified in the British Pharmacopoeia, is unstabilised and is not suitable for use in sterilizers.

10.11 BS 3970 permits other “primary materials” to be used for the generation of formaldehyde, though formalin is by far the most common. If other materials are used, the user should ensure that adequate information on safety and usage is supplied by the manufacturer of the product.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Polymerisation

10.12 When formalin is allowed to stand or evaporate, white flocculent masses of paraformaldehyde are precipitated. Paraformaldehyde is a mixture of polymethylene glycols (of the general form $(CH_2O)_n$, xH_2O, where n is 6-50) formed by the reaction of formaldehyde with water. It is readily converted back to formaldehyde gas by heating.

10.13 Paraformaldehyde may be formed in LTSF sterilizers where the formaldehyde gas is allowed to condense on a cold, wet surface. As the reaction removes formaldehyde from the chamber atmosphere it can lead to a failure of the sterilization process. Paraformaldehyde deposits may also block pipework in the heat exchanger and so reduce the efficiency of vaporisation of the formalin. Polymerisation is controlled mainly by careful handling of condensate (see paragraphs 10.32–10.37). Heated doors, provided on some models, are also helpful.

10.14 Experience has shown that on larger LTSF machines an occasional flushing cycle, in which the formalin supply is replaced with water and a cycle run with an empty chamber, is beneficial in reducing polymerisation problems. Flushing cycles may conveniently be run overnight.

Safety precautions

10.15 Where LTSF sterilizers are used to decontaminate soiled items before cleaning, operators should be aware that the sterilant may not have penetrated below the surface of the soil and that decontamination may therefore not be complete. Care is required in the subsequent handling of the item before it is cleaned.

10.16 Formalin is a toxic liquid which requires careful handling and secure storage.

Effects on health

10.17 Formaldehyde gas has a pungent odour which is very irritating to the eyes and respiratory tract, with a threshold of detection by smell at around 0.8 ppm, though the threshold for irritation may be lower. The threshold for eye irritation may be as low as 0.01 ppm; 4 ppm usually causes the eyes to water. Mild effects on the throat may occur at 0.5 ppm; 10 ppm causes severe irritation to the eyes, nose and throat. Formaldehyde is assigned a maximum exposure limit of 2 ppm (both short-term and long-term limits) under the COSHH Regulations 1999 (see Schedule 1). The presence of formaldehyde in the air can therefore be sensed by personnel at levels below the maximum exposure limit; in this respect, LTSF sterilization is safer than EO sterilization.

NOTE: Refer also to EH40 ‘Occupational Exposure Limits’ Table 1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.18 Workers regularly exposed to formaldehyde may become acclimatised to the effects at low concentrations. There is no evidence to suggest that exposure to formaldehyde leads to chronic impairment of lung function. There have been only a few case reports of occupational asthma associated with formaldehyde exposure, despite its widespread use in industry. However, skin contact has been shown to cause allergic contact dermatitis.

10.19 Although there is no epidemiological evidence that formaldehyde is associated with cancer in humans, HSE advises that it should be regarded as a potential carcinogen.

10.20 Formalin liquid can cause irreparable damage if splashed in the eyes. Eye-washing facilities should be provided. Hazard labels should be displayed prominently in all areas in which formalin is handled and used.

Replenishing the formalin supply

10.21 In normal operation of LTSF sterilizers, the greatest risk of exposure occurs when the formalin supply in the sterilizer is replenished. A written procedure for the filling and the connection of formalin tanks should be devised, based on a risk assessment complying with the COSHH Regulations. Care should be taken that the exposure limits given in Schedule 1 are not exceeded. All staff whose duties include replenishing the formalin supply should receive instruction.

10.22 Formalin should be stored in a closed container in a locked cabinet at a temperature of 15-25ºC. Vessels required for handling the formalin, such as jugs and funnels, should also be kept in the cabinet.

10.23 On certain older sterilizers replenishment of the formalin supply is a matter of removing the empty tank from the sterilizer and installing a full one in its place. On newer sterilizers, formalin is decanted into the tank from a storage container.

10.24 The decanting operation should be done in a well-ventilated room where an accidental spillage will not endanger staff or patients. A safety cabinet or fume cupboard is desirable. The following precautions should be observed when decanting is necessary.

a. Dress in appropriate personal protective equipment (PPE), ie. apron, facemask and gloves (see paragraphs 2.14-2.15).

b. Remove the formalin tank from the sterilizer and take it to a bench or worktop near a sink or hand-basin where plenty of running water is available.

c. Take the formalin bottle from the storage cupboard.

   (i) Check the expiry date. If the date has passed, the solution should not be used.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

(ii) Examine the solution to ensure that polymerisation and separation have not taken place. The solution should be clear, with no sign of white particles or sediment. If there are any signs of polymerisation, the solution is not suitable for sterilization and should not be used.

d. Check the quantity of formalin to be decanted into the tank.

e. Decant the solution slowly into the tank. Do not lift the storage bottle above chest height.

f. When the decanting is complete, wash any jugs or funnels used in the process with ample clean, cold water.

g. Return the tank to the sterilizer and install it in accordance with the manufacturer's instructions.

h. Return the formalin storage bottle and filling vessels to the cabinet and lock the door.

i. Remove the PPE, discard or clean as appropriate, and return it to its storage location.

Product compatibility

10.25 LTSF is a suitable process for a wide variety of items which are unsuitable for sterilization by high-temperature steam or dry heat. This includes many materials and items of equipment with integral plastic parts which could be damaged by heat. Complex items, such as certain electromedical equipment, may be sterilized by this process.

10.26 For example, LTSF can be used for sterilizing ophthalmic and cardiology items such as retinal and cataract detachment probes, cardiac catheters and pacing electrodes. It is also useful for elastic bougies, artificial joints, foetal scalp electrodes, amniotic membrane perforators and similar heat-labile items.

10.27 The reversible adsorption of formaldehyde by some materials must be considered. The high surface area of fabrics can adsorb large quantities of formaldehyde (effectively absorption) and these may remain for long periods unsuitable for patient use.

10.28 Because of the hazards associated with LTSF, it should not be used to sterilize items which could be processed by other means. A survey by the Central Sterilising Club showed that many items processed in hospital LTSF sterilizers carry only an intermediate infection risk (see Table 2 in Chapter 2) and LTS disinfection would have been more appropriate. Examples include face masks, ventilator tubing, nebulisers, airways, mattresses, sheepskins, breast milk expressors and toys.

NOTE: Sterilization and disinfection of heat-labile equipment, by Central Sterilising Club 1986.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Items which should not be processed by LTSF

10.29 The following items should not be processed by LTSF:

a. items which may be damaged by the conditions of temperature, pressure, moisture and chemical environment prevailing during the cycle;

b. items in sealed containers (the sterilant will not reach them);

c. oily or greasy items (oil or grease will impede the penetration of the sterilant);

d. items contaminated with body fluids (hardened, fixed protein deposits will be produced); eg. “dirty returns” from operating theatres, clinics, etc.;

e. electrical or other items requiring a dry process, e.g. fully assembled air drills, dental hand pieces and infant ventilators;

f. certain flexible fibre-optic endoscopes (differential expansion will crack the sealants and let moisture penetrate the optics);

g. items which may absorb and retain unacceptable quantities of formaldehyde.

Design of the load

10.30 The loading condition should be designed with two aims in mind:

a. to permit the rapid removal of air from the load items and the rapid penetration of steam and formaldehyde; and

b. to ensure that the condensate formed during the cycle is quickly drained clear of the load.

Air removal

10.31 The presence of air in the load can impede the penetration of steam and formaldehyde and thereby drastically reduce the effectiveness of the sterilization process. The principles of ensuring effective air removal for LTSF sterilizers are the same as those for porous load sterilizers (see paragraphs 5.13-5.16).

Handling of condensate

10.32 As in all steam sterilizers, water condenses during the heating stages of the LTSF cycle. This problem is particularly acute when sterilizing metal items.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.33 In contrast to porous load sterilizers (see paragraphs 5.17-5.24), where it is preferable to retain condensate close to the load items to permit re-evaporation, condensate formed in LTSF sterilizers should be drained clear of the load as quickly as possible. This is for two reasons:

a. excessive moisture may impede the penetration of formaldehyde gas into the load (especially where items have narrow lumens);

b. condensate allowed to remain on the load will promote the formation of paraformaldehyde (see paragraph 10.13).

10.34 Chamber furniture should therefore be made from materials of high thermal conductivity (such as aluminium) to reduce heat-up time and so avoid cool surfaces. Open mesh supports should be used to allow drainage as well as gas penetration.

10.35 Packs should be arranged in a manner which will permit the free drainage of condensate.

10.36 To retain heat and reduce condensate formation, the door should remain closed whenever the machine is not in use.

10.37 LTSF sterilizers should always be preheated prior to use. This may be either from a previous LTSF cycle, or from an LTS cycle used specifically for preheating.

Packaging materials

10.38 The basic considerations for packaging are similar to those for porous load sterilizers (see paragraphs 5.25-5.28), except for the following:

a. the extent to which packaging materials will retain both moisture and formaldehyde residuals may affect the efficacy of the process;

b. materials which are slow to attain the sterilization temperature may promote polymerisation;

c. materials of high heat capacity promote the formation of excessive amounts of condensate.

10.39 It is therefore recommended that packaging should be kept to a minimum.

10.40 Packaging may consist of paper, used as plain or creped wraps, or in the form of bags or, in combination with plastic film, as pouches. Light cardboard boxes, or corrugated polypropylene boxes, adequately vented and overwrapped with paper or other material as a bacterial barrier, are also suitable. When particularly delicate instruments are to be processed, the use of open-cell foam for support and protection is acceptable.

10.41 To assist in the detection of paraformaldehyde deposits, packaging materials should preferably be of dark colour (such as green) rather than white.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.42 If packaging designed for porous-load sterilizers is used, Users should note that any process indicators in the form of printed panels will not reliably respond to the LTSF process. If specific LTSF indicators are not available (they should conform to BS EN 867: Part 2) plain bags should be used.

10.43 Extensive guidance on packaging may be found in Part 5 of this SHTM.

Performance qualification

10.44 Decisions on which loading conditions require PQ tests should be made by the user in consultation with the Microbiologist and Test Person.

Selection of cycle variables

10.45 The concentration of formaldehyde in the chamber during the holding time will have been determined during performance qualification and is typically around 15 g m^{-3} for an operating temperature of 73°C. This is equivalent to the evaporation of 40 ml of formalin per cubic metre of the chamber volume (this is the volume of the pressure vessel, not the usable chamber space).

10.46 Other cycle variables are preset by the manufacturer.

Cycle monitoring and documentation

10.47 Documentation as listed in paragraph 2.57 should be recorded. Each cycle should be noted in the sterilizer process log (see paragraph 3.11).

10.48 A routine microbiological test should be carried out with every production load as described in Part 3 of this SHTM. Note that the full result of the test will not be known until the biological indicator has been cultured for 7 days.

10.49 A batch process record should be generated for each production cycle. The batch process record will contain the following:

a. the temperature (“chamber temperature”) recorded by a sensor in the active chamber discharge;

b. the pressure (“chamber pressure”) recorded by a sensor in the chamber.

10.50 The operator should note the indicated amount of formalin consumed during the cycle and check that the gas removal stage has been completed satisfactorily before opening the door.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Product release and storage

10.51 The load may be released for degassing provided that:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. the correct amount of formalin has been taken from the tank;

c. the chemical indicator used in the routine microbiological test shows a uniform colour change;

d. there is no visual evidence of polymerisation (see paragraph 10.59);

e. the packaging is undamaged;

f. the load items are visibly dry.

10.52 The load may subsequently be released as sterile provided that the microbial culture results of the routine microbiological test described in Part 3 of this SHTM are satisfactory.

10.53 It is common practice in some units to release loads on the strength of the batch process record and not wait until the result of the microbiological test is known. The rationale for this is that the BPR confirms that the load has been exposed to a high-grade LTS disinfection process and is therefore safe for use. A subsequent failure of the microbiological test would lead to the sterilizer being withdrawn from service for investigation but would not normally lead to the recall of the released goods.

10.54 While such practices have been justified on the grounds of economy, they would not be acceptable under the EU Directives on medical devices. If the microbiological test shows a failure, the machine is, by definition, not working to the specifications established during validation and the process is therefore not adequately controlled (see paragraph 10.58).

10.55 A degassing time for each load will have been established during performance qualification. This will typically be no more than one hour. An active degassing system is not necessary. Goods processed in an LTSF sterilizer should be stored in such a way that air from the ventilation system cannot carry traces of formaldehyde over goods from other types of sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Troubleshooting

Cycle fault

10.56 The automatic controller may indicate a fault for a number of reasons, including:

a. a vacuum leak greater than a preset value (normally 5.0 ± 0.2 mbar min^{-1});

b. failure to attain the sterilization temperature;

c. insufficient formalin for a complete cycle.

10.57 Should a fault develop, the risk of exposure to formaldehyde is much greater than in normal operation. The Maintenance Person should be notified immediately. The batch process record should be carefully compared with the master process record to establish the precise point the cycle has reached. If it is suspected that formaldehyde has not been withdrawn from the chamber, the door of the sterilizer should not be opened until the loading area has been evacuated. Both the room ventilation and local exhaust ventilation should be operating. Provided the chamber has reached atmospheric pressure, the door can then be cranked partially open by an operator wearing a respirator. The chamber and load should be left overnight with the ventilation systems running during which time the formaldehyde will safely disperse.

Failure of the routine microbiological test

10.58 Failure of the microbiological test shows that the prescribed sterilization conditions have not been attained. If the batch process record shows that the physical cycle variables were satisfactory, then suspicion should fall on the formaldehyde component of the process.

a. The concentration of formaldehyde in the chamber was too low. There are several reasons why this might be.

(i) Insufficient formalin was consumed. This would normally lead to a fault indication and would have been revealed by inspection of the formalin level indicator.

(ii) Some of the formaldehyde was polymerised (see paragraph 10.59);

(iii) Some of the formaldehyde was dissolved in condensate. Check that there are no places in the load or chamber where standing water could collect (this could happen if chamber furniture or loading trolleys become dented).

(iv) Some of the formaldehyde was absorbed into the load. This is improbable if performance qualification tests have been conducted and previous loads have been processed satisfactorily.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

b. The loading condition is too great a challenge to the penetration of formaldehyde. Again, this is unlikely if performance qualification has been satisfactory.

Polymerisation of formaldehyde

10.59 The scientific background to formaldehyde polymerisation is discussed in paragraph 10.12. Evidence that polymerisation has occurred during a cycle is normally in the form of patchy white deposits of paraformaldehyde in the chamber and on the load items. There are three main causes to be considered.

a. Too much water was present in the chamber. Principles for avoiding wetness are discussed in paragraphs 10.32–10.37. If the loading condition has been processed many times before without difficulty, then the problem may lie in the steam supply which should be tested for dryness as described in Part 3 of this SHTM.

b. Too much formalin was used in the cycle. This is unlikely if the formalin indicator is working correctly and has been read correctly.

c. Failure (or partial failure) of the heat exchanger. If white streaks are visible in and around the steam entry port, it is likely that liquid formalin has entered the chamber. This implies that the temperature in the heat exchanger was too low for complete vaporisation.

11. Operation of ethylene oxide sterilizers

Introduction

11.1 This chapter gives guidance on the routine operation of clinical sterilizers designed to sterilize load items by exposure to ethylene oxide gas (EO).

11.2 The guidance given here assumes that the sterilizer is to be used to process medical devices in compliance with the EU Directives discussed in Chapter 1. Due to its toxicity, EO should not be used for sterilization of medicinal products.

11.3 Sterilization by EO should be regarded as a last resort, only to be used when other forms of sterilization are not possible. The wide variety of items processed in hospital SSDs will increase the difficulty in validating the process to achieve consistently low levels of residual EO. Items sterilized by EO may therefore contain higher levels of residuals than are desirable.

The process

11.4 EO is a highly penetrative, non-corrosive agent which has a broad-spectrum action against viruses, vegetative bacteria, bacterial spores, fungi, and other living cells under optimal conditions of concentration, relative humidity, temperature and exposure time. It may be used at temperatures and pressures which minimise damage to sensitive equipment. Typical operating temperatures are in the range 20-60°C.

11.5 Two types of EO sterilizer are employed in the NHS.

11.6 In low-pressure sterilizers, of chamber volumes around 150 litres, the sterilant is pure EO at sub-atmospheric pressure. The gas is supplied from a single-use, disposable cartridge contained within the chamber. The cartridge limits the amount of EO in use at any one time and so reduces the toxic and explosive hazards. The chamber is designed to contain the effects of an explosion of the contents of a single cartridge. Compared with high-pressure sterilizers (see paragraph 11.7), low-pressure machines are relatively cheap to install and to run, requiring no piped EO service and no gas disposal plant. The low pressure in the chamber allows pressure-sensitive equipment to be processed safely.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.7 In high-pressure sterilizers, of chamber volume up to 500 litres, the sterilant is EO diluted with another gas, supplied from cylinders. The mixtures are chosen to expose the load to an EO concentration of around 500-1000 mg litre^{-1} while keeping the potential hazards to a minimum Two gas systems are in common use:

a. EO with chlorofluorocarbons (CFCs) or hydrochlorofluorocarbons (HCFCs) at pressures up to 2 bar: CFCs have traditionally been used as a diluent gas but are no longer acceptable for environmental reasons; HCFCs require even more critical control of humidity than other systems and are themselves due to be phased out;

b. EO with carbon dioxide at pressures up to 6 bar.

11.8 The operating cycle of an EO sterilizer constructed to BS EN 1422 will have the following stages, though the order may be varied slightly.

a. *Chamber preheating*. With the load in place, the chamber is heated to a preset working temperature.

b. *Air removal*. Sufficient air is removed from the chamber and load to permit the subsequent attainment of the sterilization conditions and to ensure that the admission of EO will not result in a flammable or explosive mixture.

c. *Automatic leak test*. A vacuum leak test is carried out to ensure that air does not leak into the chamber. For sterilizers operating at pressures higher than 1.05 bar, a pressure leak test is also carried out to ensure that EO does not leak out of the chamber.

d. *Conditioning*. The load is heated and humidified to a preset sterilization temperature and humidity (at least 40% RH). The length of this stage will depend on the extent of any preconditioning.

e. *Gas injection*. Gas is admitted to the chamber until the operating pressure has been attained.

f. Ga*s exposure.* The temperature and gas pressure (or concentration) are maintained within limits throughout the chamber and load for a preset holding time.

g. *Gas removal*. Gas is removed from the chamber to reduce the concentration below the flammable limit when air is admitted at the end of the stage. Some gas will still be left in the load.

h. *Flushing*. Sufficient gas is removed from the load so that there is no longer a safety hazard to the operator when the sterilizer is unloaded. The flushing agent is normally filtered air or an inert gas.

i. *Air admission*. Air is admitted to the chamber until the pressure approaches atmospheric pressure.

j. *End of cycle*. If the door remains unopened for more than 15 min after the end of the air admission stage, the gas removal and/or flushing stages are automatically repeated to prevent an accumulation of gas in the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.9 Typical process times, including degassing after the cycle is complete, can range from 12 to 24 hours depending on the sterilization temperature, gas concentration and the nature of the load.

11.10 Since the sterilization process is ultimately dependent on chemical action, a routine microbiological test is required for each production load to confirm that sterilization conditions have been attained (see paragraph 11.43).

Safety precautions

11.11 EO presents hazards not found in conventional sterilizers. The gas is toxic, flammable and explosive. Extensive guidance on safety precautions to be followed in handling EO can be found in Appendix 3. See also 'Ethylene oxide sterilization section' (HBN 13 Supplement 1) published by NHS Estates.

NOTE: Management Executive Letter MEL(1995)48 modifies HBN 13 Supplement 1 for use in Scotland.

Product compatibility

11.12 EO sterilizers can be used to process heat-sensitive materials which cannot withstand low-temperature steam. They should not be used to process products which can be sterilized by alternative methods; that is by high-temperature steam, dry heat or LTSF.

11.13 A survey by the Central Sterilising Club showed that many items processed in hospital EO sterilizers carry only an intermediate infection risk (see Table 2 in Chapter 2) and LTS disinfection would have been safer and more appropriate. Examples include face masks, ventilator tubing, airways, breast milk expressors, plastic vaginal speculae, amniotic membrane perforators and eye patches. None of these items requires EO sterilization and some may be designated by the manufacturer as single-use only.

NOTE: Sterilization and disinfection of heat-labile equipment, by Central Sterilising Club 1986.

11.14 It is common practice to use EO to resterilize items such as cardiac catheters that are intended by the manufacturer to be used only once. While this may be justified on economic grounds, attention is drawn in paragraphs 2.22-2.25 to the difficulties in validating cleaning procedures for such items and the possible legal implications of reusing them. Users also should bear in mind that some medical devices designed for single-use may have been originally sterilized by radiation. In certain circumstances these may be weakened by subsequent exposure to EO and should therefore not be resterilized.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.15 Low-pressure EO is suitable for items such as certain flexible endoscopes and electronic equipment which would be damaged by exposure to an LTSF process.

11.16 Certain types of EO sterilizer, notably those employing EO diluted with carbon dioxide, operate at pressures up to 6 bar. Users should ensure that load items would not be damaged by exposure to such pressures.

11.17 Care should be taken that materials submitted for sterilization do not undergo undesirable reactions with EO. If doubt exists about this, it is advisable to contact the supplier of the gas.

Items that should not be processed by ethylene oxide

11.18 The following items should not be processed by EO:

a. items that could be sterilized by another process;
b. items which may be damaged by the conditions of temperature, pressure and chemical environment prevailing during the cycle;
c. medicinal products;
d. ventilatory and respiratory equipment;
e. soiled items;
f. plastic items previously sterilized by radiation;
g. items which may absorb and retain unacceptable quantities of EO residuals.

Design of the load

11.19 Packaging materials and methods should be selected which are compatible with the EO sterilization process and which maintain sterility and the quality of the contained product. Packaging should be designed to allow removal of air and penetration of both steam and EO.

11.20 Because a wide variety of EO processes are in use, packaging suitable for one EO sterilizer may not be suitable for another. For example, package seals may be weakened and possibly fail in a cycle with relatively high humidity and several large and rapid changes in pressure, where seals of the same type would have been satisfactory for a cycle employing less extreme conditions.

11.21 The extent to which packaging absorbs or adsorbs EO and its permeability to EO may have a major influence on the efficacy of the cycle and the subsequent aeration process. Cartons (shelf packs, transit cartons) may be convenient but they may increase the humidification time, the gas exposure time and subsequent level of EO residuals.

11.22 Because of the need to control humidity, the extent to which packaging absorbs moisture may have a major influence on the efficacy of the process

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

and must be considered before a satisfactory humidification stage can be demonstrated.

11.23 Process control is also a concern since packaging material that has become dehydrated may absorb excessive moisture during the conditioning phase; if this possibility were not recognised during validation the achieved cycle lethality may be adversely affected.

11.24 In practice, many of the packaging materials routinely used for steam sterilization in hospitals are equally suitable for EO. However, Users should be aware that because of the lower temperatures employed in the EO process a wider range of materials is available.

11.25 Paper bags or plastic/paper pouches are usually found to be the most convenient for small items. Polythene bags with gas exchange ports of Tyvek are also suitable.

11.26 Large procedure trays containing endoscopes or other heat-sensitive equipment may be wrapped in sheets of plain or crepe paper, or textiles. Moulded foam inserts may be used to provide mechanical protection.

11.27 Biological indicators should be placed in the load before preconditioning (see 11.43).

Performance qualification

11.28 PQ tests are required for loading conditions representing every production load. Decisions on which loading conditions require PQ tests should be made by the user in consultation with the Microbiologist and Test Person.

11.29 Because of the wide variety of items processed by EO, it is not always practicable to conduct PQ tests for every possible loading condition. Users are advised to categorise load items by the degree to which they can absorb and retain moisture and EO, and then ensure that loads are made up of items in the same category. For example, rubber absorbs EO readily, while electronic devices do not.

11.30 The amount of microbial contamination (the bioburden) after cleaning may need to be determined as part of the performance qualification process, though this is not normally required in hospitals where a wide range of items are to be sterilized and gas exposure times are calculated to be more than sufficient to deal with the maximum anticipated bioburden. Where such determinations are required they should comply with BS EN 1174.

Preconditioning

11.31 If EO sterilization is to be effective, it is essential that the humidity within any part of the load should not be less than 30% RH, and that there should be no free water within the chamber.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.32 To ensure that these extremes of humidity are not exceeded when sterilizing different types and sizes of load which have been stored in unknown ambient temperatures and humidity, it may be necessary to subject the load to a preconditioning treatment in a known environment. Preconditioning may be done within the sterilizer chamber before the start of the operating cycle, or in a purpose-built room or cabinet. Specifications for preconditioning rooms or cabinets can be found in Part 2 of this SHTM.

11.33 Preconditioning may not be necessary where workloads are small. In such cases the conditioning stage of the operating cycle may be satisfactory (see paragraph 11.8d). However, Users should note that the humidity instruments attached to the sterilizer may not be as reliable as those provided for a purpose-built preconditioning room or cabinet. For this reason, preconditioning is always recommended.

11.34 Within limits, the humidity within the chamber can be determined from the mass of steam injected, the pressure change within the chamber, the moisture absorbent characteristics of the load and the temperature and humidity of the load before it is placed in the sterilizer chamber. However, whenever preconditioning is to be done in the sterilizer chamber, the humidity should be by direct measurement (but see paragraph 11.46a) and within limits its value should be known for each cycle.

11.35 All packaged product within the preconditioning area should be identified. For each batch processed, the levels of the physical values achieved during preconditioning should be recorded. These should include the following.

a. the ambient temperature of the packaged product entering the preconditioning room;
b. the time when the packaged product enters the preconditioning room;
c. the time when the packaged product leaves the preconditioning room;
d. the temperature record for the period the packaged product is in the preconditioning room;
e. the humidity (RH) record for the period the packaged product is in the preconditioning room.

11.36 The temperature and humidity within the preconditioning area should be set to the same values that will prevail during the gas exposure time. The temperature within the load at the end of the preconditioning period should not deviate by more than ± 5°C from the nominal conditions within the area and the RH should not deviate by more than ± 15% RH from the nominal conditions in the area. The time taken to achieve these conditions during validation should be noted and used as the minimum specified for routine operations.

11.37 The preconditioning area should be subject to performance qualification. PQ should be performed with the preconditioning area in both fully loaded and typical partly loaded states and carried out with the loading patterns and pallet spacings specified in documented procedures.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.38 The reference position for monitoring temperature and RH during preconditioning should be that at which it is most difficult to achieve the desired conditions. Data for this routine monitoring should be reviewed before the load is released for sterilization.

11.39 The ambient temperature of items entering the preconditioning area should be at or above the minimum temperature specified during validation. It is not generally necessary to routinely determine the temperature of load items before preconditioning where the conditions of storage are known.

Selection of cycle variables

11.40 The EO concentration prevailing during the gas exposure stage will have been established during performance qualification. A concentration of at least 300 mg litre^{-1} is commonly used. Concentrations greater than 1200 mg litre^{-1} do not result in a substantial increase in the effectiveness of the sterilization process.

11.41 Apart from adjustment of flushing times, other cycle variables are preset and cannot be modified by the user.

Cycle monitoring and documentation

11.42 Each cycle should be noted in the sterilizer process log (see paragraph 3.11). The following information should be recorded for each load processed:

a. for preconditioning (if used), the temperature and humidity monitored and recorded from a position which can be related to that at which it is most difficult to achieve the specified conditions;

b. time of commencement and removal of load from preconditioning (if used) of each load;

c. time of commencement of the operating cycle;

d. chamber temperature and pressure during the operating cycle measured from a representative position within the chamber;

e. evidence that the gaseous sterilant has been admitted to the chamber;

f. a measure of the quantity of EO used or the concentration of EO in the chamber;

g. duration of the gas exposure time;

h. time, temperature, pressure changes (if any) and/or the operation of the air supply (if used) during aeration;

i. the results of the routine microbiological test.

11.43 A routine microbiological test should be carried out with every production load as described in Part 3 of this SHTM. Note that the full result of the test

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

will not be known until the biological indicators have been cultured for 7 days.

11.44 A batch process record should be generated for each production cycle. The batch process record will contain the following:

a. the temperature ("chamber temperature") recorded by a sensor in the coolest part of the chamber;

b. the pressure ("chamber pressure") recorded by a sensor in the chamber.

Chamber humidity

11.45 A load which has been preconditioned may lose moisture during the air removal stage of the operating cycle and steam may be injected during the conditioning stage (before gas injection) to maintain the moisture content at the specified level.

11.46 The humidity within the chamber should be monitored in one of two ways:

a. by direct measurement of RH. Many RH sensors are poisoned by absorption of EO and provision should be made either to isolate the sensor from the chamber atmosphere before EO is admitted, or to remove the sensor for degassing after the sterilization cycle is complete. Note that the RH as perceived by a sensor at a low pressure may be different from that measured at a higher pressure;

b. by monitoring the rise in temperature and pressure as steam is admitted; care should be taken to ensure that the measured values truly relate to RH and are reproducible. Details of the calculation are given in Part 3 of this SHTM: Appendix 2.

EO concentration

11.47 The pressure rise at gas injection provides the primary, though indirect, measure of the EO concentration in the chamber. The measuring equipment should have sufficient sensitivity to allow recordings of small quantities of gas which may be admitted throughout both the gas injection and gas exposure stages. Details of the calculation are given in Part 3 of this SHTM: Appendix 2.

11.48 Since the EO concentration is critical to the efficacy of the cycle, a second, independent system is required to confirm that the pressure rise is due to EO. Either of the following may be used:

a. monitoring the change in mass of the gas supply cylinder or cartridge;

b. metering the volume of gas delivered to the chamber.

11.49 Where a sterilizer is supplied from a disposable cartridge, it can be assumed that the entire contents of the cartridge are released into the chamber. However, it should not be assumed that the mass of the contents corresponds precisely to the manufacturer's stated value. As a matter of

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

routine, the cartridge should be weighed immediately before it is placed in the sterilizer and after it has been removed to establish the mass of gas consumed, and the results noted in the sterilizer process log.

Product release

11.50 The load may be released for degassing (see paragraph 11.52) provided that:

a. the preconditioning records are satisfactory;

b. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

c. the correct amount of EO has been injected into the chamber;

d. the chemical indicators used in the routine microbiological test show a uniform colour change;

e. the packaging is undamaged;

f. load items are visibly dry.

11.51 The load may subsequently be released as sterile provided that the microbial culture results of the routine microbiological test described in Part 3 of this SHTM are satisfactory and approved by the Microbiologist.

Degassing

11.52 Most, if not all, materials retain varying amounts of EO following sterilization. The residual EO in items for medical use should be reduced to a safe level, both for personnel handling the items and for the patient. Other compounds may also be present as reaction products of EO, such as ethylene chlorohydrin, and the concentration of these may also need to be reduced. Reference in this SHTM to reduction of residual EO should be read as applying equally to any other toxic reaction products which may be present.

11.53 Certain materials, such as polyvinyl chloride, silicone and rubber, are particularly absorbent and require longer degassing times. If not removed, residual EO will give rise to burning sensations and other irritant or toxic effects when the sterilized item is implanted or in contact with body tissue.

11.54 Permitted levels of EO residuals, and methods for their determination, are given in BS EN 30993: Part 7.

11.55 Reduction of residual EO occurs naturally as gas diffuses from the product into the surrounding air down the concentration gradient. Under normal ambient conditions this process may be very slow and significant amounts of EO may be present in the environment. For these reasons degassing by

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

storage under ambient conditions is not recommended; mechanical degassing should be used.

11.56 The time required for degassing depends on a number of factors:

a. the composition, form and mass of the items in the load;

b. the concentration of residual EO when the load is removed from the sterilizer (this will in part depend on the EO concentration and gas exposure time, but more importantly on the extent and nature of the flushing stage in the sterilizer);

c. the temperature at which degassing takes place;

d. the concentration of residual EO which is acceptable for the intended use of the product.

11.57 The time required under the prevailing conditions should be determined for each type of product as part of performance qualification. Where this is impracticable, such as where a sterilizer is used for low numbers of a great variety of items, the degassing process should be determined for the item which has the longest degassing time. This is likely to be the largest and most complex item made from polyvinyl chloride.

11.58 A validated and monitored degassing procedure should be followed. Degassing can be performed within the sterilizer or in a separate chamber or area (see Part 2 of this SHTM). The temperature profile and air flow rate during degassing should be monitored and recorded.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Troubleshooting

Failure of the routine microbiological test

11.59 Failure of the microbiological test shows that the prescribed sterilization conditions have not been attained. If the test itself appears to have been carried out correctly (the biological indicators should be checked to make sure the correct type has been used) and the batch process record is satisfactory, then the following possibilities should be considered.

a. The concentration of EO in the chamber was too low. There are several reasons why this might be.

   (i) Insufficient EO was admitted. This would normally lead to a fault indication and would be revealed by inspection of the chamber pressure record and the secondary method (mass or volume, see paragraph 11.48).

   (ii) Some of the EO was polymerised. Green streaks on the chamber walls near the inlet port suggest that liquid EO entered the chamber. The preheater should be checked.

   (iii) Some of the EO was absorbed into the load. This is improbable if performance qualification tests have been conducted and previous loads have been processed satisfactorily.

b. The humidity in the chamber was either too high or too low. Humidity is critical to the operation of EO sterilizers and even small deviations from the ideal level can have large effects on the efficacy of the cycle. Incorrect humidity is the single most common cause of failure. If the preconditioning records are satisfactory, suspicion should fall on the sterilizer humidifying system.

c. The loading condition is too great a challenge to the penetration of EO. This is unlikely if performance qualification has been satisfactory.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12. Operation of laboratory sterilizers

Introduction

12.1 This chapter gives guidance on the routine operation of high-temperature steam sterilizers ("laboratory sterilizers") designed to process materials and equipment for use in clinical laboratories.

12.2 These sterilizers are not suitable for processing either medical devices or medicinal products and are therefore not subject to the EU Directives discussed in Chapter 1.

Sterilization conditions

12.3 European Standards for medical devices and medicinal products require that for a product to be labelled "sterile", no more than one micro-organism should survive in 10^6 load items (see BS EN 556). There is no universally accepted probability of survival for laboratory purposes. In laboratory practice for make-safe loads, the high initial concentration of micro-organisms is considered to be balanced by a higher acceptable probability of survival than in items intended to be used on patients. This has allowed the standard sterilization conditions adopted for medicinal products and medical devices (see paragraphs 2.43-2.55) to be used for laboratory make-safe loads.

12.4 The same standards are also used for sterilizing culture media, fabrics and equipment and glassware; for these loads (but not for make-safe loads) times and temperatures may be reduced if necessary to minimise deterioration of the product. Account should also be taken of the contributory effect of high temperatures during the heat-up and cooling stages on the degradation of culture media constituents.

12.5 Examples of recommended sterilization conditions are shown in Table 9.

12.6 The effect of the initial cell population (bioburden) on the number of survivors after heating reinforces the need to reduce numbers by cleaning equipment and glassware before sterilization. In microbiology laboratories it is possible, with good laboratory practice and by using dehydrated culture media from reputable manufacturers, to ensure that there are minimal numbers of contaminating micro-organisms in media prepared for sterilization. However, in discard boxes to be subjected to a make-safe process, the numbers of micro-organisms present are inevitably several orders of magnitude greater and no re-treatment is possible to reduce the concentration of what may be very heat-resistant spores.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Safety precautions

12.7 Users should ensure that operational procedures are in accord with the safety guidelines set out in the HSC document ‘Safe working and the prevention of infection in clinical laboratories’ and the accompanying ‘Model rules for staff and visitors’.

Table 9: Recommended sterilization conditions for laboratory sterilizers

Name of operating cycle	Sterilization temperature [°C]	Maximum temperature [°C]	Minimum holding time [min]
Make-safe of small plastic discard (a)	134 126 121	138 130 125	3 10 15
Make safe of contained fluid discard (a)	134 126 121	138 130 125	3 10 15
Sterilization of culture media (pre-set cycle)	121 115	124 118	15 30
Sterilization of culture media (variable cycle)	102-134 121 (b)	 124	Up to 60 15
Disinfection of fabrics	134 126 121	138 129 124	3 10 15
Sterilization of glassware and equipment	134 126 121	138 129 124	3 10 15
Free steaming (variable cycle)	102-104 95 (b)	 98	Up to 60 15
Culture media preparator	121 115	124 118	30 15

a. All bands for make-safe are 4 degrees wide to conform with BS 2646: Part 3.

b. Although the cycle is variable, this temperature band should be used for testing purposes.

12.8 The COSHH Regulations 1999 introduce new controls on biological agents which are of relevance to users of laboratory sterilizers.

Hazards

12.9 Due to the wide variety of loads processed in laboratory sterilizers, the range of potential hazards is wider than for a typical clinical sterilizer (see paragraph 2.10). Additional hazards may include:

a. spillage of biohazardous material;

b. spillage of hot material;

c. spillage of corrosive substances;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. vapour from volatile chemicals.

12.10 Access to the loading area should be limited to personnel aware of the hazards from potentially infective material. The loading position should not be obstructed.

12.11 All materials awaiting sterilization should be placed so they cannot be overturned, spilled or damaged.

12.12 Loading and unloading procedures should be designed to avoid health hazards and also injuries to personnel by the elimination of awkward lifting positions and excessively heavy load containers (see paragraph 2.8). Heavy loads should not be lifted into or out of vertically mounted chambers by personnel of unsuitable build or strength. Consideration should be given to the provision of mechanical assistance.

Operating procedures

12.13 A written standard operating procedure based on the manufacturer's instructions and local conditions of use should be adopted and should include the following:

a. a statement specifying the safe operating limits of the sterilizer including the maximum pressures and temperatures for safe operation;

b. a statement that operators should be instructed to note and report any defects or unusual or out-of-range conditions to their supervisor;

c. training requirements for the operators of the sterilizer and a statement that those unfamiliar with the equipment are forbidden to operate it unless supervised, or until they are considered competent in its use;

d. maintenance requirements: the scope of user maintenance should be defined and restricted to cleaning, functional checks and any user safety checks recommended in the instruction manual.

12.14 Operating instructions should always be readily accessible and users should ensure that they are followed.

12.15 Certain laboratory sterilizers are provided with a switch to override the thermal door-lock during the cooling stage of the cycle (see Part 2 of this SHTM). The switch is protected by a key, code or tool which is not available to the operator. The responsibility for the operation of the thermal door-lock override should be assigned to the user or other senior member of the laboratory staff. The override should only be used if all the implications of such action are documented and understood.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operating cycles

12.16 Operating cycles recommended in this SHTM are as follows:

a. make-safe of small plastic discard;
b. make-safe of contained fluid discard;
c. sterilization of culture media (preset or variable cycle);
d. disinfection of fabrics;
e. sterilization of glassware and equipment;
f. free steaming.

12.17 The specialised sterilizer known as a culture media preparator is also discussed.

12.18 Sterilizer loads should be carefully segregated to ensure that the appropriate cycle is selected for each type of load. Particular care should be taken to ensure that culture media, discard, glass containers with caps fitted, and contained fluid are processed in sterilizers fitted with a thermal door-lock, demonstrated to be effective on these cycles (see Part 2 of this SHTM).

12.19 Materials processed in laboratory sterilizers can be either “clean” or “dirty”. Clean work is material which will be used within the laboratory, such as culture media, tubing and filters. Dirty work is discard material which is to be made safe. In larger laboratories, separate sterilizers are often designated for clean and dirty work.

12.20 The discovery of non-sporing infective agents with an increased resistance to chemical and heat treatment (“slow viruses”, “prions”, “TSE agents”) has led to the need for increased temperatures and holding times for treatment of material from a suspected case of infection by these agents. None of the standard cycles described here is effective in inactivating such agents. Advice can be found in Appendix 2.

Make-safe of small plastic discard

12.21 This cycle corresponds to the “make-safe” cycle specified in BS 2646. It is designed to sterilize infected material held in plastic containers not exceeding 50 ml in volume. Examples of such containers include Petri dishes, specimen bottles and other small plastic items intended for disposal.

12.22 Although the containers would normally be unsealed, the limits on volume ensure that any fluid held in a sealed container does not present an explosion hazard when the door is opened at the end of the cycle. Glass containers and larger plastic containers should be processed with the make-safe cycle for contained fluid discard (see paragraph 12.30). Items of unknown content should likewise be treated as contained fluid discard.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.23 Items made from polystyrene, such as plastic Petri dishes, start to soften at around 70°C. Any air remaining in the chamber at that point may become trapped as bubbles within the melting plastic and prevent complete sterilization. The hardened plastic mass removed at the end of the cycle may then contain pockets of viable micro-organisms that may cause a health hazard if the plastic is subsequently broken. Users should therefore ensure that the air-removal stage of the cycle is substantially complete before the load temperature attains 70°C. That is why plastic Petri dishes are specified for the small-load and full-load thermometric tests described in Part 3 of this SHTM.

12.24 Items for making-safe should be placed in a discard box as specified in Part 2 of this SHTM. It is important that the box is of the type used for performance qualification, otherwise the specified sterilization conditions may not be achieved.

12.25 Discard should be stored in the box at the work station for later sterilization. Once in the box, items should not be handled until after they have been made safe. They should not be transferred from one box to another. The box and contents should be sterilized together.

12.26 Discard should be enclosed when the box is moved. Loose-fitting lids are satisfactory for transport within a laboratory. Alternatively, the discard material may be placed in a discard bag (see paragraph 12.27) inside an open box, providing the neck of the bag is closed before the box is moved. Whenever discard material is transported outside the laboratory suite a sealed and locked lid should be fitted. The lid should be opened or removed before the cycle begins and sterilized along with the box.

12.27 Discard bags, if used, should always be contained in a discard box and opened widely before sterilization to permit the removal of air and the penetration of steam. The open mouth of the bag should not be folded back over the rim of the box, since this would impede the removal of air from the space between the bag and the box. Bags with identification markings for discard material are available which are designed to melt at 134°C to assist air removal.

12.28 Discard boxes awaiting sterilization should not be stored in the loading area.

12.29 Load temperature probes should not be inserted into discard loads. Any probes provided in the chamber should be stowed in a safe, fixed position, usually on a bracket provided for this purpose.

Make-safe of contained fluid discard

12.30 This cycle is a variant of the “liquids sterilization” cycle specified in BS 2646. It is designed to make-safe infected material in sealed glass containers of any size or sealed plastic containers of volume greater than 50 ml.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.31 While essentially the same as the culture media cycle (paragraph 12.35), higher sterilization temperatures are preferable. Lower sterilization temperatures should only be used if plastic containers are to be processed.

12.32 Fluid containers should be placed in discard boxes to prevent contamination of the chamber if a bottle breaks during the cycle (see paragraph 6.7 about pressure inside bottles).

12.33 A risk assessment should be made before corrosive chemicals or materials and chemicals (including disinfectants) likely to produce harmful vapour are processed. Such materials should be enclosed in a sealed, unbreakable container, preferably of metal.

12.34 Load temperature probes should not be inserted into discard loads. Any probes provided in the chamber should be stowed in a safe, fixed position, usually on a bracket provided for this purpose.

Sterilization of culture media (preset or variable cycle)

12.35 This cycle is a variant of the “liquids sterilization” cycle specified in BS 2646. It is designed to sterilize culture media in open or sealed containers.

12.36 Since culture media are normally damaged by sterilization at 134°C the maximum sterilization temperature is set at 121°C.

12.37 A variable cycle, in which combinations of sterilization temperature and holding time can be set by the operator, is necessary for some heat-labile products. It is normally provided in addition to the preset culture media cycle.

12.38 The culture media cycle is also suitable for disinfecting unwrapped equipment, such as tubing sets, where a glassware and equipment cycle is not available (see paragraph 12.48).

12.39 Culture media are particularly sensitive to heat, the degree of deterioration being related to the time the medium is maintained above the sterilization temperature. The heating and cooling stages also contribute significantly to this deterioration, so heating and cooling times should be as short as possible. Large volumes of fluids will heat up and cool down slowly, therefore volumes of fluid should be kept small; a maximum container volume of 500 ml is recommended.

12.40 Agar-based media take longer to heat up than water-based media; this differential is greater the larger the volume. When media are to be sterilized in volumes of over 100 ml, agar-based and water-based products should be processed separately.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.41 Loads should be designed to process containers of similar size. For example:

a. up to 100 ml;

b. 101 ml to 1000 ml;

c. 1001 ml to 3 litre.

12.42 Containers should be loosely capped unless they are specifically designed to be sealed. However, sealing bottles can increase the likelihood of an explosion during sterilization (see paragraph 6.6 about pressure inside bottles) and extends the cooling time.

12.43 A fault may result in contaminated or over-heated culture media. After a fault, a careful assessment should be made before the batch is reprocessed or discarded.

Disinfection of fabrics

12.44 This cycle is a variant of the “glassware and equipment” cycle specified in BS 2646. It is designed to disinfect (but not sterilize) fabric materials such as towels, clothing, wrapped animal bedding, and other porous materials.

12.45 If the fabrics are required to be sterile and dry at the end of the cycle, a machine complying with the performance requirements for a clinical porous load sterilizer should be specified. This will require validation and periodic testing in accordance with the schedule for porous load sterilizers in Part 3 of this SHTM.

12.46 The cycle differs from the glassware and equipment cycle (see paragraph 12.48) in that more pressure pulses will be required to remove air from the load.

12.47 The fabrics cycle is also suitable for sterilizing empty glassware without caps and for disinfecting wrapped tubing and wrapped filters (but see paragraph 12.49).

Sterilization of glassware and equipment

12.48 This cycle corresponds to the “glassware and equipment” cycle specified in BS 2646. It is designed to sterilize clean, empty glassware (without caps) and equipment such as tubing and filters. Loads must not contain any fluids.

12.49 Some microbiological filter membranes may be damaged by the rapid fluctuations in pressure used by an active air removal system, and it may be necessary to provide a separate filter cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Free steaming

12.50 This cycle is not specified in BS 2646. It is designed to melt solidified agar by exposing it to steam near atmospheric pressure. It is normally a variable cycle. If the workload is heavy, this will not be a cost-effective way of using a sterilizer and a Köch steamer may be more suitable.

Culture media preparator

12.51 Many of the problems which relate to sterilizing culture media can be solved by the use of small sterilizers in which the media constituents are placed directly into the chamber thus avoiding the use of glass containers and their attendant hazards. Since these small machines have a unique function, their design is specialised in comparison with other laboratory sterilizers and BS 2646 is not applicable (see Part 2 of this SHTM).

12.52 The manufacturer's recommendations on operation should be followed.

Performance qualification

12.53 Some loads processed in clinical laboratories may not be represented by the reference loads used in the commissioning tests described in Part 3 of this SHTM. In these cases, thermometric PQ tests should be undertaken to establish master process records for these loads.

Product release

12.54 The load may be released for use provided that:

a. during the whole of the cycle the values of the cycle variables as shown on the batch process record are within the permitted tolerances marked on the master process record established during performance qualification;

b. not more than one container (or 1%, whichever is the greater) has burst or broken.

12.55 The load should be examined for damaged containers. The occasional broken bottle or bag may be acceptable provided intact containers have not also been damaged.

12.56 Discard for disposal outside the laboratory must be safe to handle.

12.57 Other materials processed in the sterilizer will be used in the laboratory. "Fit for use" should be defined by the user.

12.58 Blooming of plastic containers is a surface effect that does not harm the container or the contents. The user should decide whether blooming is acceptable.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Troubleshooting

Faults on make-safe cycles

12.59 A written procedure based on a risk assessment should be established for dealing with a fault on a make-safe cycle, taking into account the nature of the load. The usual practice is to decontaminate the sterilizer by flushing the chamber with steam. Where this is not possible, the user should proceed on the advice of the Laboratory Safety Officer. The guidelines given in HSG(93)26, 'Decontamination of equipment prior to inspection, service or repair', should be followed.

12.60 When considering the appropriate course of action, users should note the following:

a. the Laboratory Safety Officer should be notified before any attempt is made to open the sterilizer;

b. chamber condensate should be considered to be contaminated with viable micro-organisms;

c. disinfection of the chamber and/or pipework should not involve prolonged contact with disinfectants corrosive to metal;

d. a contaminated sterilizer should never be removed from the laboratory for repair.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13. Reporting of incidents

Introduction

13.1 The general framework for the reporting of adverse incidents and defective equipment in the NHS in Scotland are set out in MEL(1995)74.

13.2 Management should designate, for each sterilizer, a responsible person to act as liaison officer for the reporting of incidents. For the purposes of this SHTM, the user is assumed to fill this role.

13.3 The user should be familiar with the reporting procedures and with statutory reporting requirements. Training may be required.

13.4 Operators and others concerned with the operation of sterilizers should know what action to take in the event of an incident or failure.

13.5 The user should ensure that a sufficient supply of the correct reporting forms is available at all times.

13.6 The Authorised Person should advise, for each type of sterilizer, which types of defects are to be considered as serious. The list should include all defects which may result in failure to sterilize or danger to personnel or damage to the product.

13.7 If a serious defect occurs, the sterilizer should be withdrawn from service and should not be used until any necessary repairs have been made and a repeat validation has been carried out (see Part 3 of this SHTM). If the defect involves a pressure vessel, an inspection by the Competent Person (Pressure Systems) is required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Department of Health reporting procedures Annex A

General guidance

Purpose of the reporting system

1 An adverse incident is an event which adversely affects, or has the potential to effect, the health and safety of patients, users or other persons. Local incidents may often have implications for other healthcare services. IT IS ESENTIAL, THEREFORE, THAT ALL ADVERSE INCIDENTS AND DEFECTIVE EQUIPMENT ARE REPORTED PROMPTLY. Serious deficiencies in the technical performance of equipment should also be reported, as should any observation which gives cause for concern regarding safety, even when an actual incident has not occurred. The central collation of adverse incident reports is essential for the identification of trends which may result in the issue of warnings to users of potentially hazardous equipment or unsafe procedures. The term “equipment” is taken to include any items, device, supplies, service, product, system, or plant as detailed in Annexes B and C.

Health and Safety Executive

2 Under their statutory powers, the Health and Safety Executive (HSE) or Local Authority Inspectors may:

- identify inadequacies in a product’s design;
- issue instructions for use, or manner of use;
- make observations and recommendations.

If any action by the HSE or Local Authority on NHS premises might have implications for other users and/or patients, staff, visitors or contractors, it should be reported to ***Scottish Healthcare Supplies (SHS)***.

Reporting

3 Reports should be submitted in accordance with:

Annex B: reports relating to all *medical equipment*: including medical devices, hospital laboratory equipment, medical supplies (excluding medicinal products) and certain dietary products;

Annex C: Reports relating to *estates equipment*: engineering plant, installed services including piped medical gas and medical scavenging systems, buildings and building fabrics, vehicles.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

All adverse incidents etc. relating to products in Annexes B and C should be reported to Scottish Healthcare Supplies in full at the following address:

Incident Reporting and Investigation Centre (IRIC)
Scottish Healthcare supplies
Trinity Park House
South Trinity Road
EDINBURGH
EH5 3SH

Daytime help and report line: 0131 551 8333
Emergency: 0131 552 6380
Fax: 0131 552 6535

Procedures to be followed and information to be supplied

4 The initial report of an incident should contain as much essential detail as available. However, it should never be delayed on this account and serious cases should be reported by the fastest means possible. **All oral reports should be supported in writing**, preferably using the standard Adverse Incident Report Form (Annex D). Copies of this form are available form Scottish Healthcare Supplies (SHS).

5 All material evidence should be labelled and kept secure, under the charge of a responsible officer. This includes the equipment and, where appropriate, packaging or other means of batch identification. The equipment should not be interfered with in any way except for safety reasons or to prevent its loss. If necessary, a record should be made of all readings, settings and positions of switches, valves, dials, gauges and indicators, together with any photographic evidence and eye witness reports. In serious cases, this record should be witnessed, and the witness should also make a personal written record.

6 Defective items should not be allowed to be repaired or returned to the supplier or discarded before an investigation has been carried out. In addition, items should not be cleaned (but see paras. 11-12 below). The manufacturer or supplier of a defective product should be informed promptly, and may be allowed to inspect the product if accompanied by an officer from the Health Board, NHS Trust or other NHS body, or SHS, with knowledge of the product so as to prevent tampering or false claims. The HSE may also wish to inspect the equipment. In the case of a large batch of consumable items may be possible to pass samples to the manufacturer if this will aid the investigation. However, the manufacturer must not be allowed to exchange, interfere with or remove any part of the product if this would prejudice the investigations of SHS or other official bodies.

7 Where clinical need requires equipment to be kept in use, and the defective part(s) are clearly identifiable and removable, they may be removed, secured and labelled for later inspection, and the equipment repaired for re-use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8 Where a manufacturer wishes to investigate a defective, or possible defective, CE marked medical device, this should be reported to SHS who will seek guidance from the medical Devices Agency (the UK Competent Authority). It should be noted that from June 1998 *all* medical devices must be CE marked before they can be placed on the market, in accordance with the medical Device Regulations. Active implantable medical devices however, *must* be CE marked as from 1 January 1995.

9 As far as “estates and associated equipment” incidents are concerned as set out in Annex C, the SHS will oversee any necessary investigations (using private contractors as necessary) and liase with the NHS in Scotland Property and Environment Forum.

Notification system

10 Where the results of investigations have implications for other users a Hazard Notice, Safety Action Notice or other safety warning may be issued. A sample *Hazard Notice* is given in Annex F and a sample *Safety Action Notice* is given in Annex G. General Managers and Chief Executives are responsible for ensuring adequate distribution systems for these publications are in place.

Handling of contaminated products

11 Requirements for the forwarding of contaminated products for investigation are detailed in:

- SHHD letter DGM (1987) 66 dated 6 November 1987 (updated guidance to be issued soon).
- Safety Action Bulletin No 63 SAB (90) 61 issued September 1990.
- Hazard Notification HAZ 1991/007 issued 11 March 1991.

All products, devices and sample which have been or could have been in contact with blood, other bodily fluids of pathological samples must be accompanied by a Contamination Status Certificate when being passed to SHES or the supplier/manufacturer for examination. The Contamination Status Certificate should be presented external to the packaging which contains the potentially contaminated item in order that the certificate may be examined before opening the packaging. The requirement also applies to unused disposable items except where packaging seals are unbroken. A sample of a suitable Contamination Status Certificate is reproduced as Annex E and may be copied or adapted for local use.

12 Advice should be sought from the SHS Incident Reporting and Investigation Centre prior to the sending or transporting of contaminated products for examination by SHS or the supplier/manufacturer. Where possible, products should be decontaminated before being handled. This should be carried out using a method recommended by the manufacturer to avoid destroying vital evidence. It is illegal to send contaminated products through the post.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Other action/responsibilities

13 This reporting system does not replace the duty of local staff to take other action as required legally, by local procedures or in line with other national requirements eg:

- Preventing further use of equipment which may be defective;
- Reporting to particular local NHS officers (eg. Radiation Protection Advisers);
- Reporting notifiable incidents to the Health and Safety Executive under the Reporting of Injuries, Disease and Dangerous Occurrences Regulations 1995, and the Ionising Radiations Regulations 1999;
- Reporting to the Procurator Fiscal in the case of a fatal accident;
- Informing the manufacturer of a serious adverse incident involving CE marked equipment to assist him in fulfilling his obligations under certain EC directives adopted as UK regulations.

Food

14 Problems with food, other than special dietary products, should be reported to:

- Scottish Executive Health Department
- Scottish Executive Rural Affairs Department
- Scottish Healthcare Supplies, Contracts Branch for Food which is on central contract to the NHS.

Drugs

15 Guidance on reporting problems involving medicinal products (drugs alerts) is contained in NHS Circular 1991 (GEN) 25 issued September 1991 and Circular 1993 (GEN) 16 issued on 14 December 1993.

Notes

16 Official notifications to the HSE which are copied to SHS under the terms of this circular should be clearly stated as such. Notification to SHS does not count as, or substitute for any other report.

17 If a patient dies unexpectedly, the clinician in charge of the case should report the death immediately to the Procurator Fiscal. Pending instructions from the Procurator Fiscal or his officer, any implicated product must not be interfered with in any way unless this is necessary for safety or to prevent the loss of samples or material evidence. Although the manufacturer of suspect equipment should be informed immediately, neither he nor his agent should be allowed to inspect the equipment or remove any part of it without the Procurator Fiscal's prior agreement. SHS may be required to impound implicated equipment on behalf of the Procurator Fiscal.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18 As a result of regulations implementing EC directives, manufacturers of CE marked devices will be required by law to report to the UK Competent Authority (Medical Devices Agency) any serious incident (ie. death or injury) involving their products. The first directive applies to Active Implantable Medical Devices (for example, implantable cardiac pacemakers), and the UK regulations came into force on 1 January 1993. The second directive covers a much wider range of Medical Devices and the UK regulations came into force for a transitional period commencing on 1 January 1995 and became mandatory in June 1998. The EC directive on In Vitro Diagnostic Devices 98/79/EC is implemented by the In Vitro Diagnostic Medical Devices Regulations 2000 (SI 1315).

Annex B

Reports relating to all medical devices, hospital laboratory equipment, medical supplies (excluding medicinal products) and certain dietary products

Reportable cases

1 Adverse incidents involving medical equipment may arise due to short comings in the equipment itself, user practice, service, maintenance, modification or adjustments, management procedures, instructions for use or environmental conditions.

2 A report should be sent if equipment is involved in one of the following:

- death;
- injury;
- deterioration in health;
- unreliable test results leading to inappropriate treatment or medication;
- where there is a potential for any of the above to occur.

NOTE: Single incident, when added to other information or reports, might indicate a national or international problem.

Product categories

- **Imaging and Radiotherapy Equipment**: X-Ray, CT, MRI, ultrasound, nuclear medicine, image intensifiers, fluoroscopy, film processors.
- **Electromedical Equipment**: infusion pumps, fluid warmer, automatic, tourniquets, physiological monitoring and measurements, and equipment used in: dialysis, cardiology, physiotherapy, opthamology, audiology, speech therapy, electrotherapy, endoscopy , obstetrics.
- **Life Support Equipment**: anaesthetic machines, ventilators, humidifiers, resuscitators, defibrillators, pacemakers, suction and oxygen equipment, cardiac bypass equipment, baby incubators, radiant warmers, breathing systems.
- **Operating Department Equipment**: microscopes, operating tables, trolleys, patient transfer apparatus, heating and cooling pads, blood warmers, nerve stimulators.
- **Powered Surgical Equipment**: Diathermy, drills, saws, lasers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

- **General Ward Equipment**: mobile examination lamps, powered and non-powered beds, ripple mattresses, pressure garments, thermometers, blood pressure monitors, weighing machines, diagnostic sets, patient hoists and lifting apparatus.
- **Dental and Chiropody Equipment**: instruments, chairs, curing lights, drills, water/air/suction.
- **Laboratory Equipment**: analysers, centrifuges, media preparators, safety cabinets, warming cabinets, incubators, refrigerators, test equipment.
- **Cleaning and Sterilisation Equipment**: autoclaves, sterilisers (steam, gas, chemical, dry heat), stills, disinfectors, instrument and equipment washers.
- **Aids for the Disabled**: wheelchairs, walking aids.
- **Implants**: heart valves, pacemakers, defibrillators, infusion pumps, orthopaedic prostheses.
- **Post Mortem Equipment**.
- **Single Use Devices**: syringes, needles, administration sets, catheters, dressings, sutures, etc.
- **Orthotic and Prosthetic Appliances**.
- **Certain Dietary Products**: enteral food preparations, ready-to-feed (RTF) preparations solely for hospital use.
- **Electrical Interference Problems**: involving any of the above.
- **Aspects of Control of Substances Hazardous to Health (COSHH)**: involving any of the above.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Annex C

Reports relating to estates systems and equipment: engineering and plant, installed services including piped medical gas and medical gas scavenging systems, buildings and building fabrics, vehicles

Reportable cases

1 Adverse incidents in estates equipment may arise due to shortcomings in the equipment itself, user practice, service, maintenance, modifications or adjustments, management procedures, instructions for use or environmental conditions.

2 A report should be sent if equipment is involved in one of the following:

- death;
- injury;
- deterioration in health;
- damage;
- where there is a potential for any of the above to occur.

NOTE: Single incident, when added to other information or reports, might indicate a national or international problem.

Product categories

- **Buildings and Grounds**: components, services and plant used in maintenance and construction.
- **Engineering Plant and Services of all Types**: lifts, water systems, boilers and steam systems, electrical generators, heating, ventilation, air-conditioning, water, drainage, electrical systems including high voltage installations and any other fixed plant (but not fixed medical equipment).
- **Fire Protection Installations and Equipment**.
- **Transport**: vehicles and equipment.
- **Equipment**: in laundries, catering departments, work shops and any plant or equipment used for maintenance or cleaning.
- **Piped Medical Gas and Vacuum Installations**: oxygen, medical air etc, vacuum insulated evaporators and anaesthetic scavenging systems.
- **Fixed Luminaries**: including operating and examination lamps.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

- **Communications Equipment**: telephones (including radio telephones), nurse call, paging, alarms, building management systems, radio and television, IT structures cabling/data, VHF/UHF communication equipment.
- **Lighting Protection and Anti-Static Precautions**.
- **Incinerators and Waste Disposal Systems**.
- **Fuel Supply and Storage Systems**.
- **Fume Cupboards and Microbiological Safety Cabinets**: (installation aspects only), ductwork and interaction with ventilation systems.
- **Electrical Interference Problems**: involving any of the above.
- **Legionella Protection Equipment and Systems**.
- **Building Environmental Aspects of Control of Substances Hazardous to Health (COSHH)**: involving any of the above.

Urgent reports

are required in the respect of:

- An explosion or sudden fracture of a pressure vessel, pressurised system or steam/high pressure hot water main.
- A major electrical explosion eg. of power transformers or high voltage switchgear.
- A runaway and crash of a passenger lift.
- Piped medical gas system malfunction.
- Fire alarm system failure.

ADVERSE INCIDENT REPORTING

PRODUCT CATEGORIES

Reports relating to all medical equipment including medical devices, hospital laboratory equipment, medical supplies (excluding medicinal products) and certain dietary products.

- Imaging and Radiotherapy equipment; *X-Ray, CT, MRI, ultrasound, nuclear medicine, image intensifiers, fluroscopy, film processors.*
- Electromedical equipment; *infusion pumps, fluid warmers, automatic tourniquets, physiological monitoring and measurement, dialysis, cardiology, physiotherapy, ophthalmology, audiology, speech and language therapy, electrotherapy, endoscopy, obstetrics.*
- Life support equipment; *anaesthetic machines, ventilators, humidifiers, resuscitators, defibrillators, pacemakers, suction and oxygen equipment, cardiac bypass equipment, baby incubators, radiant warmers, breathing systems.*
- Operating Department equipment; *microscopes, operating tables, trolleys, patient transfer apparatus, heating and cooling pads, blood warmers, nerve stimulators.*
- Powered surgical equipment; *diathermy, drills, saws, lasers.*
- General ward equipment; *mobile extension lamps, powered and non-powered beds, ripple mattresses, pressure garments, thermometers, blood pressure monitors, weighing machines, diagnostic sets, patient hoists/lifting apparatus.*
- Dental and Chiropody equipment; *instruments, chairs, curing lights, drills, water/air suction.*
- Laboratory equipment; *analysers, centrifuges, media preparators, safety cabinets, incubators, warming cabinet, refrigerators, test equipment.*
- Cleaning and sterilisation equipment; *autoclaves, sterilisers (steam, gas, chemical, dry heat) stills, disinfectors, instrument and equipment washers.*
- Aids for the disabled; *wheelchairs, walking aids.*
- Implants; *pacemakers, defibrillators, infusion pumps, orthopaedic prostheses, heart valves.*
- Post Mortem equipment;
- Single Use Devices; *syringes, needles, administration sets, catheters, dressings, sutures, etc.*

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

- Orthotic and Prosthetic Appliances;
- Certain Dietary products; *enteral food preparations, ready-to-feed (RTF) preparations solely for hospital use.*
- Electrical interference problems; *involving any of the above.*
- Aspects of Control of Substances Hazardous to Health (COSHH)*; involving any of the above.*

Reports relating to estates systems and equipment:- engineering systems and plant, installed services including piped medical gas and medical gas scavenging systems, building and building fabrics, vehicles

- Buildings and Grounds; *components, services and plant used in maintenance and construction.*
- Engineering Plant and Services of all types; *lifts, water systems, boilers and steam systems, electrical generators, heating, ventilation, air conditioning, water drainage, electrical systems including high voltage installations and any other fixed plant (but not fixed medical equipment).*
- Fire Protection installations and equipment;
- Transport; *vehicles and equipment.*
- Equipment; *in laundries, catering departments, work shops and any plant or equipment used for maintenance or cleaning.*
- Piped medical Gas and Vacuum installations; *oxygen, medical air etc., vacuum insulated evaporators, anaesthetic gas scavenging systems.*
- Fixed Luminaires; *including operating and examination lamps.*
- Communication equipment*; telephones,(including radio telephones) nurse call, paging, alarms, building management systems, radio and television, IT structured cabling/data, VHF/UHF communication equipment.*
- Lightning Protection and Anti-static precautions;
- Incinerators and waste disposal systems;
- Fuel Supply and Storage systems;
- Fume Cupboards and Microbiological Safety Cabinets (installation aspects only) ; *ductwork and interaction with ventilation systems;*
- Legionella Protection Equipment and Systems;
- Electrical interference problems; Involving any of the above.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

- Substances Hazardous to Health (COSHH); Involving any of the above.

13.12 The user is recommended to display a notice on or near each sterilizer setting out the appropriate reporting procedure.

Statutory reporting procedure

13.13 The Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1995 place responsibilities on employers to report certain incidents and dangerous occurrences to the local office of the Health and Safety Executive (HSE). The action to be taken following any incident with a sterilizer will need to be detailed in hospital procedures to ensure compliance with this legal requirement.

13.14 The user must notify HSE immediately, normally by telephone, if any of the following should occur:

a. any fatal injuries to employees or other people in an accident connected with the operation of the sterilizer;

b. any major injuries to employees or other people in an accident connected with the operation of the sterilizer;

c. any of the dangerous occurrences listed in the Regulations.

13.15 The user must send a written report to HSE within seven days of any incident including:

a. any of the notifiable incidents listed above;

b. any other injury to an employee which results in their absence from work or being unable to do their normal work for more than three days;

c. any of the cases of ill health listed in the Regulations.

13.16 A record must be kept of any injury, occurrence or case of disease requiring a report. This should include the date, time and place, personal details of those involved and a brief description of the nature of the event.

13.17 Examples of dangerous occurrences applicable to sterilizers include:

a. the explosion, collapse or bursting of any closed vessel;

b. electrical short circuit or overload causing fire or explosion;

c. any explosion or fire resulting in the suspension of normal work for more than 24 hours;

d. an uncontrolled or accidental release or escape of any pathogens or substance from any apparatus or equipment;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

e. any incident where breathing apparatus malfunctions in such a way as to deprive the wearer of oxygen.

13.18 Examples of reportable diseases applicable to sterilizers include:

a. poisoning by ethylene oxide;

b. any illness caused by a pathogen.

13.19 Full details may be found in the guidance which accompanies the Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1995.

13.20 Incidents and dangerous occurrences which are reported to HSE should also be reported either to the Scottish Healthcare Supplies, as appropriate, by telephone during the first working day after the incident and then followed by a written report.

Glossary

The following list of definitions has been adopted in SHTM 2010 and used in Part 2. Certain pressure terms have been modified to comply with the requirements of BS EN 764. Paragraph references indicate where further information may be found in Part 2. Cross references to other terms are shown in bold type. References in parentheses at the end of definitions are to this part of SHTM 2010.

absolute pressure	pressure for which the zero value is associated with absolute vacuum.
aeration	a part of the **sterilization process** during which **sterilant gas** and/or its reaction products desorb from the **load** until predetermined levels are reached. See **degassing** and **flushing**.
air detector	a device used to determine that sufficient air or other **non-condensable gases** have been removed from the **chamber**.
allowable pressure	of a pressure vessel, a limit to the **operating pressure** specified for safety reasons. See **design pressure**.
automatic controller	a device that, in response to predetermined **cycle variables**, operates the **sterilizer** sequentially through the required stages of the **operating cycle**.
batch process record (BPR)	a permanent record of one or more **cycle variables recorded** during a complete **operating cycle** by instruments fitted permanently to the **sterilizer**.
Biological indicator	a device, consisting of an inoculated carrier contained within a primary pack, designed to test the efficacy of an **operating cycle**.
Bowie-Dick test	a test, used mainly with porous load sterilizers, to show whether or not steam penetration into a **standard test pack** is even and rapid.
cartridge	in **EO sterilizers**, a portable, single-use, simple vessel containing **sterilant** gas under pressure from which the gas is delivered by puncturing the cartridge.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

chamber	the part of the **sterilizer** in which the **load** is placed.
chamber exhaust ventilation (CEV)	a ventilation system designed to extract gas from the **chamber** of an **EO sterilizer** supplied from a **cartridge**.
chamber furniture	shelves, pallets, loading trolleys and other fixed or movable parts that support the **load** within the **chamber**.
chamber temperature	the lowest temperature prevailing in the **chamber**.
chemical indicator	a device designed to show, usually by change of colour, whether specified values of one or more **cycle variables** have been attained.
clinical sterilizer	a **sterilizer** designed to process **medical devices** or **medicinal products** to be used in the clinical care of patients.
commissioning	the process of obtaining and documenting evidence that equipment has been provided and installed in accordance with the equipment specifications and that it functions within predetermined limits when operated in accordance with the operational instructions.
conditioning	in **EO sterilizers**, the treatment of a **load** within the **operating cycle**, but prior to **sterilization**, to attain a predetermined temperature and humidity throughout the load.
contained fluid discard	discard material held in sealed glass containers or sealed plastic containers of volume greater than 50 ml (see **small plastic discard**).
cooling stage	the period of the **operating cycle**, after the **holding time** has been completed, during which the **load** remains in the **chamber** while the load cools to a safe temperature.
culture media preparator	a specialised **laboratory sterilizer** designed for the **sterilization** and dispensing of culture media.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

cycle complete	recognition by the **automatic controller** that the preset values for the **cycle variables**, necessary for a successful **operating cycle**, have been attained and that the sterilized **load** is ready for removal from the **chamber**.
cycle variables	the physical properties, for example time, temperature, pressure, humidity and gas concentration, that influence the efficacy of the **operating cycle**.
dedicated steam supply	a supply of steam produced by a generator for the exclusive use of a **sterilizer** or group of sterilizers.
degassing	1. in **LTSF** and **EO sterilizers**, an **aeration** procedure in which **sterilant** gas and its reaction products are desorbed from the **load** by defined treatment outside the **sterilizer** after completion of the **operating cycle**. 2. a pre-heating treatment of boiler feed-water to reduce the amount of **non-condensable gases** in the steam supply.
design pressure	of a pressure vessel, the pressure chosen for the design calculations. See **operating pressure**, **allowable pressure**.
discard	laboratory material which is, or may be, infected by micro-organisms and is to be made safe before disposal.
discard bag	a bag, usually of plastic, designed to receive solid **discard** material before being placed in a **discard box** for processing by a **make-safe** cycle.
discard box	a box designed to contain discard material for processing by a make-safe cycle.
disinfection	a process used to reduce the number of viable micro-organisms in a **load** but which may not necessarily inactivate some viruses and bacterial spores.
disinfector	an apparatus designed to achieve **disinfection**.
double-ended sterilizer	a **sterilizer** in which there is a door at each end of the **chamber**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

dry-heat sterilizer	a **clinical sterilizer** designed to sterilise **loads** by exposure to hot dry air near atmospheric pressure.
dryness value	a dimensionless quantity, approximating to the dryness fraction, derived to determine whether steam is of the correct dryness for **sterilization** purposes. A dryness value of 1.0 represents dry **saturated steam**.
EO sterilizer	a **clinical sterilizer** designed to sterilise **loads** by exposure to **ethylene oxide** gas or EO gas mixtures.
equilibration time	the period which elapses between the attainment of the **sterilization temperature** in the **chamber** and the attainment of the sterilization temperature in all parts of the **load**.
ethylene oxide (EO)	**sterilant** gas used to sterilise items that would be damaged by exposure to heat or moisture. Chemical formula CH_2CH_2O.
F_O	a quantity, measured in minutes, used to determine the efficacy of an **operating cycle** and equivalent to a continuous period at a temperature of 121°C.
fail-safe	an attribute of **sterilizer** design whereby failure of any component or its associated services does not create a safety hazard.
fault	the recognition by the **automatic controller** that the preset **cycle variables** for the **operating cycle** have not been attained and that **sterilization** or **disinfection** has been jeopardised.
flash sterilizer	a device designed to achieve **sterilization** by exposing the **load** to a very high temperature steam for a few seconds.
fluid sterilizer	a **clinical sterilizer** designed to sterilise fluids in sealed containers by exposure to **high-temperature steam** under pressure.
flushing	in **LTSF** and **EO sterilizers,** an **aeration** procedure by which remaining **sterilant** gas is removed from the **load** within the **chamber** by the passage of air or other inert gas.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

formaldehyde	**sterilant** gas used in combination with **low-temperature steam** to sterilise items that would be damaged by exposure to **high-temperature steam.** Chemical formula HCHO. Also known as methanal.
formalin	formaldehyde Solution BP. A 38% aqueous solution of **formaldehyde** stabilised with 10% w/v ethanol, commonly used as the primary material for generating formaldehyde gas.
free steaming	a process, used in **laboratory sterilizers,** in which the **load** is exposed to steam near atmospheric pressure.
free-standing	of a **sterilizer,** installed in a room which is not separated into a **plantroom** and a **loading area**.
full load	a specified **load,** used in thermometric tests, to represent the maximum size and mass of load which the **sterilizer** is designed to process.
gas exposure time	in **EO sterilizers,** the time for which the **chamber** is maintained at the specified temperature, gas concentration, pressure and humidity.
gauge pressure	pressure equal to the difference between the **absolute pressure** and local atmospheric pressure.
high-temperature steam	steam at a temperature above the boiling point of water at local atmospheric pressure.
holding time	the period during which the temperature in all parts of the **chamber, load** and any coolant fluid is held within the **sterilization temperature band.** It follows immediately after the **equilibration time**.
hot-air sterilizer	see **dry-heat sterilizer**.
indicated	an indicated value is that shown by a dial or other visual display fitted permanently to the **sterilizer** (see **recorded** and **measured)**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

installation checks	a series of checks performed by the contractor to establish that the **sterilizer** has been provided and installed correctly, is safe to operate, does not interfere with nearby equipment and that all connected services are satisfactory and do not restrict the attainment of conditions for **sterilization**.
installation tests	a series of tests performed by the contractor after the **installation checks** to demonstrate that the **sterilizer** is working satisfactorily.
integral steam supply	a supply of steam produced in a sterilizer **chamber** or in a generator directly connected to it. The pressure in the sterilizer chamber is equal to that in the generator.
Köch steamer	a laboratory apparatus designed to expose a **load** to steam near atmospheric pressure and commonly used for melting solidified agar.
laboratory sterilizer	a **sterilizer** designed to sterilise, disinfect or **make-safe** laboratory materials and equipment.
load	collectively, all the goods, equipment and materials that are put into a **sterilizer** or **disinfector** at any one time for the purpose of processing it by an **operating cycle**.
load item	one of several discrete containers, packs or other units that together constitute a **load**.
load-temperature probe	a movable temperature sensor fitted within the **sterilizer chamber** and designed to record the temperature inside selected **load items**.
loading area	the room or area in front of the **sterilizer** in which the operator works and from which the sterilizer is loaded and unloaded. It is commonly separated by a fascia panel from the **plantroom**.
loading condition	a specified combination of the nature and number of **load items,** the items of **chamber furniture,** and their distribution within the **chamber**.
loading factor	the average fraction of the **usable chamber space** occupied by a load during normal operation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

local exhaust ventilation (LEV)	a ventilation system designed to extract small amounts **EO** or **formaldehyde** vapour released during normal operation of a **sterilizer** and its ancillary equipment.
low-temperature steam (LTS)	steam at a temperature below the boiling point of water at local atmospheric pressure.
LTS disinfector	a clinical **disinfector** designed to disinfect **loads** by exposure to **low-temperature steam** at sub-atmospheric pressure.
LTSF sterilizer	a **clinical sterilizer** designed to sterilise **loads** by exposure to **low-temperature steam** and **formaldehyde** gas at sub-atmospheric pressure.
mains steam supply	the supply of steam produced for distribution to a range of steam-consuming equipment by an independent common boiler.
make-safe	a process, used in **laboratory sterilizers,** to reduce the microbial content of contaminated material so that it can be handled and disposed of without causing an infection hazard or environmental contamination.
master process record (MPR)	a **batch process record** obtained from a thermometric **commissioning** or **performance qualification** test and annotated to show the permitted tolerances for **cycle variables** during subsequent testing and routine production.
measured	a measured value is that shown on a test instrument, such as a thermometric recorder or a test pressure gauge, attached to the **sterilizer** for test purposes (see **indicated** and **recorded**).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

medical device	any instrument, apparatus, appliance, material or other article, whether used alone or in combination, including the software necessary for its proper application, intended by the manufacturer to be used on human beings for the purpose of: diagnosis, prevention, monitoring, treatment or alleviation of disease; diagnosis, monitoring, treatment, alleviation or compensation for an injury or handicap; investigation, replacement or modification of the anatomy or of a physiological process; control of conception; and which does not achieve its principal intended action in or on the human body by pharmacological, immunological or metabolic means, but which may be assisted in its function by such means. (Source: EU Council Directive 93/42/EEC.)
medicinal product	any substance or combination of substances presented for treating or preventing disease in human beings or animals. Any substance or combination of substances which may be administered to human beings or animals with a view to making a medical diagnosis or to restoring, correcting or modifying physiological functions in human beings or in animals is likewise considered a medicinal product. (Source: EU Council Directive 65/65/EEC.)
module	a standard unit of **chamber** size being a rectangular box measuring 300 x 300 x 600 mm of volume 54 litres.
non-condensable gases (NCGs)	gases which cannot be liquefied by compression under the range of conditions of temperature and pressure used during the **operating cycle**.
noted	a noted value is that written down by the operator, usually as the result of observing an **indicated, recorded** or **measured** value.
operating cycle	the set of stages of the **sterilization** or **disinfection** process carried out in sequence and regulated by the **automatic controller.** It is synonymous with the terms “sterilization cycle” for **sterilizers** and “disinfection cycle” for **disinfectors**.
operating pressure	the pressure in the **chamber** during the **plateau period** of an **operating cycle**. See **allowable pressure**, **design pressure**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

override	a system by which the progress of the **operating cycle** can be interrupted or modified as necessary.
paraformaldehyde	a mixture of polymethylene glycols formed by the reaction of **formaldehyde** with water.
performance class	an integer, from 1 to 20, related to the total cycle time for a **sterilizer** with a **full load**.
performance qualification (PQ)	the process of obtaining and documenting evidence that the equipment, as commissioned, will produce acceptable product when operated in accordance with the process specification.
performance requalification (PRQ)	the process of confirming that the evidence obtained during **performance qualification** remains valid.
periodic tests	a series of tests carried out at daily, weekly, quarterly and yearly intervals.
personal protective equipment (PPE)	equipment, including clothing, which is intended to be worn or held by a person at work, which protects against one or more risks to his or her health and safety.
plant history file	a file containing **validation**, maintenance and other engineering records for each **sterilizer**.
plantroom	the room or area to the rear of the **sterilizer** in which services are connected and which provides access for maintenance. It is commonly separated by a fascia panel from the **loading area**.
plateau period	the **equilibration time** plus the **holding time**.
porous-load sterilizer	a **clinical sterilizer** designed to process, by exposure to **high-temperature steam** under pressure, porous items such as towels, gowns and dressings, and also **medical devices** that are wrapped in porous materials such as paper or fabrics.
preconditioning	treatment of a **load** to attain predetermined conditions, such as temperature and humidity, before the start of an **operating cycle**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

pressure ballasting	a technique used in **fluid sterilizers** by which the pressure in the **chamber** is maintained at or near to the pressure inside the **load** containers during all or part of the **operating cycle**.
pressure vessel	a collective term describing the sterilizer **chamber,** jacket (if fitted), door(s) and components that are in permanent open connection with the chamber.
priming	of a steam generator, the delivery of steam containing water in suspension due to violent boiling or frothing.
process indicator	a **chemical indicator** used to distinguish between processed and unprocessed load items.
pyrogen	a bacterial toxin that causes a rise in body temperature and which is not destroyed by steam **sterilization**.
recommissioning	a procedure to confirm that operational data established during **commissioning** remain valid.
recorded	a recorded value is that shown on the output of a recording instrument fitted permanently to the **sterilizer** (see **indicated** and measured).
revalidation	a procedure to confirm an established **validation,** consisting of **recommissioning** followed by **performance requalification**.
safety hazard	a potentially detrimental effect on persons or the surroundings arising directly from either the **sterilizer** or its **load**.
saturated steam	steam whose temperature, at any given pressure, corresponds to that of the vaporisation curve of water.
small load	a specified **load,** used in thermometric tests, to represent the minimum size and mass of load which the **sterilizer** is designed to process.
small plastic discard	**discard** material comprising or held in plastic containers not exceeding 50 ml in volume.
sterilant	an agent used to effect **sterilization,** such as steam, hot air or a sterilising gas.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

sterile	condition of a **load item** that is free from viable micro-organisms. See BS EN 556 for the requirements for a **medical device** to be labelled “sterile”.
sterilization	a process undertaken to render a **load sterile**.
sterilization conditions	the ranges of the **cycle variables** which may prevail throughout the **chamber** and **load** during the **holding time**.
sterilization process	the complete set of procedures required for **sterilization** of a **load,** including the **operating cycle** and any treatment of the load before or after the operating cycle.
sterilization temperature	minimum acceptable temperature of the **sterilization temperature band**.
sterilization temperature band	the range of temperatures which may prevail throughout the **load** during the **holding time.** These temperatures are expressed as a minimum acceptable (the **sterilization temperature)** and a maximum allowable and are stated to the nearest degree Celsius.
sterilizer	an apparatus designed to achieve **sterilization**.
sterilizer process log	a log, kept by the User, which contains records for each production cycle.
superheated steam	steam whose temperature, at any given pressure, is higher than that indicated by the vaporisation curve of water.
thermal door lock	an interlock fitted to certain **sterilizers** to prevent the door from being opened until the temperature in the **chamber** and **load** falls below a preset value.
transportable	requiring no permanent connections or installation and capable of being moved manually without mechanical assistance. Synonymous with “bench-top”.
type tests	a series of tests conducted by the manufacturer to establish the working data for a **sterilizer** type.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

usable chamber space	the space inside the **chamber** which is not restricted by **chamber furniture** and which is consequently available to accept the **load**.
utilisation factor	the fraction of the open hours for which a sterilizer is available to process loads.
validation	a documented procedure for obtaining, recording and interpreting data required to show that a **sterilization process** will consistently comply with predetermined specifications.
works tests	a series of tests to establish the efficacy of each **sterilizer** at the manufacturer's works.

Appendix 2: Sterilization of items contaminated with TSE agents

Introduction

A2.1 The following information is extracted from the HSE document 'Precautions for work with human and animal Transmissible Spongiform Encephalopathies', compiled by the Advisory Committee on Dangerous Pathogens and issued to the NHS under Department of Health circular PL(94)CO/5.

A2.2 The term transmissible spongiform encephalopathy (TSE) describes a rare and fatal degenerative condition of the central nervous system occurring in man and in certain animal species. The three TSEs that are recognised in man are:

a. Creutzfeld-Jakob disease (CJD);

b. Gerstmann-Straussler-Scheinker syndrome (GSS);

c. kuru.

A2.3 The two chief TSEs in animals include:

a. scrapie (in sheep);

b. bovine spongiform encephalopathy (BSE).

A2.4 Similar diseases include transmissible mink encephalopathy (TME), chronic wasting disease (CWD) in Rocky Mountain elk and captive mule deer, and TSEs in small numbers of exotic ungulates and cats.

A2.5 Although these diseases appear to be caused by transmissible agents, the nature of these agents remains uncertain.

A2.6 Animal TSEs are classified as Hazard Group 1. Human TSEs are now classified as Hazard Group 3 (formerly Hazard Group 2) as required by the COSHH Regulations 1999, although full Containment Level 3 precautions are not always required.

Sterilization

A2.7 All agents of TSE exhibit an unusual resistance to conventional decontamination methods used in clinical and laboratory practice. They are not significantly affected by a number of standard chemical agents such as formalin and ethylene oxide, and infectivity persists after autoclaving at conventional times and temperatures (such as 121°C for 15 min). In

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

addition, only extremely high doses of ionising and UV irradiation have been successful in reducing infectivity.

A2.8 The Advisory Committee on Dangerous Pathogens recommends porous load sterilization as the method of choice in most situations. Two processes are recommended:

a. a single cycle at 134-138°C for a minimum holding time of 18 min;

or

b. six cycles at 134-138°C for a minimum holding time of 3 min.

A2.9 The latter represents the standard operating cycle for a porous load sterilizer (run six times) and may be used if the single, longer cycle is not available.

A2.10 Although no practical problems appear to have arisen with this time and temperature combination, recent preliminary studies of a scrapie agent under rigorous experimental conditions have shown some residual infectivity. This may be due to the use of relatively high-titred and more thermostable strains. Further work is planned to confirm the appropriate lower temperature limit.

A2.11 Users should consult Annex 2 of the HSE document for specialised advice on:

a. the effectiveness of other sterilization processes;
b. treatment of work surfaces and non-heat-stable equipment;
c. decontamination and disposal of liquids;
d. decontamination of microbiological safety cabinets;
e. fixation for histology;
f. disposal of tissue.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Appendix 3: Safety of EO sterilization

Introduction

A3.1 Ethylene oxide presents hazards not found in conventional sterilizers. The vapour is extremely flammable and irritates both the eyes and the respiratory system. Poisoning by ethylene oxide is a reportable disease listed in Schedule 2 of 'The Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1995'.

A3.2 Much of the guidance in this appendix is drawn, with permission, from 'Guidelines for the safe operation of ethylene oxide sterilization plant' published by ICI plc but no longer available.

A3.3 The advice is primarily aimed at users of large sterilizers supplied from cylinders. Many of the precautions described here will not be necessary for users of small sterilizers supplied from disposable cartridges. However, all users of EO sterilizers are strongly advised to make a risk assessment of the worst case accident that could occur. The amount of EO that could be involved is of prime consideration; the small amount contained in a cartridge is unlikely, for example, to lead to spillages of liquid.

A3.4 Personnel exposure to ethylene oxide should not exceed the maximum exposure limits given in Table 1.

A3.5 Persons employed on plant handling EO should be adequately trained and provided with detailed operating instructions.

A3.6 A selection of physical and chemical properties of EO is listed in Table A1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table A1: Selected properties of ethylene oxide

Relative molecular mass	44.05
Form	Liquefied gas
Colour	Colourless
Odour	Ethereal
Odour threshold	450-700 ppm
Boiling point	10.5 C
Flash point (open cup)	-17.8 C
Flammable limits in air (v/v)	3-100%
Auto ignition temperature	429 C
Vapour pressure	139kPa (20 C), 349 kPa (50 C)
Density of liquid at 4°C	890 kgm^{-3}
Solubility	Miscible in water
Vapour density (air=1)	1.5

Sources: 'Product safety data', ICI Chemicals & Polymers Ltd, 1995; 'Information relevant to the installation of, and ancillary equipment for, ethylene oxide sterilizers', CEN TC 102 WG6 N67+, CEN (unpublished).

Fire and explosion hazards

A3.7 EO is highly flammable and forms explosive mixtures with air at all concentrations above 3% (v/v). There is no upper explosive limit as normally expected for hydrocarbons; exothermic reaction replaces combustion at higher concentrations up to 100%. The auto-ignition temperature in air at atmospheric pressure is 429°C, and the decomposition temperature in the absence of air is 560°C.

NOTE: Further Guidance is contained in NHS in Scotland Firecode.

A3.8 Because of its flammability and low boiling point, EO is akin to liquefied petroleum gas (LPG). An essential difference is that it is fully miscible with water. At concentrations in water below 1% w/w the vapours are not flammable at air ambient temperature, so a leakage of liquid EO can be rendered non-flammable by diluting it 100-fold with water. In the open air appreciably less dilution (24-fold) can extinguish burning EO.

A3.9 Fire risks in general and electrical classifications are covered by conforming to typical codes related to the storage of LPG or liquefied natural gas (LNG) products and to the selection of electrical installations for use in flammable atmospheres. Additional precautions are called for because of the thermal instability of EO.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.10 Accumulation of electrostatic charge does not take place in EO because of its high electrical conductivity (>3mS m^{-1}). There is thus no reason to limit flow velocities in pipework.

A3.11 The aim should be to handle EO in closed equipment and to deal promptly with any leaks or spillages whenever these occur.

A3.12 For detecting leaks, gas detectors with automatic alarms located at strategic points (eg. near the sterilizer door) are recommended.

A3.13 The prime defence against escaped EO is the use of water in very large quantities to dilute the EO and render it non-flammable. Insufficient amounts of water, on the other hand, may promote the vaporisation of EO from large spillages.

Polymerisation

A3.14 Liquid EO is very susceptible to polymerisation initiated at ambient temperature by acids, bases or catalysts, such as anhydrous chlorides of iron, aluminium, tin and metal oxides. Iron rust is a moderate initiator for this reaction and therefore it should be substantially removed from any equipment containing EO. Purely thermal initiation starts at around 100°C and once started, iron is a promoter. The polymerisation is highly exothermic and if the temperature is not controlled the polymerisation is self-accelerating, leading to vaporisation of unreacted EO and possibly to explosive decomposition of the vapour.

A3.15 Slow polymerisation can occur, producing solid polymer, which is thermally stable. Solid polymer is soluble in the monomer. The polymer may also contain considerable amounts of dissolved monomer which during dispersal, may be released into the atmosphere. Further guidance is contained in NHS in Scotland Firecode.

Toxicity hazards

Vapour toxicity

A3.16 EO boils at 10.5°C and vaporises at normal atmospheric temperature and pressure so that exposure of personnel to vapour, rather than liquid contact, is the more likely hazard. High concentrations of the gas in contact with the skin may produce serious burns if not removed immediately. It has been reported that concentrations of 2000 ppm retained in rubber gloves have caused skin irritation.

A3.17 Exposure to EO vapour causes irritation of the eyes and respiratory system accompanied by headache. The vapour has anaesthetic properties. Signs and symptoms may include nausea, vomiting, coughing, irritation to the nose, loss of smell and, progressively, dizziness, stupor and coma. These effects are noticeable at concentrations greater than 50 ppm. Acute symptoms are normally delayed except in the case of serious exposure.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Fluid build-up in the lungs (pulmonary oedema) may occur up to 48 hours after exposure and could prove fatal. The effects of low concentrations of EO are not thought to be cumulative, though the evidence is equivocal and the subject of continuing research.

A3.18 The sweetish smell of pure EO is not apparent until the concentration reaches several hundred ppm (figures between 400 and 700ppm have been quoted), far above the level at which harm is caused. Personnel concerned with the operation of EO sterilizers cannot rely on smell to protect themselves against exposure. It is essential that EO environmental tests are carried out at least once a year and that there is an effective system for personal monitoring.

A3.19 Adverse reproductive effects (reduced fertility and embryotoxicity) have been reported in rats exposed to high concentrations for prolonged periods. Epidemiological studies on human reproductive effects have so far been inconclusive although spontaneous abortions and an excess of foetal deaths have been reported among women exposed to EO. The exposure levels are not known.

A3.20 EO is mutagenic in a wide variety of in vitro and in vivo biological test systems. It has been shown to cause cancer in animals and HSE advises that it should be regarded as a potential human carcinogen.

Effects of liquid EO on skin and eyes

A3.21 Liquid EO can persist under open conditions, particularly at low temperatures. Serious freeze burns can result from contact from liquid splashes or spray. Solutions of EO in water cause more rapid burning than the dry material. Delayed inflammation of the skin may also result.

A3.22 The eyes are particularly susceptible to serious permanent damage from splashes, even of dilute solutions. The onset of effects may be delayed for several hours.

Workplace monitoring and recording

A3.23 Atmospheric concentrations of EO should be monitored in the appropriate working area and any abnormalities should be reported, investigated and corrected.

A3.24 While background atmospheric monitoring of the sterilization and quarantine areas is recommended, regular personal monitoring of operators working in these areas is regarded as essential in assessing exposure.

A3.25 All assessment of operator exposure should be based on personal monitoring unless this can be obtained from workplace air sampling by showing the necessary correlation. Monitoring should be based on an 8-hour exposure unless it has been shown that exposure occurs only at specific times; in such cases the shift exposure may be calculated from

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

measurements made at these times. Additionally, spot measurements should be made at times of peak exposures with a view to reducing these levels.

A3.26 Plant monitoring may be useful for the early detection of leaks but considerable thought should be given to the siting of sample points and the frequency of sampling.

A3.27 Records should be established of the names and job classification of operators who work in areas where exposure to EO may occur. All personal monitoring results should be recorded. Records should be kept of all cases of acute exposure to EO. All of these records should be kept for at least 30 years.

A3.28 Users setting up monitoring systems are strongly recommended to obtain advice both from gas manufacturers or suppliers and also from properly qualified occupational health consultants.

Personal sampling

A3.29 Personal sampling should be undertaken to evaluate the level of exposure of individuals. It is the only technique recognised by HSE as producing results for judging compliance with the established exposure limits.

A3.30 A number of methods based on collection of atmospheric EO on a solid adsorbent, such as charcoal, are available. There are principally two types;

a. active sampling using a small pump;

b. passive diffusion.

A3.31 Both systems require the subsequent desorption and estimation of EO.

Environmental monitoring

A3.32 Systems which are currently in use for environmental monitoring are based on several analytical techniques including infrared spectroscopy, flame ionisation, photoionisation, mass spectrometry and gas chromatography. It should be borne in mind that each suffers from limitations dependent upon interference from other compounds which may be present concurrently with EO. The system to be established should be considered in relation to the particular installation for which it is intended.

A3.33 Newer and simpler techniques are continuously being developed and the current state-of-the-art should be considered before commitment to any particular system is made.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.34 The principal systems available are as follows:

a. Colour-changes indicator system (1-30ppm). This system is for spot monitoring and cannot give accurate time-weighted average reading of exposure. The MEL for EO is at the low end of the detection range, hence accuracy is poor. The system does not pinpoint the source of emissions.

b. Direct-reading infrared analysers (0.2-1000ppm). This equipment can be portable for single-point monitoring. More elaborate static units are available for continuous cycle and multipoint monitoring. These systems can give accurate time-weighted average figures for specific points and extremely good historical perspective, but give no indication of concentrations in the air breathed by personnel.

c. Gas chromatography. As with infrared there are both portable and static units providing a sensitivity of 0.1ppm, depending upon sample size and analytical system. All gas chromatography applications for time-weighted average readings require charcoal tubes for adsorption and desorption.

Personal protective equipment

A3.35 Personal protective equipment (PPE) guarding against the effects of EO should not need to be used as a matter of routine, since the sterilizer design, ventilation systems and operating procedures should preclude the presence of harmful concentrations of EO.

A3.36 Where work in contact with EO is unavoidable, the following items of PPE should be available:

a. for exposure to EO vapour – respiratory protective equipment and eye protection;

b. for exposure to EO liquid – air breathing hood, protective suit, gloves and rubber boots.

A3.37 There should be training programmes to ensure that the relevant people are able to use PPE correctly and quickly. Training should be carried out by a suitably qualified instructor.

A3.38 Suitable arrangements should be made for periodic maintenance of the equipment.

A3.39 Records should be kept of both training and maintenance.

Respiratory protective equipment

A3.40 Where atmospheric concentrations of EO are, or could reasonably be expected to be, above the Maximum Exposure Limit (see Table 1), suitable respiratory protective equipment should be worn. This may be self-contained breathing apparatus, compressed air line breathing apparatus or a suitable

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

canister respirator, the type of equipment being selected according to the levels of EO which may be present.

A3.41 The equipment should comply with all relevant British or European Standards. In selecting suitable equipment, reference should be made to BS 4275: 1997 ‘Guide to implementing an effective respiratory protective device programme’.

A3.42 The system chosen should be adequate for the protection of the wearer under all foreseeable circumstances. Factors to be taken into consideration are:

a. the highest possible exposure level;
b. the longest possible excursion time;
c. the nominal protection factor of the equipment; this will indicate the efficiency of the equipment (the best nominal protection factor is conferred by positive-pressure breathing apparatus);
d. the goodness of fit of face masks.

Breathing apparatus

A3.43 Full, positive-pressure breathing apparatus provides a totally enclosed respiratory environment for the wearer. Because of the design, there is a 30-min usage limit.

A3.44 Two sets of breathing apparatus for rescue work should be kept outside the EO working area.

Chest-mounted canister respirator

A3.45 Canister respirators should only be used when the atmospheric concentrations of EO are known to be within the levels for which the canister is designed and the duration of use should be within the life of the canister. These devices rely on a good seal between the respirator and the face of the wearer; if this seal is lessened by facial hair, spectacles, etc., a very much lower degree of protection will be achieved.

A3.46 The canister filters the air to a full face mask. It should not be used in atmospheres where the exposure level is likely to be in excess of 0.2% by volume. There is a specified time limit for usage. HSE recommends that canisters be discarded after each use unless tests against EO can show that desorption does not occur on re-use. Canisters should be degassed before disposal.

Cartridge respirator

A3.47 The cartridge fits directly into an ori-nasal mask. It should not be used in atmospheres where the EO level is likely to exceed 1000ppm. The useful life of the cartridge is 30 min for exposure to maximum concentration. It is

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

essential to adhere closely to the manufacturer's or supplier's instructions. Cartridges should be degassed before disposal.

Protective clothing

A3.48 In emergency situations when handling liquid EO and when atmospheric concentrations are high, full protective clothing should be worn. This should provide complete protection to the skin and eyes. Particular note should be taken of the construction of the clothing, such as the sealing of seams, and of the ability of the material to limit the permeation of EO on to the skin. If any clothing becomes contaminated with liquid EO it should be destroyed.

Emergency procedures

A3.49 Comprehensive written procedures should be prepared covering shut-down, evacuation and rescue. This should involve an assessment of the worst possible consequences of an incident. The procedures thus described should be tested and audited at regular intervals.

A3.50 A fire certificate issued by the Home Office may be required. Guidance from the local fire brigade should be sought. Emergency procedures should be agreed with the fire officers and displayed in a permanent form in a prominent position. Further information is available in NHS in Scotland Firecode.

A3.51 Liaison with the local accident and emergency department is recommended, particularly to ensure that the specific hazards associated with exposure to EO are known and that the remedial treatment is available.

A3.52 First aid procedures relevant to the nature of the sterilization operation should be drawn up and agreed. Sterilizer operators and first-aiders on the site should be trained in these procedures.

Leaking cylinder

A3.53 If the cylinder is in an enclosed area, evacuate the area. Wear suitable protection. Check that the cylinder valve is closed. Move the cylinder to a fume room or open space downwind and away from persons and buildings. Post warning notices and seal off the area. The suppliers should be contacted in the event of difficulty.

Fire fighting advice

A3.54 In the event of a leakage of gas becoming ignited, the fire brigade should be called immediately. The fire should be extinguished only by closing the valve. No attempt should be made to put out the flame in any other way but, provided it is safe to do so, the cylinder should be cooled by copious spraying with water. The person directing the spray should take up a position where he or she will be protected should a cylinder explode. If flame from

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

the burning leak impinges on cylinders, the building should be evacuated immediately and no fire-fighting attempted.

A3.55 Cylinders which have not become heated should be moved to a safe place in the open as quickly as possible, making sure any valves are turned off first. If this is not possible, such cylinders should be kept cool by spraying with water from a safe position.

A3.56 On arrival at the premises, the fire brigade should be informed of the position of all cylinders, even those that are not directly threatened by the fire.

Spillage

A3.57 In any area where the spillage of liquid EO can occur a piped water supply should be provided. Escaped EO should be diluted with copious quantities of water sufficient to dilute the EO to less than 4%. At this concentration the vapours are not flammable. Restricted amounts of water may only serve to increase the vaporisation of EO.

A3.58 In the event of spillage, the area should be evacuated immediately. Re-entry should only be by personnel wearing full protective clothing - i.e. procedures should be prepared in accordance with Firecode in Scotland and the appropriate HTMs: rubber boots, non-absorbent overalls, gloves and breathing apparatus. The supply source should be isolated, if possible. Spillages should be cleared by drenching with sufficient water to dilute the EO at least 100-fold and never by mopping up. It should be remembered that EO is heavier than air so higher concentrations will tend to accumulate at ground level.

A3.59 EO is a persistent contaminant, and particular attention should be paid to the cleansing of contaminated clothing and equipment. Where decontamination is not possible (such as on leather items), the article should be destroyed.

First aid advice

A3.60 In the event of an accident personnel should take steps to protect themselves and isolate any sources of escaping EO. If someone is exposed to EO, medical attention should be sought immediately.

A3.61 In all cases of severe or suspected exposure to EO the person should be immediately removed from the contaminated area to a well ventilated area by trained personnel wearing the necessary protective equipment. The following action should be taken.

A3.62 If the skin has been affected:

a. remove all contaminated clothing;

b. if liquid EO is on the skin, allow it to evaporate;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

c. wash skin copiously with water for 15 minutes. Exposed skin should be treated with high-pressure water such as a hose or strong shower – gentle washing is not sufficient.

A3.63 If EO has been inhaled:

a. lay the casualty flat and keep him warm and still;

b. if breathing has stopped, given artificial respiration with a Brooks airway; do not attempt mouth-to-mouth or mouth-to-nose resuscitation. If oxygen is available it should be administered by a suitably qualified person.

A3.64 If the eyes have been affected, flush copiously with water for 15 minutes.

A3.65 If EO has been swallowed, activated charcoal may be used to adsorb unreacted EO. It should be administered as an aqueous slurry of 240 ml of water to 30 g charcoal. The usual dose is 30-100 g in adults. EO is irritating and usually serves as its own cathartic.

A3.66 The possibility of delayed effects following exposure should not be overlooked.

Control and handling of cylinders

A3.67 The gas should be supplied to an agreed specification guaranteed by the supplier. The specification should include:

a. details of the composition and pressure of the gas or gas mixture;

b. a technical description of the construction and fittings of the cylinders;

c. individual cylinder identification to allow the rotation of stock.

A3.68 A procedure should be defined for the acceptance of deliveries of gas cylinders from the supplier. The procedure should include the following details:

a. confirmation of the identity of the gas by reference to the manufacturer's product identification; a copy of the code and procedure should be prominently displayed in the goods received and in the gas storage areas;

b. the leak testing of each cylinder using a suitable leak detection device or soapy water. Leak tests should be carried out:

(i) on the joint between the cylinder neck and the discharge valve;

(ii) around the valve control handle stem;

(iii) around and inside the valve discharge orifice.

A3.69 Any cylinders found to be leaking or otherwise not conforming to the specification should not be accepted and will remain the responsibility of the supplier, who should be informed immediately.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.70 The manufacturer's recommendation regarding the maintenance of residual pressure or weight in nominally empty cylinders for return should be followed.

A3.71 Cylinders should be stored in a cool, well-ventilated, secure area (see Part 5 of this SHTM for guidance). EO should be stored away from fire risk and sources of heat. A suitable cylinder handling trolley should be provided.

Information and training

A3.72 All personnel employed in the operation of EO sterilizers, including maintenance personnel and operators, should receive adequate, documented training. Personnel should not commence their duties until this training has been completed and detailed operating instructions have been provided. Maintenance personnel should be trained and certified by the manufacturer of the sterilizer.

A3.73 As a minimum, training should include:

a. operational policies;
b. safety provisions;
c. connection and disconnection of gas cylinders;
d. first aid;
e. emergency procedures;
f. use of respiratory equipment;
g. duties to be performed;
h. actions in the event of a fire.

A3.74 On completion of training, employees should be assessed to ensure that the training programme has been understood. No person should be permitted to work with EO until he or she has attained an adequate level of proficiency.

A3.75 All personnel coming into contact with EO should be informed of the hazards and provided with a hazard data sheet.

Maintenance

A3.76 Maintenance should only be performed by suitably trained and qualified personnel. Before working on equipment known to contain EO, the equipment should be drained, isolated, washed out with water and demonstrated to be clear of flammable vapour (by gas analysis, for example).

A3.77 Systems which have carried EO but which are thought to be free of any residue should nevertheless be thoroughly purged with nitrogen before work commences.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.78 Planned, regular maintenance of all elements of the gas supply system is essential to safe operation.

A3.79 A list of spares vital for safe operation should be compiled and a stock maintained.

A3.80 Before any work is carried out on equipment known to contain EO, or that has carried EO, or is thought to be free of EO, the local exhaust ventilation should be known to be effective. If work is to be carried out on the supply line from the manifold (cylinder supply) or pipe systems that have carried EO, they should first be purged with a non-flammable gas such as nitrogen before work commences.

A3.81 A procedure should be defined for the maintenance of lines and fittings which have contained EO and for subsequent pressure and vacuum testing. The following details should be included:

a. compulsory wearing of face shields, respiratory protection (where appropriate) and gloves;
b. disconnection and isolation of the source of EO;
c. the source of purging gas, together with any entrained material, shall be vented to a safe location (provision should be made for the handling and disposal of polymerised EO which may contain EO monomer);
d. on completion of the maintenance schedule, pressure testing at an appropriate pressure, with leak testing as required;
e. vacuum testing as appropriate;
f. checking that all valves and other control settings are correct before putting the sterilizer back into service.

A3.82 Where potentially flammable EO mixtures are present, sources of ignition should be prohibited. For example:

a. smoking and the use of naked flames should be strictly prohibited and matches or other means of ignition should not be carried into the work area;
b. tools made from spark-producing metals should also be prohibited; only tools and equipment which do not induce sparks should be issued;
c. garments containing synthetic fibres likely to induce static discharge should not be worn; conductive footwear should be used.

Appendix 4: Guidance to management on the appointment of an Authorised Person (Sterilizers)

Introduction

A4.1 The Authorised Person (Sterilizers) is defined as a person designated by management to provide independent auditing and advice on sterilisers and sterilization and to review and witness documentation on validation. The shorter term “Authorised Person” is used in this SHTM.

A4.2 The specific requirements for the services of an Authorised Person should be based upon the core responsibilities outlined in Part 1 of this SHTM, namely:

a. to provide general and impartial advice on all matters concerned with sterilization;

b. to advise on programmes of validation;

c. to audit reports on validation, revalidation and yearly tests prepared by the Test Person;

d. to advise on programmes of periodic tests and periodic maintenance;

e. to advise on operational procedures for routine production.

A4.3 The Institute of Healthcare Engineering and Estate Management (formerly the Institute of Hospital Engineering) is the registration authority for Authorised Persons. The address is given in Appendix 1.

A4.4 In appointing an Authorised Person, management should ensure that there is no conflict of interest that would compromise his or her impartiality in carrying out the assigned duties. Candidates should be required to declare any such interest at an early stage. Management should carefully assess whether such declared interests are likely to affect the ability of the candidate to carry out the duties defined above or any proposed extension to them. A candidate employed by a sterilizer manufacturer, for example, may be able to discharge all the core duties satisfactorily but be considered unsuitable to offer advice on procurement of new equipment. See also paragraph A4.7.

A4.5 Management should ensure that the selected candidate has the appropriate qualifications and experience for the sterilizers for which he or she will be responsible. Not all Authorised Persons will be qualified to advise on all types of sterilization process. It may be necessary to appoint one or more Authorised Persons specialised in different processes; namely steam, dry heat, LTSF or EO. In such cases, there should be a clear definition of each appointee’s sphere of responsibility.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A4.6 In normal circumstances an Authorised Person should have exclusive responsibility for each machine in his or her charge. It is not good practice for more than one Authorised Person to be contracted to share continuing responsibility for a particular machine. This does not prevent Users seeking a second opinion where the need arises, though such action should be the exception rather than the norm.

Contractual arrangements

A4.7 Authorised Persons are required to comply with the 'Code and rules of conduct and disciplinary regulations for registered Authorised Persons (Sterilizers)' issued by the Institute of Healthcare Engineering and Estate Management. Management should ensure that no part of the contract, nor any subsequent instructions, conflict with the code and rules of conduct.

A4.8 A term of contract is suitable for the procurement of the services of an Authorised Person. The minimum term should be one year, although a five-year term has the advantage of greater continuity, enabling the appointee to become familiar with each of the sterilizers for which he or she is responsible. Casual appointments on a one-off basis are unlikely to foster the mutual confidence necessary for a consistent quality of service.

A4.9 The contract should specify the core responsibilities outlined above and further explained below (see paragraph A4.13). Provision should be made for extensions to the contract to include, for example, the duties associated with the validation of a new sterilizer or the introduction of a new product.

A4.10 Management may also require the Authorised Person to undertake additional duties outside the range of the core responsibilities. To enable this assistance to be given when needed, the contract should include the terms of payment for such additional work. Examples of additional services are given in paragraph A4.24.

A4.11 Formal lines of accountability should be made clear in the contract. The Authorised Person should normally report in the first instance to the user, who bears the day-to-day responsibility for the operation of the sterilizer.

A4.12 On appointment, the Authorised Person should be notified in writing of the names, addresses and telephone numbers of key personnel defined in Part 1 of this SHTM; namely, the Executive Manager of the contracting organisation, the user, the Competent Person, the Test Person, the Maintenance Person and the Microbiologist; and for medicinal products, the Production Manager and Quality Controller. The Authorised Person should be notified promptly in writing of any changes to this information.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Core responsibilities

A4.13 The following are the core responsibilities that should be written into the contract.

General advice

A4.14 The Authorised Person is required to provide general and impartial advice on all matters concerned with sterilization. This will usually be provided in response to enquiries by telephone, post, fax or electronic mail, as appropriate. In some cases site visits may be required.

Validation programmes

A4.15 The Authorised Person is required to advise on programmes of validation for the processes for which he or she is qualified. These programmes should be based on the guidance given in Part 3 of this SHTM and any other regulatory requirements that may be specified.

Auditing of validation and yearly tests

A4.16 The Authorised Person is required to audit reports on validation, revalidation and yearly tests prepared by the Test Person.

A4.17 The Authorised Person should be given reasonable notice of the date of commencement any validation, revalidation or yearly tests which he or she is required to audit.

A4.18 Whether audits require a visit to the sterilizer is a matter of professional judgement dependent on the type of sterilizer, its operational history, the experience of the Test Person and the complexity of the performance qualification procedures. As a rule, site visits are recommended. However, since an Authorised Person cannot effectively audit a machine that he or she has not seen, site visits are essential on at least the following occasions:

a. for each sterilizer, before or during the first audit following appointment;
b. during the initial validation of a newly installed sterilizer.

A4.19 In order to perform this work effectively, the Authorised Person should have access to the sterilizer itself, the plant history file, the sterilizer process log and any other documentation bearing on the functioning of the sterilizer. He or she should also have reasonable access to the user, Test Person and other key personnel, and sterilizer operators. During site visits the Authorised Person should be provided with a quiet room in which to examine documentation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A4.20 Within an agreed period following completion of the tests as notified in paragraph A4.17, the Authorised Person should provide a report of the audit. The report should include the following information:

a. names of the user, Executive Manager and the Authorised Person;
b. details of the Test Person who carried out the work, including:
   (i) name;
   (ii) relevant qualifications;
   (iii) name of employer;
c. information for each sterilizer tested including:
   (i) identification of the sterilizer (including manufacturer, model and serial number and any inventory number);
   (ii) type of process;
   (iii) dates of manufacture, installation and validation;
   (iv) date of the audit;
   (v) a list of the tests carried out (validation, revalidation or yearly, as appropriate) and a statement as to whether each was satisfactory;
   (vi) a summary of the evidence that the test equipment used in the tests was properly calibrated;
   (vii) detailed comments on the outcome of the audit, especially if there is any evidence of deterioration in performance, with recommendations;
   (viii) a signed and dated recommendation as to whether the sterilizer should be considered fit for use.

A4.21 Where the Authorised Person has reason to recommend that the sterilizer is not fit for use, this information should be conveyed to the user before leaving the site, both in writing and (if possible) verbally, in advance of the full report.

Test and maintenance programmes

A4.22 The Authorised Person is required to advise on programmes of periodic tests and periodic maintenance. Advice should cover the following:

a. programmes of daily, weekly, quarterly and yearly tests, based on the schedules in Part 3 of this SHTM;
b. maintenance schedules, based on the guidelines in Part 4 of this SHTM;
c. implementation of written schemes of examination for pressure vessels issued by the Competent Person (Pressure Vessels).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operational procedures

A4.23 The Authorised Person is required to advise on operational procedures for routine production. Examples where advice may be needed include:

a. load design;
b. packaging;
c. product compatibility;
d. product release;
e. documentation;
f. safety;
g. training requirements;
h. compliance with legislation and standards.

Additional services

A4.24 Examples of services which would not be included in the core responsibilities may include:

a. advice on the planning, operation and quality control of whole departments;
b. delivery of training;
c. auditing of periodic tests at more frequent intervals (quarterly or weekly);
d. technical consultancy for tendering, equipment and services;
e. preparing procurement specifications for sterilizers and washer disinfectors;
f. risk assessments for health and safety purposes.

NHSScotland, P&EFEx, June 2001

Preface

SHTM 2010 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of the following types of sterilizer in use in the National Health Service:

a. clinical sterilizers:
   (i) high-temperature steam sterilizers used for processing porous loads (including instruments and utensils wrapped in porous materials);
   (ii) high-temperature steam sterilizers used for processing aqueous fluids in sealed containers;
   (iii) high-temperature steam sterilizers used for processing unwrapped solid instruments and utensils;
   (iv) dry-heat sterilizers (hot-air sterilizers);
   (v) low-temperature steam (LTS) disinfectors and low-temperature steam and formaldehyde (LTSF) sterilizers;
   (vi) ethylene oxide (EO) sterilizers;

NOTE: Despite their name, LTSF sterlizers are disinfectors.

b. laboratory sterilizers:
   (i) high-temperature steam sterilizers used with one or more specialised operating cycles;
   (ii) culture media preparators.

No guidance is given on sterilization by irradiation, hydrogen peroxide, gas plasma or filtration. Users who wish to employ these processes bear the responsibility of ensuring that the validation procedures comply with the principles outlined in Part 3 of this SHTM and that the intended operating procedures will ensure an efficacious process for the different types of load.

This SHTM is intended primarily as a guide for technical personnel, whether specialists in sterilizers and sterilization procedures or those responsible for maintenance and testing. It is also intended for those responsible for the day-to- day running of sterilizers, and will also be of interest to supplies officers, architects, estates managers and others in both the public and private sectors.

Detailed information on the planning and design of a sterile services department, including the level of provision of sterilizers, is given in Scottish Hospital Planning Note 13; *Sterile services department*. Guidance for laboratory installations can be found in Scottish Hospital Planning Note 15; *Accommodation for pathology services*.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Although this edition of SHTM 2010 reflects established sterilizer technology, it is recognised that considerable scope exists for the utilisation of emerging technology in the management of sterilizers. This will be kept under review with the aim of introducing recommendations for such technology at the earliest opportunity so that the procedures essential for the efficient, safe and effective operation of sterilizers can be optimised.

The sterilizers described in this SHTM may not be suitable, without modification, for safely processing articles infected with Hazard Group 4 pathogens nor agents, such as those associated with transmissable spongiform encephalopathies, which are unusually resistant to sterilization. Design considerations for sterilizers intended to process articles infected with such organisms are discussed in Part 2.

This part of SHTM 2010 contains detailed supplementary information that expands upon the guidance given in Parts 1 to 4 and should be read in conjunction with them.

NOTE: Information about Hazard Groups may be found in the HSC document 'Categorisation of pathogens according to hazard and categories of containment' (4th edition 1995) compiled by the Advisory Committee on Dangerous Pathogens.

Section A

The lethality of heat sterilization processes – the F_0 concept

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Contents

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A1. Introduction

A1.1 There are several, well established, time temperature relationships for thermal sterilization methods which are regarded as equally acceptable (see Part 3 of this SHTM, Table 8). Clearly temperatures other than those shown, when maintained for an appropriate time, will also be capable of producing a sterile product.

A1.2 For a moist heat sterilization process, we can expect a particular time at a particular temperature to have a predictable lethal effect against a standardised population of organisms. If we choose particularly resistant organisms and assume they are present in numbers in excess of that likely to be encountered in real product we can define standard exposure conditions which will always yield a sterile product in a correctly operated sterilizer. Actual exposures can then be related to these standard exposure conditions.

For example, in the laboratory it is possible to produce conditions where the time to attain a pre-selected sterilization temperature, and the time to cool to ambient temperature after sterilization, is so short that it may be disregarded: a so-called “square wave exposure” system. This will enable very accurate determinations of the thermal resistance of micro-organisms under well defined conditions, and from several such determinations at different temperatures an accurate determination of the change in thermal resistance with temperature to be made.

Operational sterilizer cycles do not produce this rapid heating and cooling but have relatively slow temperature changes. The product is thus exposed to temperatures somewhat below the chosen sterilizing temperatures for considerable periods. It is apparent that there will be some lethal effect on micro-organisms during the heating and cooling phases of any particular sterilization cycle since microbial death occurs over a wide range of temperatures, albeit at different rates.

The F_o concept recognises this and allows us to take account of the lethality obtained during the heating and cooling phases.

A1.3 For heat sensitive products it is desirable to minimise the heat treatment given to the product and reduce the energy input to a level which, while providing adequate assurance of sterility, will minimise the degradation of the product. Because the F_o concept allows us to take account of the inactivation of micro-organisms throughout the cycle, not just during the sterilization hold period, we can thus obtain a cycle with the required lethality but with minimum thermal degradation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A1.4 In summary, optimisation of thermal sterilization processes may be achieved by means of the *F* method which uses a knowledge of the lethality of the particular process at different temperatures to assess the overall lethality of the cycle and express this as the equivalent exposure time at a specified temperature.

A1.5 *F* is defined as the equivalent time in minutes at 121.1°C to produce a given sterilization effect.

A1.6 Where the specified temperature is 121.1°C (250°F) and the Z value is 10°C the term F_0 is used.

The F_0 value of a saturated steam sterilization process is the lethality expressed in terms of the equivalent time in minutes at a temperature of 121ºC delivered by that process to the product in its final container with reference to micro-organisms possessing a Z value of 10.

The total F_0 value of a process takes account of the heating up and cooling down phases of the cycle and can be calculated by integration of lethal rates with respect to time at discrete intervals.

A1.7 The F_0 method may be used for assessment, or control, of processes where difference in temperature is the only factor influencing the efficacy of the cycle. For example, it may be applied to the steam sterilization of aqueous fluids in sealed containers but it is not applicable to steam sterilization of porous loads where air removal is also a key factor and failure to achieve direct contact with Dry Saturated Steam can lead to failure, regardless of whether the required temperature was achieved within the load.

A1.8 Similar concepts are also used for dry heat sterilization processes and for depyrogenation by exposure to dry heat.

A1.9 There are a number of pre-requisites which it is necessary to consider before the use of the F_0 method is appropriate. These include:

- the efficacy of the sterilization process under consideration is dependent only on temperature eg. air removal is not critical. Thus in a porous-load steam sterilizer where impaired air removal can allow air to persist in random locations throughout the load, and where it may be present in sufficient quantity to impair sterilization, the use of the F_0 method for cycle control or monitoring is inappropriate;
- the sterilizer to be used has cycle control which is adequate to ensure that production cycles consistently reproduce the conditions established during validation. F_0 monitoring of a process may not be used to justify the use of a sterilizer which demonstrates excessive temperature variation within the load or poor reproducibility from cycle to cycle etc;
- temperature profile studies/validation studies have been conducted to establish the uniformity of conditions throughout load and to identify the location of those parts of the load which are slowest to heat up and fastest to cool down;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

- the loading composition and pattern of production cycles is controlled within the limits established during validation to ensure that the results obtained remain valid;
- production controls and bioburden studies are adequate to maintain a known, low level, of microbial contamination and the thermal resistance and temperature dependence (D and Z values respectively) of the most resistant contaminant(s) are known or the assumed values are in accordance with the Pharmacopoeial recommendations.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A2. Fundamental concepts

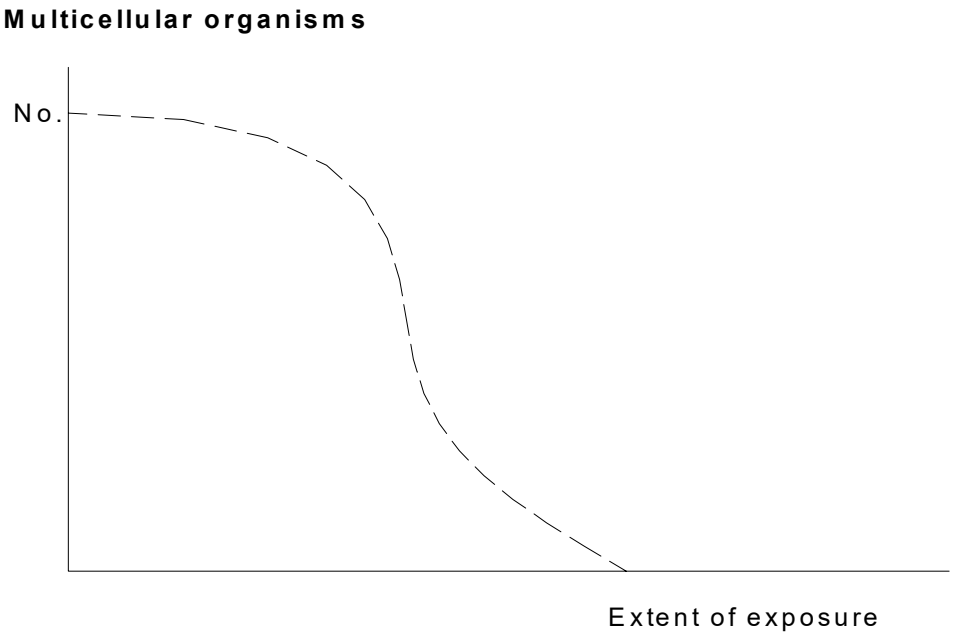
A2.1 In order to use the F_o concept correctly it is important to understand the facts, definitions and assumptions on which the model is based. It has become common place to use certain functions and terms in the analysis and interpretation of data on the effect of physical or chemical stress on microbial survival. These terms are discussed below.

How microbes die: the logarithmic order of death

A2.2 Organisms which die as a result of an imposed stress die in an orderly, and predictable, manner. This can be represented as survivor curve, showing the number of organisms still living at various times after the beginning of exposure to the stress condition.

A2.3 The order of death is, in principle, the same for all multicellular organisms. The survivor curve remains constant for as long as individuals can recover from that length of exposure; then as the first individuals die, the frequency of death rapidly increases until only a few very resistant organisms remain, and they succumb shortly after the majority of the population (see Figure A1). In a unicellular organism the individual is dead when a single cell dies, whereas in multicellular organisms the death of one cell is not likely to kill the individual. The multicellular organism will survive until enough cells have been killed to cause death.

Figure A1: Arithmetic survivor curve for multicellular organisms



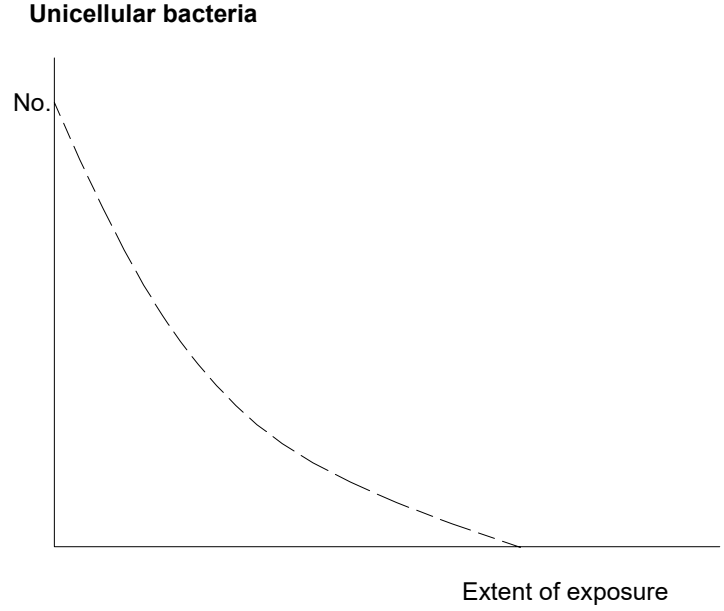
© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A2.4 Whichever multicellular organisms are tested, for example insects or plants, and whatever the lethal stress, the survivor curve remains essentially the same. This was accepted as universally true for all organisms until the early 1900s when workers such as Harriet Chick [see Chick (1908)] showed that in an homogeneous culture of a single strain of bacteria the cells died at a constant rate when exposed to a particular lethal stress.

A2.5 It was apparent that these bacteria were dying in a manner which was somewhat unexpected. This may be illustrated by taking as an example the survival of microbial spores subjected to heat stress. An experiment may be devised in which all factors other than the heating time are held as constant as possible. If a number of biological indicators, each bearing a known number of bacterial spores, are subjected to a thermal sterilization process, at a predetermined temperature for various increments of exposure time, and then the survivors on each indicator enumerated, the data obtained shows the number of colony forming units remaining viable after each exposure time.

A2.6 A survivor graph can be prepared showing the number of survivors as a function of the length of heating time. Both the number of survivors and the time may be plotted on an arithmetic scale (see Figure A2).

Figure A2: Arithmetic survivor curve for unicellular bacteria

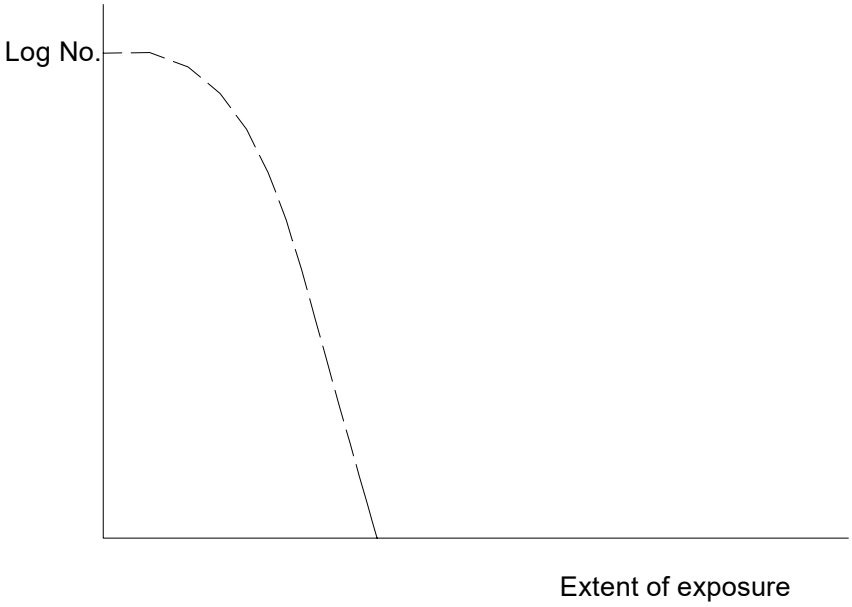


A2.7 Alternatively the number of survivors may be plotted on a logarithmic scale as a function of time on the arithmetic scale, which is referred to as a semi-log survivor curve (see Figures A3 and A4). While both the arithmetic and semi-log survivor curves accurately represent the death of bacteria the latter is more useful in sterilization studies where interest is concentrated on the rate of destruction as the number of survivors approaches zero.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure A3: Semi-log survivor curve for multicellular organisms

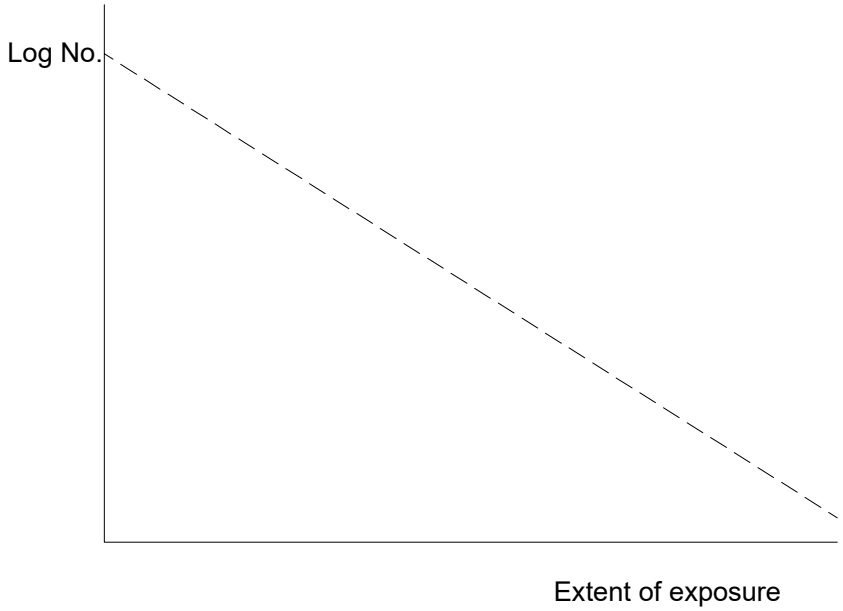
Multicellular organisms



A2.8 It is usual to use the latter approach since in sterilization studies we are interested in the rate of destruction as the number of surviving micro-organisms approaches zero, which is best shown using a logarithmic plot.

Figure A4: Semi-log survivor curve for unicellular bacteria

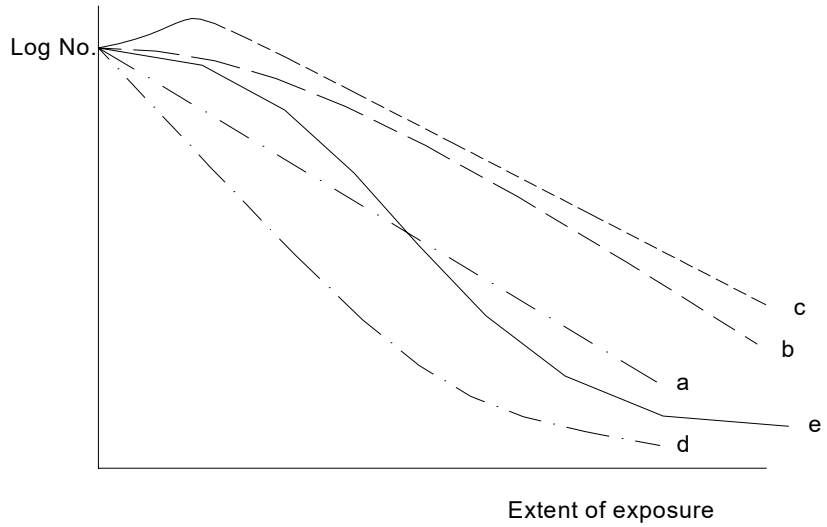
Unicellular bacteria



A2.9 Experience has shown that the semi-log survivor curve for heat stress often approximates to a straight line for part or all of the survivor curve. However there are many recorded instances where deviations from the “ideal” straight line condition occur (see Figure A5).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure A5



Microbial survivor curves showing typical deviations from the linear model; curve **a** is a theoretical linear survivor curve; curve **b** shows an initial "shoulder" followed by a linear survivor curve; curve **c** shows an initial increase in count, "activation", followed by a linear survivor curve; curve **d** shows an initial linear survivor curve followed by a decreasing rate of kill, "tailing"; curve **e** shows the sigmoidal survivor curve often encountered in experimental determinations.

Conditions resulting in a non-logarithmic order of death

A2.10 Typical survivor curves for bacterial spores exposed to moist heat sterilization processes are shown in Figure A5 in which the logarithm of the number of surviving organisms is plotted against time and various types of response are illustrated:

- *Curve a* – exponential – constant fraction of the population is inactivated per unit time;
- *Curve b* – shows an increasing death rate after an initial period where there was little or no inactivation – a "shoulder";
- *Curve c* – initial activation (increase in population) followed by a constant death rate;
- *Curve d* – decreasing death rate with a low number of highly resistant organisms surviving for a prolonged period – "tailing";
- *Curve e* – a sigmoidal survivor curve of the type frequently encountered in experimental determinations of resistance. This type of survivor curve may be regarded as a composite of elements of the survivor curves described above.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Factors influencing the nature of the survivor curve

A2.11 There are a number of factors which have a significant effect on the nature of the survivor curve. Workers such as Moats *et al* (1971) have discussed these factors in detail. Some of the key factors can be summarised as follows:

- *Growth index*. During recovery there are many instances when not all viable spores will germinate and outgrow within a short time period. The percentage of those present which do germinate and grow immediately on incubation is referred to as the growth index. The growth index varies both with the species of bacterial spore and the cultural conditions in which it was grown and is to be recovered. It may be as high as 100%,for example for Bacillus subtilis, but may be as low as <1%, for example for Bacillus stearothermophilus. Sublethal heating may increase (activate) or decrease (deactivate) the growth index and give rise to non-linear survivor curves. [see Favero (1967), Finley and Fields (1967)] The interaction of activation and inactivation on the thermal treatment of heat resistant dormant spores of B stearothermophilus can be described mathematically. [see Shull *et al*. (1963)]
- *Cell clusters*. The usual method of counting the number of surviving bacteria is by the plate count method which gives the number of colonies developed from a known volume of suspension inoculated onto the surface of solid growth medium. The number of colonies is equal to the number of bacteria present only when each colony arises from a single cell.

  When the cells are in clusters, for example Staphylococcus spp., or in chains, for example Streptococcus spp., one colony may represent a large number of cells. All the time there are one or more surviving cells within the aggregation a colony will be formed and death therefore becomes evident only when the last cell is dead. Such clusters “die” like multicellular organisms and show convex survivor curves (see Figures A3 and A5, curve b).
- *Cell age*. It has been demonstrated that young cells, that is, the exponential growth phase of a culture, are more susceptible to both chemical and physical stress than old cells from the stationary phase of a culture. Furthermore if old cells are transferred to a new environment they do not all begin to grow at the same time and a culture develops in which both old and young cells coexist leading to heterogeneous resistance and concave survivor curves (see Figure A5, curve d).
- *Mixed populations*. Where more than one strain or species is present, with different resistances to the lethal stress being imposed, a non-linear survivor curve, typically of concave form, will arise (see Figure A5, curve d).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Factors influencing the heat resistance of spores

A2.12 Any assessment of thermal resistance of micro-organisms must involve consideration of those factors which may affect the thermal resistance.

A2.13 These factors include the species and strain of organisms to be considered; its physiological state, which will in part depend on its immediate cultural history, the manner in which it is presented to the sterilization process, for example the suspending menstruum; and the recovery conditions which are used in an attempt to grow the organism after exposure to the process; as well as the exposure conditions used, for example whether dry heat or moist heat (direct contact with dry saturated steam or being in an aqueous solution) was used, and the exposure temperature. [see Russell (1971).]

A2.14 The nature of the product also affects the thermal resistance of contaminating organisms; the protective effects of various salts and carbohydrates in solution are well documented in the literature.

A2.15 The influence of changes in the manufacturing environment and/or process on the nature and extent of contaminating micro-organisms must also be considered.

Treatment of sterilization-process microbial survival data

A2.16 A mathematical approach to the resistance of bacteria to thermal death is required to allow calculation of equivalent lethality. Two factors need to be considered; the thermal resistance of the micro-organism at a particular temperature and the change in that resistance which occurs with changes in temperature.

These two factors are analogous to the rate constant and temperature coefficient of a chemical reaction, respectively.

A2.17 Spore inactivation in moist heat may be considered as a monomolecular first order reaction, that is where the rate of reaction is governed by the concentration of the reactant, in this case the bacterial spores.

This may be expressed as

$$\frac{dN_a}{dt} = k\,C_a$$

Where t = time,

C_a = spore concentration

k = a reaction rate constant at constant temperature

Then $(\log C_a^0 - \log C_a) = k\,(t - t^0)$

where the superscript 0 indicates initial conditions.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A2.18 A semi-logarithmic plot of concentration versus time will yield a straight line of slope k. k has dimensions of time^{-1}. The negative reciprocal of the rate constant k is equivalent to the number of minutes required to inactivate 90% of the organisms present, that is a 1 log reduction. This value is referred to as the D value and, as stated, mathematically it is inversely proportional to the inactivation rate constant k.

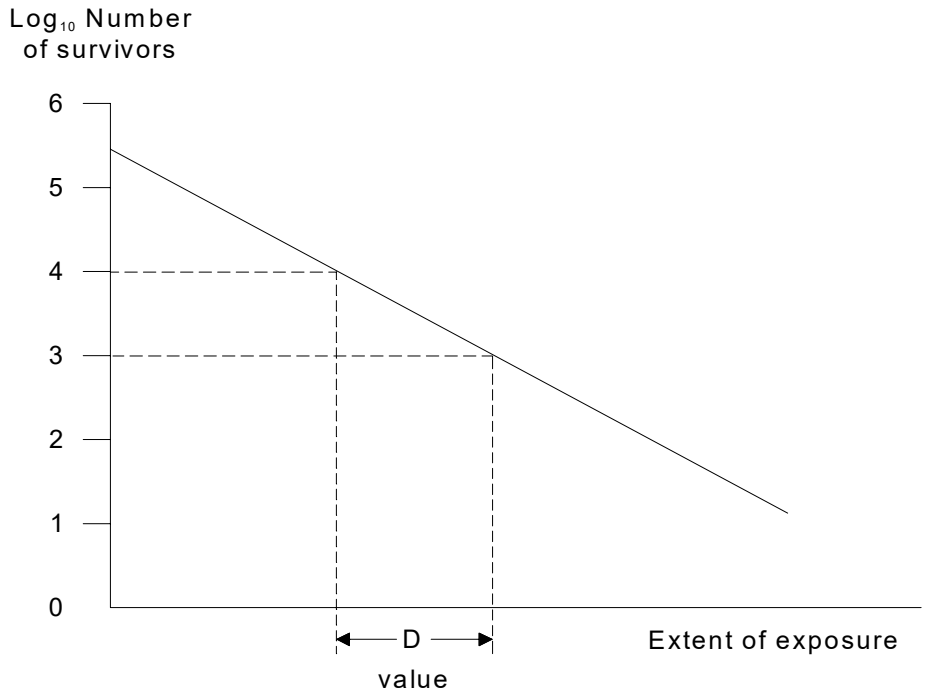
D = 2.303 /*k*.

Decimal reduction value (D value)

A2.19 The D value is used as a measure of the resistance of a defined micro-organism to a defined sterilization process. It is a convenient way to describe the slope of a linear semi-log survivor curve.

A2.20 More particularly it may be defined as the extent of exposure, under stated conditions, necessary to produce a 90%, or 1 log, reduction in the bacterial population (see Figure A6). It is usually stated in minutes, except for sterilization processes using ionising irradiation where it is given in kiloGreys (units of absorbed radiation dose).

Figure A6: Decimal reduction value



A2.21 For moist heat sterilization processes it is often given a subscript to indicate the temperature at which it was determined, for example D_{121}. Although this in itself is insufficient definition of the conditions under which the determination was made to allow valid comparison.

A2.22 The D value is highly specific to the experimental conditions under which it was determined. Even apparently minor changes in experimental procedure,

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

for example incubation temperature, recovery medium can have a dramatic effect on the apparent D value.

A2.23 The D value is only relevant to the survivor curve when the survivor curve is truly a straight line over the range of population values of interest, including the “probability” zone.

A2.24 It is not necessary to construct a survivor curve to determine D value The determination may be done by a replicate unit method involving fractional-unit- negative (FN) data. A number of replicates are heated for a certain time and the number viable and the number sterile are determined. [see Pflug and Schmidt (1968).]

Then where r = total number,
p = growth,
q = sterile,
U = time in min,
N_0 = initial population per replicate unit
N_U = population per replicate unit after time U,

then

$N_U = \log_n(r/q) = 2.303 \log (r/q)$

and

$$D = \frac{\textit{duration of treatment}\ (\min)}{\log \textit{initial no} - \log \textit{final no of spores}}$$

$$= \frac{U}{\log N_o - \log N_U}$$

The temperature dependence of resistance

A2.25 A common measure of the temperature dependence of a chemical reaction is the Q_{10} value. This is defined as the change in reaction rate constant k for a 10°C change in temperature:

$$Q = \frac{k^{(T + 10^{\circ} C)}}{k_T}$$

A2.26 For most chemical reactions Q_{10} has a value of about 2, but for spore inactivation in moist heat $Q_{10} \approx 10$ to 18 and for spore inactivation in dry heat $Q_{10} \approx 2.2$ to 4.6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A2.27 Other measures of temperature dependence include the Arrhenius equation;

$$k = A \exp(-E_A(RT)^{-1})$$

Where k = the reaction rate constant;
A = the frequency factor;
E_A = the activation energy;
R = the universal gas constant;
T = the absolute temperature.

A2.28 However, the temperature dependence of reaction rates for spores is generally expressed as a Z value,

Where $$Z = \frac{\log Q_{10}}{10}$$

or $$Z = 2.303RT^2E_A^2$$

Z value

A2.29 The *Z* value is a measure of the change of inactivation rate with temperature. It is the slope of a plot of *D* value on a logarithmic scale against temperature on an arithmetic scale (see Figure A7).

A2.30 The *Z* value allows comparison of the lethal effect of heating at different temperatures. [See Bigelow (1921).]

A2.31 As originally defined *Z* is numerically equal to the number of degrees Fahrenheit change in temperature required to reduce the *D* value by 90%, or 1 log. Considerable confusion, and error, can be caused where the temperature scale used is not specified. Although values are now usually given in °C care must be taken when using published data, for example from the official compendia, to note whether the *D* value is quoted in °F or °C.

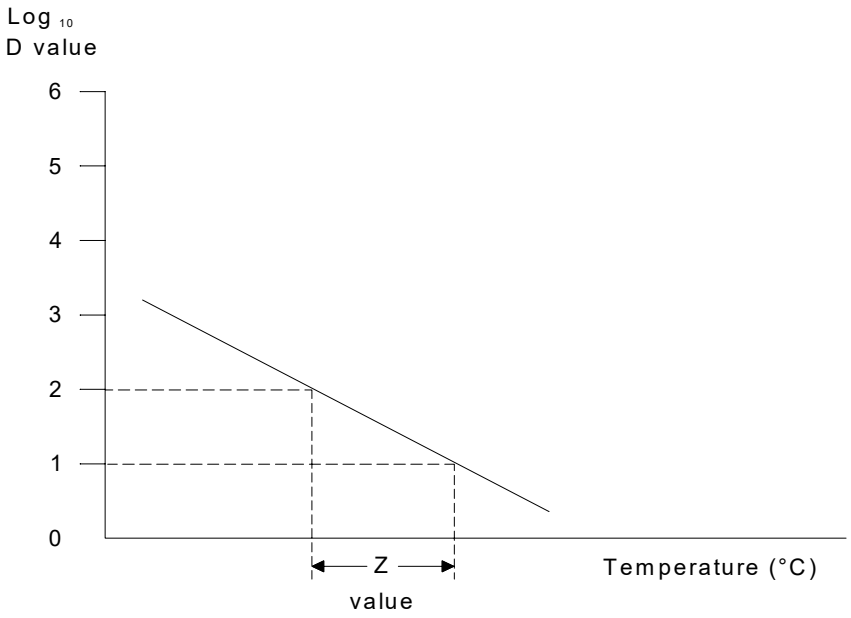
A2.32 The mathematical relationship with the D value can be expressed as:

$$\log D_2 - \log D_1 = \frac{(T_1 - T_2)}{Z}$$

A2.33 It should be noted that, the greater the *Z* value, the greater the increase in temperature which is required to give a tenfold decrease in *D* value. Hence the assumption of a *Z* value higher than in fact exists will give an additional margin of safety. The *Z* value assumed for most thermophiles, such as Bacillus stearothermophilus, is 10°C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure 7: Thermal resistance curve



A2.34 The straight-line relationship holds good only over a limited temperature range for an homogenous culture of a single strain of micro-organisms. Mixed cultures give a non-linear relationship, but in practice one sub-population, either by virtue of its resistance or its prevalence, will be controlling with regard to attainment of sterility.

Lethal rates

A2.35 The usefulness of the temperature dependent model lies in being able to calculate the lethality over a range of temperatures, which will include those experienced during heating-up and cooling-down of a load in a steam sterilizer.

A2.36 The relative lethality at a temperature, T_{exp}, compared to the known lethality at a particular reference temperature, T_{ref}, is dependent on the *Z* value.

Thus, the lethality L is given by the equation

$$L = 10^{(T_{exp} - T_{ref}) Z^{-1}}$$

Lethality factors for any temperature deviation from the reference temperature and for any *Z* value can be calculated using this formula (see Table A1).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A2.37 A new variable *F*, the thermal death time can be defined. The change in *F* with temperature is analogous to the change in thermal resistance (*D* value) with temperature and both are dependent on the *Z* value. Plots of log *D* versus temperature and log *F* versus temperature both have slope Z:

$$\frac{D_T}{D_{121}} = \frac{F_T}{F_{121}} = 10^{(T-121)/Z}$$

F value

A2.38 The *F* value expresses heat treatment in terms of the equivalent effect of a stated time at some stated temperature for a particular Z value, that is to say that the *F* value is the equivalent time in minutes at 121.1°C (250°F) for an organism of specified *Z* value.

A2.39 F_0 is the *F* value when *Z* is 18°F (10°C):

$$F_0 = \sum 10^{(T-121)/Z} \Delta t$$

where t is the chosen time interval, and T is the temperature in the container.

NOTE: For dry heat *F* values, *F* is equal to the time in minutes at 176°C (350°F).

A3. Sterility

A3.1 In order to utilise the F_0 method it is first necessary to decide on the extent of treatment which will be necessary to provide the required level of assurance that the product is sterile. Several different definitions are in common use.

Sterility assurance

A3.2 If the survivor curve is extrapolated beyond $\log_{10}0$, that is one surviving organism, we reach a region of "probability" of finding a single surviving organism. For example at $\log_{10}[-1]$ we expect to find, not 0.1 organisms surviving in every sample but, one in every ten samples with a surviving micro-organism.

We can thus determine from the survivor curve a theoretical probability of any one unit of product being non-sterile.

A3.3 The standard, BS EN 556, in common with a definition in the *European Pharmacopoeia*, states that a product may be regarded as sterile when the theoretical level of not more than one micro-organism is present in 1×10^6 sterilized units of the final product.

A3.4 This calculation may be based on data, obtained by investigation, on the extent and resistance of microbial contamination immediately prior to sterilization (the Bioburden) or on a theoretical contamination of 10^6 micro-organisms per unit of product presumed to be of a type having known high resistance to the process, for example bacterial spores. In the latter case the cycle is often referred to as a "12D" or "overkill" cycle and was first proposed by Esty and Meyer (1922) for processing low-acid canned food products.

A3.5 The *British Pharmacopoeia* in Appendix XVIII 'Methods of Sterilization' states: "For aqueous preparations sterilized by heating in an autoclave the preferred combination of temperature and time is a minimum of 121°C maintained throughout the load during a holding period of 15 minutes." However, it goes on to say: "Other combinations of time and temperature may be used provided that the process chosen delivers an adequate level of lethality when operated routinely within the established tolerances."

A3.6 In Annex 2, 'Guidance on application of the F_0 concept to aqueous preparations', the British Pharmacopoeia suggests that "in general for aqueous preparations a microbiologically validated steam sterilization process that delivers, in total, an F_0 value of not less than 8 to every container in the load is considered satisfactory".

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A3.7 In certain circumstances, however, use of a steam sterilization process that delivers, in total, an F_0 of less than 8 may be considered justifiable, for example where the product is especially heat sensitive. The nature of processes delivering an F_0 of less than 8 is such that great care must be taken in order to ensure that adequate assurance of sterility is consistently achieved. It is necessary not only to validate the process microbiologically but also to perform continuous, rigorous microbiological monitoring during routine production to demonstrate that the microbiological parameters are within established tolerances so as to give a theoretical level of not more than one living micro-organism per 10^6 containers in the final product.

A3.8 The *European Pharmacopoeia* also states that the recommended method for parenteral products is moist heat sterilization at a minimum of 121°C maintained throughout the load for a minimum of 15 minutes. Other time temperatures can be used but the crucial requirement is delivery of an adequate level of "lethality" to the product. The use of F_o is recognised with an F_o of 8 being the usually acceptable minimum. It is emphasised that this requires a low pre-sterilization bioburden and the absence of heat resistant spores.

Calculation of F_0 values

A3.9 Reliable F_0 value calculations are simply achieved with modern microprocessor based control and monitoring systems. However F_0 values can be calculated manually, and many of the available computer programs employ essentially similar methods:

a. *Graphical method*. In the graphical method *F* reference paper is used on which the lethal rate per minute, at particular temperature, is represented by length on the vertical axis. The horizontal axis has a corresponding arithmetic scale for time such that the area of a rectangle delineated by the ordinate 121.1°C and a length corresponding to one minute on the abscissa is equal, by definition to an F_o of one. The cumulative area under the curve as the cycle progresses represents the cumulative lethality of the process (see Figure A8). In practice the temperature profile is plotted and the area under the curve determined using a planimeter. The area measured is then converted to an F_o value using the scale of the *F* reference paper.

b. *Summation method*. In the summation method the lethal rate at each specific temperature is calculated or read from a table (see Table A1) and multiplied by the time for which that temperature persisted. The values obtained for each temperature are summed to give the overall F_o value for the cycle.

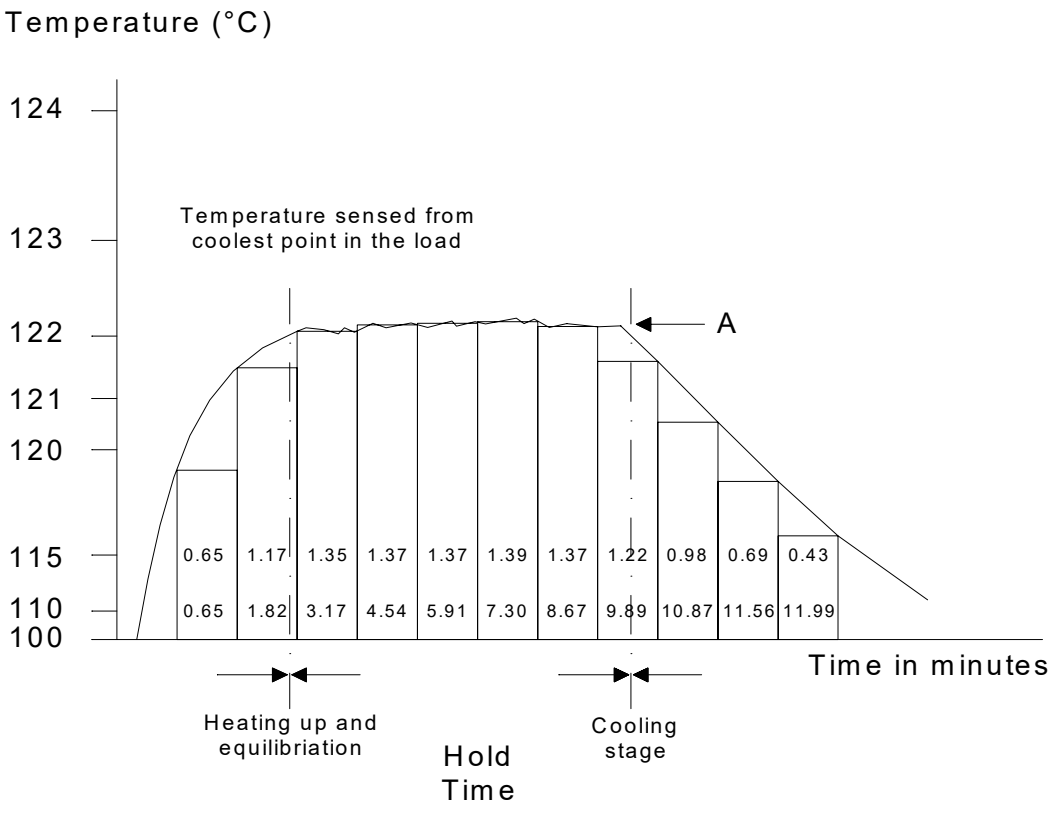
© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A3.10 The accuracy of the integration is affected by a number of factors.

These include:

- the choice of time interval between successive temperature measurements. BS 3970 Part 2 specifies a maximum interval of two seconds;
- whether the minimum, maximum or average temperature during the chosen time interval is used. (Since the method is an approximation based on summing discrete data to represent continuous data there will always be some error, which may be positive or negative; each may be correct for different purposes);
- the location of the sensor(s) from which the temperature is read and the adequacy of the validation of sensor location;
- should be used only over the temperature range for which *Z* has been determined. The *Z* value for any micro-organism does not remain constant over all possible temperatures. Therefore any particular lower temperature limits for the integration need not be set since, for a Z value of 10, F_0values below 105°C make so little contribution. For example, 40 minutes exposure at 105°C is equivalent to one minute at 121°C.

Figure A8: Graphical determination of F_0 values



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

The ordinate scale (temperature) of *F*-reference paper is proportional to the lethal rate so that the area beneath the curve is a measure of the *F* value. The cumulative values during the cooling stage are not used for sterilizer control but may be used in monitoring to provide an accurate assessment of the overall lethality delivered by the sterilization cycle. Within each box the figures in italics indicate the F_0 value calculated for that time-temperature rectangle. The lower figures indicate the cumulative F_0 value through the cycle. The F_0 controller, set to provide an F_0 value of 9, initiates the cooling stage at point A. The total monitored F_0 value of the cycle is 11.99.

NHSScotland Property and Environmental Forum

A4. Applications of the F_0 concept

General

A4.1 Part 3 of this SHTM states that if a fluid sterilizer is fitted with an F_0 integrating system, then the recorder should be capable of computing and printing values of F_0 for each channel with integration times no greater than 2 s. This is also a requirement of BS 3970: Part 2.

Control of sterile cooling fluid (in a steam sterilizer for fluids in sealed containers)

A4.2 It is a requirement that if the coolant is derived from a water or steam service and is intended to come into contact with the load containers, the operating cycle must expose the coolant to sufficient heat to ensure that it is free of microbial contamination by the end of the holding time. This is checked by calculating an F_0 value for the heat treatment received by the coolant. If the test recorder is not capable of calculating F_0 both BS 3970 and Part 3 of this SHTM recommend the following procedure:

a. from the measured temperatures, identify the point during the heat-up time at which the coolant temperature first reaches 108°C. Note the temperature (T°C) at subsequent one minute intervals until the end of the holding time;

b. for each measurement, calculate the incremental F_0 (ΔF_0) from the following equation:

$$\Delta F_0 = \log_{10}\left[\frac{T - 121}{10}\right] \text{ minutes}$$

where T is the lowest temperature of the coolant water for each one minute time interval

c. the F_0 value is the sum of all ΔF_0.

The test should be considered satisfactory if the F_0 for the coolant is not less than 8 minutes.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

F_0 controlled sterilizers – Control of operating cycles in steam sterilizers for fluids in sealed containers

A4.3 The operating cycle for steam sterilizers used to process aqueous fluids in sealed containers may be divided into several stages.

1. heat up (and, where necessary, air removal) – the chamber atmosphere attains the required temperature;
2. equilibration time – all parts of the load attain or exceed the minimum temperature of the sterilization temperature band;
3. holding time – all parts of the load are maintained at a temperature within the sterilization temperature band;
4. cooling stage – the load is cooled to a temperature at which it will be safe to handle.

A4.4 Stages 2 and 3 may be controlled by one of the following:

a. adjustable timers of an automatic controller in conjunction with temperature sensors within the active chamber discharge and within containers of the load;
b. a simulator control system;
c. an F_0 system.

A4.5 Provision for adjustment of the equilibration time (stage 2) is necessary and may be achieved by one of the following:

a. an operator adjustable timer on the instrument panel;
b. a simulator control system;
c. an F_0 integrating system.

A4.6 When an F_0 control system is fitted, the control function should be limited to the initiation of the cooling stage (stage 4) once a selected F_0 value has been attained.

A4.7 In addition to the minimum requirement of two temperature sensors (see 13.1.4 of BS 3970 Part 1) two further temperature sensors shall be provided for use in two load containers.

A4.8 The control system shall be designed to integrate from the temperatures sensed within containers of the load at selected locations at time intervals not exceeding 2 seconds.

A4.9 The range of F_0 values selectable shall include 1 to 30.

A4.10 When tested in accordance with Test method 1, the Individual values of F_0 determined using the reference instrument shall be within the ranges stated in Table A2 for each of the F_0 values indicated by the sterilizer under test.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Table A2: Permitted Ranges For F_0 Values

F_0 value indicated by sterilizer under test	Permitted range for F_0 values determination by the reference instrument*
1	1 to 1.05
15	15 to 15.7
30	30 to 31.5

* The reference instrument is described in Test method 2

Monitoring operating cycles in steam sterilizers for fluids in sealed containers

A4.11 For aqueous products in sealed containers temperatures are measured (with thermocouples or RTDs) throughout the heating and cooling stages as well as during the sterilization hold period. The slowest container to heat and the fastest container to cool may be used to determine the minimum lethality received by the load. these locations are often found in different locations.

A4.12 Determination of the maximum temperatures in the load may also be necessary for thermolabile products where deterioration may be a problem.

A4.13 It is essential that during commissioning and validation it is established that the position of containers which need to be monitored remains consistent from cycle to cycle. A sterilizer where the slowest part of the load to reach temperature is found in different parts of the load on successive cycles is not suitable for control or monitoring by F_0 values and is in urgent need of skilled attention. For air-ballasted sterilizers this may involve additional requirements on monitoring the circulation of the chamber atmosphere to ensure that the location of the cool point remains constant.

A4.14 Calculation of the F_0 value delivered by a process may be estimated from the lowest temperature-time curve registered from the containers in the load. The process is satisfactory if the registered F_0 value is within the minimum and maximum limits established during validation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Validation of operating cycles in steam sterilizers for fluids in sealed containers

A4.15 The use of F_0 control or monitoring systems places additional requirements on the validation process.

A4.16 As described in Part 3 of this SHTM, paragraph 8.4 'Sterilizer function using a full load' '... the temperature of all sites monitored within the load ..... shall be within 1°C of each other throughout stage 3'. This requirement applies regardless of whether an F_0 system is used.

Container cool point

A4.17 Container mapping is necessary to determine the container cool point. Container mapping studies should be conducted prior to conducting loaded chamber heat penetration studies in order to determine the position within the liquid-filled container which is slowest to attain temperature.

A4.18 Small volume containers and those of cylindrical form where the length:diameter ratio is large are the least likely to demonstrate a detectable cold spot.

The number of thermocouples within the container should be sufficient to monitor the upper, middle and lower layers of the central region of the container. Using an excessive number of temperature probes may introduce significant errors in the determination.

A4.19 The profile point requiring the longest exposure time to equilibrate with the chamber temperature should then be used in subsequent F_0 studies and monitoring (but see later for degradation/product stability considerations).

A4.20 Suitable container entry systems for the insertion of temperature probes into sealed containers are described in part 3 of this SHTM (Figure 3).

A4.21 Independent measuring equipment should be to the standard described in part 3 of this SHTM, Chapter 6.

A4.22 The test should be carried out as described in part 3 of this SHTM for a thermometric test for a full load (see paragraph 14.10) except that the load should be containers of the type and number to be used in practice and filled with the product to be sterilized or a suitable substitute with similar thermal characteristics, (see paragraph A4.31 below).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Load cool point

A4.23 It is necessary to determine the coolest point within a specified load type and configuration of load. Cool points arise because of varied rate of heat transfer throughout the load and studies are needed to ensure that the cool points are identified so that they may be exposed to sufficient heat lethality.

A4.24 The study is carried out in the same manner as the performance qualification described in part 3 of this SHTM (see paragraphs 8.13 to 8.28 performance qualification).

A4.25 Similar studies may be used to identify those containers which attain temperature maxima or most prolonged exposure to the equilibrium temperature for product degradation and/or stability studies.

A4.26 The F_0 value for the process may then be determined by integrating the lethal rates throughout the heating process using one of the methods previously described.

Microbial challenge studies

(See also part 3 of this SHTM paragraphs 8.29 to 8.36)

A4.27 Biological challenges may be used during validation studies in order to demonstrate the process lethality provided by the sterilization cycle. Calibrated biological indicators used for this purpose act as bioburden models and can be used in obtaining data to calculate F_0 values delivered by the cycle or to supplement physical temperature measurement, for example from thermocouples.

A4.28 The number of spores to be used in the BI can be calculated from the following formula

$$D_{prod} (\log N_{prod} + 6) = D_{bi} (\log N_{bi} + 1)$$

Where D_{prod} = the resistance of the most resistant organism in the product bioburden;

N_{prod} = the number of organisms in the product to be sterilized;

D_{bi} = the resistance of the BI organism;

N_{bi} = the number of organisms on the BI.

A4.29 Designated liquid-filled containers are inoculated with the indicator organism by injecting an aliquot of a calibrated spore suspension into the suspending menstruum to provide the calculated concentration of spores. The containers chosen should be those previously established by temperature measurement as having the lowest delivered lethality.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A4.30 The suspending menstruum should be the product to be sterilized unless this contains preservatives, antimicrobials or other substances which inhibit the growth of the indicator micro-organisms.

A4.31 If it is necessary to use a product substitute it should be selected to have similar physical characteristics to the product this should include heat capacity (specific heat), density, viscosity, thermal conductivity.

A4.32 Great care needed when using inoculated product to minimise the possibility of contaminating the production environment.

A4.33 Microbial challenge studies should be conducted concurrently with heat penetration studies.

Product degradation and stability versus cycle lethality

A4.34 When heat-sensitive thermolabile products are to be sterilized it is important that adequate assurance of sterility is not obtained at the expense of product degradation or stability.

A4.35 For sterilization the temperature dependence of the process is described by the Z value, that is the change in temperature required to give a tenfold change in the rate of microbial kill. Increasing or decreasing the temperature of the process requires a corresponding decrease or increase in exposure time to maintain the same cycle lethality or F_0 value.

A4.36 For any given temperature, microbial death and chemical degradation take place at different rates. The relationship between time and temperature which exists for microbial lethality cannot be extrapolated to the product degradation reaction.

A4.37 If the degradation reaction is not altered significantly by the change in temperature the extent of degradation will increase as process (exposure) time is extended. Conversely, if the degradation reaction is highly temperature dependent (high activation energy) a decrease in temperature may more than compensate for the increase in time, resulting in less degradation.

A4.38 The key variable is the activation energy, E_A . If the activation energy for the chemical degradation reaction is lower than that of the microbial death curve, that is it is less temperature dependent, then it can be assumed that a decrease in sterilization temperature will result in greater product degradation.

A4.39 Furthermore it cannot be assumed that sterilization cycles of equivalent lethality, but which differ with regard to time and temperature, will yield product of equal quality.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A4.40 The assumption that degradation reactions follow first-order reaction kinetics is probably a good approximation in most cases where a single active drug product is contained in the solution.

A4.41 Experience has shown that a decrease in sterilization temperature can have a marked deleterious effect on product and its long term stability.

A4.42 Sterilization of glucose solutions in plastic containers may require a sterilization temperature in the range 115-118°C in order to protect the thermolabile container. The increased time required for sterilization compared with a traditional cycle at 121°C used for similar solutions in glass bottles results in a noticeable increase in caramelization.

A4.43 The activation energy of the lethal reaction for bacterial spores with a *Z* value of 10°C is high (typically around 60 kcal/mole) compared to most first-order liquid-phase decompositions. Thus products that degrade with heat are more affected by an increase in time than an increase in temperature. For example, expressed as a *Z* value the temperature effect of the degradation of glucose would have a *Z* value of about 33°C.

A4.44 The use of *F* values based on the *Z* value of the most resistant contaminating organism found during bioburden studies rather than an assumed *Z* value of 10°C may be necessary for particularly thermolabile products. Great care is needed in the application of this technique because of the inherent variability of microbial contamination and the rigorous process control and monitoring needed to minimise this.

Product stability

A4.45 Product stability may also be related to degradation during sterilization. Chemical reaction kinetic studies on many products indicate that product stability over the desired shelf life can be extrapolated from the extent of degradation measured just after sterilization. In some cases a degradation product formed during sterilization triggers subsequent deterioration and the specific factors affecting the formation of the degradation product would need to be investigated.

A4.46 Both microbial lethality and degradation are cumulative with respect to time and temperature, so variations in the heating and cooling phases of the cycle will affect the extent of degradation, and thus product stability, as well as lethality.

A4.47 Degradation and stability studies should consider the entire cycle and not just the dwell time. These effects are more pronounced for products where the degradation reaction has a lower activation energy.

A4.48 F_0 values are generally calculated from the coolest part of the load. For degradation and stability purposes the hottest part of the load is of more consequence. The entire range of temperature and time experienced throughout the load must be recorded in order to substantiate degradation and stability claims.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Cycle development studies

A4.49 Determination of F_0 values is often of value in the development of appropriate operating cycles for steam sterilization of both fluids in sealed containers and wrapped goods and porous loads. However, since temperature measurement alone cannot reliably detect failure to obtain direct contact with dry saturated steam, it is not practicable to use F_0 values for monitoring or controlling porous load cycles.

The use of F_0 values for porous load cycles should be limited to determining suitable sublethal cycles for biological challenge studies.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

A5. Test methods

Test for F_0 control compliance

Apparatus

A5.1 Glass bottle, of nominal capacity 1 litre, complying with DIN 58363.

A5.2 Independent F_0 reference instrument, as described in section F.

Procedure

A5.3 Install the reference instrument.

A5.4 Place 1 litre of cold water in the bottle. Insert the two temperature sensors of the F_0 control system and the sensor of the reference instrument so that the sensing points of all three are at about 85% of the bottle depth and over the approximate centre of the bottom of the bottle. Seal the bottle.

A5.5 Select the required F_0 value on the control panel and perform a cycle in which automatic control is terminated manually immediately at the beginning of stage 4. Note the value of F_0 shown by the reference instrument.

A5.6 Repeat the procedure described in paragraph A5.5 twice.

A5.7 This test procedure shall be carried out for F_0 values of 1, 15 and 30.

A5.8 Calculate the mean of the three replicate values for each setting of F_0 control and check for compliance with the values given in Table A2.

Test for performance of reference instrument

Apparatus

A5.9 Temperature regulated heat source capable of being controlled at a given temperature within 0.10°C in the range 115°C to 126°C.

A5.10 Thermometer traceable to national standards to include the range 100°C to 130°C complying with BS 593 and graduated at intervals of 0.1°C.

A5.11 Temperature logging device computing F_0 values of the sensor(s) with integration at least every 2 s and means of print out, together with suitable temperature sensor(s).

A5.12 Stopwatch.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Procedure

A5.13 Install the sensor(s) into the temperature regulated heat source.

A5.14 Adjust the heat source so that it maintains a temperature of 121±0.1°C.

A5.15 Allow the equipment to integrate F_0 for 15 minutes timed with the stopwatch. Note the indicated F_0 value.

A5.16 Repeat with the temperature source maintained at 115±0.1°C for 30 min.

A5.17 Repeat with the temperature source maintained at 126±0.1°C for 10 min.

A5.18 The replicate F_0 values obtained at 121°C shall lie within the range 14.66 to 15.34.

A5.19 The replicate F_0 values obtained at 115°C shall lie within the range 7.36 to 7.71.

A5.20 The replicate F_0 values obtained at 126°C shall lie within the range 30.90 to 33.36.

NHSScotland Property and Environmental Forum

Glossary

D value The *D* value (or Decimal Reduction Value) is a measure of the resistance of a micro-organism to a particular type of sterilization process. It is the value of the appropriate parameter of the process (duration or absorbed dose) required to reduce the number of viable micro-organisms to 10% of the original number.

In connection with sterilization by heating in an autoclave the D value is expressed by the time minutes at a defined temperature (the temperature is often shown as a subscript, for example D_{121}).

Z value In connection with sterilization by heating in an autoclave the Z value relates the heat resistance of a micro-organism to changes in temperature. The Z value is the change in temperature required to alter the D value by a factor of 10.

F_0 A quantity, measured in minutes, used to determine the efficacy of an operating cycle and equivalent to a continuous period at a temperature of 121.1°C for an organism with a Z value of 10°C.

C1. Introduction

C1.1 This section discusses the factors which should be considered in the selection and use of packaging for terminally sterilized products, that is, those materials which are sterilized in their packaging.

Packaging for medical equipment which has been cleaned, decontaminated/disinfected and serviced ready for return to use is not included in this guidance.

C1.2 It does not consider those products which are sterilized and then aseptically packed in sterilized packaging materials nor does it cover packaging of terminally sterilized components to be used in aseptic manufacturing.

Sterilization processes

C1.3 Because the product is sterilized in its packaging it is necessary that the packaging maternal is compatible with the sterilization process to be used.

C1.4 The sterilization processes included are those which are generally available for use either directly or through a sub-contractor. It does not include requirements for new processes which are currently under development or at an early stage of their introduction for practical use. This would include, for example, those systems employing gaseous or plasma phase peracetic acid and/or hydrogen peroxide.

C1.5 Sterilzation processes included are:

a. Steam – for clinical use (see SHTM 2010 Part 1, paragraph 2.1 (a)):
   (i) for wrapped goods and porous loads;
   (ii) for aqueous fluids
      - in rigid containers;
      - in flexible containers;
   (iii) for unwrapped instruments and utensils
      - externally supplied steam;
      - internally generated steam;
b. Steam – for laboratory use (see SHTM 2010 Part 1, paragraph 2.1 (b)):
c. Low-temperature steam and formaldehyde. Note. The packaging materials, systems and procedures described are also suitable for use with disinfection processes intended for use with wrapped goods, for example Low Temperature Steam Disinfectors (LTS);
d. Ethylene oxide;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

e. Dry heat (hot air);

f. Ionising irradiation (gamma and beta).

Product applications

C1.6 The sterile products for which packaging is considered include:

- medical devices and surgical instruments:
  - primarily those products, including re-usable instruments, utensils and textiles, which are processed by Sterile Service Departments, including units directly serving operating theatres (although the same principles apply to other manufacturing systems which have a wide range of product specifications produced singly or in small numbers. Only passing reference is made to high speed automated packaging systems.);
  - re-usable instruments processed in clinics and general practices (dental and medical);
- pharmaceutical manufacturing of sterile products;
- laboratory product manufacturing, for example culture media for microbiology;
- discard (or make-safe) prior to disposal of potentially infective material.

C1.7 Consideration is given to materials and systems for both single-use and re-usable packaging.

C1.8 Single-use packaging includes, for example, ampoules, single-trip bottles, paper bags, paper/plastic pouches & reels, paper wraps, vacuum formed trays, etc.

C1.9 Re-usable packaging includes, for example, multiple-trip bottles, procedure trays, sterilization containers, textile wraps, etc.

C1.10 This guidance section also makes reference to labelling, storage and distribution giving both guidance and particular requirements necessary to ensure compliance with extant regulations.

Responsibility

C1.11 Part 1 of SHTM 2010 (paragraph 1.15 (h)) Identifies the procedures for production, quality control and safety as a major responsibility of management.

C1.12 The provisions of this section should be reviewed by those responsible for the management of sterile production and adapted to local circumstances (for example taking into consideration the nature of the product, the volume of production, the sterilization process(es) available, etc.).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C1.13 It should be used as the basis for the development of written policies, specifications and procedures to be used in the control of sterile production.

General performance requirements

C1.14 The purposes for which packaging is used are:

- to contain the product;
- to permit sterilization of the packaged product;
- to protect the product from deterioration and damage;
- to maintain the sterility of the product through distribution and storage to the point of use;
- to prevent contamination of the product.

C1.15 In addition the packaging must:

- permit identification of the number and type of product contained, the lot number, the manufacturer and the expiry date (by labelling);
- include specification of storage conditions which the packaging is designed to withstand;
- provide any necessary instructions for the correct use of the product (by labelling and/or instruction sheets);
- present the product in a manner which allows it to be removed aseptically immediately before use.

Packaging operations

C1.16 The procedures and controls implemented for packaging operations must be designed to ensure that:

- each product produced is in the correct type of pack;
- each pack is correctly and effectively sealed;
- each pack is correctly labelled with all the necessary information.

Quality control

C1.17 The nature of packaging for terminally sterilized products is such that:

- it is not possible to test the packaging on finished product in a manner which permits its subsequent distribution for use;
- it is not possible to test any one sample for all necessary characteristics;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

- it is not possible to test each pack immediately before use to ensure that the packaging has performed correctly throughout sterilization, distribution and storage.

C1.18 Adequate control of the quality of packaging can only be obtained through a comprehensive programme including:

- design, and design verification;
- specification of packaging procedures;
- validation of packaging procedures;
- control of purchased material;
- control and monitoring of the packaging process;
- training for all who produce, handle or use sterile packs.

C1.19 Labelling is an essential part of packaging and procedures are required to ensure that particular care is taken to avoid labelling errors.

C1.20 The importance of proper control over all aspects of the packaging process cannot be over-emphasised. When products such as medical devices or medicinal products are presented wrongly labelled, contaminated, or damaged their use can cause serious adverse effect and may, in extreme cases, be lethal.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C2. Regulatory requirements and standards

C2.1 So far as requirements for packaging, including labelling, are concerned, the chief areas of legislation with which managers should be familiar are those concerned with safety, consumer protection, medicinal products, medical devices, active implantable medical devices and in vitro diagnostics.

The legislation relevant to sterilizers is also discussed in SHTM 2010 Part 1, Chapter 3, to which reference should be made.

Safety

C2.2 Manufacturers have two specific obligations under the Health and Safety at Work etc Act 1974:

1. to take all reasonably practicable steps to ensure that their products have been designed and manufactured so as to be safe when used for the intended purpose;
2. to ensure that persons who use their product in further manufacturing and retailing operations have adequate information and advice about how the products should be used to ensure safety.

C2.3 There is also a more general requirement under common law to protect all persons involved with the use of the product.

Medicinal products

C2.4 Where a packaging material or system is used to contain a medicinal product the licensing provisions of the Medicines Act 1968 apply.

Further information may be found in ‘Guidance to the NHS on the licensing requirements of the Medicines Act 1968’ published by the Medicines Control Agency.

C2.5 The Medicines (Standard Provisions of Licences and Certificates) Amendment Regulations 1992 (SI 1992/2846) give statutory force to the European Commission document ‘The rules governing medicinal products in the European Community Volume IV Guide to Good Manufacturing Practice for medicinal products’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Guide to Good Manufacturing Practice for medicinal products

C2.6 The principles and detailed guidelines of good manufacturing practice deal with a number of aspects of packaging including:

- Documentation, which should include:
  - a formal, written specification for packaging materials;
  - formally authorised packaging instructions for each product, pack size and type;
  - a record kept for each batch or part batch processed.
- Purchase, handling and control should be treated in the same manner as starting materials with particular attention paid to printed material;
- Packaging operations should be designed to minimise the risk of mix-ups by the inclusion of a line clearance procedure and special care should be exercised to avoid mislabelling.

The packaging should be verified as being of the correct type, clean and in the correct quantity and there should be suitable on-line control and monitoring to verify the adequacy of the packaging operation.

Consumer protection

C2.7 Part 1 of the Consumer Protection Act 1987 implements Directive 85/374/EEC (the Product Liability Directive) and provides for compensation to be paid to persons suffering injury from a defective product. The implications of this legislation are discussed in SHTM 2010 Part 1 (paragraphs 3.26 to 3.28 inclusive).

Active Implantable Medical Device Regulations 1992

C2.8 The Active Implantable Medical Devices Regulations 1992 (SI/1992/3146) implements Council Directive 90/385/EEC. Schedule 2, paragraph 7 of these regulations requires active implantable medical devices to be designed, manufactured and packed in a non-reusable packaging according to procedures which are sufficient to procedures which are sufficient to ensure that:

a. the device is sterile when placed on the market;

b. if handled in accordance with conditions as to storage laid down by the manufacturer, the device remains sterile until the packaging is removed and the device is implanted.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Medical Devices Regulations

C2.9 The Medical Devices Regulations 1994 (SI/1994/3017) implements Council Directive 93/42/EEC of 14 June 1993 concerning Medical Devices and came into effect on 1 January 1995.

C2.10 Regulation 11 concerns the procedure for systems and procedure packs and requires, inter alia, that any person who puts devices bearing the CE marking together, within their intended purpose and within the limits of use specified by their manufacturers, in order to place them on the market as a system or procedure pack, shall draw up a declaration by which he states that he has packaged the system or procedure pack and supplied relevant information to users incorporating relevant instructions from the manufacturers, and that the whole activity is subjected to appropriate methods of internal control and inspection.

C2.11 The Essential Requirements described in Annex 1 (of the Directive) include a number of specific requirements for packaging and labelling which are summarised below.

General requirements

C2.12 The devices must be designed, manufactured and packaged in such a way that they are suitable for the functions specified by the manufacturer.

C2.13 The devices must be designed, manufactured and packed in such a way that their characteristics and performances during their intended use will not be adversely affected during transport and storage taking account of the instructions and information supplied by the manufacturer.

Requirements regarding design and construction

C2.14 The devices be designed, manufactured and packed in such a way as to minimise the risk posed by contaminants and residues to the persons involved in the transport, storage and use of the devices and to the patients taking into account the intended purpose of the product.

C2.15 The devices and manufacturing processes must be designed in such a way as to eliminate or reduce as far as possible the risk of infection to the patient, user and third parties.

C2.16 Devices delivered in a sterile state must be designed, manufactured and packed in a non-reusable pack and/or according to appropriate procedures to ensure that they are sterile when placed on the market and remain sterile under the storage and transport conditions laid down, until the protective packaging is damaged or opened.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C2.17 Packaging systems for non-sterile devices must keep the product without deterioration at the level of cleanliness stipulated and, if the devices are to be sterilized prior to use, minimise the risk of microbial contamination; the packaging system must be suitable taking account of the method of sterilization specified by the manufacturer.

C2.18 The packaging and/or label of the device must distinguish between identical or similar products sold in both sterile and non-sterile condition.

C2.19 Each device must be accompanied by the information needed to use it safely and to identify the manufacturer, taking into account the training and knowledge of the users.

C2.20 This information comprises the data on the label and the data in the instructions for use.

C2.21 As far as practicable and appropriate, the information needed to use the device safely must be set out on the device itself and/or on the packaging for each unit or, where appropriate, on the sales packaging.

C2.22 If individual packaging of each unit is not practicable the information must be set out in the leaflet supplied with one or more devices.

C2.23 Instructions for use must be included in the packaging for every device. By way of exception, no such instructions for use are needed for devices classified in Class I or IIa if they can be used safely without any such instructions. The majority of, but not all, products produced in hospital based sterilization units would fall into this category, for example re-usable surgical instruments which are in Class I. Exceptions include implants, and may include devices intended for use on skin wounds that have breached the dermis. In case of doubt reference should be made to the classification criteria given in Annex IX of the directive or advice sought from the competent authority (Medical Devices Agency, DoH).

C2.24 Where appropriate this information should take the form of symbols. Any symbol or identification colour used must conform to the harmonised standards. In areas for which no standards exist, the symbols and colours must be described in the documentation supplied with the device.

C2.25 The label must bear the following particulars:

a. the name and trade address of the manufacturer;
b. the details strictly necessary for the user to identify the device and the contents of the packaging;
c. where appropriate, the word STERILE;
d. where appropriate, the batch code, preceded by the word LOT, or the serial number;
e. where appropriate, an indication of the date by which the device should be used, in safety, expressed as the year and month;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

f. where appropriate, an indication that the device is for single use;

g. if the device is custom made, the words “custom made device”;

h. if the device is intended for clinical investigations, the words "exclusively for clinical investigations";

i. any special storage and/or handling conditions;

j. any special operating instructions;

k. any warnings and/or precautions to take;

l. year of manufacture for active devices other than those covered by e. This indication may be included in the batch or serial number;

m. where applicable, method of sterilization.

C2.26 If the intended purpose of the device is not obvious to the user the manufacturer must clearly state it on the label and in the instructions for use.

C2.27 Wherever reasonable and practicable, the devices and detachable components must be identified, where appropriate in terms of batches, to allow all appropriate action to detect any potential risk posed by the devices and detachable components.

C2.28 Where appropriate the instructions for use must contain the following particulars:

1. information to avoid certain risks in connection with implantation of the device;
2. the necessary instructions in the event of damage to the sterile packaging and where appropriate details of appropriate methods of re-sterilization;
3. if the device is reusable, information on the appropriate processes to allow re-use, including cleaning, disinfection, packaging and, where appropriate, the method of sterilization of the device to be re-sterilized, and any restriction on the number of re-uses.

C2.29 Where devices are supplied with the intention that they be sterilized before use, the instructions for cleaning and sterilization must be such that if correctly followed the device will still comply with the general requirements specified in Section 1, Annex 1 of the directive.

C2.30 The instructions for use must also include details allowing the medical staff to brief the patient on any contra-indications and any precautions to be taken.

Glass containers EEC Directive 75/107

C2.31 Capacity tolerances for bottles specified as measuring containers were defined in the Directive and are summarised in Table C1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Two methods of capacity verification were specified, the Standard deviation method and the Mean range method.

Table C1: Capacity tolerance for bottles as measuring containers

Nominal capacity C (ml)	Capacity tolerances as %	
	of C	in ml
50 – 100	–	±3
100 – 200	±3	–
200 – 300	–	±6
300 – 500	±2	–
500 – 1000	–	±10
1000 – 5000	±1	–

British and European standards

C2.32 The rapid development in European Standards, which are required to be adopted as national standards by all European members of the European Committee for Standardisation (CEN), is largely due to the role that such standards have in demonstrating compliance with legislation implementing European Directives.

CEN is recognised by the European Union as a competent body for the adoption of harmonised standards.

C2.33 For the purpose of the European Directives on Medical Devices and Active Implantable Medical Devices a harmonised standard is a technical specification (European standard or harmonisation, document) adopted, on a mandate from the European Commission, by CEN.

C2.34 There is a presumption of compliance to the essential requirements of the Directive for devices which are in conformity with the relevant harmonised standards the references of which have been published in the Official Journal of the European Communities.

C2.35 A number of standards are in preparation which are relevant to packaging and labelling of terminally sterilized products.

The following list is not exhaustive. The standards discussed are in various stages of preparation. All EN standards are available in the UK as British Standards; there is now a dual numbering system so that EN *** will be numbered as BS EN ***.

C2.36 EN 1041 *Terminology symbols and information provided with medical devices - Information supplied by the manufacturer with medical devices*

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

This standard specifies the information to be supplied by the manufacturer of medical devices necessary to comply with the requirements of the Directive.

C2.37 **BS EN 980** *Terminology symbols and information provided with medical devices - Graphical symbols for the labelling of medical devices*

This standard defines a number of symbols to be used in labelling medical devices. The use of these symbols will both facilitate provision of all the essential information on small packs and minimise the need for multi-lingual labelling.

C2.38 **BS EN 868 series** *Packaging materials for sterilization of wrapped goods*

This standard is presented in a series of separate parts. The first part specifies the general requirements for packaging materials to be used for medical devices which are to be terminally sterilized and provides requirements, guidance and test methods for the validation of packaging materials and systems.

The subsequent parts of the standard specify requirements for a variety of packaging materials and systems. Conformity with the specified requirements in these parts of the standard may be used as one means of demonstrating compliance with some, or all, of the requirements of Part 1.

C2.39 **BS EN 867 series** *Non-biological systems for testing sterilizers*

This series of standards specifies the requirements for chemical indicators used in testing sterilizers. Part 2 of the standard specifically addresses the performance requirements for process indicators, whether used independently of, or printed on, labels or packaging materials. Detailed specifications are given for performance criteria relevant to all the sterilization processes considered in this Section (see paragraph C1.5).

C2.40 **BS EN 724** *Guidance on the application of EN 29001 and EN 46001 and of EN 29002 and EN 46002 for non-active medical devices*

This standard provides guidance on suitable methods and procedures, including aspects of packaging, for the manufacture of medical devices in conformity with the requirements of the Quality System standards which may be used to demonstrate compliance with the requirements of the Directive.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C2.41 **BS EN 550** *Sterilization of medical devices - Validation and routine control of ethylene oxide sterilization*

This standard specifies requirements for the development, validation, process control and monitoring of the sterilization of medical devices using ethylene oxide and gives guidance on means by which these requirements may be met. The importance of packaging in the correct functioning of an ethylene oxide sterilization process is recognised.

C2.42 **BS EN 552** *Sterilization of medical devices - Validation and routine control of sterilization by irradiation*

This standard specifies requirements for the development, validation, process control and monitoring of the sterilization of medical devices using ionising radiation and gives guidance on means by which these requirements may be met. The importance of specifying and controlling packaging from validation through to routine batch control is emphasised.

C2.43 **BS EN 554** *Sterilization of medical devices - Validation and routine control of sterilization by moist heat*

This standard specifies requirements for the development, validation, process control and monitoring of the sterilization of medical devices using moist heat.

The methods used are based on monitoring physical factors and control of the packaging is an essential part of the system.

C2.44 **BS EN 1174** series *Sterilization of medical devices - estimation of the population of micro-organisms on product*

This standard describes methods for determining the extent of microbial contamination on products, including packaging, prior to sterilization.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3. Design considerations

C3.1 The manufacturer of the sterile product is responsible for adopting a design for the pack which is suitable for its intended purpose.

C3.2 However, in many cases the design of the packaging material and/or system may be controlled by the manufacturer of the packaging material and/or packaging system and sold as suitable for a particular range of applications.

C3.3 The choice of such a pre-designed, commercially available packaging system does not absolve the sterile product manufacturer from the responsibility for ensuring that:

- the design of the packaging system, including the selection of materials, is suitable in all respects for the intended application (see Chapter C6)
- the packaging system as received from the supplier is in conformity with the specification against which the choice was made (see Chapter C5)
- the production facilities, including the skills of production personnel, are compatible with the packaging system chosen and have the demonstrated capability to fill, seal and sterilize the packaging in accordance with the instructions provided by the manufacturer of the packaging system, (see Chapters C7 - C9).

C3.4 The packaging is required to fulfil a number of functions. These may be summarised as: “to minimise the safety hazard to the manufacturer, user or patient arising from interaction of the product with its environment under the conditions of sterilization, transport, storage and use as specified by the producer of the packaging system and/or sterile product”.

C3.5 The design should include consideration of at least the following:

- the compatibility of the packaging with the sterilization process;
- the compatibility of the packaging with the labelling system;
- the compatibility of the packaging with the users’ requirements at the point of use, for example aseptic opening;
- the sensitivity of the pack contents to particular risks, for example irradiation, moisture, mechanical shock, static discharge.
- the compatibility of the packaging with the contents, for example the medical device or medicinal substance, in order that the packaging has no adverse effect on the medical device or vice versa;
- the protection provided by the packaging against adverse environmental influences which may reasonably be anticipated, for example mechanical shock, vibration, chemical or microbial contamination;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.6 The emphasis to be given to each of these considerations will be different for each of the various sterile products manufactured but, compatibility with the sterilization process and the subsequent protection against microbial contamination are paramount in providing the user with a sterile product.

C3.7 In many cases historical data may be used to provide satisfactory evidence that the packaging is suitable for its intended purpose where packaging to the same specification has previously been used satisfactorily for a particular product, or one that is similar in all essential respects.

C3.8 The design documentation should include details of the product to be packaged, the sterilization process to be used, the storage and transport conditions as well as the specification of the packaging materials and processes to be used.

Compatibility with the sterilization process

C3.9 There are two important aspects to sterilization compatibility:

a. the ability of the packaging material to permit the attainment of the required conditions for sterilization in the process with which it is intended to be used;

b. the ability of the packaging material to withstand the sterilization process without deterioration which adversely affects its protective performance.

C3.10 Both attributes should be demonstrated.

Moist-heat/steam sterilization processes

C3.11 For effective sterilization by moist heat all parts of the load should be in contact with water or saturated steam at the required temperature for the required time.

Sterilizers for wrapped goods and porous loads

C3.12 Items to be sterilized, other than aqueous products in sealed containers, should be packaged in a pack which allows removal of air and penetration of steam but which prevents recontamination after sterilization.

C3.13 This is normally achieved by the use of materials which are permeable to air and steam but have an effective maximum pore size which is small enough to exclude microbial contamination under the specified storage and transport conditions.

C3.14 This includes wrapping in porous materials, the use of rigid containers which are fitted with filters or valves, or a combination of these methods.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.15 Effective sterilization requires complete permeation of the porous materials with the moisture and heat of the steam. This may occur rapidly or slowly and depends, inter alia, on the size and density of the pack, the method of air removal, the nature of the porous material etc.

C3.16 With packaged solid, hollow or fibrous products air may become trapped, randomly, in the sterilizer chamber and load. The microbial lethality of elevated temperatures under dry and moist conditions are vastly different. The presence of air can cause an unacceptable impairment of the sterilization process.

C3.17 Unpredictable air retention is of particular concern with porous wrapping materials. Hence for effective sterilization of wrapped goods and porous loads it is important to employ a sterilization process which incorporates forced air removal prior to the sterilization stage.

C3.18 Preliminary tests on the product and its packaging in order to determine the levels and rates of change of pressure, temperature and vacuum which start to cause unacceptable changes in the performance qualities of the medical device and/or its packaging may be necessary.

C3.19 Performance qualification should be performed on the introduction of new or modified packaging unless equivalence either to a validated reference load or to previously validated packaging has been demonstrated.

C3.20 Materials used for packaging should be compatible with the sterilization process not only in permitting passage of steam and air as required by the process but also in not contributing any other inhibitory factors. For example they should not generate gases which could mimic the presence of retained air and restrict the penetration of steam.

Sterilizers for unwrapped instruments and utensils

C3.21 Sterilizers not intended for use with wrapped goods, for example bowl and instrument sterilizers, and small transportable electrically heated sterilizers rely on steam flow to remove air. Although the air may eventually be displaced from wrapped loads the process is slower and less predictable than when forced air removal is used.

C3.22 The only packaging suitable for unwrapped instrument and utensils sterilizers are “instrument orientation” trays which are constructed of open mesh or with sufficient ventilation holes to ensure that they present no barrier to air removal and steam penetration.

C3.23 BS 3970 Part 4 requires that load containers for transportable sterilizers should be designed to permit free draining of condensate and penetration of steam by perforation of appropriate surfaces. The perforated surfaces should have not less than 10% of their area as uniformly distributed perforations, each perforation being at least 20 mm^2.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Aqueous products in sealed containers

C3.24 Sealed glass or plastics containers containing aqueous solutions permit moist heat sterilization of the contents by virtue of the moisture present in the product.

C3.25 The container must have a gas-tight seal if the composition of the contents is not to be modified by evaporation of water from the contents or the ingress and condensation of steam from the sterilizer chamber.

C3.26 The container must be able to withstand the considerable internal pressures which will be generated during the sterilization process. This increase in pressure arises from the volumetric expansion of the container being insufficient to compensate for the volumetric expansion of the liquid, the increased vapour pressure of the liquid and the increased pressure of the heated air in the vacuity.

C3.27 The pressure generated in a correctly filled 1 litre bottle when it is heated to 121°C may exceed 8 bar.

C3.28 Plastic containers, particularly those made of polymers which undergo a reduction in tensile strength at the temperatures used for steam sterilization, are often only suitable for use in sterilizers which include air or gas ballasting to increase the pressure throughout the cycle and thus restrain the container from bursting. A similar approach may be used to sterilized devices used as packaging for example pre-filled syringes.

C3.29 The safety of operators will be at serious risk from the violent failure of containers and dispersal of their contents if the containers are removed from the sterilizer at too high a temperature (see SHTM 2010 Part 3 paragraph 14.20 d).

C3.30 The use of unsealed containers to avoid this problem is unacceptable. Not only is the composition of the contents subject to unpredictable changes, but liquids such as molten agar might still be boiling violently. Splashes from hot liquids of high thermal capacity can cause serious burns.

C3.31 Containers which are “unsealed” but plugged with porous material, or have the cap in place but left loose, that is not screwed tightly closed, may also become unsafe at elevated temperature. The evaporation of water from residues of the contents which boiled over during the early stages of the cooling process can effectively seal the container. It is important to emphasise that these are not theoretical considerations but represent a real hazard which has, in the past, caused injury to a number of personnel.

Low-temperature steam and formaldehyde

C3.32 The basic considerations for packaging for this process are similar to those for steam sterilizers for porous loads and wrapped goods.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.33 However, the thermal characteristics (both the thermal capacity and thermal conductivity) of the packaging can be of importance:

a. Materials which are slow to attain the required temperature may promote the polymerisation of the formaldehyde gas.

b. Materials of high thermal capacity promote the formation of excessive quantities of condensate which also may adversely affect the sterilization process.

C3.34 In addition, the extent to which the packaging material will absorb and adsorb both moisture and formaldehyde gas may affect the efficacy of the process.

C3.35 In general packaging should be kept to the minimum compatible with adequate protection for the product and the maintenance of sterility.

Ethylene oxide

C3.36 The packaging should be designed to allow removal of air and penetration of both steam and ethylene oxide and it should be demonstrated that the specified sterilization process does not affect adversely the functioning of the packaging.

C3.37 Impervious packaging materials are unsuitable for ethylene oxide sterilization.

C3.38 There are a considerable number of different ethylene oxide sterilization processes ranging from those employing pure ethylene oxide at sub-atmospheric pressures to those which use a mixture of ethylene oxide and carbon dioxide at pressures of several bar.

C3.39 The nature of the process, including the rate of air removal and the nature of the humidification stages used, will influence the suitability of packaging to be used in the process.

C3.40 A sterilization process that employs a high moisture content and several large and rapid changes in pressure may affect the strength of package seals, with a consequent loss of integrity, whereas. package seals of the same type would have been perfectly satisfactory for a process employing less extreme conditions.

C3.41 The extent to which the packaging absorbs moisture may have a major influence on the efficacy of the process and must be considered before a satisfactory humidification stage can be demonstrated.

C3.42 The extent to which the packaging absorbs or adsorbs ethylene oxide, and its permeability to ethylene oxide may have a major influence on the efficacy of the process and the subsequent aeration process used to remove the potentially toxic residuals.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.43 Process control is also a concern since packaging material that has become dehydrated may absorb excessive moisture during the conditioning phase; if this possibility was not recognised during validation the achieved cycle lethality may be adversely affected.

C3.44 The use of cartons (shelf packs, transit cartons) may be convenient for handling product but increase the post-sterilization level of ethylene oxide residuals, the necessary humidification time and the length of the gas exposure stage of the cycle (by inhibiting gas penetration). All the packaging which is intended to go into the sterilizer must be compatible with the process.

C3.45 The standard on validation of ethylene oxide sterilization processes (see BS EN 550) includes the requirement that the packaging specification be part of the definition and documentation of the sterilization process. The validation report should include or reference details of product sterilized, including packaging specification and load patterns in the sterilizer.

C3.46 It is therefore necessary that product used for physical and microbiological performance qualification studies should be packaged in an identical manner to that to be used routinely when they are presented for sterilization.

C3.47 The introduction of a new, or altered, packaging material or system requires validation. Physical and microbiological performance qualification studies should be performed on the introduction of new or modified packaging, although demonstration of equivalence to a previously validated package would satisfy this requirement.

C3.48 Many of the packaging materials for hospital use are the same as those for use in steam sterilizers because of similar permeability requirements; however, the lower temperatures involved in the process permit a wider range of materials to be used.

Hot-air sterilizers

C3.49 The thermal conductivity, specific heat and ability to withstand temperatures of 165°C, 175°C or 185°C (depending on the process used) for extended periods, without deterioration which impairs the utility of the packaging, are obvious considerations.

C3.50 The packaging does not need to be porous since the heat transfer normally takes place by conduction.

C3.51 However, in sealed packaging the contents of the pack when heated can exert a considerable pressure and may be sufficient to rupture the packaging material or its seals.

C3.52 Vented packaging systems that allow pressure equilibration may be suitable for use in hot air sterilizers which operate with a chamber atmosphere which has been filtered through a bacteria retentive filter. This is particularly important the during the post-sterilization cooling stage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Irradiation

C3.53 The standard for validation of radiation sterilization processes (BS EN 552) requires that the process specification should include descriptions of the dimensions, density and orientation of the product within the packaging, as well as the pattern for the loading of product within the container to be used to transport the packs through the irradiator. This should be established and documented before commencing performance qualification studies.

C3.54 The orientation of the product during irradiation is one of the factors ensuring uniformity of dose and the ability of the packaging to maintain consistent orientation of the product must be considered.

C3.55 The density of the packaging, and hence its “transparency” to the radiation to be used may be an important consideration, particularly in the case of electron beam irradiation.

C3.56 Although radiation sterilization is a low-temperature process there is nevertheless some increase in temperature above normal ambient temperatures and this should be considered.

C3.57 There is no requirement for the packaging to be gas permeable. If the packaging is gas tight it may reasonably be assumed to be a satisfactory barrier to microbial contamination.

C3.58 Many materials are structurally altered by the radiation process; they may become hardened and embrittled, or discoloured, for example.

C3.59 These radiation induced changes may be beneficial or disadvantageous to the subsequent performance of the packaging or they may simply be aesthetically unacceptable, for example the yellowing which occurs with some PVC materials.

C3.60 Many polymers are now available specifically formulated with stabilisers which make them suitable for use in irradiation processes. The adhesives used to seal packages must also be considered for potentially adverse effects of the radiation.

C3.61 For most hospital users, with only small numbers of items to be irradiated, the advice of the sub-contractor providing the irradiation sterilization service should be sought. Based on their experience of radiation sterilization of similar products they will often be able to suggest appropriate packaging which can be validated by comparison with previously validated products.

Compatibility with the labelling system

C3.62 The importance as labelling as an integral element of the product packaging has been stressed (see paragraphs C1.15 and C2.19 to C2.30).

C3.63 Labelling may take a number of forms, including:

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

- labelling printed directly on the packaging;
- printed labels attached to the surface of the packaging by adhesive, etc.

C3.64 Whether labels are printed directly on the packaging or onto discrete labels which are subsequently attached to the pack, the labelling system should:

a. not adversely affect the compatibility of the packaging with the sterilization process to be used, for example by excessively restricting the porous area available for gas exchange;

b. not be rendered illegible by the sterilization process to be used;

c. not employ ink of a type which may

(i) transfer to the pack contents;

(ii) react with the packaging to impair its utility;

(iii) change colour and render the label illegible;

(iv) interfere with the sterilization process by, for example, evolution of volatile components.

C3.65 Labels fixed to the surface of the packaging must be able to withstand exposure to the sterilization process and the defined storage and transport conditions without becoming detached.

C3.66 Given the low cost of computerised label printing systems there can be little justification for using hand-written labels with the inevitable variation in legibility that this causes.

C3.67 Writing on the packaging also presents an unacceptably high risk of causing damage to, for example, paper packaging, which may not be readily visible but is sufficient to breach the microbial barrier properties of the material.

Furthermore, some pens, such as ‘felt-tip’ pens and ‘marker’ pens, have inks which may release volatile components in sufficient quantities to interfere with the correct functioning of a steam sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Compatibility with requirements for aseptic opening

C3.68 Failure to consider adequately how a pack is to be opened and the contents removed may significantly increase the chance of contamination occurring. With inadequate provision for aseptic opening a 10^{-3} probability of contamination is easily possible which compares unfavourably with a 10^{-6} probability of sterility required as a minimum standard before labelling a product as sterile (BS EN 556).

C3.69 The means of sealing or closing the pack should be tamper evident in order that the user may rely upon the integrity of the contents.

C3.70 For sterile products the other major consideration at the point of use must be the ability to remove the product from the packaging without it becoming contaminated with micro-organisms, in other words the aseptic removal of the product.

C3.71 The provision of aseptic removal may be influenced by a number of elements in the design of the packaged product including:

- the type of product;
- the packaging system chosen;
- the method of closure or sealing;
- the number of layers of packaging material;
- the arrangement of the contents of the pack;
- the use of special equipment to remove the contents.

C3.72 Sterile medicinal products include both parenteral and topical preparations. The former are predominantly aqueous solutions whereas the latter may be aqueous solutions, oils, emulsions (ointments or creams), or dry powders.

C3.73 The packaging system employed for sterile medicinal products will normally consist of a closed rigid or flexible container as the primary pack. This may be closed by being hermetically sealed or by being sealed with a penetrable (or removable) elastomeric closure (such as a bung, stopper or disk) held in place with a screwed cap or crimped overseal.

C3.74 Sterile medicinal products are usually best presented in single-use form. Where a multi-use presentation is employed there will be a requirement for a suitable preservative to be included in the product formulation.

C3.75 The primary pack may need to be overwrapped if it is necessary to provide for aseptic handling of the primary pack.

C3.76 Sterile medical devices may be presented as single items such as individual instruments, dressings, etc. or, as a single pack containing multiple items;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

the composition of which is designed so that contents comprise the items required for one (or more) particular procedure(s).

C3.77 These are commonly described in a variety of terms such as:

- Basic packs (dressing packs which may or may not contain instruments);
- Composite packs (instruments, dressings and other equipment/utensils);
- Supplementary packs (which include instruments, utensils, dressings for use with basic packs and composite packs);
- Procedure packs (which contain all the instruments, drapes, dressings and utensils required for a particular procedure);
- Linen packs (which contain all the drapes required for a particular procedure);
- Gown packs, dressing packs, etc.

C3.78 The packaging system employed for sterile medical devices may consist of flexible or rigid packaging, or the two types used in combination; and may be intended for single use, or be re-usable or be a combination of single use and re-usable.

C3.79 These may be closed by heat-seal, adhesive, compression gaskets, or tortuous path closures. A common format used in hospital SSDs is a pack formed from a rigid tray wrapped in a flexible packaging material. The tray may be re-usable metal or plastic, such as polypropylene, or single use, such as metal foil, moulded pulp, folded cardboard.

C3.80 For medical devices the arrangement of the pack contents will be of importance. The contents generally are arranged so that when the pack is opened they are available in an order convenient to the user for the intended purpose and suitable for aseptic removal.

C3.81 The method of opening the sealed or closed pack and/or removing the contents affects the aseptic removal capability. The various sealing and closing methods may involve particular risks with regard to transfer of contamination from the outside surface of the pack, or to transfer of fragments of the packaging.

C3.82 Tortuous path seals formed by the folding of flexible packaging material may be constructed so that they may be opened without touching the inner surfaces.

C3.83 Pealable seals are used on heat sealed, and some adhesive-sealed, flexible packs and on many commercially produced packs, for example lidded blister packs. The construction of the seal should allow the opposing surfaces to be grasped easily and the seal on separating should not cause fibre shedding by, say, the splitting or tearing of either surface.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.84 Both flexible and rigid packaging systems are used which are intended to be broken, cut or torn open, for example ampoules, paper bags and pouches. It is important that this can be done without introducing contamination into the pack contents either from fragments of the packaging (for example glass particles from an ampoule), or from instruments used in the opening procedure, such as scissors for cutting open paper bags.

C3.85 Rigid re-usable containers for dry goods should have a tamper evident seal which must be broken before the container can be unlatched and the lid opened.

C3.86 Both single-use and re-usable containers for liquids, particularly those intended for topical administration or laboratory use, may have a seal which is formed from a compressible gasket (for example a rubber wad or stopper) held in place by, or as an integral part of, a screw capped lid. Aseptic removal of the contents will depend not only on the ease with which the cap and gasket can be removed but also on the method used subsequently to dispense the contents, for example pipetting, pouring.

C3.87 Both single-use and re-usable containers for liquids, particularly those intended for parenteral administration, may have a seal which must be punctured and penetrated by a suitable device to remove the contents, for example using a hypodermic needle and syringe to remove the contents of a vial.

C3.88 The potential risk of introduction of contamination from surface of seal should be considered. The external surface of the seal may need protection (overseal) which can be removed immediately before use, or the instructions for use may require pre-treatment of the seal surface, for example by swapping with a 70% m/v aqueous solution of spore-free isopropanol.

C3.89 For re-usable systems the ability of the closure to re-seal after each penetration will be an important consideration in the maintenance of sterility.

C3.90 The seal for either single-use or re-usable systems must be of a material which will not be damaged by the penetrating needle to the extent that fragments of the closure will contaminate the contents of the container.

C3.91 Sealed packs should always be carefully inspected for seal integrity, or adventitious contamination, before being opened and this requirement should be drawn to the users' attention both in the labelling of the pack and on any instructions for use or training programme which may be given.

Compatibility with the contents

Medical devices

C3.92 The suitability of the packaging for use with the particular medical device should be established. This should include limiting values for physical

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

characteristics of both the medical device as well as the stresses which will be imposed during sterilization and subsequent transport and storage.

C3.93 Factors to be considered include, but are not limited to:

- the mass and configuration of the medical device to be packed;
- the presence of sharp edges or protrusions;
- the need for mechanical and other protection;
- interactions with the packaging materials.

C3.94 Consideration of product interaction should also include physical contamination with the packaging material. Small particles introduced into the body during, for example, surgical procedures are widely reported to cause clinical problems including inducing adhesions, granulomata and foreign body reactions in tissues.

Medicinal products

C3.95 Factors to be considered include:

- interactions with the packaging materials, including adsorption, absorption and chemical reactions with components of the packaging materials, for a period not less than the specified storage life under the specified storage conditions;
- adverse effects on the contents due to gas or water vapour permeability, such as permitting loss of water from a formulation, or permitting the ingress of oxygen and subsequent oxidation of one or more components of the formulation.

C3.96 Materials used for packaging should be compatible with the contained product. For example packaging intended for use with parenteral fluids should not shed particulate material to an extent which could compromise the quality of the parenteral being administered.

Laboratory products

C3.97 Factors to be considered include all those noted in the two previous sections for medical devices and medicinal products.

Toxicity

C3.98 Packaging materials and/or systems should not release material known to be toxic in sufficient quantity to cause a health hazard either before, during or after sterilization under the specified conditions of use.

C3.99 Evidence that the packaging material and/or system does not either contain material known to be toxic, or contain material which may react during the sterilization process to form a substance known to be toxic, in sufficient

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

quantity to cause a health hazard is normally sufficient to meet this requirement.

C3.100 Manufacturers of packaging are aware of this requirement and should be able to provide evidence that the formulation of the packaging has been reviewed by a competent toxicologist and found to meet this requirement.

Biocompatibility

C3.101 The biocompatibility of the packaging should be assessed with regard to the intended use of the pack contents. If particular requirements for the product to be sterilized, for example freedom from particulate matter, cannot be established from the material specification for the packaging under consideration expert advice should be sought. In the first instance this advice should come from the manufacturer of the device, who has a legal obligation to specify any particular requirements for the safe sterilization of the product.

C3.102 Test methods for bio-compatibility are described in BS EN 30993; they require the services of a specialist laboratory.

Preservation of sterility

C3.103 The packaging materials and/or systems assembled in the form in which it will be presented to the sterilizers, when assembled, stored, transported and used in accordance with the producer's instruction, should preserve the sterility of the contents from the time at which they are rendered sterile to the expiry date specified by the manufacturer and/or the point of use.

C3.104 Preservation of sterility is achieved by preventing the ingress of micro-organisms. Many factors affect the probability of such ingress occurring. These include, but are not limited to:

- the concentration of micro-organism in the environment;
- the size of particle on which the micro-organisms occur;
- environmental conditions of temperature, humidity and pressure;
- the rate of change of these environmental conditions;
- flow rates through the layers of packaging material;
- pore size and other filtration parameters of the packaging material.

C3.105 There is no universally applicable, single test method which can be used to establish the microbial barrier properties of a pack.

For particular types or sizes of pack there are tests which may be of value as an overall monitor of microbial barrier properties.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.106 For most practical purposes it is necessary to infer satisfactory microbial barrier performance from a combination of tests designed to test attributes of the packaging which are related to microbial barrier properties, for example to test the gas tightness of seals.

C3.107 The time for which any packaging system will maintain the sterility of the pack contents is event related not time related. It is therefore necessary to define, and control, the conditions for both storage and transport, within which the pack will maintain the sterility of the contents.

Storage and transport of sterile packs

C3.108 It is necessary to ensure that the packaging is able to provide the protection necessary to maintain the performance characteristics of:

- the packaging during storage and transport under the specified conditions;
- the contents during storage and transport under the specified conditions.

C3.109 When handled according to instructions, the packaging should protect the product from physical damage and maintain the sterility of the medical device up to the point of use.

Number of layers of packaging material

C3.110 Products may be packaged in a single layer of packaging material, or in multiple layers. Multiple layers of packaging may be used to reduce the likelihood of contamination during storage and when the pack is opened.

C3.111 When two layers of packaging are used to facilitate aseptic removal of the contents:

- the outer wrap is sealed and acts as a barrier to microbial penetration to the product from the environment,
- the inner wrap may, or may not, be sealed and may, or may not, be intended to be a barrier to environmental microbial contamination. It acts as a protective cover during removal of the product.

C3.112 When the inner wrap is a microbial barrier it may serve to provide additional assurance of the maintenance of sterility.

C3.113 This inner wrap, having been maintained in a sterile state by the presence of the outer wrap, may be handled by persons, wearing sterile gloves and about to undertake an aseptic procedure.

C3.114 Moulded plastic shields covering hypodermic needles, plastic end-caps on intravenous administration sets are two examples of inner wraps found on commercially sterilized products. They may also serve additional functions

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

unrelated to the sterile nature of the product, such as mechanical protection, protection of operators from hazards associated with the product etc.

C3.115 Double wrapping is essential for equipment that will be used in an aseptic environment such as an operating room or a protective isolation unit.

C3.116 In particular instances, triple-wrapped product may be necessary to permit the adoption of procedures with a high level of assurance that there will be no contamination, for example transfer of laboratory products into a sterility test containment facility or transfer of equipment and components into an aseptic manufacturing environment.

C3.117 Single wrapping may be more economical and appropriate when the product, although sterile, will not be used in an aseptic environment and will not be used parenterally or to penetrate tissue, for example Ryles tubes, oesophageal and suction tubes, urine bags, rectal examination sets etc.

C3.118 The various layers of packaging may be used to provide for different functional requirements, for example many surgical instrument and dressings packs are wrapped with an inner layer of paper or cloth which is used to provide a sterile field when opened onto a table, trolley or tray at the point of use.

C3.119 Two or more layers of packaging may be used together to provide a functional requirement which neither alone could meet, for example a single layer of textile may not be an adequate barrier to microbial penetration but two layers in combination may provide satisfactory performance.

Primary and secondary packaging

C3.120 If two layers used together are needed to meet a basic performance requirement then layers both together constitute the primary pack.

Secondary packaging

C3.121 Several individual units, each wrapped in its own primary packaging, may be packed together in a “shelf pack” which may consist of a carton, plastic film wrap, film-wrapped carton or similar.

C3.122 For distribution, multiples of individual units or shelf packs may be packed in transit containers.

C3.123 These may be intended as single-use, for example fibreboard cartons or re-usable, for example plastic or aluminium boxes. Their primary function is to withstand the predictable risks arising during transport and distribution.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C3.124 Some or all of the secondary packaging may be applied before sterilization, especially in commercial sterilization. When this is the case the packaging, in its entirety as presented to the sterilization process, must meet the requirements for sterilization compatibility.

C3.125 When re-usable transport containers are employed, a documented and monitored procedure for maintaining them in a clean, hygienic condition and a good state of repair is necessary.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4. Packaging materials and systems

C4.1 The following section summarises various packaging systems and materials that are available, including methods of effecting suitable seals or closures, their suitability for use with sterilization processes which may be employed by hospital users, and equipment necessary for their effective use.

C4.2 The summary is wide ranging and comprehensive, but not exhaustive. The absence of a particular system or material should not be taken as implying that it is unsatisfactory for use, nor should the inclusion of a particular system or material been seen as an endorsement of its use.

C4.3 The choice of suitable packaging systems and materials will be based on a number of factors. These include, but are not limited to:

- compatibility with available sterilization processes and other factors (see paragraph C3.5);
- particular requirements of the user;
- availability and cost of suitable automatic equipment for filling, sealing, labelling;
- availability and cost of suitable re-processing facilities for re-usable packaging;
- availability and cost of suitable disposal methods for used single-use packaging;
- standardisation of packaging systems within a single production unit.

C4.4 There is no one packaging system that is “correct” for all applications; and for any particular application there may be several systems available none of which is perfect. It may then be necessary to prioritise the requirements to be met by the packaging and select the system which most nearly meets these requirements (Table C2). The two characteristics which are afforded the highest priority most often are compatibility with the sterilization process and maintenance of sterility in storage and distribution.

Sterilization compatibility

Steam sterilization

Wrapped goods and porous loads

C4.5 Goods are normally double wrapped; at least one of the layers will usually be a sheet of paper, paper bag or paper/plastic pouch.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.6 The inner lining may be chosen primarily for its absorbency in order to retain condensate in a position from which it will be successfully evaporated during the drying stage of the sterilization cycle.

Table C2: Selection of packaging materials by sterilization process

Sterilization process	Re-useable packing	Single-use packing
Steam sterilization		
for wrapped goods and porous loads*	Containers(valves or filter) Textiles (cotton and/or synthetics)	Papers Plastic/paper pouches Cellulose/synthetic wraps Spun-bonded polyolefins up to 121°C
for instruments and utensils	Free-draining “instrument orientation” trays	
for aqueous fluids	Glass bottles Glass vials Plastic bottles	Glass bottles Glass vials/ampoules Plastic bottles Plastic pouches
Ethylene oxide	Containers (valve or filter)	Papers Plastic/paper pouches Spun-bonded polyolefins (eg.. Tyvek)
LTSF	Polypropylene boxes Open cell foam (for instrument protection)	Plastic/paper pouches Papers
Dry heat	Metal (eg.. Aluminium) canisters Glass containers	Metal foils Plastic films
Radiation		Treated paper Polyethlene Polypropylene Metal foils Various laminates Cardboard (PVC)

* the same packing materials are also suitable for use with LTS disinfectors

Fluids in sealed containers

C4.7 Glass or plastic bottles, vials or ampoules are used for rigid containers and plastic pouches, usually a laminated construction to optimise the performance characteristics, are suitable for flexible containers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Dry heat

C4.8 Aluminium cans or tubes, glass tubes or jars, each of which may be sealed with push on caps, screw caps or crimp-on foil caps, are suitable for dry heat sterilization. Crimp-on foil caps with a pre-printed colour change indicator are also available.

C4.9 Items may be wrapped in heavy or light gauge metal foil or, for items such as laboratory glassware the foil may be used simply to seal the open end of the product.

C4.10 Plastic bags of the sort sold for roasting meat in domestic ovens may also be suitable.

LTSF

C4.11 Packaging may consist of paper, used as plain or creped wraps, or in the form of bags or, in combination with plastic film as pouches.

C4.12 Light cardboard boxes, or corrugated polypropylene boxes, adequately vented and overwrapped with paper or other material as a bacterial barrier are also suitable. When particularly delicate instruments are to be processed the use of an open cell foam for support and protection is acceptable.

C4.13 The quantity of packaging should be kept to the minimum possible.

Irradiation

C4.14 Polythene/polyester/nylon or metal foil may be used. The material may be non-porous and gas impermeable which gives good microbial barrier properties. Paper, spun-bonded polymers and non-wovens can also be used but lose the advantage of a process that can deal with impermeable packaging.

Ethylene oxide

C4.15 For ethylene oxide sterilization a high permeability to air, steam and ethylene oxide is essential.

C4.16 Paper bags or plastic/paper pouches are usually found to be most convenient for small articles. Wrapping in sheets of plain or crepe paper, or textiles, may be required for large procedure trays containing endoscopes or other thermolabile equipment.

C4.17 Moulded foam inserts may also be used to provide protection for sensitive equipment such as endoscopes.

C4.18 Polythene bags with gas exchange ports of Tyvek are also suitable.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Bacterial barrier properties

C4.19 The basic requirement is for a material which will not allow the product within the pack to be contaminated by the ingress of microbes in the environment from the time that it is removed from the sterilizer, during transport and storage up to the point of use.

C4.20 With a non-porous material, where gas flow through the material can only occur through diffusion, the material itself will be an absolute barrier to microbial contamination. The microbial barrier properties of the pack will then depend on the adequacy of the seal or closure. For example, an ampoule, if correctly sealed by fusion, and having no cracks or other flaws, will be an absolute barrier to microbial contamination.

C4.21 When a porous material is used the barrier to microbial penetration will not be absolute; there will be always a finite possibility of a micro-organism penetrating the barrier and potentially contaminating the pack.

C4.22 The probability of a micro-organism penetrating the barrier will depend on many factors, including, but not limited to:

- the rate of air flow through the web, which may be influenced by the rate and extent of environmental changes in pressure and temperature;
- the relative humidity, which can affect both the pore size and surface charge of natural fibrous materials (paper, linen etc.);
- the type and number of micro-organisms in the environment;
- the form in which they are presented, for example as single organisms or, as they are more usually found, on relatively large particles such as skin squames;
- the nature of the product, which may influence whether contaminating organisms can survive or multiply.

C4.23 The effect of these various factors is not the same for all materials. For example some porous materials are better at excluding particles of a given size at very low flow rates while other materials perform best at higher flow rates.

C4.24 It is apparent that the storage conditions will also be a controlling factor in the maintenance of sterility. Dirty, damp conditions can give rise to high microbial counts in the environment; large and rapid changes of temperature, and changes of pressure (including the slamming shut, or violent opening, of doors) will lead to an exchange of air between the contaminated air of the environment and the interior of the pack.

C4.25 The ability to maintain sterility is primarily “event related” rather than “time related”, although even under controlled conditions there is a greater probability of an adverse event having occurred after prolonged storage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.26 The most sensitive time for contamination through porous wrapping material is when steam sterilized product has been removed from the sterilizer and is cooling down. During this process air will be taken into the warm and humid environment in the pack.

Materials used in packaging

C4.27 The materials of which the packaging is made will necessarily limit the sterilization processes with which it is compatible as well as affecting its ability to meet other performance requirements.

C4.28 Performance requirements for packaging materials include:

- permeability to air, steam and gaseous sterilants, (although this does not apply to materials intended for use with aqueous fluids in sealed containers, dry-heat sterilization by hot air or sterilization by ionising irradiation);
- resistance to penetration by micro-organisms from the surrounding environment;
- resistance to punctures, tears and other mechanical damage which would breach the barrier to microbial penetration;
- freedom from loose fibres and particles;
- freedom from toxic ingredients and non-fast dyes;
- compatibility with the contents under the proposed sterilizing conditions;
- compatibility degraded by with the sterilization process to be used, that is, not degraded by it.

Textiles

C4.29 Textile fabrics are used for packaging; traditionally these are woven cotton materials but may also be cotton/polyester blends.

C4.30 Specialist fabrics are also available which may are intended to be water repellent while at the same time being gas permeable. This may be achieved by several means, for example a particularly tight weave of polyester fibres, or a laminated construction with a middle lamella of a suitable polymer film. Care needs to be exercised in using these fabrics that the flow rate of both air and steam through the fabric is adequate for the sterilization process.

C4.31 Textiles are often used as a wrapping material for heavy packs, especially of theatre instruments, which are to be sterilized in a porous-load steam sterilizer.

C4.32 Textiles are stronger than paper, and stronger than many non-wovens, and will resist tearing and rupture.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.33 However, textiles are generally a less efficient bacterial barrier than sterilization grade wrapping paper and should always be used in two or more layers. The second layer may be a textile wrap also or a suitable sterilization grade wrapping paper. Alternatively, a sterilization grade paper bag may be used to enclose the textile-wrapped pack.

C4.34 Textile wraps are re-usable.

Papers and non-wovens

C4.35 Both papers, which are made from cellulose fibres, and non-wovens, made from a combination of cellulosic and synthetic fibres, may be used. Both types are suitable for porous-load steam sterilization and most gas processes because they are permeable to air, steam and other gases.

C4.36 The original papers used for steam sterilization wrappers were kraft papers produced for general purposes. Purpose made papers with better controlled porosity and microbial barrier properties, and with enhanced wet strength and water repellency are now used. These are available as plain sheets, creped sheets which give better drape characteristics, as bags and in combination with a plastic film as pouches (or reel material from which pouches can be made).

C4.37 Good drape and handle characteristics are also provided by crepe paper (BS EN 868-2: 1999).

C4.38 Plain papers may be used as wraps or preformed into bags or pouches. The bags and pouches may be plain sided or may be gussetted to accommodate bulky items.

C4.39 Wet strength and water repellency are specifically improved over “normal” papers by the impregnation of the paper with high wet-strength resins.

C4.40 The water content of the paper may be maintained at a relatively high level, thus improving the feel and drape of the paper and minimising superheating due to exothermal rehydration, by the addition of humectants such as sorbitol.

C4.41 Over many years experience the various forms of paper packaging have been demonstrated to provide an effective microbial barrier.

C4.42 Non-wovens are generally less effective as a microbial barrier and may need to be used in, or as one of, two layers; they are however generally softer with better handling and drape characteristics.

C4.43 British Standards exist for all the paper packaging materials and should be used as the basis for purchasing specifications. (These standards will be replaced in due course with European Standards currently in preparation; the draft standards cover the same range of requirements as the existing standards.)

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.44 Non-woven materials, made from a combination of natural and synthetic fibres are also widely used. These are often used where otherwise re-usable textiles would be used. They are generally of greater porosity than paper wraps and for this reason may not be as effective as a microbial barrier. They have higher tear and puncture resistance and are softer with better drape qualities. They may also show extremely good water repellency.

Synthetic materials and laminates

C4.45 Polymeric materials, or plastics, may be used in the manufacture of rigid, semi-rigid, or flexible packaging systems.

C4.46 They may be in the form of sheet or film, which is non-porous, or be produced as a spun-bonded or non-woven sheet which is porous.

C4.47 Plastic materials are also used in the manufacture of moulded containers, for dry products or for liquids.

C4.48 Film or sheet material may be an absolute barrier to microbes if it is free from pinholes. Although it may be non-porous that does not necessarily mean that it will be impermeable. Most polymers have some permeability to gas, air, and water vapour. The extent of the permeability varies with temperature, concentration gradient of the diffusing substance etc. and although generally low may be important, for example in the long term storage and stability of a pharmaceutical product.

C4.49 Plastic materials are generally robust and resistant to tearing. The extent to which they show puncture resistance depends much more on the polymer and film thickness used. There have been in the past major problems with thin-film moulded polyethylene commercially produced packs being breached by the sharp edges of the product within.

C4.50 Plastic materials can usually be heat-sealed to give a high-integrity barrier.

Polyethylene (polythene)

C4.51 Polyethylene is effectively impermeable to air and water and is not suitable therefore for general use in ethylene oxide sterilization processes without special precautions. However very thin films (up to 0.076 mm) thick allow the passage of ethylene oxide (by dissolving in the thin film and then evaporating from the inner surface). Paper laminated with a thin polythene film may thus be used to provide a heat sealable paper for use in ethylene oxide sterilization.

C4.52 High-density polyethylene is produced as a spun-bonded, non-woven (known commercially as Tyvek) paper-like material. It is very tough, and although it is porous like paper it is water repellent.

C4.53 In commercial use it has been found to provide a satisfactory bacterial barrier. It is frequently used in packs which are to be ethylene oxide sterilized and may be used with a clear film in the form of a pouch, as

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

venting panels in impermeable bags made of, for example polythene, or as a sealing lid on blister packs.

C4.54 It has also been found suitable for use in steam sterilizers operating at sterilization temperatures up to 121°C.

C4.55 It has some disadvantages in that it may attract dust and fibres owing to its electrostatic character, it can be difficult to print on and also it may be difficult to seal, although these latter difficulties largely can be overcome by using non-oil based inks and lacquering with a suitable heat-seal lacquer, respectively. It is also expensive compared with paper.

C4.56 At temperatures above 125°C even high-density polythene has softened too much to be used on its own as an effective packaging material and it is therefore unsuitable for steam sterilization at 126°C or 134°C or for hot-air sterilization.

C4.57 Polythene can be sterilized by ionising radiation.

Polyester

C4.58 Polyester, in the form known as oriented or crystallised polyester, is used as a laminate with polythene in the construction of paper/plastic pouches and reel material.

C4.59 The polythene forms the inner surface which is heat sealed to the paper. The outer layer of the plastic laminate is polyester which gives the required mechanical strength at elevated temperature as well as a good printing surface.

Polyvinyl chloride (PVC)

C4.60 PVC generally has a very low stability to both heat and ionising radiation.

C4.61 PVC will absorb ethylene oxide in large amounts. This is exacerbated by the ethylene oxide combining with the phthalate plasticiser, from which it is aerated only very slowly under ambient conditions.

C4.62 Some grades of PVC are used for the moulded bases of commercially available blister packs.

Polypropylene and polycarbonate

C4.63 Both polypropylene and polycarbonate are relatively heat stable materials.

C4.64 Polypropylene has a very low permeability to air, moisture and ethylene oxide. It has been used extensively, either separately or in combination with other polymer laminates, as flexible, semi-rigid or rigid containers for heat sterilization of water and aqueous fluids.

C4.65 Polypropylene has been laminated with aluminium foil for use as packaging for wet or oily materials such as skin swabs, alcohol wipes.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.66 Polycarbonate has been used extensively for the manufacture of autoclavable laboratory bottles (at 121°C).

C4.67 Certain grades of polypropylene, specifically formulated for the purpose, can be radiation sterilized.

Nylon

C4.68 Nylon is heat stable, and is also steam permeable but it is impermeable to air. Packaging constructed entirely from nylon film is unsuitable for steam sterilization because the air retained in the package may interfere with effective sterilization. It may however be used effectively in combination with a porous material, such as paper, to form a steam-sterilizable pouch.

Glass containers

C4.69 Glass containers, are usually in the form of ampoules, vials, jars or bottles and come in a variety of capacities and shapes, with several different closure systems.

C4.70 Three different grades of glass are available.

a. Soda glass is normally the cheapest (also referred to as Grade I). It is subject to hydrolytic attack particularly when autoclaved containing aqueous solutions. Solutions sterilized in bottles made of soda glass may become contaminated with reactive silicates and show an increased pH. Such bottles are rarely intended for more than a single use.

b. Sulphated soda glass, also referred to as Grade II, is soda glass which is protected against hydrolytic attack by a surface coating of sulphate. The coating is normally applied by sublimation of ammonium sulphate onto the surface of the hot glass concurrently with annealing during the manufacturing process. Bottles made of sulphated soda glass are rarely intended for more than a single use and, if re-used, the sulphate coating is eventually lost and the glass is once again subject to hydrolytic attack.

c. Borosilicate glass, also referred to as Grade III, is much more resistant to hydrolytic attack than Grade I or II glass and is generally the preferred material for containers which are to be used for autoclaving aqueous solutions. Providing there is a suitable cleaning process compatible with the intended end-use, bottles made of borosilicate glass may be re-used a number of times.

C4.71 Borosilicate glass also has better thermal shock resistance characteristics than soda glass when used in a similar container.

C4.72 Glass containers may also be used for dry heat sterilization, and can withstand radiation sterilization. However, irradiation causes a darkening of the glass which may be aesthetically unacceptable.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Metals

C4.73 Metals are used in the fabrication of sterilization containers for use in both steam and hot-air sterilization processes, and to a lesser extent in gas processes such as LTSF or ethylene oxide. Since the material is neither porous nor permeable it must be constructed with a suitable venting system for use in sterilization processes other than dry heat or radiation.

C4.74 The choice of metal should be based on consideration of both its corrosion resistance to the sterilization process, for example in a steam atmosphere, and on its thermal characteristics. The ideal material would have a high thermal conductivity and a low heat capacity and would attain the required temperature quickly, uniformly and without the formation of excessive amounts of condensate.

C4.75 In practice, the choice is usually between aluminium, anodised or otherwise surface treated to give it suitable corrosion resistance, and a suitable grade of stainless steel.

Single-use packaging

C4.76 Both flexible and rigid packaging systems are available which are intended for single use.

C4.77 The recently enacted medical device regulations (see Chapter C2) include a requirement that sterile medical devices be designed, manufactured and packed in a non-reusable pack and/or according to appropriate procedures to ensure that they are sterile when placed on the market. There is thus a clearly stated preference for single-use packaging as the primary packaging for sterile medical devices.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Paper or textile wraps

C4.78 For wrapping materials two different folding methods have been adopted, both of which, when correctly executed, provide a suitable tortuous path to prevent the ingress of contamination.

C4.79 For large packs the parcel fold is the preferred method (see Figure C1).

C4.80 The pack contents are placed on the wrap, approximately in the centre of the wrap. The long edge of the contents should be aligned parallel to the long edge of the wrap.

C4.81 One of the long edges of the wrap is folded over the pack contents to overlap the centre line, and the edge of the wrap is turned back on itself. The fold made by the turning back of the wrap should overlap the centre line of the contents.

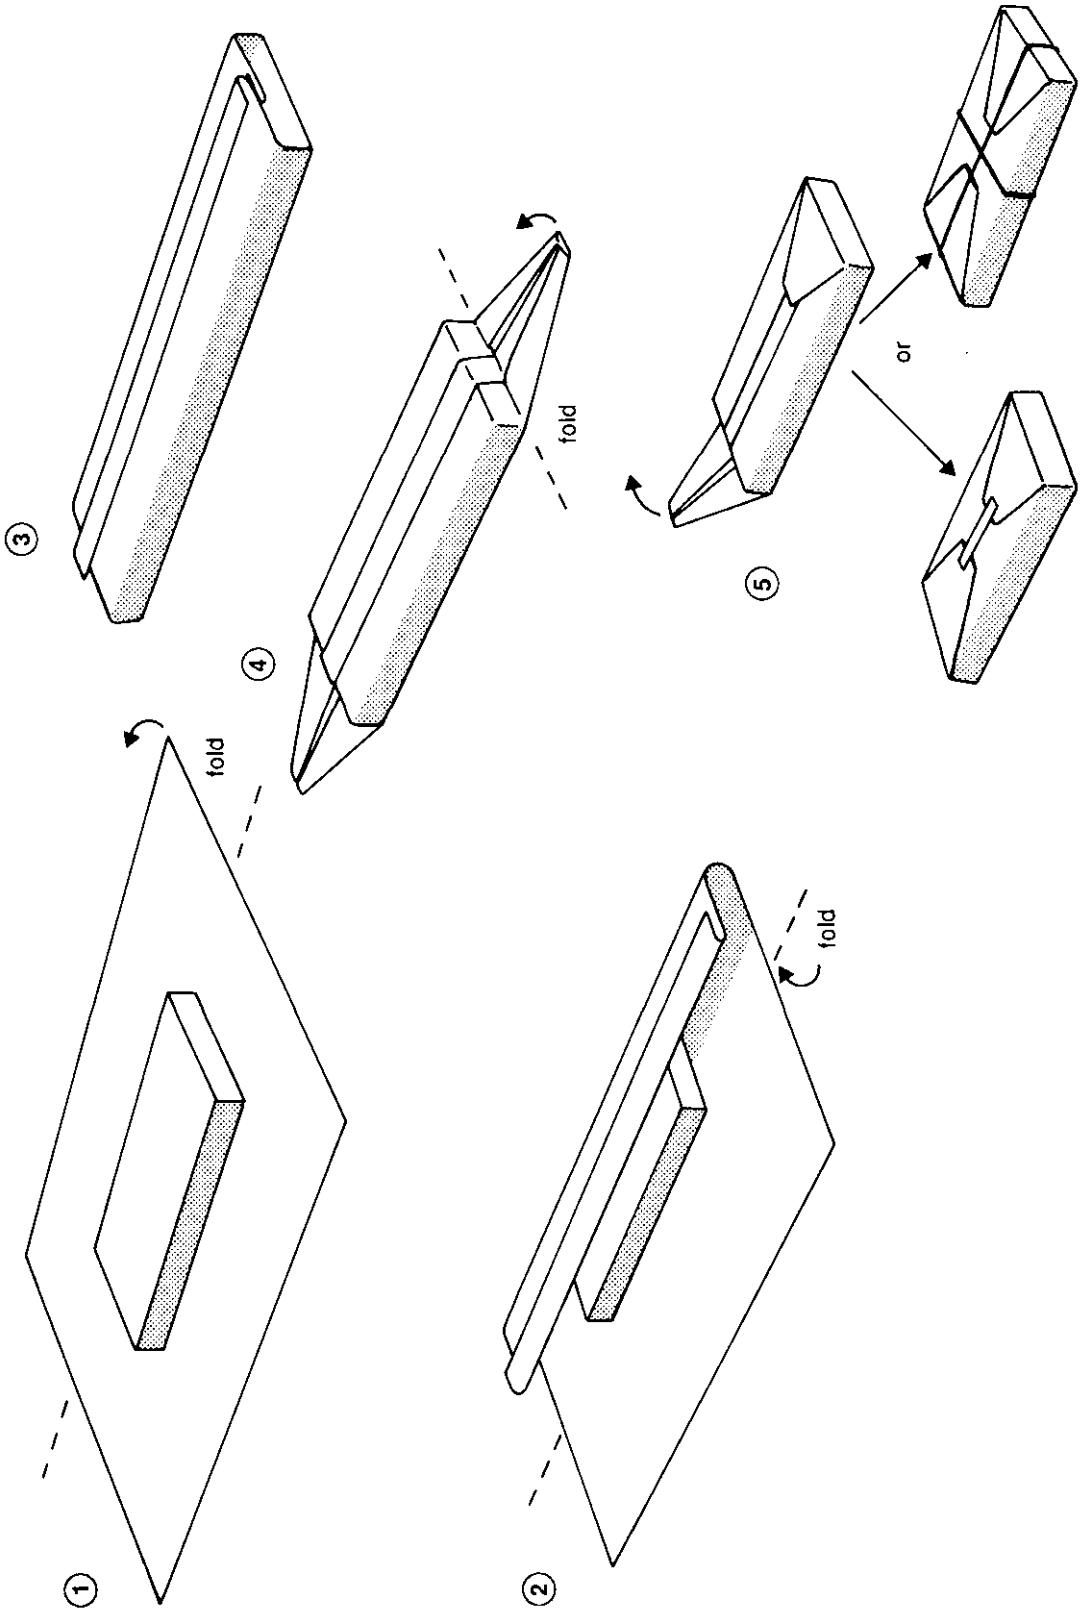
C4.82 The opposite side of the wrap is then folded over pack contents to overlap the centre line (and the side already folded over the pack contents), and the edge is turned back on itself.

C4.83 The ends beyond the short side of the contents are then folded to a point and each is then folded over the contents.

C4.84 The same procedure may then be repeated for an outer wrap(s).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure C1: Diagrammatic representation of method for closing paper, non-woven or textile wrap using the parcel fold



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.85 The wrap is secured in position using pressure-sensitive adhesive tape (high-temperature masking tape or autoclave indicator tape) or by tying with tape or cords.

C4.86 For smaller packs the envelope fold is preferred (see Figure C2).

C4.87 In the envelope fold method the contents are placed on the wrap diagonally and slightly off the centre line.

C4.88 The section of the wrap with the shorter corner-to-pack length is folded over the contents by bringing the corner to the centre.

C4.89 This is repeated with the corners to the right and left of the first folded corner.

C4.90 In each case the corner is turned back to provide a flap for opening.

C4.91 Finally the larger fold is brought over the top and tucked in under the earlier folds with a corner protruding, to facilitate aseptic opening.

C4.92 The envelope fold if properly executed is quite secure without further attention but if preferred may be secured also with tape or by tying.

Paper bags, paper/plastic pouches

Folding

C4.93 Folding is the simplest method to obtain a satisfactory closure for both pouches and bags, although it may not be convenient for high volume production (see Figure C3).

C4.94 The corners at the open end of the bag or pouch are folded diagonally to give mitred corners.

C4.95 The top of the bag or pouch is then folded over three times in succession and secured in place with a piece of high-temperature masking tape, or autoclave indicator tape.

C4.96 The folded top should always be secured with tape; staples should never be used because of the holes that are then made in the package.

C4.97 The folded top may be opened by cutting through the bag or pouch with a pair of sterile scissors. For non-critical applications it may be torn open; it should not be opened by removing the tape and unfolding the closure.

Self-seal

C4.98 Self-seal bags and pouches are closed by folding as described for plain top bags and pouches, above. However the bag or pouch is manufactured with an impact adhesive coating in a small area of the paper, which is protected before use by a piece of “release paper”.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.99 When the bag has been filled the top is folded over as previously described, the release paper is removed and the adhesive patch is pressed onto the surface of the bag to secure the folded top in place.

Heat seal

C4.100 Paper bags and paper/plastic pouches and reel material are available in forms suitable for heat sealing.

C4.101 The melting point of the heat-seal will effectively limit the maximum temperature at which the pack can be used. Heat-seal packaging should not be used at temperatures above those specified by the packaging manufacturer.

C4.102 Heat sealing is performed by compressing the opposing sides of packaging, coated on one or both inner surfaces with a lacquer, adhesive or polymer film, between heated plates.

C4.103 Packaging intended for heat sealing may be film coated, grid lacquered, or have an adhesive band.

C4.104 Film-coated heat-seal packaging has a thin film of a suitable polymer, such as polythene, laminated to the inner surface. When heated this melts sufficiently to fuse with the opposing surface and form a seal. The heat-seal polymer may be laminated to another plastic or to paper. The polymer film, if applied to the paper element, may limit the porosity of the pack.

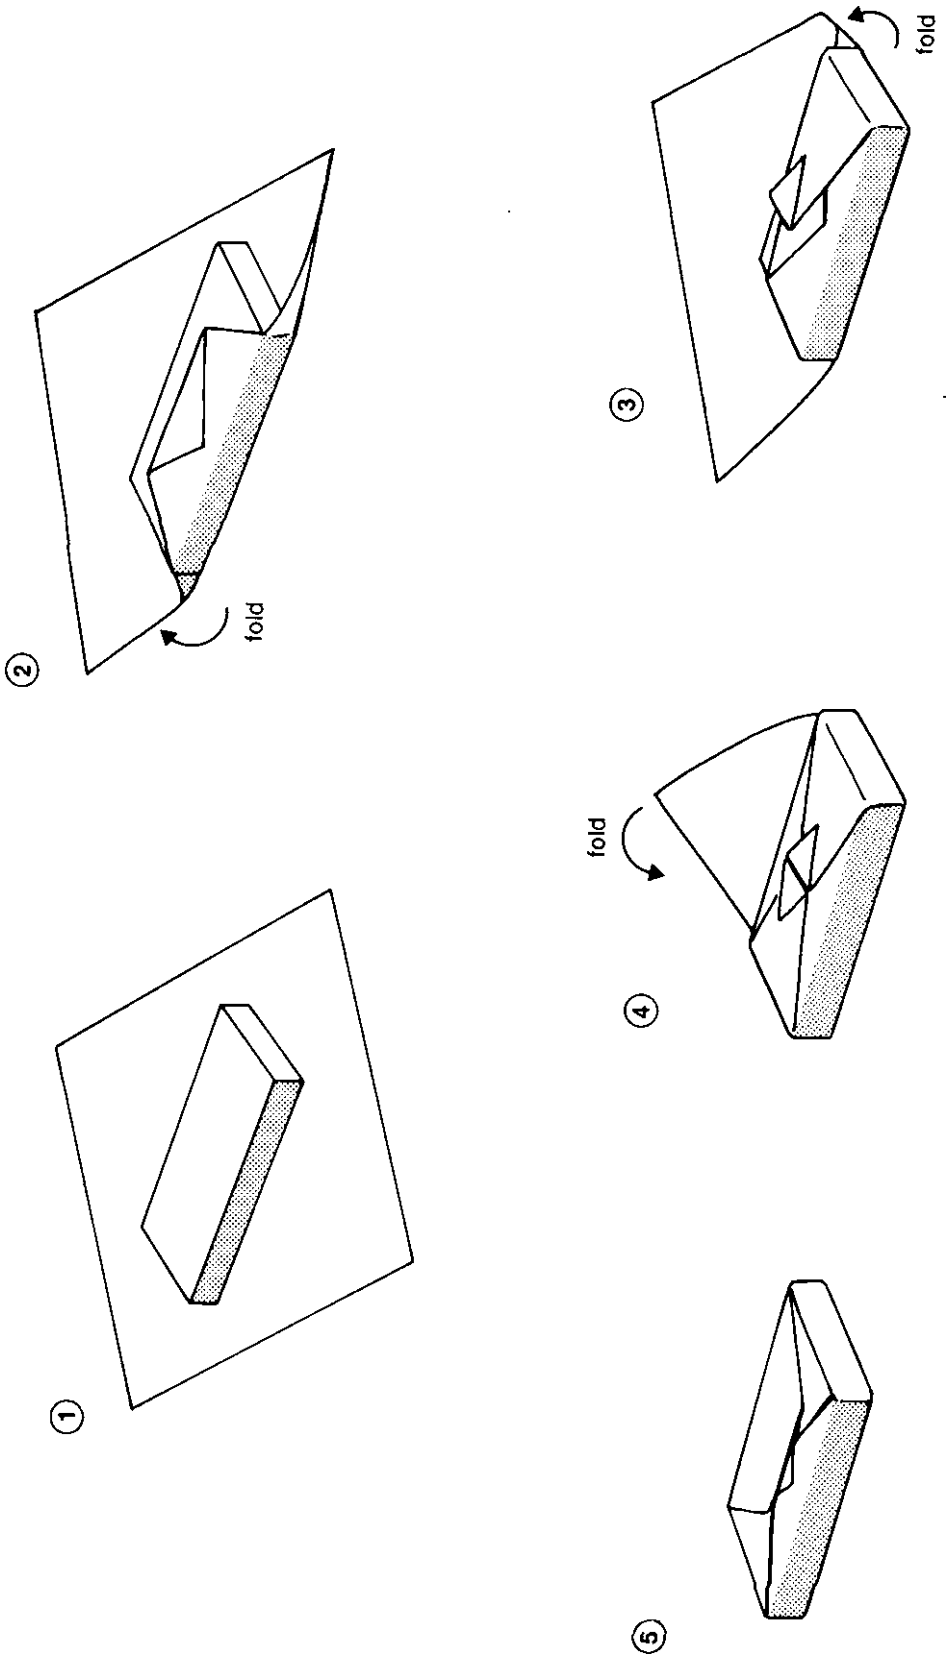
C4.105 Grid-lacquered heat-seal packaging has one side, usually the paper, printed with a heat-seal adhesive in a repeating diamond pattern all over the inner surface. Care needs to be taken that the width of the heat-seal is sufficient to ensure that there is a continuous seal across the width of the packaging.

C4.106 Adhesive-coated heat-seal packaging has a band of heat-seal adhesive printed on the inner surface of the packaging in the area where the heat-seal is to be made. The adhesive is coloured, usually blue, to aid identification of the heat-seal area.

C4.107 The seals need to be peelable. They should peel without splitting, tearing or shedding paper fibres since fibres can cause adverse reactions if introduced into open wounds.

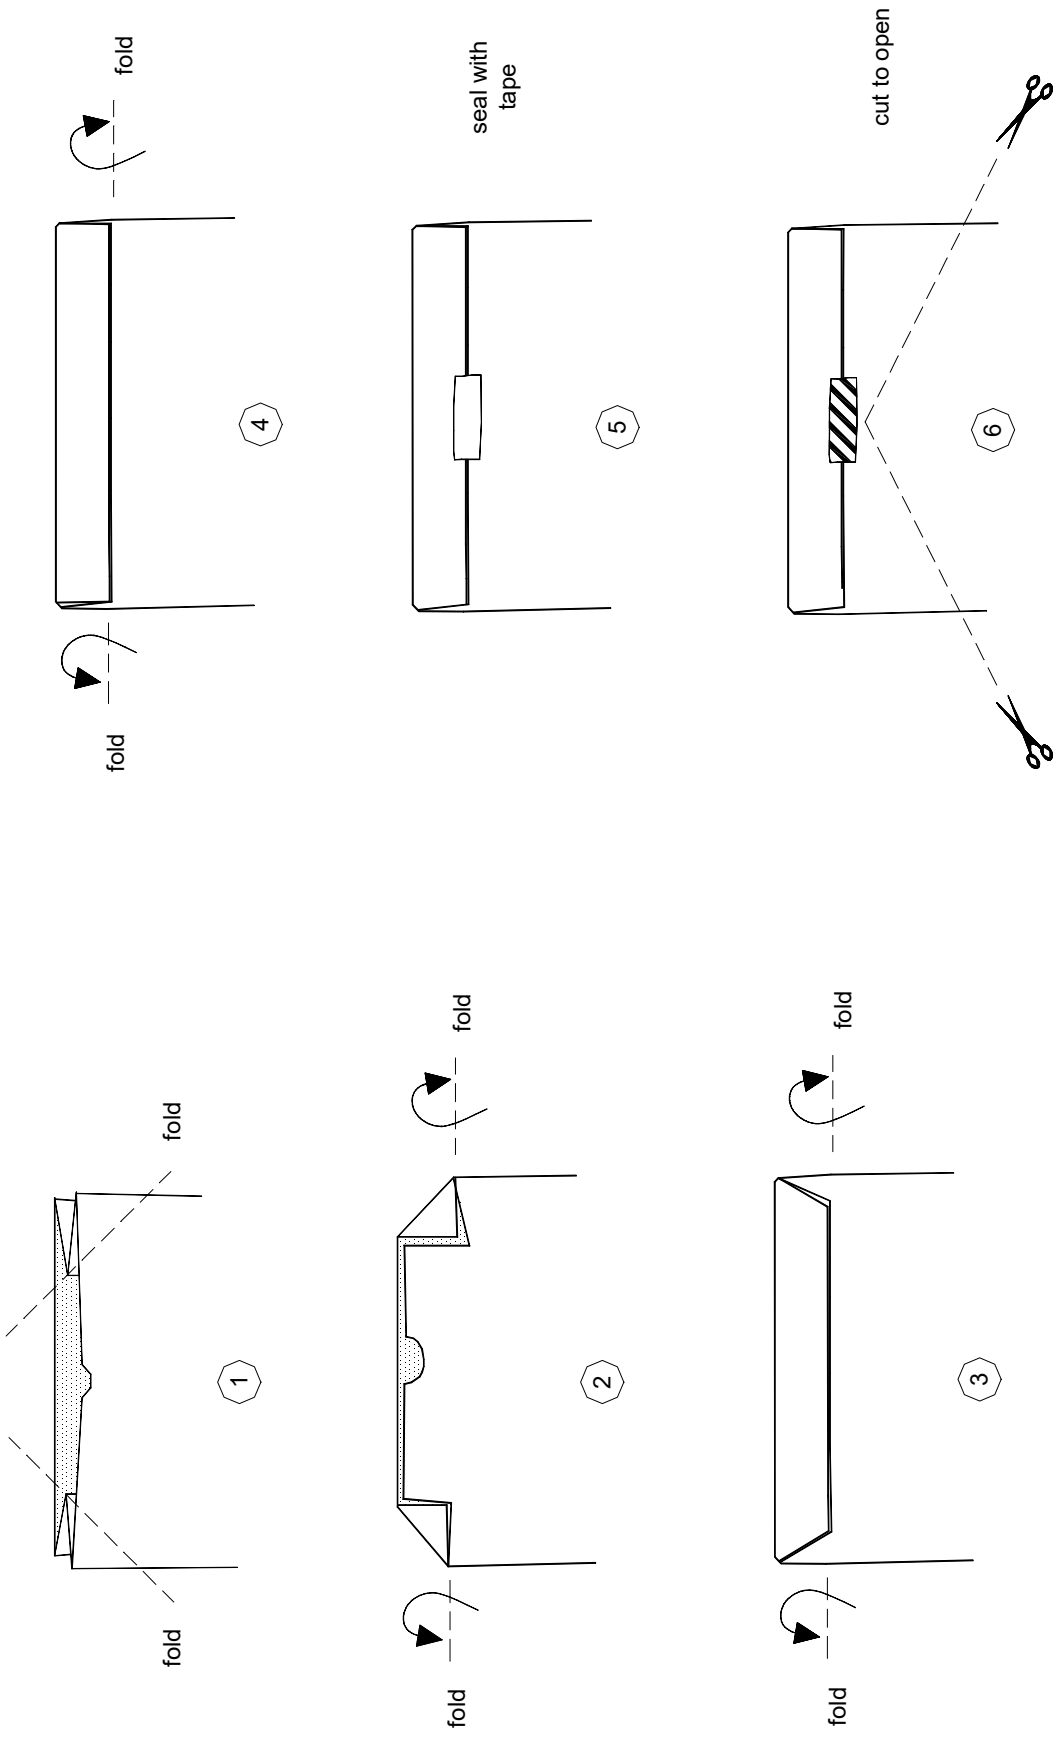
© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure C2: Diagrammatic representation of method for closing paper, non-woven or textile wrap using the envelope fold



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure C3: Closure method for plain top sterilizer bags



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.108 Peelability is a compromise between seal strength and the peel characteristics required which can only be achieved by use of the correct heat-sealing conditions.

C4.109 The heat-seal may be a single line, in which case it should be not less than 5 mm deep and extend across the width of the pack, or a series of lines each about 1 mm wide and 1 mm apart to give a seal width of about 9 mm, with each line extending across the full width of the pack.

C4.110 The heat-sealing process must be undertaken with care. Creases in the packaging material can result in inadequate or uneven seals.

C4.111 A weak point in the heat-seal of paper bags may often be found in the corners where the paper is folded back on itself and in gusseted packs where four thicknesses of material become two. This latter problem can be minimised by reverse folding the gusset in the area to be heat sealed, before sealing.

C4.112 The effect of the sterilization process on heat seals must be considered. The elevated temperatures involved in steam sterilization can weaken the seals. Ethylene oxide gas leaves many seals unaffected but can cause embrittlement of others.

C4.113 Heat sealing is not only used for flexible packaging. It may be used also on rigid packaging when lids are sealed onto moulded plastic bases. The base tray may be moulded in-line just before filling or may be pre-formed. The lid may be of paper, Tyvek or other porous material for use in steam or gas sterilization processes or of impermeable film for use with radiation sterilization.

Glass containers

C4.114 Bottles and vials are extensively used for aqueous solutions for use as topical and parenteral medicines, microbiology media, laboratory reagents, in vitro diagnostics, disinfectants, etc. which are to be sterilized by moist heat.

C4.115 Glass containers may also be used for hot air sterilization of non-aqueous liquids, such as oils.

C4.116 Containers should never be filled with a volume greater than the manufacturer’s recommended maximum.

Ampoules – fusion seal

C4.117 Two forms of glass ampoule are available; one form intended only for automatic (or semi-automatic) filling and sealing and one which is suitable for manual sealing.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.118 Ampoules intended for automatic filling and sealing may be supplied, internally clean, sterile and apyrogenic, with the neck closed by a “bubble” of glass. During the automatic filling process this “bubble” is melted by a flame directed vertically downwards to open the ampoule immediately prior to filling. This normally takes place in an environment controlled to be free from contamination. This type of ampoule is not suitable for manual filling and sealing operations.

C4.119 The relevant DIN standards may be used as suitable specifications.

C4.120 Ampoules are sealed by fusion. After filling, the neck of the ampoule is heated, almost invariably in a gas flame, until the glass softens and the walls of the neck coalesce, surplus unmelted glass in the neck above the point of melting is drawn away and the fused end of the neck is allowed to cool.

C4.121 For any given design of ampoule, the temperature of the flame, the duration of heating and the time and speed at which the surplus neck material is drawn off all affect the quality of the seal. When correctly performed the seal is as strong, or stronger than other parts of the ampoule.

C4.122 Ampoules for use in freeze driers are similarly sealed by fusion.

C4.123 Ampoules are opened by breaking off the neck. This may be facilitated by the inclusion of a deliberate weak point, in the form of a break ring, at the base of the neck during manufacture. Other methods which are available include notching the neck of the ampoule with a glass file, creating a fracture line by the application of a hot wire or rod and several commercially available devices.

C4.124 Whichever method is to be employed, users should be given appropriate instructions and training and should always take precautions to protect their hands from injury due to broken glass.

C4.125 Ampoules are produced to a high level of consistency and faults in sealing are likely to be due to poor setting up or control of the sealing method and rarely, if ever, due to variations in the ampoules.

C4.126 After the ampoules have cooled, careful visual examination, preferably using a magnifier and a polarised light source, should be used to inspect the seal and any showing cracks, thinning or “blowing” of the seal and sharp protrusions or “tails” of glass, should be rejected.

C4.127 A vertical drop of 10-15 cm, for example inside a tube of suitable diameter so that the sealed end impacts onto a solid surface, such as a plastic laminate, may also be used to test the ampoule seal. A satisfactory seal will survive, whereas a weak seal will break.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Vials and bottles

C4.128 As manufactured, glass bottles are generally clean, sterile and apyrogenic. Nevertheless they should be washed before use since they may have become contaminated during packaging and distribution, unless special precautions were taken to avoid this happening.

Screw caps

C4.129 Screw caps may be made of metal or plastic. They may be used to used to retain in place a separate elastomeric seal, such as a stopper or a wad, or they may incorporate a seal within the cap. In either case the seal is formed by compression of a deformable sealing material between the cap and the glass container. The compressive force applied is a key factor in creating a leak-tight seal.

C4.130 Metal caps may “back-off” during autoclaving. The differential thermal expansion of the metal of the cap and the glass of the bottle combine to make the cap unscrew slightly during processing. This rarely happens with plastic screwcaps.

C4.131 The problem can be minimised for metal caps by careful control over the extent to which the cap is tightened before sterilization.

C4.132 Devices to control the force used to tighten the cap (torque) should be used both to ensure reliable sealing and to minimise the risk of overtightening which can damage the cap or make it difficult to remove.

Crimp caps

C4.133 Crimp caps are metal, or sometimes plastic, capsules used to retain an elastomeric seal, usually in the form of a stopper, in position in the neck of the container.

C4.134 During the application of the crimp seal, pressure is applied to compress the stopper slightly against the top surface of the neck finish of the bottle. The skirt of the overseal is bent under the base of the retaining rim on the bottle neck by the crimping device. This retains the stopper in place and maintains it under slight compression to provide a good seal.

C4.135 During steam sterilization of the sealed container the pressure applied by the crimp may be released to some extent by the thermal expansion of the metal capsule. This, and the high internal pressure generated within the container, may cause the seal to leak. It should not be assumed that a seal which is demonstrably leak tight at room temperature will remain so throughout the various stages of steam sterilization.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Re-usable packaging

Textiles

C4.136 Textiles are used in combination with aluminium trays for packs of theatre instruments.

C4.137 The textile wraps should be laundered before each re-use.

C4.138 Control should be exercised over the laundry process to ensure that fabric softeners and fresheners are not used since many of these contain volatile components which will evolve gas during steam sterilization and compromise the efficacy of the sterilization process.

C4.139 The importance of thorough inspection before re-use cannot be over-emphasised. A light table should be used, and wraps with pinholes, clearly visible as points of light, should not be used.

C4.140 The location of the defect should be clearly marked and the item sent for repair by means of a heat-seal patch. Sewn patches are not acceptable because of the needle holes created around the patch.

C4.141 Worn textile wraps are readily discernible since the light will shine through the more open weave that occurs as the fabric wears. These should no longer be used as a sterile packaging wrap.

Containers for solid goods

Impermeable or unvented containers

C4.142 Aluminium tubes with crimped foil caps and larger canisters (made from aluminium, copper or stainless steel) with slide or screw-fit caps may be used satisfactorily for hot-air sterilization. Containers of this sort are used frequently for pipettes or glassware in the laboratory.

Open-topped trays and perforated containers

C4.143 Trays for containing sets of theatre instruments, or similar, are often constructed in aluminium. Plastics such as polypropylene may also be used. The trays may have solid bases and sides or be equipped with drainage ports to allow condensate formed during steam sterilization to run off.

C4.144 When condensate drainage is provided it is necessary to ensure that the condensate is not discharged onto other parts of the sterilizer load, which will then emerge from the sterilizer wet.

C4.145 Trays may be overwrapped in textiles, single-use wraps or bags, or a combination of these materials to achieve the required protection, absorbency and microbial barrier properties.

Instrument orientation trays

C4.146 These trays, usually constructed in metal, are fitted with retaining clips designed to hold a particular set of instruments in position. They are often found in dental practice and also for use with sets of orthopaedic instruments and rigid endoscopic instruments.

C4.147 They are almost invariably fully vented, or unlided, and in this condition may be suitable for use in a steam sterilizer intended for unwrapped instruments and utensils (see paragraph C3.23).

Dressings drums

C4.148 Perforated metal containers, fitted with a filter material and closable louvres were specified in BS 3281, 1960 (now withdrawn), for use as “dressings drums”. These were intended to contain dressings and porous goods sufficient for a number of clinical procedures. The product has been regarded as obsolete except for its use, until recently, as a convenient container for towels for the Bowie and Dick test. Even this use has now been discontinued.

C4.149 There is, however, a new generation of re-usable rigid containers intended for use as a packaging system in steam (and in some cases, gas) sterilization processes. These are intended to contain instruments and/or porous goods which will be used in a single clinical procedure. They are thus more akin to the trays described in paragraphs C4.143 to C4.145 than to the obsolete dressings drums.

Re-usable rigid containers

C4.150 BS EN 868-8 specifies performance requirements for rigid re-usable containers.

C4.151 Container systems are constructed in a variety of materials and those from various manufacturers differ greatly in design, construction and mode of operation.

C4.152 The containers are constructed from impermeable materials. The joint between the lid and the base is sealed by means of a suitable gasket, which should be accessible for inspection and cleaning between uses.

C4.153 In order to permit the flow of gases (air and steam and, where applicable, sterilant gas) in and out of the container that is required by the sterilization process the containers are fitted with one or more sterilant ports.

C4.154 Two different operating principles are used for the sterilant ports, although both may be used in combination. The exchange of gases may be through a porous filter material or through a valve system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.155 The filter system is little different in principle from the porous packaging systems considered previously. Its compatibility with the sterilization process depends on its porosity and on being able to provide the necessary flow rate through the filter to permit attainment of the sterilizing conditions within the container.

C4.156 The ability to maintain sterility depends on the filter efficacy and whether it is able to exclude particles of a size which may contain viable organisms. The small area of surface available compared with the volume of the pack produces relatively high flow rates across the filter material and this influences the materials which can be used effectively.

C4.157 If a re-usable filter is used then great care is needed to ensure that:

- it has not become partially blocked, thus impairing the flow of gases and compromising the sterilization process;
- it has not been damaged, thus allowing the passage of unfiltered gases which would compromise the maintenance of sterility.

C4.158 Both re-usable and single-use filters need to be installed correctly so that the filter is effectively sealed in the holder and there is no passage of unfiltered gases around the filter.

C4.159 The alternative system for sterilant ports is the valve system.

C4.160 Outside the sterilizer the valve is normally closed and, if the seals on the valves are effective, presents an impermeable barrier to external contamination.

C4.161 The valve system has to be arranged to open automatically in the sterilizer to permit the exchange of gases between the container and the environment.

C4.162 A number of systems are used by the various manufacturers but most depend on valves which open in response to a pressure difference between the container and its surroundings. A diagram of the operation of such a system is shown in Figure C4.

C4.163 It is apparent that a finite pressure difference must exist across the valve before it will open. The magnitude of the pressure difference will depend on the force exerted by the springs keeping the valve closed.

C4.164 If the pressure difference required to open the valve is too great, the contents of the container will not be exposed to the sterilizing conditions in the sterilizer chamber. The correct functioning of the container is closely related to the pressure change characteristics of the sterilization cycle.

C4.165 If the required pressure difference is too small the valve will open outside the sterilizer due to changes in ambient pressure and temperature, thus allowing the inflow of unfiltered air from the environment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.166 Some container systems are also fitted with a valve in the base of the container which is used to allow condensate to drain away, to assist in drying the contents of the container.

C4.167 The condensate drain valve may be fitted with a thermostatic device to open the valve when it is above a specified temperature, say 80°C, or it may operate on pressure differential as previously described for valved sterilant ports.

C4.168 After repeated use, the springs controlling a valved system will age and the force exerted by them will change. It is essential that the manufacturer's instructions for maintenance, testing and replacement of key components such as seals, sterilant ports and drainage valves are followed rigorously.

C4.169 The performance of either type of container may be seriously affected both by the nature of the sterilization cycle (particularly the characteristics of the air removal phase and the drying stage) and by variations in the quality of services supplied to the sterilizer (for example the dryness fraction of the steam). These variables are sterilizer and site specific respectively.

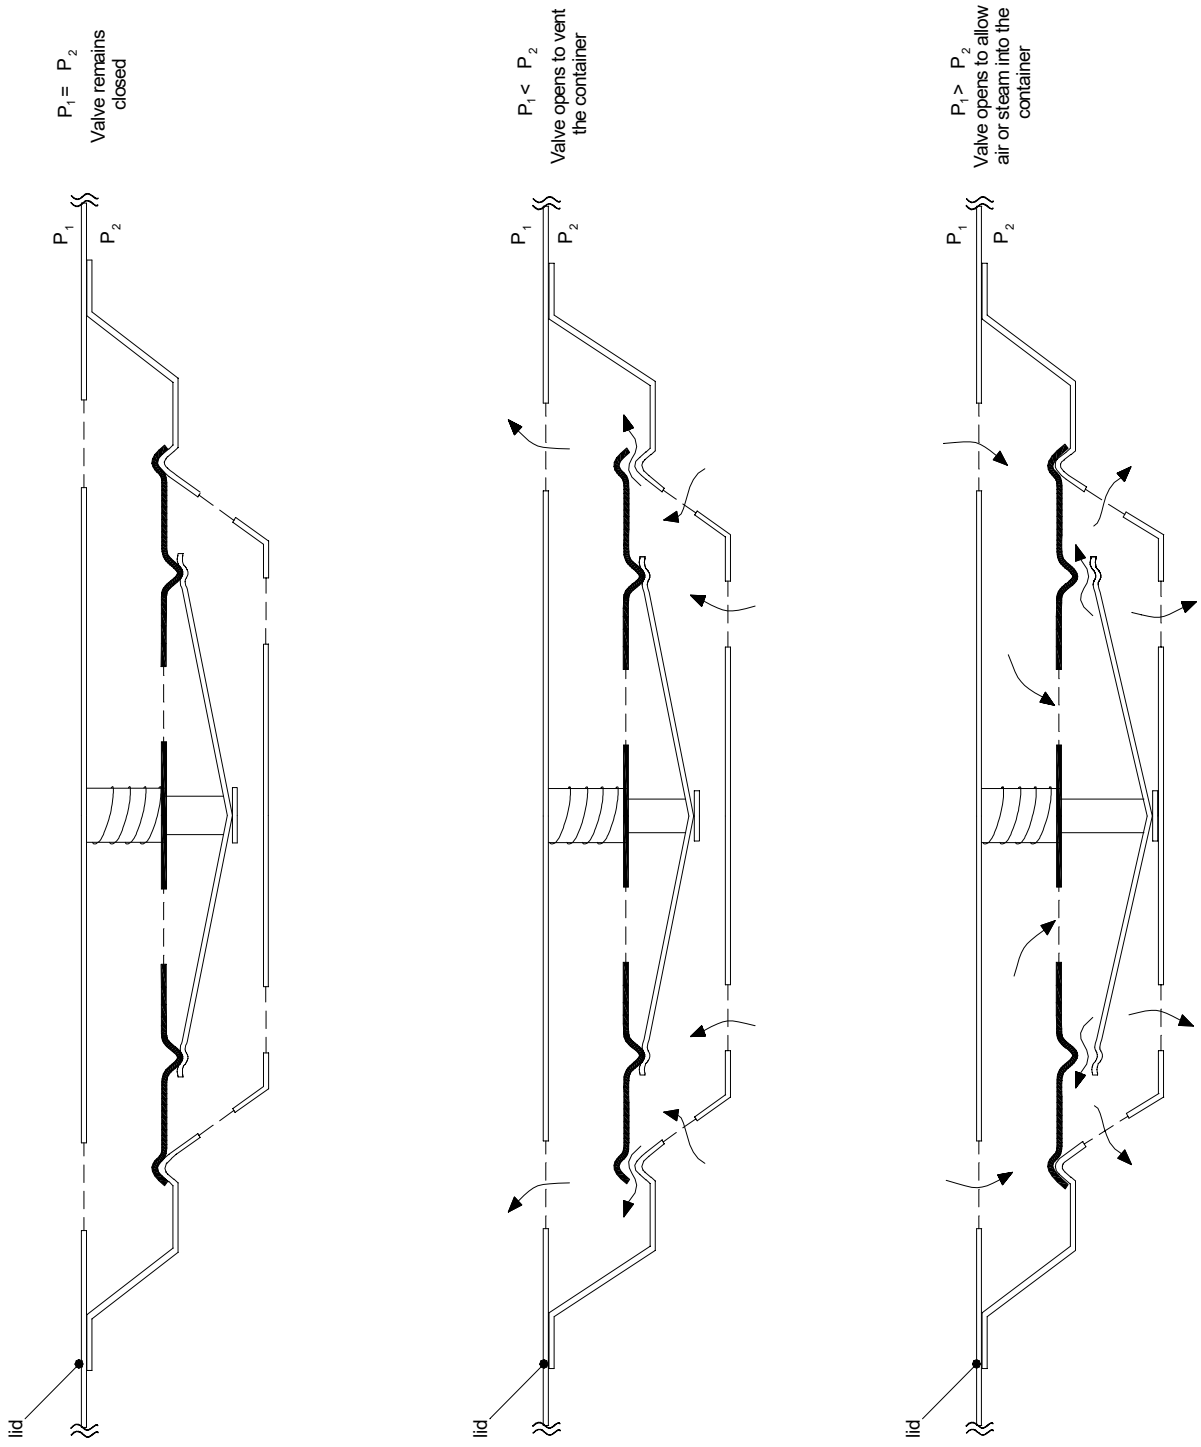
C4.170 It is necessary, therefore, to establish, by appropriate on-site testing, that any particular design which it is intended to use functions correctly in the specific sterilization cycle with which it is to be processed, in the sterilizers which will be used in practice.

C4.171 Re-usable containers have a number of apparent advantages. They offer excellent mechanical protection to the contents and a convenient, modular system for storage and distribution.

C4.172 The use of a solid-walled container gives the impression of providing good protection against microbial and other environmental contamination. In practice the barrier properties are dependent on the adequacy of gaskets and seals and the sterilant ports described above.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Figure C4: Diagram to show the principle of operation of value-type re-usable container systems



NOTE: The above diagrams are intended to be an idealised example of the operation of a valved system. They do not represent any commercially available system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.173 The condition and function of filters, valves, sealing gaskets and locking systems needs to be verified on each container before each use.

C4.174 Between uses containers should be disassembled and cleaned following the manufacturer's recommendations. These usually suggest cleaning by washing with a mild detergent, either manually or in a washer/disinfector.

C4.175 The choice of detergent should accord strictly with the manufacturers recommendations since a number of cleaning agents in common use can cause corrosion or surface cracking on the metal or plastic surface of containers.

C4.176 These containers are often used to return used and soiled instruments, which are potentially contaminated. Whenever practicable they should be decontaminated and cleaned in a washer/disinfector.

C4.177 Most containers are fitted with interior baskets or mesh trays used to hold the instruments. These may be suitable to contain returned instruments as they are processed through a washer disinfector.

C4.178 In use the containers need to be properly loaded if they are to be used successfully. The manufacturers recommendations concerning the maximum weight, the proportion or density of metal ware or rubber goods and the presence and location of absorptive materials in the load should be followed.

C4.179 Some containers are intended to be used in conjunction with porous packaging materials, either as an inner or outer layer of packaging, whereas others are intended to be used, and will only function correctly, without any other packaging being present during sterilization. It is important that the manufacturer's instructions are followed.

C4.180 Containers which are not intended for use with a second layer of packaging, that is those which can only function as a single packaging layer, are not suitable for use in an aseptic environment (see paragraph C3.111).

C4.181 Containers manufactured to the proposed European Standard will be sized in relation to the standard loading module for large steam sterilizers (see EN 285). High packing densities within the sterilizer chamber can be achieved and it is important to ensure that the maximum permitted load for the sterilizer is not exceeded.

C4.182 To avoid problems with moisture retention within the container it may be necessary to increase the time allowed for the drying stage of the sterilization cycle.

C4.183 Each container should be fitted with a tamper evident closure system which should provide a clear indication when the integrity of the closure has been compromised.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.184 The containers are designed to stack for storage purposes. Containers from any one manufacturer should stack securely but containers of different provenance may not.

C4.185 When purchasing this type of packaging system all the containers should be from the same manufacturer to ensure compatibility.

C4.186 Re-usable containers are often promoted on the basis that they are more cost effective than single-use packaging. A decision based on cost grounds requires careful evaluation of the initial capital cost, cleaning and maintenance costs (including all equipment, components, consumables and labour required), the working life (the number of re-uses) which the manufacturer is prepared to guarantee, the likelihood of damage or loss and the cost of eventual disposal.

Glass containers

C4.187 Bottles intended for single use should not be re-used. Bottles intended for multiple use are available for most applications.

C4.188 Re-usable containers should not be used for solutions intended for parenteral administration.

C4.189 The information given for single-use screw cap and crimp-on closures is equally applicable to re-usable containers, with the following additional requirements.

Vials and bottles

Cleaning

C4.190 Before bottles can be satisfactorily re-used a cleaning procedure is required which has a demonstrated capability to remove any dirt or contamination, as well as any residues from the previous use. It is also important that the cleaning process is well controlled and ensures that there are no residues of cleaning agents.

C4.191 Cross-contamination can be most easily controlled by ensuring that whenever possible re-usable containers are only refilled with the same product, for example by reserving a set of bottles only for sterile water and another set only for sterile isotonic saline and so on.

Inspection

C4.192 Inspection of the bottles after cleaning and prior to re-use should include a careful visual examination of the neck finish. A chipped or cracked neck finish could prevent an adequate seal or lead to the failure of the seal during transport or storage. Bottles that have been damaged in this way should be scrapped.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C4.193 Inspection of the outer surface of the bottle should also be made. Bottles being sterilized are subjected to considerable stress both from the high internal pressures generated and from thermal shock. Scratches or other mechanical damage on the outer surface of the bottle weaken it and significantly reduce the pressure and the thermal shock which can be tolerated without breakage.

C4.194 One bottle breaking in a sterilizer load may provide sufficient force to cause others to break also. Re-usable bottles with surface damage should be rejected and either used for applications which do not require steam sterilization or be scrapped.

C4.195 The inspection of the neck finish should also consider any damage to the screw threads or the retaining shoulder on the outside of the neck of bottles which are closed with screw caps or crimped seals respectively.

Screw caps

C4.196 Screw caps, and the elastomer wads, stoppers or bungs used in conjunction with them, are often regarded as re-usable, and many of them may be satisfactorily re-used a number of times.

C4.197 The screw cap should be separated from any sealing wad and both should be thoroughly cleaned and inspected for damage before re-use.

C4.198 Metal caps that have been dented, or are showing visible signs of wear on the threads, should be scrapped.

C4.199 Rubber wads and rubber stoppers should also be carefully inspected for surface damage and any showing cuts, abrasions, staining or permanent deformation should be scrapped.

C4.200 Plastic screw caps with a built-in seal are also commonly used. These should be inspected very carefully for damage to the thin sealing gasket which is moulded into the inner surface of the cap. Any damage to this area will almost certainly cause the cap to leak.

Crimp caps

C4.201 Crimp caps are not themselves re-usable but the bottles on which they may be used can be. A special tool and some care is needed to remove crimped seals without risk of injury.

C4.202 The old seal should be discarded. The seals are usually fabricated from aluminium and the metal can therefore be reclaimed.

C4.203 The elastomer seal should also be scrapped.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C5. Purchase, quality control and storage

C5.1 The purchase, handling and control of packaging materials should be given similar attention to that given to components and other materials incorporated directly into the product.

Purchase

C5.2 All packaging materials should be purchased, whenever possible, to a British Standard or other suitable specification from approved suppliers.

C5.3 Packaging material should be purchased only to an agreed, written specification. When it is intended to purchase a catalogue item, the specification for that item should be obtained from the supplier and used as the basis of that purchase, and all subsequent purchases of the material. This should ensure that the user is informed of any changes in specification subsequently made by the supplier.

C5.4 The purchase order should be based on not more than the quantity which can reasonably, be expected to be used within the manufacturer's stated shelf life for the product.

C5.5 Although paper products, and other packaging materials, have a prolonged shelf life the manufacturer's expiry date may relate to other properties of the product such as a process indicator or a heat-seal adhesive whose performance may deteriorate on storage.

C5.6 The specification and purchase order should require that the material be delivered in unopened containers, using covered vehicles, suitably protected from water damage or soiling and that it is handled with care to prevent mechanical damage.

C5.7 The packaging materials should be supplied suitably wrapped to provide the required protection when it is stored under the specified conditions.

Specification

C5.8 For medical devices and medicinal products, and generally for laboratory products also, the specification should include:

- a description of the materials including:
  - the designated name and any code or reference;
  - the size;
  - the quantity in each unit pack delivered;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

- the reference, if any, to a pharmacopoeial monograph, British Standard or other published specification;
- the approved suppliers, and if possible, the original producer of the material;
- a specimen of printed materials;

- directions for sampling and testing, or reference to written procedures;
- qualitative and quantitative requirements with acceptance limits;
- storage conditions and precautions including the maximum period of storage.

Quality control

C5.9 In many cases users of packaging materials will lack the facilities necessary to carry out a comprehensive independent assessment of delivered materials for conformity to their purchase specification.

C5.10 Nevertheless every reasonable step should be taken to establish conformity. This requires that each delivery should be examined to ensure that:

- there is no visible damage to the shipment;
- the delivery note, the label description and the purchase order are in agreement concerning the quality, size and number of the material;
- that each consignment has clearly identifiable lot numbers;
- that each lot delivered is accompanied by a Certificate of Analysis or Certificate of Conformity, or if the delivery is a further supply from a lot previously received that the appropriate certificate is on record.

C5.11 When, due to the nature of the packaging or the product, it is necessary to carry out tests, other than a careful visual appraisal, on incoming packaging materials a random sample should be taken and submitted for analysis.

C5.12 There should be a formal sampling plan which should take account of:

- the quantity received;
- the quality required;
- the nature of the material, and the risk involved if the material is not to specification, for example if the product makes contact with the packaging material;
- the established reliability of the packaging manufacturer.

C5.13 The number of samples taken should be specified statistically, in accordance with a recognised standard, such as BS 6000 or BS 6001.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C5.14 In confirming that the material supplied is identical in every respect with the material ordered particular attention should be paid to printed labels and packaging materials.

C5.15 A system for segregating delivery of packaging materials which have not been examined from those which have been found suitable for use should be implemented.

C5.16 Provision should be made for the temporary secure storage, prior to disposal or return to the supplier, of material which was delivered but, on examination was found not to conform to the specified requirements.

Storage

C5.17 Packaging materials should be stored under conditions which are maintained within those specified by the manufacturer of the packaging. This is best achieved by environmental control of the storage area.

C5.18 The temperature, and where necessary the humidity, of the storage environment should be monitored with a maximum-minimum thermometer and hygrometer, even if the store is not environmentally controlled.

C5.19 Paper and other moisture sensitive packaging materials should not be stored adjacent to:

- external walls or other surfaces which may be at a lower temperature than the ambient temperature of the store;
- sources of heat which could cause dehydration of the packaging material.

C5.20 Sheet materials should be stored flat, not on edge.

C5.21 Packaging materials should be stored on shelves, clear of the floor.

C5.22 Pre-printed labels and other printed packaging materials should be stored in secure conditions which exclude unauthorised access and should be transported in separate containers in order to avoid mix-ups.

C5.23 Packaging materials should be issued for use only by authorised personnel following an approved and documented procedure.

C5.24 Outdated or obsolete packaging material, especially printed material, should be destroyed and this disposal recorded.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C6. Validation of packaging systems

C6.1 All materials and procedures for packaging should be specified in documented form.

C6.2 Before a particular packaging system is adopted for a product, or group of similar products, it should be evaluated to establish its suitability.

C6.3 This evaluation should be documented.

C6.4 Specific testing may not be necessary when appropriate data are available, historically from similar use (whether by the same or different sterile product manufacturers), from the manufacturers of the packaging system or from an independent third party.

C6.5 The factors that need to be considered for evaluation include, as a minimum, those listed in paragraph C3.5.

C6.6 The compatibility of the packaging with the sterilization process can be established for many packaging systems by demonstrating conformity of the packaging and the sterilization process with published standards, for example sterilization-grade paper bags manufactured in conformity to BS EN 868-4 for use in a sterilizer conforming to BS EN 285 and operated in accordance with the guidance given in this SHTM may be presumed to be compatible.

C6.7 Re-usable containers should be subjected to thermometric performance tests before they are adopted as a packaging system. This may be accomplished using a container modified to provide a gas-tight thermocouple entry port and carrying out tests essentially similar to the small load and full load tests described in SHTM 2010 Part 3 paragraphs 13.7 to 13.14 and 13.15 to 13.24 respectively.

C6.8 The tests should be carried out with a container fully loaded with items of the type which it is intended to process. If both instruments and textiles are to be processed the container should be tested under both fully loaded conditions. The full load test should be carried out with the sterilizer fully loaded with fully loaded containers.

C6.9 The temperature profile obtained should not show any delay in the contents of the container equilibrating with the sterilization temperature in the chamber, when compared to the results obtained using a small-load test pack.

C6.10 Load dryness should be verified using either the hospital load test described in SHTM 2010 Part 3 paragraph 13.37 or, when quantitative results are necessary, by a modification of the method described in SHTM 2010 Part 3 paragraphs 13.25 to 13.36.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C6.11 The compatibility of the packaging with the labelling system will usually be established by using the labelled pack for such tests as may be necessary.

C6.12 The compatibility of the packaging with the user's requirements at the point of use, for example aseptic opening, should be verified by consultation with the user. Testing is rarely required.

C6.13 The sensitivity of the pack contents to particular risks, such as irradiation, moisture, mechanical shock, static discharge and the compatibility of the packaging with the contents, for example the medical device or medicinal substance, in other words, that the packaging has no adverse effect on the medical device or vice versa, will usually be apparent from historical data. When new products are to be packaged and sterilized, the instructions which the device manufacturer is required to provide should be followed.

C6.14 The protection provided by the packaging against adverse environmental influences which may reasonably be anticipated, such as mechanical shock, vibration, chemical or microbial contamination, may be considered in two stages:

a. First, the extent to which the environment to be encountered during transport and storage may be controlled. Secondly, the protection provided by the packaging.

b. Adequate performance of the packaging should be demonstrated under the anticipated conditions of use by simulating the abuses a pack may encounter during routine methods of transit and storage.

C6.15 Guidance on the methods to be adopted is given in BS EN 22872: 1993.

C6.16 The protection provided by the packaging against microbial contamination should also be evaluated.

C6.17 Tests for bacterial penetration of packaging are beyond the experience and competence of most hospital users and could only be carried out by specialist subcontractors. There is no agreement on suitable test methods, or performance standards, for the microbial barrier properties of sterile packs.

C6.18 The microbial barrier properties of a sterile pack are dependent on both the materials of which the packaging is made and the construction of the package.

C6.19 Materials that are impermeable to gases may reasonably be assumed to present an absolute barrier to microbial contamination. When such materials are used in the construction of a pack which is hermetically sealed (for example glass ampoules) the barrier may also be assumed to be absolute.

C6.20 Package testing may be avoided by the compilation of evidence that the materials of construction are themselves an adequate barrier together with evidence that all seals and closures are adequate barriers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C6.21 Two different approaches have been adopted to testing porous materials for their ability to exclude microbial contamination; tests based on physical particulate retention (for example the methylene blue test specified in British Standards for sterilization packaging) and tests based on the use of micro-organisms (for example the tests specified in German standards for sterilization packaging).

C6.22 For many materials a standard specification has been adopted which specifies the physical and/or chemical characteristics of the material which have been shown to provide satisfactory performance against a standard penetration test. Whenever possible materials in compliance with one of these standards should be adopted so that purchases are to an agreed specification which will give the required level of assurance.

C6.23 The methods available for verification of the adequacy of the seal or closure depend on the method chosen. Seals formed in impermeable packaging materials can be tested by one of several leak test methods but these are not generally applicable to seals formed in porous materials, nor to closures which rely upon a tortuous path to exclude microbial contamination.

C6.24 Heat seals are also dependent for their success on the performance of the heat sealer used. Several methods for testing heat seals are available but visual examination of the quality and uniformity of the seal from samples of packaging taken before and after sterilization and before and after storage and journey trials may be sufficient.

C6.25 Closures which rely on a tortuous path formed by folding are very dependent for their success on the skill of the operator forming the closure. There is good published evidence, from a number of studies carried out over many years, that the closures described in paragraphs C4.78 to C4.97 are satisfactory.

C6.26 For packaging materials to be used in gas or irradiation sterilization processes it may be necessary to determine the extent and nature of microbial contamination on the packaging before sterilization. This should not be necessary for steam sterilization processes operating at 134°C for not less than three minutes.

C6.27 When knowledge of the packaging bioburden is required this information should be sought from the packaging manufacturer or it should be determined in accordance with BS EN 1174 by an appropriately experienced laboratory.

C6.28 When re-usable packaging systems are being evaluated it is important that the cleaning, inspection and maintenance procedures and methods are also evaluated for their ability to consistently restore the packaging system to the required condition for re-use.

C6.29 Before any performance testing is undertaken a test protocol should be prepared. This should document:

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

- the tests to be performed, including full details of the equipment and methods to be used, personnel etc;
- the purpose of the tests;
- the sequence in which the tests are to be carried out;
- the format in which the results are to be documented;
- the pass fail criteria for each attribute being evaluated.

C6.30 The test protocol and the written report of the results should form part of the validation documentation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C7. Facilities and environmental control for packaging operations

Packaging operations

C7.1 In SSDs the assembly of components, placing them in primary packaging and sealing or closing the packaging usually is referred to as a “packaging operation”. Thus is in contrast to pharmaceutical and laboratory practice where the same operation is described usually as a “filling operation” and the term “packaging operation” is reserved for the subsequent, often post-sterilization, application of secondary packaging. In the following section “packaging operation” refers to the application of primary packaging and any secondary packaging which is included in the sterilization process.

C7.2 Detailed guidance on suitable facilities is given in Scottish Hospital Planning Note13; *Sterile services department* and Scottish Hospital Planning Note 29; *Accommodation for pharmaceutical services*.

General requirements

C7.3 All areas used for the reception, inspection, storage, filling, and sealing of packaging require a high standard of finish and cleanliness.

C7.4 Areas where clean, unpacked product is to be handled for, say, assembly and packaging, need a controlled environment to minimise the potential for recontamination of product by, for example mechanical ventilation or gowning procedures.

C7.5 All exposed surfaces should be smooth, water resistant and sufficiently durable to withstand frequent cleaning. The construction and any fitments should be designed to be free from crevices and sharp internal corners, which can trap dirt.

C7.6 Areas where product, ready for incorporation into primary packaging, and primary packaging materials are exposed to the environment for significant periods should be controlled to defined standards of environmental cleanliness.

C7.7 For SSDs there should be a dedicated room where the production of packs, trays etc. takes place. This should be a controlled environment. SHPN 13 recommends that packaging facilities for SSDs should be controlled to BS 5295 Class L and a detailed summary of the environmental needs of the various areas is provided in SHPN 13, Appendix 5.

C7.8 The GMP Guide for Pharmaceuticals recommends that parenteral solutions should be filled under a laminar flow work station (Grade A) within a cleanroom controlled to Grade C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C7.9 The provision of controlled, clean environments has additional implications for staff hygiene, gowning and entry procedures and the behaviour of personnel within the facility. These requirements are fully described in the relevant GMP guides.

C7.10 Doorways throughout the facility should be wide enough, and free from damaged or rough edges, to eliminate the danger of packs of product on trolleys being damaged as they are wheeled through.

Facilities for packaging operations

Cleaning

C7.11 All operational areas of a sterile-product manufacturing facility need to be maintained to a high standard of cleanliness.

C7.12 Detailed cleaning procedures and schedules should be documented and their implementation monitored.

C7.13 For guidance on suitable procedures and schedules see ISSM Guide to Good Manufacturing Practice for NHS Sterile Services Departments and The DoH MRS Guide to Water and Environmental Cleaning.

C7.14 Surface finishes and cleaning methods must be compatible. Appendix 6 of SHPN 13 suggests appropriate finishes.

C7.15 Cleaning equipment and facilities for the storage and preparation of cleaning materials and equipment should be provided separately for areas between which cross-contamination could be problematic.

Cleaners' room

C7.16 SHPN 13 recommends the provision of a dedicated cleaning facility for the packing room, and a separate, dedicated, cleaning facility for the linen preparation area (if one is used).

C7.17 The cleaning facility provides storage for cleaning equipment and materials, a sink or sluice with hot and cold water of the appropriate quality and other facilities needed for the cleaning and preparation of the cleaning equipment. In addition, it usually accommodates consumable items for operational areas which are normally replaced by the cleaner. This would include plastic waste bags, liquid or leaf soap refills for dispensers in changing rooms etc.

C7.18 Hand washing and drying facilities should also be available in the cleaning facility.

C7.19 Whether or not separate facilities are provided, it is necessary to ensure that separate cleaning equipment is used for the assembly/packing area and other areas within the unit.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Sterile services departments - SSD

C7.20 The packing room receives single-use materials from materials' store and reusable goods after the completion of appropriate decontamination procedures.

C7.21 The decontaminated re-usable goods will include components to be incorporated into packs and may include re-usable packaging, such as textiles, instrument trays, re-usable containers.

C7.22 Within each of the areas supplying the packing room, or at the interface between these areas and the packing room there is usually provision of inspection/verification facilities to ensure that all product transferred into the packing room is the correct item and in a suitable condition for use.

C7.23 In the packing room these goods are then assembled into the combinations specified to form the pre-set trays and procedure packs which are required. These are then packed in preparation for sterilization (see SHPN 13).

Linen room

C7.24 Cleaning facility - dedicated required same as packing room. Textiles for incorporation into packs may be product items, such as surgical drapes, towels or gowns, or they may be wrapping materials.

C7.25 Textiles for wrapping purposes may be received in the SSD as laundered linen which has already been checked and folded to an agreed pattern or in bulk form, unchecked and unfolded.

C7.26 The SSD has an obligation to ensure that the laundry process is defined and controlled and the quality checks on the textiles to be used are rigorously applied to ensure that the pre-determined standard is maintained, even if the laundry has the devolved responsibility for inspecting the packaging textiles (see paragraphs C4.136 to C4.141).

C7.27 When unchecked linen is provided from the laundry, the SSD will require suitable inspection facilities within a linen preparation room.

C7.28 When textiles are to be used as the primary wrap for sterile packs they have to be inspected to a defined standard, which should include freedom from all tears, cuts and visible holes. A light table is essential for inspection to this standard.

C7.29 When the textiles are used only as an inner wrap and it is intended that the necessary bacterial barrier properties will be provided by an outer wrap of another material, such as a sterilization grade paper wrap or bag, a less rigorous inspection standard may be accepted for the textiles. A large flat surface where the wrap can be fully unfolded and a good standard of ambient lighting are still necessary.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C7.30 The linting of fabrics can be a major problem. Lint is a respiratory hazard and a fire or explosion hazard and together with other dust may contribute to an insanitary environment by providing a vehicle for the transfer of micro-organisms.

Packing room

C7.31 The activities undertaken in the packing area may be summarised as to:

- receive QC released single use, re-usable and consumable items. Note that in some units the QC inspection on cleaned and decontaminated items is carried out within the packing area. When this system is used, and particularly when inspection is done at the same time as assembly, great care is needed to ensure proper segregation of rejected items;
- assemble items into pre-set trays and procedure packs;
- verify that the contents match the specification;
- pack;
- close and/or seal the packaging system;
- label;
- verify the accuracy of the label;
- transfer to sterilizer.

C7.32 The packing room should be mechanically ventilated to ensure that the particulate count and pressure differentials meet the requirements of BS 5295 Class L in the “unmanned condition”.

C7.33 Although it may be possible to demonstrate that areas lacking mechanical ventilation can meet the required particulate standard when tested, this is not a satisfactory substitute. Mechanical ventilation is required to ensure that the particulate standard can be met consistently and also to ensure that there is a positive pressure relative to surrounding areas to minimise the ingress of contamination.

C7.34 SHPN 13 recommends that the air supply filters should have a minimum resistance of 85% when tested in accordance with BS EN 779: 1992.

C7.35 Humidification may also be required to avoid dehydration and subsequent problems.

C7.36 When plastic materials are being used for packaging excessively dry atmospheres can promote a build up of static electricity which causes problems, such as attraction of particulate material.

C7.37 Dry atmospheres may lead also to excessively dry absorbent materials, such as paper or cotton textiles. When steam sterilized the exothermal rehydration of these materials can lead to local superheating and impairment of the sterilization process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C7.38 Ethylene oxide sterilization requires goods to be sterilized which have been humidified to provide an optimum moisture content. This can be greatly facilitated by the maintenance of appropriate ambient humidity during assembly and packaging.

C7.39 The layout of the packing room should allow an orderly flow of work and should provide sufficient separation between activities to preclude the possibility of mix-ups, mis-labelling etc.

C7.40 Work surfaces should be of sufficient size to allow the largest wrapping materials which will be used to be fully opened without draping over the edges of the work surface.

C7.41 In-line labelling and label printing may be used to advantage, but printers are often noisy. Their location should be considered carefully to minimise the adverse effect of this noise. In addition, when it is necessary for staff to read information displayed on VDU screens it is essential that the ambient lighting is suitable.

Sterilizer loading area

C7.42 When single-ended sterilizers are used it is important to ensure adequate segregation of unprocessed goods from processed goods. Chemical process indicators in conformity to BS EN 867-2 may be of value.

C7.43 Adequate space must be available for the number and type of trolleys to be used.

Post-sterilization area

C7.44 This area provides the interface between the sterilizers and the processed goods store and should provide adequate space and facilities to allow product removed from the sterilizer to be inspected and to be quarantined until verification that the cycle was satisfactory.

C7.45 The area should provide space where packs may be allowed to cool to room temperature before they are handled.

C7.46 Each pack should then be inspected to verify that the packaging is not wet or damaged and that the seal or closure is intact.

C7.47 For gas sterilization processes an additional facility to provide the controlled removal of residual sterilant gas may be required. After verification that the sterilization cycle was satisfactory and inspection of the sterilized packs they may be transferred to the processed goods store or sent directly to despatch for immediate distribution.

Processed goods store

C7.48 The area should provide facilities where sterile packs may be stored away from excessively humid, hot or cold locations, strong light sources and

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

electrical power supplies. Adverse conditions can cause deterioration of plastics, rubber and cellulosic materials found in the packaging or the contents, giving rise to embrittlement, loss of tensile strength, and so on (see SIB(7)3 'Storage of sterile medical devices and surgical products', DHSS 1982).

C7.49 The storage area needs to be clean, dry and well ventilated but free from draughts. Ideally the environment in the store should be maintained at 18-22°C with RH 35-75%.

C7.50 Storage may be on open shelves or in closed cupboards. When shelves are used they may be solid or of wire mesh construction. The lowest shelf should be solid and should be 25-30 cm above floor level. The top of shelving stack should be a solid shelf 25-30 cm below ceiling level to allow room for cleaning, but should not be used for storage.

C7.51 Shelves should be located away from outside walls which can suffer from condensation problems, and from other sources of water such as sinks, and sprinklers.

C7.52 There should be no unlagged cold water pipes or other similar services which may cause condensation to form and drip onto packs.

C7.53 A high standard of cleanliness is required in this area. When facilities are less than ideal the inadequate conditions may be ameliorated by wrapping the sterile packs in a protective dust cover such as a polythene bag during storage. This may then be removed immediately prior to despatch. Note that, if packs are to be wrapped in dust covers, they must be allowed to cool to room temperature first.

Materials storage

C7.54 SHPN 13 Appendix 4 provides guidance on determining the space required.

C7.55 A materials store is required for the storage of incoming supplies, including single use items, consumables, and new re-usable items as well as packaging materials.

C7.56 The same store may also be used for incoming supplies of commercially produced supplies items (for example commercially produced sterile packs).

C7.57 The passageway between shelves or racking should be wide enough to permit proper use of handling equipment without causing damage to stored materials.

C7.58 Secure separate storage needs to be provided for the segregation of defective or non-conforming materials products.

C7.59 Facilities are required for the reception of purchased goods and subsequent inspection and confirmation that they are supplied in accordance with the purchase specification.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Packaging equipment

Heat sealers

C7.60 Several patterns of heat sealer are in common use:

a. Hand-operated heat sealers with scissor action jaws; many of these were designed for sealing light gauge polythene bags for food use and are rarely satisfactory for sterilization packaging.

b. Parallel-jaw sealers, which may be hand or foot operated, have one of the jaws heated and this presses against the opposing unheated jaw. Heat-seal packaging placed between the jaws is heated and compressed.

c. Heat-seal conveyors work in a similar manner, items to be sealed are but moved between heated elements of the conveyor.

C7.61 The seal integrity and strength is affected by the temperature, pressure and dwell time of the heat-sealing equipment.

C7.62 In order to ensure reproducible satisfactory sealing all three variables should be validated, controlled and monitored.

C7.63 Many of these heat sealers are available without a built-in timer, with no reproducible control over sealing pressure and with no indication of the operating temperature. The design of many heat sealers makes effective monitoring, calibration and adjustment of the operating conditions difficult.

C7.64 Any heat sealer which is to be used for sealing packs for sterilization should be monitored regularly for the controlling variable of temperature, pressure and dwell time. Machines which cannot be independently tested should not be used.

Overseal crimpers

C7.65 Crimping devices for the application of crimp-on overseals may be manual or automatic.

C7.66 The manual crimpers are available as hand-held devices or as bench-mounted, lever-operated machines.

C7.67 Most, if not all, of the manually operated crimping equipment available is pre-set for overseals of a particular size, or has sets of change parts to accommodate other sizes. The compressive force applied is not adjustable.

C7.68 It is essential that the crimper is only used with overseals, stoppers and containers of the pattern for which it is intended.

C7.69 Crimpers for applying foil caps to aluminium tubes for use in hot air sterilizers are also available. These are usually hydraulically operated.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Screw cappers – controlled torque

C7.70 Capping machines with a built-in, adjustable, torque limiter are available. The torque setting to be used varies with the size and type of cap and the stopper or other seal being used. The settings recommended by the manufacturer of the closure should be used.

C7.71 The calibration of the torque limiting device should be verified at regular intervals.

Ampoule sealers

Manual sealing

C7.72 Although it is possible to effectively seal an ampoule without a purpose-built ampoule sealer, it is difficult to get the correct temperature, sufficiently localised and in the required time.

C7.73 Commercially available ampoule sealers use a natural gas/compressed air (low pressure of the order of 2-3 psig) or gas/oxygen flame, in burners set either side of the ampoule.

C7.74 The ampoule stands on a support platform which is vertically adjustable to position the flames at the required position on the ampoule.

C7.75 The flames are positioned and adjusted so that the glass wall of ampoule neck is just by the points of the blue cones within the flames.

C7.76 The filled ampoule is rotated in the flame.

C7.77 When the glass in the heated region of the neck melts and starts to fuse the top of the ampoule is grasped with pliers or forceps and pulled upwards in a smooth but fairly rapid movement.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C7.78 This detaches the unwanted portion of the neck leaving a fused end which should be smooth and round without any sharp pointed protrusion or a long tail of glass.

C7.79 To produce consistently successful seals requires some skill, which is only achieved through practice and experience.

C7.80 Semi-automatic and automatic ampoule sealers reproduce the same sequence of events but the whole process is automatic.

C7.81 The flame temperature, the position of the flame, the dwell time, and the timing and rate of detachment of the neck extremity all affect the quality of the seal.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C8. Packaging operations

Routine operation, control and monitoring

C8.1 The materials, systems, equipment and procedures used should have been evaluated for their suitability before implementation for routine use (see Chapter C6).

C8.2 The following guidance is based on the assumption that high-speed packaging machinery capable of handling large batches will not be used. When large batches are to be processed on such equipment the guidance and requirements in the Regulations and Standards applicable to commercial manufacturers should be adopted.

Documentation

C8.3 There should be written specifications for all packs giving details of both the contents and the packaging requirements.

C8.4 The order in which the contents of composite packs should be placed, to facilitate their aseptic removal from the pack, should be documented in the pack specification and the associated packing procedure.

Packaging instructions

C8.5 There should be formally authorised packaging instructions for each product, pack size and type. These should normally include or make reference to the following:

a. the name of the product;

b. either a description of its pharmaceutical form and strength, where applicable, or a list of the contents of the pack;

c. the pack size expressed as the weight or volume of the product in the final container, where applicable;

d. complete list of all the packaging materials required including quantities, sizes and types, with the code or reference number relating to the specifications of each packaging material;

e. where appropriate, an example or reproduction of the relevant printed packaging materials, and specimens indicating where to apply any batch number, references and shelf life of the product;

f. any special precautions to be observed, including the order in which components should be assembled to facilitate aseptic removal;

g. a description of the packaging operation, including any significant subsidiary operations, and equipment, to be used;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

h. details of in-process controls with instructions for sampling and acceptance limits, where applicable.

Batch packaging records

C8.6 When products are prepared in batches a batch packaging record should be kept for each batch or part batch processed.

C8.7 The record should carry the batch number and the quantity of bulk product to be packed as well as the batch number and the planned quantity of finished product that will be obtained.

C8.8 Before any batch packaging operation begins, there should be recorded checks that the equipment and work station are clear of previous products documents or materials not required for the planned packaging operations and that the equipment is clean and suitable for use.

C8.9 The information should be entered at the time each action is taken and, after completion, the record should be dated and signed.

Packaging records for single packs

C8.10 The records kept should have a sequential batch code enabling finished pack to the manufacturing's lot number for any single, including packaging, used in the composition of the pack.

Batch numbering

C8.11 All packs produced should have a sequential batch code enabling traceability and, when necessary, the recall of defective product.

C8.12 The batch code used should indicate the date of sterilization, the machine used and the process log/cycle number.

C8.13 Batch numbering with sterilizer and cycle may conveniently be done after sterilization when inspecting each pack to ensure that it has not become wet or sustained any damage.

Labelling

C8.14 Each sterile pack should be clearly labelled with a description of the pack contents and the description “sterile”.

C8.15 Normally filling and sealing should be followed as quickly as possible by labelling to ensure that no mix-ups or mislabelling can occur.

C8.16 The correct performance of any printing operation (for example, code numbers, expiry dates), whether done separately or in the course of the packaging operation, should be checked and recorded.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C8.17 The accuracy of labelling should be checked. Special care should be taken when using individual pre-printed labels and when over-printing is carried out off-line. Roll feed labels are normally preferable to cut labels, in helping to avoid mix-ups.

C8.18 When large batches of single product are being processed the correct number of bags may be labelled for each batch. On completion of the packaging operation for each batch the number of labelled bags should be reconciled with the number of products packed and any surplus bags destroyed before commencement of a different product. Any pre-stamping or labelling of bags should be controlled by documented procedures.

C8.19 Checks should be made to ensure that any electronic code readers, label counters or similar devices are operating correctly.

Control of the packaging operation

C8.20 When setting up a programme for the packaging operations particular attention should be given to minimising the risk of cross-contamination, mix-ups, substitutions, or mis-labelling.

C8.21 Before packaging operations begin, steps should be taken to ensure that the work area and packaging equipment are clean and free from any products, materials or documents previously used, if these are not required for the current operation.

C8.22 All products and packaging materials to be used should be checked on delivery to the packaging department for quantity, identity and conformity with the packaging instructions.

C8.23 Containers and packaging for filling should be clean before filling; particular attention should be given to avoiding and removing any contaminants such as glass fragments and metal particles.

C8.24 Control of the product during packaging should include at least checking the following:

- general appearance of the packages;
- whether the packages are complete;
- whether the correct products and packaging materials are used;
- whether the labelling, including any over-printing, is correct;
- the correct functioning of packaging equipment, for example the temperature gauge reading on heat sealing equipment.

C8.25 All wrapping material used should be inspected for flaws, holes, tears, dirt, stains and other defects at the time of packaging by the operator using it.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C8.26 Any of these defects should be cause for rejection of the material, which should be scrapped.

Heat-sealing equipment

C8.27 Closing and sealing machines must be in good condition, properly set and maintained to the manufacturer's specification, and closing and sealing operations should be under constant supervision.

C8.28 For heat-sealing operations the critical variables of temperature, temperature uniformity, pressure, pressure uniformity, dwell time, and the characteristics of the packaging materials, for example the type, thickness and uniformity of the heat-seal adhesive, should, ideally, be verified at frequent regular intervals.

C8.29 If the available equipment does not provide the facility for routine monitoring of the physical operating variables then routine monitoring of process efficacy by checking the quality of the output should be adopted.

C8.30 The efficacy of the seals should be tested and proved on a regular basis, not less than daily for each heat sealer.

C8.31 As a minimum daily heat-sealing records should be kept and these should be reviewed quarterly; there should also be a quarterly check on the temperature control of each heat sealer.

Glass containers

C8.32 Because of the hazards associated with glass contamination it is essential that, if packing in glass takes place, suitable precautions are described in formal documented procedures to deal with any glass breakages which may occur.

C8.33 Equipment for handling and processing glass containers should be adequately screened to ensure that any broken glass is contained. In particular, cleaning and filling equipment must be suitably screened and it is good practice to fully enclose all conveyors between cleaning and closing.

C8.34 Conveyors for glass should not pass over areas where exposed product or components may be held.

C8.35 Suitable lidded containers to be used only for the disposal of broken glass should be provided.

QC tests

C8.36 Quantitative testing of the adequacy of packaging seals and closures requires the use of laboratory facilities and equipment not available in most hospitals.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C8.37 However, there are qualitative procedures that can be carried out which are sufficient to demonstrate a satisfactory seal, although they may be of less value in any investigation as to the cause of an unsatisfactory seal.

C8.38 These procedures are based on visual examination which can be carried out either by the operator during the various stages of the packing operation or by a QC inspector given that specific task.

Pinholes

C8.39 The performance of both porous and impermeable materials as a bacterial barrier depends on them being free from pinholes and other similar defects.

C8.40 Laboratory tests for pinholes are based on detecting the passage of a dye solution.

C8.41 However, visual examination of opaque or translucent material against a bright light is a sensitive method of detection, which may be applied in the packing room.

C8.42 The method is unsatisfactory for transparent film. However the plastic film used in pouch and reel material is typically a laminate of two films. There is a very low probability of a pinhole occurring in the same spot in both films.

Inspection of seals

C8.43 A subjective assessment may be carried out by examining and opening a number of sample packs taken from production.

C8.44 Where one of the webs being sealed is transparent the uniformity of the seal can be examined without opening the pack. In other cases it will be necessary to peel open the seal.

C8.45 In carrying out the examination the following factors should be considered:

- the appearance of the seal; it should be uniform across the entire sealed surface and should be free from creases, striations or unsealed areas;
- the seal strength; the seal should be peeled apart and attention paid to whether the force required remains constant or whether there are apparent weak spots; with practice and experience it is also possible to recognise overall increased or decreased seal strength;
- the seal characteristics; when the seal is peeled apart there should be visible evidence of the seal on both of the webs, but there should be no spitting, tearing, delamination or fibre shedding;
- the condition of the packaging, particularly in the area of the seal; excessive pressure during heat sealing may cause damage or distortion; high temperatures or prolonged dwell times may cause scorching of the paper web.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Packaging for sterile medicinal products

C8.46 Filled containers of parenteral products should be inspected individually. When inspection is done visually this should be done under suitable and controlled conditions of illumination and background.

C8.47 Operators doing the inspection should pass regular eye-sight checks, with spectacles if worn, and be allowed frequent breaks from inspection.

C8.48 When other methods of inspection are used the process should be validated and the performance of the equipment checked at intervals.

Process indicators

C8.49 A system to differentiate between processed and unprocessed items should be used.

C8.50 Single-use packaging materials may be obtained pre-printed process indicators suitable for one or more sterilization processes.

C8.51 For other packaging materials suitable process indicators may be purchased printed onto adhesive packaging tape, adhesive patches or onto labels.

C8.52 Whichever system is chosen the process indicator should conform to the requirements of the relevant European standards (BS EN 867-I and BS EN 867-2).

Sterile product release

C8.53 Post-sterilization it is necessary to verify that the sterilization cycle was satisfactory and check that each pack is either:

- labelled with a reference to the number of the sterilizer cycle through which it was processed, or
- reconciled with the load manifest for the cycle, for packs which were labelled before sterilization with a reference intended to be traceable to the cycle number.

C8.54 Packaged sterile product should be inspected after sterilization and before release to ensure that the seal or closure remains intact, and that the pack is undamaged.

C8.55 The nature of the inspection will depend upon the nature of the packaging system used.

C8.56 For example, glass ampoules may be inspected for cracks and flaws visually, by means of a dye penetration test or by means of a corona discharge crack detector.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C8.57 Whenever the integrity of the packaging is in doubt the sterilized product, or in extreme cases the sterilizer load, should be regarded as non-sterile and not released for distribution.

Operator training

C8.58 All operators should receive training in the documented procedures that they will be expected to carry out.

C8.59 Particular emphasis should be placed on operator dependent techniques such as the correct folding and closure of wraps.

C8.60 Training should include instruction on the correct use of equipment, inspection techniques and test methods and on the intended use of the product.

C8.61 Training should be documented and recorded and should be reviewed periodically.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C9. Storage and distribution

Shelf life

C9.1 Time-related expiry dates for the maintenance of sterility are widely recognised as being of little value since under artificially created worst-case storage conditions packs such as textile wrapped packs could be shown to have become contaminated within 18-30 days.

C9.2 When the products were overwrapped with a dust sheet this was extended to at least nine months, and in paper/plastic pouches was found to be at least a year.

C9.3 Maintenance of sterility depends to a great extent on the storage conditions including such factors as:

- the microbial contamination of the storage environment;
- movements of air;
- movements and behavioural standard of personnel;
- environmental temperature, relative humidity;
- moisture, such as condensation;
- location in the store, etc.

C9.4 The barrier properties of the packaging material are also a contributory factor. The general concept is that the combination of the packaging and the control exerted over storage and distribution conditions should guarantee that the contents remain sterile until opened for use.

C9.5 Some form of date coding may still form a convenient inventory control system, means of assessing the frequency of usage and for deciding whether unused packs are of a type which no longer need to be produced.

C9.6 The use of arbitrary expiry dating on packs should be replaced with batch numbering and/or manufacturing date codes which can be used to facilitate good stock rotation, based on a first-in-first-out system.

C9.7 Maintenance of sterility cannot be guaranteed once the packaging has been breached and the labelling should warn the user to verify the condition of the packaging before opening the pack for use. A warning such as “sterile unless packaging opened or damaged” is usually sufficient.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Distribution of sterilized supplies

C9.8 Trolleys used for distribution within the hospital should be covered or closed with a solid bottom shelf.

C9.9 Each article to be loaded onto a trolley or into a transit container should be inspected and handled with care; packs should not be crushed together. Cramming additional packs into too small a space will invariably result in damage.

Storage of sterile supplies

C9.10 The function of this storage area may be limited to the storage of packs produced in the SSD or may also accommodate commercially produced packs and sterile devices purchased from commercial suppliers.

C9.11 Medical equipment that has been decontaminated, disinfected, cleaned, serviced, repaired and ready for re-issue may also be stored here.

C9.12 Sufficient space is required for loading trolleys and containers distribution on site and for loading containers for delivery off site.

C9.13 Entry to the area should be restricted to authorised and trained personnel.

C9.14 Staff should wash their hands before entering; where no convenient washing facility is available, it may be acceptable to substitute treating clean hands with an alcohol-based hand rub for washing.

C9.15 Movement of personnel within the area should be kept to the minimum necessary.

C9.16 The floor should be cleaned regularly by damp mopping and/or vacuuming; sweeping, brushing or the use of rotary scrubbing and polishing machines should be avoided since these may disperse contamination from the floor as an aerosol.

C9.17 Shelves, trolleys, delivery carts and transit containers should be subject to regular cleaning in accordance with a documented procedure and schedule.

C9.18 Packs should be spaced on shelves with sufficient room to avoid friction or the jarring of adjacent products when one is removed.

C9.19 Rigid re-usable transit containers may be used with advantage to contain smaller packs; these containers should also be on the cleaning schedule.

C9.20 Packs dropped on the floor should be discarded or sent for re-processing, as applicable, unless they were protected by an outer dust cover, such as a polythene bag, show no visible damage to the packaging and do not contain items which could be damaged by impact.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C9.21 Storage arrangements should be orderly to facilitate efficient rotation of stocks, batch differentiation and ease of cleaning.

C9.22 Sterilized packs should be issued in rotation based on the First-In–First-Out (FIFO) principle in accordance with a documented procedure.

C9.23 Sterilized packs should be handled as little as possible.

C9.24 After sterilization it is important that packs are stored safely in a manner which will assist in preserving the sterility of the contents.

Handling sterile packs

C9.25 It is important that all personnel who will be required to handle sterile packs (porters, drivers, SSD assistants, phlebotomists, nurses, clinicians, etc.) receive appropriate training in the correct handling procedures and why they are necessary.

C9.26 Many sterile packs will contain expensive and delicate instruments and require careful handling. All sterile packs need to be handled in a manner which will not compromise their sterile condition.

C9.27 As a minimum the following rules should apply:

a. The hands of personnel who will handle sterile packs need to be clean and dry;

b. The sterile packs need to be kept dry and must not be torn, punctured or otherwise damaged;

c. Any packs that are visibly damaged, stained or wet should be returned to the SSD for disposal or re-processing, as appropriate;

d. It should be possible to verify that the pack has been processed; this may be by means of a process indicator, or by appropriate labelling such as a sterilizer cycle number. Note that process indicators do not indicate the sterility of the pack contents, only that the pack was processed through a sterilizer;

e. Containers, distribution trolleys and any surfaces on which the packs will be placed must be clean and dry.

Transport and distribution

C9.28 There should be documented procedures for delivery and for the packaging, collection and return of used goods.

C9.29 Containers and trolleys should be easy to clean, properly maintained and should adequately isolate the goods in transit from environmental hazards.

C9.30 The cleaning procedure for bulk containers and trolleys should be documented and records should be kept of cleaning carried out.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

C9.31 In transit the contents of containers should be adequately identified by means, such as labels, which will not be erased in transit.

C9.32 Used goods being returned must be segregated from clean and sterile goods being delivered.

C9.33 Vehicles reserved for the delivery of clean and sterile goods should be used whenever possible. If dedicated vehicles are not used then each vehicle used must be cleaned after use for the return of used goods and before use for the transport of sterile goods.

C9.34 The cleaning procedure for the vehicle interior should be documented and records should be kept of cleaning carried out.

C9.35 As an alternative the use of sealed leakproof containers may be used for transport in either or both directions.

Storage in clinical areas

C9.36 The same principles apply as were discussed for the processed goods store.

C9.37 The storage facility should be secure, easy to clean and organised to aid stock rotation (for example a double-sided cupboard filled from the back but where goods are removed from the front).

C9.38 The quantity of goods stored should be limited to those actually needed within a reasonable time period.

C9.39 The place and method of storage varies, but it should be separate accommodation, not a general store with bedpans, urinals etc.

C9.40 Storage should be segregated or, if it has to be shared, it should be with other clean and/or sterile equipment.

C9.41 A high standard of cleanliness is required and packs must be kept well away from sinks and other sites of possible contamination.

Packaging for return of used items for re-processing

C9.42 A local policy for the handling of potentially contaminated and hazardous items, and practices for safe containment during transport back to the SSD need to be established.

C9.43 All returned items should be regarded as potentially contaminated and thus infective.

C9.44 Containers for returning goods should be leak proof, securely closeable and safe to handle. The container design should include the facility for clear labelling to indicate the nature of the contents.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Glossary of terms

Bioburden	Population of viable micro-organisms on an item.
Capacity (for glass containers)	The internal volume at 20°C.
Closure	Means used to close a package where no seal is formed, for example by repeated folding to construct a tortuous path.
Closure integrity	The quality of the closure which ensures that it presents a microbial barrier.
Final pack	The pack in which a medical device is sterilized. In addition to the primary pack a secondary and/or transport pack may be included.
Internal pressure resistance	The internal hydraulic pressure which a glass container at 20°C can withstand without breaking.
Microbial barrier	The ability to prevent the ingress of micro-organisms.
Multi-trip container	A glass container which has strength characteristics sufficient for it to withstand a number of filling/use operations.
Packaging compatibility	The ability of the packaging material and/or system to achieve the required performance without detrimental effect on the medical device.
Packaging material	Any material used in the fabrication or sealing of a packaging system or primary pack.
Packaging system	One or more packaging materials assembled into a single unit intended as part or all of a primary pack.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Primary pack	The sealed or closed packaging system forming a microbial barrier enclosing the medical device, and (usually) in contact with the medical device.
Seal	The result of joining of layers, for example by use of adhesives or thermal fusion.
Seal integrity	The quality of the seal which ensures that it presents a microbial barrier.
Secondary pack	The pack containing one or more medical devices, each in its primary pack.
Shelf pack	see Secondary pack.
Shipper pack	see Transport pack.
Single-trip container	A glass container designed and manufactured to be sufficiently strong to withstand only one filling/use operation.
Terminally sterilized	Descriptor for medical devices which are sterilized after being completely sealed or enclosed in at least the primary pack.
Thermal shock resistance	The ability of a glass container to withstand a sudden temperature change without breaking.
Transport pack	The pack containing one or more primary and/or secondary packs intended to provide the necessary protection during transport and storage.
Ullage	That part of the contents of a container which wants for filling. Expressed in units of volume or as a percentage of the total container volume.
Unit pack	see Primary pack.
Vacuity	The free space left above the contents in a sealed container expressed as a percentage of the nominal volume of the contents.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Validation	Documented procedure for obtaining, recording and interpreting the data required to show that a process will comply with predetermined specifications.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

SECTION D

A Contract for the Annual Testing of Sterilizers

GC/Works/4 (1998)

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

INVITATION TO TENDER

Works: **Annual Testing of Sterilizers**

Site: _____

1. You are invited on behalf of _____NHS Trust to tender, upon the basis of GC/Works/4 General Conditions (1998), for the Works described in the following enclosed documents:

   a. Abstract of Particulars;

   b. Supplementary Conditions and Annexes referred to in the Abstract of Particulars;

   c. Specification for the Annual Testing of Sterilizers.

2. Your tender with the completed Abstract of Particulars and Supplementary Clauses should be submitted on the Form of Tender and Tender Price Form also enclosed. Any obvious errors in pricing or errors in arithmetic will be dealt with as stated in the Form of Tender.

3. You are required to keep your tender confidential and not divulge to anyone, even approximately, what your tender price is or will be. The sole exception to this is information you may have to give to your insurance company, or broker, in order to compile your tender, but you must stress to them that this information is given in strict confidence.

4. You must not make any arrangements with anyone else about whether or not they should tender, or about their or your tender prices or terms and conditions. You may however, obtain any necessary subcontract quotations.

5. No tendering expenses will be reimbursed by the Employer.

6. Tenders received late will not be considered unless due to genuine postal delays. If the tender is qualified it may be set aside, or you may be required to withdraw the qualification without amending your offer. Any proposals for alternatives to the specified requirements should be submitted by way of a separate, unqualified, bid, after checking with the Employer on the procedure to follow.

7. The Employer does not bind himself to accept the lowest, or any tender.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

8. Your form of tender should be submitted in a sealed envelope prominently marked:

   FORM OF TENDER FOR ANNUAL TESTING OF STERILIZERS

   The envelopes should bear no external indication of the identity of the tenderer.

9. Tenders must be completed and returned by 12 noon on _____

   To: _____

   SIGNED by

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

INDEX

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

INSTRUCTIONS FOR TENDERERS

Tenders for the work included in the following Tender Document shall be written on the attached Form of Tender. The Price Schedule must be fully priced, extended and totalled throughout in black ink and returned under sealed cover to the _____

to arrive not later than Noon on _____ endorsed on the outside “Tender for the Annual Testing of Sterilizers.”

Tenders to remain open for acceptance for a period of 60 days from the above date.

_____NHS Trust reserves the right to decline the lowest or any Tender and no expense in submitting a tender will be reimbursed.

Tendering procedures will be in accordance with the principles of the “Code of Procedure for Single Stage Selective Tendering 1996”, the examination and correction of priced Bills of Quantities being in accordance with Alternative 2 of paragraph 6.4 of that Code.

In the event of a Contractor not tendering, the documents are to be returned immediately to the Project Manager.

The Contractor shall comply with the requirements of all regulations, codes and statutes applicable to the execution of the works.

Where in the opinion of the Project Manager any of the finished works or materials or workmanship in any part of the works, do not comply with all the relevant requirements of this specification and drawings, that part of the works shall be classified as defective work.

All work classified as defective work shall be made good to the satisfaction of the Project Manager.

TENDER AND TENDER PRICE FORM

THE ANNUAL TESTING OF STERILIZERS

_____NHS Trust

To be returned by 12 Noon on _____ to _____

1 We have examined GC/Works/4 General Conditions (1998), and the following documents:

a. Abstract of Particulars;

b. Supplementary Conditions and Annexes referred to in the Abstract of Particulars;

c. Specification for the Annual Testing of Sterilizers.

2 We have obeyed the rules about confidentiality of tenders and will continue to do so as long as they apply.

3 We submitted to the Employer a Price Schedule and Summary of prices with an alternative. We undertake to satisfy the Employer that the prices in the summary are fair.

4 We agree that, should errors in pricing or errors in arithmetic be discovered in the summary submitted by us during consideration of this offer, we will, in addition to the chance to confirm the offer as tendered despite the errors, be afforded the opportunity of withdrawing it.

5 Subject to and in accordance with paragraphs 3 to 5 above and the terms and conditions contained or referred to in the documents listed in paragraphs 1 and 2, we offer to execute the Works referred to in the said documents in consideration of payment by the Employer of the sum shown in our accompanying Tender Price Form, which shall be deemed to form part of our tender, plus reimbursement by the Employer of Value Added Tax in accordance with Condition 19 (*VAT*).

6 We agree that differences or questions arising out of or relating to the Contract shall be resolved in accordance with Condition 28 (*Adjudication*) of the General Conditions.

Item	Preamble	£	P
	SUPPLEMENTARY CLAUSES **Asbestos** If during the execution of the work, the Contractor discovers any material suspected of being asbestos, the following procedures will apply: 1. Immediately cease work in the suspected areas. 2. Immediately notify the Project Manager by telephone, then confirm same in writing. 3. Do not commence work in the area(s) involved until instructed by the Project Manager. **Noise Control** The Contractor shall comply with statutory requirements relating to control of noise levels on site, include for complying with DOE Advisory Leaflet No.72 Noise Control on Building Sites and for fitting all compressors and percussion tools with effective silencers of a type recommended by the manufacturers of the compressors or tools. The Contractor shall not use pneumatic drills or other noisy appliances outwith normal working hours without consent of the Project Manager . The Contractor shall not use or permit employees to use radios or other audio equipment. **Inspection of Work before Covering** In cases where the Project Manager has given notice to the Contractor that the work must be inspected and/or tested previous to same being covered up or hidden, the Contractor shall give adequate notice in writing to the Project Manager before any such work shall be so covered up or hidden. Should the Contractor fail to give such notice he may be required to uncover same and make good at his own expense. **Programme** The Contractor shall prepare and submit to the Project Manager within two weeks of agreement of access and site occupation with the Employer, a programme in a form as required by the Project Manager, which shall clearly set forth the sequence of all operations and the time limits within which the Contractor proposed that each operation shall be commenced and completed. The Contractor, in the preparation of this programme, shall be held to have co-ordinated the while works embraced in this Contract.		
	Amount to Collection Page		

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Item	Preamble	£	P
	On agreement or negotiated amendment of the programme by the Project Manager, the Contractor shall be responsible for the execution of the works in conformity therewith. He shall submit copies of same, record progress and update or redraft as required to take account of any circumstances which arise affecting the progress of the works. **Limitations of Working Space** The Contractor shall not be allowed to use existing roadways or footpaths for parking or depositing material or plant unless he is given prior approval by the Project Manager . The Contractor shall at all times confine his workpeople to those parts of the site and building on which he is engaged and shall on no account allow them to trespass into any other parts of the site and buildings without the prior consent of the Project Manager . The contractor shall not be allowed to erect temporary buildings, deposit plant, store materials or rubbish on any part of the property or grounds outside that assigned to him for this contract. The Contractor shall allow in his tender for all necessary preparatory work and later, at the completion of the contract, for removing debris and reinstating the storage etc. areas to their original condition, all to the satisfaction of the Project Manager . The original condition shall be established with the Project Manager prior to the commencement of work. The Contractor shall take all necessary precautions to minimise nuisance or discomfort to the occupiers of adjacent premises arising from his operations. Any damage, structural or otherwise caused to the existing buildings by the construction process shall be made good at the Contractor's expense.		
	Amount to Collection Page		

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Item	Preamble	£	P
	The Employer reserves the right to send their own or other workmen to the site to execute work not included in this contract and the Contractor shall be required to afford such workmen all reasonable facilities for the execution of their work but the Contractor shall not be entitled to any profit on the cost of such work. The Contractor will liaise and co-operate with the Project Manager and will take all reasonable steps to ensure that the works are carried out in such a fashion as will in no manner, or at any time, impair the security of the existing buildings. All scaffolding or temporary access will be erected in such a fashion as, without in any way impairing the stability of the scaffold, will prevent ease of access to the scaffold by any unauthorised person. The Contractor shall maintain permanent supervision and attendance at mechanical or other dangerous plant, when in use, to ensure the safety of the staff, patients and others using the hospital. Alternatively all such plant and equipment shall be kept in a secure compound to prevent unauthorised access. On no account shall any ladders or tools be left unattended and at the end of each day's work all plant shall be removed and placed in the Contractor's site hut or other secure place. No windows, doors or hatches have to be left open after workmen have left site. The Employer will not be responsible for any such acts of vandalism by any person, to the Contractor's materials or plant. All materials will be disposed of in a proper manner off site. Any skips brought to site shall have lids which shall be securely closed when not attended. The Contractor shall not use existing sanitary fittings, gullies or drains to dispose of any materials including paint, turpentine, oils, etc. The area immediately around the site must be kept clear of rubbish, protective casings and coverings and general debris at all times. No scattered or accumulated debris will be allowed to gather and the Project Manager may require daily cleaning or clearings of any such debris to ensure compliance with this requirement. **Working Hours & Access to Site** Access will normally be outside normal hours (0800-1700 Monday to Friday). No additional costs due to overtime working will be paid for by the Employer unless that overtime has been instructed in writing by the Project Manager and he will clearly state in writing that the additional cost will be borne by the Employer. Any overtime thus authorised will be based on the standard time rates and paid net.		
	Amount to Collection Page		

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Item	Preamble	£	P
	Any overtime working by the Contractor must be agreed beforehand with the Project Manager and it should be noted that any additional costs of supervision on behalf of the Employer will be paid by the Contractor. **Fire Precautions** The Contractor is to take all necessary precautions to prevent loss or damage from fire. The Contractor is to familiarise himself and staff with all fire escape routes and procedures in use within the property involved. All escape routes to be kept operational during occupation by the Employer. **Existing Services** The Contractor shall not interfere with the operation of the existing services, such as gas, water, electricity, telephones, buried cables sewers and the like without permission of the Project Manager . **Smoking/Alcohol Policy** Smoking or the consumption of alcohol will not be permitted within any Employer property. **Employer Facilities and Equipment** All equipment necessary to carry out the works shall be provided by the Contractor. Employer equipment shall not be used. **Health, Safety and Welfare** The Contractor shall identify a Safety Officer responsible for all aspects of Health, Safety and Welfare on site including the control and actions of all Sub-Contractors in this respect. The Contractor shall permit access to the site by the Employers designated Safety Advisers who shall have the right to enter onto the Site at any time without prior notice to the Contractor. The Contractor shall implement any recommendations with regard to Health, Safety and Welfare measures which may be made by the Employer's designated Safety Advisers. Such recommendations shall not be deemed variations to the Contract if they are necessary, in the opinion of the Employer's designated Safety Adviser, to comply with the terms and conditions of any relevant Health, Safety and Welfare Acts or Regulations. The Contractor shall be deemed to be familiar with the Employer's document "Health and Safety Guide for Contractor's" and shall comply with its requirements as necessary. A copy of this document may be obtained from the Project Manager.		
	Amount to Collection Page

Item	Preamble	£	P
	Joint Code of Practice on the Protection from Fire of Construction Sites and Buildings Undergoing Renovations, Fourth Edition, June 1997. The Contractor's attention is drawn to the above Joint Code published by the Building Employers Confederation. The Contractor shall allow for compliance with the recommended standards in this Code of Practice. This contract is not deemed a "Large Project". **Method Statement** The Contractor shall present Method Statements which will describe fully his operations on site and discuss and agree with the Project Manager and Planning Supervisor prior to the commencement of the Works. The method Statements shall in particular include details about:- 1. General Site Safety 2. General Site Security 3. Protection of the General Public 4. Protection of Patients, Visitors and Staff using the Premises, etc. 5. Access and Exit Arrangements **General Facilities and Obligations** Maintaining, altering, adapting and clearing away any temporary works and making good after same shall be deemed to be included with the items. Notices, rates, fees and charges to Local Authorities and public undertakings related to the following items shall be included in the appropriate items. The Contractor shall obtain all necessary Planning and other permission for all temporary accommodation. **Pricing** Plant, tools and vehicles. Scaffolding and temporary access. Site administration and security, including safeguarding the work, materials and plant against damage and theft, include for providing all watching, accommodation and lighting if necessary. Transport of work people. Protecting the works from inclement weather.		
	Amount to Collection Page		

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Item	Preamble	£	P
	Lighting and Power for the Works Electrical power at 240 volts 50 cycles/single phase/AC required for the works will be provided free of charge by the Employer. *(Note: This should be suitably transformed to 110V for the use of power tools).* Temporary connections will be located and carried out in strict conformity with the Employer Authority's requirements and shall be approved by the Project Manager before work commences. The Contractor shall not use power provided for the Works, by the Employer for cooking facilities or heating. Building (Safety, Health and Welfare) Regulations and Health and Safety at Work Act in respect of all work people will apply. Removing rubbish, debris, protective casings and coverings from the site and cleaning the works internally and externally. These to be removed regularly and the site to be kept clean. On completion, the works shall be cleaned, which shall be deemed to include where necessary scrubbing floors, cleaning glass both sides, removing all stains from facework, cleaning sanitary fittings and leaving the whole premises clean and ready for occupation. The Contractor may make reasonable use of existing facilities as he so wishes subject to the approval of the Project Manager with the Employer's consent. **Insurance** Allow for the costs in complying with insurance provisions. **Materials and Workmanship** The Contractor will supply all materials that may be necessary for the due and proper completion of the work (except those materials specified to be supplied by the Employer under direct purchase arrangements or as part of sterilizer testing agreement). The materials shall be new unless otherwise described and shall be the best procurable of their respective kinds and so far as practicable. All goods and materials unless otherwise described, shall be in accordance with the latest revised BS current at the date of tendering. The contractor shall be responsible for providing all tools, equipment and instruments for the execution of the work. This is to include provision of 3 sets of Huckaback towels or cotton sheets to the requirements of SHTM 2010 Part 3. The Contractor shall provide all labour and pay all expenses in connection therewith and do everything necessary for the due and proper completion of the work. Workmanship shall be in accordance with the latest revised BS Code of Practice. **Samples** Samples of proposed materials and workmanship shall, if required by the Project Manager be submitted for approval and those samples kept by the Project Manager who shall have the power to reject all such materials and condemn such workmanship as do not correspond with the approved samples.		
	Amount to Collection Page		

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Item	Preamble	£	P
	Nuisance The Contractor shall take the necessary precautions to prevent nuisance from water, smoke, dust, rubbish and other cause. **Existing Furniture, Fittings and Equipment** Prevent damage to any furniture, fittings and equipment left in the existing property. Move as necessary to enable the work to be executed, cover and protect as necessary and replace as required. Including but not limited to: Fire fighting equipment, carpets, shelving, building fabric etc. **Making Good Defects** Allow for arrangements with the Employer and giving reasonable notice of the precise dates for access to the various parts of the Works for the purpose of making good defects. **Maintenance Instructions** Where applicable allow for obtaining and handing over to the Project Manager at practicable completion any maintenance instructions provided by manufacturers, suppliers or sub-contractors. **Control of Noise, Pollution and all other Statutory Obligations** The attention of the Contractor is drawn to the provisions of Section 60 of the Control of Pollution Act 1974 with reference to the control of noise in relation to any demolition or construction works and the need, particularly where such works are adjacent to occupied property where a high sensitivity to noise may be anticipated to ascertain what requirements, if any, shall apply to the works in this respect. The restrictions may relate to the type of plant to be used, the methods of working to be adopted, the hours of working permissible and may in addition impose a maximum noise level at the site boundary which may not be exceeded. The Contractor is to be held responsible for complying with such requirements, restrictions or consents, together with any other stipulations to which his attention may be drawn from time to time by the competent Authorities and is to allow in his tender for any costs or expenses arising from such compliance. No instructions issued to the Contractor by the Project Manager or his authorised representative shall relieve the Contractor from compliance with the Control of Pollution. The Contractor will at all times ensure that his operatives create the minimum of noise consistent with the work being undertaken. All necessary noise, including the playing of transistor radios and like will be prohibited. No discomfort or annoyance from the noise will be occasioned to patients or staff where such noise is reasonably avoided.		
	Amount to Collection Page		

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Item	Preamble	£	P
	Fire Precautions Before any works are carried out, the Contractor is to discuss his proposals with the Project Manager and Fire Prevention officer, to ensure that he is fully aware of any fire hazard that may be involved. He is to draw the attention of all his workmen to the special vulnerability of Employer property and patients in the event of fire, and the dangers involved in the careless disposal of matches, cigarettes and tobacco ash must be fully impressed on them. The Contractor's workmen are to be required strictly to conform with all "NO SMOKING" rules applicable in specific areas of the property. Fire escape routes are to be kept unobstructed and, if necessary illuminated at all times and the Contractor will post such notices as are necessary to ensure compliance with this requirement. **Year 2000 Compliance** Prior to the start of the project certificates of Year 2000 compliance must be made available to the Project Manager demonstrating that any parts or equipment to be installed is compliant with: BSi DISC PD 2000-1 A Definition of Year 2000 Conformity Requirements. NHS Estates Guidance, The Year 2000 problem, Testing of estates embedded systems and devices. Details of year 2000 compliance tests and test procedures must be submitted to the Project Manager for all the equipment being installed. On completion of the project, or stages of the project, Year 2000 compliance must be demonstrated and certificates issued to the Project Manager before the systems become operational.

CERTIFICATE OF NON-COLLUSION

_____NHS Trust

to be returned by _____

The essence of selective tendering is that the client shall receive bona fide competitive tenders from all those tendering. In recognition of this principle we certify that this is a bona fide tender, intended to be competitive and that we have not fixed or adjusted the amount of the tender by or in accordance of any agreement or arrangement with any other person. We also certify that we have not done and we undertake that we will not do at any time before the hour and date specified for the return of this tender any of the following acts:-

a. communicating to a person other than the person calling for those tenders the amount or approximate amount of the proposed tender, except where the disclosure in confidence of the approximate amount of the tender was necessary to obtain insurance premium quotation required for the preparation of the tender.
b. entering into any agreement or arrangement with any other person that he shall refrain from tendering or as to the amount of any tender submitted.
c. offering or paying or giving or agreeing to pay or give any sum of money or valuable consideration directly or indirectly to any person for doing or having done or causing or having caused to be done in relation to any other tender or proposed tender for the said work any act or thing of the sort described above.

In this certificate the word “person” includes any person and any body or association, corporate or unincorporate and “any agreement or arrangement” includes any such transaction, formal or informal, and whether legally binding or not.

PARTICULAR SPECIFICATION FOR THE ANNUAL

TESTING OF STERILIZERS

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

PARTICULAR SPECIFICATION

1. REGULATIONS

All work shall be carried out in accordance with.

1.01 All relevant Acts or Parliament, statutory instruments and regulations.

1.02 Any public health, security and conduct requirements as from time to time be issued to the Contractor by the Employer.

1.03 Any relevant Safety Regulations published by the Employer copies of which are available from the Project Manager.

2. COMPLIANCE WITH BRITISH STANDARDS

2.01 All work and material shall company with relevant European and British Standards and Codes of Practice.

3. RESPONSIBILITIES OF THE EMPLOYER

The Employer shall be responsible for:

3.01 The keeping of each item of Mechanical and Electrical Plant in such a condition that its functions in accordance with the requirements of SHTM 2010, BS 3970, BS 2646 and BS 3421.

3.02 Arranging for statutory inspections to be carried out (under a separate contract).

3.03 Maintenance of a record for each item of Mechanical and Electrical Plant in accordance with the requirements of SHTM 2010.

This shall contain details of all maintenance and remedial works carried out on each item of equipment to the following standards:

A.	Failures	Date Symptoms of failure
B.	Visits by other Contractors	Date Details of Work carried out including details of tests and replacements. Date and time of completion
C.	Statutory Inspections	Date Details of any remedial work required. Signature of competent person carrying out inspection.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

4. INSTRUCTIONS

4.01 The Person from whom the Contractor will be required to accept instructions and attend any urgent or necessary recommissioning is listed in the Abstract of Particulars.

4.02 All requisitions for emergency action will be made by telephone to the Contractor's office or central control point and will be confirmed in writing within 7 days by the Project Manager.

5. DOCUMENTATION

5.01 The Contractor must ensure that on each occasion his staff enter the details of any work carried out on the plant in the Plant History Record before leaving the site.

5.02 The Contractor, within 14 days of the completion of the tests, shall supply the Project Manager with a Test Report carried out under this contract as detailed in Appendix D, together with 3 copies.

6. DESCRIPTION OF THE WORK

6.0l The Contractor shall undertake annual tests as described in Appendix B – Testing Philosophy & Procedures and Appendix C - Annual Performance Tests on those Sterilizers listed in Appendix A - Sterilizer Inventory.

6.02 The Contractor shall employ persons, experienced, qualified and preferably certified to a minimum City and Guilds standard, who would be competent to perform all the required tests, documentary evidence of this shall be provided. The Employer may require the said persons to demonstrate his/her competence by performing a test laid down by the Project Manager, to be witnessed by Project Manager or his/her nominated representative, prior to the letting of the Contract or during the period of the Contract.

6.03 The Contractor shall demonstrate that he has all the necessary equipment which is detailed in Part 3, Paragraph 6.1 – 6.63 of the current edition of Scottish Health Technical Memorandum 2010 (SHTM) and either evidence of its calibration or the means of verifying its calibration.

Current certification of accuracy traceable to the National Physical Laboratory and where appropriate to NAMAS Standards will be required.

6.04 The Contractor shall prepare a schedule of the order and time in which he would perform the tests on the Sterilizers listed in Appendix A, to be agreed by the Project Manager prior to the awarding of the Contract.

6.05 The Contractor will confirm his intention to perform the scheduled test with the Project Manager or his/her nominated representative 14 days in advance.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

6.06 The Project Manager or his nominated representative will arrange for the Local Maintenance Engineer to be available to rectify any faults which the Contractor identifies during the test.

6.07 The Contractor shall on completion of an annual test, make a signed and dated entry in the Plant History Record that the Sterilizer complies or does not comply, with the performance requirements. In the event of non-compliance the Contractor shall notify the Project Manager or his local nominated representative (normally a departmental manager) within 24 hours.

6.08 The Contractor shall issue to the Project Manager, or his/her nominated representative, within 21 days of any test being carried out, the results of the tests in a test report as demonstrated in Appendix D together with 3 copies.

6.09 The Contractor shall satisfy himself from the Plant History Records of each Sterilizer give the service maintenance records, and where appropriate, the microbiological records for all routine tests and ascertain they have been performed on each Sterilizer throughout the previous year and is in a condition in which tests can be undertaken safely. Comments shall be included in the Test report.

6.10 The Contractor shall nominate on Appendix 2: Schedule of Contractor's Particulars a representative who will act for the Contractor to liaise with the Project Manager on all matters relating to the Contract.

6.11 The Project Manager will take up any problems of the Contract with the Project Manager or his/her nominated representative.

6.12 The Project Manager or his/her nominated representative may visit any site at any time to inspect the Contractor's test procedures and results.

6.13 The Contractor when requested, on the appropriate form (See Appendix E) will be required to retest any sterilizer that has not satisfactorily passed the annual test criteria.

Repeat tests will be paid for at not more than the cost of the test original of the said Sterilizer as listed in Appendix A, unless investigative testing has been previously agreed.

6.14 The Contractor shall confirm a date for retesting of sterilizers within two days of receiving the request and should carry out the retesting of Sterilizers where applicable within 10 working days of receiving the request.

Appendix B

TESTING PHILOSOPHY AND PROCEDURES

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

TESTING PHILOSOPHY & PROCEDURES

The Testing of Sterilizers required under the contract are those called for in the Scottish Health Technical Memorandum No. 2010, Part 3 (SHTM 2010).

The relevant clauses required for the execution of this contract in fulfilling the procedures for annual testing are presented in full in Appendix C.

Calibration of Instruments

It is the Contractors responsibility to ensure that all instruments used in executing the work are suitably calibrated and hold current certificate of calibration clearly traceable to National Physical Laboratory, British Accreditation Service and that the test system calibration is checked immediately before and immediately after each annual test and ‘is recorded and included in each Test Report. Copies of current certificates are to be forwarded to the Project Manager.

Test Equipment

The relevant clauses required for compliance of equipment used for sterilizer testing are those called for in the Scottish Health Technical Memorandum No. 2010 Part 3 (SHTM 2010) Chapter 6.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Appendix C

ANNUAL PERFORMANCE TESTS

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

YEARLY AND REVALIDATION TESTS

The tests are listed in the Scottish Health Technical Memorandum 2010, Part 3, Chapters 7 – 19.

The results of tests done should be recorded in the Plant History Record for each sterilizer in the form of a report as described in Appendix D.

This contract requires the yearly tests to be carried out only on those Sterilizers which are listed in SHTM 2010, Part 3, Chapters 4-5 (Check the relevant detail in Schedule of periodic tests to establish those tests only required for yearly testing in the tables).

The Contractor shall include in his report to the Project Manager if he becomes aware that the daily, weekly or quarterly tests have not been satisfactorily carried out. The contractor should be satisfied that the sterilizers are in a condition in which the tests can be undertaken safely.

NHSScotland Property and Environmental Forum

REPORTS

Each annual test carried out must be fully reported in the format shown.

Each report will consist of:

1. Title page with details of NHS Trust or Hospital, Department, Manufacturer, Sterilizer type, References and date of test and person(s) carrying out the test.
2. Sequence Test Sheet listing each test carried out, a brief statement on test result and any adjustments or actions taken.
3. Test Report Sheet giving detailed analysis of the test carried out with a conclusion and recommendations.
4. Test Sheets showing details of test carried out (See specimen test sheets).

NOTE: Test sheets may be replaced by suitable computer printouts providing they are authorised by Project Manager.

5. Associated test recorder thermocouple charts, including calibration checks, sterilizer recorder charts, and/or print-outs, Bowie/Dick sheet where applicable. All annotated and suitably identified.
6. Each reports must be suitably bound and forwarded to the Contract Administration together with 2 copies – charts need only be incorporated into the original report.

Procedures for determining the sound power generated by a sterilizer

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Contents

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

E. Procedures for determining the sound power generated by a sterilizer

Introduction

E.1 This test, to be carried out by the manufacturer of a sterilizer, is based on the test in Appendix D of BS 3970: Part 1: 1990 and BS EN 285.

E.2 Except where otherwise stated here, the sound power levels of sterilizers are determined by the method described in BS EN ISO 3746. The information given here is by itself not sufficient to permit the test to be carried out by personnel unfamiliar with the requirements of BS 4196 and BS EN ISO 3746.

E.3 Measurements made by this method have a standard deviation of up to 5 dB for discrete tone sources and up to 4 dB for wide-band noise sources. The uncertainties can be minimised by careful consideration of the conditions in which the test is carried out.

a. The environmental correction factor, K, depends on the relative sizes of the sterilizer and the test room and the sound absorbing qualities of the room. For a given sterilizer, the larger the room the smaller the value of K. Although BS EN 285 specifies that K should be less than 7 dB, this is a relatively high value and the manufacturer should aim to achieve K = 2 dB or less. This figure can normally be achieved by carrying out the test in a sufficiently large room. The assembly hall in which the sterilizer is constructed should be suitable;

b. Another source of error is the ambient background noise. Table 4 of BS 4196: Part 6 gives correction factors for different levels of background noise, but the lower the correction factor the more reliable the result will be. The correction is essentially zero if the background noise level is 10 dB or more below the level measured when the sterilizer is operating. It should be possible to achieve this on the manufacturer's premises if the test is carried out when the factory is closed and all other plant is shut down. Steam and compressed air plant not part of the sterilizer should be run on storage during the test, with boiler feed pumps and compressors switched off.

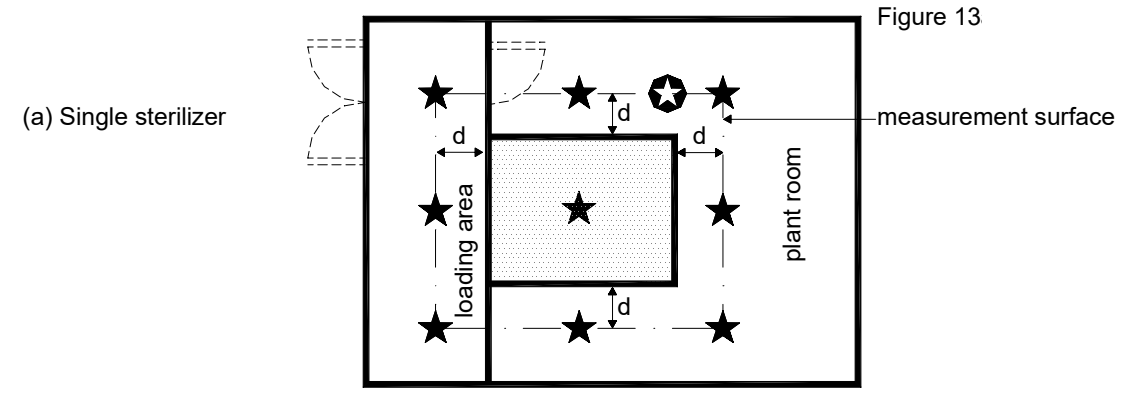
Apparatus

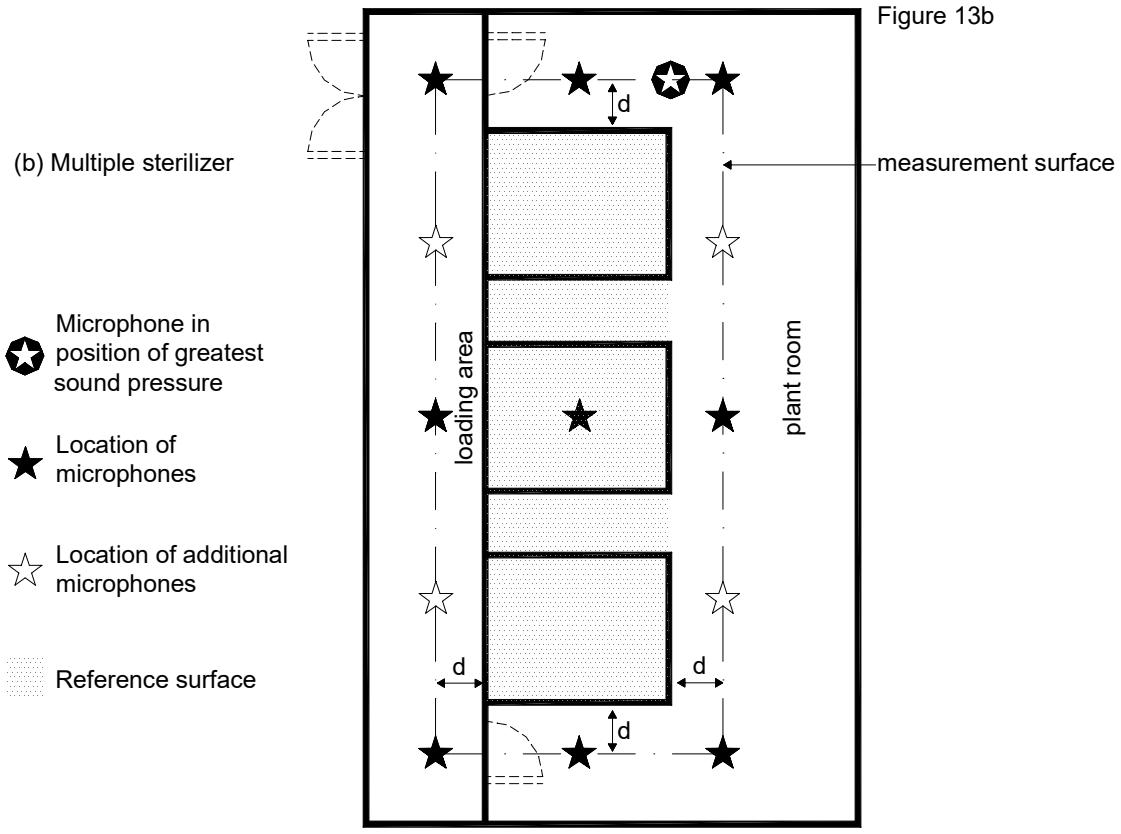
E.4 Sound-level meter, complying with type 1 of BS EN 60651: 1994, or an integrating-averaging sound level meter complying with type 1 of BS EN 60804: 1994. The sound power level is determined from at least six microphone positions (Figure E1). If the sound meter has insufficient input channels, additional instruments and/or repeated operating cycles are required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

E.5 Test room, configured so that the distance between any wall or other object in the room is not less than 3 m from any reference surface (see paragraph E.6) on the sterilizer to be tested. The room in which the sterilizer is assembled may be suitable providing the conditions discussed in paragraph E3 are met.

Figure E1: Location of microphones for sound pressure test





© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Test procedure

E.6 The test determines the A-weighted sound power using a rectangular measurement surface. The “reference surface” defined in BS EN ISO 3746 is the smallest rectangular box that just encloses the sterilizer, with a width and depth measured from the outside of the vessel lagging and a height measured from the floor to the top of the vessel lagging. The box does not include pipes and valves used to connect the sterilizer to its services.

E.7 Determine the sound absorption area, A, of the test room using the experimental method described in BS EN ISO 3746. The method of estimation described in A.3.1.1 may be used as a check.

E.8 Determine the environmental correction factor, K, as described in BS EN ISO 3746. Although BS EN 285 allows K to be as high as 7 dB, a figure of around 2 dB should be achievable as described in paragraph E.3a.

E.9 Sterilizers should be regarded as “large sound sources” as defined BS EN ISO 3746. The measurement distance, d, should be 1.0 ± 0.1 m. Microphones should be placed on the measurement surface as described in BS EN ISO 3746. At least six microphones will be required.

E.10 The test is to be carried out with all integral equipment (for example, water pumps, vacuum pumps, compressors) operating normally.

E.11 Load the sterilizer with a full load as described in Part 3 of this SHTM. If there is a choice of operation cycle, select the cycle with the highest sterilization temperature. Ensure that the pressure and flow from the steam and water services are set to levels which cause the maximum noise and are within the ranges specified for normal operation. Start the operating cycle.

E.12 Using the procedure for measuring the rectangular measurement surface described in BS EN ISO 3746, determine the A-weighted sound power level and the peak sound power level of the sterilizer either for one complete operating cycle or for a 30 min period that contains the most prominent sounds.

Test result

E.13 Record the calculated mean and peak A-weighted sound power levels in decibels to the nearest integer. Other information should be recorded in accordance with BS EN ISO 3746.

E.14 The test should be considered satisfactory if the peak A-weight sound power level at no time exceeds the mean A-weighted sound power level by more than 15 dB.

Section F

Accommodation for ethylene oxide gas cylinders, manifolds and canisters

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Contents

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

F. Accommodation for ethylene oxide gas cylinders, manifolds and canisters

General

F.1 For use in large sterilizers operating at above atmospheric pressure, ethylene oxide is mixed with carbon dioxide or chlorofluorocarbon. Given recent concerns about environmental issues however, the use of the latter is deprecated and is no longer in widespread use. The cylinders therefore are less hazardous than those of pure ethylene oxide.

F.2 Single-shot cartridges of pure ethylene oxide for use in sub-atmospheric pressure machines require care but in view of the modest volumes involved do not pose a major safety problem.

Ethylene oxide cylinders

F.3 Cylinders are categorised in accordance with Table F1 and, although ethylene oxide is supplied in mixture with inert gas, they should be stored under the toxic and/or corrosive and flammable category.

F.4 Cylinders may be stored with other industrial and medical gas cylinders in accommodation designed in accordance with SHTM 2022.

General principles

F.5 Accommodation should be well ventilated and labelled clearly to describe the gases contained. The labelling should include details of emergency action procedures and the location of keys should be identified. Cylinder storage should be designated as a “no smoking” area and appropriate labels should be posted.

F.6 Clear and secure and access is required to permit safe cylinder loading/unloading and handling with vehicular access.

F.7 The maximum temperature in the cylinder store should be that recommended by the gas supplier/manufacturer. Normally this should not exceed 38°C.

F.8 Accommodation should be free from naked flames and sources of ignition and appropriate fire extinguishing equipment should be available. Lighting protection may be necessary for isolated buildings.

F.9 For electrical equipment in the vicinity of the gas cylinders the recommendations of BS EN 60079-14, Zone 2 classification will usually be appropriate for the open-air type of installation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

F.10 Safety equipment in the form of protection goggles, gloves and a respirator should be available inside this space and also at the point of entry.

Ethylene oxide cartridges

F.11 Sufficient secure storage within the loading area in the form of a locked cabinet is satisfactory for cartridges for use in a single day.

F.12 Additional cartridges will be required for an operational unit and external storage, for example one week's supply, should be held externally. Small special-purpose cabins typically used for the storage of LPG containers fully protected from the elements will be appropriate.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Table F1: Clarification of gas cylinders typically found on hospital sites

Group classification of gas cylinder contents		Medical gas	Non-medical gas
1	Flammable	Cyclopropane – this is no longer manufactured	Acetylene LPG(eg.. Propane, butane) STG (synthetic town gas) Methane, natural gas, hydrogen
2	Oxidising and/or supports combustion	Medical compressed air Oxygen Nitrous oxide Oxygen/nitrous dioxide Oxygen/carbon dioxide Oxygen/ helium mixtures	Compressed air oxygen Nitrous oxide Oxygen/nitrous oxide mixtures
3	Toxic and corrosive		
3.1	Toxic and/or corrosive and flammable		Ammonia Ethylene oxide (C_2H_4O) Carbon monoxide C_2H_4O/CO_2 mixtures > 6% C_2H_4O
3.2	Toxic and/or corrosive and oxidising		Nitric oxide mixtures Sulphur dioxide Chlorine
3.3	Toxic and/or corrosive only		Ethylene oxide/halo-carbon mixture < 15% C_2H_4O Certain conditions only – ethylene oxide/carbon dioxide mixtures < 6% C_2H_4O
4	Others including inert, but excluding toxic or corrosive	Carbon dioxide Helium	Carbon dioxide Nitrogen Argon Helium Halo-carbon Refrigerants

1. Sample log-book for porous load sterilizers.

Schedule of periodic tests

Log book report(s) periodic tests for porous load

			SHTM 2010 Ref. Part 3
User / operator		**Daily Test**	
	1.	Warm Up Cycle	
	2.	Bowie-Dick test for steam penetration	13.39
Test Person		**Weekly tests**	
	1.	Weekly safety checks	5.7
	2.	Vacuum leak test	11.2
	3.	Air detector function test	11.60
	4.	Automatic control test	12.1
	5.	Bowie-Dick test steam penetration*	13.39
Test Person		**Quarterly tests**	
	1.	Weekly safety checks	5.7
	2.	Vacuum leak test	11.2
	3.	Vacuum leak test (temperature and pressure sensor connected)	11.2
	4.	Automatic control test	12.1
	5.	Verification of calibration of sterilizer instruments*	12.2
	6.	Thermometric test for a small load*	13.7
	7.	Vacuum leak test (sensors removed)	11.2
	8.	Air detector function test	11.60
	9.	Bowie-Dick test for stream penetration	13.39
Test Person		**Yearly and revalidation tests**	
	1.	Yearly safety checks	5.8
	2.	Steam, non-condensable gas test**	9.4
	3.	Steam superheat rest**	9.20
	4.	Steam dryness test**	9.30
	5.	Vacuum leak test	11.2
	6.	Vacuum leak test (temperature and pressure sensors connected)	11.2
	7.	Automatic control test	12.1
	8.	Verification of calibration of sterilizer intsruments*	12.2
	9.	Air detector performance test for a small load	11.45
	10.	Air detector performance test for a full load	11.53
	11.	Thermometric test for a small load	13.7
	12.	Tests for performance requalification as required by the user	8.64
	13.	Vacuum leak test (sensors removed)	11.2
	14.	Air detector function test	11.60
	15.	Bowie-Dick test for steam penetration	13.39
Test Person		**Performance requalification test**	
	1.	Performance Requalification	8.64

Sample Copy

* *May be done at the same time as the preceding test*

** *Subject to agreement between the User and Authorised person these test may be omitted providing there is no evidence of a steam quality problem.*

PLANNED PREVENTATIVE MAINTENANCE

Unwrapped instrument and utensil sterilizer

Quarterly/Yearly Maintenance Schedule

The User or maintenance Person should tick each task when it has been completed.

EO	MAINTENANCE SCHEDULES	1st Q	2nd Q	3rd Q	4th Y
Q – QUARTERLY **Y – YEARLY INTERVALS**					
Service the following items within the contract and at the frequency indicated and check for safe operation					
1.	Check fuses and connections on the electrical mains or plug				*
2.	Replace faulty indicator lamps.	*	*	*	*
3.	Check the gauges and their calibrations. Recalibrate as required	*	*	*	*
4.	Examine the door seal(s) and replace if damaged	*	*	*	*
5.	Examine the door closure mechanism and lubricate.	*	*	*	*
6.	Check the door safety interlocks as required by the scheme of inspection	*	*	*	*
7.	Examine all pipe work connections and components for leaks. Repair as required	*	*	*	*
8.	Weekly safety checks as SHTM 2010 Part 3	*	*	*	
9.	Yearly safety checks as SHTM 2010 Part 3				*
10.	Safety valve check	*	*	*	*
11.	Examine the condenser in the reservoir/ and discharge from chamber vent	*	*	*	*
12.	Examine electrical connections for security	*	*	*	*
13.	Examine timers and check their settings	*	*	*	*
14.	Carry out detailed periodic quarterly maintenance tasks in accordance with the scheme of inspection and manufacturer's instructions.	*	*	*	
15.	Carry out yearly maintenance tasks and check vessel in accordance with the scheme of inspection and the manufacturer's instructions				*
16.	Check the thermal sensor(s) and recorder and recalibrate if necessary				*
17.	Carry out yearly tests in accordance with SHTM 2010 Part 3				*
18.	Refit all covers & note the cycle count number	*	*	*	*
19.	CARRY OUT PERIODIC & AUTOMATIC CONTROL TEST(S) AS REQUIRED	*	*	*	*

Dry Heat Sterilizer – Quarterly Maintenance Schedule

Tests to be carried out in accordance with SHTM 2010.

Hospital/Location	Date	Week
Department	Ref.No	Ser.No

SAFETY CHECKS	Tick if Satisfactory	
Door Seal [ ]	Cooling interlock [ ]	Door Closed Interlock [ ]

AUTOMATIC CONTROL TEST	Production load.	Cycle number
Calibration SATISFACTORY/UNSATISFACTORY	Fill in details on weekly test sheet DHS1	

PERFORMANCE REQUALIFICATION	MPR Ref. No.

Load details		
Container type	Container size	Number of containers
Product in containers		
Batch number	Cycle number	Timer setting
Sterilizing temperature 160/170/180 °C =T°C	Temp controller setting(s)	

Measured values are in shaded boxes. Where the load probe of the sterilizer cannot be put into the load, use chamber at 80°C for t2, leave the t6 row blank, and use t4 and t7 instead of t6 in the MPR/Test comparison.

	Time	Indicated values			Recorded values	
Start t1=0	Min: sec	Chamber Temp.(B)	Load Temp.	Pressure drop across filter	Chamber Temp. (A)	Load Temp.
Load at 80°C	(t2) :	°C	°C		°C	°C
Load at 80°C	(t3) :	°C	°C		°C	°C
Chamber at T°C	(t4) :	°C	°C		°C	°C
Chamber at T°C	(t5) :	°C	°C		°C	°C
Load at T°C	(t6) :	°C	°C		°C	°C

Low Temperature Steam and Formaldehyde Sterilizer – Daily/Weekly Maintenance Schedule

LTS.F	MAINTENANCE SCHEDULES				
D = DAILY W = WEEKLY		**D**	**W**		
Service the following items within the contract and at the frequency indicated. Check for safe operation & correct readings				**U**	**M**
1.	Check all sterilizer services are turned on and correct readings are indicated on controls & gauges	S M T W Th F Sa			
2.	Check the log book & production records together with the routine microbiological test for LTSF. Complete as required	S M T W Th F Sa			
3.	Check the chart recorder or data logger. Fit new chart; replenish ink or fit new ink cartridge as required	S M T W Th F Sa			
4.	Check the chamber & clean as detailed for the type of material chamber is constructed from.	S M T W Th F Sa			
5.	Check the chamber discharge strainer. Remove & clean as required.	S M T W Th F Sa			
6.	Check the door system as required by the scheme of inspection. Clean the door seal & its contact surface.	S M T W Th F Sa			
7.	Carry out detailed periodic daily tests in accordance with HTM 2010 Part 3 Table 4.	S M T W Th F Sa			
8.	Replace faulty indicator lamps	S M T W Th F Sa			
9.	Check gauges & digital indicator(s). If faulty repair or change as required.	S M T W Th F Sa			
10.	Check the door safety interlocks & control systems as required by the scheme of inspection. Lubricate the closure mechanism as required.	S M T W Th F Sa			
11.	Examine all pipe work connections & components for leaks. Repair as required.	S M T W Th F Sa			
12.	Examine door seal(s). Replace if damaged	S M T W Th F Sa			
13.	Weekly safety checks as per HTM 2010 Part 3	S M T W Th F Sa			
14.	Carry out weekly maintenance tasks & check the pressure vessel in accordance with the scheme of inspection and manufacturer's instructions	S M T W Th F Sa			
15.	CARRY OUT PERIODIC & AUTOMATIC CONTROL TEST(S) AS REQUIRED. INSPECT RECORDS WITH USER	S M T W Th F Sa			
16.	Daily tests Satisfactory Not Satisfactory Weekly tests satisfactory Not Satisfactory	S M T W Th F Sa			
17.	Complete the log book.	S M T W Th F Sa			
18.	Notify the user of any defect or safety hazard. Complete the service records. Hand over to the User.	S M T W Th F Sa

NHSScotland, P&EFEx, June 2001

Executive summary

The quality of steam supplied to a sterilizer can have a major influence on the efficacy of the sterilization process, the quality of the sterile product and the longevity and serviceability of the sterilizer and its associated equipment. Where concern for steam quality has traditionally focused on its physical characteristics - notably dryness and the presence of non-condensable gases - new European Standards supporting legislation governing the manufacture of medical devices require more comprehensive control of the purity of the sterilizing environment.

This SHTM discusses the nature, effects and sources of chemical and biochemical contaminants in steam, and proposes a readily achievable purity specification for “clean steam” to be used for sterilization. The specification is designed to meet regulatory requirements for medicinal products and medical devices without incurring excessive expenditure.

Clean steam is defined as steam whose condensate meets the purity requirements of Water for Injections BP (including a limit on pyrogens) with additional specifications to protect against corrosion of materials used in the construction of sterilizers and medical devices.

Practical guidance is given on the generation of clean steam from the following sources:

a. from the existing mains steam supplies commonly used in hospitals;

b. from dedicated clean-steam generators;

c. in sterilizers with an internal steam supply, such as transportable sterilizers for unwrapped instruments and utensils.

With minor modifications and adjustments to operating practices, it should be possible to obtain clean steam from the majority of mains steam services currently installed in NHS hospitals. However, the necessary assurance that the supply continues to meet clean-steam specifications will require frequent testing of steam and feed water samples and close supervision of plant normally outside the control of the user of the sterilizer.

In the longer term, a dedicated clean-steam generator, solely supplying one or more sterilizers, is likely to prove a more reliable and economical source of clean steam.

Advice is given on the validation and periodic testing of clean-steam supplies, with guidance on methods of taking steam and water samples for analysis. Confirmation that a supply complies with the clean-steam specification requires a number of laboratory tests, most of which are based on those of the British Pharmacopoeia and are well within the capacity of any hospital pharmacy.

1. Responsibilities

Introduction

1.1 This chapter reviews the roles of the key personnel associated with the operation of a sterilizer and summarises their responsibilities with regard to clean steam.

Key personnel

1.2 The following key personnel are referred to in this SHTM. Further information, including qualifications and general areas of responsibility, can be found in SHTM 2010: Part 1.

1.3 **Management** is defined as the person with ultimate management responsibility, including allocation of resources and the appointment of personnel, for the organisation in which the sterilizer is employed.

1.4 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of similar authority. In small, autonomous installations the user may take on this function.

1.5 The **User** is defined as the person designated by Management to be responsible for the management of the sterilizer.

1.6 In a hospital the user could be a sterile services department manager, laboratory manager or theatre manager; in primary care he or she could be a general practitioner, dentist, or other health professional. Where a sterilizer is used to process medicinal products, the user is normally the Production Manager (see paragraph 1.13) in charge of the entire manufacturing process.

1.7 The **Authorised Person (Sterilizers)** is defined as a person designated by Management to provide independent auditing and advice on sterilizers and sterilization and to review and witness documentation on validation. The shorter term “Authorised Person” is used in this SHTM.

1.8 The Institute of Healthcare Engineering and Estate Management (formerly the Institute of Hospital Engineering) is the registration authority for Authorised Persons. The address is given in Appendix 1.

1.9 The **Test Person (Sterilizers)** is defined as a person designated by Management to carry out validation and periodic testing of sterilizers. The shorter term “Test Person” is used in this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.10 The **Maintenance Person (Sterilizers)** is defined as a person designated by Management to carry out maintenance duties on sterilizers. The shorter term “Maintenance Person” is used in this SHTM.

1.11 The **Microbiologist (Sterilizers)** is defined as a person designated by Management to be responsible for advising the user on microbiological aspects of the sterilization of non-medicinal products. The shorter term “Microbiologist” is used in this SHTM.

1.12 The **Competent Person (Pressure Vessels)** is defined as a person or organization designated by Management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a sterilizer described in the Pressure Systems Safety Regulations 2000. The shorter term “Competent Person” is used in this SHTM.

1.13 The **Production Manager** is defined as a person designated by Management to be responsible for the production of medicinal products.

1.14 The **Quality Controller** is defined as a person designated by Management to be responsible for quality control of medicinal products with authority to establish, verify and implement all quality control and quality assurance procedures. (A similar role may be defined for the manufacture of medical devices, but this is rarely the practice in hospitals.)

Responsibilities regarding clean steam

1.15 The **Authorised Person** will be able to advise the user on all aspects of the production and use of clean steam for sterilization.

1.16 The **User** will need to:

a. appreciate the nature of contaminants in steam supply (especially pyrogens), their possible adverse effects and their sources;

b. understand the requirements of legislation on medicinal products and medical devices as regards sterilization;

c. be familiar with the current and impending standards on steam sterilization and their implications for steam quality;

d. understand the difference between process steam, clean steam and BS EN 285 steam and the appropriate applications of each;

e. understand the rationale for the clean steam specification;

f. understand the engineering principles required for the delivery of clean steam and how they may be realised for mains steam, dedicated steam generators and sterilizers with internal reservoirs;

g. with appropriate advice, decide whether clean steam is required for any sterilizer unit and if so, what is the best means of achieving it;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

h. after the required engineering work is complete, be satisfied that the chosen system is capable of supplying clean steam;

i. appoint and liaise with a suitable laboratory for the analysis of steam and feed water samples;

j. arrange for the steam supply to be formally validated;

k. on completion of the validation tests, confirm that the sterilizer is fit for use with the steam supply;

l. arrange for periodic maintenance of any steam generating and distribution plant under the user's control;

m. arrange for periodic tests of the steam quality at intervals coinciding with periodic tests on the sterilizer.

1.17 The **Test Person** will need to:

a. understand the operation of the apparatus for taking samples of steam condensate for field analysis (Chapter 6) and be trained in the method of its use;

b. be aware of the correct procedures for collecting, preserving and handling samples;

c. be trained in the measurement of electrical conductivity of water samples using a portable meter.

1.18 The **Maintenance Person** will need to:

a. if maintaining transportable sterilizers, be aware of the guidance on cleaning and rinsing in Chapter 4;

b. if maintaining clean-steam generators, be suitably trained and aware of the guidance in Appendix 2.

1.19 The **Microbiologist** will be able to advise on all microbiological aspects of clean steam, including avoidance of bacterial contamination and control of pyrogens.

2. Contamination in steam supplies

Introduction

2.1 Recent years have seen a growing awareness of the need to improve the quality of steam used for sterilization, spurred on in part by regulatory requirements for medicinal products and medical devices, but also by increasing concern about the harmful effects that even minute quantities of contaminants may have upon patients.

2.2 This chapter discusses the adverse effects that impurities in the steam supply may have on patients, equipment and the sterilizer itself, identifies the products most likely to be susceptible to contamination and reviews the means by which various contaminants find their way into steam for sterilization.

Why does contamination matter?

2.3 As will be discussed in Chapter 3, quality assurance in the manufacture of medicinal products and medical devices requires that the quality of the steam used in sterilization be known and controlled. The following sections identify a number of specific contaminants which are known to have adverse effects and whose presence in steam is therefore undesirable.

Adverse effects on patients

2.4 Even small amounts of unwanted substances may be harmful to patients. The danger arises because certain medicinal products and medical devices may introduce contaminants directly into parts of the body that are normally protected by skin or mucous membranes. Water that is safe to drink, for example, may not be safe if injected into the bloodstream. Patients are particularly vulnerable to contaminants carried on sterile instruments precisely because such instruments are used to bypass the body's normal defences.

2.5 Several contaminants are known to have adverse effects on patients.

a. **Metals:** Many of these are toxic (some are cumulative poisons) and therefore their presence is undesirable. Metals of particular concern include cadmium, lead, mercury and other heavy metals.

b. **Organic compounds:** Many of these are biologically active and therefore undesirable. The chief compounds of concern are filming amines and other chemicals that may be used in boiler treatment (see paragraph 2.29).

c. **Micro-organisms:** Organisms of concern include all pathogens and all Gram-negative bacteria (which are sources of pyrogens).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. **Pyrogens:** These are bacterial endotoxins, predominantly derived from Gram-negative bacteria, which can cause severe reactions when administered intravenously (see paragraph 2.6).

e. **Particulate materia:** Solid particles can lead to a number of adverse effects if injected into the body.

2.6 Pyrogens are of particular concern because, unlike other contaminants, there are no controls on the levels of pyrogens in public water supplies from which steam is generated. Moreover, they are extremely heat-stable and are only destroyed after prolonged exposure to high temperatures (3 hours at 180°C or 30 minutes at 250°C). They are not inactivated by any of the standard sterilization processes employed for medical devices and medicinal products. Control of pyrogens, then, is a priority for steam sterilization. Detailed information about pyrogens may be found in Appendix 3.

Adverse effects on materials

2.7 As well as the obvious risks to patients, contaminants in steam may have a damaging effect on the materials of load items and the sterilizer itself.

2.8 Reactive contaminants in the steam may cause corrosion or otherwise impair the longevity or function of the product. Reactions may occur when contaminants interact directly with the product, or indirectly with materials that will subsequently come into contact with the sterilized product.

2.9 The steam also comes into direct contact with the internal surfaces of the sterilizer pressure vessel and associated equipment and instrumentation. Contaminants within the steam may react with the materials of construction and cause corrosion of the equipment or otherwise impair its longevity or function.

2.10 The reaction of steam with surfaces in contact is affected by its pH. In general steam of a low pH (acidic) will react with and dissolve metals. A pH of approximately 7 (neutral) is ideal and deviations towards alkaline (to e.g. pH 8) is acceptable.

2.11 Contaminants of concern include the following.

a. **Alkaline earth metals** cause “hardness” which can lead to build-up of lime scale on load items, in the sterilizer chamber and in pipework. Most problems are caused by calcium and magnesium, and to a lesser extent strontium.

b. **Iron**, whether in metallic or ionic form, is corrosive to stainless steel.

c. **Chlorides** in the presence of oxygen lead to pitting corrosion and (to a lesser extent) crevice corrosion in stainless steel. The effects can be controlled by limiting the amount of oxygen in the feed water (see paragraph 4.48).

d. **Phosphates** and silicates act to concentrate chloride ions and so promote their corrosive effects.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.12 Clearly the materials used in the construction of load items and of the sterilizer itself will determine which contaminants are of greatest importance in each case. BS EN 285 offers guidance on materials of construction suitable for all steam sterilizers.

2.13 Steam sampling systems also must be constructed of materials which will not react with, and hence contaminate, the sample being collected. Suitable equipment is discussed in Chapter 6.

Products vulnerable to contamination

2.14 Any product may become contaminated when the steam supplied to sterilizers comes into direct contact with it. Contaminants in the steam are deposited on the product as the steam condenses during the heating-up stage. The amount of steam condensing, and hence the amount of contamination deposited, is proportional to the heat capacity of the load item which in turn is proportional to its mass and the specific heat capacity of the material from which it is made. A massive metal item will therefore receive much more contamination than a light plastic item of similar size and shape heated to the same temperature.

2.15 The amount of contamination remaining at the end of the cycle, however, will depend on how much condensate is retained at the surface of the product. Where condensate can drain freely from unwrapped items, a small fraction of the deposited contaminants will be held in a thin film of water and the total amount remaining when the film is evaporated will be proportional to the exposed surface area of the item. Where condensate is trapped in cavities or held in the packaging close to the surface, the amount of contamination retained will be proportionally greater.

2.16 To some extent, packaging materials for steam processes (except fluids in sealed containers) have a filtering effect which protects against contamination. Particulate matter is normally trapped on the outer wrapping (giving rise to discoloured packs) but smaller particles and all molecules will pass through with the steam and be transferred to the product as the steam condenses on it. Performance requirements for packaging materials may be found in BS EN 868.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.17 Whether such contamination has any adverse effect depends upon the nature and intended use of the product. Vulnerable products are:

a. those which would permit direct transfer of contaminants to the patient, including:

(i) medicinal products;

(ii) porous goods such as dressings and swabs;

(iii) surgical instruments and utensils;

b. those which would permit indirect transfer of contaminants to a patient, such as equipment used in pharmaceutical manufacturing (see paragraph 2.18 below);

c. those which would be impaired or inactivated by the presence of one or more of the possible contaminants. These include:

(i) certain medicinal products;

(ii) laboratory products for in-vitro diagnostic use.

2.18 Various items of equipment used in the manufacture of sterile pharmaceuticals and medical devices are sterilized before use. It is important that during sterilization these items are not tainted with contaminants which may be transferred to the product being manufactured, whether that product is terminally sterilized or produced aseptically. Such items of equipment may include mixing vessels, filling heads, sterilization grade filters, filling lines, pipes and tubing for material transfer, connectors, and so on.

Sources of contamination

2.19 Contaminants delivered to the sterilizer in steam may arise from a number of sources:

a. contaminants present in the public water supply from which the steam is generated;

b. contaminants arising from treatment of the boiler feedwater;

c. contaminants arising in the distribution system carrying steam to the sterilizer.

Public water supply

2.20 While the quality of mains water supplies differs considerably from place to place, it can normally be relied upon to meet the minimum standards set out in The Water Supply (Water Quality) (Scotland) Regulations 1990. These specify more than 50 limits for a wide range of impurities including dissolved minerals, organic compounds and micro-organisms.

2.21 There are no controls, however, on the amounts of atmospheric gases dissolved in mains water, all of which will be present in small and varying

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

amounts. Air is the principal non-condensable gas that can impede steam sterilization, and carbon dioxide and oxygen are important contributors to corrosion in boiler systems (see SHTM 2010: Part 2).

2.22 While mains water contains negligible numbers of pathogens and faecal contaminants (such as Escherichia coli) it may contain low numbers of other micro-organisms. Most water authorities use chlorine as a means of microbiological control. The disinfection effect of the chlorine may be largely lost, however, by the time the water reaches the point of use.

2.23 Water taken from the mains and subsequently kept in storage tanks before use may have significantly higher counts than the original mains water. Although bacteria tend to settle out on prolonged storage in reservoirs or lagoons, the intermittent throughput in storage tanks maintains their buoyancy and can cause counts to rise rapidly. Particularly in the summer months counts as high as 105–106 ml^{-1} may not be uncommon. This is of particular concern for sterilization since some 98% of the bacteria found in water supplies are reported to be Gram-negative bacteria, which are the predominant source of pyrogens (see Appendix 3).

2.24 There are no requirements for suppliers to measure or control the level of pyrogens in mains water.

Boiler feedwater treatment

2.25 Further contaminants may be introduced either deliberately or inadvertently as a result of treatments applied to mains water before it can be used as boiler feedwater.

2.26 Dealkalisation treatments can raise the levels of dissolved air and carbon dioxide.

2.27 Base-exchange water softeners remove calcium and magnesium ions from the water and replace them with sodium ions (see paragraph 4.43). Sodium levels will therefore be raised in mains water softened by this method. The use of brine to regenerate the ion-exchange beds may temporarily raise the level of chloride.

2.28 Bacterial growth may occur in water softening, deionisation or reverse osmosis plant unless the manufacturer's operating and maintenance procedures are strictly adhered to. While bacteria will not survive the steam generating process, the pyrogens they produce could be delivered to the sterilizer.

2.29 Any chemicals added to the boiler water may be carried into the steam as contaminants either in droplets of water entrained in the steam during the evaporative process or as volatile components present as gases. Filming amines (such as hydrazine), commonly used to protect condensate return systems, are toxic and should not be used where the steam is to be used for sterilization.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Steam distribution system

2.30 Steam is chemically aggressive; the purer the steam the more reactive it is. Reaction with pipework and valves can lead to contamination of the steam with corrosion products such as magnetite (Fe_3O_4). Often in the form of fine particulates, these products are not readily removed by the strainers normally installed in steam services. Users of old installations may have occasionally noted black or reddish brown discoloration of packaging material by particles of magnetite shed from the walls of the steam pipes.

2.31 The hydrogen liberated by the formation of magnetite (400 ml for each gram of iron) may contribute appreciably to the amount of non-condensable gases in the steam delivered to the sterilizer, especially in new installations with long pipe runs.

2.32 Contamination is also likely to arise at points where water can collect, such as dead-legs, gauges and poorly maintained traps. Trapped water can result in rust, which can be shed into the steam as particles, and bacterial growth, which can lead to the formation of bio-films which periodically generate high levels of contamination as they slough off.

2.33 Guidance on avoiding contamination from mains steam distribution systems may be found in paragraphs 4.20 – 4.24.

3. Steam quality requirements

Introduction

3.1 This chapter discusses the purity requirements for steam to be used in sterilization, with special emphasis on the grade of “clean steam” recommended for general use within the NHS.

Regulatory requirements

3.2 The move towards higher quality steam for sterilization has been brought about, in the main, by regulatory requirements for the manufacture of medicinal products and, more recently, sterile medical devices (see SHTM 2010: Parts 1 and 4 for a summary of the relevant legislation). In both cases there is a clear principle that products should not be adulterated with unwanted or unspecified compounds during sterilization, or any other stage in processing. Such an objective can only be attained if the physical, chemical and biological properties of steam coming into contact with the product are known and controlled.

Medicinal products

3.3 Annex 1 of the ‘The Rules governing medicinal products in the European Community: Volume IV: Good manufacturing practice for medicinal products’ states “*Care should be taken to ensure that steam used for sterilization is of suitable quality and does not contain additives at a level which could cause contamination of product or equipment*.”

3.4 The steam quality need not be very high where the product does not come into direct contact with the steam. This is the case for aqueous products processed in fluid sterilizers, provided that the method of sealing the containers has been validated and shown to have a quantified risk of failure and that failed containers can be readily identified and removed (see SHTM 2010: Part 4 for details). However, such assurance normally requires a degree of testing and monitoring of containers that may not be justified in smaller hospital pharmacies. It may be more cost-effective to ensure that the steam is of sufficient quality that a failure of a seal will not have adverse effects on the product.

3.5 Further guidance on legislation governing medicinal products may be obtained from the Medicines Control Agency whose address may be found in Appendix 1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Medical devices

3.6 Annex I of the Medical Devices Directive, implemented by the Medical Devices Regulations 1994, lists a number of “essential requirements” for the manufacture of medical devices. Section 7.2 requires that devices are “*designed, manufactured and packaged in such a way as to minimise the risk posed by contaminants and residues to the persons involved in the transport, storage and use of the devices and to the patients, taking account of the intended purpose of the product*.” This has clear implications for the quality of steam used in sterilization processes.

3.7 The Directive is supported by the European Standard on validation and monitoring of moist heat sterilization (EN 554) which requires that the *“purity of the sterilizing environment in contact with the medical device shall not affect the safety of the product*.” (Reference should also be made to BS EN 554).

3.8 In practically all steam sterilization processes, the medical device comes into direct contact with the steam and therefore the quality of the steam must be known and controlled. Steam quality is also of concern in ethylene oxide sterilizers in which steam is used for humidification and therefore, again, comes into direct contact with the medical devices.

3.9 Further guidance on legislation governing medical devices may be obtained from the Medical Devices Agency. The address may be found in Appendix 1.

Requirements of SHTM 2010

3.10 SHTM 2010 is the NHS in Scotland Property and Environment Forum's guide to sterilization in Scotland. Part 3 describes steam quality tests for determining the non-condensable gas content, dryness and superheat values of steam supplied to porous load sterilizers, LTSF and LTS disinfectors. The steam quality specified is as follows:

a. the volume of non-condensable gases should not exceed 3.5 ml for every 100 ml of displaced water when measured by the method given in SHTM 2010: Part 3 (this is not equivalent to a fraction of 3.5% by volume of the steam, as incorrectly implied in BS EN 285 and elsewhere);

b. the superheat measured on expansion of the steam to atmospheric pressure should not exceed 25°C when measured by the method given in SHTM 2010: Part 3;

c. the dryness value should be not less than 0.9 (or, if only metal loads are to be processed, not less than 0.95) when measured by the method given in SHTM 2010: Part 3.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.11 This specification, which complies with both BS EN 285 and BS 3970: Part 1, addresses the basic requirements for assurance that the sterilization process is carried out under moist heat conditions, without excessive moisture, and without random, localised, impairment of the sterilization conditions caused by excessive amounts of non-condensable gases. The condensate from the steam should be clear, colourless and free from oil and particulates. To meet this specification steam should be generated by boiler plant which is designed, operated and maintained in accordance both with the recommendations of SHTM 2010 and of the manufacturer. Experience shows that these requirements are readily met in the majority of hospitals.

3.12 Saturated steam, which is clean and substantially free from moisture and non-condensable gases, is the minimum standard required for all sterilization processes.

3.13 The SHTM 2010 requirements, however, say little about the purity of steam for sterilization. From the discussion of the adverse effects of contaminants (see Chapter 2) it is apparent that different minimum specifications could be devised for each of the possible applications and for each of the available sterilization processes. Ideally one would review the nature and intended use of the process, together with any constraints imposed by the materials of which the distribution system and sterilizer are constructed, and select a specification appropriate to the particular circumstances. For specialised products it may be necessary to specify limits for a particular contaminant not considered in this general guidance. Such procedures would be grossly impractical, however, for the wide range of products processed in hospitals.

3.14 Although steam of the highest possible purity may be suitable for all applications it is significantly more expensive to produce than steam of a lower standard. Chemically pure steam is also highly corrosive.

3.15 There is a clear need for a steam purity specification that would meet regulatory requirements and which could be attained in hospitals without excessive expenditure. The rest of this chapter discusses three proposed grades of steam: process steam, BS EN 285 steam and clean steam. They are summarised in Table 1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 1: Classification of steam quality

Steam quality	Description	Sterilizer applications
Process steam	All-purpose steam supply, not optimised for sterilization.	Fluid sterilizers with validated closure systems Laboratory sterilizers (make safe cycles).
Clean steam	Steam whose condensation meets the specification for clean steam in Table 2.	Porous load, unwrapped instruments, LTS and LTSF sterilizers processing medical devices. Fluid sterilizers without validated closure systems Ethylene oxide sterilizers processing medical devices (steam for humidification) Laboratory sterilizers (loads vulnerable to contamination)
BS EN 285 steam	Steam whose condensate meets the specification for BS EN 285 steam in Table 3.	Not required in the NHS

Note: Clean steam may be used for all sterilizer applications

Process steam

3.16 “Process steam” is defined here as general-purpose steam whose quality has not been optimised for sterilization.

3.17 Where it is not intended to be in direct contact with medical devices, medicinal or culinary products, no specific physical, chemical or biological contamination limits are set. The steam may contain various volatile additives (such as those intended to inhibit corrosion in condensate return pipes) which are unacceptable for topical, enteral or parenteral administration to human beings.

3.18 Process steam intended for use as a heating medium in culinary applications, where it is in direct contact with food products or food contact surfaces, is sometimes known as “potable steam”. The condensate from such steam should then meet the purity requirements of drinking water.

3.19 The recommendation of this SHTM is that process steam, as defined above, is not acceptable for sterilizers in which medicinal products and medical devices are in contact with steam and therefore vulnerable to contamination. It may also be unacceptable for certain loads processed in laboratory sterilizers, but may be used where discard loads only are to be processed (see Table 1).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

BS EN 285 steam

3.20 BS EN 285 is the standard on large steam sterilizers (essentially porous load machines). When EN 285 was being developed in the first instance, it was considered desirable to include recommendations on the quality of steam with which a sterilizer should be designed to operate. The result was a specification both for steam condensate and feedwater that would ensure that the steam environment in the chamber would not "impair the sterilization process or harm the sterilizer or sterilized load." Identical recommendations are likely to appear in a future standard on sterilizers for unwrapped instruments and utensils. BS EN 1422, which sets out requirements for EO sterilizers, also recommends limits on impurities in steam used for humidification, although the permitted levels are generally higher than those of BS EN 285.

3.21 "BS EN 285 steam" is defined here as steam whose condensate complies with the specification recommended in BS EN 285 and reproduced in Table 3. It should be emphasised that steam of this quality is a recommendation and not a requirement. Sterilizer plant may conform fully to BS EN 285 without meeting the recommended specification for steam purity.

3.22 While BS EN 285 steam is appropriate for its intended use, it was not designed to meet the requirements of the legislation and standards on medicinal products and medical devices. It is not regarded as suitable for use in NHS hospitals for the following reasons:

a. BS EN 285 steam is designed primarily to protect materials, not patients; it does not, for example, set limits on pyrogens;

b. steam of this purity is chemically aggressive and will attack many materials, including iron, steel and copper, commonly found in existing steam distribution systems, sterilizers and sterilizer loads;

c. it is unlikely that steam of this purity can be generated and delivered with the steam systems currently used in NHS hospitals without excessive engineering costs.

3.23 There appear to be few, if any, sterilizer applications in which BS EN 285 steam would be preferable to "clean steam" as discussed below. The recommendation of this SHTM is that BS EN 285 steam is unnecessary for sterilizers in use in the NHS.

Clean steam

3.24 The concept of "clean steam" has been developed to meet all regulatory requirements while meeting a reasonable standard of purity that can be readily attained in hospitals without excessive expenditure.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.25 The recommendation of this SHTM is that clean steam should be provided for all clinical sterilizers where the steam may come into direct contact with medical devices, medicinal products or equipment intended for use in the manufacture of medicinal products or medical devices. It may also be required for use with laboratory sterilizers where the product is sensitive to contamination. It is expected that clean steam will in due course become the norm for all sterilization applications in the NHS.

3.26 Clean steam is defined as steam whose condensate meets the specification given in Table 2. This specification is compared with those for drinking water and BS EN 285 steam in Table 3.

Table 2: Specification for clean steam.

Determinand	Value	Recommended test for compliance
Based on Sterilized Water for injections BP:		
Acidity or alkalinity	NQ	BP test. Tests for pH are not an acceptable substitute
Ammonium	0.2 mg litre^{-1}	BP test or other suitable method
Oxidisable substances	NQ	BP test
Calcium and magnesium	NQ	BP test. Tests for hardness are not an acceptable substitute
Heavy metals substitute	0.1 mg litre^{-1}	BP test. Tests for individual elements are not an acceptable substitute.
Chloride	0.5 mg litre^{-1}	BP test or other suitable method.
Nitrate	0.2 mg litre^{-1}	BP test or other suitable method.
Sulphate	NQ	BP test.
Residue on evaporation	30 mg litre^{-1}	BP test. Conductively measurement is not an acceptable substitute.
Pyrogens	0.25 EU ml^{-1}	BP test.
Based on BS EN 285:		
Phosphate	0.1 mg litre^{-1}	Any suitable method.
Silicate	0.1 mg litre^{-1}	Any suitable method.
Routine monitoring only:		
Electrical conductivity at 25^{o}C	35 μS cm^{-1}	See Appendix 4 and Chapter 7.

NQ=not quantified; BP=British Pharmacopoeia; EU=endotoxin unit.

3.27 The purity requirements are defined in terms of physical, chemical and biochemical properties and are independent of any engineering measures that may be needed to attain them. The quality specified is to be determined at the point of delivery to the sterilizer. Provided that a suitable quality can be attained and sustained, and that the process has been validated, the source of steam can be selected on economic grounds.

3.28 Test schedules to demonstrate compliance of a condensate sample are discussed in Chapter 5, with sampling methods in Chapter 6 and methods of analysis in Chapter 7.

3.29 The rationale for the clean steam specification is discussed below under the headings of health and safety, sterilizer protection and routine monitoring.

Health and safety

3.30 Rather than make detailed assessments of the health and safety implications of all possible steam contaminants and determine safe levels for each, this SHTM adopts Water for Injections BP (identical to Water for Injections PhEur) as a suitable standard that clean steam condensate should meet. WFI has been in use throughout Europe and elsewhere for many years as the basis for pharmaceutical preparations to be administered intravenously. Steam condensate meeting the requirements of WFI can therefore be regarded as free of harmful contaminants.

3.31 The British Pharmacopoeia (BP) defines two grades of WFI: Water for Injections in Bulk (for use in the manufacture of medicinal products) and Sterilized Water for Injections (essentially WFI in Bulk that has been bottled and sterilized, and intended for dilution of medicinal products for injection). Clean steam is based upon the requirements for Sterilized WFI; experimental measurements with WFI in Bulk show that it is too acidic for the materials used in sterilizers.

3.32 The BP defines WFI both in terms of its means of production and in terms of a number of tests for specified contaminants.

3.33 First, WFI "is obtained by distilling potable water or Purified Water from a neutral glass, quartz or suitable metal still fitted with an effective device for preventing the entertainment of droplets; the apparatus must be correctly maintained to ensure the production of apyrogenic water." A high degree of purity is clearly implicit in this statement. For example, a sample of tap water treated chemically to remove only the impurities specified in the BP would not be WFI. For the purposes of this SHTM, the guidance on clean steam generation in Chapter 4 is deemed to meet the distillation requirement for WFI.

3.34 Second, Sterilized WFI is required to comply with a number of tests designed to confirm that a given water sample contains less than a certain amount of a specified contaminant. Test procedures are given in the BP and reproduced here in Appendix 4.

3.35 It has to be said that these tests are not entirely satisfactory as a specification for clean steam. They employ traditional reagent methods which rely upon the observation of colour changes, and are poor at determining the extent to which a sample deviates from specification. Moreover, limits are not always quantified: concentrations are quoted for some contaminants but not others. For this reason it has not been possible to set numerical limits for all the contaminants in Table 2. On the other hand, the tests can be carried out in any hospital pharmacy and do not require the facilities of a specialised analytical laboratory.

3.36 Where no concentration is quoted (*acidity* or *alkalinity, calcium and magnesium, oxidisable substances* and *sulphate*), the only safe way of ensuring that a sample meets the WFI specification is to conduct the test described in the BP; there are no generally accepted equivalent concentrations.

3.37 Where the BP does quote an equivalent concentration, however (*ammonium, nitrate, chloride* and *residue on evaporation*), the way is open to employing a variety of modern analytical techniques to demonstrate compliance (see Chapter 7), though the stated concentrations are not precise and should be treated with caution.

3.38 While the BP quotes a concentration for *heavy metals* (expressed as Pb), the test responds to different metals in varying degrees and it is not possible to express the BP limit as a simple sum of individual elements. For this reason the BP test alone should be used to ascertain compliance; alternative methods are not recommended (see paragraphs 7.18–7.20 for more details).

3.39 The limit for *pyrogens* is 0.25 endotoxin units (EU) ml^{-1} (see Appendix 3 for a discussion on the meaning of the endotoxin unit). The BP test for pyrogens (bacterial endotoxins) is the LAL test described in Appendix 4.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.40 It is likely that these traditional tests will be replaced by more precise quantitative tests in the future. If so, the requirements for clean steam will be modified accordingly. *Clean steam should always comply with the current pharmacopoeial specification for Sterilized Water for Injections*.

Sterilizer protection

3.41 The WFI specification is designed to ensure that water can be administered safely by injection and is therefore regarded as a suitable minimum standard for health and safety purposes. It is not, however, concerned with effects on materials, and so additional specifications have been added to lessen the corrosion problems discussed in Chapter 1.

3.42 The levels at which *phosphate* and *silicate* begin to contribute to corrosion are poorly understood and little experimental work has been done. The levels in Table 2 have therefore been taken from the BS EN 285 specification without modification.

3.43 The BP test for *chloride* is considered adequate to limit its corrosive effects on stainless steel.

Routine monitoring

3.44 For the reasons explained in Chapter 7, *electrical conductivity* is a convenient diagnostic tool for routine monitoring of steam quality once the system has been validated. The BP does not specify a conductivity for Sterilized WFI. While it is possible to determine a corresponding value experimentally, experience shows that the evaporative residue in steam samples is considerably lower than the BP value of 30 mg litre^{-1} and therefore a correspondingly lower conductivity would be appropriate for routine monitoring. A figure of 35 µS cm^{-1} has been adopted as a reasonable upper limit for contaminants that may be found in the steam supply. Conductivity is to be measured only during field testing of the steam supply and is not specified where samples are subject to a full laboratory analysis.

3.45 The drinking water and BS EN 285 conductivities are specified at 20° C, which is below room temperature in many sterilizer installations. A standard temperature of 25° C has been chosen for clean steam because it can normally be attained without the need for refrigeration.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4. Clean steam in practice

Introduction

4.1 This chapter discusses the principles by which steam conforming to the clean-steam specification of Chapter 3 may be generated. It offers practical guidance on how to achieve clean-steam standards for sterilizers supplied by mains steam, sterilizers supplied by a dedicated clean-steam generator and for sterilizers (such as transportables) which generate steam from an internal reservoir.

4.2 Full costings should be obtained when the relative merits of different steam supplies are being assessed. The cost of the testing required to demonstrate that a mains steam system can consistently produce clean steam may amount to a considerable fraction of the capital cost of a dedicated clean-steam generator.

How steam is made

4.3 At first sight it may be surprising that there should be any contaminants in steam at all. Steam is generated by boiling, in which liquid water is converted into a gas. One might expect that any impurities in the water would be left behind, as in distillation, while pure steam in the form of H_2O molecules was delivered to the sterilizer.

4.4 Boiling occurs at a temperature where evaporated water vapour has sufficient pressure to displace the water immediately below the surface to form bubbles of steam. (At lower temperatures evaporation occurs only from the surface.) The bursting of bubbles from the surface of the boiling water is accompanied by the ejection of small droplets of water. *These droplets contain the same dissolved and suspended solids that are present in the water in the boiler*. They are readily entrained in the flow of steam and thus carry contaminants to the sterilizer. Even if the water droplets subsequently evaporate, the contaminants will still be present in the form of solid particles.

4.5 “Priming” is a related phenomenon where significant quantities of the boiler water can sporadically be carried over into the steam. This is often as a result of a sudden increase in the demand for steam, which reduces the pressure above the water and effectively lowers the boiling point, so increasing the violence of bubbling. A too-high level of water in the boiler can also lead to priming. Priming can be reduced by standard good operating practice, such as running the boiler at or near its maximum permissible pressure, using pressure-reducing valves where the demand causes a reduction in pressure in the distribution system, and maintaining correct water levels.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.6 High concentrations of impurities in the boiler water also promote carry-over. They reduce the surface tension and so increase the agitation of the water surface. They can also cause the formation of a stable foam above the water surface leading to severe carry-over. Slugs of water are intermittently discharged from the boiler along with the steam, severely prejudicing the quality of the steam.

4.7 A crucial aspect of boiler design, therefore, is to ensure the best possible separation and removal of such entrained moisture.

Summary of requirements for clean steam

4.8 From the above considerations and the discussions in Chapter 1, the requirements for generating clean steam can be summarised as follows:

a. feedwater should be as free as possible of contaminants, especially those specified for clean steam in Table 2;

b. the boiler should be designed to prevent water droplets being carried over into the steam;

c. the boiler should be operated to prevent foaming and priming;

d. the distribution system carrying steam from the boiler to the sterilizer should be resistant to corrosion.

4.9 It is apparent that a boiler system designed and operated to provide minimal carry-over of entrained water droplets will be able to maintain a low level of contaminants in the steam even where the quality of feedwater is poor. Feedwater treatment, then, may not be the decisive factor in the ability of a system to deliver clean steam. However, if the feedwater is of low quality, even small deviations from optimum operating conditions may result in large amounts of contaminants being carried over and delivered to the sterilizer. The designer of a robust clean-steam supply will therefore ensure that all the above requirements are met.

4.10 A suggested process for assessing how a clean steam supply may be achieved is illustrated in Figure 1.

Clean steam from the mains steam supply

4.11 Recent tests have shown that clean steam can be obtained from well-designed, constructed and operated conventional boilers and distribution systems of the type found in most NHS hospitals. If steam from this source is chosen, it is essential to demonstrate compliance and identify maintenance and boiler treatment regimes necessary for reproducibility.

4.12 Where a central supply does not deliver steam of acceptable standard, it is possible that the quality may be sufficiently improved by changes in operating practice and relatively minor engineering modifications. However, it is unlikely

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

to be economical to embark on extensive remedial works such as the introduction of new feedwater treatment plant or the replacement of distribution pipework. It may be more cost-effective to install a dedicated clean-steam generator solely to supply sterilizers (see paragraph 4.26 onwards).

Boiler design and operation

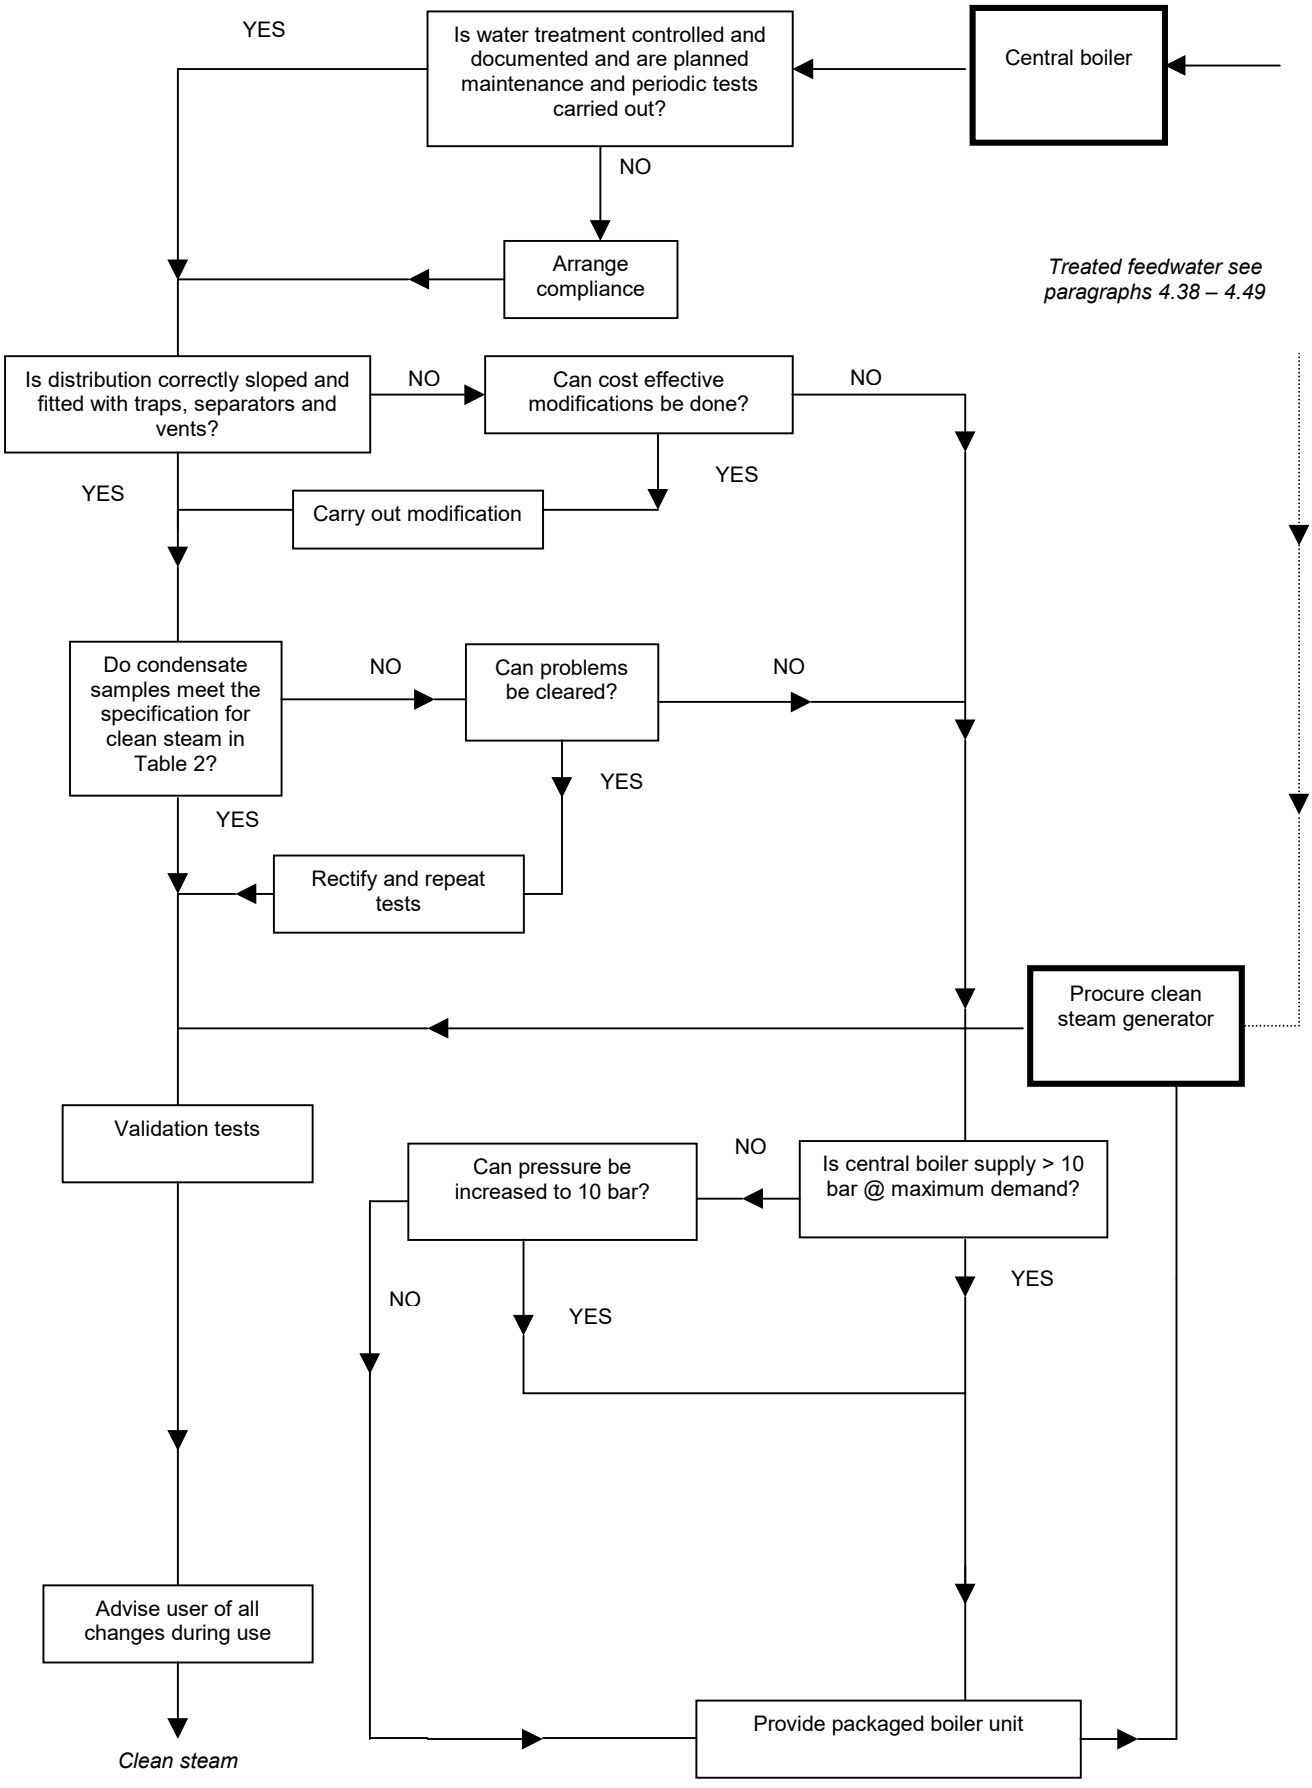
4.13 The first step in assessing whether clean steam can be supplied from the mains is to examine the design and operation of the boiler plant.

4.14 An important consideration is the proportion of boiler feedwater that is fresh “make-up” water rather than steam condensate returned from the distribution system. In most large hospitals where steam is supplied centrally only a small fraction of the steam demand is due to sterilizers (which discharge most of their condensate to waste) and therefore the bulk of the condensate is returned to the boiler. This makes it more feasible to control the level of contaminants in the boiler. While the nature of the feedwater treatment is also of importance, the requirements for clean steam are unlikely to be achieved if the proportion of make-up feedwater exceeds 15%.

4.15 The level of total dissolved solids (TDS) in the boiler water is an important factor both in the prevention of foaming (see paragraph 4.6) and for the contaminants that may be present in the entrained water droplets. Acceptable TDS levels if clean steam is to be produced are typically below 2000 ppm. While some control of TDS concentration can be exercised by appropriate feedwater treatments, the boiler usually has a “blow-down” facility to allow accumulated sludge to be expelled from the bottom of the vessel. The water level gauge and TDS sensor element should also be blown down at regular intervals.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 1: How to provide clean steam



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.16 Filming amines, which are often added to feedwater to prevent corrosion of condensate return pipes, are toxic and are not acceptable for boilers supplying clean steam for sterilizers. If it is not possible for the boiler to be operated without filming amines, then another source of steam must be found.

4.17 While the boiler is unlikely to have been designed with the requirements of clean steam in mind, it should nonetheless have some means of preventing water being carried over into the steam. The chief precaution against carry-over is good practice in operating the boiler so that foaming and priming do not occur (see paragraph 4.5). Discussion with boiler-room staff will ascertain the degree to which operating procedures are successful in this regard.

4.18 Steam sampling points on the boiler, as discussed in Chapter 5, are desirable and should be installed if they are not already fitted.

4.19 As the operational management of the steam supply will normally be outside the user's control, the user will also need to assess whether the boiler-room management are aware of the principles of clean steam and whether the necessary cooperation will be forthcoming (see paragraph 4.25d). Well-trained and knowledgeable boiler personnel, and clean and tidy working conditions, are all good signs.

Distribution system

4.20 The distribution system also influences the quality of steam delivered to the sterilizer. The design of distribution systems suitable for the delivery of dry, saturated steam is considered in SHTM 2010; Part 2.

4.21 A purpose-built distribution system for clean steam would normally be constructed of stainless steel. However, when a large conventional installation has been in use for a number of months, a hard protective layer of oxide (magnetite) may have formed on the inside of the steam pipes (see paragraph 2.30). Providing the steam condensate is neutral or alkaline, this coat will remain intact and permit the use of the pipework for the distribution of clean steam. Acidic condensate in the presence of moist air, however, can break down the layer leading to corrosion which may then be shed as contaminating particles.

4.22 As a precaution, final steam filters capable of removing all particles down to 5 µm in size should be installed on all distribution systems.

4.23 It is important that the distribution system is free of dead-legs and other places where condensate may become trapped. During periods when the steam supply is off, such accumulations may become a focus of microbial growth. The trapped water may then be swept up into the steam when the supply is restored. Although the micro-organisms may be killed by the steam, pyrogens will not be inactivated at the temperature of the steam and may be delivered to the sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.24 Other key points for a distribution system suitable for clean steam include:

a. correctly sized automatic air vents throughout the pipework distribution system to minimise the amount of air and other non-condensable gases delivered to the sterilizer;

b. properly sized and selected steam traps to remove condensate;

c. steam pipeline velocities kept below 25 m s^{-1} to allow steam traps to remove entrained moisture effectively and to prevent condensate being drawn out of them;

d. steam separators near the steam take-off on boiler plant prone to generating wet steam;

e. strainers to protect control valves, steam traps, etc.

Quality assurance

4.25 Where a mains steam supply is found to be capable of meeting the clean-steam specification, users should assess whether the steam quality can be maintained under all operating conditions. There are several points to consider.

a. Frequent testing of the steam at the sterilizer will be required to provide assurance that the clean-steam specification is consistently met.

b. Competing demands on the steam service from other units in the hospital may degrade the steam quality at the sterilizer.

c. Steam quality is apt to vary through the year as the boiler room responds to changing seasonal demands.

d. An otherwise effective clean steam supply may quickly deteriorate if appropriate periodic maintenance is not carried out.

e. Arrangements should be made for the user to be warned of imminent engineering modifications, maintenance and changes in steam generation, distribution and operating practice. If changes are likely to be made without the user's knowledge, the supply cannot be considered a reliable source of clean steam.

Clean steam from a clean-steam generator

4.26 A dedicated clean-steam generator, whether supplying one or several sterilizers, is the recommended solution where clean steam cannot be reliably obtained from the mains supply. Since the bulk of the condensate from sterilizers is discharged to waste and not returned to the boiler, such generators may have to run on practically 100% make-up feedwater.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.27 A dedicated system must therefore:

a. minimise the amount of non-condensable gases and other contaminants in the boiler feedwater;

b. prevent liquid water leaving the boiler and being delivered in the steam;

c. prevent microbial growth in any storage tank or pipework;

d. be constructed from materials resistant to corrosion and particle shedding, such as low-carbon stainless steel (type 316L).

4.28 The capacity of the generator should be sufficient to meet both maximum and minimum demands while still maintaining the requirements for dryness and non-condensable gases specified in SHTM 2010: Part 3 (see paragraph 3.10).

Moisture separation

4.29 An essential component of a clean-steam generator is a means of separating entrained water droplets from the steam before it is delivered to the sterilizer. The baffles used in some conventional boilers are not normally adequate for this purpose, but good results have been obtained on experimental machines using cyclonic separators which essentially spin-dry the steam by causing it to rotate at high speeds.

4.30 The manufacturer will have measured the efficiency of moisture removal by spiking the feedwater with high levels of endotoxin (at least 10^3 EU ml^{-1}) and testing samples of the steam for endotoxin levels by means of the LAL test (see Appendix 4). (This work should be undertaken only by personnel with appropriate training and experience.) Tests on an experimental clean-steam generator have shown that reduction factors greater than 105 can be consistently achieved.

4.31 Adequate moisture removal should be maintained over the entire range of steam demand, typically up to 200 kg h^{-1} for each sterilizer.

Heating

4.32 A single 500-litre porous-load sterilizer requires a steam generator capable of converting energy at a rate of up to 50 kW. A group of sterilizers will require a proportionately higher heating power.

4.33 Where existing sterilizers are supplied from a central boiler the ideal solution is to install a generator heated by mains steam. The steam generator is then effectively a steam-to-steam calorifier, in which the mains steam is used only to heat the feedwater and does not come into contact with the clean steam for the sterilizer. Primary steam requirements for this type of calorifier will normally be 300 kg h^{-1} for each sterilizer at a minimum pressure of 10 bar and operating on 100% condensate return. Where mains steam is not available, a small packaged boiler may be a convenient source of steam for heating, but should not itself be regarded as a source of clean steam.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.34 Generators may be heated by electricity, but size for size, an electrically heated generator cannot match a steam-to-steam generator for heating power. Experience shows that the pressure in the boiler cannot be maintained at a high enough level to ensure adequate removal of droplets by the cyclonic method described above. Gas-fired heating is not recommended for stainless-steel boilers.

Materials

4.35 The boiler and other parts of the generator that come into contact with feedwater or steam should be constructed of corrosion-resistant stainless steel (such as low-carbon 316L grade).

4.36 Pipework connecting the clean-steam generator to the sterilizer should be also constructed in stainless steel. Since the generator can be sited close to the sterilizer, it is a false economy to re-use existing sections of the steam supply system.

4.37 While existing sterilizers should not be harmed by a carefully-designed clean-steam system, steam-contact surfaces of iron, mild steel or copper should be avoided in new machines. In most cases this will require contact surfaces to be fabricated in stainless steel as specified in BS EN 285.

Feedwater treatment

4.38 Since there is no return of chamber condensate from the sterilizer, the quality of feedwater is crucial to the performance of a clean-steam generator. It is especially critical for those generators that operate on a straight-through principle and have no reservoir of water within the boiler.

4.39 Water drawn from the public supply may be hard, that is containing significant concentrations of the salts of the alkaline earth metals (chiefly calcium and magnesium), and may also have traces of other contaminants which need to be removed. To assess the need for water treatment, users are recommended to obtain an analysis of the mains water from the supply company. Under The Water Supply (Water Quality) (Scotland) Regulations 1990 such an analysis must be supplied to customers on request and free of charge.

4.40 Although the stated water quality may be relied on most of the time, gross contamination of water supplies may occasionally occur due to engineering works and treatment failures. Users should take adequate precautions to protect any installed equipment from damage in such circumstances.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.41 Full water treatment consists of three stages:

a. softening (to remove scale-forming contaminants which may harm the boiler);

b. purification (to remove other undesirable contaminants);

c. degassing (to remove corrosive and non-condensable gases).

4.42 The need for softening treatment will depend on the hardness of the local water supply. Where the water is soft it may be possible to achieve the clean steam requirements without further treatment. In such cases users should be aware that the quality of the steam will vary with the quality of the water supply, and that frequent monitoring will be required to ensure that the clean steam specification is maintained.

4.43 In hard-water areas a base-exchange softening plant will normally be required. In this process calcium and magnesium ions are exchanged for sodium ions in a zeolite column (permutite process). The columns are periodically regenerated by flushing with brine (sodium chloride). It is important that the flushing is carried out in accordance with the manufacturer's instructions to prevent chloride ions being introduced into the softened water.

4.44 Microbial growth may occur in the columns unless the equipment is correctly operated and scrupulously maintained. Although mains water should be free of micro-organisms, a recirculating system should be fitted to maintain a flow of water through the columns at times of low demand. The softened water should be monitored regularly for microbial content. Periodic sanitising of the columns may be required and in-flow filters and regular decontamination may be needed to prevent colonisation. Although the brine flushing process should destroy most micro-organisms, bacteria such as *Bacillus* species and *Staphylococcus aureus* are tolerant of high salt concentrations.

4.45 Steam generators that are highly efficient at removing water droplets may be able to attain clean-steam standards without the need for further purification of the feedwater, but this can only be determined by experiment. Until clean-steam technology has been further developed and proven, users are recommended to consider installing feedwater purification plant.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.46 Purification may be achieved either by reverse osmosis or deionisation. In reverse osmosis (RO), water is forced through a semi-permeable membrane which filters out contaminants to a high degree of efficiency. In deionisation (DI), ions and charged particles are removed either by electric fields or by ion exchange in resin beds. Although RO cannot normally attain the degree of purity possible with DI methods, it is more than adequate for feedwater intended for purpose-built clean-steam generators. Moreover:

a. RO is cheaper to install and to run than DI;

b. RO removes particulate matter, organic molecules and pyrogens that DI cannot;

c. RO water is less corrosive to steel and copper than DI water;

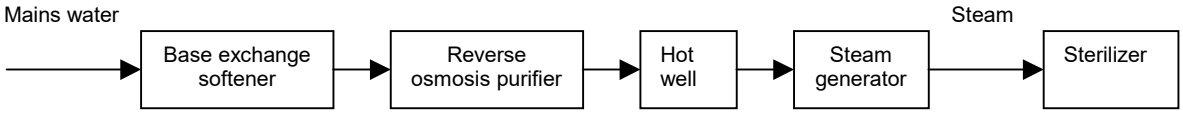
d. maintenance requirements are less demanding than for DI units.

4.47 When seeking quotations for the supply of water purification plant, the user should ensure that the manufacturer is aware of the intended use of the purified water and establish that it will not be corrosive to the materials of the clean-steam generator.

4.48 Further treatment of the feedwater to remove dissolved gases will be necessary. This is usually achieved by pre-heating the water in a “hot well” maintained at temperatures of 80–190°C (at atmospheric pressure) to drive dissolved gases out of solution. The hot well is often provided by the manufacturer of the steam generator as an integral part of the unit.

4.49 A schematic illustration of a complete water treatment system is shown in Figure 2.

Figure 2: Typical feedwater treatment for a clean steam generator



Internally generated clean steam

4.50 A large number of sterilizers in use in the NHS generate steam from a reservoir of water within the machine. Examples of such machines include:

a. transportable sterilizers (bench-top) for unwrapped instruments and utensils;

b. small EO sterilizers in which water is used to generate steam for humidification;

c. certain laboratory sterilizers with internal reservoirs.

4.51 These machines can be readily converted to clean steam, although demonstrating compliance poses severe difficulties. While it may be possible

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

to modify a sterilizer so that steam samples may be taken from the chamber, the amount of steam generated in each cycle is so small that the volume of condensate obtained is insufficient for the required laboratory tests.

4.52 The problem is compounded since manufacturers have traditionally provided neither steam sampling points nor drainage valves on transportable sterilizers. Users should consider specifying such features when procuring new sterilizers. For the foreseeable future, however, assurance of clean steam conditions in the chamber must rely on good operating practice rather than the testing of samples.

Feedwater quality

4.53 The first consideration is the quality of the feedwater. Because there is normally nothing in these sterilizers to prevent entrained moisture or carried-over water reaching the load from the reservoir, the purity of the steam must be assumed to differ little from that of the water in the reservoir. If the feedwater itself complies with the clean steam specification then, provided that the sterilizer chamber and reservoir are known to be clean and free of corrosion, the steam generated from it can also be presumed to be clean. *The quality of feedwater, then, is critical to the attainment of clean-steam conditions in the chamber*.

4.54 It follows from the definition of clean steam (see paragraphs 3.24–3.45) that the feedwater for these sterilizers should meet the purity requirements of Sterilized Water for Injections BP.

4.55 The situation is complicated, however, as soon as production loads are introduced into the chamber. Most sterilizers with an internal reservoir are designed to hold sufficient water for several operating cycles. After each cycle the condensate, together with any contaminants introduced with the load items, will be drained down into the reservoir. After a few cycles the level of contaminants in the feedwater may be so high that the steam generated from it no longer meets clean-steam specifications.

4.56 The possibility of pyrogens accumulating in the reservoir is of particular concern. Some pyrogens will be washed down from load items, while others may arise from bacterial growth, especially where the sterilizer is unused for long periods between refills. Even if such bacteria are subsequently killed by the sterilization process, pyrogens will not be inactivated and will be deposited on the next load. The level of pyrogens in the steam may exceed the permitted maximum for clean steam even though Sterilized WFI was used as the original feedwater.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A practical approach

4.57 By following good operational practice and using Sterilized WFI it is possible to meet in full the requirements for clean steam. Whilst good operational practice should also be employed in the maintenance and cleaning of the reservoir and chamber, the use of Sterilized WFI may not always be justified.

4.58 Small transportable (benchtop) steam sterilizers are used in various healthcare premises, ranging from chiropody clinics to primary care premises in which, increasingly, minor surgical procedures are performed. The procedures for which sterilized instruments from a small steam sterilizer are used, therefore, vary widely. In some circumstances, the user may decide that Sterile Water for Irrigation may be a suitable alternative to Sterilized WFI. Sterile Water for Irrigation is sterilized nonpyrogenic distilled water, intended to be used for cleaning and irrigating body surfaces, wounds and body cavities. It differs from Sterilized WFI primarily in having a higher maximum endotoxin limit (0.5EU per ml compared with 0.25EU per ml for WFI). It is readily available in 1 litre, or larger, packs and at a similar price to the retail price for distilled water.

4.59 At the end of each working day the reservoir and chamber should be drained and left dry. The contents of part-used containers of sterilized feedwater should be discarded.

4.60 Small ethylene oxide sterilizers using steam for humidification are more likely to process products for complicated procedures, and Sterilized WFI is recommended.

4.61 Similarly, laboratory sterilizers with internal reservoirs used to process products vulnerable to contamination, or sterilizers processing medicinal products with unproven closure systems, should utilise Sterilized WFI.

Good operating practice

4.62 In view of the above considerations, it is clear that the key to achieving clean steam in this type of sterilizer lies in appropriate operating procedures, adhered to rigorously.

4.63 Sterile Water for Irrigation should be used during validation tests of a new sterilizer, at the time of all periodic or revalidation tests.

4.64 The following procedure should be used during validation tests of a new sterilizer, at the time of the yearly or revalidation tests, and where a sterilizer has not previously been used to generate clean steam:

a. where practicable, examine all internal surfaces (reservoir, chamber, connecting pipework and other surfaces in contact with steam or feedwater) for signs of dirt, obstructions, scaling and corrosion; if present, consult the manufacturer for advice on cleaning and repair and remedy accordingly;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

b. rinse all internal surfaces several times with Sterile Water for Irrigation, checking that the discarded water is clear, uncoloured and free of particulates;

c. fill the reservoir with Sterile Water for Irrigation to the level recommended by the manufacturer and run an operating cycle with an empty chamber; drain the reservoir;

d. if the sterilizer is to be used immediately, refill the reservoir with Sterile Water for Irrigation to the level recommended by the manufacturer; otherwise rinse all internal surfaces twice with Sterile Water for Irrigation and leave dry.

4.65 In routine operation the following procedures should be observed:

a. ensure that all load items are scrupulously clean and dry before being placed in the chamber;

b. when the reservoir is to be replenished, drain the contents, rinse all internal surfaces twice with distilled water and once with Sterile Water for Irrigation; refill the reservoir with Sterile Water for Irrigation to the level recommended by the manufacturer;

c. at the end of the working day, or whenever the sterilizer is to be unused for several hours, drain the reservoir, rinse all internal surfaces once with distilled water and once with Sterile Water for Irrigation and leave dry;

d. when the sterilizer is to be used again, rinse all internal surfaces once with Sterile Water for Irrigation and refill the reservoir with Sterile Water for Irrigation to the level recommended by the manufacturer.

4.66 A guiding principle is that water is not allowed to remain standing in the reservoir for more than a few hours. If water has inadvertently been allowed to stand for a long period, or is suspected to have become contaminated, drain the reservoir and repeat the rinsing procedure in paragraph 4.64b.

5. Testing for compliance

Introduction

5.1 This chapter discusses the testing regimes necessary for the initial validation of a clean-steam supply and for subsequent periodic testing. Methods for taking samples are given in Chapter 6 and their analysis is discussed in Chapter 7.

Where to take samples

5.2 For a thorough assessment of the quality of the steam supply, samples of water and steam should ideally be taken throughout the steam-generating and distribution system from incoming water to steam at the sterilizer, though such extensive sampling will rarely be needed in practice. Examples of points at which water and steam samples may be taken include:

a. *mains water*; which after suitable treatment will be used as feedwater to the boiler;

b. *treated water*; which may include one or more distinct treatment stages. Samples should be taken from the inlet and outlet pipes as close as possible to the treatment plant. To monitor the various stages of water treatment samples should be taken after each stage.

c. *feedwater*; the water admitted to the boiler from the hot well, but without any dosing treatments admitted simultaneously or separately to the boiler;

d. *boiler water*; the water in the boiler prior to blow-down;

e. *boiler steam*; the steam leaving the boiler;

f. *steam for use in sterilizer*; the steam delivered to the sterilizer, sampled at the steam service pipe.

5.3 The sampling points should be chosen so that the samples obtained will allow, when required, the identification and quantification of significant changes which may occur in contamination levels at each stage in the process. For example, sampling before and after a base-exchange water softener may reveal an increase in bacterial endotoxin levels from a contaminated ion-exchange column. A full set of sampling points at strategic locations will allow such problems to be investigated with a minimum of disruption, even though most of them will rarely be used in routine operation. Guidance on the design and use of sampling points is given in Chapter 6.

5.4 The design and construction of the system will determine how many sampling points would be of value. For a mains system supplying a large hospital, all the above points may be desirable. For a sterilizer with an adjacent, dedicated

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

clean-steam generator supplied from a simple treatment plant, fewer would be needed.

Validation and periodic testing

5.5 Validation tests should normally be carried out on the following occasions:

a. on initial validation of the steam-raising and distribution plant;

b. on initial validation of the sterilizers served by the steam plant, if not the same occasion;

c. on yearly testing or revalidation of the sterilizers;

d. where there is operational evidence that the steam quality may have deteriorated;

e. after any significant modification of the steam plant or its operation which might adversely affect the quality of the steam.

5.6 Periodic tests should be carried out on quarterly testing of the sterilizers.

5.7 As a minimum, samples for validation should always include both the feedwater and the steam for use in the sterilizer. Testing the steam without testing the water from which it is raised can lead to a false sense of security. For example, high levels of pyrogens in the feedwater will not necessarily produce contamination in the steam when the boiler is operating under loads which do not induce carry-over or priming. But during normal operation this could occur and therefore the contamination in the feedwater would require urgent investigation and remedial action.

5.8 Once a clean-steam supply has been validated, periodic testing of steam quality will be necessary for assurance that the clean-steam specification continues to be met. Quarterly testing of electrical conductivity is recommended here (see paragraphs A4.39–A4.48), but the frequency will depend upon the particular application and the consistency of control established from historical data. Other tests may be desirable if one or more of the possible contaminants is critical for the process or product.

Mains steam supply

5.9 Formal validation should be carried out once the user is satisfied that the chosen system is capable of supplying clean steam and boiler operating procedures have been established. Much exploratory testing may be required before this point is reached.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Validation test

5.10 The user should consult boiler room records to establish how the demand on the boiler varies through a typical working day (in a large hospital sterilizers themselves are likely to contribute only a small fraction of this load). The object is to ensure that times of highest and lowest demand can be reliably identified so that representative steam samples can be taken.

5.11 Because of the large amount of steam contained within a mains distribution system, it may take several minutes for steam produced in the boiler to arrive at the sterilizer. The quality of the steam at the sterilizer, then, may not be representative of the quality at the boiler. In particular, the steam in the pipes may have been generated under more favourable conditions at a time of less extreme demand and therefore be of higher quality, so invalidating the tests. On the other hand, steam that has been standing in the pipes is more likely to have received contamination from the distribution system. For these reasons users should take care to ensure that the steam sample was indeed generated when the boiler was operating at the presumed demand. This may require the pipework feeding the plant room manifold to be flushed with fresh steam immediately before samples are taken. In practice the samples should be satisfactory if the boiler demand has been steady for several minutes and remains steady while the flushing takes place and the samples are taken.

5.12 Two samples each of both feedwater and steam at the sterilizer should then be taken:

a. at a time of highest demand;

b. at a time of lowest demand.

5.13 Samples should consist of:

a. a full set of duplicate samples for laboratory analysis as described in paragraphs 6.18–6.25;

b. a field sample as described in paragraphs 6.8–6.17.

5.14 Where more than one sterilizer is supplied from the same steam manifold, the steam samples should be taken at the sterilizer furthest downstream from the boiler. It is not necessary to sample the steam at each sterilizer.

5.15 Samples should be subject to a full laboratory analysis as described in Chapter 7. The field sample should be tested for electrical conductivity on site as described in Appendix 4.

5.16 If the steam samples do not conform, the feedwater analysis should be examined to determine whether the failure could be remedied by a simple adjustment of the treatment regime. If not, further samples may need to be taken at other points in paragraph 5.2 to establish where the problems are arising.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.17 When validation has been completed successfully, the mains supply may be used as a source of clean steam for sterilization. Users, however, should proceed with caution until sufficient experience has been gained to build confidence in the system. During the first year of clean-steam operation, the validation tests should be repeated at intervals chosen to coincide with the peak variations in seasonal demand. Such additional tests will provide further assurance that the system is capable of meeting the clean-steam specification under all normal operating conditions. If any tests fail during this period corrective action should be taken and the tests repeated.

Periodic tests

5.18 Periodic testing of the steam supply (testing of feedwater is unnecessary) should be carried out quarterly to coincide with the quarterly tests scheduled for the sterilizer. The test should consist of a conductivity measurement of a field sample (see Appendix 4). Provided that the conductivity value remains below the limit established during validation, the steam supply may be regarded as continuing to meet the clean-steam requirements. Failure of the periodic test requires further investigation, however, normally by a full laboratory analysis of both feedwater and steam.

5.19 Revalidation should be carried out once a year, to coincide with the yearly testing of the sterilizer.

Dedicated clean-steam generator

5.20 A dedicated clean-steam generator supplying one or more sterilizers does not suffer competing demands from other equipment and is more likely to be within the user's control. Consistency of steam quality can therefore be demonstrated more readily than for a mains steam supply.

Validation test

5.21 Validation can normally be carried out as soon as the contractor has installed the equipment and completed his own installation tests.

5.22 The user should first establish the conditions under which the steam generator will be subject to the highest and lowest demand. Depending on the design of the steam plant, it is possible for either to constitute the worst-case conditions for carry-over of moisture. For example, a large plant designed to supply several sterilizers and relying on a cyclonic separator for removal of entrained water droplets may be inefficient at the lower velocities generated by a single sterilizer on light load. The other extreme requires the generator to operate at the lowest pressure and at the highest demand rate which would be expected under normal use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.23 The highest demand on the boiler usually occurs when all sterilizers are operating simultaneously. However the period of peak demand is brief (steam admission into the chamber) and it is difficult to synchronise the operating cycles so that the peaks coincide for long enough to allow a sample to be taken.

5.24 An alternative method is to vent steam from the relief valve on the plant room manifold. Users should first ensure that the steam will be discharged to a safe position outside the building (see SHTM 2010: Part 2 for guidance). By its very nature, the relief valve is designed to limit pressure in the system under all conditions and therefore creates a demand on the boiler that is greater than the maximum demand of the sterilizers. If steam samples collected under these conditions comply with clean-steam specification then the User can be confident that the generator will cope with the demand of the sterilizers. If not, then the generator may still comply if loaded at the lesser demand of the sterilizers. Further testing will be required.

5.25 A third possibility is to install a discharge valve on the steam manifold designed to simulate the peak demand of all sterilizers operating at the same time.

5.26 Lowest demand in normal operation typically occurs when a single sterilizer is on stand-by, with steam only being used to heat the jacket. However, since that steam will not come into contact with load items, its quality is not critical and it matters little whether it is clean or not. It may be better to regard the lowest demand as occurring during the holding time of a single sterilizer.

5.27 Unlike the mains systems discussed in paragraph 5.10, the amount of steam contained within the distribution system will be small, the steam produced in the boiler will arrive at the sterilizer almost instantly, and the steam sample collected can be assumed to be representative of that created in the boiler.

5.28 Two samples each of both feedwater and steam at the sterilizer should then be taken:

a. under conditions of highest demand;

b. under conditions of lowest demand.

5.29 Samples should consist of:

a. a full set of duplicate samples for laboratory analysis as described in paragraphs 6.18–6.25;

b. a field sample as described in paragraphs 6.8–6.17.

5.30 Where more than one sterilizer is supplied from the same steam generator, the steam samples should be taken at the sterilizer furthest downstream. It is not necessary to sample the steam at each sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.31 Samples should be subject to a full laboratory analysis as described in Chapter 7. The field sample should be tested for electrical conductivity on site as described in Appendix 4.

Periodic tests

5.32 Periodic testing of the steam supply (testing of feedwater is unnecessary) should be carried out quarterly to coincide with the quarterly tests scheduled for the sterilizer. The test should consist of a conductivity measurement of a field sample (see Appendix 4). Provided that the conductivity value remains below the limit established during validation, the steam supply may be regarded as continuing to meet the clean-steam requirements. Failure of the periodic test requires further investigation, however, normally followed by a full laboratory analysis of both feedwater and steam.

5.33 Revalidation should be carried out once a year, to coincide with the yearly testing of the sterilizer.

Internally generated clean steam

5.34 As explained in paragraph 4.50, transportable sterilizers pose problems in demonstrating compliance with clean steam due to the difficulty of obtaining adequate steam samples. For this reason, no validation or periodic tests are specified for these sterilizers.

5.35 Users should follow the good practice guidance given in paragraphs 4.63−4.67. In particular, the cleaning and rinsing procedure described in paragraph 4.65 should be carried out on validation, revalidation and yearly testing of the sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6. Sampling

Introduction

6.1 This chapter discusses methods for taking water and steam samples for both field and laboratory analysis.

6.2 Field samples will normally be taken and analysed by the Test Person in the course of testing the sterilizer. Laboratory samples may be taken either by personnel from the receiving laboratory or by the Test Person if qualified to do so.

Sampling points

6.3 As discussed in Chapter 5, sampling is required in each part of the system where the composition of the water or steam may need to be confirmed, or where changes in composition may need to be determined. Sampling points should be designed and constructed to ensure that:

a. the sample taken is as nearly as possible representative of the water or steam being sampled in that section of the system;

b. the sample can be taken without contaminating it;

c. the sample can be taken safely.

6.4 When possible, samples should be taken from flowing rather than static parts of the system. For example, for sampling a tank the samples are best taken from the inflow or outflow pipes but not from the static reservoir in the tank.

6.5 Where boiler water is to be sampled the position of the sampling point must be chosen with care. The composition of water at various locations in the boiler may show considerable variation. For boilers with forced circulation the sampling point is best located on the discharge side of the pump.

6.6 It is good practice to install coolers to ensure that representative samples of the boiler water may be taken safely.

6.7 Guidance on the design and construction of sampling points is given in BS 6068: Section 6.7.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Sampling for field analysis

6.8 This method is suitable for taking steam and water samples to be tested for electrical conductivity during periodic tests. It should not be used for samples intended for laboratory analysis.

Apparatus

6.9 Figure 3 shows the apparatus connected to a pitot tube identical to the one specified for the steam quality tests in SHTM 2010: Part 3. The pitot is fitted to the steam supply pipe near the sterilizer. This standard pitot is not suitable for the system for laboratory samples described below (see paragraph 6.18) so Figure 4 shows an alternative pitot which may be used for all steam testing. If this pitot is used for field samples or the tests in SHTM 2010: Part 3, the ball valve, nipple and socket should be removed.

6.10 Steam is led through a length of polypropylene tubing and is condensed as it passes through a bath of cold or iced water.

6.11 This apparatus is suitable for use for samples which are to be analysed immediately, such as for periodic tests for electrical conductivity. It is not suitable for samples intended for more sensitive analysis in the laboratory since the polypropylene is contra-indicated for several of the determinands of interest. It is also unsuitable where samples are to be taken for pyrogen testing since the polypropylene tubing cannot withstand the extended exposure to high temperatures needed to ensure that all components of the sampling system are free from pyrogens (see paragraph 6.22).

Method

6.12 Clean the polypropylene sample bottle and the polypropylene tube with dilute hydrochloric acid and rinse several times with distilled water. Detergents should not be used. Leave them to dry.

6.13 If the pitot is not already fitted, isolate the steam supply and vent the pipe of pressure. Fit the pitot tube into the pipe and secure the polypropylene tube to it with a clip.

6.14 Restore the steam supply and allow steam to vent through the polypropylene tube for at least 5 minutes to restore the steam service to its stable operating temperature. Ensure that the condensate drains freely. Close the steam valve.

6.15 Coil part of the polypropylene tube into sufficient number of coils to ensure condensation of steam, place it in the 8-litre container and retain it in place. Fill the container with enough cold water (ice may be added if required) to immerse the coils.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.16 Open the steam valve. The steam will condense in the coils and condensate will emerge from the end of the tube. Allow the first 50 ml of condensate to discharge to waste and then collect approximately 250 ml in the sample bottle.

6.17 Seal and label the bottle. The electrical conductivity should be measured promptly as described in Appendix 4.

Sampling for laboratory analysis

6.18 This method is suitable for taking all required samples, including those to be subjected to full laboratory analysis including the test for pyrogens.

Apparatus

6.19 The apparatus is shown in Figure 5. All components, including the condenser and valves, are constructed in stainless steel. The tubing is made in short sections which are connected by compression joints to form the required length and configuration. The sections are short enough to allow each element to be thoroughly cleaned, sterilized and depyrogenated before use.

6.20 The standard pitot used with the field sampling apparatus described above is not designed to take compression fittings and so cannot be used with this apparatus. It should be replaced with the modified pitot and ball valve shown in Figure 4.

6.21 The apparatus is suitable for taking samples for all the determinands of interest. It may be used for steam condensate or water samples throughout the steam-raising system. In theory there is a risk of some contamination of the sample from metals which could be extracted from the stainless steel. However the grade of steel chosen is no more reactive than those used in the construction of steam pipes and equipment. If, for whatever reason, the steam reacts with the sampling apparatus it will also have reacted with the installed system.

Method

6.22 All the stainless steel components should be depyrogenated by processing in a dry-heat sterilizer at a sterilization temperature of 180°C for 3 hours. If a suitable oven is available they may alternatively be baked at 250°C for 30 minutes (dry-heat sterilizers cannot attain this temperature).

6.23 Clean and prepare sample bottles according to the instructions from the receiving laboratory. Normally, two sets will be used for steam samples and one for control samples. Ensure that the bottles are labelled as described in paragraph 6.36.

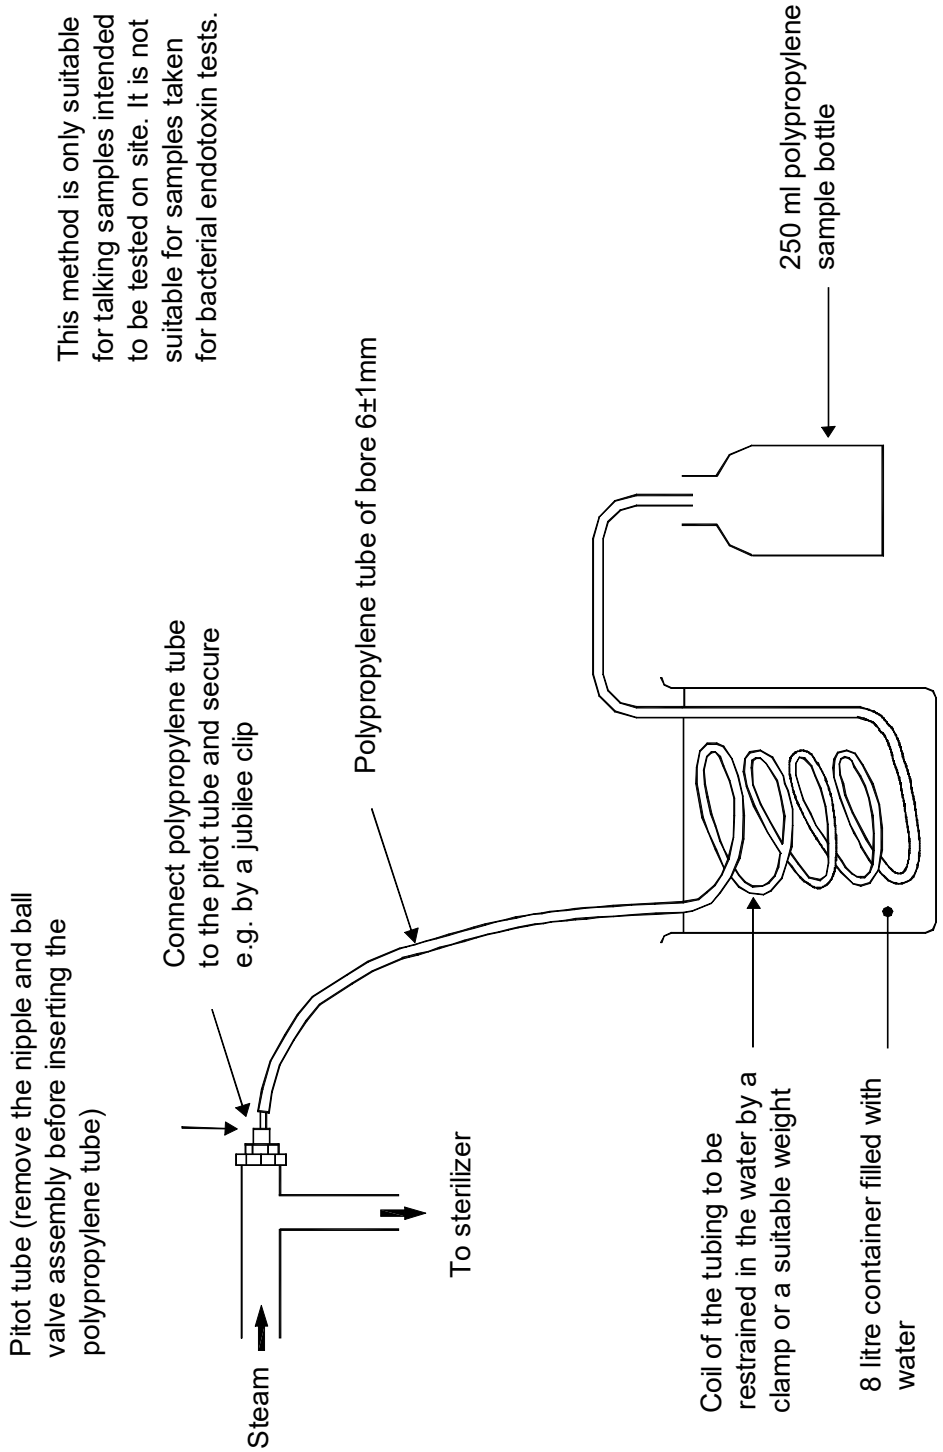
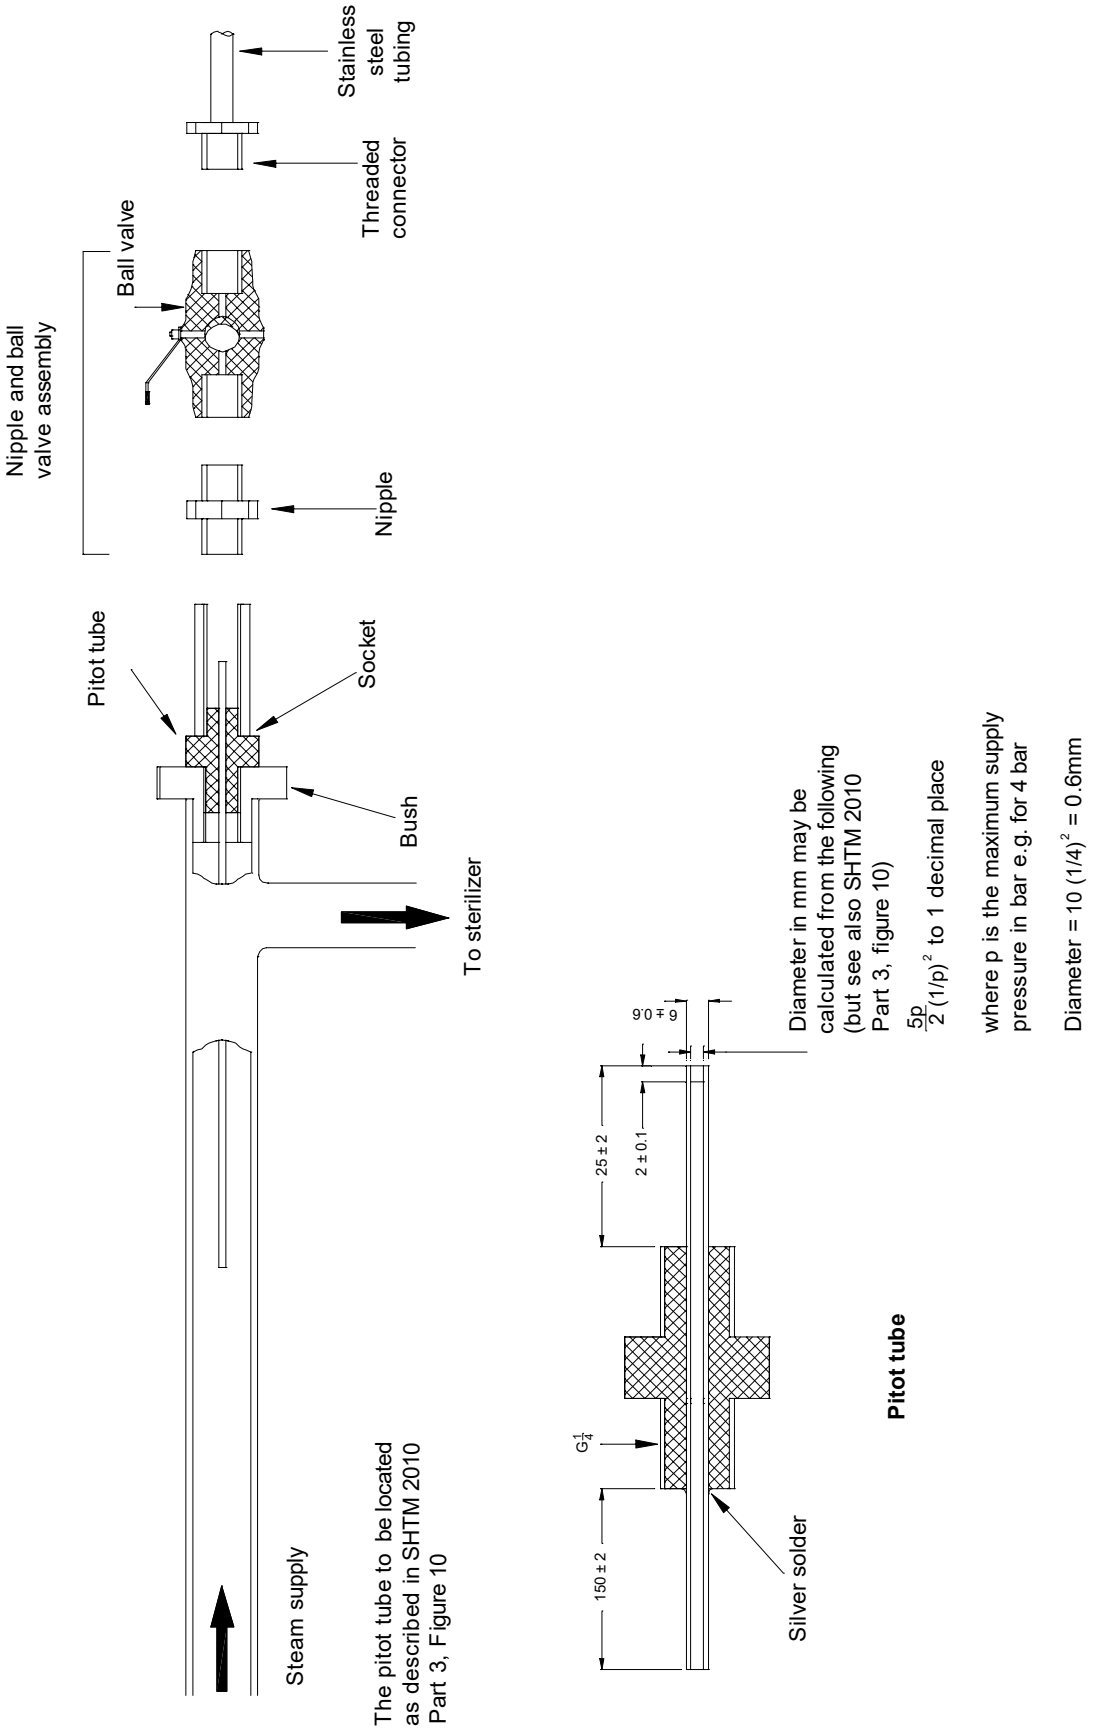
Figure 3: Steam sampling system for field analysis



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 4: Typical pitot sampling tube assembly



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.24 Open the valve on the pitot. The steam will condense in the coil and condensate will emerge from the end of the tube. Allow the first 50 ml of condensate to discharge to waste and then collect samples in the first two sets of bottles.

6.25 The third set of bottles should be filled with distilled water of known quality, which should be preserved and analysed in the same manner as the two sets of steam samples. These negative control samples provide evidence that the choice of container, cleaning system and preservative is appropriate.

Handling of samples for laboratory analysis

6.26 As soon as a steam or water sample is taken, it is important that its physical, chemical and biological properties remain stable until it arrives at the laboratory for analysis. The conditions in which the sample should be kept are determined by the contaminants for which the water is to be tested. The material of the sample container is also important since it may interact with substances in the water; plastic is suitable for some parameters, glass for others.

6.27 General guidance on these points is given below; more specific advice may be found in BS EN ISO 5667-3 and BS 6068-6.3. The laboratory carrying out the analysis will normally provide all the necessary containers, preservatives and labels with full instructions for their use.

Containers

6.28 There is no one material suitable for all contaminants of interest. Containers may be made variously from polyethylene, polystyrene, polypropylene, glass or borosilicate glass. The receiving laboratory should supply the appropriate containers with full instructions for their use.

6.29 Each type of container requires a different cleaning procedure to ensure that samples are not contaminated by residues. Again, the instructions of the receiving laboratory should be followed.

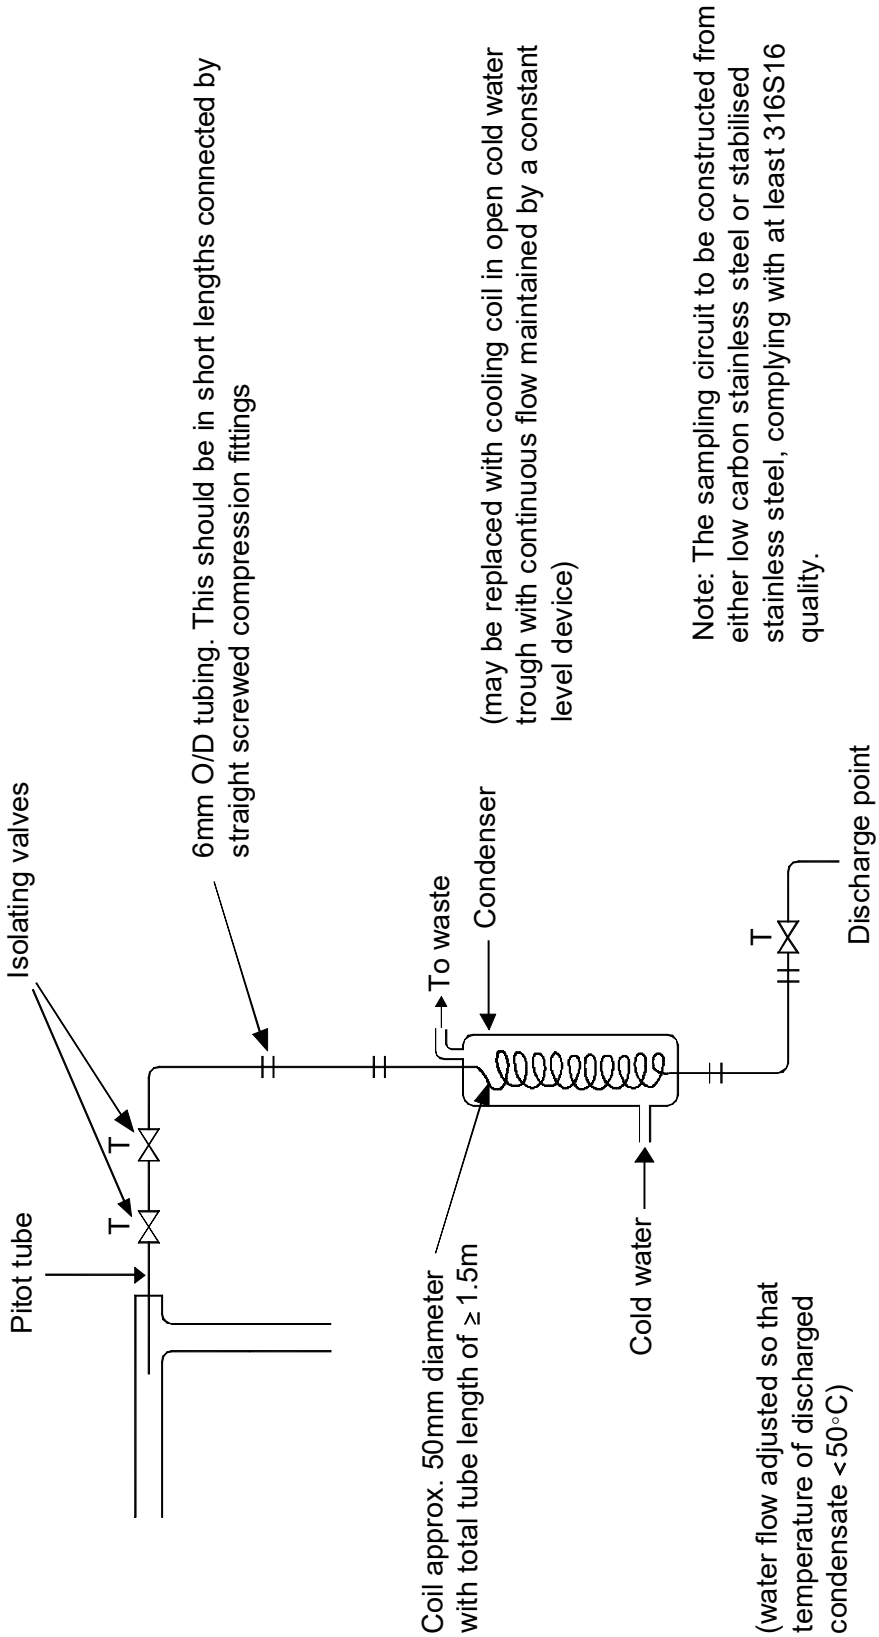
6.30 Observe the laboratory's instructions on filling and closing the bottles. Most bottles should be filled to the brim and then stoppered or capped to ensure that as little air as possible remains above the sample. A small air space should be left above samples to be frozen.

Sample preservation

6.31 The purpose of preservation is to transfer the sample to the laboratory in a manner which, as far as may be practicable, maintains the concentration and state of the contaminant of interest unchanged from the moment the sample was taken.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 5: Steam sampling system for laboratory analysis



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.32 There are many possible interactions which can occur that will adversely affect the sample. The contaminant of interest may:

a. polymerise or, if already a polymer, depolymerise;

b. react with other constituents of the sample;

c. react with atmospheric oxygen or carbon dioxide becoming dissolved in the sample;

d. be consumed, modified or be produced in higher concentrations by micro-organisms growing in the sample;

e. react with, or be adsorbed or absorbed by, the material of which the container is constructed.

6.33 The extent to which these and other reactions will modify the sample is a function of several factors. The sample itself, and the extent and nature of any contaminants present, will determine which reactions and changes may occur. The more contaminated a sample is the more likely it is that changes will occur. The temperature during transport and storage, the exposure to light, the material of which the container is made and any special precautions used in the preparation of the container, and the elapsed time before analysis will all have a significant effect.

6.34 While it is desirable for all samples to be cooled (normally at 2−5°C) some will require the addition of an acid preservative and others will need to be frozen. The receiving laboratory will specify the preservative treatment for each container and supply suitable reagents where necessary.

6.35 Few preservative treatments for the contaminants specified for clean steam are valid for more than 24 hours and some for a much shorter time. Prompt despatch and analysis are therefore essential.

Identification of samples

6.36 Each container must be legibly and unambiguously labelled with a water-resistant label at the time of sampling. The laboratory will supply suitable labels and instructions. The information to be noted will normally include:

a. the establishment at which the sample was taken;

b. the date and time at which the sample was taken;

c. the name of the person taking the sample;

d. clear identification of hazardous materials present (e.g. acids used as a preservative);

and either

e. a reference number, which unambiguously relates to contemporaneous notes of the following information;

or

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

f. the sampling point;

g. the nature of the sample (e.g. condensed steam);

h the determinand(s) for which the sample is to be analysed;

i. any preservative treatment;

j. notes on any observations pertinent to the analysis, such as an event not in accordance with the sampling procedure which may affect the analysis.

Packaging and transport

6.37 The samples should be packaged securely in containers providing suitable protection from breakage or external contamination during transport. The containers should be kept as cool as possible during transport. For transporting small quantities of samples, domestic cool boxes provide suitable protection and cooling.

6.38 The transport container should be accompanied by a list of the samples being sent, and a duplicate retained. The list should be sufficiently comprehensive to allow confirmation of the identity of each sample in the consignment.

7. Analysis of samples

Introduction

7.1 This chapter discusses the means by which a sample of steam condensate may be analysed for compliance with the clean-steam specification. The tests are equally suitable for testing samples of steam or water from elsewhere in the steam supply system, provided the limitations of the pharmacopoeial tests are understood (see paragraph 3.35).

7.2 The methods of collecting samples are discussed in Chapter 6.

Testing of samples

7.3 The quality of a water sample cannot be assessed merely by visual inspection. To determine whether a steam sample conforms with the requirements for clean steam it is necessary to carry out tests for all the determinands listed in Table 2.

7.4 Appendix 4 describes all the tests, with the exception of phosphate and silicate (see paragraph 7.23) required to analyse a sample for compliance. These tests are taken from the British Pharmacopoeia and should be well within the capacity of any hospital pharmacy. Although they do not require expensive analytical equipment, they are intended to be used by trained personnel in a properly equipped laboratory and are not suitable for on-site determinations under field conditions.

7.5 Laboratories invited to carry out these tests should be accredited to a recognised standard.

7.6 The field test for electrical conductivity is also described in Appendix 4. Note that it is required to be preceded by the BP test for acidity or alkalinity, which may also be carried out in the field.

Reporting of results

7.7 The report obtained from the laboratory in respect of each test should contain the following information:

a. the exact identity of the water sample;

b. the date and time the sample was received;

c. the date and time at which the test was commenced;

d. the storage conditions if (b) and (c) are not the same date;

e. the determinand for which the sample was analysed;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

f. for non-quantitative tests, a statement as to whether the result complies with specification;

g. for quantitative tests:

(i) the numerical value expressed in the unit specified (see paragraph 7.11) for each of the duplicate determinations;

(ii). the mean of the results of the duplicate determinations and the uncertainty which may be associated with the final result;

h. a description of any sample pre-treatment;

i. a description of the method used, including reference to specific items of equipment, calibration standards, etc;

j. any deviations from the method or other facts which might reasonably be expected to influence the result obtained; and should be signed both by the analyst responsible for carrying out the determinations and the analyst or quality controller responsible for checking the report.

Alternative methods

7.8 Where numerical values are given in Table 2, laboratories may offer alternatives to the BP tests of equivalent or greater accuracy and sensitivity if these are methods which they routinely use. (Users should note that such methods will generally be more expensive than the BP tests.) Experienced analysts with appropriately equipped laboratories may favour the use of one of the many instrumental analytical techniques available. Instrumental methods which provide the same or better precision than the BP tests are suitable. See paragraph 7.23 for guidance on phosphate and silicate.

7.9 For any given determinand there will usually be several methods which are suitable and cover the range of concentrations of interest. The choice of method will be determined by a number of factors including availability of equipment, previous experience with the method, cost, sensitivity to interfering substances which may be present in the sample, etc. Significance should be given to:

a. the limit of detection, which must be lower than the specified limit for the contaminant;

b. the accuracy of the method, which will be of particular importance in observing changes in quality;

c. the likely presence of interfering substances in the samples to be tested.

7.10 For further guidance see *General principles of sampling waters and associated materials*, 2nd edition, in the series, *Methods for the examination of waters and associated materials*.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Comments on the tests

7.11 Since there are several ways in which numerical results from any given analysis may be presented, the user should specify that the results are quoted in the units used in the clean-steam specification in Table 2 so that the sample can readily be compared with the specification.

7.12 The following sections give background information on interpreting the results of some of the clean-steam tests and explains the relationships between them.

Concentrations; residue on evaporation

7.13 The levels of some of the impurities in Table 2 are expressed as mass concentrations in units of milligrams per litre (mg $litre^{-1}$). An alternative unit seen occasionally is milligrams per kilogram (mg kg^{-1}) which is identical to parts per million by mass (ppm). Since one litre of pure water has a mass of almost exactly one kilogram, these units may be taken to be numerically equivalent for steam condensate. Hence:

1 mg $litre^{-1}$ = 1 mg kg^{-1} = 1 ppm = 0.0001% by mass.

7.14 Alternatively, concentrations may be expressed in moles or millimoles per litre (mol $litre^{-1}$, mmol $litre^{-1}$), where one mole is equal to Avogadro's number of entities (atoms, molecules or ions). A concentration of one mole per litre is known as a "molar" (M) solution. To convert to a mass concentration, the relative molecular mass (RMM, formerly known as "molecular weight") of the entity is required. Thus:

(Mass concentration / mg $litre^{-1}$) = (RMM / g mol^{-1}) × (molar concentration/mmol $litre^{-1}$).

7.15 It is important to understand precisely what the reported concentration represents, since the same units are often used in different ways to express the results of the same analytical procedure. For example in the determination of phosphate the results may be reported as mg $litre^{-1}$ of P, P_2O_5 , or PO_4 (see paragraph 7.24). Although the three values will be different, they represent the same experimental result.

7.16 The sum of the concentrations of individual ionic species must always be less than the concentration of total dissolved solids (measured as residue on evaporation). Unfortunately the BP tests are not sufficiently quantitative to allow this check to be made. However, the residue figure should be consistent with the electrical conductivity as described in paragraph 7.28 onwards.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Acidity and alkalinity

7.17 The test for WFI in Bulk corresponds approximately to a pH in the range 4.2 to 7.0. Since a pH of 7.0 represents a neutral solution, the test requires the sample to be acidic. This is unacceptable for steam condensate, since acidic conditions promote corrosion of materials. For this reason the clean-steam specification adopts Sterilized WFI as a purity standard; the acidity-alkalinity test then corresponds to a much more acceptable pH in the approximate range 6.8 to 8.4.

Heavy metals

7.18 In the BP test for heavy metals the sample is concentrated by a factor of 10 by evaporation and then calibrated against a standard solution containing 1 mg litre^{-1} of lead ions. The test fails if the sample contains a sufficient concentration of heavy metals to produce a more intense brown colour than the standard solution subjected to the same test. The colour is not easy to discern and so the test should be carried out in conditions of good controlled lighting.

7.19 In normal circumstances the test will react to metals which form acid-insoluble sulphides, but the BP gives no indication of which metals will be detected. Table 4 shows the result of experimental work to determine the sensitivity of the test to various metals (Healthcare Science Ltd 1996). This shows that only lead, copper and silver can be detected at the 0.1 mg litre^{-1} limit, mercury must be present at 1.5 mg litre^{-1} before it is detected. Cadmium and zinc give a pale yellow colour (but not brown) at 0.6 mg litre^{-1} and zinc gives a pale white opalescence at 1.2 mg litre^{-1}. The test is insensitive to antimony, iron, nickel, cobalt, manganese and tin.

Table 4: Sensitivity of the BP test for heavy metals.

Metal	Concentration in sample (mg litre^{-1})
Lead	0.1
Copper	0.1
Silver	0.1
Bismuth	0.6
Mercury	1.5

The table gives the concentration of each metal that will cause the same reaction as 0.1 mg litre^{-1} of lead.

7.20 It is therefore not possible to express the 0.1 mg litre^{-1} figure as an equivalent sum of concentrations of individual metals. For this reason the test cannot be replaced by more precise quantitative tests for individual elements.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Pyrogens

7.21 In the BP test for pyrogens, the water sample is incubated with a reagent known as LAL (Limulus amoebocyte lysate) derived from the horseshoe crab, *Limulus polyphemus*. If a clot forms, the amount of endotoxin in the sample may be estimated from the known sensitivity of the lysate. The limit of detection is 0.03 EU ml^{-1}.

7.22 The test should not be confused with the alternative “test for pyrogens”, also described in the BP, which is carried out on live rabbits.

Phosphate and silicate

7.23 These contaminants differ from the others in that they are not listed in the pharmacopoeial specification for Water for Injections. Consequently there are no simple BP tests that can be used to demonstrate compliance. A suitable analytical method for phosphate may be found in BS EN 1189 and BS 6068-2.28 (ammonium molybdate spectroscopic method) and for phosphate and silicate in *Phosphorous and silicon in waters, effluents and sludges* 1992 in the series *Methods for the examination of waters and associated materials*.

7.24 Conversion factors for different expressions of phosphate are as follows:

1.00 mg $litre^{-1}$ P = 3.07 mg $litre^{-1}$ PO_4 = 4.58 mg $litre^{-1}$ P_2O_5.

Electrical conductivity

7.25 Pure water, which contains no ions except H^+ and OH^- (formed by the dissociation of H_2O) is a poor conductor of electricity. Any dissolved ionic species will raise the conductivity of the water sample. Measurement of the conductivity therefore provides a simple means of measuring the concentration of ionic species. That is why conductivity is so useful in monitoring steam quality.

7.26 The SI unit of conductance (reciprocal of resistance) is the *siemens* (S) which has the same dimensions and magnitude as the older unit, the *mho* (or reciprocal ohm). The SI unit of conductivity is the *siemens per metre* (S m^{-1}) but the practical unit for aqueous solutions (and the unit used in this SHTM) is the *microsiemens per centimetre* (µS cm^{-1}). This gives a numerical value of conductivity which is the same order of magnitude as the concentration of dissolved ionic species expressed in milligrams per litre.

1 mS m^{-1} = 10 µS cm^{-1}.

7.27 A number of factors affect the measurement of conductivity. These include:

a. the ionic species present (the particular ions, and the extent to which they become hydrated);

b. polarisation; gases produced at the surface of the electrodes will increase the electrical resistance and rapidly reduce the current to near zero. This

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

can be avoided by the use of an alternating voltage which prevents the build-up of gases at the electrodes;

c. temperature; for which the relationship with conductivity is non-linear. Temperature compensation is therefore essential.

7.28 When a water sample contains predominantly ionisable solids in solution, and the composition of the various constituents is reasonably constant, the conductivity is proportional to the concentration of total dissolved solids (TDS) for concentrations up to 10 000 mg litre^{-1}. A measured conductivity is multiplied by a suitable conversion factor to give an estimate of the TDS in mg litre^{-1}. The conversion factor can be derived experimentally for waters of consistent ionic composition by making direct comparison of the measured mass of total dissolved solids and the electrical conductivity. It should be emphasised that TDS values estimated this way are not as reliable as direct measurements by gravimetric methods and reported as *residue on evaporation.*

7.29 Conductivity meters calibrated directly in TDS mg litre^{-1} are available, but readings should be not be taken at face value. The conversion factor being used must be established and shown to be appropriate.

Appendix 2: Operation and maintenance of clean-steam generators

Introduction

A2.1 Clean-steam generators are steam boilers and are subject to the Pressure Systems Safety Regulations 2000.

A2.2 Users should ensure that operation and maintenance of the generator is carried out correctly, both to ensure safety and also to maintain the quality of the steam.

A2.3 Steam generators are subject to a written scheme of examination for pressure vessels.

A2.4 Guidance on the design, maintenance, testing and operation of steam generators may be found in HSE Guidance Note PM 5*, Automatically controlled steam and hot water boilers*.

A2.5 The advice of the boiler manufacturer about water supply, water treatment, blowing down and other operational practices should be strictly observed.

A2.6 Failure to provide adequate supervision, with consequential inadequate control of water quality and insufficient blow-down, has resulted in such severe corrosion of steam generators that in some cases internal parts have collapsed and operators have been put in danger.

Operation

A2.7 A risk assessment should be undertaken to establish the level of supervision required. While it is not acceptable for steam generators to be left continuously unattended, it is not necessary for an operator to be present at all times. The amount and frequency of attention necessary in each case will depend largely on the nature of the water supply, water treatment arrangements and the intensity of use. The operator, who may also be the sterilizer operator, should be adequately trained.

Maintenance

A2.8 Because there is little condensate return to these steam generators, their feedwater is usually almost 100% make-up, and as a result the concentrations of dissolved and suspended solids in the boiler water quickly build up to very high levels. Such boilers are provided with a “blow-down” facility to expel

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

deposits of sludge from the bottom of the boiler. It is essential that an effective blow-down regime is established and adhered to. There are three possibilities:

a. continuous blow-down - sludge is expelled continuously;

b. automatic intermittent blow-down - sludge is expelled automatically under the control of a conductivity device;

c. manual intermittent blow-down - sludge is expelled manually under the control of the operator.

A2.9 With manual blow-down there is a risk of affecting the steam quality if this is undertaken at a time when there is a high demand for steam. For this reason manual blow-down should be undertaken at times of light load, preferably when none of the sterilizers are operating. Continuous and automatic blow-down systems need to be carefully managed to ensure they do not affect steam quality.

A2.10 Guidance on blow-down may be found in HSE Guidance Note PM 60, *Steam boiler blow-down systems* (PM 60).

A2.11 Generator vessels constructed from stainless steel will be subject to the same risk of stress corrosion cracking encountered in stainless steel sterilizer chambers (see SHTM 2010: Part 4) To minimise the risk, the manufacturer's guidance on feedwater quality should be followed.

A2.12 A record of all tests and maintenance should be kept in the machine's plant history file.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Appendix 3: Pyrogens

Bacterial endotoxins

A3.1 Bacterial endotoxins are a group of compounds, derived predominantly from Gram-negative bacteria, which give rise to high temperatures and fever-like reactions when injected into man and other mammals. This febrile reaction is referred to as *pyrexia* and compounds which can cause this reaction when injected are known as *pyrogens*. Bacterial endotoxins are not the only pyrogenic compounds but they are by far the most common and are also of the greatest significance in sterile product manufacture.

A3.2 The majority of bacterial endotoxins causing a pyrogenic reaction are lipo-polysaccharides (LPS) from the outer membrane of Gram-negative bacteria. They consist of a lipid A molecule with long polysaccharide side chains. The toxicity resides in the lipid portion of the molecule. The lipid moiety is hydrophobic and on its own would be insoluble in water but it is rendered soluble by the polysaccharide side chains. (The polysaccharide side chains are the molecules in the bacterial membrane which provide the surface antigens used to characterize individual strains of bacteria.)

A3.3 Organisms other than Gram-negative bacteria may give rise to endotoxins. For example fragments of the cell wall peptidoglycan from β haemolytic *Streptococci* produce a similar pyrogenic reaction.

A3.4 The relative molecular mass (RMM) of the LPS is typically in the range 3 000 –25 000 daltons. However, there is usually significant aggregation of endotoxin molecules in aqueous media; a number of molecules group together with the hydrophobic lipid moieties to the centre and the polysaccharide side chains to the outside. This effective increase in the size of the endotoxin explains why ultrafilters with cut-offs within the range 20 000–100 000 daltons can be used to effect almost complete removal of bacterial endotoxins from solution.

A3.5 Bacterial endotoxins are extremely heat-stable and are only destroyed after prolonged exposure to high temperatures (3 hours at 180°C or 30 minutes at 250°C). They are not destroyed by any of the sterilization processes commonly employed for medical devices and medicinal products.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Clinical significance

A3.6 In small doses the injection of endotoxins causes pyrexia (fever), transient leukopenia followed by leukocytosis, hyperglycaemia, haemorrhagic necrosis of certain tumours, abortion, altered resistance to bacterial infection, various circulatory disturbances and vascular hyperreactivity to adrenergic drugs. When injected in larger amounts, endotoxins cause shock, usually accompanied by severe diarrhoea; absorption of endotoxin from the bowel is a major cause of terminal irreversibility in haemorrhagic shock.

A3.7 Endotoxins appear to cause pyrexia, not directly but through an endogenous pyrogen released from polymorphonuclear leukocytes.

A3.8 Endotoxins are generally assumed to play a large role in the vascular, metabolic, pyrogenic and haematalogic alterations which occur in severe Gram-negative infections but the evidence is indirect since, unlike most bacterial exotoxins, no specific protective antibody is available.

A3.9 Subcutaneous injection of microgram quantities of endotoxins produces a mild inflammatory reaction but, when the injection is repeated with the same or a different endotoxin 24 hours later, the originally injected site becomes haemorrhagic within a few hours. This reaction (the Shwartzman reaction) is accentuated by the presence of cortisone. A similar programme of injections given intravenously to rabbits causes bilateral cortical necrosis of the kidneys and death.

A3.10 Many sterile medical devices are intended for use on wounds where the dermis may have been breached. The sterile product may thus come into direct contact with the vascular system and if endotoxins are present may cause a pyrogenic reaction.

Detection and measurement

A3.11 The classic method of detection of pyrogens in pharmaceutical products is by measurement of the temperature rise in rabbits to which the substance has been administered. This method does not readily permit assay of the amount of endotoxin present. However it is sensitive to all pyrogenic substances, whether or not they are bacterial endotoxins.

A3.12 In-vitro assay, which depends on the gelation of extracts of lysed blood cells of the horseshoe crab *Limulus polyphemus*, can be used quantitatively and will detect picogram quantities of lipopolysaccharide (endotoxin) in the so-called LAL test (Limulus amoebocyte lysate). A modification of the LAL test to provide a chromogenic test has been made, which allows reading of the endotoxin concentration by spectrophotometry. A turbidimetric method, which requires dedicated capital equipment, is also available as a quantitative method. Sensitivities as low as 0.001 EU ml^{-1} are available.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.13 There is considerable variability in endotoxins derived from different bacterial species and it is difficult to set limits of permissible amount in terms of mass per unit volume. The US Food and Drugs Administration devised a unit of potency, the *endotoxin unit* (EU), to overcome this problem. The units are related to the endotoxin derived from *Escherichia coli* assigned by comparison with a USP reference endotoxin. The 1st International Standard for Endotoxin, established in 1986, consists of lyophilised endotoxin from *E. coli* 0113:H10:K(-)ve with trehalose (normally supplied in ampoules containing 14 000 EU). This, or another suitable preparation (such as the European Pharmacopoeia Biological Reference Preparation) the activity of which has been determined in relation to the International Standard using a gelation method, permits standardisation of the sensitivity of the lysate.

Generation of bacterial endotoxin

A3.14 Endotoxins arise, almost without exception, from the cell wall of Gram-negative bacteria. This is present both on the surface of the living bacteria and as persistent fragments of dead bacteria. As previously noted the endotoxins are thermally very stable.

A3.15 Gram-negative bacteria include a wide range of organisms, for example:

a. the sheathed bacteria e.g. *Sphaerotilus spp* which are large rods in a mucilagenous sheath found anchored to the substrate in running water (also called sewage fungus);

b. some 17 genera of budding or stalked bacteria such as *Caulobacter*;

c. the aerobic rods and cocci which include:

   Pseudomonas spp, which are ubiquitous;
   Xanthomonas spp, common plant pathogens;
   Halobacterium spp, which live in saturated brine;
   Brucella spp, etc;

d. the facultative anaerobes:

   Escherichia, indicator of faecal contamination;
   Salmonella, Shigella, intestinal pathogens;
   Erwinia, plant pathogen;
   Enterobacter, Serratia, Proteus, soil and aquatic;
   Vibrio, commonly marine aquatic;

e. the obligate anaerobes of the family *Bacteroidaceae*, *Bacteroides*, *Fusobacterium*.

A3.16 These, or any other Gram-negative species, will inevitably give rise to endotoxins. However there are other organisms, such as β haemolytic *Streptococci*, where the cell wall peptidoglycan produces the same reaction as endotoxins from Gram-negative bacteria.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.17 The quantity of endotoxin produced per cell varies from about 4 femtograms (fg) in bacteria growing in very pure water to as much as 16 fg for those grown under nutrient-rich conditions. For *E. coli*, 0.03 EU ml^{-1} corresponds to approximately 0.003 ng per ml of endotoxin. Allowing that each cell produces approximately 6 fg of endotoxin then 500 bacteria per ml would give rise to 0.03 EU ml^{-1}.

A3.18 None of the sterilization processes used routinely for the preparation of pharmaceuticals, medical devices or surgical instruments will destroy or remove endotoxins once they are present. The only method of control therefore is to prevent the growth of significant numbers of Gram-negative bacteria within the product or in any component or material which directly comes into contact with it.

A3.19 Gram-positive bacteria, with the exceptions noted above, do not produce endotoxins. The Gram-positive bacteria include organisms such as the family *Micrococcaceae*, which contains the genera *Staphylococcus* and *Micrococcus*, and the spore formers of the genera *Bacillus* and *Clostridium*. It is among these organisms that those species most resistant to radiation and thermal sterilization are found.

Regulatory requirements

A3.20 Pharmacopoeial specifications for water include several different grades of which the two principal grades are Purified Water and Water for Injections (WFI).

A3.21 In the European Pharmacopoeia (EP) WFI is required to be prepared from potable water or purified water “by distillation in an apparatus of which the parts in contact with the water are of neutral glass, quartz or suitable metal and which is fitted with an effective device to prevent the entrainment of droplets. The apparatus must produce water free from pyrogens and to ensure this correct maintenance is essential. The first portion of the distillate obtained when the apparatus begins to function is discarded.”

A3.22 The United States Pharmacopoeia (USP), however, permits the use of reverse osmosis for the preparation of WFI. In all other respects the limits set, and the test to determine compliance, are essentially similar.

A3.23 USP XXII suggests an aerobic viable count limit of 500 cfu/ml for potable water and 100 cfu/ml for purified water (although normal practice would be not to accept >50 cfu/ml for purified water).

A3.24 WFI (both USP and EP) is required to be free from pyrogens and there is a specified limit for bacterial endotoxins of < 0.25 EU ml^{-1}.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A3.25 Where a product, such as a wound irrigation solution, is required under the terms of the product licence to be “non-pyrogenic” the endotoxin standard for WFI would apply even though the product is not actually for parenteral administration.

Requirements for clean steam

A3.26 The requirement for parenterally administered medicinal products to be free from pyrogens is immediately apparent. It is not always recognised, however, that a similar requirement exists for medical devices or that the steam sterilization process can be a source of pyrogen contamination.

A3.27 In the sterilization of solid goods (as opposed to aqueous fluids) steam in the sterilizer chamber condenses on the surface of the goods. This condensation process is necessary to heat the goods to the required temperature and provide the moist conditions necessary for rapid sterilization. At the end of the sterilization stage the condensate is evaporated from the load by reducing the pressure in the sterilizer chamber (drying vacuum) to produce a cooler, dry load.

A3.28 Bacterial endotoxin carried in the steam supply will be deposited with the condensate and tends to become concentrated on the surface of the goods when the condensate is evaporated off during the vacuum drying stage. In consequence, items intended for use in invasive procedures, or for use in the preparation or administration of parenteral products, should be sterilized in a sterilizer which is supplied with “pyrogen-free” steam.

A3.29 For practical purposes steam for use in sterilizers may be regarded as pyrogen-free when a condensed, representative, sample meets the European Pharmacopoeial standard for Water for Injections, i.e. less than 0.25 EU ml^{-1}.

A3.30 Two factors are of greatest importance in ensuring that the steam supply is pyrogen free:

a. the quality of the feedwater to the steam raising plant, high levels of pyrogens or high bacterial counts in the feedwater will ensure that limited carry-over of water as droplets in the steam will make a significant contribution to the pyrogen level;

b. the performance of the steam raising plant, in particular that its design, construction and mode of operation ensure that there is the minimum carry-over of entrained droplets of water.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Summary

A3.31 The following key points summarise the topics discussed above:

a. most pyrogens are bacterial endotoxins;

b. endotoxins are lipopolysaccharides formed by the cell wall of Gram-negative bacteria;

c. endotoxins are very stable molecules and are not destroyed by normal sterilization processes;

d. 90% of the bacteria growing in purified waters are Gram-negatives;

e. pyrogen testing was traditionally done by administering the substance to rabbits and observing whether there is a temperature rise;

f. endotoxin testing may be done *in-vitro* using the Limulus Amoebocyte Lysate (LAL) test;

g. the endotoxin limit for WFI (EP) is < 0.25 EU ml^{-1};

h. endotoxins are also of significance for medical devices, surgical equipment and equipment used to prepare parenteral medicinal products;

i. if the steam when condensed is within the endotoxin limit for WFI (EP) it may be regarded as “pyrogen-free”;

j. control of pyrogens in the steam is achieved by appropriate control of the boiler and its feedwater.

Appendix 4: Tests for clean steam

Introduction

A4.1 This appendix contains procedures for the testing of steam condensate samples for compliance with the clean-steam specification of Chapter 3. The tests for chemical purity and the test for bacterial endotoxins are derived from the tests for Water for Injections in the British Pharmacopoeia. A procedure for the field measurement of electrical conductivity is also given.

Laboratory tests for chemical purity

A4.2 The tests in this section are extracted from the British Pharmacopoeia 1993. They are essentially identical to corresponding tests in the European Pharmacopoeia. The tests should be conducted only by suitably trained persons familiar with pharmacopoeial custom and practice.

A4.3 The following tests are for Sterilized Water for Injections.

Acidity or alkalinity

A4.4 To 20 ml add 0.05 ml of *phenol red solution*. If the solution is yellow, it becomes red on the addition of 0.1 ml of 0.01 M *sodium hydroxide VS*; if red, it becomes yellow on the addition of 0.15 ml of 0.01 M *hydrochloric acid VS*.

NOTE: The method given in the 1993 edition of the BP is incorrect and is amended in the BP Addendum 1995.

Ammonium (0.2 ppm)

A4.5 To 20 ml add 1 ml of *alkaline potassium tetraiodomercurate solution* and allow to stand for 5 minutes. When viewed vertically the solution is not more intensely coloured than a solution prepared at the same time by adding 1 ml of *alkaline potassium tetraiodomercurate solution* to a mixture of 4 ml of ammonium standard solution (1 ppm NH_4) and 16 ml of *ammonia-free water* (0.2 ppm).

Calcium and magnesium

A4.6 To 100 ml add 2 ml of *ammonia buffer pH* 10.0, 50 mg of *mordant black 11 triturate* and 0.5 ml of 0.01 M *disodium edetate*. A pure blue colour is produced.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Heavy metals (0.1 ppm)

A4.7 In a glass evaporating dish evaporate 150 ml to 15 ml on a water bath. 12 ml of the resulting solution complies with *limit test A for heavy metals*. *Use lead standard solution (1 ppm Pb*) to prepare the standard (0.1 ppm).

A4.8 Limit test A for heavy metals: To 12 ml of the prescribed aqueous solution add 2 ml of *acetate buffer pH 3.5*, mix, add 1.2 ml of *thioacetamide reagent*, mix immediately and allow to stand for 2 minutes. Any brown colour produced is not more intense than that obtained by treating in the same manner a mixture of 10 ml of either *lead standard solution (1 ppm Pb*) or *lead standard solution (2 ppm Pb*), as prescribed, and 2 ml of the solution being examined. The standard solution exhibits a slightly brown colour when compared to a solution prepared by treating in the same manner a mixture of 10 ml of water and 2 ml of the solution being examined.

Chloride (0.5 ppm)

A4.9 When the nominal volume of the final container is 100 ml or less, 15 ml complies with the *limit test for chlorides (0.5 ppm).* Use a mixture of 1.5 ml of *chloride standard solution (5 ppm Cl)* and 13.5 ml of water to prepare the standard. Examine the solutions down the vertical axes of the tubes.

A4.10 Limit test for chlorides: To a solution of the specified quantity of the substance being examined in 15 ml of *water* or to 15 ml of the prescribed solution add 1 ml of 2 M nitric acid, pour the mixture as a single addition into 1 ml of *silver nitrate solution R2* and allow to stand for 5 minutes protected from light. When viewed transversely against a black background any opalescence produced is not more intense than that obtained by treating a mixture of 10 ml of *chloride standard solution (5 ppm Cl)* and 5 ml of water in the same manner.

Nitrate (0.2 ppm)

Sulphate

A4.12 To 10 ml add 0.1 ml of 2 M hydrochloric acid and 0.1 ml of *barium chloride solution R1*. The solution shows no change in appearance for at least 1 hour.

A4.11 To 5 ml in a test tube immersed in ice add 0.4 ml of a 10% w/v solution of *potassium chloride*, 0.1 ml of *diphenylamine solution* and, dropwise with shaking, 5 ml of *sulphuric acid*. Transfer the tube to a water-bath at 50°C and allow to stand for 15 minutes. Any blue colour in the solution is not more intense than that in a solution prepared at the same time and in the same manner using a mixture of 4.5 ml of *nitrate-free water* and 0.5 ml of *nitrate standard solution* (2 ppm NO_3) (0.2 ppm).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Oxidisable substances

A4.13 Boil 100 ml with 10 ml of 1 M *sulphuric acid*, add 0.2 ml of 0.02 M *potassium permanganate* and boil for 5 minutes. The solution remains faintly pink.

Residue on evaporation (30 ppm)

A4.14 Evaporate 100 ml to dryness on a water bath and dry the residue to constant weight at 100°C to 105°C. For containers with a nominal volume of 10 ml or less, the residue weighs not more than 4 mg (0.004%) and for containers with a nominal volume greater than 10 ml, the residue weighs not more than 3 mg (0.003%).

Laboratory test for pyrogens

A4.15 The following text is based on the bacterial endotoxin test from the British Pharmacopoeia 1993. Additional information pertinent to the analysis of steam condensate samples is given in notes.

A4.16 The test for bacterial endotoxins (LAL test) uses a lysate of amoebocytes from the horseshoe crab, *Limulus polyphemus*. The addition of a solution containing endotoxins to a solution of the lysate produces turbidity, precipitation or gelation of the mixture. The rate of reaction depends on the concentration of endotoxin, the pH and the temperature. The reaction requires the presence of certain bivalent cations, a proclotting enzyme system and clottable protein; these are provided by the lysate.

A4.17 The limit for a given material or preparation is expressed as the maximum allowable endotoxin concentration (MAEC) in endotoxin units per millilitre (EU ml^{-1}) for a defined solution of that material or preparation.

NOTE: The maximum allowable concentration for clean steam condensate is 0.25 EU ml^{-1}.

A4.18 Before carrying out the test for endotoxins on the sample, it is necessary to verify:

a. that the equipment used does not absorb endotoxins;

b. the sensitivity of the lysate; and

c. the absence of interfering factors.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: New borosilicate glass test tubes have a relatively high affinity for endotoxin in aqueous solution and may give rise to artificially low readings if used to make dilutions of endotoxin. Strict adherence to the reagent manufacturer's recommendations for choice and preparation of test equipment is necessary.

A4.19 Carry out the test in a manner that avoids microbial contamination. If necessary, treat equipment to eliminate endotoxins.

Reagents

A4.20 **Limulus amoebocyte lysate**. A lysate of amoebocytes from the horseshoe crab, *Limulus polyphemus*. Reconstitute the lysate as stated on the label. For each batch, confirm the stated sensitivity as prescribed under Sensitivity of the lysate. The sensitivity of the lysate is defined as the lowest concentration of endotoxin that yields a firm gel in the test conditions and is expressed in EU ml^{-1}.

NOTE: The LAL reagent is selected for the required sensitivity to endotoxin. 0.125 EU ml^{-1} is used to test for compliance with a maximum allowable endotoxin concentration of 0.25 EU ml^{-1}. The various commercially available LAL reagents differ in product compatibility, inhibition endpoints and buffer capacity. There may also be lot-to-lot variation within supplies from any one manufacturer.

A4.21 **Water BET**. Water that gives a negative result in the conditions prescribed in the test for bacterial endotoxins on the preparation being examined. It may be prepared by distilling water three times in an apparatus fitted with an effective device to prevent the entrainment of droplets or by other means that give water of the requisite quality.

A4.22 **0.1 M hydrochloric acid BET**. 0.1 M *hydrochloric acid* that has been prepared using *water BET*. After adjustment to pH 6.5 to 7.5 with 0.1 M *sodium hydroxide BET* it gives a negative result in the conditions of the test.

NOTE: The reconstituted lysate may be subdivided into suitable aliquots and frozen and stored at -20°C or below for up to 3 months. Frozen lysate should only be thawed once.

A4.23 **0.1 M sodium hydroxide BET**. 0.1 M *sodium hydroxide* that has been prepared using *water BET*. After adjustment to pH 6.5 to 7.5 with 0.1 M *hydrochloric acid BET* it gives a negative result in the conditions of the test.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Standard preparation

A4.24 The Standard Preparation is the 1st International Standard for Endotoxin, established in 1986, consisting of freeze-dried endotoxin from Escherichia coli 0113:H10:K(-ve) with trehalose (supplied in ampoules containing 14 000 EU), or another suitable preparation the activity of which has been determined in relation to the International Standard using a gelation method. (For this purpose the European Pharmacopoeia Biological Reference Preparation is recommended.)

NOTE: Reconstitute the Standard Preparation according to the manufacturer's instructions. Mix by repeated vortexing and prepare working standards by serial dilution using *water BET* and pyrogen-free dilution tubes.

Procedure

A4.25 Unless otherwise prescribed, prepare the solutions and dilutions used in the test using *water BET*.

NOTE: Lyophilised endotoxin has a threshold limit value of 5 EU kg^{-1} h^{-1}. Over-exposure may result in fever, nausea and shock. Avoid inhalation of the powder and injection of the reconstituted solution.

A4.26 If necessary, adjust the solution being examined to pH of 6.5 to 7.5 using 0.1 M *hydrochloric acid BET*, 0.1 M *sodium hydroxide BET* or a suitable buffer.

NOTE: The "solution being examined" may be the sample, dilutions of the Standard Preparation, control solutions, as appropriate.

A4.27 Add a volume of the lysate appropriate to the chosen receptacle (for example a slide or tube) to each of the requisite number of such receptacles maintained at 36°C to 38°C.

NOTE: Reaction tubes are recommended. The volume of lysate added should be 0.1 ml.

A4.28 At intervals that will permit the examination of each receptacle and the recording of each result, add to each receptacle an equal volume of the solution being examined and immediately mix gently with the lysate.

A4.29 Incubate the reaction mixture, without vibration and avoiding loss of water by evaporation, for a constant period that has been found suitable in the chosen experimental conditions (usually 20 to 60 minutes), examine the receptacle and record the result.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: Vibration during the incubation period can prevent stable gel formation. An unstirred water bath should be used since vibration from the motor in a stirred bath may interfere with the reaction. The tube should be incubated for 1 hour.

A4.30 A positive result is indicated by the formation of a firm gel that does not disintegrate when the receptacle is gently inverted. A result is negative if such a gel is not formed.

NOTE: Turbidity can be confused with initial stages of gelation. It is essential that all apparent gel formation is verified by demonstrating a stable gel on inversion through 180°.

Sensitivity of the lysate

A4.31 Prepare not fewer than four replicate series each of not fewer than three dilutions of the Standard Preparation such that at least the final dilution in each series gives a negative result. Examine the dilutions, and a negative control solution consisting of *water BET*, as described under *Procedure*. Calculate the average of the logarithm of the lowest concentration of endotoxin in each series of dilutions for which a positive result is found. The antilogarithm of this average gives the estimated lysate sensitivity. The estimated lysate sensitivity is confirmed if it does not differ by more than a factor of 2 from the stated sensitivity. The estimated sensitivity is then used in all tests performed using this lysate.

Interfering factors

A4.32 Operate as prescribed under *Sensitivity of the lysate* but to prepare the dilutions of the Standard Preparation use the sample at the maximum valid dilution calculated from the expression:

$$\frac{\textit{Maximum allowable entoxin concentration}}{\textit{Sensitivity of the lysate}}$$

both values being expressed in EU ml^{-1}.

A4.33 If the sensitivity of the lysate determined in the presence of the sample does not differ by more than a factor of 2 from that determined in the absence of the sample, the latter does not contain factors that interfere in the experimental conditions and it may be examined without further treatment.

A4.34 If the sensitivity of the lysate determined in the presence of the sample differs by more than a factor of 2 from that determined in the absence of the sample, the sample acts as an inhibitor or an activator. The interfering factors must be eliminated by suitable treatment such as dilution, filtration, neutralisation, dialysis or addition of substances that displace absorbed endotoxins. The use

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

of a more sensitive lysate permits the use of a greater dilution of the sample and this contributes to the elimination of interference.

A4.35 Ultrafiltration may be used when the interfering factor passes through a filter with a nominal separation limit corresponding to a molecular weight of 10 000 to 20 000. Asymmetrical membrane filters of cellulose triacetate or polysulphone have been found to be suitable. The material retained on the filter, which contains the endotoxins, is rinsed with *water BET* or a suitable buffer and endotoxins are recovered in *water BET* or a suitable buffer. The test volume and the final volume used to recover the endotoxins are determined for each preparation being examined.

A4.36 Establish that the chosen method effectively eliminates interference without removing endotoxins by repeating the test for interfering factors using the sample to which the Standard Preparation has been added and which is has then been submitted to the chosen treatment.

Test for bacterial endotoxin in the sample

A4.37 Carry out the method described under *Procedure* in duplicate using the maximum valid dilution of the sample which has been treated if necessary to eliminate interfering factors. Examine at the same time a negative control consisting of *water BET* and two positive controls each of which contains the Standard Preparation at a concentration corresponding to twice the stated sensitivity of the lysate and one which contains the sample (treated if necessary to eliminate interfering factors after the addition of the Standard Preparation) at the concentration being used in the test. The test is not valid unless the negative and both positive controls give the appropriate results.

Interpretation of results

A4.38 The sample complies with the test if a negative result is found for both test mixtures. The sample does not comply with the test if a positive result is found for both test mixtures. If a positive result is found for one test mixture and a negative result for the other, repeat the test; the sample complies with the test if a negative result is found for both test mixtures.

NOTE: For a given batch of lysate of calibrated sensitivity λ EU ml^{-1}, a positive result will indicate the presence of endotoxin within the range 0.5 λ to 2 λ EU ml^{-1}.

Field test for electrical conductivity

A4.39 The only test of steam condensate or feedwater that can be reliably carried out on site is a test for electrical conductivity. Guidance on the interpretation of conductivity measurements is given in Chapter 7.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A4.40 A portable conductivity meter is required, accurate to 1% over a range which includes 1.0 to 30 µS cm^{-1} with a resolution of 0.1 µS cm^{-1}. It should be temperature-compensated over the range 0°C to 40°C, so that it gives readings standardised to 25°C. The instrument should be designed to measure the conductivity of very pure water.

A4.41 Commercially available meters usually have temperature compensation set at 2% per °C either as standard or as a default value. The compensation effect is often user-adjustable over the range 0-5% per °C, but unless there are unusual local circumstances (such as a particularly ubiquitous contaminant) the temperature compensation value should be set at 2% per °C.

A4.42 Several standard conductivity reference solutions are also required, preferably with conductivities which bracket the expected value. A range of such standards, including pure water standards (also known as absolute water) is available commercially, standardised at 25°C and traceable to national standard reference materials. The standards should be allowed to equilibrate to room temperature in the area in which the tests will be conducted.

A4.43 Carry out the BP test for acidity or alkalinity (see paragraph A4.4). If the sample is fresh condensate, there is no need to boil the sample as described in the test. If the sample complies with the test, then it may be tested for conductivity.

A4.44 Wash the meter probe with Purified Water BP or with the sample water. Measure the conductivity of the standards. Use the results to calibrate the meter in accordance with the manufacturer's instructions.

A4.45 Measure the temperature of the sample. For effective temperature compensation, this test is best carried out with both sample and standards near a temperature of 25°C. If the sample is hotter, allow it to cool until the temperature is approximately 25°C.

A4.46 Wash the meter probe either with Purified Water BP or with the sample water. Measure the conductivity of the sample.

A4.47 The test should be considered satisfactory if the measured conductivity:

a. does not exceed the value specified for clean steam in Table 2;

b. is consistent within experimental errors with the value measured during validation.

A4.48 If the conductivity has risen substantially from the value determined during validation, the cause should be identified and corrected.

Glossary

The following terms have been used in this SHTM. Chapter or paragraph references to where more information may be found are given in brackets. Cross-references are shown in bold.

bacterial endotoxins
A group of compounds derived predominantly from **Gram-negative** bacteria, which give rise to high temperatures and fever-like reactions when injected into mammals. Also known as **pyrogens** (Appendix 3).

blow-down
The process of removing sludge from a boiler by using the internal pressure to expel it from a valve in the bottom of the vessel (4.15, A2.8).

carry-over
The delivery of substantial quantities of liquid water in steam due to **priming** or **foaming** (4.5).

clean steam
Steam whose **condensate** meets the purity requirements of **Water for Injections BP** with additional limits for phosphate and silicate (3.24).

clean-steam generator
A boiler designed to produce **clean steam** (4.26).

condensate
Water formed by the condensation of steam.

Conductivity
A measure of the ability of a material to pass an electric current. Reciprocal of resistivity (7.25).

cyclonic separator
A device forming part of a **clean-steam generator** that removes entrained water droplets from steam by causing the steam to rotate at high speed (4.29).

degassing
A pre-heating treatment of boiler **feedwater** to reduce the amount of **non-condensable** gases in the steam supply (4.48).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

deionisation (DI)
A water purification process in which ions and other electrically charged particles are removed from solution either by the influence of an electric field or by ion exchange columns (4.46).

dryness value
A dimensionless quantity, approximating to the dryness fraction, derived to determine whether steam is of the correct dryness for sterilization purposes. A dryness value of 1.0 represents saturated steam (3.10).

BS EN 285 steam
Steam whose **condensate** meets the recommended purity requirements for steam contained in BS EN 285 (3.20).

endogenous infection
Infection due to re-activation of organisms in a dormant focus.

endotoxin unit (EU)
A measure of the potency of **bacterial endotoxins** in relation to those derived from E. coli (A3.13).

feedwater
Water that is to be used for the generation of steam.

foaming
The production of a head of foam within a boiler, often due to a raised level of **total dissolved solids**, which is drawn off with the steam so leading to a wet and contaminated steam supply (4.6).

Gram-negative
A class of bacteria that do not take Gram's stain and which are also sources of **bacterial endotoxins (pyrogens)** (A3.14).

hot well
A tank in which **feedwater** is maintained at a high temperature to drive off dissolved gases before it is admitted to a boiler (4.48).

make-up water
Freshly treated water often mixed with returned steam **condensate** to make feedwater for a boiler.

medical device
Any instrument, apparatus, appliance, material or other article, whether used alone or in combination, including the software necessary for its proper application, intended by the manufacturer to be used for human beings for the purpose of diagnosis, prevention, monitoring, treatment or alleviation of disease; diagnosis, monitoring, treatment, alleviation of or compensation for an injury or handicap; investigation, replacement or modification of the anatomy or of a physiological process; control of conception; and which does not achieve its principal intended action in or on the human body by pharmacological, immunological or metabolic means, but which may be

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

assisted in its function by such means (source: EU Council Directive 93/42/EEC) (3.6).

medicinal product
Any substance or combination of substances presented for treating or preventing disease in human beings or animals. Any substance or combination of substances which may be administered to human beings or animals with a view to making a medical diagnosis or to restoring, correcting, or modifying physiological functions in human beings or in animals is likewise considered a medicinal product (source: EU Council Directive 65/65/EEC) (3.3).

non-condensable gas
Gases which cannot be liquefied by compression under the range of conditions of temperature and pressure used during the **operating cycle** of a sterilizer (3.10).

packaged boiler
A small local boiler used to supply steam for a **clean-steam generator** (4.33).

parenteral
Of a **medicinal product**, administered by means other than through the digestive tract, and especially by injection.

pitot
A metal tube of narrow bore inserted along the axis of a steam pipe and designed to extract a sample of steam for testing or collection (6.9).

potable steam
Process steam intended for culinary applications and meeting the purity requirements of drinking water (3.18).

priming
Of a boiler, the delivery of steam containing water in suspension due to violent boiling or frothing (4.5).

process steam
Steam whose quality is not optimised for sterilization (3.16).

pyrogen
A **bacterial endotoxin** that causes a rise in body temperature and which is not destroyed by steam **sterilization** (Appendix 3).

residue on evaporation
The mass of solid remaining when a given volume or mass of aqueous solution is evaporated. Unit: mg litre^{-1} or ppm. See also **total dissolved solids** (7.16).

reverse osmosis (RO)
A water purification process in which impurities are filtered out by forcing the water through a semi-permeable membrane (4.46).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Sterilized Water for Injections BP (Sterilized WFI)
A grade of **Water for Injections BP** designed for dilution of sterile medicinal products intended for subsequent intravenous administration (3.31).

Sterile Water for Irrigation
Sterile Water for Irrigation is a sterile, nonpyrogenic preparation of Water for Injections BP, containing no antimicrobial agent or other substances.

total dissolved solids
The mass of solid material dissolved in a given volume or mass of aqueous solution. Unit: mg litre^{-1} or ppm. See also **residue on evaporation**.

Water for Injections BP
A pharmaceutical preparation designed for administration by injection consisting of distilled water that meets the purity specifications of the British Pharmacopoeia (3.30).

Water for Injections in Bulk BP
A grade of **Water for Injections BP** designed for use in the manufacture of medicinal products that are to be terminally sterilized and intended for administration by injection (3.31).

Scottish Health Technical Memorandum 2040

(Part 1 of 6)

Overview and management responsibilities

The control of legionellae in healthcare premises – a code of practice

ARCHIVE

IMPORTANT NOTE
LEGIONELLA
SHTM 2040 and the HSC Approved Code of Practice and Guidance (L8) 2000

HSC's Approved Code of Practice came into effect on 8 January 2001. At this time i.e. December 2001 the UK Health Department's Guidance HTM 2040 (SHTM 2040 in Scotland) has not been aligned with the ACOP. Work is ongoing but it is unlikely that HTM 2040 and SHTM 2040 will be updated until late 2002 and launched on a UK basis.

L8 takes cognisance of 'hospitals' but requires considerable interpretation for practical application. The revised UK Health Department Guidance will undertake to address this issue.

In the meantime this version of SHTM 2040 must be read as subordinate to the new ACOP.

1. Introduction

General

1.1 The guidance contained in this part is applicable to new and existing sites, and is for use at various stages during the inception, design, upgrading, refurbishment, extension and maintenance of a building.

1.2 The approach should be to remove all potential sources of seeding, growth and spread of legionellae. Where this ideal cannot be achieved in existing situations, steps should be taken to control and prevent legionellae by sound operational management.

1.3 The control of legionellae is a continuing responsibility. The effectiveness of precautionary measures should be continually monitored, and a continuing programme to ensure awareness should be devised. Although knowledge of legionellosis has improved markedly in recent years there is a continuing misunderstanding about the method of dissemination. Many people are under the impression that cooling towers are the only source of legionellae in building service systems. All water systems are capable of colonisation by legionellae, and taps are just as capable of generating an aerosol as showers or, indeed, cooling towers.

1.4 The biggest risk is complacency leading to the deterioration of water hygiene to the extent that an outbreak of the disease occurs.

1.5 The general manager/chief executive has the responsibility of ensuring that designated staff are appointed.

1.6 This SHTM does not include advice on water supplies for clinical equipment such as dialysers, nebulisers and respiratory humidifiers or for water services for pharmacy and dental departments. Users of clinical humidifiers and nebulisers are reminded that sterile water, not tap water, should be used and that they should be emptied and cleaned thoroughly following each period of use. All equipment with water reservoirs should be stored dry. Water for any other purpose should meet any identifiable local requirements, but users must recognise that any water system may provide a suitable environment for legionellae and other water-borne organisms.

1.7 SHTM 2027; *Hot and cold water supply, storage and mains services* should be consulted for guidance on the general design and operation of water systems in healthcare premises.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

A48235836

Application to premises

1.8 Precautions to prevent outbreaks of legionnaires' disease are required even in those premises which have to date not been infected. The guidance should be used for all sites where there is in-patient or out-patient accommodation, for example hospitals, clinics, health centres and Blood Transfusion Service premises.

Priorities

1.9 Premises designed since 1988 should be in compliance with SHTM 2040; The control of legionellae in healthcare premises – a code of practice, with reference to SHHD/DGMs (1988)50; (1989)35; 1989(77); 1990(51) and 1991(15).

1.10 All existing premises should be regularly reviewed to identify where they do not meet the advice of this SHTM. A realistic programme should be prepared to eradicate any shortfall. Priority should be given to patient areas, although the exact priority will depend on local circumstances.

NOTE: Reference must be made to Health and Safety Commission, 'Legionnaires' disease, The control of legionella bacteria in water system – Approved Code of Practice and Guidance' issued 2000.

2. Statutory obligations

Health and Safety at Work

2.1 Employers have a general duty, under the Health and Safety at Work etc Act 1974, to ensure, so far as is reasonably practicable the health, safety and welfare of their patients, employees and visitors. These duties are legally enforceable, and the Health and Safety Executive (HSE) have successfully prosecuted occupiers of premises under this statute for outbreaks of legionnaires' disease. It falls upon both the owners and occupiers of premises to ensure that there is a management regimen for the proper design, installation and maintenance of plant, equipment and systems. Failure to have a proper system of work and adequate control measures can also be an offence even though an outbreak has not occurred.

Control of Substances Hazardous to Health (COSHH) Regulations

2.2 Also relevant are the Control of Substances Hazardous to Health (COSHH) Regulations 1999 which came into force in 1999. In the context of hot and cold water supply, storage and mains services, these regulations apply to micro-organisms, including legionellae, which could create a health hazard. These regulations also apply to the chemicals which may be used to control the growth of organisms in water supply.

Reporting requirements under health and safety legislation

2.3 The Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1995 came into force on April 1996. These place a responsibility on employers to report cases of work related disease to the HSE. The list of reportable diseases includes a number of infections which could be related to work within health services and includes legionellosis.

The Public Health (Infectious Diseases) Regulations 1975 requires that a properly appointed officer shall inform the Chief Medical Officer of any serious outbreak of the disease which to his knowledge has occurred. Reference should also be made to Public Health (Notification of Infectious Diseases) Scotland Regulations (1988) and amendment regulations 1989.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

NOTE: Further advice is given in the Scottish Infection Manual: 'Guidance on Core Standards for the control of infection in Hospitals, health care premises and at the community interface' issued by the Public Health Policy Unit Room 401, St. Andrews House, Scottish Executive Health Department, Edinburgh EH1 3DG.

Water Supply Regulations

2.4 The Water Supply (Water Quality) (Scotland) Regulations 1990 (as amended) apply to water stored and distributed within any hospital which is used for drinking and any domestic purpose.

2.5 The Private Water Supplies (Scotland) Regulations 1992 (Statutory Instrument No. 2790) cover private water supplies (Boreholes and Wells).

NOTE: Legionellosis is a notifiable disease: 'The European Community Directive Relating to the Quality of Water Intended for Human Consumption'; Council Directive 80/778/EEC.

Food Safety Act

2.6 The Food Safety Act 1990 covers for water used for food preparation or food manufacture, and also includes water used for drinking.

NOTE: Reference should also be made to Food Safety (General Food Hygiene) Regulations 1995, and Food Safety (Temperature Control) Regulations 1995.

Approved Code of Practice

2.7 The Health and Safety Commission have published 'Legionnaires disease, The control of legionella bacteria in water systems – Approved Code of Practice and Guidance 2000'. This single publication replaces the 1995 ACOP and the technical guidance HSG 70. This has allowed information to be consolidated, with the aim of making it easier to read and understand the duties under the law.

2.8 The health service, with responsibility for the wider aspects of public health and the operation of NHS premises, is expected to be particularly vigilant. The courts will expect a higher standard of care from public bodies, given the resources available to them and the greater risks to the occupants of these premises. Though the number of outbreaks of legionnaires' disease is relatively small, outbreaks are considered to be avoidable. Management must also acknowledge that incidents or outbreaks cause widespread

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

A48235836

concern especially if associated with healthcare premises. Investigation of these outbreaks has shown that they are generally related to a breakdown in management systems. Design flaws and defects have also been implicated as the cause of some outbreaks.

2.9 Hence, managers need to satisfy themselves, by monitoring, that the procedures are being implemented. It is not sufficient merely to devise procedures.

2.10 It is a widely held misconception that wet cooling towers are the only source of the disease, and that a building without such a tower presents no risk. All water systems are liable to colonisation by legionellae.

2.11 The prohibition of wet cooling towers is not envisaged; in some instances, they provide the only practicable solution. The relevant statutory requirement is to assess risk and the measurements to prevent (or where it is not reasonably practicable to prevent, to minimise) the risk from exposure to legionellae.

2.12 The Notification of Cooling Towers and Evaporative Condensers Regulations 1992 requires the registration of cooling towers and evaporative condensers to the local authority.

NOTE: Directors of environmental health are required to maintain a register of cooling towers and whirlpool spas in association with the Health and Safety Executive.

3. Management responsibility

Management accountability

3.1 The chief executive or general manager has overall responsibility for all aspects of the quality of water supplies within his/her organisation.

3.2 The procedures instituted should be such as to demonstrate that any person on whom the statutory duty falls has fully appreciated the actual and potential risks of legionellae. Though compliance with this guidance may be delegated to staff, or undertaken by contract, accountability cannot be delegated.

3.3 Regular assessments should be made at least annually, using this guidance, to establish the extent of risk. Shortfalls should be clearly recorded and the proposed control measures, with timescales, developed. A review should be undertaken whenever there is a substantial change in physical environmental conditions.

3.4 The objective must be to institute management procedures to ensure that compliance is continuing and not notional. The prime purpose of the assessment is to be able to demonstrate that management has identified all the relevant factors, has instituted corrective or preventative action, and is monitoring that the plans are being implemented.

3.5 This guidance should be applied to all healthcare premises, however small, where there is a duty of care under the Health and Safety at Work etc Act 1974. Smaller premises, such as clinics, present a risk in the same way as a major hospital. Intermittently used areas, for example premises not used over the weekend, may present ideal environments for the growth of legionellae.

NOTE: Reference should be made to Part 6 of this SHTM 'Supplementary guidance applicable to intermittently used healthcare premises'.

Role of infection control team

3.6 The infection control team (legionella) should be nominated in writing by the chief executive or general manager for advising on and monitoring infection control policy for legionnaires' disease. The infection control team (legionella) should be involved in the production of the policy and management procedures for the control of legionellae. Similarly, the team has a key role in formulating the plans for its implementation.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

NOTE: Reference should be made to the Scottish Infection Manual 1998: 'Guidance on Core Standards for the Control of Infection in Hospitals, Health Premises and at the Community Interface' issued by the Public Health Policy Unit Room 401, St. Andrews House, Edinburgh, Scottish Executive Health Department, Edinburgh EH1 3DG.

3.7 Additionally, the policy should be acceptable to the control of infection team and any amendment to that policy must be agreed by the team.

Nominated person

3.8 A nominated person (legionella), possessing adequate professional knowledge and with appropriate training, should be nominated in writing by the general manager or chief executive to devise and manage the necessary procedures for the prevention of legionnaires' disease. The persons will be required to liase closely with other professionals in various disciplines. In addition, the person should possess a thorough knowledge of the control of legionellae and would ideally be a Chartered Engineer.

NOTE: Training courses on minimising the risk of legionellae in water systems are available from The Property and Environment Forum Executive.

3.9 This person's role, in association with the infection control team and maintenance staff, involves:

a. advising on the potential areas of risks and identifying where systems do not comply with this guidance;

b. advising on the necessary continuing procedures for the prevention of legionellae;

c. monitoring the implementation and efficacy of those procedures;

d. approving and identifying any changes of those procedures;

e. maintaining adequate records.

3.10 Implementation of an effective maintenance policy must incorporate the creation of fully detailed operating and maintenance documentation and the introduction of a logbook system. The "nominated person" should appoint a deputy to whom delegated responsibilities may be given. The deputy should act for the nominated person on all occasions when the nominated person is unavailable.

3.11 The nominated person should be fully conversant with the design principles and requirements of water systems and should be fully briefed in respect of the causes and effects of contamination with legionella. The appointment of an engineer as the nominated person is appropriate in that the responsibility can extend to the operation and maintenance of the associated plant. It is

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

A48235836

recognised that the nominated person cannot be a specialist on all matters and must be supported by specialists in specific subjects such as water treatment and microbiology, but he/she must undertake responsibility for calling upon and co-ordinating the activities of such specialists.

Hazard assessment

3.12 Legionellae, which causes legionellosis, are naturally widespread in water systems. It is exceptional for a water supply, either public or private, to be entirely free from aquatic organisms, and for this reason it is important that appropriate measures are taken to guard against conditions which may encourage microbial multiplication. Provided water is derived from the public mains and its quality is preserved in the storage and distribution system by correct design, installation and maintenance, it can be regarded as being microbiologically acceptable for use without further treatment. Strict adherence to the guidance in this SHTM will not eradicate legionellae, but there will be reduction in the risk of an outbreak.

3.13 The number of organisms which cause infection has not been reliably determined and is likely to vary from person to person. However, all patients are at risk, and those who are immunocompromised can be particularly susceptible.

3.14 Particularly susceptible patients will be those found in departments concerned with:

a. head/neck cancer;
b. bone marrow transplant;
c. renal dialysis;
d. leukaemia;
e. organ transplant;
f. AIDS.

3.15 Outbreaks have been linked to the inhalation of infected aerosols. Most people recognise that showers and wet cooling towers generate aerosols. Less well known is that a ‘fog’ of aerosols is generated when a bath or basin is filled. Aerosols can be generated from any water outlet, and no water outlet can be considered free from potential risk. Hence baths, spa baths and hydrotherapy pools also represent hazards. If the water is contaminated, the possibility of the organism being entrained in the aerosol increases.

3.16 These aerosols are buoyant and can remain suspended in the air for a relatively long time. Any air movement will distribute them over quite large distances. Recently it has been shown that the organism can survive even after the “wet” layer of the aerosol has dried.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

3.17 For certain immuno-compromised patients there may be other routes of infection. However, since these represent minimal risk, the SHTM does not deal with these aspects.

Prevention

3.18 It has been suggested that the following “chain of causation” must exist for legionellosis to be acquired:

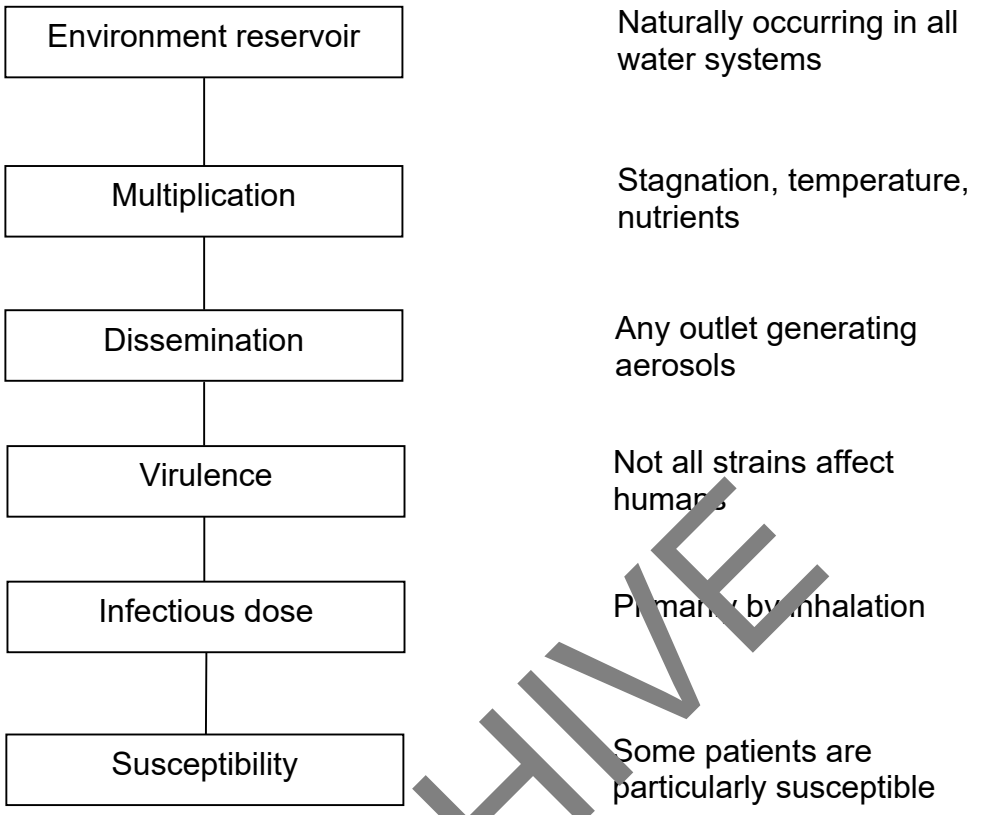
a. an environmental reservoir;
b. opportunity for multiplication;
c. a mechanism for dissemination;
d. virulence to the human host;
e. inoculation of an infectious dose;
f. host susceptibility.

(See Figure 1, Chain of causation.)

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Figure 1: Chain of Causation



ARCHIVE

3.19 Employing this hypothesis, the key preventative measures that may be applied are those which break the chain of causation. Strict procedures for water supply hygiene and disinfection are essential and particular attention should be paid to outlets.

NOTE: Refer to EH M(92)3 and SHPN2.

3.20 Simple precautions to achieve this objective are:

a. removing all taps and outlets and associated pipework which are not needed, due to disuse or under-use;

b. ensuring that the hot water from the calorifier is at or above 60°C and that it does not fall below 50°C in the circulation pipework;

c. keeping the length of the pipework carrying blended water at 24-45°C to the minimum (never more than 2 m);

d. reducing the length of dead-legs or spurs from the main hot water circulation system to the minimum (maximum 5 m);

e. avoiding water stagnation;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

f. introducing an appropriate level of maintenance and ensuring correct and safe operation;

g. maintaining the cleanliness of water systems;

h. using adequate water treatment in wet cooling towers;

i. keeping storage cisterns clean and sealed from extraneous matter and insulating where necessary to maintain temperatures below 20°C;

j. reducing the amount of water stored (24 hours maximum).

3.21 Where systems are known to be of uncertain quality or where consistent problems have been identified, a regimen of additional water treatment systems may be appropriate.

Monitoring and record keeping

3.22 Based on this guidance and the results of the risk assessment, a written operational plan should be devised. This should clearly identify who has overall accountability for the premises, and who is responsible for devising and carrying out the procedures. The record should include the systems, plant and equipment which pose a potential threat, and a detailed schedule of the preventative maintenance procedures. Finally, provision should be made in the plan for evaluation of the efficacy of the measures.

Water supply and distribution

3.23 It is exceptional for a water supply, either public or private, to be entirely free from aquatic organisms, and consequently it is important that appropriate measures are taken to guard against conditions that may encourage microbial multiplication. Legionellae, like other opportunist pathogens including *Aeromonas hydrophila* and *Pseudomonas aeruginosa*, are common in the environment and as such can seed treated water systems during construction.

3.24 Micro-organisms can also be introduced during refurbishment, repair, alteration or during routine inspection and sampling.

3.25 Hospital sites are generally large and often contain complex storage reservoirs and distribution systems similar to those operated by the water authorities. The water authorities or a specialist consultant can assist with the design, specification, tendering and commissioning of such water systems.

3.26 Wherever possible, publicly supplied mains water should not be mixed with private supplies. Each should be separately identified. Where mixing does occur it must be protected by a Type A air gap.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Water treatment regimen

3.27 The regimen of water treatment chosen should be agreed by the infection control doctor (legionellae) and the nominated person (legionellae). The regimen should be of proven efficacy, and substances and products to be used in contact with potable water supplies must be listed in the current edition of the Water Bylaws Scheme's (WBS) Water Fittings and Materials Directory (WFMD).

NOTE: Reference should be made to SHTN 2. The WRc, byelaws scheme is not in itself sufficient. For new materials CCM committee or WRc Medenham (J Fawells Dept.) approval on toxicity levels is required.

3.28 Chemical conditioning systems which are used in conjunction with potable water systems should be selected very carefully. Addition of any substance must not cause a breach of any requirement in the Water Supply (Water Quality) (Scotland) Regulations, and any system for introducing a substance must be listed in the current edition of the WFMD.

3.29 Consideration should be given as to whether or not the process kills only the organisms flowing through the equipment (leaving no residual disinfecting agent in the water) or whether agents are released into the water circuits.

3.30 Further care should be taken to ensure that adequate filtration and/or reverse osmosis is used to provide a pure water supply free of contaminants for water serving clinical processes, for example dialysis equipment.

Air conditioning

3.31 Air-conditioning and ventilation systems have been shown to provide a route for distributing contaminated air throughout a building. Particular attention should be paid to the humidification process. Ductwork should be examined for evidence of "ponding", that is, places where water has collected.

NOTE: Refer to SHTM 2025; *Ventilation in Healthcare Premises*.

Design and build contracts

3.32 An outbreak of legionnaires' disease has been associated with healthcare premises built under the "design and build" type of contract, under which the client retains no clerk of works on-site and there is no "commissioning" period on completion of the work. It is essential to ensure that, immediately before occupation, the measures outlined in this SHTM have been taken for disinfection and maintenance of temperatures. A nominated person (legionellae) should be appointed immediately before handover. (Adequate

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

documentation, including “as-fitted” drawings, should be available at the time of handover.)

NOTE: Refer to SHTN No. 1, PCD.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

4. Epidemiology

General

4.1 Although legionnaires' disease was first recognised in July 1976, when an outbreak occurred among delegates attending an American Legion Convention in Philadelphia, the cause of the outbreak was not identified until January 1977 when the Center for Disease Control in Atlanta reported the isolation of the aetiological agent which they named *Legionella pneumophila*. Diagnostic tests were developed which revealed earlier outbreaks of the disease and sporadic cases dating back to the 1940s. Thus the infection was not new, but had escaped recognition.

4.2 Legionnaires' disease is an illness characterised mainly be pneumophila. Typically it begins quite abruptly with high fever, chills, headaches and muscle pain. A dry cough soon develops, and most patients suffer difficulty with breathing. About one-third of patients also develop diarrhoea or vomiting and about half become confused or delirious. The case fatality rate is similar to that of most other types of pneumonia.

4.3 *L. pneumophila* can also cause a short febrile (feverish) illness without pneumonia known as Pontiac fever. Since *L. pneumophila* was originally isolated, several other species of legionella capable of causing pneumonia have been described in the UK and elsewhere. The 1988 outbreak of non-pneumonic legionellosis at Lochgoilhead in Scotland, now referred to as Lochgoilhead fever, was attributed to the species *L. micdadei*. Legionellosis is the generic term used to cover legionnaires' disease, Pontiac fever and Lochgoilhead fever.

4.4 To date, at least 37 different species of legionellae are recognised. The species most commonly associated with disease outbreaks is *L. pneumophila*. Fourteen different serogroups of *L. pneumophila* have been described, *L. pneumophila* serogroup 1 being most commonly associated with cases of legionnaires' disease in the UK.

4.5 There are various sources of the organism and various routes of transmission to humans. Domestic hot water services in large buildings have been shown to be the most common source, but evaporative cooling towers serving the air-conditioning plant in these types of establishment have also been implicated. A poorly maintained whirlpool spa has also been show to be a source, as have individual wall-mounted humidifiers and nebulisers using tap water.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

4.6 In all these instances, the infection is considered to have been acquired by inhalation of small water droplets carrying the bacteria. Aerosols containing such droplets may be generated by running taps or showers and during the normal operation of cooling towers and evaporative condensers. Survival of the bacterium in an aerosol is enhanced if the ambient relative humidity is greater than 65% and if it is sheltered from direct sunlight. Viable bacteria contained within aerosols may travel great distances.

4.7 The incubation period (the time between exposure to the organism and the development of first symptoms) may range from 2-10 days. There is no record of person-to person spread of infection. The bacterium is not highly virulent, but may infect individuals who are susceptible. In most outbreaks fewer than 5% of people exposed to the source of infection have contracted legionnaires' disease, although in some hospital units such as renal and oncology wards, greater attack rates have been reported.

Risk of infection

4.8 The principle route of infection is through inhalation of the bacteria into the lungs. The risk increases with increasing numbers of inhaled bacteria. Other infection routes may include ingestion and external wounds.

Source of bacteria

4.9 The bacterium is ubiquitous, surviving and multiplying in water. It is widespread in natural fresh water including rivers, lakes, streams and ponds and may also be found in wet soil. Airborne dispersal may occur when water droplets are created. There is a strong likelihood of very low concentrations of the bacteria existing in all open water systems including those of building services. There is also a risk where earthworks are taking place near to open windows or intakes to air-conditioning/ventilation systems.

4.10 The risk is related to the number and types of bacteria in the water at the point of use.

Aerosol generation

4.11 Contaminated water presents a risk when it is dispersed into the air as an aerosol. This risk increases with reduced droplet size for two reasons. First the smaller the droplet, the longer it remains airborne. Second, small droplets (5 microns diameter or less) penetrate deeply into the lung and cannot easily be expelled. However, larger droplets can evaporate and become smaller ones, still containing the initial number of organisms. Aerosols are produced merely by water streams breaking up after striking a surface or by a bubble bursting on the water surface.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

4.12 In both a cooling tower and an evaporative condenser, water is distributed over large areas of wetted surfaces to create intimate contact between air and water, increasing the opportunity for the formation of aerosols. Water services are also capable of generating aerosols from the impact of tap water hitting wash-basins, sinks and baths, and from showers.

4.13 In whirlpools and spas the refreshing agitation of the water is achieved by the combination of air jets and pulsating water flow. Splashing of water and bursting of the air bubbles as they break through the water surface creates an aerosol immediately above the water surface.

4.14 The risk increase with the number of “infected” droplets in the aerosol generated, especially if the size of the droplet in the aerosol is within the range 2 to 5 microns in diameter.

Number of inhaled bacteria

4.15 Two factors determine the number of bacteria actually inhaled:

a. the concentration of bacteria in the air:

   (i) this is determined both by the concentration of bacteria in the water and by the amount of contaminated water dispersed into a given air volume. The concentration of live bacteria in the air falls rapidly with distance from the source. Where a cooling tower and the fresh-air inlet to a building are both at roof level, it may be possible for contamination from the tower to reach the air inlet and hence enter the building;

   (ii) the quantity entering will depend primarily on the separation distance between the tower and the fresh-air inlet. Increasing this distance of separation and locating the air inlet upwind (prevailing wind) of the tower will help to reduce the likelihood of water droplets containing legionellae from entering the building;

b. the duration of exposure to the contaminated air;

   (i) exposure in a shower is usually limited to few minutes, while exposure in a spa is usually longer. Exposure to airborne legionellae distributed in a building from a contaminated cooling water system may take place whenever the tower is operating, which may be most of the day during the summer;

   (ii) the risk increases with the number of legionellae in the air and with the respiratory rate of the individual, and the length of time the person is exposed. The chances of legionella infections occurring increase with the number and susceptibility of people exposed.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Susceptibility of individuals

4.16 While previously healthy people may develop legionnaires' disease, there are a number of factors which increase susceptibility:

a) increasing age, particularly above 50 years (children are rarely infected);

b) sex: males are three times more likely to be infected than females;

c) existing respiratory disease which makes the lungs more vulnerable to infection;

d) illnesses, such as cancer, diabetes, kidney disease or alcoholism, which weaken the natural defences;

e) smoking, particularly heavy cigarette smoking, because of the probability of impaired lung function;

f) patients on renal dialysis, or on immuno-suppressant drugs which inhibit the body's natural defences against infection.

ARCHIVE

5. Ecology

5.1 The following conditions have been found to influence the colonisation and growth rate of legionella:

a. water temperatures in the range 20-45°C favour growth. It is uncommon to find proliferation below 20°C, and the organisms do not survive long above 60°C. The optimum laboratory temperature for the growth of the organism is 37°C , that is, body temperature. Organisms may, however, remain dormant in cool water, multiplying only when the temperature reaches a suitable level;

NOTE: The death curve is logarithmic with time for a given temperature.

b. the presence of sediment, sludge, scale and organic material provides a good nutrient source for legionellae. Evidence suggests that the presence of iron oxide (rust) also favours the growth of the organism;

c. legionellae have been shown to colonise certain types of water fitting, pipework and material used in the construction of water systems. The presence of such materials and of large quantities of sediment may provide nutrients for legionellae and can make eradication difficult;

d. other commonly encountered organisms in water systems such as algae, amoebae and other bacteria may serve as an additional nutrient source for legionellae. Algal slime may provide a stable habitat for multiplication and survival. Legionellae have been shown to proliferate rapidly in association with slime water-borne amoebae;

e. exposure to direct sunlight may inhibit the growth of legionellae while stimulating the growth of algae and the formation of slimes;

f. biofilms are thought to play an important role in harbouring and providing favourable conditions in which legionellae can grow;

NOTE: A biofilm is a slime which develops on surfaces in contact with water.

g. stagnant water encourages colonisation.

Appendix: Management checklist

Legionellosis risk assessment

1. Appoint infection control doctor (legionella) and nominated person (legionella).

NOTE: A logbook recording the action taken on this checklist is recommended.

2. Produce record of drawings and schematics for all water systems. The drawings/schematic should show:

NOTE: Existing drawings should be checked for accuracy.

a. layout and arrangement of all calorifiers and pumps;
b. layout and arrangement of all cisterns, humidifiers and cooling towers;
c. all other water systems, such as hydrotherapy pools, which may present a legionellosis hazard;
d. dead-legs and blind ends, with lengths and diameter indicated;
e. operation and check points for cross-referencing with operational instructions and temperature records.

There should also be adequate documentation which details the engineering design intent and maintenance and operation procedures.

3. Identify work needed to be carried out for compliance with this SHTM and HSC(L8)2000. This will require:

a. tracing all water pipework;
b. measuring the time taken to achieve recommended temperatures at hot and cold water outlets;
c. measuring temperatures at all cisterns, calorifiers, humidifiers and cooling towers, and at other strategic points to check compliance;
d. checking layout and arrangement of cisterns, calorifiers, pumps, humidifiers, cooling towers and other water systems which may present a legionellosis hazard;
e. identifying little-used outlets and associated pipework which could be removed.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

4. Develop schemes for risk minimisation and control in order of priority, having considered cost, risk and difficulty.

5. List all buildings in priority order of non-compliance and potential risk.

6. Devise an agreed management programme for the minimisation of risks identified in (5) above. This should be an action plan identifying resources and time-scales.

7. Manage the programme described in (6) above and identify compliance failures for remedial action.

8. Review the programme at yearly intervals to record progress in implementing the programme. All changes to the water systems and functional content should be recorded and evaluated.

Scottish Health Technical Memorandum 2040

(Part 4 of 6)

Validation and verification

The control of legionellae in healthcare premises – a code of practice

ARCHIVE

IMPORTANT NOTE
LEGIONELLA
SHTM 2040 and the HSC Approved Code of Practice and Guidance (L8) 2000

HSC's Approved Code of Practice came into effect on 8 January 2001. At this time i.e. December 2001 the UK Health Department's Guidance HTM 2040 (SHTM 2040 in Scotland) has not been aligned with the ACOP. Work is ongoing but it is unlikely that HTM 2040 and SHTM 2040 will be updated until late 2002 and launched on a UK basis.

L8 takes cognisance of 'hospitals' but requires considerable interpretation for practical application. The revised UK Health Department Guidance will undertake to address this issue.

In the meantime this version of SHTM 2040 must be read as subordinate to the new ACOP.

1. Introduction

1.1 The guidance contained in this part is applicable to new and existing sites, and is for use at various stages during the inception, design, upgrading, refurbishment, extensions and maintenance of a building.

1.2 The approach should be to remove all potential sources of seeding, growth and spread of legionellae. Where this ideal cannot be achieved in existing situations, steps should be taken to control and prevent legionellae by sound operational management.

1.3 The control of legionellae is a continuing responsibility. Effectiveness of precautionary measures should be continually monitored, and a continuing programme to ensure awareness should be devised. Although knowledge of legionellosis has improved markedly in recent years, there is a continuing misunderstanding about the method of dissemination. Many people are under the impression that cooling towers are the only source of legionellae in building service systems. All water systems are capable of colonisation by legionellae, and taps are just as capable of generating an aerosol as showers or indeed cooling towers.

1.4 The biggest risk is complacency leading to the deterioration of water hygiene to the extent that an outbreak of the disease occurs.

1.5 Good practice design alone will not prevent outbreaks of legionellae.

1.6 The SHTM does not include advice on water supplies for clinical equipment such as dialysers, nebulisers and respiratory humidifiers, nor for sterile water services for pharmacy departments. Users of clinical humidifiers and nebulisers are reminded that sterile water, not tap water, should be used and that they should be emptied and cleaned thoroughly following each period of use. All equipment with water reservoirs should be stored dry. Water for any purpose should meet functional and local requirements, but users must recognise that any water system may provide a suitable environment for legionellae and other water-borne organisms and systems should therefore be designed to take account of this.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

2. Validation and verification considerations

Commissioning and testing of hot and cold water systems

2.1 The hot and cold water service systems should be commissioned and tested in accordance with BS 6700 and SHTM 2027; *Hot and cold water supply, storage and mains services*. BS 6700 details procedures to ensure that:

a. materials and equipment installed comply with other British Standards and are not otherwise unsuitable;

b. the work is done entirely within the specification for the scheme;

c. the installation complies in every respect with current water byelaws and regulations and the requirements of British Standards;

d. all the requirements of current legislation are met, both during construction of the installation and when it is completed, particularly with regard to the Health and Safety at Work etc Act 1974.

NOTE: The Trust Infection Control Team should be advised of the testing. Further information on the role of the Infection Control team is given in the Scottish Infection Manual – Guidance on Core Standards for the Control of Infection in hospitals, healthcare premises and in the community interface (1998).

2.2 "As installed" drawings and operating/maintenance instructions must be supplied at the time of handover. Schematics will also be useful. Certified records of pressure testing and disinfection should also be made available.

Pressure testing

2.3 Pressure testing must be carried out before disinfection. Except where otherwise specified, testing of underground pipelines should be carried out in accordance with BS 5886, CP 312 and CP 2010-2, as appropriate for the pipeline material.

2.4 Open pipes should be capped and valves closed to avoid contamination. After pressure testing it will be impracticable to drain the system completely.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Disinfection

2.5 The system should be disinfected in accordance with BS 6700. Disinfection should be carried out within seven days of the system being brought into use unless:

a. hot water temperatures are maintained;

b. cold water temperatures are maintained;

c. regular (every seven days) flushing is carried out.

NOTE: The contract should specify this for the period that the system is under the contractor's control. Refer to SHTN 2 for details.

2.6 Once filled, systems should not be drained unless full disinfection is to be undertaken before the system is brought into use again.

2.7 For design and build contracts, the brief must include the requirement that adequate certification of disinfection is provided by the contractor. On other contracts, tests must be witnessed and certified. During the post-handover period prior to occupation it is the client's responsibility to ensure system temperatures are maintained and regular flushing is carried out, or to implement full re-disinfection.

ARCHIVE

Temperature testing

2.8 These tests should be performed prior to contractual handover and bringing the system into use. Separate temperature measuring and recording equipment should be used, that is, independent of any building management system. It will be necessary to have systems fully operational and to simulate typical draw off of water.

NOTE: Reference should be made to SHTM 2027 Part 4, 'Validation and verification' for guidance.

2.9 Tests should include:

a. measuring the incoming water temperature at the main water meter;

b. testing the inlet, outlet and surface water temperatures of cisterns and cold water feed/header tanks for the hot water calorifiers. The temperature should not be greater than 2°C above that measured at (a);

c. testing the flow and return temperatures of calorifiers and boilers. These should not be less than 60°C and 50°C respectively;

d. testing the temperature at hot and cold water draw-off points, at sinks, wash-hand basins and baths, etc. A steady state temperature of

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

between 50°C and 60°C at hot water draw-off should be reached within one minute. At cold water draw-off a temperature of not greater than 2°C above the temperature measured at (a) should be reached within one minute.

Discharge of waste water used during disinfection procedures within buildings

2.10 External bodies responsible for sewers should be informed before chlorinated water used for disinfecting an installation is discharged. Additional disinfection guidance is given in HSC(L8) 2000 The control of legionella bacteria in water systems – Approved Code of Practice and Guidance. It is preferable, therefore, to establish and agree procedures beforehand; this may simply involve the dilution of the discharge or de-chlorination.

2.11 When required, de-chlorination can be achieved using either sulphur dioxide or sodium thiosulphate (20 g of sodium thiosulphate crystals is required to de-chlorinate 500 litres of water containing 20 mg/l free chlorine).

2.12 If possible, it may be preferable to add the sodium thiosulphate to the chlorinated water at the point of discharge into the foul sewer rather than into systems. This will avoid the need for draining and washing systems of any residual chemical which would otherwise mop up any chlorine that may be present in the water.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

3. Cold water systems

General

3.1 The requirements for disinfection subsequent to flushing out to remove debris, etc, are essentially those given in BS 6700. Further guidance is available in 'A Guide to Pre-Commission Cleaning of Water Systems', issued by BSRIA, 1991, which deals with the design/installation considerations, system flushing and chemical cleaning. Background notes on disinfection by chlorine are given in SHTM 2040, 'Good practice guide'; Appendix 1.

3.2 Alternative disinfectants may be used provided satisfactory disinfection is achieved. The infection control team should be consulted.

3.3 Proprietary solutions of disinfectant should be used in accordance with the manufacturers' instructions and will have to take due regard of the requirements under COSHH and other health and safety regulations.

3.4 A suitable proprietary test kit should be used for site measurements of residual disinfection agents.

3.5 Disinfection should not be undertaken before materials, for example linings in cisterns, have fully cured.

Installations outside buildings

3.6 Pipework under pressure from the mains should be disinfected through an injection point and the disinfectant residual measured at the end of the pipeline. It is normal water industry practice to use a chlorine dose of not less than 20 mg/l (ppm) and, because the nature of the installation is likely to lead to unavoidable contamination, it is usual practice to leave the chlorine solution in the pipes for 24 hours before thoroughly flushing out with fresh water. Junctions which are to be inserted into existing pipelines should be disinfected prior to installation.

3.7 All disinfection of pipework under pressure from the mains must be carried out in accordance with the requirements of the local water undertaking. Failure to ensure close liaison between the contractor and the water authority during design, construction, pressure testing or commissioning could present a potential risk of back-siphonage of contaminated materials or chemicals into the public water supply. Site supervision to ensure compliance with any requirements specified by the local water authority is strongly recommended.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Cold water installations within buildings

3.8 All cistern(s) should be internally cleaned to remove all visible dirt and debris. Cistern(s) and distributing pipework should be drained, filled with fresh water and then drained completely. The cistern(s) should then be refilled and their supply servicing valves closed. On re-fitting it is normal practice to add high doses of sodium hypochlorite to the water in the cistern(s), for example to give a calculated chlorine concentration of 50 ± 10 mg/l (ppm) in the water and leave the water to stand for one hour. Whatever disinfection method is used, the concentration should be adjusted if necessary. The use of a high dose ensures an adequate residual concentration to allow proper disinfection of the downstream services. Each tap or fitting should then be opened, progressively away from the cistern(s), and water discharged until the disinfectant is detected. Each tap or fitting should then be closed, and the cistern and pipes left charged for a further one hour. The tap(s) furthest from the cistern(s) should be opened and the level of disinfectant in the water discharged from the tap(s) measured. If the levels set in the British Standards are not achieved the disinfection process should be repeated.

3.9 As soon as possible after disinfection the distribution pipework should be drained and thoroughly flushed through with fresh water and re-filled. Appropriate hazard warnings should be placed on the taps throughout the building during disinfection procedures.

3.10 After disinfection, microbiological tests for bacterial colony counts at 22°C and 37°C and coliform bacteria including Escherichia coli for drinking water should be carried out under the supervision of the infection control team to establish that the work has been satisfactorily completed. Water samples should be taken from selected areas within the distribution system. The system should not be brought into service until the infection control team certifies that the water is of potable quality.

Storage cisterns

3.11 Cold water storage cisterns are installed in the majority of hospital buildings/departments. A maximum of 24 hours total on-site storage capacity is recommended. The quantity of water stored should be carefully assessed in relation to the daily requirement in order that a reasonable rate of turnover is achieved. Storage of unnecessarily large quantities of potable water will result in low rates of turnover and a consequent deterioration in the quality of water. The storage capacity should be reduced where it is known or established that it is excessive and where it is practicable to do so. An example would be where there are two cisterns in parallel, one of which can be left empty and blanked-off (pipe sections should be removed). Alternatively, the steady water level in the cisterns should be lowered. This can be done most easily if the float controlling the water supply has a

ARCHIVE

thumbscrew adjustment as prescribed in BS 1212: Part 2. The design capacity should not allow for future extensions.

ARCHIVE

A48235836

4. Hot water services

Hot water installations within buildings

4.1 Cold feed cisterns, hot water calorifiers, water heaters, direct-fired HWS boilers and distribution pipework should be disinfected in accordance with paragraphs 3.8 to 3.11; no heat source should be applied during the disinfection procedure, including final flushing.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

5. Evaporative cooling towers

General

5.1 The following paragraphs give general guidance on the operation and maintenance of cooling towers.

5.2 Before the identification of legionellae and its association with evaporative cooling systems, cooling towers were maintained for maximum service life. The aim of maintenance was to minimise fouling, thus ensuring optimum thermal efficiency.

5.3 Most evaporative cooling systems are uncomplicated in construction, simple in operation and usually located close to the refrigeration plant. Significant deterioration is possible, therefore, before plant inefficiency becomes evident.

5.4 It is essential that the utmost care and diligence is exercised in the operation and maintenance of cooling towers. The operation, maintenance and water treatment of evaporative cooling systems must be considered with regard to the associated health risks, in addition to operational efficiency.

Operating and maintenance documents

5.5 Operating and maintenance documents must be available for each installation and must be complete at the time of handover. If unavailable, operating and maintenance documents must be prepared by the user and should include the following:

a. the design intent description, usually prepared by the designer and including the system function and its description. It should also include the design requirements in respect of water treatment regimen, flow rates, static and dynamic pressures, thermal capacities, system volumes, operating temperatures, control sensor locations, operating set points and all other relevant information. If commissioning information is not available it will be necessary to recommission the plant in order to prepare records of the operational parameters of the entire system;

b. a description of how the plant and system as a whole are set to work and how they are shut down;

c. a fault diagnosis schedule, description of the alarm/warning system and details of courses of corrective/diagnostic action in event of a fault condition. The schedule should also include a checklist and give guidance on checking possible causes of complaint originating from the occupier;

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

A48235836

d. manufacturer's installation instructions and literature;

e. spares information;

f. operation instructions for individual items of plant;

g. maintenance information for individual items of plant and maintenance frequencies;

h. record drawings of the installation;

i. plantroom and system schematic diagrams (framed copies should be mounted in the respective plantrooms);

j. lubrication charts with frequencies;

k. valve charts showing valve number, type and purpose and, where applicable, design flows/settings/pressure drops;

l. logbooks.

NOTE: Schedule 3 of the Consumer Protection Act 1987 required that sufficient information is made available to the operator for him/her to safely operate the plant.

Logbooks

5.6 The purpose of a logbook system is to improve the efficiency and effectiveness of installation and maintenance, and also to provide a record of various tasks and observations so that the plant history can be reviewed at any time by the maintenance engineer. It will prove essential to the maintenance engineer in the operation of a planned plant maintenance scheme, and, if properly followed, will prevent unacceptable conditions developing as a result of ineffective maintenance.

5.7 The logbook should:

a. identify the installation requiring attention, in this case an evaporative cooling system, and should describe its form, function and how it operates;

b. record the results of the initial commissioning and any recommissioning so that observations made during maintenance checks can be compared;

c. define the maintenance task or observation required and the frequency;

d. provide for the recording of maintenance observations and results and for comments to be made in respect of any defect seen during the inspection. This facility should exist for each item of plant individually and for overall system observations;

e. provide preliminary guidance on fault diagnosis and checking to assist with immediate on-site correction or adjustment;

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

f. provide for, and make reference to, any separate observation sheet required to record extensive or abnormal observations which cannot be noted on the routine inspection sheets;

g. facilitate cataloguing and cross-referencing to other logbooks for plant/installations on the same site (for example, the refrigeration plant, the chilled water installation, the air-conditioning plant and the heat source).

Operational checks

5.8 This section of the SHTM is intended to assist maintenance staff in the planning of operational and functional checks. It identifies typical tasks and recommends observation frequencies. It is only a general guide, as it is not possible to cover all aspects which relate to a specific installation.

NOTE: As an aid to the preparation of a suitable logbook system, a sample logbook for an evaporative cooling system is included in SHTM 2040, 'Good practice guide'.

5.9 Details of operational and functional tasks must be drawn up for each site by the "nominated person". These, together with the completion of log sheets, will enable a proper historical record to be compiled of all works carried out and observations made.

5.10 Frequencies are indicated for initial guidance only, as they will vary to suit a particular site, its location, the design parameters and particular provisions, for example manual operation rather than automatic control methods.

5.11 The user's needs must be considered before commencing any operational or maintenance tasks. Where standby or dual facilities are not provided, the timing of these tasks must be carefully planned to minimise inconvenience.

6. Air-conditioning and mechanical ventilation

General

6.1 Air-conditioning and ventilation plant and ductwork should be inspected at the access point(s) quarterly to see that it is clean and to report on its general condition.

Fresh air inlet

6.2 In the case of existing installations the use of portable smoke generators or smoke bombs may be helpful in observing the discharge plume from cooling towers and discharges from extract systems in order to assess any potential risk.

NOTE: The wind conditions will vary from day to day and sufficient tests to provide a representative sample will be necessary. The tests should be repeated with the cooling tower fan(s) both on and off.

Scottish Health Technical Memorandum 2040

(Part 5 of 6)

Good practice guide

The control of legionellae in healthcare premises – a code of practice

ARCHIVE

IMPORTANT NOTE
LEGIONELLA
SHTM 2040 and the HSC Approved Code of Practice and Guidance (L8) 2000

HSC's Approved Code of Practice came into effect on 8 January 2001. At this time i.e. December 2001 the UK Health Department's Guidance HTM 2040 (SHTM 2040 in Scotland) has not been aligned with the ACOP. Work is ongoing but it is unlikely that HTM 2040 and SHTM 2040 will be updated until late 2002 and launched on a UK basis.

L8 takes cognisance of 'hospitals' but requires considerable interpretation for practical application. The revised UK Health Department Guidance will undertake to address this issue.

In the meantime this version of SHTM 2040 must be read as subordinate to the new ACOP.

Appendix 1: The use of sodium hypochlorite solutions for chlorination of cooling water systems in hospitals

1.1 Chlorine is an excellent and fast-acting biocide, widely used for controlling microbial growth in cooling waters of wet, evaporative heat exchangers. However, it is essential to note the following four facts, which determine its efficiency during use.

a. chlorine has no detergent cleansing powers. It is essential that slime and debris are removed by thoroughly cleansing before chlorine is used, otherwise micro-organisms will survive disinfection as a result of the physical shielding afforded by these slimes;

b. chlorine is a highly reactive chemical and will very rapidly combine with organic matter, ammonium compounds and any oxidisable materials (for example ferrous and manganous salts, hydrogen sulphide) present in the water or on wetted surfaces. These reactions will greatly reduce, or even neutralise completely, the disinfecting power. In practice, the level of free available residual chlorine (that is, that available for disinfection) will always be less than that calculated from the dose added, and will decline progressively after addition. For these reasons, chlorine should only be used in systems which are already clean, and the level of free available residual chlorine in the water must always be checked after adding chlorine and allowing it to become completely mixed with the circulating water;

c. chlorine should not be used with other biocides, since they may neutralise each other, unless they are known to be compatible;

d. the disinfecting effect is greater at pH values at or below the neutral pH value of 7.0. Temperature will also affect the efficacy. At pH values above 8.0 the disinfecting power is greatly reduced. This is because the disinfecting activity is mainly brought about by hypochlorous acid (HOCl), which exists in pH-dependent equilibrium with hypochlorite ions (OCl-), in solution. For example, in water at 30°C and pH 7, 71% free available residual chlorine will exist as hypochlorous acid, whereas at pH 9 there will only be 2.4% hypochlorous acid, and 97.6% will be in the form of hypochlorite ion OCl-, which is not as powerful a disinfectant as HOCl (see Figure 1, Effect of pH on chlorination (as HOCl)).

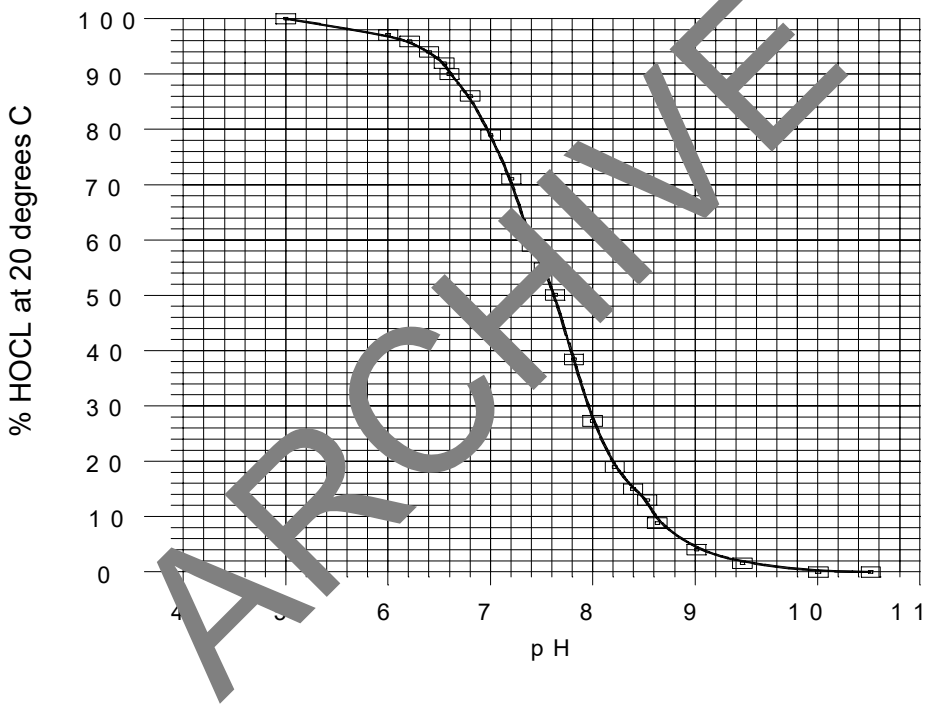
Sodium hypochlorite and available chlorine

1.2 Sodium hypochlorite solutions are the most suitable for chlorinating hospital and other cooling waters. Other chemicals such as bleaching powder ("chloride of lime"), "high-test hypochlorite" or "slow-release tablets" (chloroisocyanurate compounds) are less convenient to prepare or use, and liquefied chlorine gas is too hazardous.

1.3 Sodium hypochlorite solutions are sold containing 10-15 percent available chlorine. They contain sodium hydroxide which helps to prevent degradation of the sodium hypochlorite during storage. The commercial preparation has a pH value of about 11 and also contains sodium chloride.

Figure 1: Effect of pH on chlorination (as HOCl)



ARCHIVE

1.4 It is conventional to express the strengths of chlorine compounds and similar oxidising disinfectants in terms of "available chlorine". This is for analytical convenience, since it provides a common reference of oxidising power for various chemicals used in the disinfecting of water (for example chlorine, hypochlorous acid, hypochlorite ion, chloramines, chlorine dioxide and sulphur dioxide. Chlorine itself (Cl_2) is assumed to be 100 percent available.

1.5 Commercial sodium hypochlorite contains 10-15 percent (w/v) available chlorine, representing a dilution of about 10 to 7 times respectively.

1.6 In tests of treated water for the presence of available residual chlorine, the hypochlorous acid and hypochlorite ion both react by oxidation, so both are

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

measured. This makes it easy to determine the dose of available chlorine added by calculating the dilution (as shown in Table 1).

1.7 This table does not allow for deterioration in strength of the hypochlorite solution, or for chlorine demand within the water and cooling circuit. Hence, the actual concentration of free residual chlorine in the water must always be checked after the dose has been added and properly mixed with the cooling water.

Care in storage and use of sodium hypochlorite solutions

1.8 Solutions must be stored in a dark, cool, well-ventilated place and handled with care according to instructions on the label. They must not be stored or mixed with other chemicals such as acids, ammonia, ammoniacal compounds or cleaning materials because of the risks of evolution of poisonous, chlorine gas and the spontaneous formation of explosive nitrogen trichloride. The solutions are caustic, causing burns to the eyes and skin, are poisonous and will rapidly bleach and rot clothing and woodwork and corrode metals. They must only be placed in glass or plastic containers. When handled, waterproof protective clothing and eye shields must be worn. Any splashes on the eyes, skin or clothing should be washed off immediately with plenty of cold water. If swallowed, medical advice should be sought immediately. Further information on the safe handling of sodium hypochlorite solutions is given in the Department of Environment's publication, 'Swimming Pool Disinfection Systems Using Sodium Hypochlorite – Guidelines for Design and Operation' (DOE, 1979).

Chlorination of hospital cooling water systems to suppress bacterial growth

Routine chlorination as an alternative to other biocides

1.9 If chlorine (or biocide) is/are not added to the cooling-water circuits, legionellae and other micro-organisms may become established because of the favourable operating temperature range and if sufficient nutrients are present. Nutrients may be derived from such sources as contaminated make-up water, dust, leaves, bird droppings and from decaying microbial slime. Low concentrations of free available residual chlorine will prevent growth of legionellae and other micro-organisms, thereby preventing the build up of slimes even if nutrients are present in the water. The concentration of free available residual chlorine needed to suppress microbial growth will depend upon the quality of the water being circulated and the condition of the pipework.

1.10 It is essential that the chosen level is maintained since the free chlorine will be absorbed constantly by organic matter and microbial growth in the system

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

– and lost by chemical degradation when the water cascades through the tower packing. Experience has shown that control is achieved when the free available residual chlorine level is maintained constantly at 1-2 mg/l, and to avoid corrosion, a level of 3mg/l is the maximum which should be permitted.

1.11 Where continuous dosing and control is not possible, it may be possible to maintain a similar level of control by dosing intermittently (not less frequently than weekly), to achieve an initial level of 10 mg/l as free available residual chlorine, after allowing for the solution to become completely mixed with the cooling water. If the level falls below 1 mg/l before the next dosing, the frequency of dosing should be increased.

Periodic cleaning and disinfection of the cooling circuit

1.12 Because sodium hypochlorite in solution has no detergent or penetrative properties, the aim must be to use thorough mechanical cleaning with brushing and rinsing to remove the slime and debris before the system is disinfected and returned to service. The procedure outline in this SHTM is based upon practical engineering and microbiological experience such as described by Colbourne *et al* (1978).

1.13 The procedure recognises that disinfection is a function of both time and concentration. Practical experience in water supply industry for disinfection of pipelines and storage reservoirs, within buildings and in ships, has shown that satisfactory disinfection of cleaned structures can be obtained if the concentration x time product (CT) is at least 50 mg h/l. To achieve this degree of treatment, the dose of available chlorine added, as calculated from Table 1, must be considerably in excess, to allow for chlorine demand. Table 2 indicates the actual dose of chlorine available which may have to be added to achieve a CT product of 50 mg h/l. Experience has shown that when doses of 20 mg/l or less are used, there is a risk of disinfection failure because of the effect of chlorine demand.

1.14 Provided that the procedure has been followed correctly, there is no benefit in extending the contact period. Indeed, if the procedure has been applied incorrectly and the level of chlorine is less than that required, increasing the contact time would create conditions where untreated water stagnate in a water system, thereby allowing time for bacterial growth. There is a risk of accelerating corrosion/deterioration of the materials of construction if chlorinated water is left to stand in pipework overnight on a repeated basis.

Appendix 2: Questionnaire: Assessment of serviceability of existing cooling systems

1. Are they registered with local authority?

2. Siting of cooling tower

   a. Is the cooling tower located near a fresh-air intake to an air conditioning or ventilation system?

   b. Is it possible for wind to carry the cooling tower discharge vapour towards the windows of a nearby area or department where there are patients?

   c. Is the siting such that good access is available for maintenance purposes?

   d. Is the siting or tower configuration such that the wind could cause reversal of air flow and spray to carry over from the air-inlet louvres?

3. Cooling tower

   a. Are all the internal parts of the cooling tower readily accessible, or can they be rendered so?

   b. Is corrosion apparent either internally or externally?

   c. Is fouling apparent within the tower?

   d. Is debris, sludge or slime apparent in the tower water?

   e. Are the drift eliminators closely fitting and firmly seated in their support grid?

   f. Is the pack, or any other part of the tower, manufactured from natural materials such as timber?

   g. Are natural rubbers used as seals or gaskets in the spray system or elsewhere?

   h. When operating at full load, is excessive drift visible from the tower discharge?

   i. Is there a coarse strainer located over the outflow pipe from the tower?

   j. Is the drain from the pond piped to discharge above a gulley connected to the foul water drain system?

   k. Is the overflow from the pond piped to discharge above a gulley connected to the foul water drainage system?

   l. Is there a readily accessible pond water sampling point available?

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

m. Is there a readily accessible water sampling point available to sample tower make-up water?

n. Is there a strict water treatment programme in operation to control:

(i) Total Dissolved Solids (TDS);

(ii) pH;

(iii) total hardness;

(iv) chlorides;

(v) scale;

(vi) slime;

(vii) water treatment chemical/additive levels;

(viii) corrosion;

(ix) sludge;

(x) algae;

(xi) micro-organisms?

o. Is the tower and the entire distribution system cleaned and disinfected at the correct intervals?

p. Is there a regular maintenance programme and recording/logbook system in operation?

q. Is a water meter installed on the feed to the make-up valve? Is it accurate?

4. The distribution system

a. Is the pipework distribution system clearly visible and accessible?

b. Is the pipework system easily dismantled for inspection or is it provided with inspection points?

c. Is there a risk of water stagnation in the pipeline strainer assembly? (This can occur with duplicate sets if precautions against stagnation are not taken.)

d. Is there a risk of water stagnation in the maintenance bypass across the 3-way control valve? (This will occur if the bypass valve is fully closed. Flow should be encouraged or the bypass removed.)

e. Where duplicate pumps are installed, do they alternate on a daily basis?

f. Are there adequate manual drain points installed, with drain discharge lines piped to discharge above a gully connected to the foul water drainage system?

g. Are there adequate, readily accessible water sampling points installed in the distribution system?

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

h. Is the automatic TDS drain line piped to discharge above a gulley connected to the foul water drainage system?

i. Are there adequate thermometers and pressure gauges installed to enable the system performance to be monitored and understood?

j. Is a regular maintenance programme and recording/logbook system in operation?

k. Does an internal inspection of the condenser and pipework system indicate fouling is present?

ARCHIVE

A48235836

Appendix 3: The course of action if an outbreak of legionnaires' disease is suspected

3.1 The nominated person will usually be informed of a suspected case of legionnaires' disease possibly associated with healthcare premises by either the outbreak control team or the local Consultant in Communicable Disease Control (CCDC). If a case is suspected, then the hospital outbreak team will normally work in association with the Directors of Public Health and the Scottish Centre For Infection and Environmental Health and the local CCDC to search for the source of the causative organism. It is essential that systems are not drained or disinfected before samples have been taken. The nominated person's role is an important one – guiding the team to the various water systems within the building and, in particular, to the points from which the samples can be taken. Easy access to these sampling points is essential.

NOTE: The hospital outbreak control team (the team) should include the consultant in communicable disease control.

3.2 The investigation will concentrate upon all potential sources of legionella infection, including:

a. the domestic hot and cold water distribution system;
b. wet spray cooling water systems;
c. showers or spray washing equipment;
d. drainage systems and traps;
e. spas, whirlpool baths or therapy pools;
f. humidifiers in ventilation systems;
g. cooling coils in air-conditioning systems;
h. fountains and sprinklers.

3.3 To assist in such investigations, the nominated person must be able to provide details of all associated equipment, including all documentation. He/she must assist by advising the investigating team on the extent of the servicing on the site, and by locating taps and sample points.

3.4 The nominated person must also identify the locations of any medical equipment used for dental care, respiratory therapy and within haemodialysis units, etc.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

3.5 Off-site information will also be required, such as whether there have been any local excavation or earthmoving works, alterations to water supply systems, or drainage systems or any other factors which may have a bearing on the site.

3.6 The address and telephone number of the nearest weather station will be required – this is likely to be a local airport, university or college department.

3.7 The team is responsible for identifying the cause of infection, and will advise on cleaning, disinfection, any modifications, and long-term control measures.

When maintenance task is satisfactorily completed the operative is to tick the box opposite. If task cannot be completed due to mechanical failure, insert a cross in the box opposite and note defect in the observation sheet

Job Description	Date of inspection							
1. Cooling tower No …….. **a) isolate electrical supply to tower** **b) isolate condenser water pumps and/or valve to tower being serviced.** **c) remove fan guard, wipe clean, inspect for rust spots, rub down apply rust inhibitor and paint. When replacing guard lightly grease holding bolts.** **d) clean fan casing, impeller, housing, holding bolts and framework. Inspect all steelwork for rust spots, rub down, apply rust inhibitor and paint. Apply protective grease to bolts and parts exposed to vapour.** **e) remove dirt eliminators, brush and wipe clean, apply hose as necessary. Inspect for signs of fouling. If fouling is present apply chemical dispersant and remove. Similarly clean eliminator support grid and housing. Inspect for signs of rust, rub down, apply rust inhibitor and paint.** **When complete replace eliminators taking care to place the correct way up, to align and seal to prevent moisture by-passing.**								
Engineer's signature

Job Description	Date of inspection							
f) remove all spray nozzles and clean. Replace all suspect grommets and washers. **If trough distribution system, remove trough and wipe clean, hose as necessary and rod through all nozzles.** **Inspect distribution pipe for signs of rust, rub down, apply rust inhibitor and paint.** **g) remove pack from tower and clean by scraping, wiping , brushing and application of hose. (Method to be sympathetic to material.) If fouling is present use chemical dispersant to remove fouling or if more appropriate dispose of media and replace with new. Similarly clean inside of tower casing and pack support grid. Inspect for signs of rust, rub down, apply inhibitor and paint. When complete take care with replacement to ensure by-passing does not occur.** **h) clean louvres and screens. Inspect for signs of rust, rub down, apply inhibitor and paint.** **i) isolate ball valve and pond outflow pipe.** **Drain pond.** **Clean out debris and sediment, hose out pond until clear.** **Remove strainer and scrub clean.** **Clean outflow pipe orifice.** **Hose through all drain lines and sampling pipes.** **If fouling is present use chemical dispersant and remove.** **When clean and dry inspect pond for signs of rust, rub down, apply inhibitor and paint.**

Maintenance sheet for condenser water circulation system monthly tasks

When maintenance task is satisfactorily completed the operative is to tick the box opposite. If task cannot be completed due to mechanical failure, insert a cross in the box opposite and note defect in the observation sheet

Job Description	**Date of inspection**							
1. Condenser water circulation Pump No 1 a) isolate electrical supplies locally. b) remove guards, inspect for rust and make good as necessary. c) wipe clean motor, shaft, pump casing and parts as appropriate. d) check all bearings and adjust as necessary. e) lubricate pump bearings with …. shots of grease type …….. f) check belt drives for correct alignment and tension and adjust as required. g) check pump glands for excessive leakage, adjust or replace as required. h) clean drip cups and rod through as required. i) check tightness of all holding down bolts and anti-vibration mountings. Realign if required. j) bring pump back into service.								
Engineer's signature								

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Job Description	Date of inspection							
2. Condenser water circulation Pump No 2 Where dual pump installations exist draw up additional maintenance sheet and implement maintenance function.								
3. Dosing pump for chemical A a) check pump bearing and where not sealed for life oil or grease to manufacturers instructions. b) disconnect pump discharge and run for set time discharging contents into measuring container to check duty remains satisfactory. c) tighten pump holding down assembly on top of chemical treatment tank.								
4. Dosing pump for chemical B Where more than one dosing is installed draw up maintenance sheets for each system and implement maintenance function.								
5. Strainer a) remove strainer basket, insert standby basket, bring service back on line, empty and clean basket.								
6. Pressure gauges and thermometers a) clean all glass dial gauges and mercury in glass stem thermometers to ensure clarity of reading.								
Engineer's signature

Frequency 6 monthly

Maintenance sheet for condenser water circulation system – 6 monthly tasks

When maintenance task is satisfactorily completed the operative is to tick the box opposite. If task cannot be completed due to mechanical failure, insert a cross in the box opposite and note defect in the observation sheet

Job Description	**Date of inspection**							
1. Valves a) clean all valve spindles of dust or deposits. b) operate valve through two full cycles from fully closed and reset to precise original position. c) inspect gland and adjust gland nut as required. Repack gland if required. d) lubricate valve as required by manufacturer.								
2. 3-Way control valve a) check valve spindle for signs of wear and distortion. Replace as necessary. b) check glands and adjust as necessary. c) check terminals and tighten or check pneumatic tubing and tighten nipples if necessary.								
3. Automatic air vents a) isolate feed to AAV, dismantle, remove float and clean float and needles. Clean ports and needle seats. b) blow through discharge lines.								
Engineer's signature								

ARCHIVE

A48235836

Job Description	Date of inspection							
4. Drains and sample points a) open all drain lines and sample points to blow clear. Check discharges to ensure lines freely drain over gully to waste.								
5. Strainer a) remove flow monitor, inspect and operate paddle. Chemically clean and replace. b) check and tighten cable terminals.								
6. Flow monitor a) gain access to NRV clack and inspect for freedom of operation scoring or erosion. Renew disc if required and reassemble.								
7. Conductivity cell a) remove conductivity cell from pipeline, inspect and clean as recommended by manufacturer.								
8. Thermometers a) check all thermometers pockets for thermoconductivity paste and replenish as required.								
Engineer's signature

Appendix 5: Empty times for cooling tower ponds (approx.)

Pond litres	Capacity (gals)	Cooling tower drain valves sizes mm (inch)									
		25 (1.0)		38 (1.5)		50 (2.0)		63 (2.5)			
		Tank depths		Tank depths		Tank depths		Tank depths			
		0.5m	1.0 m	0.5 m	1.0 m	0.5 m	1.0 m	0.5 m	1.0 m		
150	(35)	5 min	-	-	-	-	-	-	-		
259	(57)	8 min	5 min	5 min	-	-	-	-	-		
345	(76)	11 min	8 min	7 min	-	-	-	-	-		
968	(213)	30 min	20 min	15 min	10 min	10 min	5 min	5 min	-		
1,500	(330)	50 min	35 min	20 min	15 min	15 min	10 min	10 min	5 min		
2,800	(616)	1 hr 30 min	1 hr 00 min	40 min	30 min	25 min	15 min	15 min	10 min		
5,500	(1,210)	3 hr 00 min	2 hr 00 min	1 hr 15 min	1 hr 00 min	45 min	30 min	30 min	20 min		
8,500	(1,870)	4 hr 30 min	3 hr 00 min	2 hr 00 min	1 hr 30 min	1 hr 15 min	45 min	45 min	30 min		
11,000	(2,420)	6 hr 00 min	4 hr 00 min	2 hr 30 min	2 hr 00 min	1 hr 30 min	1 hr 00 min	1 hr 00 min	40 min		

Times assume no hose and gate valve.

Notes

1. Ball type valves should be specified to minimise "clogging".
2. The drain from the gully must be of sufficient size to take the flow from the pond.

ARCHIVE

Appendix 6: Cooling towers – operational checks

6.1 These tasks should be carried out weekly. Usually, visual inspection is sufficient.

Evaporative cooling system operational checks

6.2 The specimen logbook, page 2, details the checks and tasks to be covered. It is expected that the engineer will exercise discretion (as to the degree of involvement) where weekly charts are indicated. The tasks listed entail observation from close inspection and do not require dismantling or draining of plant, etc. (More detailed examination is covered under routine maintenance.) For instance, a "pond inspection" on a weekly basis is intended to be a visual inspection of the pond to establish the following:

a. correct operating water level;

b. water appears clean and free from slime, with no foreign matter floating or submerged.

Make-up water operational checks

6.3 Readings and tests as shown in the logbook, page 3, should be carried out on a weekly basis. The readings are required to ensure that the minimum amount of water is used, and that water temperature is maintained to reduce the risk of microbial growth and to suit the chemical treatment programme.

System water operational tests

6.4 The tests given in the logbook, page 5, should be carried out weekly to ensure proper control of the water treatment programme so as to restrict the development of *Legionella pneumophila*, the accumulation of scale, slime, sludge, etc.

Equipment checks

6.5 Each item of equipment should be checked using the senses of sight, touch, smell and hearing as applicable. This type of check will complement the readings taken from instruments and will allow comprehensive details to be recorded on the log sheet. Where such checks show that corrective measures can be carried out quickly and efficiently at the time of the inspection (using minimal tools and equipment), this should be done. Where

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

A48235836

the checks identify more time-consuming remedial action, with the use of specific plant and materials, the work should be carried out at the earliest opportunity following inspection. A preventive planned maintenance scheme should avoid the need for unforeseen, substantial maintenance tasks being identified through the weekly inspections.

6.6 Typical observation checks are listed below:

a. pond:
   (i) check water level is properly marked on the pond and is maintained;
   (ii) check overflow is clear;
   (iii) check ball valve flow and proper shut-off;
   (iv) check water for leaves and foreign matter;
   (v) check for slime and signs of scaling;
   (vi) check for leaks;
   (vii) check for signs of corrosion, for example rusting, algae blistering, oxidisation, etc.
   (viii) check clear visibility of sump;
   (ix) check screen in pond and clean as necessary;
   (x) check drains are free;
   (xi) check discharge from pack for uniformity;

b. tower casing:
   (i) check rattles and vibration;
   (ii) check the casing for water and air leaks while in operation;
   (iii) check for drift from tower discharge;
   (iv) check for signs of corrosion, for example rusting, blistering, oxidisation, etc.
   (v) check paint or protective coating for damage;
   (vi) check louvres and screens for leaves, growth and other deterioration;

c. tower intervals:
   (i) check pack for correct location, alignment, seal and absence of distortion;
   (ii) check pack for condition and signs of deterioration, scale, algae slime, poor water flow/coverage;
   (iii) check casing and inside structure for signs of corrosion, rusting, blistering and oxidisation;

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

(iv) check sprays, sparge or troughs for efficient operation and uniformity of distribution of water over pack when operating;

(v) check drift eliminator for correct location, alignment and lack of distortion and seal;

(vi) check drift eliminator for signs of deterioration, scale, algae, slime or blockage;

d. cooling tower fan:

(i) check for noise vibration and free running;

(ii) check drive method where applicable for correct adjustment, alignment and operation;

(iii) check cage, guard and screen for corrosion and proper location and fixing;

(iv) check motor full-load current and record;

(v) check condition of impeller, shaft, housing, scroll, shaft, bearing and supports, etc;

e. sump immersion and trace heating:

(i) check power available and isolator position;

(ii) check operation manually;

(iii) check thermostat setting;

f. pipework distribution system:

(i) check for signs of leaks;

(ii) check for signs of corrosion;

(iii) check for vibration;

(iv) vent all air cocks and check all AAVs and discharge lines;

(v) check all drains are operable and gulleys are clear;

g. manual valves and cocks:

(i) check all valve glands for leaks or solid deposits collecting around spindle;

(ii) check for the correct setting of all valves (fully open, closed, partially open, etc.);

h. automatic 3-way control valves and associated equipment:

(i) check 3-way control valve fully operational;

(ii) check 3-way valve maintenance bypass valve is closed save for bleed facility;

(iii) check for positive shut-off as applicable;

(iv) re-establish automatic control, calibrate detector and set to design temperature;

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

A48235836

i. strainer:

(i) compare system flow to bypass flow and assess if strainer might be partially blocked;

(ii) check that spare strainer basket is available;

j. circulating pump:

(i) check each pump for smooth running and freedom from noise and vibration;

(ii) check bearings from grease and high temperature;

(iii) check shaft and drives for signs of wear;

(iv) check belts and pulley for correct alignment and tension belts;

(v) check guards for proper fixing and absence of vibration and corrosion;

(vi) check clearance of guards for free operation;

(vii) check glands for excessive leakage and check drip lines are clear and free draining to gulley;

(viii) operate stop cocks and auto-change facility as applicable;

(ix) operate each pump via on/off/auto switch to prove operation;

(x) measure suction and discharge pressures, record and compare with design. Increase in pressure difference will indicate reduction in flow, possibly caused by strainers or condenser tube fouling. Note observations;

(xi) record hours run for each pump;

(xii) check pump mounting condition and effectiveness;

(xiii) check foundations, securing bolts and pump alignment with pipework and assess any movement creeping;

k. condenser:

(i) vent condenser via air cocks to relieve any air pockets;

(ii) measure condenser water inlet and outlet pressures and record;

(iii) record condenser pressure differential and compare with design and flow as measured in (h) above and assess any fouling;

(iv) record water entry and leaving temperatures;

(v) record refrigeration machine full-load current associated with water temperature difference and compare with manufacturer's chart to assess load-cross check with flow and temperature difference readings taken;

l. flow monitor

(i) stop/start pumps and check free operation and ready switching of flow monitor;

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

(ii) check refrigeration machine shuts down on no-flow;

(iii) check action of “delay-on” timer to refrigeration circuit and others as applicable;

m. dosing system(s) – for each system:

(i) check contents of drum(s) and note volume remaining;

NOTE: Checking frequency will depend on dosing rates and capacity for the chemical containers/drums, for example, small containers may be exhausted in as little as three days.

(ii) top up drum(s) with water treatment chemicals and record new volume of contents;

(iii) manually operate dosing pump(s) and check for correct operation and freedom from vibration, etc;

(iv) manually override controller(s) to cycle pump(s) automatically, check controller calibration, reset and leave under automatic control;

NOTE: Initially while plant is settling down, then after less frequently.

(v) check dosing pump(s) duty/calibration manually;

(vi) check setting and operation of any timers.

Scottish Health Technical Memorandum 2040

(Part 6 of 6)

The control of legionellae in healthcare premises

Supplementary guidance applicable to intermittently used healthcare premises

ARCHIVE

IMPORTANT NOTE
LEGIONELLA
HTM 2040 and the HSC Approved Code of Practice and Guidance (L8) 2000

HSC's Approved Code of Practice came into effect on 8 January 2001. At this time i.e. December 2001 the UK Health Department Guidance HTM 2040 (SHTM 2040 in Scotland) has not been aligned with the ACOP. Work is ongoing but it is unlikely that HTM 2040 and SHTM 2040 will be updated until late 2002 and launched on a UK basis.

L8 takes cognisance of 'hospitals' but requires considerable interpretation for practical application. The revised UK Health Department Guidance will undertake to address this issue.

In the meantime this version of SHTM 2040 must be read as subordinate to the new ACOP.

Disclaimer

The contents of this document are provided by way of guidance only. Any party making any use thereof or placing any reliance thereon shall do so only upon exercise of that party's own judgement as to the adequacy of the contents in the particular circumstances of its use and application. No warranty is given as to the accuracy of the contents and the Property and Environment Forum Executive, which produced this document on behalf of NHSScotland Property and Environment Forum, will have no responsibility for any errors in or omissions therefrom.

The production of this document was jointly funded by the Scottish Executive Health Department and the NHSScotland Property and Environment Forum.

NHSScotland, P&EFEx, December 1999

1. Introduction

General

1.1 Scottish Health Technical Memorandum (SHTM) 2040; *The control of legionellae in healthcare premises – a code of practice*, provides guidance for those with responsibilities in this area. However, Scottish Health Technical Memorandum 2040 is considered to be perhaps more applicable to continuous occupied healthcare sites and to the types of building services likely to be present, than to intermittently used healthcare sites offering a range of out-patient services.

1.2 This supplement seeks to provide a framework for the assessment of the risk of legionellae infection which derives from intermittently used healthcare premises and prescribes appropriate control measures which may be put in place. This document provides guidance on the measures to be taken to ensure safe intermittent operation of domestic hot water plant and hot and cold water supply services.

ARCHIVE

Application to premises

1.3 The guidance offered in this supplement is applicable for all intermittently used healthcare sites. These sites are considered to be premises such as health centres, clinics, offices etc. which are not used on a 24 hour basis.

1.4 There may be instances however, where staff may occupy intermittently used healthcare premises for longer periods of time such as an overnight stay. If during this period of occupancy, there is known to be “zero” demand on the hot water services provided to the premises, the guidance in this supplement is considered to be appropriate. However, should hot water services be required by staff during a period of occupancy such as an overnight stay, more comprehensive control measures are required as detailed in the main text of Scottish Health Technical Memorandum 2040.

Priorities

1.5 All intermittently used healthcare premises should be reviewed regularly to identify where they do not meet the standards outlined in this guidance. A realistic programme should be prepared to eliminate any shortfall.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

2. Overview and management responsibilities

Statutory requirements

2.1 It is the responsibility of management to ensure that intermittently used healthcare premises comply with all health and safety statutory requirements. These are detailed in the main text of Scottish Health Technical Memorandum 2040.

2.2 Duties under the Health and Safety at Work etc Act 1974 extend to risks from the legionellae arising from work activities. More specifically, the Control of Substances Hazardous to Health Regulations relate to the risks from hazardous micro-organisms, including legionellae, and chemical such as biocides and chlorine. Under these Regulations, risk assessments and the adoption of appropriate precautions are required.

NOTE: Reference should be made to the Scottish Infection Manual – Guidance on core standards for the control of infection in hospitals, healthcare premises and at the community interface for the role of the Infection Control Team.

Management responsibility

2.3 The chief executive or general manager has overall responsibility for all aspects of water supplies within his/her organisation.

2.4 Scottish Health Technical Memorandum 2040 Part 1 outlines the managerial responsibilities and requirement for the effective management for healthcare premises. The requirements for intermittently used healthcare premises should form part of this overall system.

Nominated person

2.5 A nominated person (legionellae), possessing adequate professional knowledge and with appropriate training, should be nominated in writing for the prevention of Legionnaire's disease in intermittently used healthcare premises.

2.6 The requirements and responsibilities of the nominated person are outlined in the main text of Scottish Health Technical Memorandum 2040 Part 1.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Site contact

2.7 The person who manages the site should appoint a “site contact” and confirm this in writing to the “nominated person” as defined above. The “site contact” should, on behalf of the “nominated person”, undertake to ensure that specific site information and appropriate routine checks for the premises are completed and duly recorded within the site’s log book.

Epidemiology

2.8 For details of the epidemiology of Legionnaire’s disease refer to the main text of Scottish Health Technical Memorandum 2040 Part 1.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

3. Design considerations

General

3.1 For details of the design requirements and considerations that should be applied to the design up to the contract document, refer to the main text of Scottish Health Technical Memorandum 2040 Part 2, ‘Design Considerations’. All modifications and alterations to the existing systems should comply as far as practicable with the requirements of SHTM 2040. Reference should also be made to Scottish Health Technical Memorandum 2027; *Hot and cold water supply, storage and mains services*.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

4. Validation and verification

General

4.1 For details of the validation and verification requirements and considerations that should be applied, including testing and commissioning aspects, refer to the main text of Scottish Health Technical Memorandum 2040 Part 4, ‘Validation and Verification’.

ARCHIVE

5. Operational management

Operational considerations

5.1 A risk assessment diagram has been devised to assist in assessing the risk from legionellae in relation to the range of equipment and facilities likely to be available in intermittently used healthcare premises.

NOTE: Refer to Appendix 2: Intermittently used healthcare premises – checklist for assessing the risk from legionellae.

5.2 Assistance in identifying whether the facility under review is categorised as an intermittently used healthcare premises for the purposes of this document, is provided within this risk assessment diagram.

5.3 Those premises identified as being intermittently used healthcare premises may present a lower risk due to the nature of the systems involved and this document attempts to match the sophistication of the control measure to the complexity of the system. Such controls and inspection frequencies are detailed in the supplementary notes to the risk assessment diagram.

5.4 Those premises identified as being intermittently used healthcare premises, but unable to meet in its entirety the requirements outlined in the risks assessment diagram and supplementary notes are deemed to be of a higher risk. Such premises will require more comprehensive control measures to be put in place. The controls and inspection frequencies to be applied to premises in this category are detailed in the main text of the 'Operational management' part of Scottish Health Technical Memorandum 2040 (Part 3).

5.5 A standard survey sheet specifically for intermittently used healthcare premises and the varying facilities and equipment likely to be provided, has been designed. This form should be completed for each site; this ensures a written record is available for every site under consideration. It is recommended that the user refer to the risk assessment diagram when completing the standard survey sheet.

NOTE: Refer to Appendix 3: Intermittently used healthcare premises – water systems survey sheet.

ARCHIVE

Background to risk assessment and monitoring

5.6 In undertaking a suitable and sufficient risk assessment, it is essential that consideration be given to the chances of being exposed to the hazard, coupled with the consequences of the exposure; in this instance the hazard being the contraction of legionellae infection.

5.7 Systems susceptible to colonisation by legionellae and which incorporate the potential to create and disseminate water droplets should be identified and the risk they present assessed.

5.8 In completing a risk assessment of intermittently used healthcare premises, the following points have been addressed when developing the diagram for assisting in the assessment of risk in relation to legionellae:

a. the potential for droplet formation;
b. water temperature;
c. the likely risk to those who will inhale water droplets;
d. the susceptibility of the potentially exposed population;
e. means of preventing or controlling risk.

5.9 The majority of intermittently used healthcare premises offer only basic water related services i.e. sanitary accommodation and washing facilities, providing both a hot and cold water supply for staff and patient use.

5.10 Ideal conditions for the colonisation and growth of legionella organisms may occur in intermittently used healthcare premises if water supply is being held in storage and/or pipework in the temperature range of 20°C to 45°C and if water supplies are stagnant for long periods of time.

5.11 Whilst a greater number of susceptible people may indeed access intermittently used healthcare premises, the facilities offered are unlikely to be used other than on an infrequent basis.

ARCHIVE

Hazard assessment

5.12 Legionellae, which causes legionellosis, are naturally widespread in water systems. It is exceptional for a water supply, either public or private, to be entirely free from aquatic organisms, and for this reason it is important that appropriate measures are taken to guard against conditions which may encourage microbial multiplication. Provided water is derived from the public mains and its quality is maintained in the storage and distribution system by correct design, installation and maintenance, it can be regarded as being microbiologically acceptable for use without further treatment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

5.13 Strict adherence to the additional guidance provided in this supplement read in association with the main text of Scottish Health Technical Memorandum 2040 will not eradicate legionellae, but there will be reduction in the risk of an outbreak.

Monitoring and record keeping

5.14 Based on the results of risk assessments completed and the guidance contained in this document, a written operational plan should be devised and regularly reviewed. A realistic programme should be prepared to tackle any area where action is indicated.

NOTE: Refer to Appendix 1: Guidance in developing an operational plan for the management of intermittently used healthcare premises.

5.15 Records of risk assessment completed, and the implementation of the operational plan should be retained throughout the period for which they remain valid, and for at least a further period of two years.

6. Good practice guide

General

6.1 For details of the course of action if an outbreak of Legionnaire's disease is suspected, refer to 'Overview and management responsibilities' part of Scottish Health Technical Memorandum 2040.

Reference should also be made to the Scottish Infection Manual.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Form

Appendix 1: Guidance in developing an operational plan for the management of water systems in intermittently used healthcare premises

An operational plan should:

a. Be in written form and available for inspection.

b. Be prepared by or approved by the nominated person (legionella).

c. Detail the frequencies of routine inspection and maintenance. The minimum frequencies are detailed in HSC(L8) 2000. The control of legionella bacteria in water systems – Approved Code of Practice and Guidance. However, the risk assessment may indicate that increased frequencies are appropriate in some cases.

d. Name the nominated person and the site contact.

e. Be reviewed when the risk assessment is reviewed.

f. Detail known weaknesses and identify remedial actions including timescales.

g. Be signed and dated by the nominated person (legionella) and identify the premises to which it applies.

h. Identify the person or persons responsible for each action called for in the plan including checking temperatures, inspection of systems, time controls etc.

A copy of the operational plan should be retained by the nominated person (legionella), the site contact, the Infection Control Team and any other person upon whose actions the successful implementation of the plan depends.

Intermittently used healthcare premises
Checklist for assessing the risks from legionella

Supplementary notes

Note 1 Storage tanks should be insulated to ensure that stored water does not exceed 20°C. Consideration should be given to the location of storage tanks to minimise casual heat gains.

Note 2 Tanks should be provided with close fitting lids secured to the tank. Vents and overflows should be fitted with mesh screens to prevent access by insects and rodents. Tank lids should allow easy access for cleaning and inspection.

Note 3 Water storage should be kept to the minimum required by operational considerations (requirements of Scottish Health Technical Memorandum 2027 or Water Authorities Guidelines) to ensure that water turnover is as high as possible. Reducing storage time reduces the effects of heat gains and helps to maintain temperatures below 20°C.

NOTE: The volume of stored water can be reduced by lowering the water level in the tank.

Note 4 To ensure pasteurisation, stored water must reach a temperature of 60°C throughout the system at least one hour before the water systems to be used and maintained throughout the occupancy. The temperature at the bottom of a calorifier can be significantly below that at the top and this should be taken into account. Calorifiers in which the heating element is not at the bottom will have difficulty in meeting this requirement. Domestic hot water circulators should be sized to ensure that the temperature within the distribution circuit is above 50°C at all points. Where a temperature of 50°C cannot be maintained, alterations to the systems should be considered.

Note 5 Showers fed from the mains with the hot water at point of use are preferred to showers fed from calorifiers. Where point of use heating is used, the amount of heated water left in the system after operation should be minimised. If showers are provided which are not fed directly from the mains supply, calorifier temperature should be maintained at above 60°C 24 hours a day.

Note 6 A system of regular inspections should be used to ensure that the risk of contamination and multiplication of the organism is minimised.

Note 7 Where Thermostatic Mixing Valves are fitted, the operational requirements of Pressure and Temperature ranges of the valve must be established and recorded.

APPENDICES

1.0 GENERAL INTRODUCTION

Purpose of Document

This specification is based on the NBS suite of specifications.

The development of the ~~design,~~ manufacture, supply, installation, wiring, setting to work and commissioning of the works described in this document shall be undertaken by the Specialist Sub-contractor and is referred to in this document as “the Sub-contractor”.

To carry out the development of the design, the Sub-contractor shall obtain the necessary supporting documentation including but not limited to that listed in Appendix A.

This specification relates to the Domestic Hot and Cold water services serving the Adult and Children’s Hospitals and the adjacent Energy Centre.

This specification shall be read in conjunction with all other mechanical and electrical engineering services specifications and the architectural drawings.

Carbon Target

The hospitals have a stringent carbon target of 80kg/m^2 per annum and the engineering services have been designed with this strictly in mind. The Sub-contractor shall not deviate from the proposed designs without consulting with the Contractor and providing evidence on how the deviation impacts on energy usage and hence the carbon target.

Pumps

All pumps shall be fitted with IE2 efficiency motors to EN 60034-30:2009 as standard, and suitable for operation in ambient temperatures of 40 degrees C.

2.0 SCOPE

The scope of work covered by this specification shall include, but not be limited to the following:

- Site wholesome water mains.
- The domestic cold water service
- The domestic hot water service.

3.0 SPECIFIC EXCLUSIONS

The following are specifically excluded from the scope of this specification:

- RO Water for Renal use
- RO Water for Endoscopy use
- Fire Hydrant Main
- Water Treatment Equipment
- ~~Laboratory Hot & Cold Water~~

4.0 INTERFACES AND DEMARCATIONS

The domestic hot and cold water services shall be provided as complete working systems serving the Adult and Children's Hospitals. The Sub-contractor shall provide information to other parties including for power supplies and BMS interfaces.

The site water mains shall be provided as complete working systems serving the Adult and Children's Hospital, the Energy Centre and the Laboratory Building.

5.0 APPLICABLE STANDARDS

All elements of the works shall be in accordance with the requirements of current legislation, regulations and industry standards unless otherwise stated.

The domestic hot and cold water systems shall accord with all appropriate Scottish Hospital Technical Memoranda, Codes of Practice and relevant British and European Standards, Scottish Water Regulations *(Byelaws)* and to the approval of the local Water Authority and Appendix A.

The site wholesome water mains shall comply with the requirements of Water for Scotland 2nd Edition 2007, and to the requirements of the Water Authority.

6.0 DESIGN CRITERIA

General the domestic hot and cold water systems shall comply with the Scottish Water Regulations and current Codes of Practice

Electricity Supply Characteristics

LV power characteristics: 400/230 V, 3-phase, 50 Hz, 230 V, 1-phase, 50 Hz.

System Design Conditions

Boosted Wholesome Water	-	*7.7 bar*
Boosted General Purpose Water	-	*7.7 bar*
Incoming Water Pressure	-	*1.0 bar*

7.0 LIAISON

The Sub-contractor shall include for liaison with:-

Health and Safety Professionals. As well as the Health and Safety requirements of *Parts A, B and C of this specification,* the Sub-contractor shall include for close liaison with Health and Safety professionals including the Hospital Board's Health and Safety Advisors and the CDM Co-ordinator and shall comply with the CDM Regulations and all Health and Safety Regulations.

The Contractor. The Sub-contractor shall liaise with the Contractor through whom all communications must flow. Drawings and other documentation will be available via the Contractor. The Sub-contractor shall include for liaison with members of the Contractor's team with an interest in the planning and administration of the domestic hot and cold water supply installations.

Other Sub-contractors. The Sub-contractor shall liaise with other Sub-contractors as necessary to ensure that all interfaces between the domestic hot and cold water supply installations and other systems are allowed for.

The Hospital Board. The Sub-contractor shall include for liaison in conjunction with The Contractor with members of the Hospital Board's team with an interest in the planning and administration of the domestic hot and cold water supply installation.

The Architect. The Sub-contractor shall include for review of the Architect's loaded 1:50 drawings, reflected ceiling plans and wall elevations and shall liaise as necessary with the Architect to assist with the production of these drawings

The Structural Engineer. The Sub-contractor shall liaise with the Structural Engineer and provide them with all necessary information for them to undertake the design.

The Local Water Supply Undertaker. The Sub-contractor shall liaise with the Local Water Supply Undertaker or their licensed agents to ensure that all aspects of the installation comply with the Scottish Water Regulations.

8.0 SYSTEM DESCRIPTION

Site Water Mains

Two separate water main connections for wholesome water shall be taken from the new 250 HPPE Scottish Water main crossing the hospital land from Hardgate Road to Govan Road. The connection locations shall be as shown on Horizons Hydro Engineering Drawing No F25214-400-002 and the two pipe shall run as two separate underground main supplies to the basement tank room of the Adult and Children's Hospital, and as two separate supplies to the Laboratory Building and a single supply from the connection nearest to Govan Road to serve the Energy Centre.

The two respective water main connections to the Scottish Water main shall be metered but shall have a branch connection before the meter to serve an un-metered site fire hydrant main.

Both incoming main meters shall have direct readings and a BMS interface.

The two separate incoming water mains shall not be interlinked at any part of the installation.

Incoming Water Supply to the Adult and Children's Hospital

Wholesome cold water will be derived from 2 No. separate incoming water main supplies entering the basement tank room. Each supply will be capable of isolation by valves within the building. A water meter will be incorporated on each supply within the tank room with direct reading and a BMS interface.

Shared incoming flow from water mains

Both incoming water mains shall be fitted with motorised shut-off valves to enable the two mains to have an equal operational running time to supply water to the storage tanks. The valves shall operate on an alternative eleven hours per 24 hour day and shall have a BMS interface.

Each water supply to each tank shall be fitted with an electrically operated shut-off valve to operate in response to a high level alarm in the tank and thus reduce the amount of water discharged through tank warning and overflow pipes. The shut-off valves shall have a BMS interface.

Emergency By-pass

Provision shall be made in the tank room on both incoming water mains for an emergency by-pass connection from the water mains to the two bulk storage tanks. This provision is to be used in the event of main filter plant failure.

Cold Water Storage Tanks

Bulk potable quality water storage tanks will be located within the basement tank room. The tanks will store 100% of the total main hospital water storage.

The tanks shall be arranged to give two streams of flow with 1/3 of storage capacity in the 2 No. break tanks and 2/3 of storage capacity in the 2 No. main *(bulk)* storage tanks.

The tanks will be insulated and complete with raised ball valve housings, self-draining bases, flushing drain and all necessary connections to comply with Water Authority requirements. Each tank shall have a central division plate.

Ballvalves shall be of the delayed action type valve with pilot valve control kit.

Separate connections will be made from the main cold water storage tank header to the booster sets.

The whole of the domestic water services installation will be boosted in pressure to ensure adequate flow at outlets points, such as showers, etc.

Water Filtration

Twin filtration plant shall be served from the 2 No. break tanks and shall supply filtered water to the 2 No. main storage tanks.

Wholesome Water Booster Sets

Two separate packaged wholesome (potable) grade water booster sets will be provided within the tank room.

Each booster set will comprise:

- Dedicated control panel
- Multiple variable speed duty pumps to maintain a constant discharge pressure.
- Accumulator vessel

Provision for an emergency stool piece shall be allowed between pump delivery/header lines of the two pump sets to enable one pump set to be connected into the other pump set supply in the event of a pump set failure.

General Purpose Water Booster Set

A general purpose water booster set complete with break tank in overhead frame shall be provided in the tank room to serve general use Category 5 risk outlets such as external watering points, hoses etc, to avoid cross contamination with the wholesome (potable) water supply.

The booster set will comprise:

- Dedicated control panel

- 3No Variable speed pumps
- Accumulator vessel.

Water Booster set for Dental Chairs

A small packaged booster set with integrated break tank shall be provided to serve the dental chairs in the Children's Hospital. The unit shall be suitable for locating in a cupboard.

All booster cold water pump sets shall be as detailed in the booster pump schedule and as shown on the drawings.

Domestic Cold Water System

From the bulk storage tanks, the wholesome boosted cold-water service will be routed via the main distribution routes to roof plant level and vertical risers to feed the various departments.

A pressure reducing valve shall be installed on the main distribution pipe into each plant room to allow for balancing of pressures serving the different areas of the hospital.

In the plantrooms, the wholesome boosted cold water service will feed un-vented HWS plant, and a number of direct connections to demand points within the building, including system pressurisation units, and dedicated water service systems storage tanks, via type AB air gaps for prevention of cross contamination.

Subject to compliance with SHTMs or with Hospital Board approval, cold water service outlets which may be subject to misuse or for clinical convenience or temperature maintenance and BREEAM compliance may use proximity switching, timed flows, shut off valves and flow regulation to serve this purpose.

Flexible Supply Hoses for Final Connections

No flexible hoses (or tails) connections shall be used.

Hot Water Service Installation

General

All hot water supply systems will be designed and installed to meet the requirements of SHTM 04-01 Part A and B.

Hot Water System

The hot water distribution system will be designed for 60ºC flow and 55ºC return circulating temperature.

Domestic Hot Water (DHWS) will be generated and stored utilising plate heat exchangers and buffer storage vessels (DHWS plant). The DHWS plant and distribution system will be fed from the boosted water system, and thus be pressurised.

The DHWS plant will be directly heated from the main primary MTHW heating circuit from the Energy Centre. The storage temperature will be controlled through the BMS by 2-port control valves on the primary heating system, along with 2-port direct acting control valves to provide protection override in the case of high hot water flow temperatures.

The DHWS plant system will be capable of achieving higher storage temperatures for carrying out a pasteurising process to minimise contamination from Legionella bacterium within the storage buffer vessel. Each storage buffer vessel and plate heat exchanger will be isolated from the distribution system while the process is carried out.

The DHWS distribution system will be configured with a pumped return to maintain temperatures within the system in accordance with SHTM 04-01. The pumped return system will minimise “dead legs” and reduce water consumption by providing the correct temperature of water at the outlet with minimum delay.

The system will have isolating valves generally as the cold water system. In addition, the return water pipework will be provided with valves that isolate and automatically regulate the flow rate, in order to maintain satisfactory temperatures throughout the system.

The hot and cold water system pressures will be equalised at each service outlet for successful blending of hot and cold water through anti-scalding devices prior to use.

The anti scalding devices will be used throughout the hospital where service outlets provide water for personal hygiene washing. Designated outlets will use unmixed hot water at system temperatures where utensils or garment washing is required.

Subject to compliance with the SHTMs or with Hospital Board approval, hot water service outlets which may be subject to misuse or for clinical convenience may use proximity switching, timed flows and flow regulation for water conservation purposes as described for cold water services.

Hot Water Supply Plant (DHWS plant)

The DHWS plant shall be instantaneous type plate heat exchangers with buffer vessels, to provide instantaneous heated water with reduced storage capacity. The DHWS plant shall be housed in the plant rooms as indicated in the equipment data sheets. All DHWS plant shall be factory assembled onto skids and supplied as fully fitted with buffer vessel, expansion vessel, pumps, control panel, controls and gauges.

Each hot water supply plant (plant) shall be arranged as a bank of 3 No. skids. Each skid shall have its own separate plate heat exchanger (phe), and its own buffer vessel. Each phe and buffer vessel is nominally rated at 50% of the total HWS output capacity for its supply zone to cater for isolation of one unit for maintenance and to provide 50% resilience to the hot water supply.

Refer to Equipment Data Sheets of plant & equipment for further details.

Thermostatic Mixing Valves

These valves are provided on each sanitary fitting that requires the hot water delivery temperature to be limited to a safe working maximum. All valves shall comply with the requirements of NHS Specification DO8; NHS Health Guidance Note (HGN) entitled “Safe Hot Water and Surface Temperatures” and be a WRAS listed pattern.

Types of valves to be used (as defined in the HGN) shall be used as indicated on the attached “Matrix of Hot Water Temperatures and Thermostatic mixing valve requirements for sanitary assemblies”.

In addition, the valves shall be appropriate to the system pressure at point of installation.

Valves shall be supplied with in-built check valves and have tamper-proof adjustment. Connections shall be suitable for stainless steel.

Double check valves to be duplicated at TMVs.

Where the thermostatic mixing valves are not provided the Contractor shall affix a permanent label adjacent to the unprotected hot tap clearly stating “VERY HOT WATER”.

Valves shall be factory pre-set to provide maximum delivery water temperatures as follows:

Bidet	-	38°C
Shower	-	41°C
WHB	-	41°C
Bath	-	44°C

Upon completion of the installation, each valves performance shall be checked in accordance with the requirements of Section 5 of the HGN for commissioning, including all necessary paperwork.

HWS Secondary Pumps

All the domestic hot water systems shall be provided with return water circulation pumps. These shall be run continuously with the standby pump supplied loose to allow removal and replacement of operational unit in the case of a fault.

The buffer vessels shall be provided with their own circulation pumps as part of the equipment package. All pumps shall be as detailed on the pump equipment schedule and as shown on the drawings.

Thermostatic Balancing Valves

Each HWS return loop shall be provided with a thermal balancing valve to ensure the HWS return temperature is maintained at 55°C.

The tamper-proof multi-function thermostatic balancing valves shall be suitable for use in domestic hot water circulation systems and shall include drain point, temperature gauge point and automatic disinfection point.

The valves shall provide a thermal balance in the hot water installation by keeping a constant temperature in the system, thus limiting the flow in the circulation pipes to the minimum required level. The valves shall have a minimum flow rate no greater than 0.02 litres/second.

Water Meters

Water meters shall be provided as indicated on the drawings to measure cold water consumption to various systems and parts of the building.

In addition, meters shall be provided to key ‘cost centres’ such as restaurants, kitchens, retail units, etc.

DOMESTIC WATER FLOW REGULATION

To reduce the overall water consumption of the development, all sanitary fittings shall be furnished with flow regulating devices to both hot and cold supplies to the fitting. These devices shall be factory fitted into the outlet side of the fitting isolating valves, and shall regulate the flow (and thus pressure) of each fitting.

These devices shall be as Arrow Valves Ltd. (Tel. No: 01442-823123).

Alternatively, loose regulators may be provided from the same manufacturer for insertion into the outlet side of the local isolating valve.

MATERIAL & WORKMANSHIP CLAUSES

S10 HOT AND COLD WATER SUPPLY SYSTEMS

GENERAL

All domestic stored water shall be of wholesome quality.

The main domestic water supply tanks have be sized for 24hr storage with a 10% additional margin.

The tanks shall be joined at a header arrangement with each tank capable of being isolated for repair or maintenance.

From the bulk storage tanks, the potable boosted cold-water service will be routed via the main distribution routes to roof plant level and vertical risers to feed the various departments. In the plantrooms, the *wholesome* (potable) boosted cold water service will feed un-vented HWS calorifiers, and a number of direct connections to demand points within the building, including system pressurisation units, and dedicated water service systems storage tanks, via type AB air gaps for prevention of cross contamination.

At each main plant area a pressure-regulating valve will be provided to maintain appropriate water pressure at all levels in the building providing convenience of use and minimizing water consumption.

All specific department areas will be provided with isolation provision, with draining down facilities for maintenance and shutdown.

All main distribution and dropper connections will be provided with isolating valves, with local isolation valves installed to isolate and shut down individual ward/department areas.

It should be noted that domestic supplies can only connect to outlets and equipment that are suitable for potable quality water supplies, in accordance with the *Scottish* Water Regulations.

All items of hot and cold water plant and system controls must be capable of being fully interrogated by the building management system through the independent network protocol.

The hot water distribution system will be designed for 60ºC flow and 55ºC return circulating temperature.

Anti scalding devices shall be used throughout the hospital where service outlets provide water for personal hygiene washing. Designated outlets will use unmixed hot water at system temperatures where utensils or garment washing is required.

Subject to compliance with the SHTMs or with Board approval, hot water service outlets which may be subject to misuse or for clinical convenience may use proximity switching, timed flows and flow regulation for water conservation purposes as described for cold water services.

110 INCOMING WATER SUPPLY

- Water company: Scottish Water/Business Stream
- Volume flow rate: 25 l/s from 2No incoming main supplies respectively.
- Position of incoming mains water supply: As schedule and drawings. Two mains supplies shall be taken from the new main crossing the hospital grounds, one connection from Govan road end and one from Hardgate Road end.

Each main shall be capable of supplying 25l/s.
Site water mains shall be installed in accordance with Water for Scotland 2nd Edition and NJUG requirements for utility .apparatus with regards to depth, colour coding, identification markers, and position, and to the requirements of Scottish Water. Site water mains shall be WRAS approved PE barrier pipe suitable for the site contaminated ground conditions and approved by Scottish Water. All backfill shall be from a clean source. A water meter will be incorporated with direct reading and a BMS interface onto both incoming mains supplies at the location identified by Scottish Water and also sub meters within each building served by the site water mains. All sub meters will be linked to the BMS. All water meters will be fitted with isolation valves and non return valves.

130 PUMPED COLD WATER SUPPLY SYSTEM

Bulk wholesome quality water storage tanks and break tanks will be located within the basement of the hospital building. The tanks will store 100% of the total main hospital water storage.

Separate connections will be made from the cold water storage tank header to the booster sets.

The whole of the domestic water services installation will be boosted in pressure to ensure adequate flow at outlets points, such as showers, etc. duplicate packaged wholesome water grade booster sets will be provided within the tank room.

A separate general purpose water booster set will serve Category 5 outlets.

Each booster set will comprise:-
Dedicated control panel
Multiple variable speed duty pumps to maintain a constant discharge pressure including a standby pump
Accumulator vessel

Water supplies for vending machines, ice makers and chilled drinking water points shall be installed as per drawing with valved-off connections for final connection by others.

All incoming water for wholesome storage will pass through a filtration system with a 0.2 micron capacity.

The filtration plant will be in duplicate and served by duplicate break tanks of one third of total capacity.

Each filtration plant will be capable of supplying full peak water demand to the bulk cold water storage tanks.

- Type: Flooded suction or suction lift to directly pressurize hot and cold water systems.
- Water meters: As shown on drawings.
- Pressure booster sets: As section Y20.
- Pumps: As schedule.

- Storage tank or cistern: Glass fibre reinforced cisterns, as section Y21.
  - Accessories: As schedule and requirement for wholesome water.
- Pipelines:
  - Below ground: As section Y10 and NJUG.
  - Above ground: As section Y10.
- Pipeline ancillaries: As section Y11.
- Thermal insulation:
  - Pipelines: As section Y30.
  - Tanks: As section Y30.
- Vibration isolation: Inertia bases, to acoustic consultant recommendations.
- Sanitary appliances: All taps, shower mixers, and sanitary ware shall be as Architects schedules.
- Drinking water outlets: All domestic water shall be wholesome. Drinking water points shall be shown on drawings..
- Flush control devices: As schedules.
- Water coolers: As schedule and drawings.
- Controls: All items of Cold water plant and system controls must be capable of being fully interrogated by the building management system through the independent network protocol..
- Accessories: As schedule.
- Completion:
  - Cleaning and chemical treatment: Flushing and chemical treatment, as section Y12.
  - Plant and equipment identification: As section Y32 and as SHTM/HTM 04 .
  - Commissioning: Commissioning of cold water supply systems, as section Y50 and as SHTM/HTM 04.

160 INDIRECT HOT WATER STORAGE SUPPLY SYSTEM

Hot water storage shall be via the buffer vessels/Storage calorifiers supplied with the plate heat exchangers. The DHWS distribution system will be configured with a pumped return to maintain temperatures within the system in accordance with SHTM/HTM 04-01, associated HGN Safe Hot Water and Surface Temperatures and SHTM/HTM 04-01. The pumped return system will minimise dead legs and reduce water consumption by providing the correct temperature of water at the outlet with minimum delay.

- Capacity: As schedule.
- Primary heat source: MTHW system Comprising of gas fired hot water boiler and CHP units, as section T20.
  - Primary: Sealed.
- Storage unit: Hot water storage shall be via the buffer vessels/Storage calorifiers supplied with the plate heat exchangers.
- Pumps:
  - Primary hot water supply: Close coupled in line, as section Y20. All parts in touch with the wet system shall be stainless steel.
  - Secondary hot water supply: Close coupled in line, as section Y20 All parts in touch with the wet system shall be stainless steel.
- Pipelines: As section Y10.
- Pipeline ancillaries: As section Y11.
- Thermal insulation:
  - Pipelines: As section Y30.
  - Cylinders: As schedule.
- Controls: All items of Hot water plant and system controls must be capable of being fully interrogated by the building management system through the independent network protocol..
- Sanitary appliances: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.

- Accessories: As schedule.
- Completion:
  - Cleaning and chemical treatment: Flushing and chemical treatment, as section Y12.
  - Plant and equipment identification: As section Y32.
  - Commissioning: Commissioning of Hot water supply systems, as section Y50 and as SHTM/HTM 04.

SYSTEM PERFORMANCE

The hot and cold water supply system shall be install, flushed, cleaned, tested and commissioned as per Water Regulations SHTMs and HTMs. Where any standards or documents contradict one another the Sub-contractor shall contact the Contractor for further guidance.

220 COLD WATER SUPPLY

- Incoming mains water supply:
  - Site factors: Two water mains from the external water main shall run separately in the ground to give security of supply. They shall enter the basement of the Acute/Children's Hospital and run at high level in the basement corridor to enter the basement cold water storage tank room. Each of the supplies will connect to the duplicate break tanks serving the filtration plant to ensure that in the event of a mains failure both break tanks will continue to be supplied by the other incoming water main. From the bulk storage tanks, the wholesome boosted cold-water service will be routed via the main distribution routes to plant level and vertical risers to feed the various departments. See drawings for details.
- Type of system: Pumped from a storage tanks.
- Design parameters: To SHTM/HTM 04-01.
- Daily consumption: As schedule.
- Storage capacity: The main domestic water supply tanks shall be sized for 24hr storage.

250 PIPELINE SIZES

- ~~Sizing: Calculate sizes to meet simultaneous demand for the building in accordance with BS 6700 Appendix D or BS EN 806-3. Submit proposals.~~
- Performance:
  - Water velocity (maximum): 1.3 m/s for hot water and 2.0 m/s for cold water.
  - Filling time (maximum) for cold water storage cistern: As schedule.

PRODUCTS

The Sub-contractor shall supply and install services and equipment to perform as per specification. The Contractor shall submit details of all mechanical equipment for comment and place orders in a timely fashion to ensure delivery as per programme. Where a particular manufacture is specified, the Contractor shall include for that manufacturer. Where considered appropriate, provide for equivalent standard alternatives to be offered for consideration. This must be done in a timely manner and the Sub-contractor shall provide all details including but not limited to:

- detailed description
- Cost comparison
- Technical comparison
- References to standards
- References to SHTM/HTMs

310 DEZINCIFICATION

- Fittings, pipelines and equipment located below ground or in concealed or inaccessible locations: Resistant to dezincification, e.g. gunmetal.

320 WATER METERS

Water meters shall be installed as indicated on drawings. Stool pieces between isolating valves will be provided for temporary removal of the meters during the flushing of the system or when meters are removed for repair.

- Standard: To ISO 4064-1.
- Type: In-line meters. Shall be capable of being read by the clients BMS system. .
- Manufacturer: As schedule.
  - Product reference: As schedule.
- Size: To suit service.
- Pressure class: As schedule.
- Temperature class: To suit service.
- Metrological class: As schedule.
- Connections: As schedule.
- Indicating device: Type 2 - digital.
- Features: Pulsed output for remote monitoring.
- Accessories: To BS EN 14154-2.

375 INSTANTANEOUS WATER HEATERS, PACKAGED PLATE HEAT EXCHANGERS

The package instantaneous water heaters shall be served from the MTHW system. The units shall be arranged in banks of three. With 100% duty 50 % standby with each unit capable of meeting 50% of the total load. Each skid mounted unit shall consist of a heat exchanger, buffer vessel, expansion tank, pumps, valves and control panel.

The Integrated control panel shall incorporate a PID controller with a 7 day timer, an automatic night set-back facility, an anti-legionella pasteurisation cycle facility, common fault volt-free signal, alarm message display, remote operating temperature display, remote temperature setting capability, remote enable/disable, high temperature cut-out (manual reset), low temperature alarm, pump protection and valve output indication

The units shall be selected for quite operation and come complete with vibration isolators. The storage temperature will be controlled through the BMS by control valves on the primary heating system, along with 2-port direct acting control valves to provide protection override in the case of high hot water flow temperatures.

The storage system will be capable of achieving higher storage temperatures for carrying out a pasteurising process to minimise contamination from Legionella bacterium within the storage vessel. Each storage vessel will be isolated from the distribution system while the process is carried out.

- Type: Instantaneous.
- Manufacturer: As schedule.
  - Product reference: As schedule.
- Package unit: Plate heat exchanger complete with primary pump, control valves and control panel.
- Primary medium: Medium temperature hot water.
  - Flow rate: As schedule.
  - Inlet temperature: As schedule.
  - Outlet temperature: As schedule.

- Pressure: As schedule.

- Secondary medium: Water.
  - Feed Boosted.
  - Peak flow rate: As schedule.
  - Outlets: As schedule and drawings.
- Accessories: As schedule. The units shall come as a complete package read for use. .

376 BUFFER VESSEL

Hot water storage shall be via the buffer vessels/Storage calorifiers supplied with the plate heat exchangers.

- Manufacturer: As schedule.
  - Product reference: As schedule.
- Capacity: As schedule.

480 FLUSH CONTROL DEVICES

All taps, shower mixers, and Sanitary ware shall be as Architect’s schedules.

- Manufacturer: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.
  - Product reference: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.
- Flush rate: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.
- Water supply valve: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.
- Sensor unit:
  - Material: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.
- Movement detector: All taps, shower mixers, and sanitary ware shall be as Architect’s schedules.
- Power supply: All taps, shower mixers, and sanitary ware shall be as Architect's schedules.

490 WATER COOLERS

- Manufacturer:
  Water coolers, drinks and vending machines shall be supplied and installed by others. The Sub-contractor shall supply services to the coolers and vending machines at locations shown on drawings and agreed with the Contractor.
  - Product reference: Supplied by others.
- Type: Supplied by others.
- Flow rate: Supplied by others.
- Temperature of delivered water: As SHTM/HTM 04-01.
- Water inlet: As required.
- Power supply: As required.

EXECUTION

The Sub-contractor shall ensure all works carried out shall be done is a safe manner and comply with Health and Safety Regulations. This shall include clean and tidy working and working in confined spaces. Due to the size of the water systems being installed all pressure testing and commissioning equipment shall be cleaned and chlorinated before each use. This is to prevent the systems from being contaminated with pseudomonas.

620 INSTALLATION GENERALLY

- Installation: To BS 6700.
- Performance: Free from leaks and the audible effects of expansion, vibration and water hammer.
- Fixing of equipment, components and accessories: Fix securely, parallel or perpendicular to the structure of the building.
- Preparation: Immediately before installing tanks and cisterns on a floor or platform, clear the surface completely of debris and projections.
- Corrosion resistance: In locations where moisture is present or may occur, avoid contact between dissimilar metals by use of suitable washers, gaskets, and the like.

630 INSTALLING WATER METERS

- Standards: To BS EN 14154-2.
- Interconnection to Building Management and Monitoring System (BMMS): Required.

660 UNVENTED HOT WATER STORAGE DISCHARGE PIPES

- Fall (minimum): 1 in 80.
- Discharge: Via an air break and tundish.
  - Size: At least the diameter of the outlet of the safety device.
  - Tundish discharge: At least one diameter larger than the outlet of the safety device.
  - Discharge point: As shown on drawings.

COMPLETION

The Sub-contractor shall protect the system from damage or interference during the works.

The Sub-contractor shall Test, flush and clean the system as per section Y12, Y50, SHTM/ HTM's and TR/20.

The Sub-contractor shall submit O&M's as required by The Contractor

The Sub-contractor shall provide training as per section Y12, Y40 & Y50.

The Sub-contractor shall provide spares as per section Y12, Y40 & Y50.

The Sub-contractor's defects and liability period shall be as the contract prelims.

910 HYDRAULIC PRESSURE TESTING OF HOT AND COLD WATER SUPPLY SYSTEMS

- Standard: To BS 6700.
- Notice (minimum): 1 week.
- Pressure: 1.5 times working pressure.
- Duration of test: 1 h.

980 DOCUMENTATION

O& M documentation shall be issued at least three months before completion of any part of the contract.
The contents and format shall be agreed with the Contractor. The document shall be issued/uploaded on ZUTEC.

The Sub-contractor shall provide instruction to the clients engineers and maintenance staff in the safe operation of all systems and items of equipment for an adequate and reasonable period of time based on the manufactures' recommendations and best practice. The Sub-contractor shall provide adequate and qualified staff in order to carry out their maintenance and repairs during the defects liability period.

990 OPERATING TOOLS

- Tools: Supply tools for operation, maintenance and cleaning purposes.
- Keys: Supply keys for valves and vents.

APPENDIX A

SUPPORTING DOCUMENTATION

In order to carry out the design, the Sub-Contractor shall require access at least to the documentation listed below.

The following information is, or shall be, available from the Contractor:-

1. Standard General Conditions and Preliminary Clauses
2. ZBP Drawings
3. ZBP Schedules
4. Nightingale Associates: Sanitary Schedule
5. Nightingale Associates: Building Plans
6. Nightingale Associates: Building Sections
7. Nightingale Associates: Wall Elevations
8. ZBP: Automatic Controls and Building Management System Specification :
   ZBP-XX-XX-SP-660-401 to 406
9. ITPD Documentation and Appendices

Drawings for other specialist systems shall be developed by other Sub-contractors during the detailed design period and shall be made available by The Contractor when complete.

Description of Domestic Water System

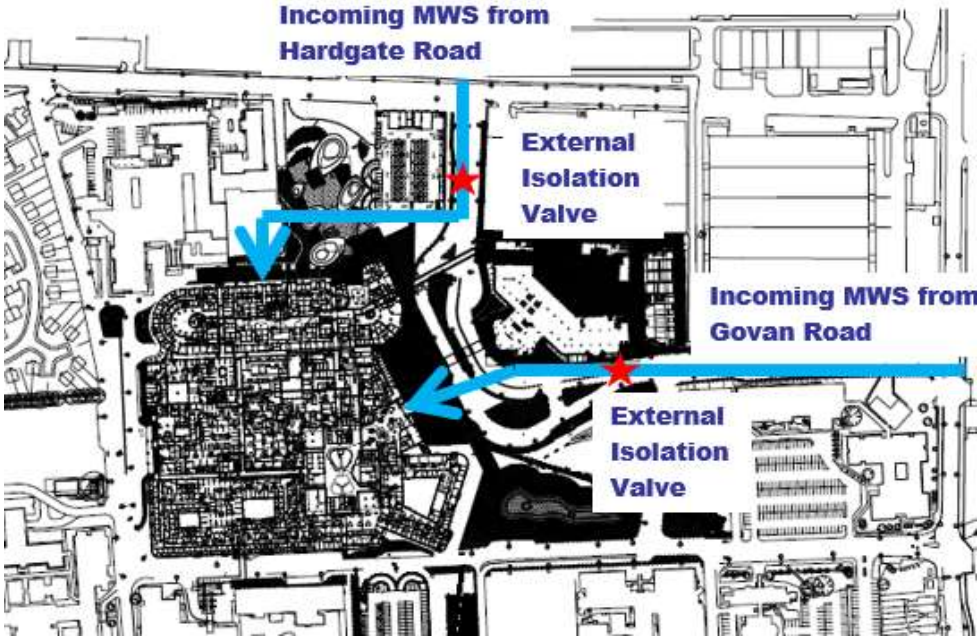
Overview

This description relates to the Domestic Hot and Cold water system serving the Adult and Children's Hospitals at the time it was handed over to GGHB by MPX.

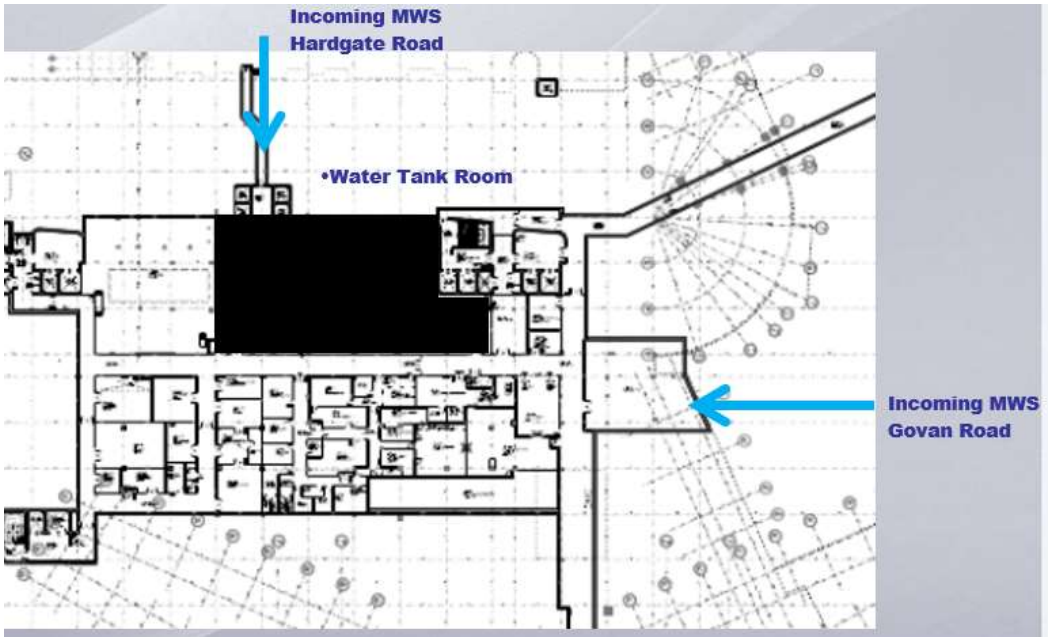
Multiplex understands GGHB have carried out modifications to the water system, but is unaware of the details of those modifications.

The operational procedures, monitoring, control measures and preparedness are matters for GGHB.

Two separate wholesome water main connections are provided from the Scottish Water network. One from Hardgate Road and the other from Govan Road as illustrated below.



The two wholesome cold water supplies are piped underground to the basement tank room of the Adult and Children's Hospital as illustrated below.



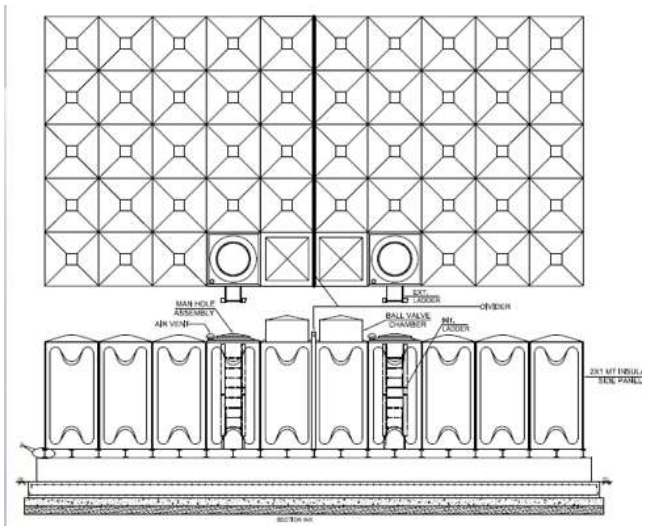
Bulk potable water storage tanks are located within the basement tank room. The tanks store all of the water required for the Adult and Children's Hospital.

Within the basement tank room there are 5no. water tanks.

- The tanks are arranged to give two streams of flow with 1/3 of storage capacity in the 2 break tanks and 2/3 of storage capacity in the 2 main storage tanks.

All cold water storage tanks are two compartment tanks and are piped in such a way as to allow tank maintenance without disrupting the water supply to the building.

The below is a typical example of water storage tanks with compartment divider.



The two wholesome cold water supplies are piped to the break tanks, from these tanks the water is passed through the water filtration plant supplying filtered water to the two main storage tanks.

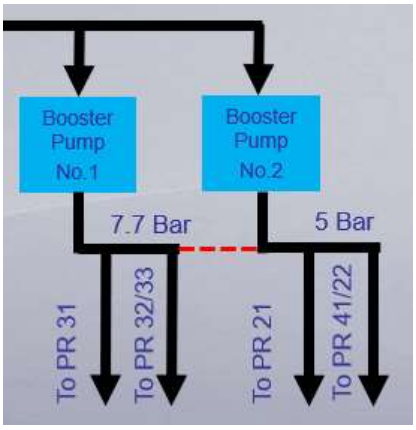
The below is an image of a typical filtration plant.

The whole of the domestic water services installation is boosted in pressure to ensure adequate flow throughout the building.

There are two separate packaged wholesome (potable) grade water booster sets located within the basement water tank room. One serves Plant Room (PR) PR21, PR22 and PR41 and the other serves PR31,PR32 & PR33.

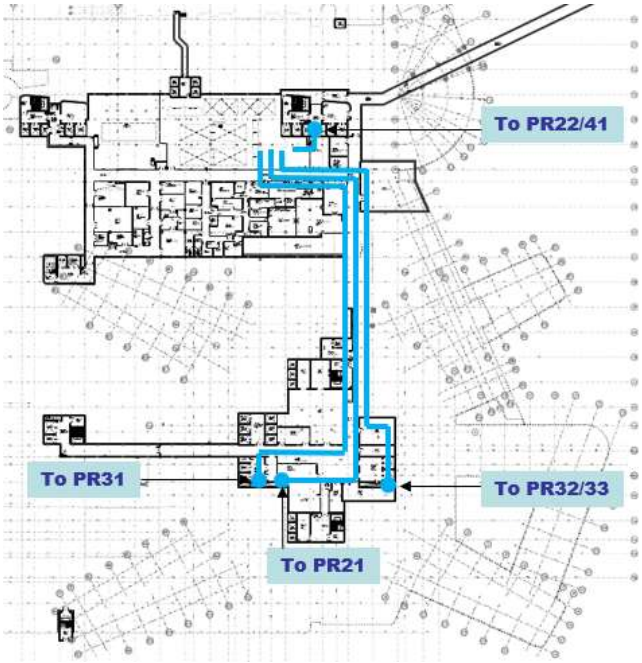
An emergency link is provided between the two booster pump sets to enable one pump set to be connected into the other pump set supply in the event of a pump set failure.

The below is an example of a typical packaged water booster set along with a diagram showing the emergency connection.



There is also a trade water booster set within the basement water tank room. This provides water to high risk outlets such as external watering points, hoses etc to avoid cross contamination with the potable water system.

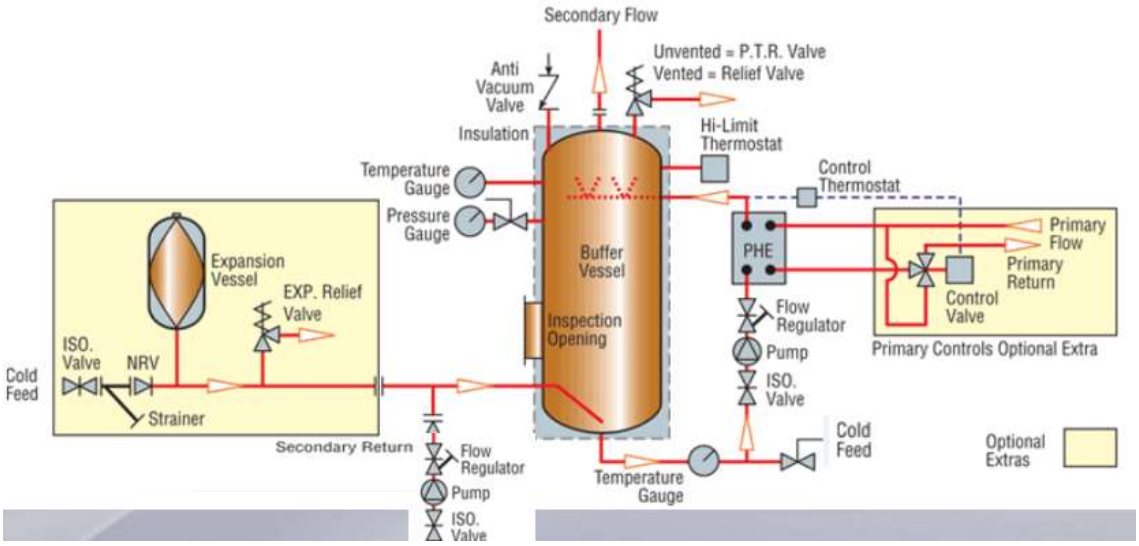
The cold-water service pipework is routed via the basement to vertical risers where the pipework is distributed to the various plantrooms for the generation of hot water. This is illustrated in the below diagram.



Domestic hot water is generated within plantrooms PR21, PR22, PR31, PR32, PR33 & PR41 utilising plate heat exchangers and buffer storage vessels. This provides instantaneous heated water with reduced storage capacity.

The domestic hot water is in-directly heated from the MTHW circuit from the energy centre.

The below image represents a typical arrangement.



The potable cold water service and hot water service is then distributed to outlets within the hospital departments.

The hot water is circulated to the outlet and back to the plate heat exchanger / buffers by a hot water return pump so that temperature is maintained throughout the system. These pumps run continuously.

Below is an image of a typical hot water return pump.

Domestic Water Services Valves

There are various valves installed within the domestic hot and cold water services systems, some examples of the main valves are as follows;

Isolation valves – These are used on both cold and hot water pipework to assist with system isolation for maintenance activity.

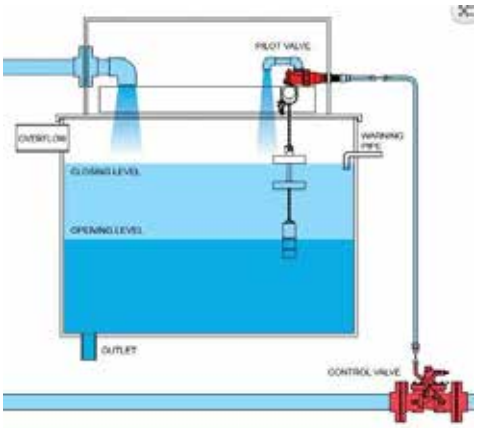
Thermal balancing valves – These are installed on the hot water return pipework to provide isolation for maintenance activity and automatically regulate the water flow rate to maintain temperatures throughout the system.

Multi-Therm
Figure 141 or Figure 143

Multi-Fix
Figure 150 or Figure 151

Pressure reducing valves - The hot and cold water system pressures are equalised by use of pressure reducing valves, these assist with successful blending of hot and cold water through anti-scalding devices prior to use (thermostatic mixing taps).

Cold water tank float valves – Each cold water storage tank is fitted with a Keraflow float valve. This maintains the water level within the tanks. These float valves are adjustable and can be used to reduce the water storage volume if water turnover is slow.



Thermostatic mixing valves – These valves are provided at sanitary fittings and are either separate valves or integral to the taps, these limit the hot water delivery temperature to a safe working maximum.

<u>Domestic Water meters</u>

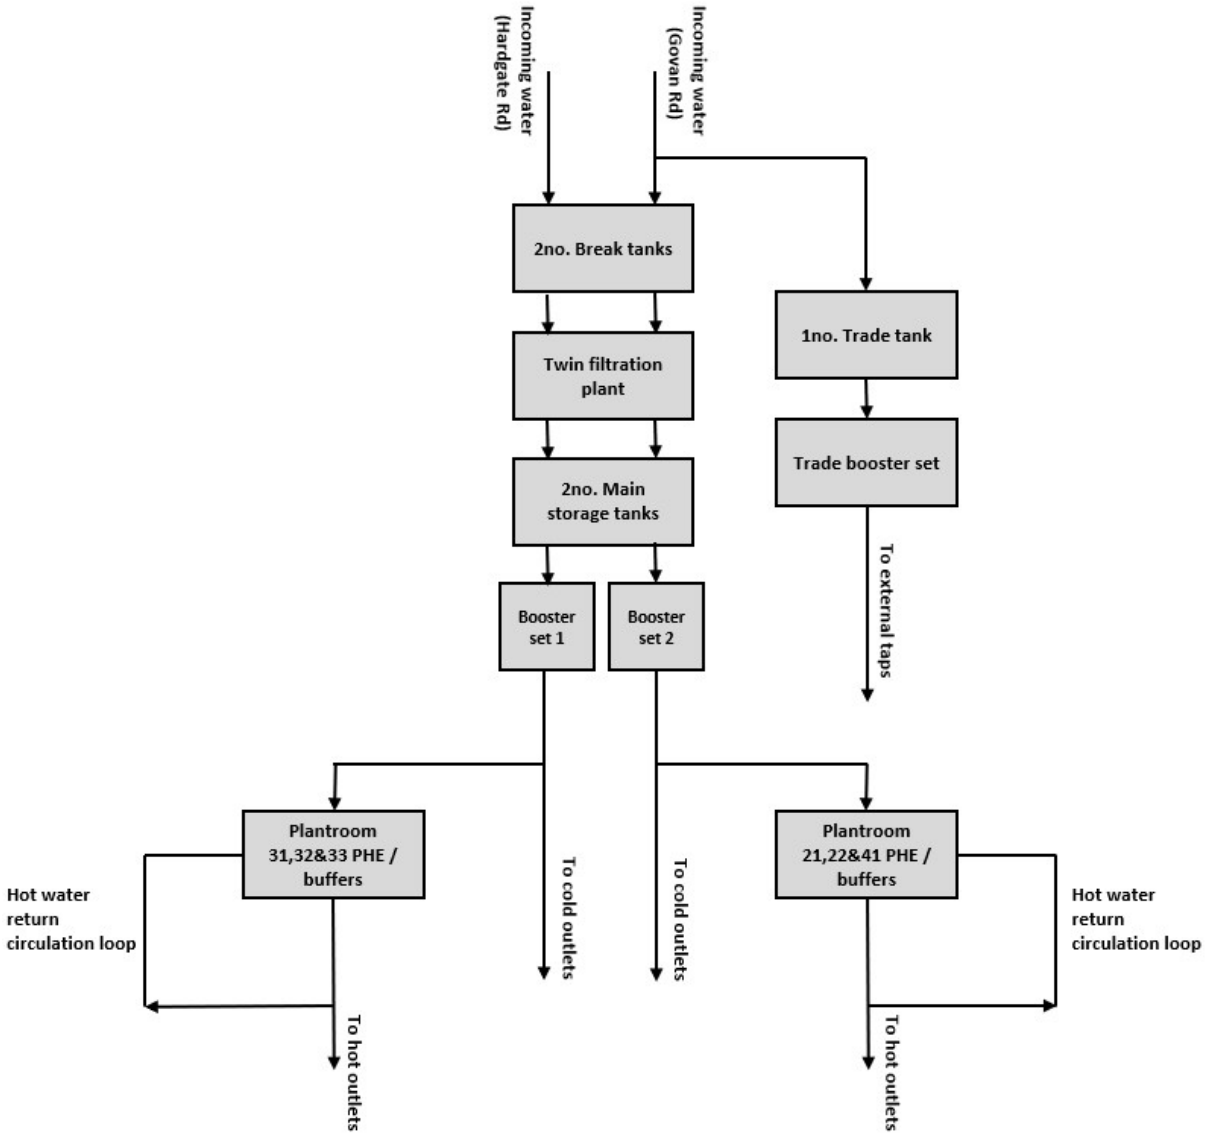
Water meters have been installed on the incoming mains, water supply to each plantroom, cold feed to each of the hot water PHE/buffer plants, kitchen/restaurant supplies, retail unit supplies and renal water plant supplies. All meters are linked back to the BMS to provide remote reading of meters.

Pipework Materials

Pipework ranges in size from 15mm to 200mm in diameter.

- Pipework sizes 15mm to 108mm are of the stainless steel pressfit pipe and fittings type.
- Pipework sizes 150mm to 200mm are of the stainless steel metric tru bore pipe and fittings type.

Simplified flow diagram



Notes

The following are excluded from this description,

- RO Water for Renal use
- RO Water for Endoscopy use

- Fire Hydrant Main

Reverse osmosis (RO) water is an ultrapure water supply for on-line haemodiafiltration treatments. RO water treatment plant is located in plantrooms 21, 31 and 32 and is piped to dialysis stations within various departments.

ABSTRACT

A survey was undertaken of the water quality and plumbing systems of two Scottish hospitals experiencing corrosion of the copper pipework. Waters were also concentrated aseptically from various sites within the hospitals and one metre lengths of copper pipework were withdrawn from the hot water supply for microbiological examination. Extensive pitting corrosion was evident at several sites and a copious biofilm was observed by scanning electron microscopy. Microbiological analysis of the black tubercles covering the perforated areas indicated the presence of anaerobic sulphate-reducing bacteria (SRB) and a variety of aerobes, including *Pseudomonas* and *Alcaligenes* spp., pink-pigmented facultatively methylotrophic bacteria and fungi. Fewer SRB and fungi were detectable in the thinner biofilm associated with the site experiencing minor corrosion but no pitting. The water quality of both the badly and less corroded sites was similar but the hot water supply of the latter was maintained at 60°C whilst the former rarely exceeded 50°C.

Une enquête sur le terrain a été entreprise au niveau de la qualité des eaux et des systèmes de distibution de plusieurs hôpitaux de Glasgow connus ou suspectés pour avoir des problèmes de corrosion au niveau des canalisations en cuivre. Les eaux de plusieurs sites hopitaliers sont concentrées stérilement et un canalisation d'un mètre de long est prélevée du circuit d'eau chaude pour examen microbiologique. On remarque une importante corrosion par piqûres à plusieurs endroits et un biofilm abondant est observé en microscopie électronique à balayage. Les analyses microbiologiques des amas noirs au niveau des surfaces perforées indiquent la présence de bactéries anaérobies sulfatoréductrices (BRS) et

A48235836

d'une flore aérobie comprenant des *Pseudomonas* et des champignons. Les eaux concentrées contiennent aussi des BSR et la même flore aérobie bien que peu de champignons soient détectés. Un plus grand nombre de BSR et de champignons ont été trouvés au sein d'un fin biofilm présent sur un site expérimenté ou seulement une corrosion mineure sans piqûres était observée. La qualité des eaux des deux sites plus ou moins corrodés est similaire bien que la première soit maintenue à 60°C tandis que la seconde excède rarement 50°C.

A48235836

INTRODUCTION

Copper pipework has a twenty-five year guarantee against manufacturing defects and under normal operating conditions is expected to last the lifetime of the building. Many millions of metres of copper plumbing tubes continue to give excellent service supplying hot and cold water in both domestic and industrial buildings. However, it is now apparent that the plumbing systems of a few institutional buildings in certain soft water areas have suffered severe deterioration. In particular, pitting corrosion has resulted in perforation of copper tube in such diverse areas as Scotland, Saudi Arabia and West Germany, although corrosion in the latter country appears to be of a modified form to that experienced elsewhere. The corrosion process was so well established in some Scottish hospitals that renewed sections of the plumbing system suffered identical pitting in a matter of months. This unique corrosion problem cannot be explained simply in terms of chemical corrosion *per se* and suspicion has fallen on the possible involvement of microorganisms, as exemplified by the role of biofilms in corrosion of the steel legs of drilling platforms in the sea (Hamilton, 1985). In this process, sulphate-reducing bacteria (SRB) in a complex microbial consortium use sulphate in the water as an electron acceptor for anaerobic growth, liberating hydrogen sulphide in the biofilm which attacks the steel and establishes a corrosion cell.

The extent of corrosion of copper tubing in Scottish hospitals is not known but replacement costs could be very high. Moreover, the escape of aerosolised water sprays through perforated tubing poses a potential health risk, particularly if *Legionella* spp. were present in the water or able to grow in biofilms (Colbourne and Dennis, 1988; Keevil *et al.*, 1988) adjacent to the perforations. Even in the absence of such pathogens, aquatic bacteria may, when aerosolised, be involved in processes giving rise to humidifier fever and other lung infections. Indeed, any biofilm which is resistant to the toxic effects of copper may well harbour and protect potential pathogens which are normally inhibited by this metal (Gadd and Griffiths, 1978; Falkinham *et al.*, 1984; States *et al.*, 1984). Growth of individual bacterial species or complex microbial consortia and the development of biofilms is markedly affected by the local environment, including changes in nutrient availability, pH, temperature, oxygen concentration, redox potential and metals concentration (Ellwood *et al.*, 1982; Keevil *et al.*, *1987*, *1988*; *Glenister et al.*, 1988). Accordingly, the aim of this investigation was to assess the water quality and plumbing systems of two Scottish hospitals and establish physico-chemical and microbiological parameters of importance to the corrosion process.

A48235836

MATERIALS AND METHODS

Water Supply and Sampling

The soft, peaty water was supplied from an upland catchment (Scottish loch). Water at various points in the plumbing of the hospitals was collected for chemical analysis (Anon, 1979) and determination of assimilable organic carbon (AOC; Stanfield and Jago, 1987). A continuous monitor was installed in one hospital close to the calorifier to study E_h, pH, temperature and dissolved oxygen fluctuations over a 24-hour period. In addition, 10 *l* samples of the incoming mains supply (hydrant), the stores supply (first tap off the holding tank) and water from the calorifiers (first tap off calorifier) or representative of that flowing through the rest of the distribution system (furthest tap in system) were concentrated aseptically by passage through 0.2 μm nylon membrane filters followed by resuspension in 50 ml of the filtrate. Swabs of various taps, cold water holding tanks and calorifier outlets were suspended in 10 ml of the local water supply. The hot water flow to suspect sections of copper pipework was stopped and one metre lengths were cut and immediately sealed at one end with a bung covered with sterile plastic sheet. The tube was filled to the brim with water from that part of the supply and sealed.

Microbiological Analysis

The sealed tubes were reopened in an anaerobic cabinet containing an atmosphere of 80% N_2:10% H_2:10% CO_2 to exclude oxygen that can kill any strict anaerobes present in the samples. The waters were aseptically decanted into sterile containers and some of the pipes were seen to contain large black nodules which were clearly associated with perforations through the metal. These were scraped off with a sterile dental probe and resuspended by vortex mixing in either 5 ml of the membrane-filtered water (Colbourne *et al.*, 1988) obtained from the site or sterile Page's (1967) amoebal saline which was found to be better in the present study for maintaining the viability of the aquatic bacteria. The concentrated waters, resuspended swabs and biofilm were plated (0.1 ml) onto modified Postgate's (1984) Medium agar (to isolate SRB), mineral salts agar containing 0.2% (v/v) methanol (to isolate methylotrophic microorganisms; Colby and Zatman, 1973), minimal R2A agar (to isolate the majority of aerobic and anaerobic microbes and reduce the risk of substrate shock preventing recovery of oligotrophs; Reasoner and Geldreich, 1985) and BCYE agar (to isolate more fastidious aerobes, legionellae and anaerobes; Pasculle *et al.*, 1980). Dilutions of

A48235836

samples were also inoculated into SRB anaerobic broth (Micran, Aberdeen) in triplicate to determine the concentration of SRB by the most probable number (MPN) technique. Biofilm was also streaked directly onto the agar media without resuspension. All samples were incubated at 30°C, both anaerobically in 80% N_2:10% H_2:10% CO_2, and aerobically in 5% CO_2 in air. The number and morphology of colony forming units (cfu) were ascertained after three, six and nine days incubation. The isolated bacteria were tentatively identified by their biochemical reactivity using the API (API 20NE, API-Biomerieux, Basingstoke) and automated Vitek (MacDonald Douglas Bactomatic) database systems. Those colonies suspected of being *Legionella* spp. after growth on BCYE agar (by morphology and purple colouration) were subcultured onto GVPC Legionella Selective Agar (Dennis *et al.*, 1984). L. bozemanii was confirmed by fluorescence of colonies under UV irradiation and reaction with a specific antiserum raised in guinea pigs.

Scanning electron microscopy of suspected biofilms was performed according to the method of Keevil *et al.*, (1987) on 1 cm diameter disks which had been cut out along the lengths of the recovered pipe. These disks were also observed for corrosion under a binocular microscope at low magnification. The waters and resuspended biofilms were observed at 1000 x magnification after Gram staining for the presence of microorganisms.

RESULTS

Pipe Corrosion

The interior surfaces of the copper pipework from the first hospital (hospital X) were covered with a heavy film (Fig.1a,b). Large black tubercles in the tubing taken approximately 100 metres from the calorifier (site 1; Fig.1c) were clearly associated with extensive pitting corrosion (Fig.1d), leading to perforations through the tubing and escape of water. Fewer and smaller tubercles with no perforations were observed in tubing from hospital X at a point less than 60 metres from the calorifier (site 2). The pipework of the second hospital (hospital Y) is supplied with water from the same public supply and it also contained a heavy deposit (not necessarily biofilm; see later) but there was little or no evidence of tubercle formation or corrosion (site 3; Fig.1e,f).

A48235836

Chemical Analysis

The chemical quality of the water supplying the two hospitals was typical of an upland surface source with a natural colour from the dissolved humic acids of peaty soil (Table 1). The low mineral content and poor buffering capacity resulted in a variable pH of 7.4 - 9.3. These variations are most probably associated with lime dosing at the water treatment works and the passage through the distribution network but they might also indicate changes within the plumbing itself. Apart from pH, water chemistry remained reasonably constant throughout the plumbing but copper concentrations increased approximately 30-fold in the hot water at hospital X where pitting corrosion was severe and 60-fold at hospital Y experiencing little corrosion in the sample observed. These increases may have been due to corrosion processes in the pipework but the copper concentrations are still well within EC limits. Carbon available for microbial growth (AOC) was abundant in the incoming water supply (Table 2). This value increased from approximately 7.8 in the hydrant water supplying the two hospitals to 12.4 in the holding tank of the first hospital which may reflect concentration of organic debris in the tank. By comparison, the AOC of London water (lowland, hard surface water) is typically only 3.0. The AOC decreased to values of 4.8 and 1.4 in the plumbing systems of hospitals X and Y, respectively. This depletion may indicate prolific biofilm activity assimilating the available carbon.

Temperature and Oxygen Analysis

The site survey was undertaken in late autumn so the temperature of the hydrant and tank samples was only 10°C, sufficient for survival but not growth of microorganisms (Table 1). A continuous monitoring system revealed that the temperature of the hospital X hot water rarely exceeded 50°C and was more often at 40°C for many hours (Fig.2). This is contrary to the DHSS Code of Practice (1988) stating the need for maintaining a water temperature of at least 50°C. Even when the first outlets downstream from the calorifier were at 50°C the temperature at outlets more distant decreased (Table 1). In the case of hospital X which experienced severe corrosion the temperature was only 43°C at the distant tap outlet after flushing and was as low as 28°C when no water was flowing. A similar low temperature was noted at the distant outlet in hospital Y when no hot water was flowing. Perhaps significantly, however, the temperature of the flowing hot water was always above 56°C and little or no corrosion of pipework was evident. The generally low temperatures at hospital X experiencing corrosion were complemented with marked variation in the dissolved oxygen concentration: a sharp fall

No coliforms or Pseudomonas aeruginosa were detectable in the waters. *The number of aerotolerant spp. and the AOC value in the mains water of hospital y were 50 cfu/ml and 8.1, respectively.

A48235836

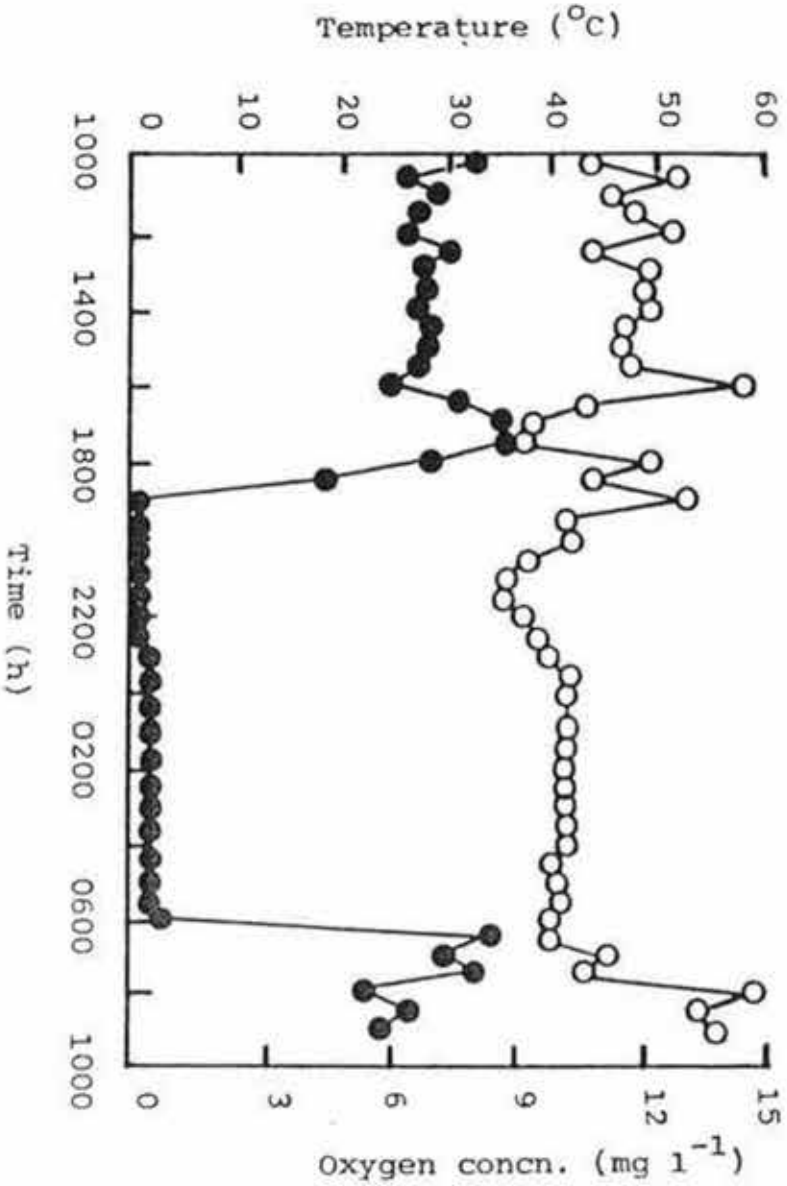

Figure 2 Continuous monitoring of the temperature (O) and dissolved oxygen concentration (●) of the hot water supply at hospital X over a 24 hour tome course

A48235836

occurred overnight for 12 out of 24 hours when little water was used, establishing anaerobic conditions in the water column (Fig.1).

Microbiological Analysis

The incoming cold water to both hospitals contained low counts of bacteria (Table 2). The composition of the aerobic microbial flora after up to nine days incubation on agar media comprised mainly slow-growing, Gram-positive streptococci, micrococci, and Gram-negative rods and bacilli which were predominantly white, yellow or red in colouration. Using the API and Vitek databases, some of the Gram-negative species were tentatively identified as *Alcaligenes*, *Achromobacter and Flavobacterium* spp., (white colonies) and *P. paucimobilis* (yellow colonies). Legionellae were recovered from the base of the vertical calorifier in hospital Y: the temperature of the preflush water was only 27°C and a high count of viable bacteria was detected in this sample. After prolonged flushing this count decreased but *Legionella bozemanii* was recovered. Presumably this had been released from biofilm near the outlet by turbulence (Colbourne and Dennis, 1988). Low numbers of fungi were present in samples from the hydrant and tanks at both hospitals. Blackening of SRB broth and anaerobic growth on SRB agar confirmed the presence of low numbers of SRB, probably *Desulfovibrio* spp., in all of the water column samples. The MPN determination was possibly an underestimate of the SRB concentration since more organisms were apparently detected at the higher dilutions. The could be due to dilution of a toxic substance, such as the relatively high copper concentration in the water.

A similar complex flora was detected in swabs (biofilm/deposits) from various sites but samples taken from the taps and tank sediments in both hospitals were negative for SRB. However, pink-pigmented facultative methylotrophs, able to grow aerobically on either R2A or methanol agar, were detected in biofilms but not in the water supply. These bacteria were probably of the genus *Methylobacterium* (Hood *et al.*, 1988). Their niche within the complex consortia might have been established due to release of C_1 compounds from AOC by the focal activity of biofilm.

When the black tubercles associated with perforations in the tubing of hospital X were recovered anaerobically, the presence of many SRB was indicated by the rapid blackening of the indicator medium. These anaerobic bacteria were also visualised as discrete colonies when the

A48235836

films were streaked directly onto Postgate's Medium agar. Many aerobic species were found, including fungi which could not be detected (visually or by culture) in the water itself. Scanning electron microscopy of the pitted surfaces revealed a copious biofilm (Fig.3a) which under increased magnification was seen to contain a complex community of rod and coccoid bacteria covered with extracellular polymeric material (Fig.3b). Their presence was confirmed by Gram stain of biofilm homogenised in water. By contrast, no black tubercles (Fig.1f) were visible in the tubing taken from hospital Y and fewer viable SRB and fungi were detected. No perforations were observed at low magnification (Fig.1e). Scanning electron microscopy revealed a much thinner biofilm with few rods and cocci (Fig.3c,d). Their presence was again confirmed in homogenised samples by Gram's stain.

DISCUSSION

Chemical analysis alone of the water supplying the Scottish hospitals could not readily explain the corrosion being experienced. By contrast, the survey indicated a link between the presence of biofilm and pitting corrosion of copper tubing. The more copious the biofilm and the greater the numbers of organisms, the more severe the corrosion. Intriguingly, McEvoy (1985) has described how a fungal isolate from fuel tank sludge, *Cladosporium resinae*, is capable of corroding steel and cupronickel alloys. Although identification of the organisms found in these biofilms has yet to be completed it is apparent that *Pseudomonas* and *Alcaligenes* spp. are present. This is of particular interest since such aquatic species are common in treated waters and produce exopoly-saccharides. The production of these polymers may explain why the biofilm consortia were covered in polymeric material. Recent work by Geesey *et al.*, (1987) has shown that microbial exopolymers can sequest copper, even when purified from the bacteria producing them. This sequestration seems to result in corrosion of the copper surface.

Perhaps as importantly, polymer formation helps to consolidate a biofilm and establish diffusion gradients whereby anaerobes can survive in the layers of the film (near the metal surface) which are depleted of oxygen by the metabolism of aerobic species in the upper layers. Biofilm consolidation can also be encouraged by the presence of fungi whose hyphae spread throughout the biofilm and tenaciously trap bacteria in a mesh-like structure. Interestingly, some of these fungi are resistant

A48235836

to comparatively high concentrations of copper (McEvoy, 1985), making them attractive candidates as early pioneer colonisers of copper tubing. Thus, it is possible to speculate on the steps which might be involved in biofilm formation and corrosion of copper tubing in soft water areas. The following tentative scheme is proposed:

1. Most surfaces acquire a "pellicle" of absorbed material from the water supply which may modify the physico-chemistry of the surface. Pellicle formation was observed on the copper tube in the present survey. Soft, upland catchment waters such as those supplying the Glasgow area contain natural organic substances derived from the soil, e.g. humic acids (Thurman, 1985). Moreover, the Scottish water contained assimilable organic carbon at levels above those found in harder, lowland river waters and aerobes such as *Pseudomonas* spp. may use the polyphenolic humic acids present as nutrients. Colbourne (1979) and others (see Andreoni and Bestetti, 1988) have shown that pseudomonads in water can utilise a wide range of organic substances as sole carbon sources; the concentration for growth being very low. The pseudomonads produce exopolymers and attach to copper surfaces whose inhibitory effects may be rendered inert due to the pellicle. Polysaccharide production is also believed to protect bacteria against the inhibitory effects of copper. The bacteria may be joined by other species such as fungi which can be copper tolerant and thus a biofilm matrix forms. At this stage, polysaccharide production may sequest copper and initiate an "aerobic corrosion" process.

2. Metabolism by aerobic members of the biofilm consortium reduces the oxygen concentration in the surrounding water (perhaps as demonstrated at hospital X) and permits the proliferation of strictly anaerobic species, such as SRB. This activity also depletes the oxygen within the deeper layers of the biofilm and permits the anaerobes to establish near the metal surface. Sulphate metabolism by the SRB produces hydrogen sulphide which forms copper sulphides and stimulates a corrosion potential, establishing the "anaerobic corrosion" process (Hamilton, 1985).

Business Development Manager March 2011

HEALTH AND SAFETY RECOMMENDATIONS

Use caution when working on Elga Process Water equipment. The following items are likely to present possible hazards - chemicals, ion exchange resins, electricity, air pressure, water pressure, hot water and hot surfaces. Please ensure personnel are familiar with these hazards and that adequate precautions are maintained.

CHEMICALS

Chemicals used on Ultrafiltration system during normal use are –

- Elgalite RU3 which is an organic acid cleaner for the Ultrafiltration membranes
- Elgalite UFC13 which is an alkaline detergent also used to clean the Ultrafiltration membranes
- Peracetic Acid used to sanitise the Ultrafiltration system

Refer to safety data sheets supplied with the above products and follow the safety instructions during use.

ELECTRICITY

The unit must be properly earthed and the correct rated fuses should be fitted. Power should be switched off at a remote isolator before commencing work on the equipment.

AIR AND WATER PRESSURE

Elga Process Water equipment operates at pressure and, where possible, this should be reduced before commencing work. Normal protection from freezing should be taken, as ice inside pressure vessels and pipework can cause rupture. Compressed air can be dangerous and great care should taken with its use.

IF IN DOUBT FURTHER INFORMATION ON SAFETY CAN BE OBTAINED FROM ELGA PROCESS WATER SERVICE

INTRODUCTION

GENERAL

Please carefully read these operating and maintenance instructions.

Ensure that the unit is installed by Elga Process Water engineers and operated in accordance with the instructions in this manual. If there are any enquiries regarding the installation, operation or servicing of the unit contact Elga Process Water Service Department.

This manual describes the operation and basic maintenance of the Ultrafiltration unit.

Every effort has been made to maximise the life of the life of the Ultrafiltration membrane incorporated in the Elga UF unit.

The Ultrafiltration skid consists of a vertically mounted ultrafiltration membrane, cleaning in place (CIP) tank, control system, motorised valves, flow meter, pressure gauges and CIP Backflush pump.

IMPORTANT NOTES

Please ensure that the following are regularly checked:

1) That pre-treatment is working reliably
2) The maximum pressure differential across the membrane during service does not exceed 0.8 bar
3) Performance Log Books are kept up to date
4) That routine membrane cleaning is carried out
5) Pressure shock owing to water hammer is avoided during normal operation

In addition, water analyses should be routinely maintained so that wide fluctuations of composition can be quickly identified.

If such fluctuations occur contact Elga Process Water Service for advice.

Performance

Notes:

- Molecular Weight Cut-Off – 100 to 150 kDaltons
- Performance information quoted refers to pre-treatment and post-deionisation applications only. For polishing or special purpose applications please consult Elga.
- It is recommended that the UF plant is protected from suspended solids by a cartridge type prefilter approximately 50 micron rating
- Nominal capacities are based on operation at 10°C. For lower temperatures consult Temperature Correction Table below.

Temperature °C	Temperature Correction Factor
10	1.0
8	0.95
6	0.90
4	0.84

Maximum Operating Pressures

Inlet	Flooded Suction
Maximum trans-membrane pressure in service	0.8 Bar (11.5 psi)
Maximum trans-membrane pressure during backwash	2.5 Bar (35 psi)

Feed Water Temperature and pH Limits

pH	Maximum Temperature
1-3	30ºC (40ºC for short periods for cleaning typically 0.5-1 hour)
3-10	40ºC Normal operation
10-13	30ºC

PROCESS AND PLANT DESCRIPTION

ULTRAFILTRATION

The UF system is a self contained water treatment package that is complementary to the Elga range of media filters, deionisers and reverse osmosis plant.

Owing to the small pore size and geometry of the system, the process is capable of removing contaminants from water without suffering adversely from fouling.

Examples of impurities which can be efficiently removed include suspended solids, colloids (silica, iron, organics etc), and High Molecular Weight Organic molecules.

The system incorporates safety features and automatic controls for ease of operation.

Elga UF plants are skid mounted systems intended for pre-treatment applications and are assembled and wet tested before despatch.

The UF is fully automatic during normal service requiring only the minimum of supervision.

Periodic chemical cleaning is required to restore membrane capacity and prevent long term deterioration in performance. Elga supply a range of chemicals specifically developed for cleaning ultrafiltration membranes operating in the water treatment industry.

Molecular Weight Cut Off (MWCO)

Ultrafiltration is a low pressure membrane separation process employing cross flow and dead ended membranes with pore sizes in the range 10-200 Angstroms.

Systems are rated by their output in litres per hour and the nominal Molecular Weight Cut Off of particles and molecules that will not pass through the membrane.

The membrane module in the Ultrafiltration unit has a MWCO of 100-150 kDaltons and an output of 5000 litres per hour per membrane

Water Recovery

The 'recovery' of a water treatment system is a measure of the proportion of the total input water that is converted to purified water or permeate. A recovery of 10% means that only 1 part in ten of the input water is converted to permeate. At 50% recovery, half of the input water is converted. At 75% recovery, three quarters of the input water is converted to permeate.

The Ultrafilter is operated as a ‘Dead End’ filter for most applications which means that the recovery is 100%. However a small proportion of the permeate is stored and used during periodic backwashing to drain. This then gives an effective recovery of 92%.

Temperature and Pressure

The PESM materials and membrane structure has temperature and pressure limitations of 40ºC and 5 bar respectively when operated on normally pre-treated water. However, the UF should not be operated above 30ºC during alkaline cleaning, and 20ºC during peracetic acid disinfection. Ambient temperature in the plant room should not exceed 35^0C.

OPERATING INFORMATION FOR ULTRAFILTER MEMBRANES

- The membranes fitted to the UF must remain damp at all times. A temporary or possibly permanent loss in performance may result if they are allowed to dry completely.
- If operating specifications are not strictly followed the warranty will be null and void.
- During the first hour of running new membranes, direct product water (permeate) to drain. For critical process applications a longer 'run in' period may be required to completely rinse the membranes.

To prevent bacterial growth and help maintain flux, it is recommended that elements are stored as stated in section Preservation and Freeze Protection, whenever the system is not in use for a period longer than 3 days. Neither non-ionic nor cationic surfactants nor any other chemical not approved in writing by Elga Process Water should be used for membrane cleaning, or come in contact with the UF membranes.

The customer is fully responsible for the effects of unapproved chemicals on the UF membranes; their use will void the element warranty.

PRE-TREATMENT

The UF Membranes in the Ultrafiltration have a finite life with the decline in performance depending mainly on the quality of the treated feedwater and remedial cleaning.

The life of the membranes is optimised by:

- The correct choice of pre-treatment for the feedwater supply.
- Routine maintenance and cleaning when necessary.
- Correct operation.

A full analysis of the feedwater is recommended to provide guidelines for adequate protection of the membranes.

In addition unusual impurities such as oil, grease and organic solvents should not be allowed to enter the unit, otherwise irreversible membrane damage may result.

PRE-TREATMENT TECHNIQUES

One of the following pre-treatment techniques may be required for UF units:

Suspended Matter

A 25 micron particulate filter is fitted as standard to the UF unit. Feed water having a high fouling index or high turbidity may require additional filtration such as suitable sand, or multimedia filter.

Temperature

For optimum performance the Ultrafiltration unit requires a feedwater temperature below 30^{o}C (maximum 40^{o}C). Note that the ambient temperature of the plant room should not exceed 35^{o}C.

PROCESS DESCRIPTION AND HYDRAULIC COMPONENTS

Refer to the flow diagrams in the 'drawings' section of this manual.

Process description

The ultrafiltration membrane is connected to a feed manifold, and concentrate manifold and a permeate manifold

During normal service, water flows into the UF module through either the top of bottom process connection depending on the valve orientation instructed by the controller. Water then flows through the centre of the hollow fibres. The inner surface of the fibres form the membrane separation barriers and water permeates radially outwards through the membranes into the collection shell and permeate manifold.

During service the ultrafiltration modules are operated at 100% recovery, that is no water is rejected from the concentrate side. The overall recovery figure is reduced to approximately 92 when for 1 minute every hour the membranes are cleaned with a flush of feed water and a backflush of permeate. Previously ultrafiltrated water which has been collected during service is pumped in a reverse direction through the membranes into the centre of the fibre and then to drain. The backflush procedure is fully automatic, being carried out by the PLC controller and automatic motorised control valves.

In addition to the automatic backwashing, periodic chemical cleaning is required to maintain the capacity and water quality. See Cleaning Cycle section

Flow Process and Hydraulic Controls

The following notes should be read in conjunction with the process drawing in the Drawing Section and the valve position schedules in Appendix 1.

During service, feed water flows into the plant through the inlet valve and into the inlet of the pump. The flow is through the Feed/CIP pump and into the UF membranes. In the membranes

the flow is in a inside to outside direction before collected at the permeate port. The Permeate then flow out through the permeate valve and off skid.

When the plant is in service a small amount of permeate passes via a flow restrictor and servo float valve to the CIP tank. This permeate is used for backflushing the modules.

When the plant is backflushed the filtered water flows out of the CIP tank through the feed/backwash pump and into the permeate port of the Ultra Filter membranes flowing through the fibres from outside to inside before collecting at the concentrate port and flowing to the drain.

ELECTRICAL CONTROLS

The operation of the unit is carried out through the HMI screen, the layout of the screens is shown in Appendix 7

The other controls on the control panel are:-

Power Isolator

The main power switch/door isolator is on the lower left of the control panel. This isolates the unit from the electrical power supply, as the valves are motorised this will not change their position, which can result in the unit continuing to operate.

Indicator Lights

There are three indicator lamps and one buzzer on the system that are positioned in the control panel:

Colour	Legend	Function
Green	24VDC Circuit	The 24 VDC circuit is ok used for valves
Green	PLC Circuit	The power circuit to the PLC is ok
Green	Instrument Circuit	The 5 VDC circuit is ok used for pressure transducers

E-Stop

If the E-stop button is pressed then the power to the CIP and intermediate pump are cut and the valves are moved to the standby position. The HMI will display an alarm, the E-Stop circuit will only come back into service once the E-Stop reset button has been pressed.

PLC Reset

If the PLC Reset button is pressed for 3 seconds then the unit plc will reset all alarms and functions.

ALARMS

UF Controller

The alarms on the UF controller –

- High Inlet Pressure
- CIP/Feed Pump Failure
- Differential Pressure exceeded
- E-Stop pressed
- CIP tank low during backwash
- Valve failure

- Chemically enhanced Backwash timeout

For all of these alarms the buzzer will be activated and the volt free contact closed, the contact for the volt free contact is given in The Electrical Connection SChedule

The valves will move to the standby position.

To acknowledge an alarm press the flashing alarm symbol in the top right hand corner and press the ack button in the alarm screen when the particular alarm is highlighted

If a valve alarm has occurred then the the RST button needs to be pressed before the unit will commence operation

INSTALLATION

MECHANICAL AND HYDRAULIC CONNECTIONS

Foundations/Drainage

The system will not require any special foundations, provided that a firm, level area, which is capable of supporting the working weight, is available.

Concentrate water from the UF process must flow to an open drain (or gully via an air break) that is capable of passing the necessary flow. The maximum flow of water to drain depends on site conditions, but may be up to 100% of the normal service feed water flow.

Operating Space

Access will be required to monitor the operating flows, pressures and conductivities. Access will also be needed to carry out adjustments or maintenance on the equipment. It is therefore recommended that a minimum of 500mm clearance be allowed around the base for this purpose.

Incoming Water

The feed water to the system must comply with the following:

(a) Available at all times at a flow equal to the required maximum service flow or greater.
(b) Flooded Suction at the required service flow rate or greater.
(c) Temperature between 5ºC and 40ºC.
(d) Filtered for suspended solids above 50 micron.

Pipework

Pipework to be connected to system should not have an excessive amount of Iron or hardness scale deposit. Piping that is heavily built up with scale or Iron deposits should be replaced.

Make sure that the pipework can be connected to the Ultrafiltration system in such a way as to impose no stresses on the inlet connection, and so that it is properly aligned and supported.

WATER SUPPLY REQUIREMENTS AND REGULATIONS

It is essential that the equipment is connected to a pressurised water supply. If connected to a mains supply the local water supply regulations or byelaws must be adhered to. These cover both plumbing and the prevention of back flow into the mains water supply . If there is any doubt, the local water supplier should be consulted.

ELECTRICAL CONNECTIONS

Electrical installation should be carried out by a competent electrician, and must conform to the appropriate standards of safety. An electrical supply of 380/400 V 3pH 50 Hz is required by the system.

The mains supply connection should be made through a separate 380/400 V 3pH 50 Hz switched supply with three phases and neutral, fused and earthed in accordance with Institute of Electrical Engineers Regulations. Current rating should be as shown above. Motor rated fuses must be used.

A 230 to 24V DC safety isolating transformer is fitted within the control panel to provide power to the low voltage valve and pump control circuits and the PLC controller has an integral 230 to 24V DC transformer built in which is used for the PLC inputs power feed and the PLC display panel power supply.

Building Management System connections

The PLC controller has two integral volt free alarm contacts that can be utilised to connect to a BMS system.

Warning Alarm (Malfunction)
Service/Standby

Terminal numbers for the above functions are shown in the electrical wiring schedule

COMMISSIONING

Ultrafiltration systems should only be commissioned by qualified Elga Process Water commissioning engineers.

No attempt should be made to operate the system until it has been commissioned since serious damage could result.

OPERATION

OPERATING PROCEDURES

The Ultrafiltration system is designed to run and rinse automatically and should not be turned off for more than a day to ensure that the regular flush and backflush cycles are completed correctly.

For the first few days of use, the operating pressures, and feed flows should be monitored every few hours and the system adjusted as the membrane beds down.

Thereafter, the flows, pressures and temperature should be monitored daily at a time when the UF system is producing water.

In general, it is advised that cleaning is carried out when pressure differential increases to no more than 10 psi during service. It is recommended that a Elga Process Water service technician with a thorough understanding of the Ultrafiltration system and their cleaning regimes carries this out. The full details of the operating procedure is given in Appendix 1

START-UP

Ensure the installation has been completed correctly in compliance with Installation and Commissioning Section

Ensure the water supply to the unit is on.

Switch the Electrical supply on

Check the Process Switch is disengaged

Turn the unit on at the door isolator.

NORMAL OPERATION

The Unit should be left to run automatically at all times. Periodic supervision of the plant is essential. Check and record the following data.

- Pre-treatment equipment should be checked for correct operation
- Log sheets should be filled in with the following information:

Daily	Monitor flows and pressures and fill in data sheet.
Weekly	Monitor Fouling Index, check log sheets for developing trends, i.e. increased pressure, reduced quality, etc. Act accordingly.

Examples of data recording sheets can be found in the 'record sheets' section.

SHUTDOWN

If the system needs to be shut down for a short period of time it can simply be turned off by pressing the process stop button on the control panel.

If, however, it is to be shut down for more than one week then the UF system should be cleaned with alkaline detergent UFC13 and filled with preservative. It is recommended that an Elga Process Water service technician with a thorough understanding of Ultrafiltration systems and their cleaning regimes carries this out.

EMERGENCY STOP

The Ultrafiltration unit can be quickly stopped in an emergency by turning the system off at the door isolator on the control panel. However this will not cause the inlet or outlet valves to close, nor change the position of the CIP or backflush valves.

Cleaning Cycle

The periodic manual cleaning cycle is controlled by the PLC.

Manual cleaning can be initiated once the system is in standby and is password protected. The screen will then prompt any further action.

CIP OPERATING PROCEDURE: -

Stage 1 Put the unit in standby mode and call for a chemical clean.
Stage 2 When the buzzer sounds and the display shows 'Close Outlet Valve' then the service valve needs to be closed, once this has been acknowledged then the unit will move to the next stage.
Stage 3 When the buzzer sounds and the display 'Add Chemicals' then the required chemicals need to be added (RU3 to remove hardness, UFC13 to remove organics).
Stage 4 When buzzer sounds and display shows 'CIP complete' then the ph of the water needs to be checked and confirmation given that ok before the service valve can be opened and the unit put back into service.

If it is necessary due to excessive contamination then the RU3 or UFC13 clean can be repeated. If a RU3 clean is not required then this can be skipped by picking the UFC13 clean initially.

The total cleaning sequence is shown below: -

Chemical Clean Sequence				
Step	**Action**	**Display**	**Controlling Function**	**Intervention Required**
1	Filling CIP Tank	Filling CIP Tank 1	High Level Float Switch	
2	Buzzer activated	Close Service Valve	operator	Acknowledgment required
3	Adding Chemicals	Add RU3	Operator	Acknowledgment of addition of chemical
4	Circulating Chemicals	Circulating Chemical	2 minutes	
5	Chemically Cleaning Filter	Cleaning Filter	30 minutes	
6	Draining Tank	Drain CIP Tank 1	Low Level Switch plus 1 minute	
7	Mains Flushing of Filter	Flush Membrane	5 minutes	
8	Draining Tank	Drain CIP Tank 2	Low Level Switch plus 1 minute	
9	Filling Tank	Filling CIP Tank 2	High Level Float Switch	
10	Backwashing Filter	Backwash Membrane 1	Low Level Switch	
11	Filling Tank	Filling CIP Tank 3	High Level Float Switch	
12	Backwashing Filter	Backwash Membrane 2	Low Level Switch	
13	Filling Tank	Filling CIP Tank 4	High Level Float Switch	
14	Flush	Membranes Flushing	PH Meter	
15	CIP Complete	CIP Complete	Operator	Acknowledgement of Service Valve opened

FLUSH

A Flush of the system can be instigated. This allows feed water to flow across and through the membrane down the permeate line to the CIP tank and then the drain.

FEED/BACKWASH PUMP

The supply to the unit can be either pressurised (min 2 Barg max 10 Barg) or flooded suction. If it is pressurised then the feed/backwash pump will have to have it's operation inhibited in the "Inhibit Pump Pressure Alarms Screen" this will limit the pump to be only used in internal operations and the inlet pressure to drive the water in Service operations. If it is in a flooded suction application then the "Inhibit Feed Pump Operation" has to be live and the pump will work in internal and service modes.

ROUTINE MAINTENANCE

In addition to the daily and weekly monitoring, the following tasks should be scheduled as part of the routine maintenance programme.

Monthly	Inspect system for leaks and tighten fittings where necessary.
Three monthly*	Replace inlet filter cartridges.
Annually*	Check function of control system. Calibrate Instruments.

***** To be carried out by Elga Process Water Engineer.

RECOMMENDED CONSUMABLES

Part No	Description	Quantity
ELGA 22694	ELGALITE UFC13 12 x 250 gm	1 Box
ELGA 22693	ELGALITE RU3 12 x 500 gm	1 Box
TBA	Cintropur NW650 25 micron bag filter	1 pack of 5

TROUBLE-SHOOTING

The following table is intended as an overall guide to trouble-shooting procedures.

Fault	Check	Action
Filtrate output low	• Pressure differential during service, Pressure gauges UF Module Feed Pressure and UF Module Back Pressure	If high run cleaning cycle
	• Inlet Pressure during service, Pressure Gauge Feed Water Pressure	If below 2 bar in service increase inlet pressure
Unit does not power up	• Check Electrical Supply and MCB's	
CIP Tank not Filling	• Float Valve allows water to flow during filtration	Flush through Float Valve
High Inlet Pressure	• Check Membrane Differential Pressure • Check Permeate line clear	Clean Membranes Clear Line
CIP Pump Fault	• Check Pump overload	Reset Overload and replace as required
Intermediate Pump Fault	• Check Pump overload	Reset Overload and replace as required
E-stop Presses	• E-Stop Pressed	Release E-Stop and press E-Stop reset
CIP tank low during Backwash	• CIP tank inlet valve	Replace or clean
Valve Failure	• Reset	Monitor valve in question and contact Elga
Chemically Enhanced Backwash Exceeded	• PH meter	Re-run Chemically enhanced backwash and contact elga

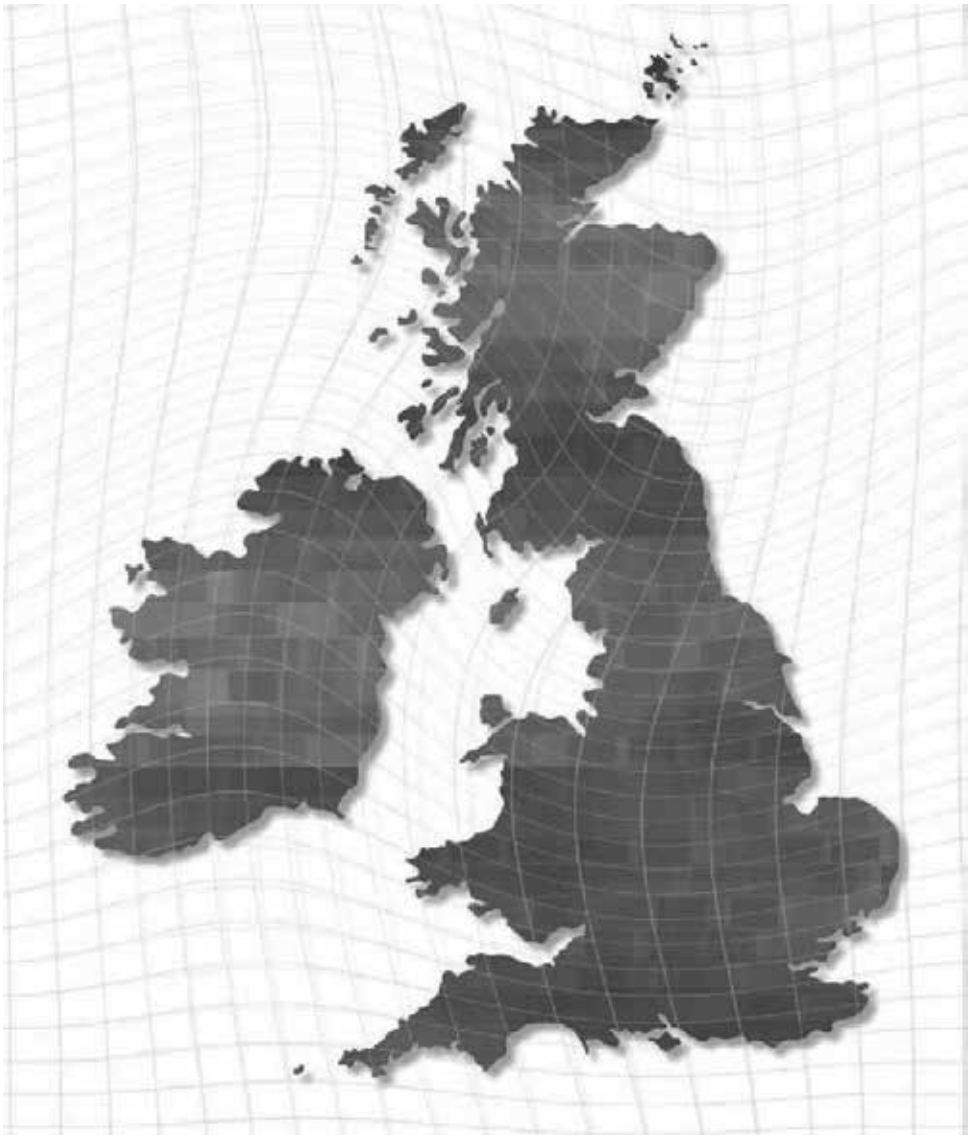
ELGA PROCESS WATER - Service

At Elga Process Water Service we work in partnership with you to ensure uninterrupted, optimal operation of your water and wastewater equipment, processes services and outsourcing requirements. Our unique blend of skills and expertise and the knowledge gathered from more than 70 years of industry experience enables us to provide a wide range of services from media exchange to 24-hour round the clock rapid response emergency service.

Our total Service capabilities include:

- A wide range of service contracts including response sensitive, all inclusive and performance qualification contracts
- Unsurpassed provision of service engineers for on site maintenance and equipment rectification
- Regeneration of DI and aqueous cleaning cylinders
- Supply of cleaning chemicals and media
- Hire equipment and cylinders for short-term requirements
- Service projects including equipment refurbishment, media and ion exchange resin re-bedding, extensions and modifications
- Training for operators and maintenance staff
- Analytical services
- Disinfection services

OUR SERVICE COVERS THE COUNTRY



For all Service requirements contact:

ELGA PROCESS WATER

Telephone: 01355 588000
Fax: 01355 588001
Website: www.elga.co.uk

GLOSSARY OF TERMS

Cleaning in Place (CIP):
Periodic cleaning of the membranes using a detergent or other suitable chemical is required to remove fouling material.

Disinfection:
Periodic disinfection of the membranes using 1% formaldehyde, 1% metabisulphite, 0.05% hydrogen peroxide, or 0.2% peracetic acid solution is required to prevent excessive growth of bacteria in the UF modules and pipework.

Fouling Index (FI) or Silt Density Index (SDI):
A qualitative measure of the particulate and colloidal content of the water.

Membrane:
The permeable material which is used to separate the water from impurities.

Module:
The pressure vessel containing an Ultrafilter element.

Filtrate/Permeate:
The treated water obtained from an Ultrafilter unit, which has passed through the permeable membrane.

Permeate flux:
Permeate flowrate per unit area of membrane per unit of pressure.

Pressure Drop (PD):
Difference between module inlet and outlet pressures.

Pre-treatment:
The process of treating water before it passes through the UF unit such as filtration and chemical dosing.

Feed Water:
Feed water to the water treatment plant from the local water supply.

Recovery:
The ratio of permeate flow to feed water flow x 100%.

Ultrafiltration (UF):
A membrane technique for purifying water.

FOULING INDEX/SILT DENSITY INDEX

The Fouling Index (FI), also known as the Silt Density Index (SDI), is an estimate of the amount of colloidal material present in a water supply. It is based on the rate at which a 0.45 micron membrane filter blocks. To perform an FI test an FI test kit is required (Elga Process Water part no. SSA041).

Operation

- Connect the filter assembly to the sample point, making sure that all fittings are pressure tight and that the filter assembly is held vertically.
- Unscrew and remove the bottom half of the clear filter holder and open the sample valve. Allow the water to run to waste for several minutes to clear the line of any debris and entrapped air.
- Turn off the water using the filter holder On/Off valve and place a filter disc by means of the forceps in the lower half of the holder. Check that the grooves of the filter support plates are facing the filter.
- Open the On/Off valves so that the water drips through the unit in order to completely wet the filter surface, and slowly screw on the bottom half of the housing with one finger over the outlet of the filter housing. This helps remove any air trapped in the filter housing.
- When the air has been expelled, tighten the filter holder.
  It is important that the filter holder assembly is not over tightened, as this may crack the top threaded section. The top of the assembly should be held whenever tightening or undoing the unit.
- Open the On/Off valve fully and adjust the pressure-reducing valve so that a reading of 2 bar is obtained.
- Once the pressure has been set, turn off the On/Off valve.
- Discard the filter used for setting up the apparatus and replace with a new filter as described above.
- Simultaneously turn the On/Off valve on, start the clock and measure the time to collect 100 ml of water using a stopwatch. This initial time, ti, is very critical, and practice will be required to co-ordinate the starting of the stopwatch with the collection of the 100 ml samples.
- The water is kept flowing through the filter and after 5, 10 and 15 minutes, measure the time required to collect further 100 ml samples. Check that the pressure gauge is reading a constant 2 bar; it may be necessary to adjust the pressure reducing valve during the test to maintain a constant 2 bar.

In areas of high fouling index it may be necessary to collect 100ml samples at 1 minute intervals; refer to section headed 'High Index Waters'.

- Included in the test results should be the feed water temperatures as this may have some bearing on the Fouling Index value, especially the, ti value.

Calculation of Results

Formula

% Blockage	=	100 [1 - ti/tf]
FI	=	SDI = % Blockage/TF
FI	=	Fouling Index (dimensionless)
SDI	=	Silt Density Index (dimensionless)
ti	=	Time in seconds for the collection of the initial 100 ml.
tf	=	Time in seconds for the collection of 100 ml at TF, the time relating to 75-80% blockage of the filter disc.
TF	=	Total time, in minutes, of the test.

The aim of the test is to select the time at which the filter disc is 75-80% blocked.

Therefore the ratio of the initial time, ti, divided by tf must be between 0.2-0.25.

Therefore ti/tf = 0.2-0.25 corresponds to 80-75% Blockage.
Example - Low Fouling Index Water

Total Time (minutes)	**100 ml Sample Time** (seconds)
0	6
5	11
10	20
15	28

ti/tf = 6/28 = 0.21

This value is between 0.2 and 0.25 and therefore the fouling index is:

$$FI = \frac{(1 - 0.21) \times 100}{15} = 5.3$$

High Index Waters

For these waters, it will be impossible to obtain even a 5 minutes reading and still have a ti/tf ratio between 0.2 - 0.25.

Repeat the test, measuring the 100 ml sample collections at 1 minute intervals instead of 5 minute intervals until the desired 75-80% plug of the filter has been achieved.

Example - High Fouling Index Water

Total Time (minutes)	**100 ml Sample Time** (seconds)
0	8
1	14
2	27
3	35
4	57
5	83

Because the ti/tf must lie between 0.2 and 0.25 then the 3 minutes value is the time to use

ti/tf = 8/35 = 0.228

$$FI = \frac{(1 - 0.228) \times 100}{3} = 25.7$$

SAMPLE POINTS

There are 3 sample ports on the UF unit, for locations see the Schematic Drawing on Page 36.

SAMPLING METHOD

1. Open Valve and allow full flow out of the valve for 2 minutes
2. Do not touch valve as this can dislodge contaminates from the internal components
3. Open Sterile container and place under stream of water and fill to appropiate level
4. Cap Container
5. Turn valve off

See attached documents

Appendix 1 Operating Procedure

The UF plant works on a 1 hour cycle including a 1 minute backwash cycle.

A manually actuated chemical enhanced backwash is required periodically to maintain the performance of the plant.

The standard operating procedure is:-

Filtrate	57 minutes
Backwash	3 minute

SAFETY DATA ON THE USE OF ELGALITE RU3

Physical Properties	
Melting Properties (Degrees C)	153
Boiling Point (Degrees C)	---
Decomposition Temperature (Degrees C)	---
PH (g/l water)	Approximately 2.6 at 10g/l
Solubility (water)	Good
Odour	Nil
Physical Form (20 degrees C)	Cystalline
Vapour Pressure (20 Degrees C)	---
Bulk Density	970 kg/Cubic Meter
Storage and Handling	
Special precautions for Storage and Handling	Store away from alkalis and handle with care
Incompatible Substances	Alkalis
Hazardous Decomposition Products	---
Hazardous Reactions	Do not mix with Alkalis
Preventive Measures	Protective Clothing
Preventive Measures	Avoid breathing dust of powder- use particle mask
Technical Protection Measures	None Required
Measures after Spillage	Sweep up carefully and wash away
Disposal	Must not be disposed of to drain without neutralization with alkalis to acceptable pH
Fire and Expolsion Hazard	
Flash Point	Non-flammable

Ignition Temperature	---
Extinguishing Media	---
Special Fire Precautions	---
Special Fire and Explosion Hazard	---

Toxicity

No experimental data available. Non toxic at low concentrations

Emergency and First aid Procedures

For Skin contact, copiously wash with water

For eyes, irrigate for 15 minutes and seek medical aid immediately

If swallowed, drink plenty of water with milk and seek medical aid immediately

Special Information

Keep out of reach of children

In case of contact with eyes, rinse immediately with plenty of water and seek medical advise

Immediately take off all contaminated clothing

Wear suitable gloves

Wear eye/face protection

OWING TO OUR POLICY OF CONTINUING DEVELOPMENT, WE RESERVE THE RIGHT TO CHANGE ANY INFORMATION GIVEN ON THIS DATA PAGE

INSTRUCTIONS FOR THE USE OF ELGALITE RU3

Applications

Elgalite RU3 is a powder cleaner based on organic acids formulated to remove iron and mineral scale.

Elgalite RU3 is a general purpose acidic cleaner suitable for reverse osmosis and ultrafiltration membrane capable of tolerating low pH.

Elgalite RU3 is usually used as a pre-rinse prior to an alkaline detergent clean on ultrafiltration membranes.

Usuage

For routine applications Elgalite RU3 is used at a rate of 1.0% in aqueous solution. Under conditions of heavy fouling, with certain membranes, concentrations of 2.0 % may be used.

Notes on Use of Elgalite RU3

See also the section entitled ‘Chemical Cleaning’ in the Ultrafiltration manual.

Use permeate water for chemical make up and recirculation. Normally pre-treated feed water should be used for displacing chemical solutions after cleaning.

Elgalite RU3 should be thoroughly dissolved in the cleaning tank prior to re-circulation. If necessary, a fresh batch of cleaning solution should be made up if the first batch becomes excessively dirty after recirculation.

Cleaning solution should be recircultaed for 30 minutes to 2 hours depending on the condition of the membranes.

Rinsing should be carried out until permeate is acceptable for the product water application.

Additional Notes for Reverse Osmosis

Concentrate should be initially directed to drain during the cleaning process to remove gross contamination from the system. When the concentrate stream clears of gross contamination the plant should be connected for recircultaion.

Appendix 3.

SAFETY DATA ON THE USE OF ELGALITE UFC 13

Physical Properties	
Melting Properties (Degrees C)	60
Boiling Point (Degrees C)	100
Decomposition Temperature (Degrees C)	100
PH (g/l water)	12 (1.2 % aqueous solution)
Solubility (water)	Good
Odour	Slight Chlorine
Physical Form (20 degrees C)	Powder
Vapour Pressure (20 Degrees C)	---
Bulk Density	950 kg/Cubic Meter (approximately)
Available Chlorine	Approximately 240 mg/l (1.2 % aqueous solution)

Storage and Handling

Special precautions for Storage and Handling	Store away from acids and handle with care
Incompatible Substances	Acids
Hazardous Decomposition Products	Chlorine gas liberated on contact with acids
Hazardous Reactions	Do not mix with Acids
Preventive Measures	Protective Clothing
Preventive Measures	Avoid breathing dust of powder- use particle mask
Technical Protection Measures	None Required
Measures after Spillage	Sweep up carefully and wash away

Fire and Explosion Hazard

Flash Point	Non-flammable
Ignition Temperature	---
Extinguishing Media	---
Special Fire Precautions	---
Special Fire and Explosion Hazard	---

Toxicity

No experimental data available.

Caution: Contaions a hazardous ingrediant caustic soda (18%)

Caution: Product is corrosive to skin and tissue. Prolonged contact under wet conditions can irritate the eyes and mucous membranes.

Emergency and First aid Procedures

For Skin contact, copiously wash with water and seek medical aid (caustic burn)

For eyes, irrigate for 15 minutes and seek medical aid immediately

If swallowed, drink plenty of water with lemon juice (not milk) and seek medical aid immediately

Special Information

Causes severe burns**.**

Keep out of reach of children

In case of contact with eyes, rinse immediately with plenty of water and seek medical advise

Immediately take off all contaminated clothing

Wear suitable gloves

In case of insufficient ventilation, wear suitable respiratory equipment.

Wear eye/face protection

Owing to the chlorine content, Elgalite UFC 13 should never be used on reverse osmosis membranes.

OWING TO OUR POLICY OF CONTINUING DEVELOPMENT, WE RESERVE THE RIGHT TO CHANGE ANY INFORMATION GIVEN ON THIS DATA PAGE

INSTRUCTIONS FOR THE USE OF ELGALITE UFC 13

Applications

Elgalite UFC 13 is a chlorinated , alkaline powder detergent based on a combination of organic and inorganic sequestering agents and chlorine.

Elgalite UFC 13 is recommended for cleaning and disinfecting ultrafiltration membranes and is effective in removing organic and inorganic colloids, biological materials and silica.

Elgalite UFC 13 exhibits very good cleaning , dispersing and soil suspension capabilities combined with the excellent disinfection properties of chlorine.

Elgalite UFC 13 is therefore a versitle cleaning agent suitable for a wide variety of foulants encountered in the ultrafiltration systems.

Usuage

For routine applications Elgalite UFC 13 is used at a rate of 1.2% in aqueous solution.

Notes on Use of Elgalite UFC 13

See also the section entitled ‘Chemical Cleaning’ in the manual.

Elgalite UFC 13 is a two component detergent supplied as two separate sachets contained within a bag. Both sachets should be dissolved in the cleaning tank water to obtain the desired detergent composition.

Use permeate water for chemical make up and recirculation. Normally pre-treated feed water should be used for displacing chemical solutions after cleaning.

Elgalite RU3 should be thoroughly dissolved in the cleaning tank prior to re-circulation. If necessary, a fresh batch of cleaning solution should be made up if the first batch becomes excessively dirty after recirculation.

Cleaning solution should be recircultaed for 30 minutes to 2 hours depending on the condition of the membranes.

Rinsing should be carried out until the levels of detergent and chlorine in the permeate are acceptable for the product water application.

Appendix 4

MONITORING UF PERFORMANCE

Routine monitoring of the UF is advisable to maintain good water quality and also protect the membranes. It is therefore recommended that a performance log is filled in at least once per day and the corrected flux calculated on a regular basis.

Corrected Flux

To compensate for varying temperature and pressures, a parameter called the corredted flux should be calculated. This value can be plotted against time to show how the performance of the pilot UF varies.

The value of the corrected flux is a relationship between the permeate flow, module inlet and outlet pressure and the membrane area. Ideally this value would remain constant with time although statistical fluctuations will be expected. A large varaiation in corrected flux over a period of time indicates that the pilot UF is not functioning correctly. This could be caused by the membranes becoming fouled, for example.

The corrected flux is calculated from the equation

$$C = \frac{QP}{TCF \times MA \times DP} \quad \text{Litres/m}^2\text{.h.b}$$

Where QP = Permeate Flowrate-bar

TCF = Temperature correction factor

A = Membrane Area m2 (45 m^2 per membrane)

P = Pressure drop across the membrane (ie P2 minus P3)

The Scottish Government

Dear Colleague

PROVISION OF SINGLE ROOM ACCOMMODATION AND BED SPACING

Further to the interim guidance issued by David Hastie, then Head of Property and Capital Planning, on 15 December 2006, the work of the Steering Group on single room provision has now been completed. This letter sets out the conclusions reached and introduces updated guidance on the future provision of single room accommodation and bed spacing in new and refurbished projects.

The background to the Steering Group's work is set out in Annex A.

Action

NHS Boards should implement the new guidance in all schemes in excess of delegated limits that have not yet submitted Outline Business Cases. For schemes within delegated limits the guidance should be applied for such projects that have not commenced procurement. The guidance is as follows:

New-build facilities

- For all new-build hospitals or other healthcare facilities which will provide in-patient accommodation there should be a presumption that all patients will be accommodated in single rooms, unless there are clinical reasons for multi-bedded rooms to be available.

Refurbishment of healthcare facilities

- For projects where the refurbishment of major healthcare facilities has been approved it is recognised that each building to be refurbished will present unique problems. However, in developing proposals for substantially refurbishing healthcare facilities NHS Boards should seek to provide the maximum number of single rooms consistent with the approach for new-build, e.g. 100%.

- In developing proposals for single room provision in refurbishments, recognising the constraints posed by existing buildings, it has been decided that the overall level of single room provision should be 50% as an absolute minimum, with due regard to the clinical needs of specific patient groups.

INVESTOR IN PEOPLE
POSITIVE ABOUT DISABLED PEOPLE

Pending the conclusion of the further work set out below schemes will be considered on a case by case basis and NHS Boards should consult with the Capital Investment Group.

Further work

- Further work is required to support clinical decision making on the need for multi-bedded areas for specific patient groups, or clinical specialties where 100% single rooms would be regarded as always appropriate. A Delphi Consultation exercise with the clinical speciality leads designated by the Chief Medical Officer is currently underway, and supporting materials will be produced in the near future. Separate advice on this issue will be issued in due course.

- Health Facilities Scotland will be asked to review and update all relevant technical guidance and also to lead the work on developing a risk matrix tool in conjunction with the Single Room Steering Group and other key stakeholders.

Yours sincerely

POSITIVE ABOUT DISABLED PEOPLE

Annex A

Background to the work of the Steering Group

Following a Peer Review of the European Union Health Property Network Report entitled "Hospital Ward Configuration: Determinants Influencing Single Room Provision", a Steering Group was established in March 2006 to take forward the recommendation that further evidence in a Scottish context should be gathered. This Group's membership was drawn from those involved in the Peer Review event who were experts in their subject and who represented a broad range of professional disciplines, both from NHSScotland and Scottish Government Health Department (now Health Directorates). The Steering Group has now reported and its recommendations have been accepted. The report will shortly be available in full at www.scotland.gov.uk/haitaskforce.

This Steering Group had as its remit:

> To consider the evidence supporting the establishment of the future level of single room provision within new-build hospitals and in the refurbishment of major hospital facilities in Scotland.

The Group also considered the related issue of the appropriate space around each bed where these are not located in a single room. For the purpose of the report, a single room was defined as "a room with space for one patient which normally contains, at a minimum, a bed, locker, clinical wash-hand basin and also sanitary facilities comprising a toilet, shower and wash-hand basin". The Group did not consider the requirements for "specialised isolation rooms" with fully engineered ventilation.

Members of the Steering Group recognised that there was a need for information which was specific to Scotland and commissioned a number of reports/studies as follows:

- Literature review
- Public attitude survey
- Nurse staffing report
- Financial impact study

In addition to these reports, the Group also had the benefit of a survey undertaken at the Golden Jubilee National Hospital of patients who had experience of both single room and multi-occupancy room provision. In relation to the financial impact of an increased level of single room provision, the Group had the benefit of the outcome of a study undertaken in Northern Ireland of the financial impact of increasing single room provision from 50% to 100%.

Having identified and evaluated options appropriate in a Scottish context, the Steering Group recognised that not only is it necessary to strike a balance between service quality and the opportunity cost in an environment which is influenced not only by clinical and "building" interest but also by the issue of patient safety and public expectation. It was also recognised as crucial that any conclusions and recommendations made regarding single room provision in future new-build and refurbished in-patient accommodation should be future-proofed and able to accommodate the changing standards expected by patients, given the lifecycle of such facilities which often extend beyond 50 years.

INVESTOR IN PEOPLE
POSITIVE ABOUT DISABLED PEOPLE

Recommendations

The Steering Group's recommendations were as follows:

1) For all new-build hospitals or other healthcare facilities which will provide in-patient accommodation there should be a presumption that all patients will be accommodated in single rooms, unless a lower percentage provision for specific patient groups has been justified to and approved by the Scottish Government Health Directorate (SGHD) as part of the Business Case approval process. Those patient groups for which 100% single room provision is considered essential will be agreed with the SGHD's Chief Medical Officer.

2) For those projects which identify a refurbishment as the appropriate option to be developed, the Steering Group recognised that it is extremely difficult for it to establish a definitive proposal as each of the buildings to be refurbished will present unique problems. However, the Steering Group's recommendation was that in developing proposals for refurbishing healthcare facilities which include in-patient accommodation, Health Boards should seek to provide the maximum number of single rooms consistent with the approach recommended for new build healthcare facilities and that the overall level of single room provision within any refurbished accommodation should be 50% as an absolute minimum.

3) For bed spacing, the Group considered that the current advice remains appropriate - namely that having regard to ergonomic criteria, primarily the space required for patient handling and other activities which take place in the immediate vicinity of the bed it is recognised that the minimum bed space should not be less than 3.6 m x 3.7m.

Accordingly when planning any new in-patient accommodation or any major refurbishments of existing accommodation it is recommended that the increased bed space is adopted.

Further work

The Group also recognised a need for further work to be undertaken and has commenced a Delphi Consultation exercise with the clinical speciality leads designated by the SGHD's Chief Medical Officer. This exercise, when completed, should identify those specific patient groups for whom 100% single room provision is essential.

Further the Group recognised that it would be helpful to Boards in developing projects for a Risk Matrix Tool to be developed. It is proposed that this be based on the SCART (Statutory Compliance Assessment Risk Tool) recently developed by Health Facilities Scotland (HFS) for use by all NHS Health Boards.

ADULT AND CHILDRENS HOSPITAL AND ENERGY CENTRE

1.0 EXECUTIVE SUMMARY: ADULT & CHILDRENS HOSPITAL

Visits to the site during October 2012 indicated that the construction and procedures are progressing in a satisfactory manner in accordance with the Employer's Requirements.

Throughout, the standard and quality of the workmanship is generally good and operations are being carried out in an acceptable manner.

Brookfield continues to undertake their Quality Assurance systems on site with inspection and checklist documentation available for the ongoing construction activities. Over the period, we have closely liaised with Brookfield and witnessed both drainage tests and 85 point check to partitions on Level 0. Our witnessing resulted in successful tests. We also have successfully carried out some witnessing of electrical testing in the Energy Centre. Other tests scheduled for the fire sprinkler testing were cancelled on three occasions due to the lack of water pressure. We await confirmation of new test date.

The standard of the work in the exemplar rooms in progress during this period is good. We shall continue to monitor the work planned for the coming month including door frames, screens, sanitary ware, ceiling trims, radiant panels bulkhead for lighting, wall protection and medical hoist. The internal finishes workmanship standards are used as a benchmark for all room completions.

The roof work is continuing on Level 1, 2 and 3 Zones G and D in accordance with the drawings.

Cladding is progressing on the south elevation and courtyards 3, 4 & 5 and the "STO" system is progressing on the south and east elevations.

Energy Centre structural work is largely completed. Various items of plant are still being installed via the north elevation. Structural quality to date appears satisfactory, although some minor snagging still remains outstanding as reported during the last period.

All mini-piling work has now been completed. Further meetings have been held with Brookfield to confirm certain issues associated with this and to confirm the nature of the 'as built' details that will be provided on ZUTEC for both the rotary piles and the mini-piles. Checks will be made to ensure that comprehensive as built records are provided.

Concreting to the main A&C building has again progressed in several areas. This has included 2nd and 3rd floors in Zones D and E, 3rd, 4th and 5th floors in Zone H, roof level in Zone A, and ground floor slabs in Zones D, E and H. Quality throughout has generally been good. Workmanship to the small 20mm step in floor slabs at all levels in Zones J and E continues to be poor and has not been satisfactorily addressed.

Structural steelwork erection to the atrium walkway has been substantially completed during the period. As noted in the last report quality wise, the main concern is the damage to the fire protection coating (shop applied) on some sections. Brookfield is aware of this and the damaged areas are receiving intumescent coating. Snagging of the structure has also been ongoing during the period. Elsewhere ancillary steelwork around cores and at stairwells has progressed, and in occasional places some minor remedial attention to bolts and cleats is required.

Sub-slab drainage in Zones A, D, E and H has progressed during the period with pressure tests proving satisfactory. Some rodding demonstration remains to be carried out when position of scaffolding permits. Drainage proposals in Zones A and B have also been reviewed during the period.

A few quality issues remain to be addressed from previous reports but these are not considered programme critical at this stage.

The M&E installation is now progressing at pace, with pre-fabricated sections and second and final fix being installed in the A&C areas. Large plant items continue to be installed in the Energy Centre and areas are now being commissioned looking towards partial completion in the coming months. Testing is now commencing in the Energy Centre.

In general terms we are satisfied that the installations continue being installed to the correct standard, and are of a good quality however we have noted again that certain items this month that have raised concern. These have been raised with the Contractor.

Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 49, 50, 51, 52, 537, 54, 55, 56, 57, 58, 59, 60, 61, 62 and 63 were issued.

- Damaged deformed boards due to poor stacking.
- Broken glass gauge to Energy Centre Tank No 1.
- Open ducts/vents.
- Seeking confirmation when damage roof insulation will be replaced.
- Requesting dry film thickness results for factory applied and site applied intumescent coating.
- Requesting method statement for air leakage tests.
- Confirm remedial action to damaged steel framework.
- Seeking confirmation if the attached holes without bolts to steelwork bridge connections reflects the design intent.
- Seeking confirmation when High level SVP in Level 3, Plant Room and Level 1, Zone G. - between CCW-003 and RAF-062 will be sealed.
- Seeking confirmation when pIpework on Level 1, Zone H STW-039 Single Bed, STW-094 Male Staff Change and STW-043 Corridor will be capped.
- Seeking confirmation when clash between spigot and electrical containment will be addressed.

- Seeking confirmation when SVP will be capped in various locations Level 1 Zone H.
- Seeking confirmation when sprinkler system is capped level 1 Zone G between CCW-OO6 and void.
- Seeking confirmation when Knauf boards will be fitted in accordance with NBS K10.

Supervisor's Notification of Defects (CI 42.2) No 11,12,13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25 and 26 were issued.

- Sprinkler heads in plant room obstructed by fire rated ductwork in plant room.
- Moterised damper inaccessible due to duct in plant room.
- Restricted access to ductwork access hatch in corridor adjacent to Zone H near Stair F.
- Ductwork obstructed by modular frame Zone H.
- Part OF Stud, Level 2 Zone D cut away.
- Fixing to cladding visible.
- Seeking confirmation when cabling in various locations on level 2 is supported properly.
- Seeking confirmation when the damper in Level 3 Pant Room is sealed properly.
- Seeking confirmation when the ductwork in various locations on Level 2 which is uncapped or falling off will be addressed.
- Seeking confirmation when the dead legs which exceed 3m in various locations on Level 1 and 2 will be addressed.
- Seeking confirmation when smoke detection heads in various locations on Level 0 Zone G will be capped.
- Seeking confirmation when the smoke detection heads in various locations on Level 1 Zone G and H will be capped.
- Seeking confirmation when the Air Handling Units exposed in Level 2, Plantroom are adequate protection.
- Seeking confirmation when the restricted access to ductwork is addressed.
- Pipework bracket inadequately fixed.
- Rodding eye partially covered by partition.

We continue to be assisted by the site teams and the NHS Project Team who produce an internal weekly report which is of assist to us in resolving various construction, mechanical, electrical, and quality issues. We continue to close out our Supervisor's Notifications and Defects when we have received satisfactory responses.

2.0 DESIGN COMPLIANCE CHECK

The drawing and specification review is complete. Previous reviews have been conducted, with comments marked on drawings and returned to Brookfield.

3.0 PROCEDURES REVIEW

3.1 Contractor's QA Procedures

Brookfield and their subcontractors have continued with their QA and checking and inspection procedures during the period. We are in discussion and liaison with Brookfield's Quality Manager on QA matters and we undertake regular reviews of their QA documentation.

The standard of the work in the exemplar rooms in progress during this period is good. We shall continue to monitor the work planned for the coming month including door frames, screens, sanitary ware, ceiling trims, radiant panels bulkhead for lighting, wall protection and medical hoist. The internal finishes workmanship standards are used as a benchmark for all room completions.

Workmanship overall is of a good standard throughout.

Below is a plan showing the partition opened up for inspection on Level 0 and part of the 85 point check list. We witnessed an 85 point check to the partitions between rooms AAW-338 and AAW-335. The partition was generally constructed in accordance with the drawings and specification. However there were two failures and they were: -1. Screw breaking the paper. 2. Mastic not applied to abutment stud. 3. Are items not applicable. These were remedied and a further inspection was carried out.

The next page shows an extract from the 85 point check list. The first column shows that the items have been constructed in accordance with the specification and the second identifies the failures.

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDRENS HOSPITAL AND ENERGY CENTRE

SUPERVISOR 'S REPORT NO. 19 **OCTOBER 2012**

19	Two beads of mastic between fireboard and soffit.	✓			Lift section if not visible (no deviation)
20	Correct fixings use for head track.	✓			Check against detail (no deviation)
21	Correct fixing centres used.	✓			Measure @ least 10 fixings (no deviation from detail)
22	Picture frame bead of mastic at junction of fireboards/soffit both sid	✓			Check both sides (no deviation)
23	Correct board used for infills in ribdeck.			✓	Check against detail (no deviation)
24	Correct number of boards used for infills.			✓	Check against detail (no deviation)
25	Correct insulation use in infills.			✓	Check against detail (no deviation)
26	Small holes in ribdeck filled with Rockwool.			✓	Visual check use torch (no deviation)
27	Bead of mastic around infill to ribdeck.			✓	Visual check use torch (no deviation)
28	Infill boards overlap fireboard by 7mm.			✓	Measure @ least 3 rib deck (no deviation)
29	Correct type of stud used, eg: C stud, I stud.	✓		✓	Check against detail (no deviation)
30	Correct gauge of stud.	✓		✓	Check against detail (no deviation)
31	Studs cut to correct length for deflection.	✓			Stud length = + 0 and - 5mm
32	Studs at correct centres (300-400-600mm)	✓			Measure top middle bottom (no deviation)
33	Doorway built to correct specification for weight of door.	✓			Check against detail (width -0 +5mm height -0 +10mm)
34	Leg of door head 250mm minimum.	✓			Measure both legs (no deviation)
35	Door head mitred.			✓	Visual check (no deviation)
36	Floor track returns up stud 300mm.			✓	Measure both legs (no deviation)
37	Correct number of screw in door head.	✓			Check against detail (no deviation)
38	Timber inserted in door stud to correct			✓	Visual check (no deviation)
39	Timber in head of double door.	✓			Visual check (no deviation)
40	Door stud cloaked in head track.	✓			Visual check (no deviation)
41	Screws at correct centres in door stud.			✓	Measure both legs (no deviation)
42	Doorfscreen formed in right location.	✓			Check against drawing (no deviation)
43	Doorfscreen formed to correct size.	✓			Check against drawing (width -0 +5mm height -0 +10mm)
44	Doorfscreen formed to correct height.	✓			Check against drawing (-0 +10 mm)
45	Screen cill at right height.	✓			Check against drawing (no deviation)
46	Mastic applied to abutment studs.		✓		Lift section if not visible (no deviation)
47	Correct fixings to abutment studs.	✓			Visual check (no deviation)
48	Fixings at correct centres to abutment studs.	✓			Measure all fixings to abutment (no deviation)
49	Flat plate fitted at deflection head.	✓			Check full length visual (no deviation)
50	Flat plate at correct distance from headtrack.	✓			Check against detail (if 15mm deflection then top of flat plate 15mm from bottom of headtrack no deviation)
51	Flat plate screwed to all studs.	✓			Visual check (no deviation)
52	Bead of mastic at junction of floor/track.	✓			Visual check (no deviation)
53	Correct type of board.	✓			Check against detail & back of board (can only be replaced with minimum performace equal or better)
54	Correct thickness of board.	✓			Visual against detail (no deviation)
55	Correct number of layers.	✓			Visual against detail (no deviation)
56	Screws fixed no more than 50mm from corners of boards.	✓			Measure top to bottom (no deviation)
57	Screws fixed at Maximum 300mm centres.	✓			Visual plus measure on any that look over (no deviation)
58	Screws arcund door openings maximum 200mm centres.	✓			Measure complete door/opening (no deviation)
59	Screws arcund glazed screens maximum 200mm centres.	✓			Measure complete door/opening (no deviation)
60	Screws to external corners at 200mm centres.			✓	Measure top to bottom (no deviation)
61	Screws not breaking paper.		✓		Visual check maximum deviation 10% of screws breaking paper (1.2 x 2.7 board = 39 screws 10% = 4 screws)
62	Screws not proud of board.	✓			Visual check (no deviation)
63	Flat plate at cross joint of outer layer of board.	✓			Lift section if not visible (no deviation)
64	Boards not too short at deflect on head.	✓			Use pre cut guage or tape - 5mm
65	Boards not too long at deflection head.	✓			Use pre cut guage or tape + 0mm
66	Boards screwed to flat plate at deflection head.	✓			Visual check (no deviation)
67	Screws to flat plates at correct centres.	✓			
68	Boards to abutments cut the right length.			✓	Use pre cut gauge check both sides
69	Joints to double layer staggered vertically.	✓			Lift section if not visible
70	Joints to double layer staggered horizontally.	✓			Lift section if not visible
71	Abutment details built correctly.			✓	Check against detail
72	All required studs for 2nd fix fixed in place.			✓	Visual check of pick up studs

We requested Brookfield to provide us with their Air Test Procedures and Programme. They have confirmed that there is no programme in place yet. However Building Sciences a UKAS accredited testing laboratory for testing in accordance with CIBSE TM23 and BS EN 13829 2001 are already on board and have been carrying out interim site inspections to check workmanship etc.

Brookfield has issued drawings to Building Sciences to mark up zonal areas / sample areas for testing. When this exercise is complete, these will be sent to the Board for approval / agreement.

A programme to carry out air tightness testing will then be developed. These will normally be arranged to be carried out in areas that are as complete as possible. The testing will also be arranged in conjunction with Mercury.

Once the marked up drawings are received back, Brookfield will be able to develop a preliminary programme which will be issued to Capita Symonds. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 22).

We have asked Brookfield to provide a method statement for the air leakage tests. Methodology will be provided by Building Sciences along with the Marked up areas for Board approval all as Communication No 22. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 55).

3.2 Early Warnings

Currently nothing to report.

3.3 Board Equipment Installation, Testing and Commissioning

Currently nothing to report.

3.4 Non Conformance Reports

We are aware of a number of NCR's raised and are being kept up to date as to their status.

4.0 CONSTRUCTION REVIEW

4.1 Visits to the Works

Site inspections were carried out by the NEC3 Supervisors on the 1st , 2nd , 3rd, 4 th, 5th, 8th, 9th, 10th, 11th, 12th, 15th, 16th, 17th, 18th, 19th, 22nd, 23rd, 24th, 25th, 26 th, 29th, 30th, and 31st October 2012.

4.2 Elements of the Works available for inspection

- Energy Centre – steelwork and cladding. Local blockwork at ground, 1st and 2nd floor levels.

- Main building – Cores A, B, C, D, E, F, G, K and L internally, Zones A, B, D, E, G and H ground floor slabs, Zones E and F basement area, ground floor suspended slabs, 1st and 2nd floor slabs. Zone H 1st to 5th floor slabs. Zones A and J 1st and 2nd floor slabs, 3rd floor Zones D and E.
- Zones A, B, D, E, G and H below slab drainage.
- External Drainage – specific sections of installation where access is possible.
- Tunnels between ACH and Labs, and Cores C to F.
- Structural steelwork to Atrium (prior to erection).
- Structural steelwork to roof at Zones D and G.
- Dual carriageway to Renfrew Road, and carriageway from Hardgate Road.
- SFS.
- Internal Partitions.
- M&E modular units.
- Roofing.
- Cladding.
- Windows.
- Sto system.

4.3 Observations from October 2012 Inspections

The visual inspections of the work carried out to date indicate that the works are generally being carried out to a satisfactory standard. We continue to be assisted by the site teams and the NHS Project Team in resolving various construction, mechanical, electrical, and quality issues. We continue to close out our Supervisor's Notification and Defects when we have received satisfactory responses. Listed below are observations still to be closed and those raised following site visits in October 2012.

4.3.1 Structural

The minipiling exercise has now been completed – full details and piling records will be included in Zutec on completion and after receipt of all tests and associated details.

Quality on all concrete works has generally appeared good but the following points remain outstanding from previous reports:-

- Finish to ground floor in Zone F and 1st floor in Zone J (as last report)
- 20mm level change detail in 1st, 2nd and 3rd floor slabs at Zones E and J has been poorly formed and remedial action is required. This situation has persisted and has not been fully addressed.
- Cracks to the soffit of the suspended ground floor slab between Cores A, B, C and D being kept under review.
- Spalling to a couple of parapet walls at the top of Core G.

We have requested Brookfield to provide details of proposed remedial action to ensure that the 1st floor slab at Zone E complies with the construction drawings and specifications. Brookfield has confirmed that they have been in dialogue with Dunnes and the works are currently being altered and once completed and checked they confirmed that they will invited Capita Symonds to inspect. We are still not satisfied with the response and would still wish to see details of proposed remedial action as requested. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 26).

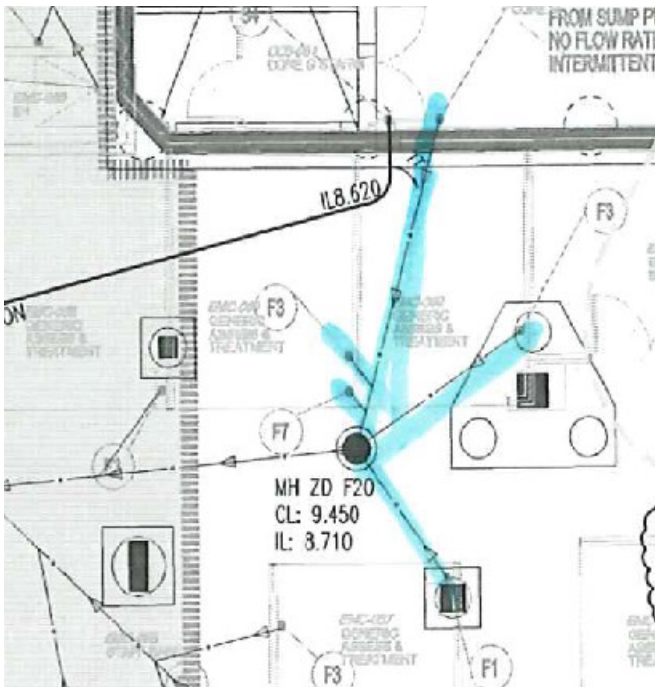
We have asked Brookfield to confirm if the attached holes without bolts to the steelwork bridge connections reflects the design intent. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 57).

4.3.2 Energy Centre

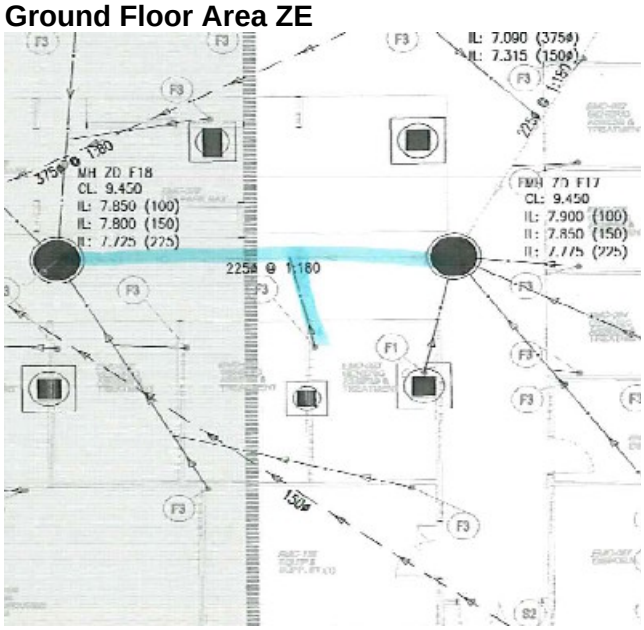
We noted that there was a broken glass gauge in the Energy Centre Tank number 1. Brookfield reported that they are aware of this item and is No 14 on their sheet EC.00.005; Page 1 of the Outstanding Works document. This will be mutually reviewed on completion of works. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 50 is closed out.

4.3.3 Drainage

Below slab drainage installation has continued during the period. Drain pressure tests have been carried out on all newly laid sections in ZE. Test records are kept by Brookfield as part of their QA procedures and some tests were independently witnessed by the NEC3 Supervisor team.



Ground Floor Area ZE



Ground Floor Area ZE

4.3.4 Dual Carriageway to Renfrew Road. (A&C)

Sections of the existing tarmac surfacing on the western carriageway just north of the Energy Centre are showing local signs of breaking up with some rutting apparent. This is unexpected for the length of time that the tarmac has been down and the amount of traffic usage, albeit this has been fairly heavy at times. Brookfield is aware of this and are monitoring with their subcontractor. Remedial work will be carried out at the appropriate time before the wearing course is applied. No change from last period.

4.3.5 Pipework.

Installation of hot, cold, heating, & chilled water pipework in the A&C hospital is progressing at pace and in general is being installed to a good standard. It was noted however that there are still some open ends being left on the pipework, although to a lesser degree than previously reported. The contractor should be reminded that these need to be sealed, to prevent the ingress of moisture and subsequent corrosion that may develop.

We have identified locations where the dead legs on hot water pipe runs are excessive and greater than the specified distance of 3m. We are working with the Contractor to review and identify all areas and to ensure this is not repeated in the future installations.

We noted that Pipework was not capped on Level 2, Gridlines E1-F & 2.1-2.3, Level 2, Plantroom, Gridlines J-I1 & 1-1.1, Level 2, THE-208 Workstation 6x Persons and Level 1, Corridor, Gridlines G1-G & 4-5.1. Brookfield has confirmed that all ends capped off including facing module. MRI Quench pipe has been returned into the opening in the wall and this end is capped off. The other issues raised is work in progress, consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 59 is closed out

There are SVP's uncapped on Level 1, Zone H STW-039 Single Bed, STW-094 Male Staff Change and STW-043 Corridor. Brookfield has intimated it is not common practice to seal SVP / RWP coming through the soffit. They will be capped off if going down through the slab to prevent blockages but not from the soffit upwards as there cannot be ingress from this direction. They acknowledge that these were capped off when this item was initially raised but as noted above, this is not common practice. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 61).

We noted that sprinkler pipework was uncapped on Level 1, Zone G between CCW-006 and Void. Brookfield has confirmed the pipe is now capped. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 62 is closed out.

Before

After

4.3.6 Ventilation

The installation of ventilation ductwork in the A&C hospital is progressing well, and has been installed to a good standard. It appears that any open ends are being sealed but we have noted some exceptions and these have been highlighted to the contractor during our weekly site inspections. The level of damage occurring during the delivery process is much reduced from that previously reported, however the contractor should be reminded that care should be taken to avoid such damage occurring.

During an inspection on site we noted that there are sections of ductwork uncapped or not covered properly. We asked Brookfield to confirm when these have been capped/covered. Brookfield has confirmed that the ductwork in Plantroom 31 Level 3 is now capped off properly. They have also informed us that the pipe running through the fire stoppping is a cable way and not a duct and therefore this is why is it not capped. Work shown on the third photograph was in progress and is now complete.

Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 38 is closed out.

We asked Brookfield to confirm remedial action to damaged steel framework shown below. Brookfield intimated that the damage shown was caused by plant working on the ground floor drainage, the section of steel damaged is sacrificial and will be removed as partitions get installed around the riser. This steelwork is designed to protect the services until the partitions are installed. Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 56 is closed out.

During our visit to site we noted the following items which required to be temporarily sealed/covered. Consequently we raised Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 51 with Brookfield. (See photos below) Brookfield has addressed the issues raised and provided photographic evidence. Capita are assisting Brookfield to identify one other location.

4.3.7 Insulation

The thermal insulation installation to the pre-fabricated sections of pipework is being completed off site, before delivery.

4.3.8 Pressure testing

Pressure testing of the modular pipework sections on a zone by zone or area by area basis is to be programmed through the commissioning meetings.

We await further information from Brookfield on their programme and methodology.

4.3.9 Medical Gases

Brookfield has confirmed that the redundant medical gas pipework has been removed and all sleeves through walls have also been capped. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 44 is closed out.

4.3.10 Energy Centre

The installation for the standby generators is progressing to completion, and the installation is of good standard. Generator on site testing is due to commence with load banks to be installed outside the Energy Centre.

We have witnessed various tests on the HV switchgear and this is now connected and awaiting to be energised.

The second batch of generators has been delivered and positioned on site.

We have raised a concern with the Contractor regarding the control of the first phase of the generator installation and await their response.

4.3.11 Trunking

Cable trunking is being installed as part of the offsite fabricated sections that are being installed in the A&C hospital and in general the installation is of a good standard.

We noted that Vertical trunking riser on Level 3 Plantroom is not covered providing passage to the floor below. Brookfield confirmed that the opening was previously boarded over but was removed for the formation of the upstand. This is being reviewed and is filled in. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 37).

There is a clash between duct spigot and electrical containment. Brookfield to confirm that this is a recorded snag and will be rectified by the ductwork installer MJ Vent. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 60 is closed out.

4.3.12 Cable Trays

Cable trays are being installed as part of the offsite fabricated sections that are being installed in the A&C hospital and in general the installation is of a good standard.

4.3.13 Cabling

Modular wiring looms are now being installed as part of the offsite fabricated assemblies and carefully tied up for protection and installation is of a good standard.

4.3.14 Conduit

Solid conduit installations are well progressed in the areas being fitted out and are of a good standard.

4.3.15 Void Detection

We asked Brookfield to confirm when the removal of dust caps from smoke detector heads has been replaced. Removal of caps at this stage of the contract may lead to the contamination of the detector heads. Brookfield has confirmed dust caps or polythene covers to all smoke detectors are to be fitted and that this is in progress. Brookfield also confirmed that Mercury is carrying out tool box talks to all operatives. Photographs of completed areas to be issued. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 40). See photo below

4.3.16 Intake Sub Station

Brookfield has confirmed that they are still pulling cables into the Intake Substation for the Energy Centre and Adults & Children's.

The main front door to the sub-station is jamming in the frame and is exceedingly difficult to open without excess force on the door handle. Brookfield to confirm when this issue has been addressed.

There are also damaged batteries from the switchgear which are still lying in the corridor and require to be correctly disposed off. Brookfield confirmed they would contact SPEN to find out when they are to be removed (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 30 & 45).

4.3.17 Partitions

There were a number of impact damaged partitions on Levels 1 and 2 and we shall continue to monitor these prior to and during final side sheeting.

A joint inspection of the replacement boards previously affected by water was carried out. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 17 is closed out.

During October rainwater entered the building through the floor joint between ZD and ZE and ZG and ZH causing water damage to a number of partially constructed partitions. It is Brookfields intention to have the affected boards replaced. We shall continue to monitor this.

During an inspection on site we noted that rainwater had damage many of the plasterboard partitions.

We noted that Pipe (MPGS) penetrations through plasterboard have not been cored to an acceptable industry standard. Insulation was not in place within 600mm bay where coiled cable drops installed. We asked Brookfield to confirm insulation will be installed and advise QA procedure for ensuring compliant installation installed before second side boarding.

Brookfield has confirmed the following:

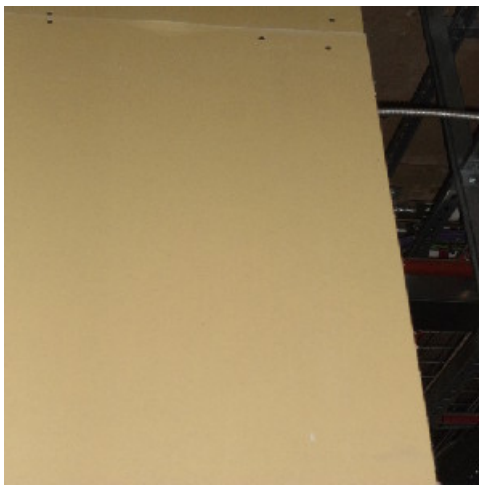
- Damage to all partitions and plasterboard repaired/replaced at 2nd fix stage, BMCE inspect all walls prior to, and after 2nd side boarding.
- ITP's are undertaken at each stage of partition construction and offered to BMCE for inspection to ensure compliance.
- Operatives would ensure insulation is installed prior to wall closure where removed by other trades. Remedial action would be to open wall from stud to stud and reinstate sticky pins and insulation.
- Astins undertake random 85 point checks (QITP check) on closed partitions, this entails reopening off the partition to ensure conformance to specification.

Brookfield has also sent a copy of the Supervisor's Communication to Mercury in relation to the pipe penetrations.

Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 47 is closed out.

We noted that plasterboard has become deformed due to poor stacking and the edges/corners are damaged. We have asked Brookfield to ensure boards are stacked properly to prevent boards being discarded. Brookfield confirmed that every effort is made to ensure the labourers store materials correctly, in this instance Astins will cut the boards into usable patress sizes and reuse at fire/acoustic stopping stage of works. Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 49 is closed out.

We noted that some boards have not been fixed in accordance with BS and NBS K10 Specification on horizontal and edge joints. This was at area THE-349 Exit Bay. Ensure screw fixings are 300mm centres, reduced to 200mm at external angles. Brookfield has confirmed that the boards have been fitted to the appropriate centres and provided photographic eveidence below Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 63 is closed out.



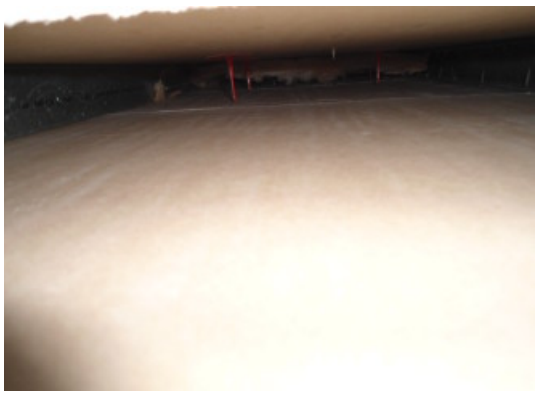
Before

Before

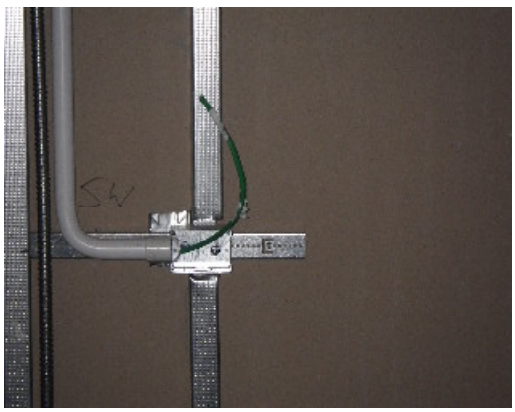
After

After

We noted that there was insulation missing from the upper sections of the boarded partitions in THE-202 General Theatre and THE-200 PREP. There was insulation also missing approx 2m in length of the boarded out partition. Confirm when the boards have been removed and the insulation has been fitted prior to boarding out the lower section to allow us to re-inspect the partition. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 64). See photos below.



A partition stud had been cut and a back box fitted. This was brought to Brookfields attention and they resolved the problem without delay by fitting an intermediate stud. (See photos below)



Before After

4.3.18 Roofs

Roofwork is continuing in Zone G and D on all levels and is being carried out in accordance with the drawings and specifications. A roof integrity test has been carried out to a substantial area of the roof on Level 4 and we await the test results.

We made a number of observations during a site inspection and these were as follows:

- Current specification we have retrieved from Aconex for Liquid Applied Waterproof Roof Coatings is NA-SP-J31 Rev0 date of issue 21/06/2010. We asked for confirmation of the current specification.
- We have asked Brookfield to confirm that the type of waterproof coating that has been applied is the "Permaquik 6100 Monolithic Membrane Roofing System" by Radmat Building Products Ltd as BBA Certificate No 97/3336. Confirm that the waterproof coating has been applied in accordance with manufacturer's recommended installation instructions and comply with the specification.

- We asked if any representatives from Radmat been on site to assess the installation process - to determine that the substrate is acceptable and thereafter to ensure that the application of PermaQuik 6100 has been carried out correctly and in compliance with Radmat's recommendations
- We asked Brookfield to confirm that a 35 year Radmat Gold Warrant will be provided as Specification NA-SP-J31.
- Confirm insulation board and filter layer comply with Specification NA-SP-J31.
- Provide roof integrity test results for Zone D Level 3.

We discussed the issues with Martin McGurk of Radmat and John O'Kane of Prater on the 10th October. Martin McGurk explained that the important issue is always in maintaining the continuum of the insulation at the corner joint. He intimated that this can be achieved in a number of ways and is not limited to the generic illustration in the Radmat catalogue. He confirmed that the method Prater had used in this instance is acceptable.

It was further explained that taking the vertical insulation board to the top of the waterproofing layer allows the vertical board to be trapped and held in place by the depth and pressure of the horizontal insulation layer. This method is commonly used where there is no further retraining method of the vertical board.

In the position shown the vertical insulation is sitting on the top face of the horizontal insulation. This is acceptable as the vertical layer is retained in place using

- A mechanical clip situated at the top of the insulation slab under the coping panel.
- The cobble layer between the paving slab edge and the face of the insulation.
- Adhesive strips applied between the insulation and the Alutrix backing of the upstand.

We were referred to Prater drawings 113-XX-XX-DT-240-007 and 113-XX-XX-DT-240-024 which illustrate that both of the configurations mentioned above are incorporated on the project. Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 52 is closed out.

There are damaged insulation boards adjacent to the hoist access and a few isolated boards elsewhere on the roof. We asked Brookfield to confirm when these are replaced and provide photographic evidence of the replacement boards. Brookfield had a meeting with Martin McGurk from Radmat on site on the 10-10-12 and also took on board the question of compression and U value performance of the insulation when depressed under load.

After the inspection a number of issues were raised by Capita in relation to the roof insulation. The discussion included areas where insulation boards were damaged and Martin McGurk confirmed that some boards were replaced during his

inspection due to damage. The final area discussed was that next to the hoist where the waterproofing was incomplete, we made the point that the damage to insulation board edges was expected and the boards were in fact sacrificial and primarily there as a protective measure for the waterproofing below. They needed to be lifted to allow the jointing and subsequent testing of the hot melt and would subsequently be replaced with new. Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 53 is closed out but we will continue to monitor the work.

During a site visit we noted that there were High level SVP,s not sealed in Level 3, Plant room. Therer was also rain water pipework uncapped on Level 1, Zone G. We have asked Brookfield to confirm when these will be sealed. Brookfield has intimated that if sealing is being queried regarding the sealing of SVP's or RWP's i.e. between pipe and slab. This is work in progress – sequential works ongoing to ensure building is watertight / firestopped. However, if by sealing, it is meant 'capping' off of pipework – then it is not common practice to seal SVP / RWP coming through the soffit. They will be capped off if going down through the slab to prevent blockages but not from the soffit upwards as there cannot be ingress from this direction. We acknowledge that these were capped off when this item was initially raised but as noted above, this is not common practice. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 58).

4.3.19 Cladding

Cladding is underway on the south elevation of Zones G & D and internal courtyards in accordance with the drawings and specifications.

We noted that there was an incorrect fixing to the cladding in Courtyard 4. Brookfield has confirmed that this fixing was a temporary measure at the time to allow the panel to be held in place and has now been rectified. Consequently Supervisor 's Communication General Matters / Other Instructions (CI 13.1) No 35 is closed.

4.3.20 Windows

Windows are progressing on the external elevations and courtyards in accordance with the specifications.

4.3.21 Basment Walls Core C

We inspected the Concrete finish to the Basement Walls Core C with Brookfield and Currie and Brown and found the painted concrete acceptable. We did highlight to Brookfield that the interface of the wall/ceiling to cover up visible gaps.

4.3.21 Water Prevention into Building

Water ingress as a result of rain penetration through walls and soffits were evident. We have asked Brookfield to advise on proposals for preventing rain penetration and QA procedure for remedials to water damaged finished/stored work elements.

(See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 46).

4.3.22 Fire protection

We asked Brookfield to provide dry film thickness results for the atrium steel in support of the fire proof certification. These must be for both the factory applied intumescent coating and the coating being applied on site. Brookfield has confirmed that they have been in communication with JD Pierce their sub contractor on the Steelwork and have received the following information;-

- Intumescent paint logs for various components.
- Steel Certs
- Welding certs

Brookfield confirmed that they will reviewed these and will follow up with a further response. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 54).

4.4 Defects from October 2012 Inspections.

Brookfield has confirmed that the original access hatches which have been labelled as out of use and new access hatches opened up. Consequently Supervisor's Notification of Defect (CI 42.2) No 03 is closed out.

During an inspection on site we noted on the first floor but more specifically within zone ZG corridor CCW115 void detection has been located in close proximity and between ventilation ducts. We believe that this does not comply with the requirements of BS5839. Brookfield has confirmed that with reference to area 1-525 & 1-528 they have carried out a site survey and agreed to the provision of additional detection as follows:

Three additional detectors required in area 1-525.
One additional detector in area 1-528.l

The photo below shows the new void detection consequently Supervisor's Notification of Defect (CI 42.2) No 04 is closed out.

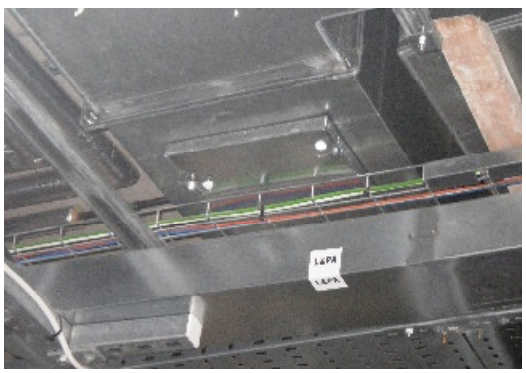
We have asked Brookfield to confirm proposals to correct the misaligned bolts at the half landing in Core G between Level 3 and Level 4. Brookfield has confirmed that they have spoken to WSP about this cleat and viewed it with them. They are looking for a new extended cleat with 4no new anchors and the existing one removed. Consequently Supervisor's Notification of Defect (CI 42.2) No 07 is closed out.

Duct access is blocked Level 2 Zone D corridor adjacent Zone E. We have asked Brookfield to confirm their solution to allow full access to the duct. (Supervisor's Notification of Defect (CI 42.2) No 08).

We have raised a Defect Notification for a Steel angle plate which is too short on Level 3 Zone G. We await a response from Brookfield. (See Supervisor's Notification of Defect (CI 42.2) No 09).

Bolts missing from angle plates in the Energy Centre. (See Supervisor's Notification of Defect (CI 42.2) No 10).

Duct access hatch blocked by chilled water pipework at ground floor area around DB cupboard AAW190. Confirm when this has been addressed.



Sprinkler head at H.L. in plant room obstructed by fire rated ductwork in plant room. Brookfield has advised us that there is a second level / layer of sprinkler pipework to be installed in the plant room. Consequently this is not a defect. This will not be fitted until a later date when other services are completed in the area. Supervisor's Notification of Defect (CI 42.2) No 11 is closed out.

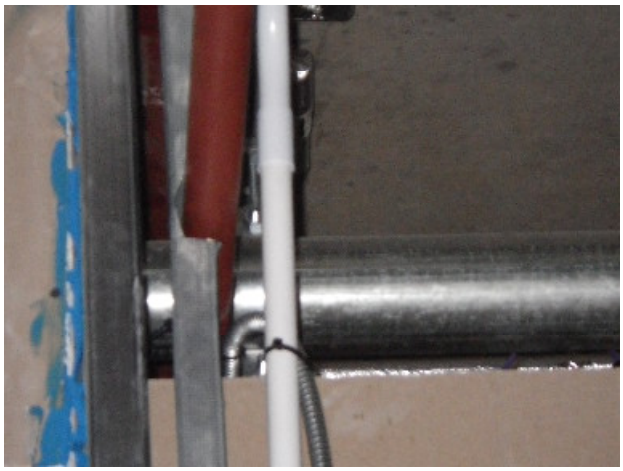
Motorised damper inaccessible due to adjacent duct in Plant Room. Brookfield is investigating this and will report. (See Supervisor's Notification of Defect (CI 42.2) No 12).

Restricted access to ductwork access hatch in corridor adjacent to Zone H near Stair Core F. Brookfield has intimated that the hatch is not restricted and access can readily be gained. We shall revisit this and report back with our findings. (See Supervisor's Notification of Defect (CI 42.2) No 13).

Ductwork obstructed by modular frame Zone H. Brookfield is investigating this and will report (See Supervisor's Notification of Defect (CI 42.2) No 14).

Part of the stud in Level 2 Zone D to the partition in room THE-173 has been cut out. This was not in compliance with Knaufs specification and would have affected the performance of the partition. Brookfield wrote to both Mercury and Astins to ensure that this does not happen again. They also confirmed that this would be discussed at the morning meetings between the sub -contractors and floor mangers. We carried out a joint inspection with Brookfield and confirm that the cut out stud was removed. Consequently Supervisor's Notification of Defect (CI 42.2) No 15 is closed out.

There were two other areas on the ground floor which we brought to Brookfield's attention and these have been resolved.



Stud cut.

Cut stud removed and new stud fitted.

One of the fixings to the cladding is visible beneath the capping pieces and the cladding is indented. We have asked Brookfield to confirm when this defect has been addressed. See Supervisor's Notification of Defect (CI 42.2) No 16).

During our inspection visit to site we noted that cabling was not supported on Level 2, THE-123 Riser, THE-165 Prep, THE-151 and THE-180. Consequently we have raised a Supervisors Notification of Defect (Cl 42.2) No 17. Brookfield confirmed that cables to be supported by half hitching the coil back up to the supporting partition. See photos below.

Before

After

Damper in the duct on Level 3, Plant room is not sealed correctly. We have asked Brookfield to confirm when this has been addressed. Brookfield are investigating this and will report. See Supervisor's Notification of Defect (CI 42.2) No 18).

The Ductwork is not capped and Level 2, Gridlines E1-F & 2.1-2.3 and Level 2, THE-350 Ultra Clean Theatre 8. Level 1, Zone G CCW-047 Bed Bay Vent Protection loose. Brookfield has confirmed that all ductwork identified has been covered. See photos below. Supervisor's Notification of Defect (CI 42.2) No 19 is closed out.

Before

Before

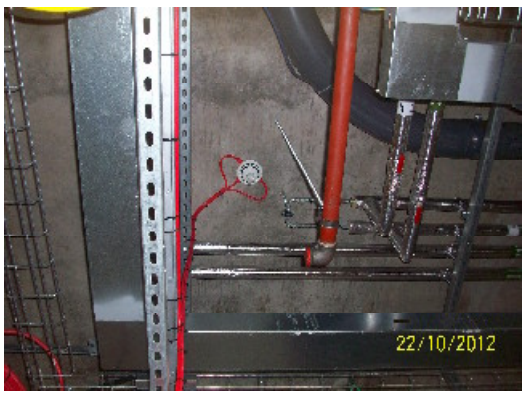
After

After

We noted a dead leg which exceeded 3m on Level 2, THE-126 Dirty UT and Level 1, Zone D CCW-201 Staff Lounge. Consequently we have raised Supervisor's Notification of Defect (CI 42.2) No 20 and have asked Brookfield to confirm when this is addressed.

There are smoke detection Heads uncapped in numerous locations on Level 0 Zone G. Consequently we have raised Supervisor's Notification of Defect (CI 42.2) No 21. See response to Supervisor's Communication No 40

There are smoke detection Heads uncapped in numerous locations on Level 1 Zones D, G and H. Consequently we have raised Supervisor's Notification of Defect (CI 42.2) No 22. See response to Supervisor's Communication No 40



The Air Handling Units is exposed. We have asked Brookfield to confirm when adequate protection has been provided. Brookfield has confirmed that the Air Handling Units has been inspected and ductwork has been connected to units. This is work in progress, however, they should have been re-covered once works were completed. The units have know been protected. Awaiting photos. (See Supervisor's Notification of Defect (CI 42.2) No 23).

Before

Before

After

After

There is restricted access to a duct hatch due to an SVP vent Level 1, Zone E Corridor space adjacent to RCF-xxx IT HUB. We have asked Brookfield to confirm when the access is unrestricted. See Supervisor's Notification of Defect (CI 42.2) No 24).

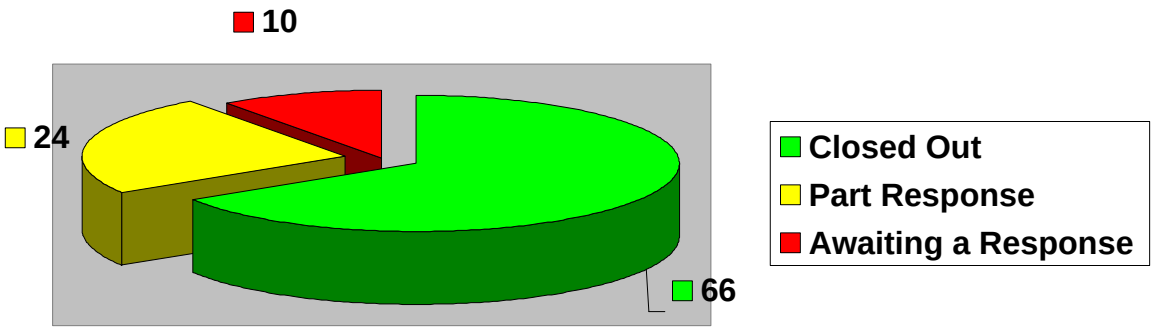
Pipework brackets are inadequately fixed on Level 1, Zone D CCW-201 Staff Lounge. Consequently we have raised Supervisor's Notification of Defect (CI 42.2) No 25).

We noted that the partition wall partly covers a rodding eye on Level 0 Room EMC-124 Office (4P). We have asked Brookfield to confirm measures to address this issue. See Supervisor's Notification of Defect (CI 42.2) No 26 and photo below.

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDRENS HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 19 **OCTOBER 2012**

5.0 INFORMATION REQUIRED



NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDRENS HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 19 **OCTOBER 2012**

Item No.	Description	Date Requested	Comment	
Items 1 to 21 have been closed out				
22	Brookfield to provide us with their Air Test Procedures and Programme.	03/07/12	Response received.	
23	Confirm if this is an adequate vehicular turning circle for an oil tanker, refrigerated articulated vehicle and a Liebherr LTM 1250-61 mobile crane to gain access and egress around the building.	19/07/12	Closed out.	
24	Confirm how and when the defects to the fire protected steelwork will be addressed	23/07/12	Closed out.	
25	Please provide details of proposed measures to ensure compliance with drawings and specifications.	23/07/12	Closed out.	
26	Provide details of proposed remedial action to ensure that the 1st floor slab at Zone E complies with the construction drawings and specifications.	26/07/12	Response received.	
27	Ensure screw fixings are 300mm centres, reduced to 200mm at external angles in accordance with BS and NBS K10. Confirm that plates are in place between sheets where double sheeted and will be located in all horizontal joints.	26/07/12	Closed out.	
28	Confirm open drainage on Levels 1 & 2 is sealed.	01/07/12	Closed out.	
29	Confirm if there are any design plans to introduce additional stiffening to 1500nn high partitions.	29/08/12	Closed out.	
30	Confirm when cabling is complete, water pumped out and batteries removed.	10/08/12	Response received.	
31	No timber in partition lintels.	29/08/12	Closed out.	
32	Advise proposed remedial action link reinforcement from pile caps Zone D.	29/08/12	Closed out.	
33	Ductwork was not capped on Level 1 Vent Plant Room. Confirm when this is done	07/09/12	Closed out.	
34	Locations throughout have drainage pipework which is uncapped Confirm when this has been addressed.	07/09/12	Closed	
35	Confirm when incorrect fixing has been rectified to Courtyard 4 cladding.	07/09/12	Closed out	
36	Insulation missing from the upper section of the boarded partition. Confirm when insulation has been fitted prior to boarding the lower section.	07/09/12	Closed out.	
37	Vertical trunking riser Level 3, Plantroom is not covered providing passage to the floor below. Confirm when this has been addressed.	11/09/12	Response received.	
38	There are sections of ductwork uncapped or not covered properly in the locations listed above. Confirm when these have been capped/covered.	11/09/12	Closed out.	
39	Part of the stud to the 60min partition in room CCU-012 has been cut out. This is not in compliance with Knaufs specification	12/09/12	Closed out.	
40	Confirm when removal dust caps from smoke detector heads have been replaced	12/09/12	Response received.	
41	Duct access hatch blocked by chilled water pipework at ground floor area around DB cupboard AAW190. Confirm when this has been addressed.	12/09/12	Closed out.	
42	Confirm when vent control is protected on Level 3 Zone D.	13/09/12	Closed out.	
43	Cables were hanging unsupported. Confirm when addressed	13/09/12	Closed out.	
44	Confirm when the redundant medical gases on Level 1 will be removed.	13/09/12	Closed out.	
45	See Supervisor's Communication No 30.	18/09/12	Response received.	
46	Advise on proposals for preventing rain penetration	20/09/12	Open	
47	Confirm remedial action to partitions Level 2 Theatres.	20/09/12	Closed out.	
48	Confirm remedial to various roofing observations.	20/09/12	Open	

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDRENS HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 19 **OCTOBER 2012**

49	Damaged and deformed boards caused by poor stacking	27/09/12	Closed out.	
50	Broken glass gauge to Energy Centre Tank number 1.	15/10/12	Closed out.	
51	Confirm when ducts/vents are temporarily sealed/covered.	03/10/12	Response received.	
52	Insulated board fixed to the internal face of the south facing parapet wall on the level 3 roof rests on the horizontal insulation. Confirm if acceptable to Radmat.	10/10/12	Closed out.	
53	Confirm when damaged roof insulation will be replaced.	10/10/12	Closed out.	
54	Provide dry film thickness results for factory applied intumescent and remedial repairs on site.	12/10/12	Response received.	
55	Provide air method statement for air leakage tests.	12/10/12	Open	
56	Confirm remedial action to damaged steel framework.	15/10/12	Closed out.	
57	Please confirm if the attached holes without bolts to the steelwork bridge connections reflects the design intent.	16/10/12	Open	
58	Level 3, Plant room. High level SVP not sealed Level 1, Zone G. - Between CCW-003 and RAF-062	16/10/12	Response received.	
59	Confirm when popework on Level 1, Zone H STW-039 Single Bed, STW-094 Male Staff Change and STW-043 Corridor will be capped.	23/10/12	Closed out	
60	Confirm when clash between spigot and electrical containment will be addressed.	23/10/12	Closed out.	
61	Confirm when SVP not wil be capped various locations Lwvwl 1 Zone H.	23/10/12	Response received.	
62	Confirm when sprinkler system is capped level 1 Zone G	23/10/12	Closed out.	
63	Kanuf boards not fitted as per BS and NBS K10 in level 2 THE-340 Exit Bay	23/10/12	Closed out.

13	Restricted access to ductwork access hatch in corridor adjacent to Zone H near Stair Core F	02.10.12	Response received.	
14	Ductwork obstructed by modular frame Zone H.	02.10.12	Response received.	
15	Part of stud, Level 2 Zone D cut away.	10.10.12	Closed	
16	Fixing to cladding visible. Confirm when this will be addressed	18.10.12	Open	
17	Confirm when cabling in various locations on level 2 are supported properly.	23.10.12	Closed	
18	Confirm when damper in duct is sealed properly in Level 3 Pant Room.	23.10.12	Response received	
19	Ductwork uncapped or falling off. Confirm when addressed. Various locations Level 2.	23.10.12	Closed	
20	Dead legs exceed 3m in various locations on Level 1 and 2. Confirm when this will be addressed	23.10.12	Response received.	
21	Confirm smoke detection heads in various locations on Level 0 Zone G will be capped.	23.10.12	Response received.	
22	Confirm when smoke detection heads in various locations on Level 1 Zone G and H will be capped.	23.10.12	Response received.	
23	Air Handling Units exposed in Level 2, Plantroom. Confirm when adequate protection has been provided.	23.10.12	Open	
24	Confirm when restricted access to ductwork is addressed.	23.10.12	Open	
25	Pipework brackets inadequately fixed	23.10.12	Open	
26	Partition wall partly covers rodding eye. Please confirm measures to address this issue	30.10.12	Open	

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDREN'S HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 19 **OCTOBER 2012**

John Redmond
Capita Symonds
Technical Advisory Services

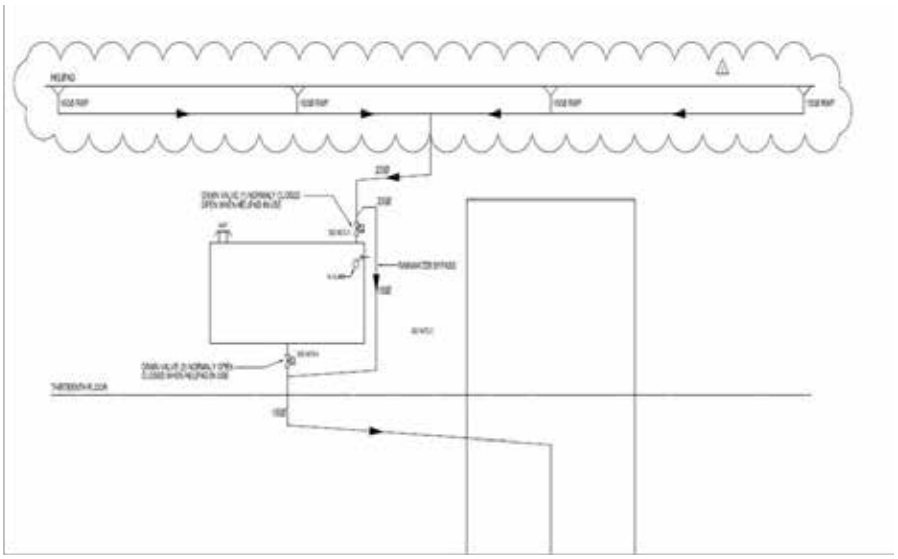
The Beacon, 8th Floor, 176 St Vincent Street, Glasgow G2 5SG

	Signed	Date
Originated by	John Redmond	31st October 2012
Completed by	Dave Ramsay	31st October 2012

SOILS & WASTE AND RAINWATER SYSTEM DESCRIPTION

1. Rainwater

The rainwater system comprises of Blucher pipe connected to the rain water outlets set into the roof. The rainwater is piped to the ground floor and connects to the underground rainwater system. There is access doors located at 1200mm above each floor slab on each down pipe for access in the event of any blockages.



- Rainwater installed using “Blucher Pipework”
- Blucher floor gullies and RWO’s
- Labelled “Rainwater”
- Helipad Holding Tank

2. Soils, Vents and Waste

The soils and waste (S&W) system stacks have been installed in Ensign cast iron pipework for diameters greater than 2". Pipework 2" and below is installed in terrain PVC. All vent pipework has been installed in terrain plastic. The S&W system takes waste from all wash hand basins, water closets and sinks to the ground floor where it connects to the underground foul waste system. The waste from the domestic wash hand basins and WC's is installed using Terrain PVC pipe and fittings. Rodding eyes are installed at each WC and WHB and at 1200mm above the floor level on all vertical drops.

Where these systems pass through the floors or fire walls there are fire collars fitted to prevent the spread of fire. The fire collars expand and seal the openings when they reach a certain temperature.

- Drainage installed using Cast Iron pipe 4" and above
- Less than 4" using plastic
- All vents in Plastic
- Rodding Eyes at 1.2m above floor – every floor & behind all IPS's
- Labelled "Drain", "Vent", "Radioactive"

3. Basement Drainage and SUMP Pumps

The basement S&W feeds into a sump pump located in Pump room FMB-024. From this sump pump the S&W is pumped back into the ground floor and underground foul waste system.

There are several other permanent sump pumps within the basement; these provide pumped drainage for the following:

- Water filtration backwash
- Emergency overflows for the CWS Tanks.
- Emergency overflows for the sprinkler system tanks.
- Emergency overflows for the renal concentrate storage tanks.
- Emergency drainage for Core G lift sump.

There are also several emergency sump pits located throughout the basement corridors, these have I.Vs, non-return valves and quick release couplings to allow a temporary sump to be installed. Details on these can be found on the record drawings and manufacturers literature.

4. Helipad Drainage

The helipad drainage has been installed in Ensign cast iron pipework complete with a rain water holding tank located on level 13 - roof. There are 2-port control valves (1) on the inlet to the tank and (2) on the outlet from the tank and a tank by-pass arrangement. These valves are manually controlled each time a helicopter comes in to land so that in the event of an incident any fuel spillages can be collected and disposed of in an appropriate manner.

4.1. Normal operation

During normal operation 2-port valve no 1 on the inlet to the tank is closed and 2-port valve no 2 is open. Rainwater is diverted through the by-pass and no rainwater enters the tank.

4.2. Helicopter Approach

When a helicopter is approaching the helipad the 2-port valve positions are moved manually by the ground crew. Valve 2 is closed and valve 1 is open. Rainwater is collected in the holding tank.

4.3. In Event of Fire

The valve positions remain in position as above and all fuel, fire-fighting foam and rainwater is collected in the holding tank until it can be removed in a controlled manner.

4.4. Normal Helicopter Departure

The valve positions are returned to normal operating conditions and the rainwater is released into the underground rainwater system via an underground petrol interceptor

For record drawing information please refer to the following drawings:

- **P(52)** series drawings for details on the pipe work distribution on the floors
- **PP** series drawings for details on the pipe work distribution in the plant rooms

PR41 - DOMESTIC WATER SYSTEM DESCRIPTION

1. Overview

There are 2 No. incoming mains water supplies serving the Adults and children's hospital building. These enter the building in the basement manifold room and basement tank room and run into the tank room to serve 2no Raw water storage tanks. These incoming mains both have double check valves, water meters, 2 port isolation valves and keraflow float valves all located within the tank room.

The water meters are linked to the BMS system and allow the user to cross reference the quantity of water used against the quantity indicated on the external meter. This will highlight if there are any leaks on the external water main (see schematic included in 2 below). The 2 port valves allow the alternative use of each incoming main every 7 hours

From the raw water storage tanks the water is then filtered through the filtration plant before being stored in the potable bulk cold water storage tanks. All cold water storage tanks are 2 compartment tanks and are piped in such a way as to allow tank maintenance without disrupting the water supply to the building. Float switches within the tanks give the filtration plant the enable and stop signals based on the water level within the tanks. These levels can be adjusted to suit the water demand so that an optimal turnover of water can be achieved.

The filtered water is then pumped to serve the building via 2 no booster sets. Each booster set is set to a different set point pressure depending on which plant room it serves. (see below). Each booster set has 2no set points which will allow either serve the building in the event of failure.

There are 5 water storage tanks in the building:

- 2 No. 100,000 Litre Raw water storage break tanks
- 2 No. 275,000 Litre Potable bulk cold water storage tanks
- 1 No. 2,800 Litre Trade water storage tank

There are 2 No water booster sets in the building:

- BS01 – Feeding Plantroom 31, 32 & 33 - 7.3 Bar
- BS02 – Feeding Plantroom 21, 22 & 41 – 5.1 Bar

2. System Description

Plant room 41 is served from booster set BS02 at 5.1 Bar. The boosted water is pumped directly from the basement to PR41. The line serving Plant room 41 is metered in the basement.

From the plant room the BCWS is distributed to each riser and the bank of calorifiers. 41CAL01, 41CAL02 & 41CAL03. The water in the calorifiers is heated via a plate heat exchanger (feed from the MTHW circuit) on each calorifier skid. Each calorifier skid consists of a storage cylinder, shunt/de-strat pump, plate heat exchanger, expansion vessel and associated pressure, temperature and vacuum safety valves.

The BCWS and HWS F&R are then distributed together allowing for equal pressures at the outlets between the hot and cold water. The hot water is circulated to the outlet and back to the calorifiers by a hot water return pump so that temperature is maintained throughout the system. There are Kemper thermostatic balancing valves installed on the system in line with the design to ensure hot water is available within 2 minutes at every outlet.

The cold feed to the calorifiers is also metered. The meter is located at the calorifier skids.

The design philosophy is that the distribution pipe work is laid out in such a way that areas of high use are at the end of lines. This ensures good turn-over of water within the system. Where this cannot be achieved temperature operated dump valves are installed.

For record drawing information please refer to the ***500*** series drawings for details on the pipe work distribution on the floors and plant rooms.

For the distribution of the domestic water systems in relation to plant rooms please see “schedule of risers” document.

Horne OPTITHERM Thermostatic Bib Tap

Type TBT02

INSTALLATION, COMMISSIONING, OPERATING AND MAINTENANCE INSTRUCTIONS

APPROVAL

The Horne OPTITHERM Thermostatic Bib Tap has been independently tested as a Type 3 TMV by WRc-NSF and approved to the requirements of *NHS Model Engineering Specifications D08: Thermostatic mixing valves (Healthcare premises),* to the following designations.

APPLICATION	DESIGNATION	HOT & COLD WATER PRESSURES	WATER TEMPERATURES
WASHBASIN	HP-WE	1 to 5 BAR (Hot and cold pressures do not need to be equal)	HOT: 52°C - 65°C COLD: 5°C - 20°C
		Static Pressure Max. 10 Bar	Differential between mixed and supply temperatures: Min. 11°C

Table 1

If the Horne OPTITHERM Thermostatic Bib Tap is operated outwith these conditions it cannot be guaranteed to operate as a Type 3 TMV.

The Horne OPTITHERM Thermostatic Bib Tap is supplied with WRAS approved integral single check valves (spring-loaded, resilient trim in-line check valve cartridge with plastic guide and stem) located in each of the hot and cold water supply inlets.

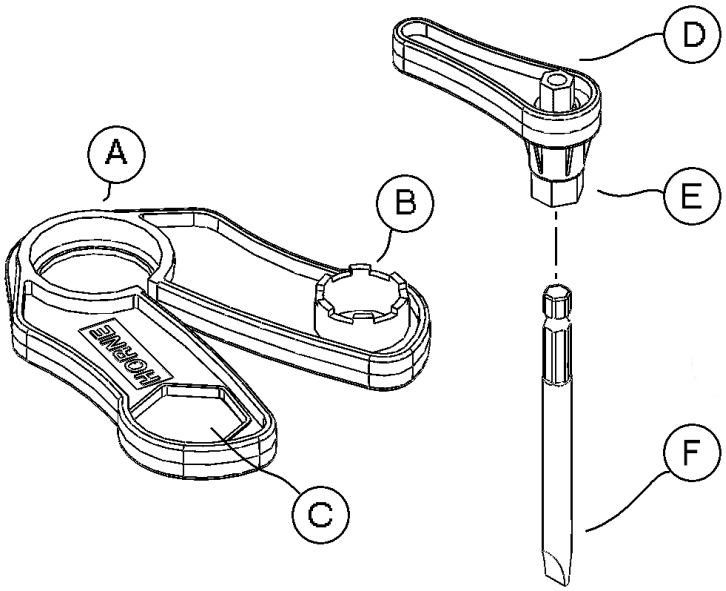
The Horne OPTITHERM Thermostatic Bib Tap is a tap containing a thermostatic mixing valve (TMV). All comments made herein regarding TMVs apply equally to thermostatic taps.

ACCESSORIES:

MULTI-TOOL:

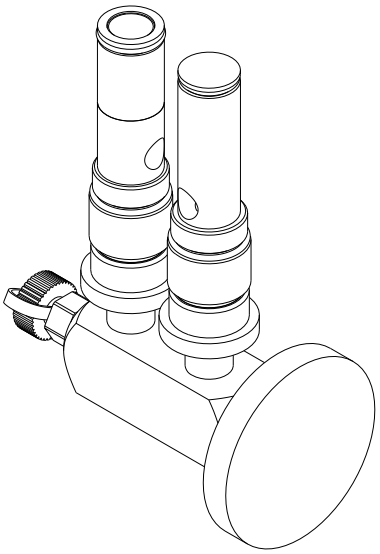
Optitherm Multi Tool (Part No. 5459) & Screwdriver bit (Part No. 5632). Available as part of full toolkit (part no. 5491).

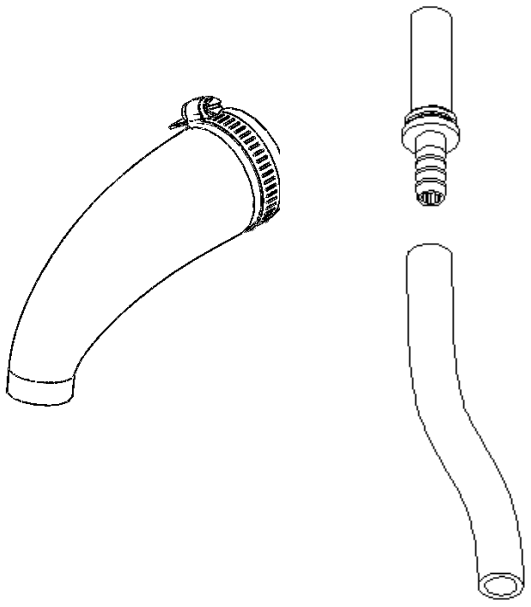
A	Endcap Gripper
B	Outlet Fitting Tool
C	26mm Ring Spanner
D	8mm Hex Key
E	12mm Hex Key
F	Screwdriver Bit



THERMAL DISINFECTION ADAPTOR:

As part of Water Quality Compliance Kit – Part no. 6006. See Section 2.4 & 4.2





FLUSHING ADAPTORS.

Part nos. 5684 (left), & 5492 (right).
The Parts on the right are also contained in Water Quality Compliance Kit, part no.6006.

Table of Contents

[1] INSTALLATION

The Horne OPTITHERM Thermostatic Bib Tap must be installed in accordance with the Water Supply (Water Fittings) Regulations 1999.

1.1 NOTE ON O-RING FITTING

Before fitting o-rings care should be taken that they, and the grooves/bores into which they fit are…

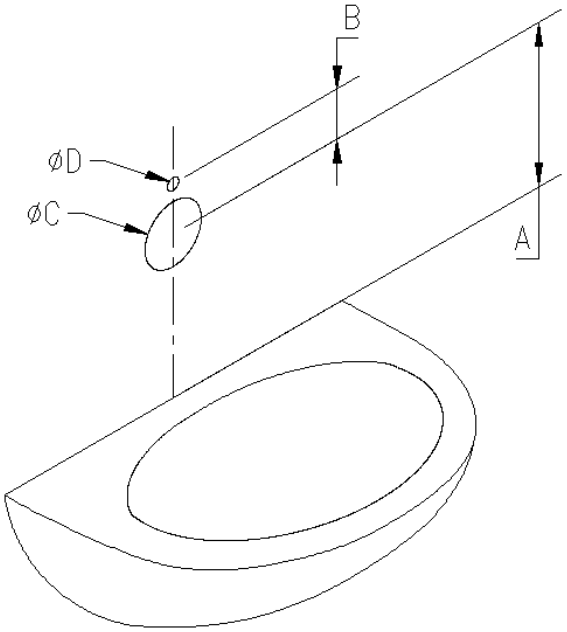
- ◊ Clean
- ◊ Free from damage (nicks, tears, etc.)
- ◊ Lubricated lightly with water or a WRAS approved silicone oil.

Failure to do this may result in leaks and considerable damage.

1.2 FITTING

The Horne OPTITHERM Thermostatic Bib Tap is intended for installation on a vertical panel above a surgical basin or bath with no tap holes.

1.2.1 Before installation, 2 holes must be bored in the panel in the configuration shown in the diagram.



A	150mm to 300mm depending on vessels to be filled. Less than 150mm will impede access for servicing. Recommended height 225mm
B	34mm
C	48mm (min 47mm, max 50mm)
D	6mm
Panel thickness	30mm maximum

Diagram 1

► Open out the last (fold out) page of this instruction booklet to see the installation diagrams ►

1.2.2 Install the spigot (5) to the panel. Ensure that the chrome bezel (7) is located around the spigot first, and that the locating pin in the bezel engages in the small hole bored previously in the panel. The bezel should be retained between the spigot and the panel. Tighten to the panel using the 1½ BSP bulkhead nut (8) supplied. Put this nut on tightly. If it works loose the tap will not be secure and the nut may be difficult to tighten later, after the panel has been fixed.

1.2.3 Attach the 10mm compression couplings (22), or optional flexible hoses (9) to the spigot with the Hot Water Supply connected to the inlet port nearest the lever with the red endcap (i.e. the left hand side as one faces the basin), and the Cold Water Supply connected to the inlet port nearest the lever with the blue endcap (i.e. the right hand side as one faces the basin). The note in 1.1 regarding o-ring fitting should be especially heeded here, as any leaks in the hose o-rings may go undetected for some time and cause considerable damage. Torque couplings or hoses to 5Nm.

1.2.4 At this stage, the screw (6) can be used to attach an electrical earth, if required.

1.2.5 Connect the couplings (or flexible hoses) to the water supply behind the panel, close the ball valves (13,14) in the spigot and test for leaks. Once this part of the installation is confirmed to be watertight, and the hot and cold supplies are confirmed to be the right way around (see section 2.2), all further work on the Horne OPTITHERM Thermostatic Bib Tap can be done with the panel in place.

1.2.6 If applicable, attach the required extension piece (4) to the spigot using the 4 no. M5 screws (2) and washers (3) supplied. Ensure that the interconnect nozzles (1) are located correctly with their o-rings between the spigot (5) and the extension piece (4). See note in 1.1 regarding o-ring fitting.

1.2.7 Offer the main tap body up to the spigot. Locate firmly over the spigot and tighten the retaining screw (15) from below. In order to get a good fit of the tap onto the spigot it is helpful to push the tap against the spigot and slightly upwards as the retaining screw is tightened – this ensures that there is no gap between the spigot and the tap body. Torque the retaining screw to 5Nm (if a torque wrench is not available, tightening fairly tightly with the 4mm hex key supplied should be adequate for this purpose).

1.2.8 Do not open the tap yet. Commence with the flushing procedure as detailed in 1.3 below.

1.3 FLUSHING OF PIPEWORK (METHOD 1)

Pipework must be flushed in accordance with Water Fittings Regulations 1999, schedule 2 G13.1 before connecting the Horne OPTITHERM Thermostatic Bib Tap.

> The most common cause for complaint regarding the performance of any TMV/thermostatic tap is traced to dirt or debris in the TMV or check valves.

1.3.1 DO NOT OPEN either tap lever before flushing the hot and cold water pipework.

1.3.2 A flushing kit (Horne part no: 5492, or as part of the Water Quality Complance Kit, part no. 6006) is available to provide means of flushing the pipework.

1.3.3 Unscrew the main bottom cover (16) using a strap wrench.

1.3.4 Remove a strainer/check-valve cartridge (20,21) using a 12mm hex key or Horne tool no. 23-5459.

1.3.5 Using an 8mm hex key or Horne tool 23-5459, screw the flushing adaptor (22) into the space occupied by one of the strainer/check valve cartridges (20,21).

1.3.6 Ensure that the hose is securely attached to the flushing adaptor and that the open end of the hose is also secure - the hot water could scald badly if the hose 'whips' unexpectedly.

1.3.7 Open the ball valve (13,14) using a flat bladed screwdriver from under the spigot, and allow the water to flow at full bore into the sink until the water flows absolutely clean.

1.3.8 Repeat on the other side so that both hot and cold supplies to the tap are flushed.

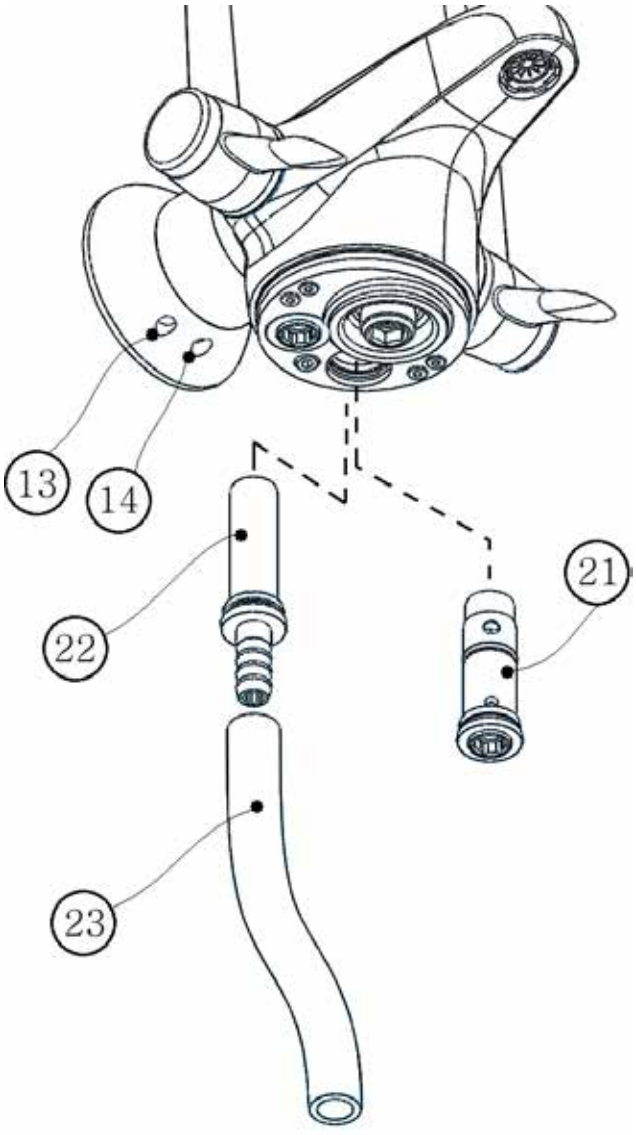


Diagram 2

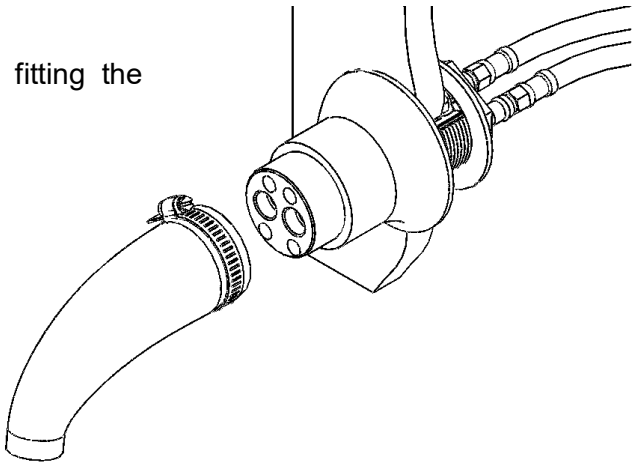
Key to diagram above				
13	Hot isolating valve		14	Cold isolating valve
21	Strainer/check-valve cartridge		22	Flushing adaptor
23	Flushing hose			

1.4 FLUSHING OF PIPEWORK (METHOD 2)

Alternatively the pipework can be flushed before fitting the Optitherm to the spigot using Horne part no.5684.



1.4.1 Connect adapter to spigot with jubilee clip around the large end.

1.4.2 Tighten the jubilee clip.

1.4.3 Open the valves from under the spigot and allow water to flow at full bore into the basin until the water runs absolutely clean.

[2] COMMISSIONING

The commissioning process comprises sections 2.1 to 2.7 below. The tap cannot be considered commissioned until these processes are all carried out.

Note that it is NOT possible to commission the Horne OPTITHERM Thermostatic Bib Tap before the hot water service (boiler) has been commissioned.

2.1 FLUSHING

Before commissioning the Horne OPTITHERM Thermostatic Bib Tap, it is imperative that flushing of the pipework has been carried out in accordance with section 1.3 or 1.4.

2.2 TEMPERATURE CHECK (COLD WATER)

2.2.1 Open the cold water isolating valve (14) and lever (12), allow the water to run for a while and ensure that cold water flows from the spout (if hot water comes out, then the supplies are connected the wrong way around). Ensure that the tap is run for long enough to draw off any deadleg to be absolutely sure. Getting this right will save frustration later.

2.2.2 To check the temperature of the incoming cold water, open the blue/cold lever (12) only, and measure the temperature after 30 seconds. This should be within the range on table 1, page 1.

2.2.3 If hot water comes out of the spout when the blue lever is turned, the inlet hoses will have to be reversed behind the panel. This necessitates removal of the spigot (section 1.1 describes fitting of the spigot).

2.3 TEMPERATURE CHECK (HOT WATER)

2.3.1 To check the temperature of the incoming hot water, follow the procedure in section 4.3 for removal of the strainer/check valve cartridge on the hot side only (see also diagram in section 1.3)

2.3.2 Screw the flushing adaptor (22: diagram 2) into the space which was occupied by the hot strainer/check valve cartridge (20).

2.3.3 Ensure that the hose (23) is securely attached to the flushing adaptor. Take care that the open end of the hose is also secure and pointing down the drain as the hot water could scald badly.

2.3.4 Carefully open the hot ball valve (13) from under the spigot and measure the temperature of water that flows out from the tube after 30 seconds; it should be within the range on table 1, page 1.

2.3.5 Re-fit the strainer check-valve cartridge (20) and the bottom cover (16).

2.4 THERMAL DISINFECTION

2.4.1 Following the hot water temperature check it is recommended that thermal disinfection be carried out using the Water Quality Compliance Kit (part no.6006) as part of the commissioning procedure. Instructions for the thermal disinfection procedure are supplied with this kit

2.5 TEMPERATURE CHECK (MIXED WATER)

2.5.1 Check that hot and cold water supplies are at or near to their designated temperatures and pressures (see sections 2.2 & 2.3 and Table 1 on Page 1 for details).

2.5.2 Open the red (safe hot) lever only and allow water to run through the TMV.

2.5.3 Measure the temperature at the spout. This is the temperature of the mixed water. Ensure that the mixed water temperature is set appropriately. For healthcare applications, basin taps should always be set to 41°C.

If necessary, make minor adjustments to the temperature setting as described in Section 2.6 below.

N.B. For TMV3 applications the mixed water at the terminal fitting should never be set to exceed 41°C.

2.6 MIXED WATER TEMPERATURE ADJUSTMENT

2.6.1 The Horne OPTITHERM Thermostatic Bib Tap is approximately set at the factory to check for correct function. However temperature must be checked and adjusted on site to ensure correct installation. For healthcare applications, basin taps should always be set to 41°C.

For other applications, where applicable, the range of temperature adjustment is 35 – 44°C.

2.6.2 It should be noted that the Horne OPTITHERM Thermostatic Bib Tap requires a temperature differential of at least 11°C to work correctly (ie. the mixed water temperature must be at least 11°C lower than the hot water temperature and 11°C higher than the cold water temperature).

To alter the temperature setting, carry out the following procedure.

2.6.3 Unscrew the main bottom cover (16) using a strap wrench.

2.6.4 Check that hot and cold water supplies are within the designated temperature and pressure ranges (see sections 2.2 & 2.3)

2.6.5 Open the red/safe-hot lever (11) and allow water to flow until the mixed water temperature has stabilised. Make sure that the dead leg from the Hot Water Supply to the Horne OPTITHERM Thermostatic Bib Tap has fully cleared.

2.6.6 Using a 4mm hex key, turn the adjusting screw (19) clockwise as viewed from below † to reduce the mixed water temperature or anti-clockwise to increase it. Adjustments of not more than half a turn at a time should be made. The temperature at the outlet should be measured and allowed to stabilise after each adjustment.

† Note screwing the adjusting screw inwards towards the cartridge will reduce the set temperature. Screwing it outwards away from the cartridge will increase the set temperature. The screw has a conventional right-hand thread.

After making an adjustment, close the red/safe-hot lever (11) for ten seconds then re-open it and measure the mixed water temperature again. If a further adjustment is required, repeat the procedure.

2.7 COLD WATER FAILURE TEST

2.7.1 Close the cold water isolating valve (14) and, after 6 seconds, measure the mixed water temperature. The flow of mixed water should immediately stop and then a drip or trickle may or may not be seen. The temperature, measured after 6 seconds, of any water coming from the tap

should not be more than 3°C above the mixed water set temperature measured in 2.4.1 above. If no water comes out this is also acceptable.

2.7.2 If the Horne OPTITHERM Thermostatic Bib Tap performs satisfactorily, open the cold water isolating valve (14) – the Horne OPTITHERM has passed the cold water failure test.

2.7.3 However, if the water coming from the tap is at a temperature of more than 3°C above the mixed water temperature setting, then the Horne OPTITHERM is not shutting off the hot water supply properly. The cartridge is likely to be contaminated with dirt or damaged. Replace the cartridge according to section 4.5.

Note that the Horne OPTITHERM may, in some circumstances, fail the cold water failure test if the hot supply temperature is not 11°C above the set mixed water temperature. The hot water temperature can be checked as outlined in section 2.3 above..

[3] OPERATION

Operation of the Horne OPTITHERM Thermostatic Bib Tap is the same as that of a conventional tap. Open the red lever to draw hot water at a safe and comfortable temperature (controlled by the thermostatic mechanism). Open the blue lever to draw fresh, cold water. The user may notice a slight pulsing of the water stream if both levers are opened. This is normal and is not a cause for concern. Note that it is not normally necessary to open both levers simultaneously as the water supplied from the hot lever is at a safe and constant temperature.

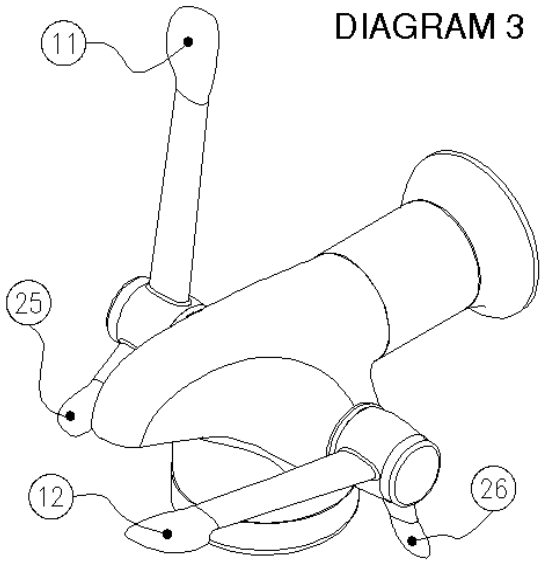
3.1 DUAL LEVER VERSION

The dual levers on the Horne OPTITHERM Thermostatic Bib Tap are a unique feature to prevent the spread of infection.

The intended mode of operation is that the user should open (turn-on) the tap using a thumb to push the short lever (25,26) backwards and downwards.

After washing, the long lever (11,12) should be returned to the original position with an elbow, thus avoiding re-contamination by touching the short lever again.

DIAGRAM 3



Key to diagram above				
11	Long lever (safe-hot)		12	Long lever (cold)
25	Short lever (safe-hot)		26	Short lever (cold)

3.2 SHORT LEVER VERSION

The short levers are pulled forwards to open (turn-on). And pushed backwards to stop the water flow.

3.3 LEVER CLUTCH

The Horne OPTITHERM is fitted with clutches on the levers to prevent lever breakage in the event of a lever being forced either accidentally or intentionally. Hence if the tap lever is found to be at an unexpected angle, simply push the lever in the opposite direction, beyond the normal 'stop'. One or two clunks should restore the lever to its correct position.

3.4 POTABLE WATER SUPPLY

When cold water is drawn (via the blue lever) from the Horne OPTITHERM Thermostatic Bib Tap the water completely bypasses the thermostatic mechanism. Hence, if the cold water supply to the Horne OPTITHERM Thermostatic Bib Tap is potable, so is the water drawn via the cold lever. NB: care should be taken to run the tap for at least 20 seconds before drawing water for drinking. This will ensure satisfactory purging of the spout.

[4] MAINTENANCE

Maintenance of all TMVs and thermostatic taps is essential. If a TMV does not operate properly, there is a risk of someone being scalded. The frequency of maintenance depends upon the condition of the water passing through the TMV. The remarks in 4.1.3 regarding in-service testing apply equally to maintenance. Generally, the thermostatic cartridge should be replaced after three years. The strainer/check-valve cartridges and ceramic disc cartridges should be replaced as necessary.

4.1 IN-SERVICE TESTING

4.1.1 Periodic testing should be carried out to check whether or not any deterioration has occurred in the performance of the Horne OPTITHERM Thermostatic Bib Tap.

4.1.2 A COLD WATER FAILURE TEST should be carried out as described in paragraph 2.7 above. If the water coming from the tap is at a temperature of more than 3°C above the mixed water temperature setting then the Horne OPTITHERM Thermostatic Bib Tap is due for maintenance.

NOTE: A TMV in need of maintenance can be undetectable in normal use and only become apparent when a disruption occurs in the hot or cold water supply pressures or temperatures.

4.1.3 The frequency of in-service testing depends upon the condition of the water passing through the tap. In-service testing must be carried out more frequently in hard water areas than in soft water areas. As a general guide, in-service testing should be carried out at least every twelve months and, where the water is hard, the interval may be less than six months. Experience of local conditions and the in-service testing record will dictate the frequency of in-service testing.

4.2 FLUSHING AND THERMAL DISINFECTION

4.2.1 Horne recommends periodic thermal disinfection in conjunction with high velocity flushing, using the Water Quality Compliance Kit (part no.6006). See paragraphs 1.3 and 1.4. The periodicity of this maintenance should be determined in conjunction with the current best practice.

4.3 CLEANING AND REPLACEMENT OF STRAINERS

4.3.1 Close the isolating valves (13,14) at the back underneath the tap spigot; open the levers and allow the residual water to drain.

4.3.2 Unscrew the main bottom cover (16) using a strap wrench.

4.3.3 Remove the strainer/check-valve cartridges (20,21) using a 12mm hex key or Horne special tool (part no. 23-5459).

4.3.4 The strainer can be removed from the top of the cartridge and cleaned or replaced as necessary.

4.4 TESTING AND REPLACEMENT OF CHECK VALVES

4.4.1 Close the isolating valves (13,14) at the back underneath the tap spigot; open the levers and allow the residual water to drain.

4.4.2 Unscrew the main bottom cover (16) using a strap wrench.

4.4.3 Remove a strainer/check-valve cartridge (20,21)

Remove the strainer basket from the top. Inspect the white plastic check valve for signs of obvious damage. Carefully insert a probe (pen or similar) down the strainer hole to ensure that the check valve element can move freely. It should spring back into the closed position when released. It should also be possible to blow through the cartridge from the top to the bottom, but not the other way around. If the check-valve is not in good condition, the whole strainer/check-valve cartridge should be replaced.

4.5 REPLACEMENT OF THERMOSTATIC CARTRIDGE

4.5.1 Close the isolating valves (13,14) at the back underneath the tap spigot; open the levers and allow the residual water to drain.

4.5.2 Unscrew the main bottom cover (16) using a strap wrench

4.5.3 To remove the thermostatic cartridge, first remove the thermostatic cover (18) using a 12mm hex key or Horne tool no. 5459. The thermostatic cartridge (17) can then be removed in one of 2 ways.

- ◊ Screw the Horne cartridge removal tool (part no. 5458) into the cartridge from underneath. This can then be pulled downwards to remove the thermostatic cartridge.
- ◊ Use a 4mm hex key to turn the adjusting screw (19) clockwise and remove it from the thermostatic cover (the adjusting screw has the same thread on it as the cartridge remover no.5458). This can be used to screw into the cartridge and remove it. Ensure that the adjusting screw o-ring is in good condition; clean; free from debris and lightly lubricated with water or WRAS approved silicone oil before re-assembly (see 1.1).

4.5.4 The new cartridge can be inserted into the tap body from below. If the o-rings are dry, they should be lubricated with some water or WRAS approved silicone oil.

4.5.5 Screw in the new thermostatic cover, again lubricating the o-ring if necessary.

4.5.6 Be sure to adjust the temperature and perform a cold-water failure test after replacing the cartridge. These processes are detailed in sections 2.4.1; 2.6 & 2.7.

4.6 REPLACEMENT OF CERAMIC DISC CARTRIDGES

4.6.1 The ceramic disc cartridges are reliable and expected to give a very long life provided that the strainers are maintained in a clean condition. If replacement is necessary a kit should be purchased from Horne for this purpose (part no. 5489). The kit will comprise…

- ◊ Endcap removal tool – (part no. 23-5459)
- ◊ Pair of ceramic disc cartridges (27) – (part nos. 44-5406 & 44-5407)
- ◊ Pair of torque control members (31) – (part no. 23-5410)
- ◊ 2 no. o-rings (32) (part no. 42-3452)
- ◊ 4 no. o-rings (33) (part no. 42-5416)
- ◊ 2 no. M4 screw (35) (part no. 41-5414)

4.6.2 Unscrew and remove the aluminium endcap using the special Horne tool (no. 5459)

4.6.3 Unscrew and remove the screw and washer (34,35). 2.5mm hex key needed.

4.6.4 Pull the lever outwards to remove

4.6.5 Remove the spline adaptor and torque control member (30,31). These may come out as one piece.

4.6.6 Unscrew the actuator sleeve (28), using a 26mm ring spanner or Horne tool no. 5459.

4.6.7 Using a 17mm spanner, unscrew the ceramic disc cartridge (27). This will be tight.

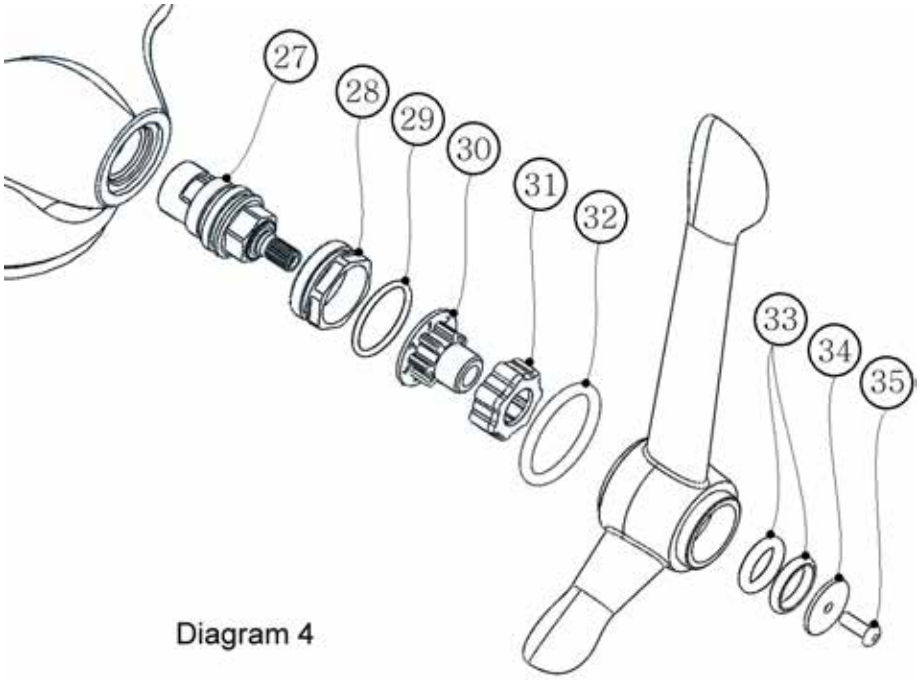


Diagram 4

4.6.8 Fit the replacement cartridge and tighten well. Note that the two cartridges are left and right handed. The cartridge with the small nicks around the 17mm spanner hex is for the left (hot) side of the tap. If the o-ring around the cartridge is dry, lubricate it with a little water or WRAS approved silicone oil.

4.6.9 Fit the new actuator sleeve and o-ring. If using a spanner for this take care not to over-tighten it as the thread is plastic - only light torque is needed. Horne tool no. 5459 can be used.

4.6.10 Remove the old torque control member (31) from the spline adaptor, and push-fit the new one. Lubricate this with a little (silicone) oil around the outside before final assembly.

4.6.11 Fit this assembly over the ceramic disc cartridge spline. Note that the spline has 20 teeth and the torque control member has 7 lobes. This allows 140 possible orientations of the lever. The correct orientation will have a lobe as near as possible to the vertical position (with the ceramic discs closed). It may be beneficial to experiment with orientations to ensure that the two levers end up aligned neatly with each other.

4.6.12 Re-fit the levers, replacing o-rings if necessary. The large o-ring goes on the in-board side and the two small ones go immediately under the penny washer on the out-board side.

4.6.13 Refit the washer and M4 screw tightly. Then fit the endcap (red on the left, blue on the right). Use the tool no. 5459 to tighten the endcap. This will prevent unauthorized removal.

4.7 REMOVAL OF TAP FROM SPIGOT FOR WORKSHOP MAINTENANCE

If desired the tap body can be removed from the spigot for off-site maintenance. Furthermore, a substitute tap body can be fitted while the original tap is being maintained. The process for this is as follows.

4.7.1 Close the isolating valves (13,14) at the back underneath the tap spigot; open the levers and allow the residual water to drain.

4.7.2 Unscrew the main bottom cover (16) using a strap wrench.

4.7.3 Loosen the tap retaining screw (15) until the head is flush or slightly proud of the bottom of the tap body.

4.7.4 Pull the tap away from the panel horizontally until it is free of the spigot. Pay careful attention not to drop it as it is rather heavy and may cause damage.

4.7.5 Rotate the tap to allow the residual water to pour out into the sink.

4.7.6 If a replacement tap body is to be fitted, follow the procedure in 1.2.7. The commissioning procedures in 2.4.1; 2.6 & 2.7 should be followed for the new tap body.

SYMPTOM	POSSIBLE CAUSE	ACTION	REFER TO SECTION
Mixed water temperature too high	Temperature setting too high. Temperature has been set when hot water supply temperature was too low	Re-adjust temperature setting ensuring hot water supply is at correct temperature.	2.4.1, 2.6
	Hot water supply has migrated into cold water supply	Inspect/replace cold check-valve assembly (21)	4.4
	Thermostat Element has failed. This can be checked by carrying out a hot or cold water failure test.	Replace Thermostatic cartridge (17) and cover assembly (18)	2.7 & 4.5
Mixed water temperature too low	Temperature Setting too low	Re-adjust temperature setting	2.4.1, 2.6
	Hot water supply temperature has fallen.	Check hot water supply temperature.	2.3
	Cold water has migrated into hot supply	Inspect/replace hot check-valve assembly (20)	4.4
	Cold valve face requires cleaning	Remove thermostatic cover (18) and clean up valve face	4.5
Mixed water flow rate too low.	Partly blocked strainers	Clean strainers	4.3
	Unusually high pressure drop in supply pipework	Check all valves are full open. Check Pressurisation unit. Check mains supply	-
	Extra Demand added to system	Check pipe sizing	-
Mixed water temp does not respond to adjusting screw	Thermostatic cartridge is seized	Replace Thermostatic cartridge (17) and cover assembly (18)	4.5
	Hot and cold inlets reversed	Reverse inlet connections (9,10). Connect hose from hot supply to inlet nearest red endcap	2.2
	Hot water supply temperature is too low	Check hot water supply	-

5.1 FAULT FINDING CHART – CONTINUED…

Mixed water temp changes and is not steady	Thermostatic cartridge is seized	Replace Thermostatic cartridge (17) and cover assembly (18)	4.5
	Thermostat element has failed. (This can be checked by carrying out a hot or cold water failure test)	Replace Thermostatic cartridge (17) and cover assembly (18)	2.7, 4.5
Water at outlet runs full hot or full cold	Hot and cold inlets are reversed	Reverse inlet connections (9,10). Connect hose from hot supply to inlet nearest red endcap	2.2
Valve continues to pass cold water when hot supply is isolated	Cold valve face is contaminated with debris	Remove loose debris from between Thermostatic cartridge (17) and cover assembly (18). Or replace (17) and (18) if no loose debris is found.	4.5
Valve continues to pass hot water when cold supply is isolated.	Element has failed, or Slide-Valve seal is damaged, or Fouling at hot valve seat	Replace Thermostatic cartridge (17) and cover assembly (18)	4.5
	If water flowing is more than 11°C above required mixed water temperature then valve may not have been commissioned with an adequate hot water supply temperature; or the set temperature may be too high. NB If this is the case the valve may not offer scald protection	Re-commission the valve, closely following the guidance in Section 2.	2.2 thru' 2.7
	If water flowing is less than 11°C above required mixed water temperature then the hot water supply temperature may not be sufficient to cause thermal shut-off. (N.B. this is possible with combi boilers).	Repeat test with hot water temperature at least 11°C above required mixed water temp.	2.3, 2.7
Water flow pulses when both levers are opened at once	This can happen when cold water pressure is low relative to the hot water pressure. Note that it is not normally necessary to open both levers simultaneously as the water supplied from the hot lever is at a safe and constant temperature.	This is not a fault condition and is normal	-
Tap does not shut-off when levers are in the closed position	Possible contamination on interconnect nozzle (1) o-rings.	Remove o-rings, clean and re-assemble	-

Contour 21

Contour 21
what works and why

An informative guide to commercial bathroom solutions for all sectors

Armitage Shanks

Contour 21
A solution for every sector

Contour 21 sanitary ware and fittings are designed to meet the rigorous demands of today's commercial installations. Tailored to the individual needs of each construction sector, Contour 21 blends striking aesthetics with enhanced durability and combines improved water efficiency with regulatory compliance.

Schools

Hospitals

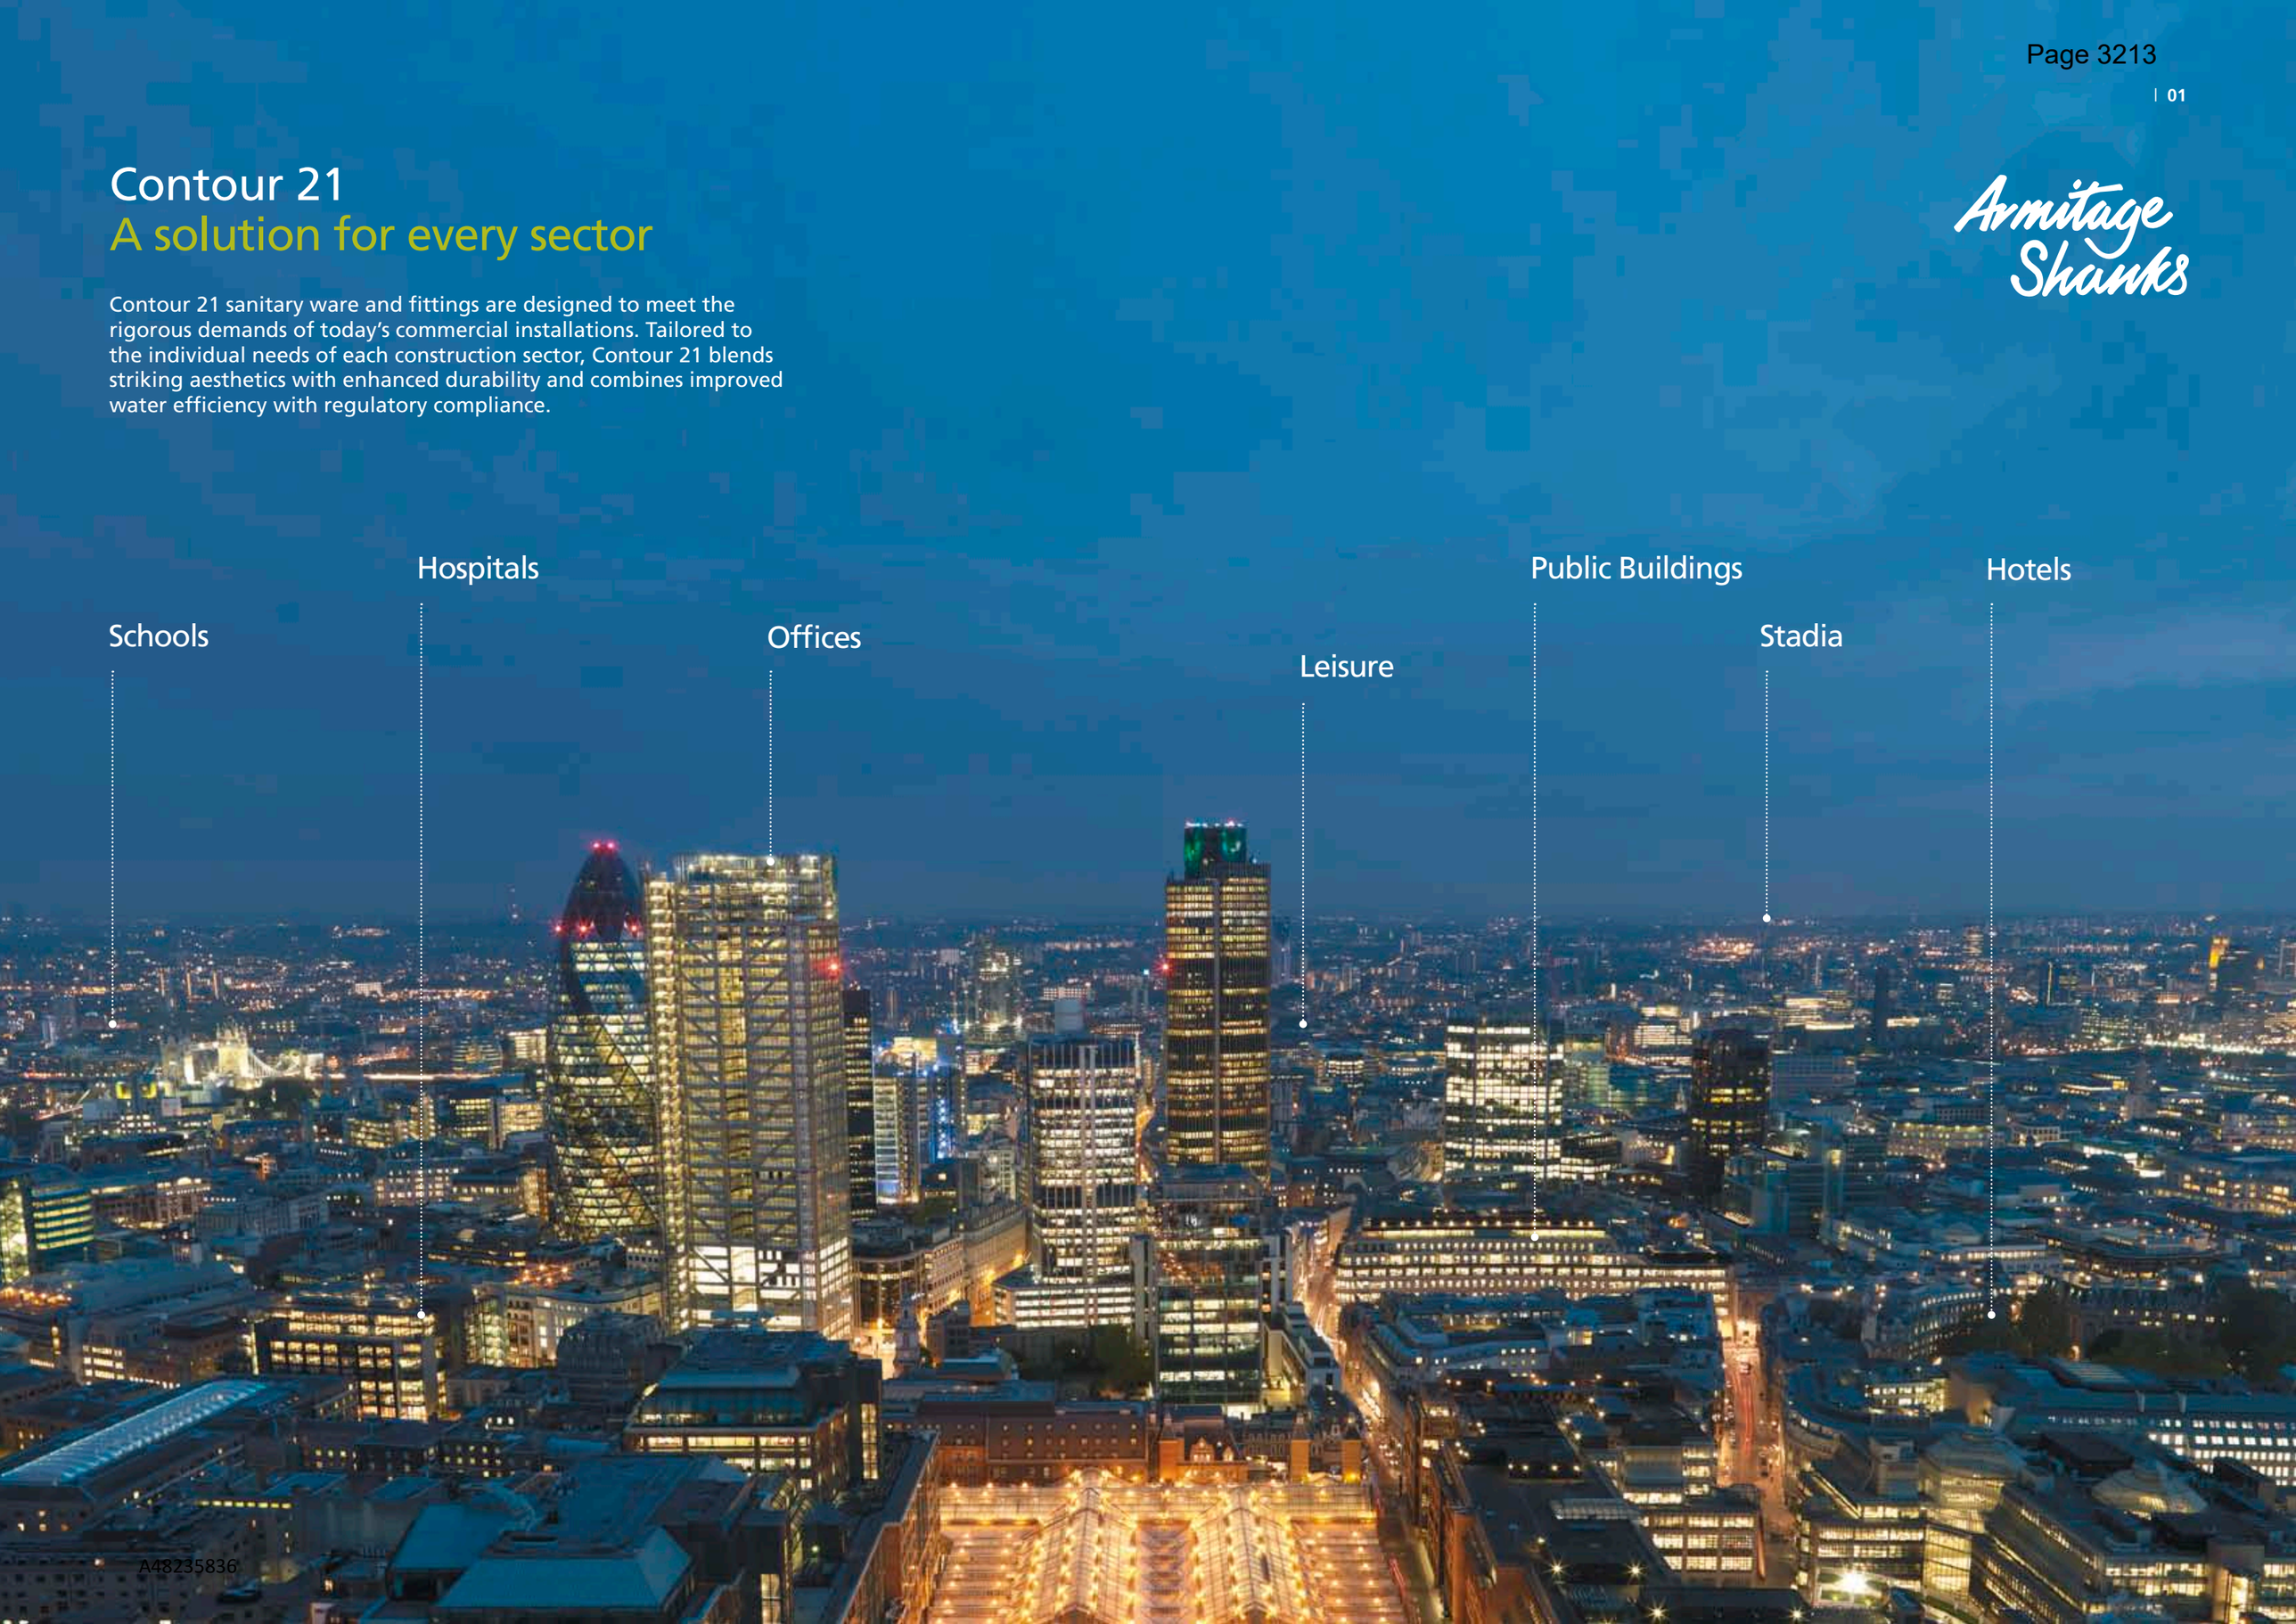
Offices

Leisure

Public Buildings

Stadia

Hotels



Contour 21
Every bathroom, every building, everywhere

Each type of building places a unique demand on the products and facilities within it. Contour 21 meets the performance and regulatory needs of every different sector, these are just a few of them.

Schools

Research has proven the common sense belief that clean, safe and functioning school toilets promote improved behaviour. Creating toilets pupils value, and can use when required, has a positive influence on their health, willingness to learn and attendance.

Armitage Shanks, the primary sponsor of the "Bog Standard" campaign for school toilet improvement, has been a key supplier to schools since 1910. School specific Contour 21 products have been designed in line with recent government guidelines to cope with heavy duty use and minimise water wastage.

Hospitals

The specification of sanitary ware and fittings for healthcare use can be a critical decision. For over 50 years Armitage Shanks has specialised in developing products that meet the complex functional requirements of hospital environments and the demands of government legislation.

Healthcare specific Contour 21 WC's and basins share modern ultra-hygienic designs which are fully compliant with the Department of Health's Health Technical Memorandum 64, while Markwik 21 mixers have been developed in line with the requirements of HFN30, HTM04 and HTM64.

Offices

Forward thinking businesses, concerned with helping their staff perform at optimum levels, realise their washrooms make a significant statement about the company's, and management's, attitude towards the people who work for it. While different organisations require different approaches, the fundamental specification factors are common; fitness for purpose, water economy, return on investment, equal access for all, easy cleaning and the effective use of space.

Contour 21's extensive product collection features hard-wearing water efficient products suitable for the smallest offices and the largest corporate headquarters.

Leisure

The scope of buildings designed to cater for the growth in leisure activities is vast; from the small town museum, to the regional music arena, from the local golf course's clubhouse to the newest shopping centre or mega mall. Whatever size the building, the necessity to design durable, aesthetically pleasing, easy to maintain washrooms is just as important.

Water management is particularly significant in entertainment or shopping facilities and Contour 21's water efficient products can help reduce water wastage and utility bills.

Part M

The Disability Discrimination Act 2004 requires that commercial and public buildings are suitable for use by disabled people. The Act defines disability as long term physical or mental disabilities, and short term conditions, such as pregnancy. The washroom requirements necessary for compliance with this Act are described in Part M of the Building Regulations.

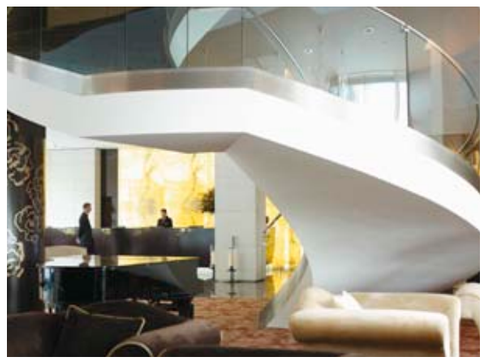
Armitage Shanks has developed Contour 21 Part M products in consultation with national disabled groups. These products meet the requirements of Part M and are suitable for an extensive range of applications.

Cardiff Millennium Stadium

Stadia

Over 1.3 million people visit Cardiff's Millennium Stadium annually. The UK's first fully retractable roof encloses almost 75,000 spectators for each major rugby or football game. Providing washroom facilities for the fans is the foundation of each successful event. While every venue may not share the prestige of the Millennium Stadium, functional, attractive and cost effective washroom design is just as important for local facilities.

Contour 21 is designed to cope with the demands of constant use in such heavy duty applications while minimising water wastage.



Hotels

Today's guest demands a lot from their room's en-suite; they expect to be impressed, they hope to be intrigued and they want to have nothing like it at home. For the hotelier however, there are concerns beyond simple aesthetics. They must balance style with ease of cleaning, performance with durability and ergonomics with water saving, particularly in public washrooms.

Achieving this may sometimes mean compromise, but with Contour 21 that is never necessary. Water efficiency, reliable performance, regulatory compliance and low maintenance are designed into every timeless Contour 21 piece.

Contour 21
Designed for the future

Commercial washrooms are subject to more stringent legislation, more inconsiderate use, harsher cleaning regimes and a tougher cost/benefit analysis than their domestic counterparts. Contour 21 has been designed specifically to meet these challenges.

Water Efficiency

Most commercial buildings, according to the Environment Agency, can reduce water consumption by around 50%. The Building Research Establishment's Environmental Assessment Method (BREEAM), sets the standard for best practice in sustainable design and is a useful measure of a building's level of achievement. When combined with the DEFRA backed Water Technology List, a collection of products that will make a positive impact on water saving, it will help to optimise the water efficiency of any project. Water saving is fundamental to the Contour 21 collection:

- Contour 21 dual flush WC's can flush on as little as 4.5/3 litres of water, a saving of up to 45%.
- Sensorflow 21's electronic washroom water management solution ensures water is only used when required.
- Contour 21 mixers are supplied with regulators to reduce their flow down to 5lt/pm at 3 bar.
- Contour 21 mixers include CLICK technology with "half" and "full" flow rate stops.
- Contour 21 non-concussive taps automatically stop water flow after a preset time, potentially saving 15%.

A48235836

Hygiene

Cleanliness and hygiene are the primary concern of public washroom users, many will even employ personal rituals aimed at avoiding physical contact with surfaces. They will use all their senses to judge hygiene; aroma, lighting, texture and colour all play a part. A washroom's physical layout and size can also be a factor as the last available WC or urinal "that no one else wants" is often perceived as below standard, or unclean. Contour 21 products can help to optimise the hygiene performance of a washroom:

- Contour 21 sanitary ware's smooth external contours eradicate dirt traps.
- Contour 21 sanitary ware's internal design minimises cavities that can harbour bacteria.
- Contour 21 and Sanura 21 hygenIQ urinal's anti-splash fin reduces urine splash back by up to 90%.
- Contour 21 WC's rimless pans eliminate a traditional bacteria haven.
- Contour 21 wall hung WC pans encourage faster more effective floor cleaning.
- Contour 21 back outlet basins are designed for "in wall" traps, making cleaning easier.
- Markwik 21 mixers can be easily disinfected, stopping the growth of bacteria such as legionella.

Durability

Commercial washrooms inevitably endure higher levels of use and receive rougher treatment than their domestic counterparts. Their durability will therefore be vital in delivering a cost effective design and specifying hard wearing, low maintenance products will help reduce full life costs. Rigorous daily cleaning regimes can degrade the finishes of products not designed for commercial environments. Commercial grade durability is built-in to the Contour 21 collection:

- Contour 21 sanitary ware is finished in high performance glaze for long term performance and colour retention.
- Contour 21 mixers use special seals to prevent commercial cleaning products entering the mixer body and damaging the cartridge.
- Contour 21 mixers and fittings are guaranteed for 5 years.
- Contour 21's anti-slip coating for baths and showers is guaranteed for 10 years.
- Contour 21 ceramic products have a lifetime guarantee.

Maintenance

Minimising the down-time of a commercial bathroom or washroom is critical to its success. An "out of order" sign will at best annoy the user, and at worst cost the owner money. Choosing sanitary ware that is designed for low maintenance, and also ease of maintenance, will help to keep a facility fully operational. Sometimes even the toughest products fail and the on-going availability of spare parts must also be considered when preparing a scheme. Contour 21 products are quick and easy to maintain and deliver long term performance:

- Contour 21 products are manufactured and guaranteed by the market leader in commercial sanitary ware.
- Contour 21 products are supported by a comprehensive, and long term, replacement parts service.
- Contour 21 sanitary ware's clean, organic design makes cleaning faster and more effective.
- Markwik 21 panel mounted mixers can be serviced from the front, without removing wall panels.

Sustainability

Sustainability is now seen as an area of competitive advantage in the commercial arena and choosing long lasting and environmentally responsible products is increasingly important. Armitage Shanks is committed to minimising the impact of its manufacturing processes on the environment. Over the last decade we have invested in cleaner, more energy efficient plant and introduced many sustainable practices:

- In 1998 less than 10% of the clay effluent we produced during vitreous china casting was re-used. Today over 80% of it is recycled for use in the production of floor tiles and bricks.
- In 2006 a new glaze Ultra Filtration System was installed at our Rugeley facility. As a result the glaze waste we send to landfill has reduced by 900 tonnes/ year and discharge fallen by 12,000m3/year.
- In 2000 producing 1kg of sanitary product created 1.36kg of CO2. By improving the energy efficiency of our manufacturing processes we have reduced that to 1.15kg of CO2/kg of product.

Contour 21
Multiple choices for multiple applications

For almost every sector of the commercial washroom market there is a Contour 21 product that has been designed to meet its needs. Because every piece has been developed with the performance, durability and regulatory demands of the broader commercial market in mind, many Contour 21 products can be used across several different market sectors. This flexibility allows the specifier to mix and match styles to create unique bathrooms over a broad spectrum of applications.

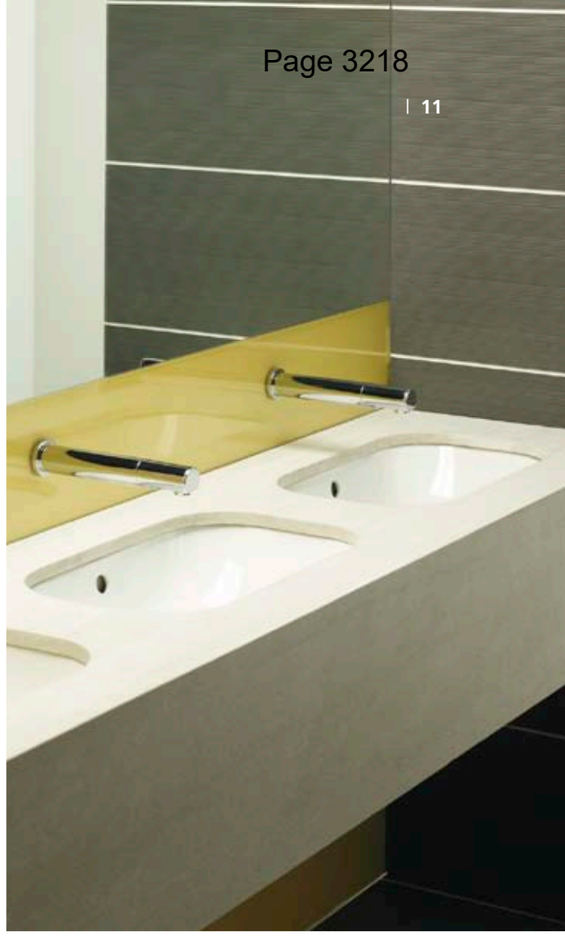
Contour 21
New products, new possibilities, new options

Established Armitage Shanks' products and exceptional new designs have joined the Contour 21 family, creating an extended sanitary ware solution for every commercial sector.

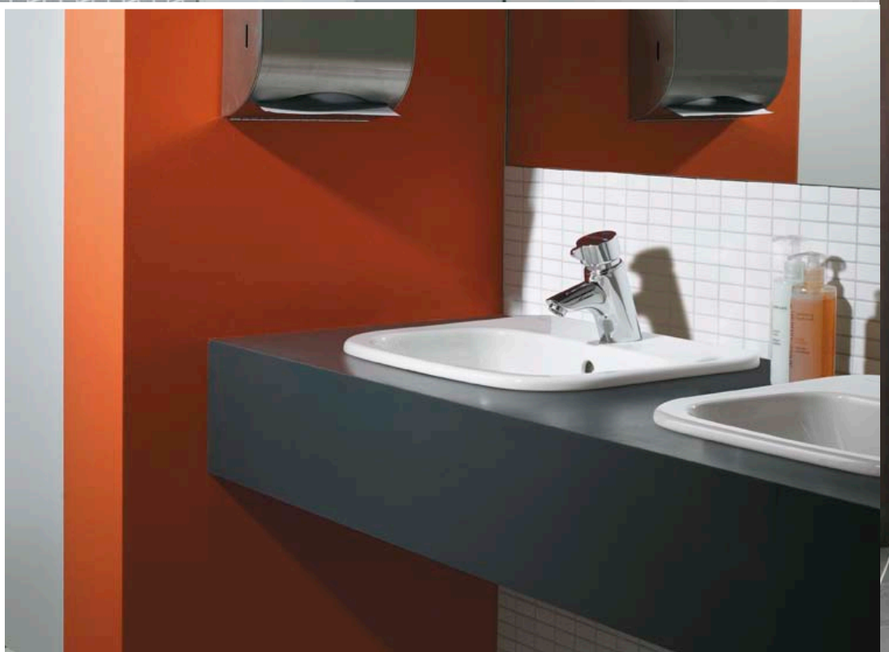
Contemporary styling defines the new members of the Contour 21 range. Redesigned Profile, Planet and Orbit basins, and a new Contour 21 under-mount basin, give a designer feel to offices and high-end leisure facilities.

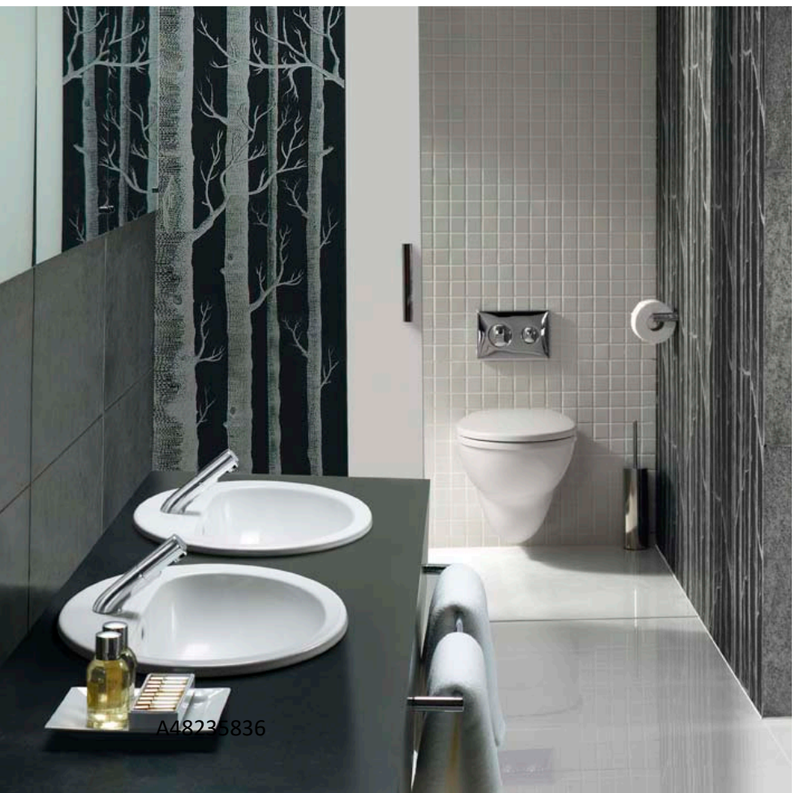
The elegant new Portman 21 pedestal basin, when combined with the new close-coupled Contour 21 WC, offers the perfect product solution where domestic products are required in a commercial application. Even the humble urinal has been reimagined and improved, thanks to the anti-splash fin of the hygenIQ Contour 21 urinal.

Page 3218



The additions to the Contour 21 family mean it can now serve an even wider range of sectors. While sharing the same durability and functionality, these new products have a "softer" commercial look suitable for installations where aesthetics are as important as performance.





A48236836

At the heart of every additional product is Contour 21's dedication to meeting the needs of the specifier. Despite looks that make these "designer commercial" products at home in a 4 Star hotel en-suite and executive washrooms, each one has been specially chosen for their ruggedness and fitness for purpose. From the smallest bathroom to the largest public facility, the extended Contour 21 collection has a choice of designs to satisfy the most demanding client.

Contour 21
Form and function perfectly combined

With durability and performance as its foundation, Contour 21's timeless and elegant aesthetics lift it beyond the constraints of normal commercial products. The "where, what and why" of the collections' key pieces are highlighted in the following pages.

Contour 21
Washbasins

Contour 21
37cm hand rinse basin (S212201)

- One centre tap hole
- No overflow or chain hole

See Contour 21 Price Guide for complete range of products and codes

Contour 21
37cm handrinse basin with right hand taphole (S247401) *Above*
37cm handrinse basin with left hand taphole (S247301) *Left*

- Right or left hand tap hole option
- No overflow or chain hole
- Part M compliant

See Contour 21 Price Guide for complete range of products and codes

Contour 21
60cm basin (S215501)

- Back outlet
- No tap holes, overflow or chain hole
- Concealed trap (not included)
- Suitable for use with ducts or panel systems
- Meets HTM64 requirements for clinical basins
- 50cm version also available

See Contour 21 Price Guide for complete range of products and codes

Contour 21
60cm accessible basin (S216801)

- One centre tap hole
- Improved design provides easier access for wheelchair users
- Side bars allow user to pull wheelchair up to basin
- Broad rim provides elbow support
- 55cm version also available

See Contour 21 Price Guide for complete range of products and codes

A48235836

Page 3222

Portman 21
40cm basin (S231401)

- Right, left or one central tap hole option
- Two tap hole option or no tap hole option
- With or without overflow or chain hole
- Compact modern design for general washroom use
- Basin with no overflow meets HTM64 requirements for non clinical use

See Contour 21 Price Guide for complete range of products and codes

Portman 21
55cm basin with semi-pedestal (S247801)
50cm basin with semi-pedestal (S248201) *Not shown*

- New from Armitage Shanks
- One, two or three tap hole option
- With overflow
- With or without chain hole
- Wall hung semi-pedestal
- Ideal for applications requiring a domestic look

See Contour 21 Price Guide for complete range of products and codes

Portman 21
50cm basin (S225401)

- Right, left or one central tap hole option
- Two tap hole option or no tap hole option
- With or without overflow or chain hole
- Midsize design for general washroom use
- Basin with no overflow meets HTM64 requirements for non clinical use

See Contour 21 Price Guide for complete range of products and codes

Portman 21
50cm basin with full pedestal (S248201)

- New from Armitage Shanks
- One, two or three tap hole option
- With overflow
- With or without chain hole
- Full height pedestal
- Ideal for applications requiring a domestic look

See Contour 21 Price Guide for complete range of products and codes

Portman 21
60cm basin (S225601)

- Right, left or one central tap hole option
- Two tap hole option or no tap hole option
- With or without overflow or chain hole
- Contemporary design for general washroom use
- Basin with no overflow meets HTM64 requirements for non clinical use

See Contour 21 Price Guide for complete range of products and codes

Portman 21
55cm basin with full pedestal (S247801)

- New from Armitage Shanks
- One, two or three tap hole option
- With overflow
- With or without chain hole
- Full height pedestal
- Ideal for applications requiring a domestic look

See Contour 21 Price Guide for complete range of products and codes

Profile 21
50cm semi-countertop basin (S249401)

- New to Armitage Shanks
- One central tap hole or two tap hole option
- With overflow
- No chain hole
- Stylish rectangular design will suit school, hotel or office projects

See Contour 21 Price Guide for complete range of products and codes

A48235836

Planet 21
50cm countertop basin (S248401)

- New from Armitage Shanks
- One central tap hole or two tap hole option
- With overflow
- No chain hole
- Stylish rectangular design will suit school, hotel or office project

See Contour 21 Price Guide for complete range of products and codes

Orbit 21
55cm countertop basin (S248601)

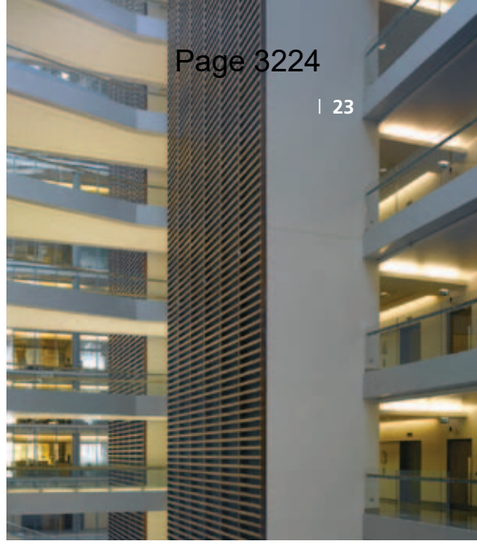
- New from Armitage Shanks
- One, two or three tap hole option
- With overflow
- No chain hole
- Oval design saves counter space when used in rows

See Contour 21 Price Guide for complete range of products and codes

Contour 21
50cm under countertop basin (S249601)

- New from Armitage Shanks
- Use with countertop or wall mounted taps, mixers and spouts
- With overflow
- No chain hole
- Simple contemporary design mounts under the counter

See Contour 21 Price Guide for complete range of products and codes



Airside
80cm washroom basin (S242801)

- One tap hole or no tap hole option
- No overflow or chain hole
- Incorporates shelf for personal belongings and washing kit

See Contour 21 Price Guide for complete range of products and codes

A48235836

Leadenhall
55cm washroom basin (S205801)

- No tap holes
- No overflow or chain hole
- Back outlet suitable for concealed trap
- Striking tapered profile, starkly upmarket design

See Contour 21 Price Guide for complete range of products and codes

Cherwell
42cm under countertop basin (S257001)

- Use with countertop or wall mounted taps, mixers and spouts
- No chain hole
- Simple and pure large hemispherical bowl
- Glazed or unglazed options

See Contour 21 Price Guide for complete range of products and codes

Marlow
56cm under countertop basin (S256001)

- Use with countertop or wall mounted taps, mixers and spouts
- No chain hole
- Graceful elliptical bowl for any modern washroom
- 48cm version also available

See Contour 21 Price Guide for complete range of products and codes

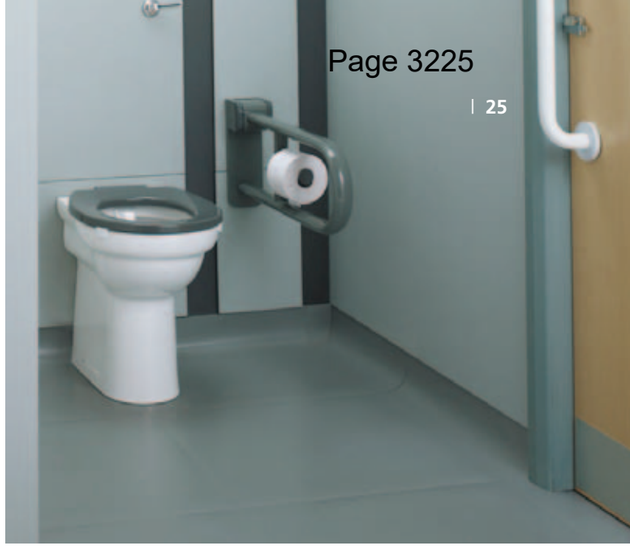
Contour 21
WC's

Contour 21
75cm projection back-to-wall WC (S305301)
70cm projection back-to-wall WC (S305501) *Not shown*

- Rimless pan
- 46cm raised height for easier wheelchair transfer
- Compliant with Part M requirements
- Available with 4.5 single flush or 4.5/3 dual flush

See Contour 21 Price Guide for complete range of products and codes

A48235836



Contour 21
Standard height rimless back-to-wall WC (S305601)

- Rimless pan
- Standard 41cm height for general use
- Standard projection
- Available with 4.5 single flush or 4.5/3 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
46cm raised height rimless back-to-wall WC (S305701)

- Rimless pan
- 46cm raised height for easier wheelchair transfer
- Standard projection
- Compliant with Part M and HTM64 requirements
- Available with 4.5 single flush or 4.5/3 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
46cm raised height closed coupled WC (S305401)

- Rimless pan
- 46cm raised height for easier wheelchair transfer
- 75cm extended projection
- Compliant with Part M requirements
- Spatula lever for easy flushing
- 4.5 syphon flush with delay fill

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Rimless wall hung WC (S307601)

- Rimless pan
- Standard projection
- Compliant with Part M and HTM64 requirements
- Available with 4.5 single flush or 4.5/3 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Rimless wall hung WC (S307701)

- Rimless pan
- 70cm extended projection
- Compliant with HTM64 requirements
- Available with 4.5 single flush or 4.5/3 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Rimless wall hung WC (S307801)

- Rimless pan
- 75cm extended projection
- Compliant with Part M requirements
- Available with 4.5 single flush or 4.5/3 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Schools 305mm back-to-wall WC (S304601)
Schools 355mm back-to-wall WC (S304701) *Not shown*

- Lowered height for use by young children
- Can also be used as a back-to-wall WC
- Available with 4/2.6 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Schools 305mm close coupled WC (S304601)

- Lowered height for use by young children
- Can also be used as a back-to-wall WC
- Available with 4/2.6 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Schools 355mm close coupled WC (S304701)

- Lowered height for use by older children
- Can also be used as a back-to-wall WC
- Available with 4/2.6 dual flush

See Contour 21 Price Guide for complete range of products and codes

Page 3227

A48235836

Contour 21
Back-to-wall WC (S309501)

- New from Armitage Shanks
- Suitable for residential/domestic installations
- Available with 6/4 or 4/2.6 dual flush

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Close coupled WC (S309201)

- New from Armitage Shanks
- Suitable for residential/domestic installations
- Available with 6/4 or 4/2.6 dual flush

See Contour 21 Price Guide for complete range of products and codes

Wentworth
Close coupled WC pan (S316201)

- New from Armitage Shanks
- Standard height for general use
- Standard projection
- 6 litre syphon flush with side lever

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Brassware

Contour 21
Dual control thermostatic shower mixer (A4127AA)

- Twin lever control
- Wall mounted
- Suitable for concealed supply pipes

See Contour 21 Price Guide for complete range of products and codes

A48235836

Contour 21
Single lever thermostatic bath mixer (A4135AA)

- Sequential control
- Closed fist use, suitable for Part M applications
- Wall mounted
- Suitable for concealed supply pipes
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Thermostatic basin mixer (A4131AA)

- Single lever operation
- Closed fist use, suitable for Part M applications
- Suitable for concealed supply pipes
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Thermostic basin mixer (A4169AA)

- Single lever operation
- Closed fist use, suitable for Part M applications
- Suitable for concealed supply pipes
- Copper trails
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Dual control exposed thermostatic bath/shower mixer (A4128AA)

- Twin lever control
- Wall mounted
- Thermal disinfection facility
- Suitable for concealed supply pipes

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Single lever built-in thermostatic shower mixer (A4129AA)

- Sequential control
- Built-in design, suitable for concealed supply pipes
- Safety temperature stop
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Single lever exposed thermostatic shower mixer (A4130AA)

- Sequential control
- Exposed design, suitable for concealed supply pipes
- Safety temperature stop
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
15cm wall mounted tubular spout (A4180AA)
23cm wall mounted tubular spout (A4183AA) *Shown above*

- Ultra hygienic no-touch operation
- Separate sensor, proximity activated
- Requires pre-mixed water
- Auto flow shut off when sensor obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

A48235836

Sensorflow 21
23cm wall mounted compact tubular spout (A4849AA)
15cm wall mounted compact tubular spout (A4846AA) *Not shown*

- Ultra hygienic no-touch operation
- Built-in sensor, proximity activated
- Requires pre-mixed water
- Auto flow shut off when sensor obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Small basin spout (A4664AA)

- Ultra hygienic no-touch operation
- Reduced overall height
- Built-in sensor, proximity activated
- Requires pre-mixed water
- Auto flow shut off when sensor obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Basin spout (A4171AA)

- Ultra hygienic no-touch operation
- Built in sensor, proximity activated
- Requires pre-mixed water
- Auto flow shut off when sensor is obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Page 3231

Sensorflow 21
Deck mounted compact basin spout (A4851AA)

- Ultra hygienic no-touch operation
- Built-in sensor, proximity activated
- Requires pre-mixed water
- Auto flow shut off when sensor obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Electronic WC flush control, panel mounted (S359967)

- Proximity activated urinal flushing
- For rimmed and rimless urinal bowls
- Mains water or tank fed water
- Auto flow shut off when sensor obstructed
- Conceal cistern included
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Basin spout (A4176AA)

- Built in sensor, proximity flow activated
- Single lever manual temperature control
- Requires pre-mixed water
- Auto flow shut off when sensor is obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Electronic WC flush control, surface mounted (A4669AA)

- Proximity activated urinal flushing
- For rimmed and rimless urinal bowls
- Mains water or tank fed water
- Auto flow shut off when sensor obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
15cm wall mounted cast spout (A4178AA)

- Ultra hygienic no-touch operation
- Built in sensor, proximity activated
- Requires pre-mixed water
- Auto flow shut off when sensor is obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Shower sensor and solenoid (A4185AA)

- Ultra hygienic no-touch operation
- Proximity flow activated
- Requires pre-mixed water
- Auto flow shut off when sensor obstructed
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Piccolo 21
Basin pillar mixers (B9142AA)

- New from Armitage Shanks
- Anti vandal outlets
- Ceramic cartridge for accurate flow control and drip free operation
- 5lt/min laminar flow regulator
- Hard wearing easy to see hot and cold temperature indicators

See Contour 21 Price Guide for complete range of products and codes

Piccolo 21
Single lever basin mixer with pop up waste (B9135AA)

- New from Armitage Shanks
- CLICK water saving cartridge
- Fitted with 5 l/min airated flow regulator
- Flow straightener option to increase flow rate at lower pressures
- Ceramic cartridge for accurate flow control and drip free operation
- Top fix fitting
- Temperature limit stop option

See Contour 21 Price Guide for complete range of products and codes

Piccolo 21
One hole bath mixer (B9138AA)

- New from Armitage Shanks
- Ceramic cartridge for accurate flow control and drip free operation
- Temperature limit stop option
- Designed for use on low or high pressure systems

See Contour 21 Price Guide for complete range of products and codes

Piccolo 21
One hole bath/shower mixer (B9139AA)

- New from Armitage Shanks
- Ceramic cartridge for accurate flow control and drip free operation
- Temperature limit stop
- Shower handset, hose and adjustable wall fixing bracket
- Designed for use on low or high pressure systems

See Contour 21 Price Guide for complete range of products and codes

Piccolo 21
Two hole bath mixer (B9140AA)

- New from Armitage Shanks
- Ceramic cartridge for accurate flow control and drip free operation
- Designed for use on low or high pressure systems

See Contour 21 Price Guide for complete range of products and codes

Piccolo 21
Two hole thermostatic bath shower mixer (A4989AA)
Two hole bath/shower mixer (B9141AA) *Not shown*

- New from Armitage Shanks
- Ceramic cartridge for accurate flow control and drip free operation
- Designed for use on low or high pressure systems
- Shower handset, hose and adjustable wall fixing bracket
- Eco button limiting flow to 50% with manual override
- Built in thermostat with cool safe to touch body
- 40°C safety stop with override facility adjustable to 43°C, 46°C or 48°C

See Contour 21 Price Guide for complete range of products and codes

Avon 21
Self closing basin pillar taps (B8267AA)

- Anti vandal design
- No pop-up waste
- Dual indices
- Self closing shut off for water economy
- Closed fist use, suitable for Part M applications

See Contour 21 Price Guide for complete range of products and codes

Avon 21
Self closing exposed thermostatic shower valve (B8264AA)

- Anti vandal design
- Suitable for fixed/overhead shower head
- Mixed water outlet on top
- Self closing shut off for water economy

See Contour 21 Price Guide for complete range of products and codes

Avon 21
Self closing built-in thermostatic shower valve (B8265AA)

- Anti vandal design
- Suitable for concealed supply pipework
- Self closing shut off for water economy

See Contour 21 Price Guide for complete range of products and codes

Avon 21
Self closing basin mixer (B8263AA)

- Anti vandal design
- No pop-up waste
- Self closing shut off for water economy
- Closed fist use, suitable for Part M applications

See Contour 21 Price Guide for complete range of products and codes

A48235836

Markwik 21
Wall mounted thermostatic basin/sink mixer (A4553AA)

- For use in medical and healthcare applications
- Long single lever sequential operation
- Built in sterilisation system
- Designed in line with HTM64, HTM04 and HFN30
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Markwik 21
Single lever thermostatic basin/sink mixer (A4803AA)

- For use in medical and healthcare applications
- Long single lever sequential operation
- Insulated cool to the touch twin pillar body
- Designed in line with HTM64, HTM04 and HFN30
- Revised design eliminates swan-neck water pocket
- Easy retrofit for replacing old non-compliant fittings

See Contour 21 Price Guide for complete range of products and codes

Markwik 21
Wall mounted thermostatic basin/sink mixer (A4554AA)

- For use in medical and healthcare applications
- Ultra hygienic proximity sensor flow start and stop
- Built in sterilisation system
- Designed in line with HTM64, HTM04 and HFN30
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes

Markwik 21
Sterilising kit for thermostatic mixers (S8293NU)

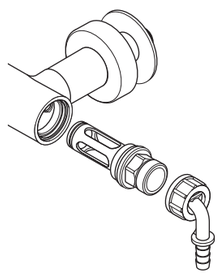
- For use with Markwik thermostatic healthcare mixers
- Easy sterilisation of healthcare mixers
- Front fixing, no need to remove fitting

See Contour 21 Price Guide for complete range of products and codes

Markwik 21
Wall mounted thermostatic basin/sink mixer (A4555AA)

- For use in medical and healthcare applications
- Ultra hygienic proximity sensor flow start and timer controlled stop
- Built in sterilisation system
- Designed in line with HTM64, HTM04 and HFN30
- TMV 3 approved

See Contour 21 Price Guide for complete range of products and codes



Markwik 21
Purging kit for Markwik Insulate products (A4556AA)
Purging kit (S8214AA) *Not Shown*

- For use with healthcare thermostatic mixers
- Flushes debris after installation
- Purging cartridge replaces maintenance cartridge
- Mixer can be flushed without affecting thermostat

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Urinals

A48235836

Page 3235

Contour 21
hygenIQ urinal (S611901)

- Improved hygiene performance
- Unique anti-splash cast fin, rimless bowl
- Splash back reduced by up to 90%
- 67cm overall height
- Concealed trap

See Contour 21 Price Guide for complete range of products and codes

Sanura 21
hygenIQ urinal (S611701)

- Improved hygiene performance
- Unique anti-splash cast fin, rimless bowl
- Splash back reduced by up to 90%
- 40cm overall height
- 50cm version also available
- Exposed trap

See Contour 21 Price Guide for complete range of products and codes

Sensorflow 21
Urinal sensor panel mounted (A4854AA)
Urinal sensor surface mounted (A4856AA)

- Proximity activated urinal flushing
- For rimmed and rimless urinal bowls
- Mains water or tank fed water
- Mains or battery power

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Part M

A48235836

Page 3236

Sensorflow 21
Wall hung WC Doc M pack (S6987AA right hand)
(S6986AA left hand) *Not shown*

- State of the art Part M compliance
- Hygienic sensor operated basin mixer
- Hygienic sensor operated WC flush
- Extended projection WC for easier wheelchair access
- Chrome grab rails and hinged support arm
- White seat with stability retainers

See Contour 21 Price Guide for complete range of products and codes

Contour 21
Close coupled WC Doc M pack (S6967AC right hand)
(S6966AC left hand) *Not shown*

- Part M compliant, LANTAC approved
- TMV 3 approved thermostatic sequential mixer
- Right or left hand tap hole basin option
- Raised height WC for easier wheelchair access
- White, blue or stainless steel grab rails and hinged support arm
- White, blue or grey seat with stability retainers

See Contour 21 Price Guide for complete range of products and codes

Part M Solutions
What works and why

- Armitage Shanks' informative guide to Part M washrooms
- Overview of section 10.3 of Part M4 of the Building Regulations
- Scale of provision required by BS6465 and section 5.7 of Part M3
- 10 approved Part M bathroom and washroom layouts

Contour 21
Part M Grab Rails

White

Blue

Stainless Steel

Grey

Charcoal

Contour 21
Fixed grab rails

Available in white, grey, blue, charcoal, stainless steel or chrome to provide contrast with their background for visually impaired users. Each rail is made of 33mm diameter polyester coated aluminium (with the exception of the stainless steel and chrome rails), has concealed fixings for improved hygiene and security and is capable of supporting 200kg.

Contour 21
Hinged support arm

A robust support that folds up and out of the way, simplifying transfer from wheelchair to WC. Slip resistant contact surfaces enhance safety and promote confidence in the user. The hinged support arm can support 200kg when fixed using best practice.

See Contour 21 Price Guide for complete range of products and codes

Guarantee

lifetime
All ceramic products

5 years
on taps and mixers, toilet seats and cistern fittings

Our confidence in the quality and reliability of our product allows us to offer outstanding extended guarantees on all our products – where the product fails within 5/25 years/lifetime we offer a free replacement or replacement part (or nearest equivalent). So when your washroom has been satisfactorily installed and is working well, please ensure you register your guarantee.

This guarantee is transferable – it applies to the product not the purchaser provided the guarantee registration is passed on to the new owner.

Liability is limited to individual products and the guarantee does not cover the consequential loss or damage or installation costs. This guarantee does not affect your statutory rights. Products must be installed, used and cared for in line with our fixing instructions and local water regulations, and room must be adequately ventilated.

Parts (e.g. flushvalves) are guaranteed for five years and will be replaced if found to be faulty. The guarantee does not cover general wear and tear.

Applies to UK and Republic of Ireland only.

You can register for guarantees on a bathroom bought on your behalf by a plumber or builder.

Colours printed in this book are as near as possible to the manufactured range of Armitage Shanks quality bathrooms. For accurate comparisons of colours, see actual ware on display at Armitage Shanks retailers. Our policy is one of continuous improvement and we reserve the right to change specification and design at any time without notice.

Products can be subject to tolerances due to manufacturing processes.

the essential specifiers series

If you would like to request the Hospital, Brassware, Part M, School, Office, Contour 21, Hotel or Trade Price List brochures from our 'Essential Specifiers Series',

call 0800 590311

For further information on any of our products;

please call

HORNE®

Product datasheet: T108A2L

INCLUSIVE DESIGN TSV1 SHOWER PANEL
Includes integral Type 3 Approved thermostatic shower valve pre-plumbed within a white epoxy-polyester powder-coated aluminium panel with lever hand controls, single function handset, flexible hose and riser rail.

FEATURES & BENEFITS

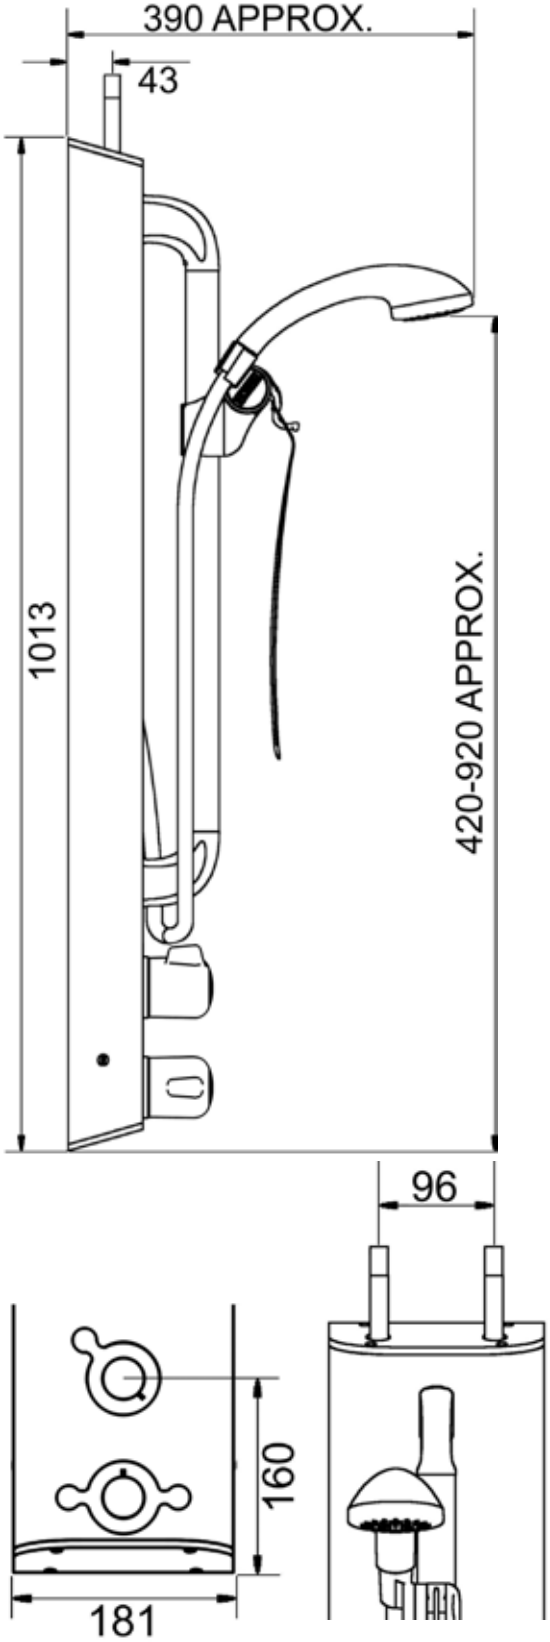
- Durable, anodised and powder-coated (RAL 9010, LRV=84) panel and robust fittings ensure long lifespan
- Integral healthcare-approved shower valve with BS 8300 compliant lever controls
- Robust riser rail with inclusive design handset holder
- Single function handset with 1.25m easy-clean and anti-kink hose with PVC liner
- Integral 8 L/min flow regulator for water and energy conservation
- Low level integral servicing valves for ease of maintenance and performance testing
- Fast and easy installation, for new or retrofit applications
- Pressure tested assembly, to 16 bar
- Optional accessories:
  - Pipe cover kit, same profile as panel
  - 2 metre hose, part number SA-108B

The TSV1-3 thermostatic shower valve is Type 3 and UK Water Regulation 4 Approved.

HORNE®

Product datasheet: T108A2L

Dimensions in mm Original Drawing Ref: 10367



The **T108A2L** shower panel is pre-plumbed with an integral dual control Type 3 approved thermostatic mixing valve, which features:

- Low level isolating servicing valves
- Integral fine mesh strainers provide essential protection to internal mechanism of the valve and ancillary fittings
- Angle pattern inlets enable easy access to the strainers
- Integral check valves prevent cross migration of water supplies
- Flushing facility to allow water supplies to be flushed clean during commissioning

Operating Conditions (Type 3 TMV):

- Range of temperature adjustment up to pre-set maximum, usually 41°C at the showerhead
- Range of hot water supply temperature: 55 — 65°C
- Maximum static pressure: 10 bar
- Minimum differential between hot water temp. and mixed water temp.: 5°C
- Range of maintained water supply pressures: 0.2—5 bar

Unequal pressures are usually acceptable if gravity-pressure supplies one of the inlets: minimum 0.2 Bar. When both supplies are pumped, pressures should be nominally balanced.

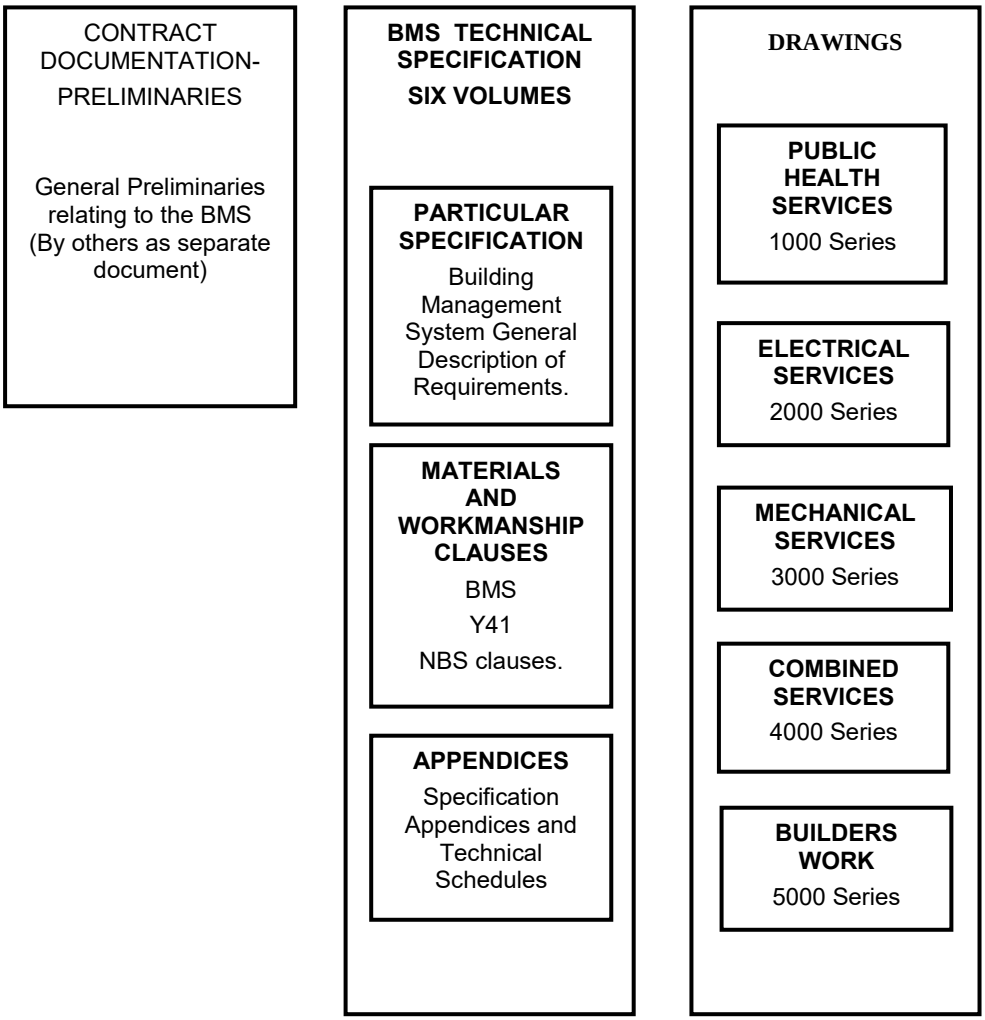
RDD COMMENT/RESPONSES

Document Revision Reviewed	**B**
RDD COMMENTS	**RESPONSE**
Front page - Development of the BMS/Controls will be managed via BMS specification clarification log	Noted
6.0 p.8 –to be developed via log process	Noted part of FDS review process
10.0 p.11 – This will be a replicated head end @ new location in labs bldg	Clause 11.1 amended to suit
10.0 p.11 para 9 – refer to log	Noted part of FDS review process
10.0 p.11 para 14 – refer to log for definition of manual control	Noted part of FDS review process
P.13 * - Link to utility monitoring – refer to logs	Noted part of FDS review process
11.0 p.14 – Boston to allocate space in rack for future retained estates server	Text amended
11.0 p.15 development required re metering (logs)	Noted part of FDS review process
11.0 p.15 – see previous note re space for retained estate server	Text amended
11.0 p.15 – storage requirements to be developed (logs)	Noted part of FDS review process
11.0 p.16 – to be reviewed via logs	Noted part of FDS review process
11.0 p.16 (AMT) – likely to be limited to fiscal meters with remainder handled on integrated ERM	Text amended as part of FDS process
11.0 p.17 – does this include positional feedback	No
11.0 p.18 – further development required via logs & Schnieder	Noted part of FDS review process
11.010.3 p.18 – has this been decided?	Text amended
11.0 p.19 – to be reviewed with Board FM team	Noted part of FDS review process
11.0 p.20 – scope to be developed & agreed	Noted part of FDS review process
11.0 p.20 (drawings) – metering strategy, meter tree, graphic proposals, controls strategy	Text amended
11.0 p.22 – review ???? supported by UPS	All plant disabled under power failure and reinstated in accordance with generator load management
Y41 445A – PC specification to be agreed with NHSGGC, HI & T	Noted part of FDS review process
Y41 915 – refer to BREEAM –MAN01	Text amended

Y40 BUILDING MANAGEMENT SYSTEM

SPECIFICATION VOLUME INDEX

OVERALL FRAMEWORK OF TENDER DOCUMENTATION
BUILDING MANAGEMENT SYSTEM TECHNICAL SPECIFICATION



Y40 VOLUME 1 – GENERAL REQUIREMENTS

CONTENTS

MATERIALS AND WORKMANSHIP CLAUSES

APPENDICES

1.0 GENERAL INTRODUCTION

1.1 Purpose of Document

This Specification is based on the NBS suite of specifications.

The development of the design, manufacture, supply, installation, wiring, setting to work and commissioning of the works described in this document shall be undertaken by the Specialist Sub-Contractor and is referred to in this document as “the Specialist”.

To carry out the development of the design, the Specialist shall obtain the necessary supporting documentation including that listed in Appendix A.

This specification relates to the Building Management System (BMS) serving the Adult and Children’s’ Hospitals and the adjacent Laboratory. The BMS serving the Laboratory/FM Building is covered by separate specifications, but the two parts of the project will ultimately form a single integrated system.

This specification shall be read in conjunction with all other mechanical and electrical engineering services specifications and the architectural drawings.

1.2 Description of Project

The two hospitals providing Adult and Children healthcare are located on the existing Southern General Hospital site and provide some 1400 beds plus associated treatment and diagnostic departments, and support facilities.

The hospitals are accommodated in a 12 storey building comprising a four storey podium and 8 storey tower rising out of the podium.

A basement houses FM support facilities and a tunnel link from the laboratory/FM building.

Plantrooms are generally located at roof level at levels 2, 3, 4 and 12, and house ventilation plant, main heating and cooling stations, and HWS generation, electrical substations and other key plant.

The building is generally constructed from reinforced concrete.

A central energy centre to the north of the hospital and laboratory/FM buildings houses heating, cooling, CHP, standby generation and fuel storage.

Main services emanate from the energy centre to serve the hospital building and laboratory/FM building, with future capacity to serve the retained estate on the remainder of the site.

2.0 EXISTING SITE AND SERVICES

Not applicable

3.0 SCOPE

The scope of work covered by this Performance Specification shall include the following:-

- Building Management System and Automatic Controls
- Power and control wiring to plant and control devices
- All containment within plantrooms necessary for the BMS and operation of plant
- Conduits in or on walls outside plantrooms (secondary containment)
- Local cable containment from main distribution boards to plant items
- Setting to work and commissioning

The following is specifically excluded from the scope of this performance specification:-

- BMS system within Laboratory/FM Building
- Host data/IT network (specified elsewhere)

4.0 PERFORMANCE SPECIFIED SYSTEMS

The BMS is a performance specified system and this specification outlines the requirements to be met by the system.

5.0 SPECIFIC EXCLUSIONS

The following is specifically excluded from the scope of this Performance Specification:-

- Power wiring feeds to main distribution boards
- Main trunking and tray runs outside plantrooms (primary arterial containment)
- The BMS shall reside on the FM data network. IT network sockets shall be provided by others in plant areas to the Specialist's requirements

6.0 INTERFACES AND DEMARCATIONS

The BMS shall be provided as a complete working system serving the Adult and Children's Hospitals and the Laboratory/FM. Allowance shall be made for future extension to other parts of the hospital site.

The BMS supplier shall provide information to other parties for mains power supplies and fire alarm system interfaces, etc.

The BMS shall be integrated with a host Internet Protocol network which will support communication, interaction, data transfer and data retrieval from and between the various engineering systems in the building. The Building Management System shall be fully integrated with this network and shall provide control over the engineering plant and facilities to enable the management of maintenance and energy usage. The BMS shall be connected to the host network via gateways.

The BMS will be provided with Graphical User Interface points which will permit the interrogation of all systems integrated with the host Internet Protocol network down to component level. It is not intended that the BMS will control the system but rather will monitor component status and provide fault alarm indication at the Graphical User Interfacessss.

7.0 APPLICABLE STANDARDS

All elements of the works shall be in accordance with the requirements of current legislation, regulations and industry standards unless otherwise stated.

The Building Management System shall accord with all appropriate Hospital Technical Memoranda, Codes of Practice and relevant British and European Standards listed in all Scottish Health Technical Memoranda and Appendix A.

8.0 DESIGN CRITERIA

External Design Conditions

Winter	-	-6°C sat
Summer	-	26.2°C db 18.5°C wb
For operating theatre plant	-	30°C db 20°C wb
Sizing for refrigeration plant		30°C

8.1 Internal Design Conditions

The internal design criteria for each space including temperature and humidity, ventilation rates, lighting level, noise levels, etc are given on the environmental sheet of the Activity Data Base (ADB) information for each room.

The specialist shall set the automatic control systems to achieve the environmental requirements for each space as defined therein.

8.2 System Operating Conditions

Incoming gas pressure:

200mbar at medium pressure
21mbar at low pressure

Incoming water pressure:

0.7bar minimum

MTHW heating at energy centre:

Flow Temperature: 105°C
Return Temperature: 75°C

LTHW CT heating:

Flow Temperature: 80°C
Return Temperature: 65°C

LTHW VT heating:

Flow Temperature: 75°C
Return Temperature: 70°C

LTHW LVT heating:

Flow Temperature: 60°C
Return Temperature: 50°C

Primary Chilled Water Flow Temperature at energy centre	-	6°C
Primary Chilled Water Return Temperature at energy centre	-	14°C
Secondary Chilled Water Flow Temperature at hospital	-	8°C
Secondary Chilled Water Return Temperature at hospital	-	13°C
Chilled Beam Flow Temperature	-	15°C
Chilled Beam Return Temperature	-	18°C

8.3 Electricity Supply Characteristics

LV power characteristics: 400 / 230 V, 3 phase, 50 Hz. 230 V, 1 phase, 50 Hz.

8.4 Energy and Carbon Target

The project has stringent energy and carbon targets and *the BMS* shall be selected and commissioned to achieve optimum performance.

Energy target: 40GJ/100m^3

Carbon emissions target: 80kg/m^2

9.0 LIAISON

The Specialist Sub-Contractor shall include for liaison with:-

Health and Safety Professionals. As well as the Health and Safety requirements of this specification, the Specialist Sub-Contractor shall include for close liaison with Health and

Safety professionals including the Hospital's Health and Safety Advisors and the CDM Co-ordinator and shall comply with the CDM Regulations and all Health and Safety regulations.

The Contractor. The Specialist Sub-Contractor shall liaise with the Contractor through whom all communications must flow. Drawings and other documentation will be available via the Contractor. The Specialist Sub-Contractor shall include for liaison with members of the Contractor's team with an interest in the planning and administration of the Building Management System.

Other Specialist Sub-Contractors. The Specialist Sub-Contractor shall liaise with other specialist sub-contractors as necessary to ensure that all interfaces between the Building Management System and other systems are allowed for. This shall include but not be limited to:-

- Fire Alarm and Detection specialist
- Security systems specialist
- IT Specialist
- Electrical Network Management System (ENMS) specialist

The Hospital. The Specialist Sub-Contractor shall include for liaison in conjunction with the Contractor with members of the Hospital's team with an interest in the planning and administration of the Building Management System.

The Architect. The Specialist Sub-Contractor shall include for review of the Architect's reflected ceiling plans and wall elevations and shall liaise as necessary with the Architect to assist with the production of these drawings. The Specialist Sub-Contractor shall ensure that the reflected ceiling plans and wall elevations show all control devices and equipment in the correct positions.

The Fire and Risk Engineer. The Specialist Sub-Contractor shall follow the recommendations of the Fire and Risk Engineer in the production of the drawings.

The Mechanical Services Contractor. The Specialist Sub-Contractor shall liaise with the Mechanical Services Contractor to obtain/provide details of:-

- Motor power requirements and characteristics
- Valve/coil pressure drops and limitations

The Electrical Services Contractor. The Specialist Sub-Contractor shall liaise with the Electrical Services Contractor to provide details of:-

- BMS power supply requirements
- Cable tray requirements

Building Control. The Specialist Sub-Contractor shall liaise, with and adhere to, the requirements of the Building Control Officer.

Any other member of the Project and Trust teams concerned with the planning and administration of the project.

10.0 BMS OVERVIEW

The computer-based system shall provide Direct Digital Control (DDC) to control, monitor and provide historic data logs for the relevant equipment and processes. The BMS shall utilise a network of standalone DDC controllers associated with each equipment/plant system. Controllers shall communicate using an open communication protocol in accordance with ISO 16484-5 and CEN TC247 at management and automation levels. Use of open protocols shall also allow the integration of plant manufacturer's bespoke controllers/control strategies where applicable.

~~The BMS shall interface with the existing system(s) within the Estates department and where possible allowing access to view all parameters within the system. This is envisaged to be in the form of a 'proprietary mimicking' package with the existing Trend head end.~~

The Specialist shall allow for an additional P.C front end for administration and programming.

The Graphical User Interface shall connect to network controllers via the Engineering Network.

The Graphical User Interface shall be covered by the 1hr UPS back up for the Engineering Network server. This is a standalone UPS provided by the Specialist.

The BMS front end shall access real time data from the BMS network and have password security and allow users to view and edit all BMS values via user friendly colour graphic displays as well as receive alarms and logged data.

Network controllers shall be located in major plantrooms and key riser locations and connect to a field network of DDC controllers associated with each equipment/plant system.

Each network node shall function as a router and the mesh network shall have a proactive discovery function to constantly search for and remember optimal linkages, providing a diverse routing capability.

The Specialist shall provide a wireless network graphical commissioning and maintenance tool, where network display screens graphically present the mesh network, all the devices in it and their connectivity levels.

The DDC controllers shall also communicate on a 'peer to peer' network level with frequency inverters to allow full bi-directional data transfer to eliminate BMS point duplication and provide more efficient performance, monitoring, alarming and metering.

The BMS shall include the facility to monitor intelligent utilities meters via an industry standard protocol interface (e.g. Bacnet or Modbus), whereby consumption metering information shall be available on the BMS.

The BMS shall generate escalating alarm screens when plant is run under manual control.

Integrated systems information shall be presented in a layered presentation format using standard layouts, symbols and colour schemes agreed with the client. The minimum level of functionality required for the integrated systems is shown in the table below:-

Integrated System	Indication	Graphic Interaction
Fire Detection and Alarm	Addressable fire zone status (normal, alarm, fault). Fire panel fault.	Monitor progress of fire over split screens with alarm history and ongoing mapped events, Isolate, silence, evacuate, test
Smoke Damper Control System	Damper open/closed/fault status. Fully automated complete with reset facility.	View status and alarms.
Smoke clearance systems	System inputs and operating status, alarms.	Monitoring.
Fire Control Interface Points	Fireman's override switch status.	Monitoring
Chillers (including MRI Chillers)	Operating status and efficiency, energy consumption, alarms, temperatures, flow switches etc.	Monitoring
Boilers and Pumping Equipment	Operating status and efficiency, energy consumption, alarms, temperatures, flow switches etc.	Monitoring
Boiler House	Presentation schedule.	
Helipad Fire-fighting Systems	Status (normal, alarm, fault). Fire panel fault.	View status and alarms.
Generators	Operating conditions, alarms Power Output.	Monitoring, link to plant reinstatement and load shedding. Part of ENMS. Critical items to be monitored by BMS
Meters	Metered data.	Monitoring, link to Utilities Management software.
Inverters	Operating status Motor current consumption, power consumption, speed and frequency. Manual override.	Scheduling, speed control, changeover with flying start and link to Utilities Management software.
HV/LV Switchgear	ACB status/tripped Bus Coupler status Power consumption Load profile information Logged data ASCO switch status Fault and alarm conditions UPS/IPS and battery status. Presentation schedule, HV & LV switch gear.	Part of ENMS system which are monitored by BMS.
Intruder Alarm	Common alarm panel fault.	Monitoring.
Nurse Call	System fault per department.	Monitoring.
Medical Gas Alarms	Main plant alarm and fault.	Monitoring.
Sprinklers	System status, alarms and faults	Monitoring.
Gas Fire Extinguishing System	Operating status, alarms and faults	Monitoring.
IPS	Operating Status Alarm/Fault	Monitoring.
Integrated System	Indication	Graphic Interaction
UPS	Operating Status On Battery/Fault	System status monitoring.

LZC Systems (CHP & PV)	Operating status power consumption energy provided	System monitoring.
RO Water	Operating Status Power and water consumption fault	Active mimic of each system front end, monitoring.
Water filtration plant	Operating Status Power and water consumption fault	Active mimic of each system front end, monitoring.
Surgeons Panels	Mimic of panel Indications. Clocks, lighting, IPS/UPS, mains power, generator power, UCV/HVAC status, temperature, humidity, air sampling, medical gas alarms and AGS system indicators.	Active mimic of each surgeon's panel.
Energy Centre Fuel System Leak Detection	Leak detection in fuel tank bunds within energy centre.	Monitoring.
Automated Material Transfer Systems (AGV)	System fault/alarm.	Monitoring.
Pneumatic transfer systems	System zone healthy - fault.	Monitoring.
Lifts	System fault.	Monitoring.
Escalators	System fault.	Monitoring.
ICT Server Rooms	Temperature, plant status, leak detection alarms.	Monitoring.
ICT Hub Rooms	Temperature, plant status, leak detection alarms.	Monitoring.
Decontamination services system	System Monitoring.	Monitoring and recording common fault.
Decontamination tracking system	System Monitoring.	Monitoring and recording common fault.

The integrated control platform shall reflect all system interactions within the graphical environment to display the relevant information on the same graphical display to provide a user friendly and intuitive format together with clear instructions where required.

11.0 BMS EQUIPMENT AND FACILITIES

The BMS equipment shall generally consist of the following: -

- Graphical User Interface Work Station
- Server (sufficient space shall be allowed in the rack for future 'retained estate' servers to the requirements advised by the Board.
- Data Storage
- Portable User Interfaces (Laptops, PDA's, portable keypads etc.)
- Engineering network
- Network Controllers
- DDC Controllers housed in distributed control enclosures
- Motorised Control Valves and Damper Actuators
- Sensors, Switches and other field mounted control & monitoring devices

11.1 Graphical User Interface Work Station

GUIWS PCs shall be provided in the following locations:-

FM Office
Labaratory/FM building
A further PC to be located in agreement with the Board.

The local plant PCs shall only display graphics and plant data relevant to that plant area.

The Graphical User Interface Work Station (GUIWS) shall provide the following facilities:

- Alarm annunciation, management, logging and reporting
- Plant operating status monitoring, logging and reporting
- Environmental conditions monitoring, logging and reporting
- Scheduling, adjustment and configuration.

Alarms shall be categorised depending on their criticality and at least ~~5~~ 3 categories shall be available, with user defined routing and annunciation options for each alarm. Highly critical alarms shall be routed to a 24hour manned position and the BMS shall have the facility to send alarms via SMS text message, email or to portable PDA.

A reports generation facility shall be provided whereby reports may be generated automatically at a scheduled time or triggered by an event. The reporting function shall also allow custom, user-defined report generation.

The BMS shall log energy consumption via the connected utility meters throughout the hospital.

The BMS shall have the facility to export energy data to third party software to demonstrate the energy performance of the building in accordance with stipulated requirements.

Dynamic flow diagrams shall provide an interactive interface and shall be supplied displaying the following features:-

- Each and every connected point, status conditions (running/stopped etc.), analogue values with engineering parameters (ºC, %RH, l/s etc.). Output positions (% open, speed, etc.).
- Monitored values set points etc., shall all be displayed with the use of colour to differentiate between different types of displayed values and different plant status.
- All calculated parameters as dictated by the controls specification (average, highest, lowest etc.)
- Selected optimiser switching times (start, stop)
- Adjustable set points and overrides
- Current sequences in operation
- Energy/efficiency calculations
- Alarm conditions, shown highlighted
- Click boxes to gain text, panels, pre-configured graphs and other displays
- To select pre-configured control actions
- In addition, a general site plan together with building and floor plans to be allowed for each level including roof void, plant areas etc.
- Generally, colour displays shall be supplied on the basis of one per plant, with main and cross indexing/paths to allow movement between the displays in a logical manner. An exit to the head/index page shall be available from each display.

- The correct performance of the displays shall form part of the plant commissioning procedures.
- The displayed values must be constantly refreshed while the graphic flow diagram remains on the screen.
- The Specialist shall include for creating all the graphics for the plant systems and sub-systems within the buildings as defined by the drawings and associated documentation.
- An engineer's utility allowing new displays to be created and changes made to those formatted shall be supplied. The use of this programme shall be considered for ease of use and its operation shall be incorporated in the training process.
- The ability to print screen information at any moment in time, including graphic flow diagram and numeric values, shall be provided.

All graphics shall be agreed in principle with the *Client and Contractor* prior to the production of graphics pages.

The GUIWS shall incorporate full graphics drawing and editing facilities to allow new graphics and changes to the structure of the graphics to be configured by the operator.

Links shall be provided from graphics to the electronic O&M manuals and associated asset register to assist fault finding and ordering of replacement components.

11.2 Server

The server, which is already provided under the lab/FM phase of the project, shall be sized to store and run all necessary proprietary software associated with the connected systems, all necessary software to run the network, data storage for all associated systems, including, energy usage logs, plant usage logs, etc.

11.3 Storage

The storage shall be sized to accommodate copies of all necessary proprietary software associated with the operation of the BMS and all interface systems together with all input data to allow access of system archive information for a period of ~~24 calendar months~~ 53 weeks on a rolling basis. The storage shall be industry standard raid configuration with resilience and automatic redundancy.

Long term storage will be dealt with under the Client's IT system.

Archive information shall include where applicable: energy usage logs, water usage logs, plant usage logs, plant alarm logs, zone temperature logs, zone humidity trend logs, access control databases, etc.

11.4 Portable User Interfaces

In addition to the main graphical user interfaces the following portable devices shall be provided, one laptop and eight PDA's allowing system interrogation from any of the distributed controllers. All graphics shall be dynamic, forming part of a layered structure, which are consistent and provide a logical and intuitive navigation facility of the building's systems and show the following as a minimum: -

- HVAC plant temperatures, set points and status conditions.
- Ventilation System status

- Valve and damper control signal positions.
- Fire Safety System status
- Electrical System status
- Filter status
- Metered data (via ERM system)
- Building plans
- Integrated systems information and facilities as previously described.

Local interrogation and adjustment shall be carried out by portable user interfaces. Wireless connection shall be provided in the main plantroom areas or otherwise via data connection at the local DDC controller or controls enclosure. Local adjustment and overrides shall be notified and logged at the GUIWS. The BMS shall be designed generally to prevent unauthorized tampering and cases of manual override causing excess energy consumption.

11.5 Network Controllers

Network controllers shall be as described in the overview above and shall be located at key locations throughout the hospital.

11.6 DDC Controllers in Distributed Control Enclosures

DDC controllers shall carry out the control and monitoring of plant and equipment as well as local metering and logging functions. The controllers shall be housed in control enclosures in a distributed configuration to suit the staged delivery and the offsite fabrication and testing of the plant systems served. This shall comprise for example one enclosure per AHU and so on.

Each enclosure shall have a panel live and common fault indication lamps and local reset pushbutton. DDC Controllers (with the exception of terminal control and monitoring only) shall incorporate ~~three position~~ manual override switches to allow selection of On, Off or Auto for each motor drive. These switches shall form an integral part of the controller and provide software feedback to the BMS.

11.7 Automatic Monitoring and Targeting (AMT)

This is part of the ERM system.

The ERM system shall be capable of exporting data to the Board's AMT system which is presently located within the site Clock Tower. The BMS software script shall be provided to ensure that all energy usage figures required for the AMT shall be available for use in the system.

11.8 Power Autonomy and Emergency System Monitoring

The BMS monitors all equipment and it is imperative that the information gathered is retained and is available in the event of loss of mains power.

All outstations, communications and network equipment shall be equipped with battery or UPS backup to provide 30 minute autonomy. This is provided by the Specialist as part of the BMS installation.

The main GUIWS and its associated accessories, screens, and printer shall be equipped with a UPS backup to provide 30 minute autonomy. This is provided by the Specialist as part of the BMS installation.

The Specialist shall configure all elements of the system to allow monitoring of the emergency systems during all failure scenarios and this facility shall be demonstrated during the system Integration Testing.

The Specialist shall carry out any modifications highlighted during the IST to ensure that the installed system provides full emergency system monitoring.

11.9 BMS System Control Strategies

The general design principal for this project is to provide local decentralized control panels to be purpose designed and integral with the ‘stand-alone’ plant and equipment. Generally, each major power consumer, e.g. Pumps, Fans etc. shall be supplied with their dedicated ‘intelligent’ inverter drive motors, to be used as the means of control and for direct interrogation of status, fault levels and energy consumption. These drives shall be powered by cables fed directly from section boards located in the respective plant rooms. All information abstracted from the invertors and other controllers shall be accessible via the BMS.

11.10 Interactive Support and Utilities Management

11.10.1 Condition Based Monitoring

The BMS shall be capable of being linked to a condition based monitoring package capable of the following: -

- 24 hour alarm analysis
- Repeated alarm analysis
- Analysis of duration from alarm acknowledgement to clearance
- Analysis of unacknowledged alarm duration
- Hardware point alarm analysis
- Analysis of an alarm failure pattern
- Analysis of control loop performance and usage
- Analysis of optimiser performance at occupancy time
- Analysis of terminal & BMS start-up and shut down times
- Analysis of user access to BMS
- Analysis of modified points and manual overrides on a per user basis
- Sensor calibration and avoidance of drift

The system shall automatically produce reports on the system performance in a user friendly, easily understood colour graphical format.

The site shall be capable of being linked to permanently manned 24/7 remote support centre.

11.10.2 Interactive Utilities Management

The system shall be capable of exporting information to a smart utilities management software, which has real time links to the utilities provider's billing system and can provide comparative analysis and profiling to check tariffs and charging with BMS metered data.

Any invoice discrepancies can be highlighted and recovered by the client.

Profile analysis functions can identify any abnormalities in energy consumption and report and alarm accordingly. Profiling can be carried out by department and areas and by system as well as on a whole building basis.

Links to plant operating logs and alarms can be provided to assist investigation.

Load shaping reports can be provided by department and areas, identifying peak demands, CO2 and carbon consumption.

11.10.3 Engineering Network

The network shall comprise a series of hubs, provided to suit the building layout and wiring topology generally located in plant areas, linked to a core switch and server located in the ~~FM Office~~ main server rooms.

Each hub shall comprise a switch which shall communicate with local field devices via Category 6A copper cable infrastructure and shall communicate with other hubs and the server via multi pair single mode blown fibres. The Specialist shall provide a fully functioning network, which shall operate entirely on its own or shall seamlessly form part of the wider hospital network if so required. In any case the network shall be fully equipped to enable access from a remote PC via the hospital IT network and via the World Wide Web in accordance with the client's own IT policy.

11.10.4 Alarm Management

Alarms generated by any outstation shall be processed by a main operator's terminal to sort into at least 12 types. Each type may have any combination of the following parameters:-

- Alarm general/critical, outstation group, point label, location
- Transmission destinations with operator time schedule
- Store associated plant parameters on initiation
- Select print action
- Select audible alarm
- Log to alarm file
- Password level for acknowledgement

Alarm Inhibition

When an alarm condition is displayed it shall be independent of any other possible alarm or cause that may initiate a string of further alarms, e.g. boiler lock-out shall not initiate flow and return water temperature alarms and space temperature alarms.

Where such circumstances occur, the software shall inhibit any such sequential alarms. The Specialist shall co-ordinate such sequences in his detailed design and submit details sufficient to demonstrate compliance with requirements. The initial alarm of such a chain

shall indicate on the GUIWS which other alarm points are covered in the particular sequence. The programme shall inhibit dialogue alarms for a period of time after start-up of associated plant to prevent spurious alarms.

The programme shall also inhibit alarms when the associated plant is switched off by the BMS.

The programme shall inhibit alarms during the start-up of each plant item. This delay time period shall be for a maximum of 10 minutes to enable the building service installation to reach a stable condition.

Critical Alarm

Urgent Operator action required. Sounds an audible alarm in the FM Office, which can be manually muted. Is indicated on the GUIWS as a message with the associated graphics schematic and recorded on the printer. GUIWS display is not eliminated until alarm acknowledged.

These alarms shall include, but not be limited to, the following:-

- Chiller failure
- Cooling systems pressurisation low/high pressure
- Boiler failure
- Heating systems pressurisation low/high pressure
- All air handling plant fans, unless provided with stand-by fans or motors
- All supply fans, unless provided with stand-by fans or motors
- All extract fans, unless provided with stand-by motors
- All pumps, unless provided with stand-by motors
- All electrical monitoring points
- All safety circuit monitoring points

Refer to the relevant Descriptions of Operation in subsequent specification volumes for further details.

11.11 Building Log Book

The Specialist shall provide a simple overview of the BMS system for inclusion in the Building Log Book to meet the requirements of the Scottish Building Regulations Non Domestic Technical Handbook.

The Specialist shall liaise with the Contractor, who is preparing the overall document, to provide the documentation in a compatible format.

11.12 Site User Training

The Specialist shall supply the following training for the FM engineering staff:-

General Engineering Staff

Off-site prior to handover; non-specific system structure, components and applications. Operation of user terminals, keyboards, use of displays, overrides, passwords.

On-site; specific system structure, outstations locations, control strategy overviews. Operation of user terminals, adjustments, trend graphs and alarm handling. Other networked components.

Engineers & Selected Staff

Off-site prior to handover; complete training courses at the Manufacturer's works, instruction in the following; all as above but also including configuration of outstation and user terminals, software, Windows/DOS file structures, password and engineering utilities, fault-finding, tuning and maintenance.

On-site, while the Board's Estate engineers shall attend the acceptance demonstrations, the Specialist shall instruct him in the specific application of the system, the structure and the control strategies adopted to meet the specification.

11.13 Drawings

As part of the development of the design the Specialist shall prepare general arrangement drawings of the Building Management and Automatic Controls Systems based on the Architect's base drawings and coordinated with other services and building elements. These drawings shall be drawn in Autocad (.dwg) with the model files drawn at 1:1 scale. One hard copy of each level together with a CD with all electronic files (PDF and .dwg) must be returned with the tender return. A proposed drawing list shall be submitted with the tender.

The drawings shall indicate as a minimum:-

- Sensor locations
- Motor Control Centre locations and sizes
- Power supply requirements
- Cable containment requirements
- Metering strategy/meter tree
- Graphics proposals
- Controls strategy

12.0 GENERAL SYSTEM REQUIREMENTS

The description of the operating requirements of each individual system is given in Volumes 2 to 6, which shall be read in conjunction with the contents of this volume.

12.1 Systems Operation

The six volumes that make up this specification shall be read in conjunction with the following:-

Schedules of Equipment
Engineering Systems Schematics
Schedules of Monitoring and Control Functions for each system type
System reference numbers

The number, size and type of wiring required for the automatic controls and the Building Management System shall be installed in accordance with the Specialist's requirements and the relevant electrical specification.

12.2 Smoke Damper System Operation

For details of smoke/fire damper operation refer to Volume 5 Ventilation Systems.

12.3 Power Failure

When a power failure occurs all plant shall be disabled.

All plant is controlled from the BMS under emergency or return of mains normal supply.

As the emergency standby generators are run up enabling signals shall be given to the BMS from the Electrical Network Management System (ENMS) to start/stop the sequence of plant start-up. A number of signals, relating to the capacity steps of generators shall determine which plants are allowed to run to limit the load on the generators. Refer to the Electrical Load Priority Schedule, document reference ZBP-XX-XX-SH-600-250 for details of sequenced starting of plant.

The timing for the starting of plants is to be sequenced in order not to overload the generators. The BMS shall confirm that power is available to the plantroom area before the re-energising sequence is initiated for those particular plants.

In the event that one or more of the generators fails during emergency power operation the ENMS shall signal the BMS to stop the plant generally in the reverse order to the starting sequence.

The information provided above and in the schedule shall be subject to final agreement. Sequence of starting shall be agreed with the client prior to the commissioning stage.

As a general overview the following shall be noted:

- Upon power failure and power restoration either from the mains or emergency standby generators all cooling valves shall be driven closed as soon as power is available until the individual plant is energised by the ENMS sequence. This will avoid hunting of the circulating pumps until a stable operating condition is achieved.
- Whilst the plants may receive an enable signal from the ENMS the restart procedure associated with safety controls, etc may extend the actual restart period. The BMS shall take cognisance of this when ramping up the plants and, for instance, hold fan inverters at a low speed to limit power draw.
- No ventilation plants shall be enabled by the BMS until the boiler plant is energised and operating at a stable condition. As the CHP will be disabled under standby generator conditions it may be necessary for additional boilers to be brought up to operating temperature to match the heating load.
- The two IT Server Rooms cooling supplies have a high priority. It is proposed that the primary chilled water mains will act as a thermal store until the first chiller can be enabled. This will require at least one ‘A’ and one ‘B’ primary circulation pump to be enabled at a very early point in the restart sequence. All major cooling plate exchanger valves elsewhere on the primary cooling system to be driven closed so that maximum capacity is available for IT cooling.
- Under emergency standby generator conditions the absorption chiller, dry air coolers and associated pumping equipment shall be disabled as this only operates in association with the CHP system.
- In the event of standby generator failure and the need to shed one or more of the chillers all secondary chilled water pumps shall be stopped immediately to remove

load from the system. Once the status of the emergency standby generator system has been established, chillers and secondary pumps will revert back to normal sequence control of the ENMS to suit the generator capacity available.

12.4 Individual User/Occupant Controls

Where individual room control of temperature is provided the user shall have the ability to adjust the temperature by a maximum of 2^{o}C around the set-point as set at the central supervisor. The set-point adjuster shall not indicate temperature but simply have +/- and direction arrow.

12.5 Control Valve Selection

Where MTHW, LTHW and chilled water systems utilise variable volume control systems they shall have differential pressure control valves (DPV) installed as indicated on the drawings, and supplied and installed by the Mechanical Contractor.

The purpose of the DPV is to automatically compensate for the rise in differential pressure across the circuit that it services, as the circuit flow rate falls under the dictate of the 2-port control valve(s), and vice versa.

DPVs used in conjunction with motorised control valves and TRVs will be arranged to maintain a constant differential pressure across the circuit.

The Specialist shall, in conjunction with the Mechanical Contractor, liaise with the DPV supplier to ensure the correct motorised control valve selections are made.

Similarly, the Specialist shall also liaise with the pump supplier, to ensure that the pump speed control system is totally compatible between the 3 elements, i.e. DPV, motorised/thermostatic valves and pump characteristic and control.

It shall be noted that the minimum pressure drop across combination of control valve and coil to be 25kPa to suit operation of Differential Pressure Control Valve. The maximum operating pressure of the control valve, coil and interconnecting pipework/accessories shall also be reviewed against the selection of the DPV.

The air handling plant in many instances has a design reserve capacity of 25% included for future flexibility. In order to avoid poor control operation from oversizing of control valves the valves for these plants shall be selected at the current design operating capacity. The Schedule of Air Handling Units identifies the flow rate that the control valve shall be selected to under this initial installation. Pipework connecting the control valve shall have the future capacity included.

12.6 Links to Laboratory Building, Energy Centre and Site Retained Estate

The BMS systems in the Laboratory and Energy Centre shall be fully integrated into the Adult and Children's' Hospital system with a fully open interface at the FM Office Front End PC.

Links shall be provided to the existing site BMS to give a common alarm only as it is unlikely that the systems will be compatible. The Specialist shall investigate the operation of the existing system(s) and prepare a report to include identifying whether exchange of real time data can take place between the systems.

12.7 Meters

The BMS shall be linked to the various system meters and equipment drives to log and indicate energy usage throughout the Hospital and Energy Centre buildings. Refer to Volume 6 of the specification for further details.

The metering graphics shall be set up in parent-child configuration to map energy use from department layouts through building sectors to whole buildings and energy centre.

12.8 System Descriptions, Primary Measurement and Control Schedules

The descriptions and schedules that follow in Volumes 2 to 6 constitute the makeup of key points for the BMS monitoring and control, and where applicable must be used in conjunction with the relevant drawings and the detailed general description of operation of the Mechanical, Electrical and Public Health services.

12.9 Key to Item Identification Letters

AFS	Air Flow Switch
AHU	Air Handling Unit
BO	Boiler/Burner
CAL	Calorifier
CH	Chiller
CT	Constant Temperature
CV	Control Valve
DATD	Direct Acting Thermostat Device
DPS	Differential Pressure Switch
EF	Extract Fan
FS	Flow Switch
FTS	Flue Temperature Sensor
HS	Humidity Sensor
HU	Humidifier
HX	Heat Exchanger
LS	Level Switch
M	Meter (All Services)
MDA	Motorised Damper Actuator
MV	Motorised Valve
PIR	Passive Infra Red (Detector)
PR	Pressurisation Unit
PU	Pump
SDP	Pressure Detector
SF	Supply Air Fan
TA	Tank
TS	Temperature Sensor
VT	Variable Temperature

12.10 Wiring Requirements for Mechanical Services

The Specialist shall supply and install the power wiring from the primary plantroom HVAC boards, provided by others, to the local secondary panel, provided by the Specialist, then onto individual items of plant.

The minimum cable size for power supplies shall be 2.5mm^2

The incoming sub-mains and the primary plantroom HVAC board shall be carried out by the Electrical Services Contractor.

The Specialist shall co-ordinate the plant power wiring with all other trades within the plantrooms.

Y41 BUILDING MONITORING AND MANAGEMENT SYSTEMS

GENERAL

110 ELECTRICITY METERING For Hospital and Energy Centre.
- Number and location of meters: Refer to electrical services schematic diagrams and BMS Specification - Volume 6.
- Monitoring period: Submit proposals.
- Reporting: Submit design proposals.

120 FUEL METERING For Hospital and Energy Centre.
- Fuel: Gas & Oil.
- Number and location of meters: Refer to mechanical services schematic diagrams and BMS Specification - Volume 6.
- Monitoring period: Submit proposals.
- Reporting: Submit design proposals.

130 WATER METERING For Hospital and Energy Centre.
- Number and location of meters: Refer to public health services schematic diagrams and BMS specification - Volume 6.
- Monitoring period: Submit proposals.
- Reporting: Submit design proposals.

130A HEAT METERING For Hospital and Energy Centre.
- Number and location of meters: Refer to mechanical services schematic diagrams and BMS specification - Volume 6.
- Monitoring period: Submit proposals.
- Reporting: Submit design proposals.

SYSTEM PERFORMANCE

210 DESIGN
- Design: Complete the design of the building monitoring and management system.
- Standards:
  - Communications network: To BS EN 50174-1.
  - Communications protocol: To BS EN ISO 16484-5.
  - Documentation of plant/ application specific functions: To BS EN ISO 16484-3.
- Proposals: Submit drawings, technical information, calculations and manufacturers' literature.

PRODUCTS

310 ENCLOSURE Integral plant control panels or standalone Motor Control Centres
- Manufacturer: Contractor's choice.
  - Product reference: Contractor's choice.
- Standard: To BS EN 62208.
- Ingress protection to BS EN 60529: IP54.
- Mechanical protection to BS EN 62262: IK05.

- Finish: Manufacturer's standard.
  - Colour: Manufacturer's standard.
- Method of fixing: Contractor's choice.
- Incoming cabling access: Top entry.
- Outgoing cabling access: Top entry.
- Locking mechanism: Cylinder locks with a standard key type.
- Identification of cable terminations: Label with circuit reference, with push-on plastics markers.
- Internal wiring: Segregate power and signal cabling. Contain within slotted trunking.
  - Wiring capacity (maximum): 45% full by volume.
- Accessories: None.

440 FIELD CONTROLLERS Located in Motor Control Centres or integral plant enclosures

- Standard: To BSRIA AG 9/2001.
- Manufacturer: Submit proposals.
  - Product reference: Contractor's choice.
- Integral enclosure:
  - Ingress protection to BS EN 60529: IP54.
- Mounting: Suitable for DIN rail mounting.
- Network communications options: BACnet MS/TP.
- Port arrangement: Manufacturer's standard.
- Controller inputs, sensors and devices: Submit proposals.
- Controller outputs, actuators and switching devices: Submit proposals.
- Internal power backup:
  - Type: Submit proposals.
  - Battery functions: Submit proposals.
- User interfaces: Access password protected programmable LCD with back light and membrane keypad.
- Accessories: None.

445A DESKTOP PC Locations as required by the client

- Manufacturer: Contractor's choice.
  - Product reference: Contractor's choice.
- Processor:
  - Clock speed (CPU): Contractor's choice.
  - Clock speed (front side bus): Contractor's choice.
  - L2 cache size: Contractor's choice.
- Operating system: Contractor's choice.
- RAM: Contractor's choice.
- Hard drive: Contractor's choice.
- Optical drive: Contractor's choice.
- Graphics card:
  - Memory: Contractor's choice.
  - Resolution: Contractor's choice.
- Network card Contractor's choice.
- I/O ports: Contractor's choice.

450 KEYBOARDS User interface

- Standard: To BS EN ISO 9241-4, -400 or -410.
- Type: USB.
- Manufacturer: Contractor's choice.

- Product reference: Contractor's choice.
- Features: QWERTY with full upper/ lower case ASCII key-set and numeric keys.

460 MONITORS User interface
- Standard: To BS EN ISO 13406-2.
- Type: LCD.
- Manufacturer: Contractor's choice.
  - Product reference: Contractor's choice.
- Size (nominal diagonal): Submit proposals.
- Resolution: 1680 x 1050.
- Response time: 5 ms.
- Display Screen: Anti-glare coated.
- Interfaces: One VGA 15 pin HD D-Sub (HD-15)
- Display positions: Adjustable height, swivel, and tilt.
- Additional features: None

510 PRINTERS User interface
- Type: Submit proposals.
- Manufacturer: Contractor's choice.
  - Product reference: Contractor's choice.

EXECUTION

620 INSTALLATION OF BUILDING MONITORING AND MANAGEMENT SYSTEMS
- General: Install in accordance with BSRIA AG 9/2001.

625 INSTALLATION OF FIELD CONTROLLERS
- Clearance (minimum):
  - Front access: 1000 mm in front of field controller.
  - Mounting height: 1000 mm from finished floor level.
- Fixing equipment: Fix on DIN rail mounted within enclosure.

627 INSTALLATION OF CABLES
- Timing: Do not start internal cabling until building enclosure provides permanently dry conditions.
- Cables: Install in one uninterrupted run.
- Arrangement: Position vertically and horizontally in line with equipment served, and parallel with building lines. Provide drip loop to prevent water entering equipment.
- Orientation: Dress cables flat, free from twists, kinks and strain.
- Cable pulling: Do not overstress.
  - Installation method: Submit proposals.
- Jointing: At equipment and terminal fittings only.
- Cables routes generally: To follow arterial containments routes as indicated on drawings.
- Cables from other systems: Segregate and cross at right angles.
  - Distance from steam and low temperature hot water systems running parallel: 500 mm minimum.
- Terminations: Support cable within 150 mm of termination.
- Balanced twisted-pair cabling:
  - Maximum untwist at terminations: 12 mm.

630 INSTALLATION OF SENSORS

- General: Install in accordance with Building Controls Group (BCG) Control sensor installation.

COMPLETION

910 INSPECTION AND TESTING
- Standard: To BS 7671.
- Notice before commencing tests (minimum): Submit proposals.
- Certificates: Submit.
  - Number of copies: Submit proposals.
- Test equipment identity: Record on test certificates.
- Certificates of calibration: Submit for each test instrument.
- Control panel test certificates: Submit.
  - Number of copies: Submit proposals.

915 COMMISSIONING
- General: Commission in accordance with BSRIA AG9/2001 and BCIA System start up and commissioning guide. Achieve the requirement to obtain BREEAM Credits (Man 1).

920 SPARES
- Spare fuses: Mount within each control panel.
  - Number: Submit proposals.
- Spare devices: Supply.
  - Number: Submit proposals.
- Spare lamps: Mount within control panel.
  - Number: Submit proposals.

925 KEYS
- Field controller enclosure door keys: Supply.
  - Number: 3 of each type used.

930 DOCUMENTATION
- Operation and maintenance instructions: Submit.
- Record drawings: Submit.

Electrical Installations

All electrical services associated with the BMS shall be installed in accordance with the Common Electrical Clauses Specification, reference ZBP-XX-XX-SP-532-247.

APPENDIX A

SUPPORTING DOCUMENTATION

In order to carry out the design, the Sub-Contractor shall require access at least to the documentation listed below.

The following information is, or shall be, available from the Contractor:-

1. Standard General Conditions and Preliminary Clauses
2. Wallace Whittle specification and drawings for Building Management System in Laboratory/FM building
3. WSP: Hospital Fire Strategy Report.
4. Nightingale Associates: Fire Strategy Drawings
5. Nightingale Associates: Building Plans
6. Nightingale Associates: Building Sections
7. Nightingale Associates: Wall Elevations
8. ZBP: Schematic diagrams (Refer to individual system descriptions).
9. *ZBP: Services general arrangement layouts*
10. *ZBP: Environmental Strategy Drawings (526 series)*
11. ZBP: Mechanical Systems Specifications.
12. ZBP: Fire Detection and Alarm systems.
13. ZBP: Common Electrical Clauses (ZBP-XX-XX-SP-532-247)
14. ZBP: Fire Fighting Installations Performance Specification (Sprinklers).
15. Schindler: (Lift supplier): Details of Lifts.

Drawings for other specialist systems shall be developed by other Sub-Contractors during the detailed design period and shall be made available by the Contractor when complete.

CONTENTS

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDREN'S HOSPITAL AND ENERGY CENTRE

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDREN'S HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 26 MAY 2013

1.0 EXECUTIVE SUMMARY: ADULT & CHILDREN'S HOSPITAL

Visits to the site during May 2013 indicated that the construction and procedures are progressing in a satisfactory manner in accordance with the Employer's Requirements.

Throughout, the standard and quality of the workmanship is generally good and operations are being carried out in an acceptable manner.

Together with Brookfield we carried out quality and compliance inspections on Level 1 Area 1-525, 1-528 and 1-526. The areas inspected were to a good standard and the defects captured by Brookfield were generally of a minor nature. We did however identify a number of defects which Brookfield recorded on to their IDMS system. These included defective opening and closing turn handles which operate the internal blinds in area1-528. We raised a Defect for this to cover the entire site. Following a meeting with Brookfield and the Manufacturer it was agreed that the operational problems would be addressed during June.

Brookfield continues to undertake their Quality Assurance systems on site with inspection and checklist documentation available for the ongoing construction activities. Over the period, we have closely liaised with Brookfield and witnessed 85 point check to the partition on Level 0 Area 529, Level 1 Area 537, Level 2 area 522b and the Children's Hospital Level 3 Area 506.

A partition checked on Level 0 had a few failures which were rectified. Brookfield and Astins also opened additional partitions in two other rooms and these had no failures.

An 85 point check was carried out to a partition formed on Level 1 Area 537. The first floor inspection to the partition between room OPD1-084 and OPD1-182 identified a number of major failures including gaps in the insulation. Insulation was also dislodged, missing, had insufficient fixings and fixings too close to the edge of the boards. As a result of this inspection two additional areas were opened up in rooms OPD1-077 and OPD1-101. In both locations insulation was missing and dislodged. Brookfield instructed Astins to open up additional partitions in the area, record and photograph these and carry out any necessary work. This was carried out and remedial measures taken to ensure that the partitions complied with the specification.

A partition checked on Level 2 area 522b and the Children's Hospital Level 3 Area 506 had no failures.

We witnessed below ground drainage tests in Zone F Pour 4/5 and Zone C Pour 3 and Zone C Pour 3. There were no issues resulting from these tests.

Civil and structural works continue to be to a generally high quality standard.

In respect of the piling records on ZUTEC, replacement of the current construction drawings by 'as built' drawings is still awaited.

Piling has commenced in the car park area and from a quality perspective appears to be progressing satisfactorily.

SUPERVISOR'S REPORT NO. 26 MAY 2013

All floors to the Atrium Bridge have now been cast and deflection checks to date have been further examined in respect of datum issues. A final report is still awaited from Brookfield in respect to this. Meanwhile the steelwork subcontractor has been carrying out remedial work to the intumescent paintwork and side cladding installation has commenced. An independent testing organisation is carrying out checks on this paintwork and their report/certificate is awaited. This is now of more significance as damage to intumescent paintwork was noticed during the period, as well as cracks in the paintwork at some web/flange locations.

Concrete slab work to the ACH has again continued apace during the period. Floor slabs are essentially completed on the 12th floor on both the SE and SW arms (Zones G and D). Work is now at the 11th floor on the NE and NW arms (Zones J and F respectively). On the Children's Hospital section the final floor slabs have been completed in Zone C. All of the work generally appears to be of good quality throughout. Ground floor slab pouring is now also substantially completed. Sub-slab final drainage tests in Zones C and F were carried out successfully.

Steelwork erection has continued to the roof of the Children's Hospital in Zones A and B. Communications have been raised with Brookfield and are listed on the following page.

Steelwork erection has also commenced on the roof of the SE arm (Zone G). Some sections of galvanised steelwork were delivered well out of shape and straightness tolerance and were being returned to the subcontractor for appropriate attention.

External blockwork has continued in Zones D and G on the south and east faces, and from a structural perspective generally appears to be satisfactory.

We have carried out general inspections of the M&E installations during the period and have conducted witness testing of HV Electrical systems and pipework water sample testing in the main A&C Hospital. The general standard of workmanship is good and the installations subject to test appear to be performing to the correct standard.

The sample AHU21 in plant room PR21 was inspected and comments provided for action by Mercury. It was agreed that this unit will form the standard for all other AHU's, therefore any issues are to be fully closed out to ensure quality installation.

The M&E installation quality is remaining at a good standard and we are satisfied that these are being installed to a compliant standard. It should however be noted that there may be some instances where AHU's may not necessarily meet SHTM 03-01 and have asked clarifi9cation on these points.

The M&E installations are progressing on all levels up to Level 8 and range from first fix module installation to almost completed areas.

The installations in the Energy Centre are well advanced with the advanced A-side systems commissioned and handed over. Commissioning programmes for the B Side have been presented and significant commissioning will be taking place from June to December 2013.

NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDREN'S HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 26 MAY 2013

We are continuing to work with Brookfield during our inspections highlighting any items that have raised concern. Items identified in this manner are generally being addressed by the site team in advance of any defect notice being raised.

With respect to the potential access issues to high level sprinkler heads raised in Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 75. Brookfield is reviewing potential access issues, in an effort to find a solution but this has not been presented for review.

In general terms we are satisfied that the installations continue to be installed to a compliant standard, and are of a good quality. However we have noted that certain items this month that have raised concern. These have been raised with the Contractor as follows:-

Supervisor's Communication General Matters / Other Instructions No 114, 115, 116, 117, 118, 119, 120, 121, 122, 123 and 124 were issued in May.

- Seeking an explanation of the rational and design philosophy and proposals to achieve 25% spare capacity.
- Requested evidence that all Atrium steelwork fire protection steelwork has been protected in accordance with the specifications. Also to include for areas hidden behind cladding panels and provide dry film thickness results.
- Seeking assurances that ground floor storm drainage has sufficient access panels to comply with Building Standards/Building Control requirements. Seeking confirmation that the 50mm above ground waste drainage connecting to 100mm is also compliant.
- Seeking confirmation that the lack of concrete foundations below 2 sets of 'goal post' elements will be addressed with no impact on the room/space requirements.
- Poorly positioned concrete bases below 3 other columns.
- Requesting proposals to address paint damage to steelwork.
- Seeking floor flatness and levelness tolerances for the Atrium Bridge.
- Seeking design philosophy in relation to the air handling unit/compliance with DW144.
- Seeking confirmation that the CDM Coordinator has considered trip hazard from low level pipes.
- Seeking confirm when remedial measures have been completed in relation to the damaged duct.

Supervisor's Notification of Defects (42.2) No 50, 51, 52, 53, 54, 55 and 56 were issued during May.

- Seeking confirmation of remedial measures to address screw fixings puncturing lead panels.
- Screw fixings not in accordance with NBS specifications.
- Seeking confirmation that remedial works were carried out to damaged roof membrane.
- Seeking confirmation of measures to address blocked access hatches.
- Seeking confirmation of measures to address internal blinds which are difficult to open/close.

- Seeking dry film thickness results and confirmation of remedial measures to damaged intumescent paint.
- Seeking confirmation of measures to address blocked access hatch.

We continue to be assisted by the site teams and the NHS Project Team who produce an internal weekly report which assists us in resolving various construction, mechanical, electrical and quality issues. We continue to close out our Supervisor's Notifications and Defects when we have received satisfactory responses.

2.0 DESIGN COMPLIANCE CHECK

Currently nothing to report.

3.0 PROCEDURES REVIEW

3.1 Contractor's QA Procedures

Brookfield and their subcontractors have continued with their QA and checking and inspection procedures during this period. We are in discussion and liaison with Brookfield's Quality Manager on QA matters and we undertake regular reviews of their QA documentation.

Together with Brookfield we carried out quality and compliance inspections on Level 1 Area 1-525, 1-528 and 1-526. The areas inspected were to a good standard and the defects captured by Brookfield were generally of a minor nature. We did however identify a number of defects which Brookfield recorded on to their IDMS system. These included defective opening and closing turn handles to the internal blinds in area1-528. We raised a Communication for this to cover the entire site.

We had concerns that the insulation removed and disturbed at high level was not being managed through the QA system. Following discussions with Brookfield they have confirmed that they will review the sign off check sheets to ensure that insulation is included as a hold point of the high level installation. We are still awaiting confirmation that they have reviewed their QA documentation.

As a result of inspections on site we have brought to Brookfield's attention a few snags and these have been loaded onto their IDMS system to be resolved as part of their snagging rectification process.

An 85 point check was carried out to a partition formed on Level 0 Area 529. The ground floor inspection in room AAW-116 identified a number of major failures including gaps in the insulation, insulation dislodged, insufficient fixings and fixings too close to the edge of the boards. As a result of this inspection two more 85 point checks were carried out in rooms AAW-123 and room AAW-133. There were no major problems found in these rooms and the insulation was intact. However there was a doubt about the need for back plates on the first skin.

An 85 point check was carried out to a partition formed on Level 1 Area 537. The first floor inspection to the partition between room OPD1-084 and OPD1-182 identified a number of major failures including gaps in the insulation, insulation dislodged, missing insulation insufficient fixings and fixings too close to the edge of the boards. As a result of this inspection two additional areas were opened up in rooms OPD1-077 and OPD1-101. In both locations insulation was missing and dislodged. See photographs below showing the faults found.

Room OPD1-101. Patress not fixed behind board and insulation missing.

Room OPD1-077. Insulation missing Gaps between insulation at low level.

Insulation missing behind pattress

Insulation set aside either side of conduit drops.

Insulation short.

As a result of this inspection two additional areas were opened up in rooms OPD1-077 and OPD1-101. In both locations insulation was missing and dislodged. Brookfield instructed Astins to open up additional partitions in the area, record and photograph these and carry out any necessary work. This was carried out and remedial measures taken to ensure that the partitions complied with the specification

An 85 point check was carried out to a partition lead lined one side and boarded the other between room THE 125 and room THE 128 in area 522b Level **2. QA checks**

had been carried out prior to the partition being completed and remedial action taken. No faults were found.

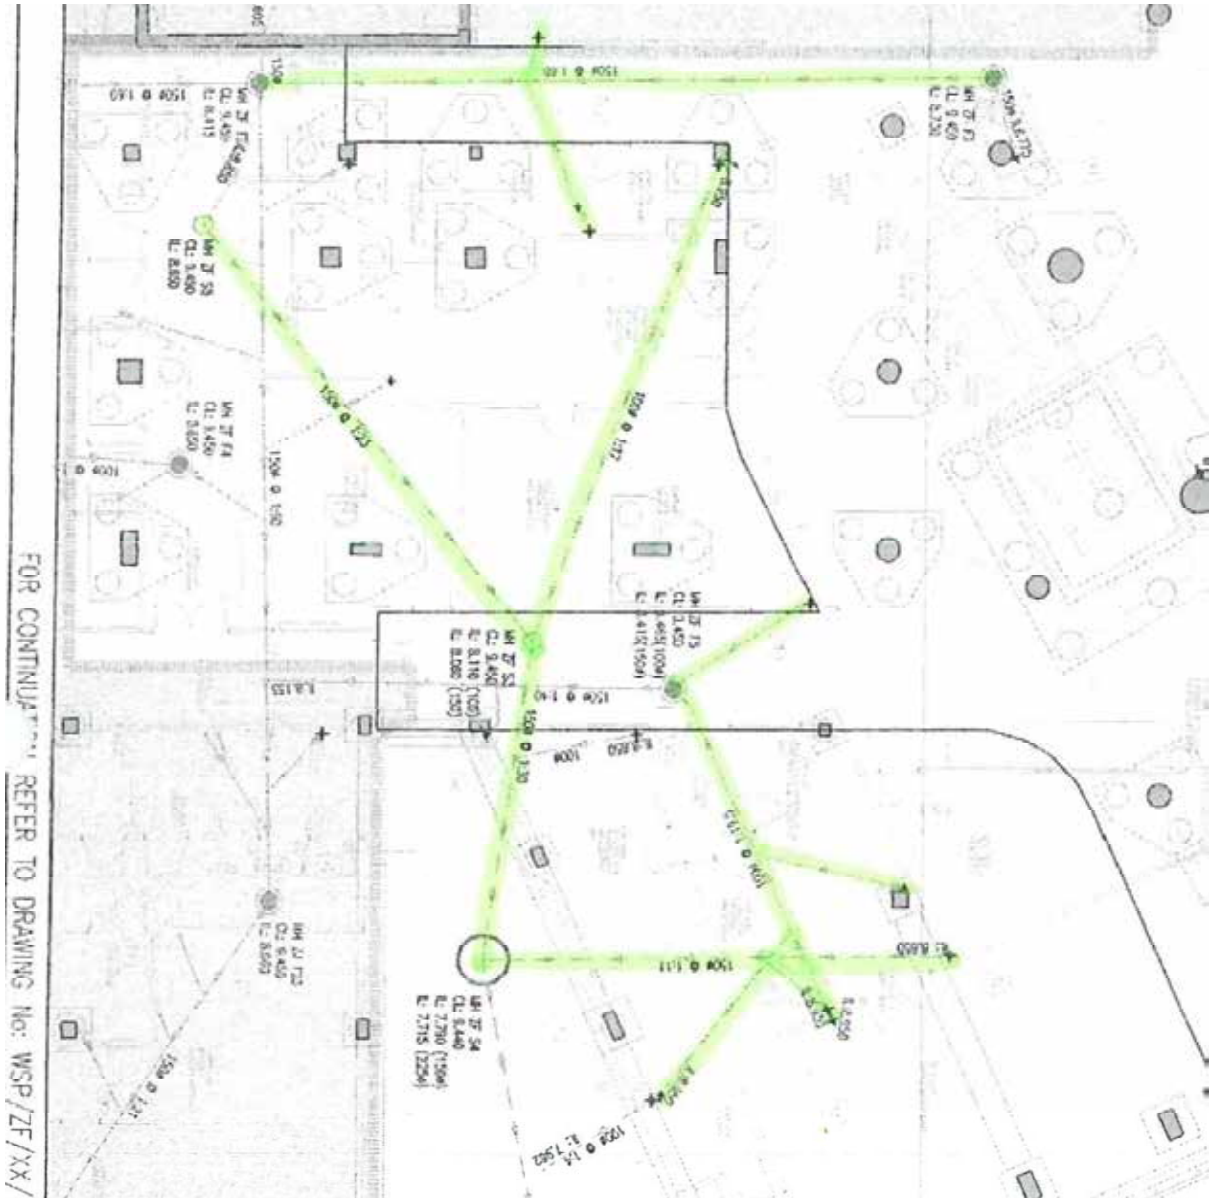
A partition checked in the Children's Hospital Level 3 Area 3-xxx had no failures.

We reviewed Brookfield's NCR Tracker and noted the issues raised by the Package Managers. We will continue to review the NCR's especially those issues in relation to the quality of the blockwork and pointing on the south and east elevations. We are also monitoring the issue in relation to water between the glass of the Structal Panels.

We raised a couple of issues with Brookfield concerning missing putty pads in level 1-510 and potential flanking issues in relation to the construction of partitions on Levels 2 and 3. These two issues have been raised as NCR's by Brookfield.

We witnessed below ground drainage tests in Zone F Pour 4/5 and Zone C Pour 3 and Zone C Pour 3. There were no issues resulting from these tests.

The next page shows an area of below ground drainage witnessed.



Zone F Pour 4/5 Final Air Test

INSPECTION OF PERMAQUIK DEPTH

Contract name: NSGH	Contract No: 1204	Drawing No:240-180 (REV C)
CONTRACTOR: PRATER LTD	SUBCONTRACTOR: JIMMY HAND	PRATER
Name of roof/ wall system: Permaquik hotmelt		

REFERENCE (see attached drawing)	DEPTH	CORRECT DEPTH	DATE	CHECKED BY	AREA OF INSPECTION
1	7mm	7-10mm	13/3/13	FRANKY MARTIN	Level 2 Zone J
2	7mm	7-10mm	13/3/13	FRANKY MARTIN	Level 2 Zone J
3	10mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
4	9mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
5	8mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
6	8mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
7	10mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
8	9mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
9	7mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
10	8mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
11	8mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
12	8mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J
13	8mm	7-10mm	13/3/13	FRANKY MARTIN	Level 3 Zone J

The above is a depth check for the roof Zone H.

3.3 Board Equipment Installation, Testing and Commissioning

Currently nothing to report.

3.4 Non Conformance Reports

We reviewed Brookfield's NCR Tracker and noted the issues raised by the Package Managers. We will continue to review the NCR's especially those issues in relation to the quality of the blockwork and pointing on the south and east elevations. We are also monitoring the issue in relation to water between the glass of the Structal Panels and potential flanking issues in the Children's Hospital Levels 2 and 3.

4.0 CONSTRUCTION REVIEW

4.1 Visits to the Works

Site inspections were carried out by the NEC3 Supervisors on the 1st, 2nd, 3rd, 6th, 7th, 8th, 9th, 10th, 13th, 14th, 15th, 16th, 17th, 20th, 21st, 22nd, 23rd, 24th , 27th , 28th , 29th ,30th and 31st May 2013.

4.2 Elements of the Works available for inspection

- Energy Centre – structurally complete. Civil works around.
- Main building – Cores A, B, C, D, E, F, G, K and L internally, Zones A, B, C, D, E, F, G and H ground floor slabs, Zones E and F basement area, ground floor suspended slabs, 1st to 9th floor slabs throughout the main hospital, to floor 12 Zones D and G, and to floor 10 Zones F and J. Zones A, B, D and G roof area.

- Zones C and F below slab drainage.
- External Drainage – specific sections of installation where access is possible.
- Tunnels between ACH and Labs, and Cores C to F.
- Structural steelwork to Atrium (limited due to access).
- Structural steelwork to roof at Zones A, B, D and G.
- Dual carriageway to Renfrew Road, turning area in front of the main entrance, and carriageway from Hardgate Road.
- Internal Partitions.
- M&E modular units.
- Roofing.
- Cladding.
- Windows.
- Sto system.
- Brickwork Courtyard 5 and south east elevation.
- Brickwork/blockwork south east elevations.
- Basement blockwork.
- Cap park piling mat area.

4.3 Observations from May 2013 Inspections

The visual inspections of the work carried out to date indicate that the works are generally being carried out to a satisfactory standard. We continue to be assisted by the site teams and the NHS Project Team in resolving various construction, mechanical, electrical, and quality issues. We continue to close out our Supervisor's Notification and Defects when we have received satisfactory responses. Listed below are observations closed out, still to be closed and those raised following site visits in May 2013.

4.3.1 Structural

In respect of the piling records on ZUTEC the current construction drawings are still to be replaced by 'as built' drawings. Piling to the new car park has commenced and from a quality perspective appears to be progressing satisfactorily to date.

Quality on all concrete works has generally appeared good but the following points remain outstanding from previous reports and we continue to monitor these:-

- Finish to ground floor in Zone F and 1st floor in Zone J.
- 20mm level change detail in all floor slabs at Zones E and J – remedial work on these areas is in progress.
- Cracks to the soffit of the suspended ground floor slab between Cores A, B, C and D being kept under review.
- Spalling to a couple of parapet walls at the top of Core G.

At the Atrium Bridge deflection checks have been further examined in respect of some datum issues. Brookfield report is awaited in relation to proposed methodology for completion of floor finishes and fenestration in relation to levels. Remedial work to the intumescent paintwork has progressed. A report/certificate is awaited from the Independent Tester. However, during the period, damaged areas to some of this

paintwork have been observed as well as some cracks in the web/flange zone of some steel sections. External cladding erection has commenced.

Steelwork to the roof of the Children's Hospital section (Zones A, B and C) has progressed and while generally satisfactory 3 areas have been raised in communications with Brookfield. concrete bases missing from 2 sets of steel 'goal posts', 3 columns not sitting on concrete foundations fully, and damaged paintwork. In the Children's Zone A atrium, at 1st floor level, steel angle fixings to the concrete core wall remain in need of remedial attention. The concrete deck above has now been cast.

Steelwork erection has also commenced on the roof of the SE arm (Zone G). Some sections of galvanised steelwork were delivered well out of shape and straightness tolerance and were being returned to the subcontractor for appropriate attention.

Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 57 has been physically addressed and a formal response received from Brookfield. Consequently this communication is now closed out.

Concrete slab work to the ACH has continued apace during the period. Slab work is essentially completed to level 12 on the SE and SW arms (Zones D and G) and is progressing on the 11th floor on the NE and NW arms (Zones J and F respectively). On the Children's Hospital concrete work is now substantially completed. Ground floor slabs in the ACH are now also substantially completed. All of the work generally appears to be of good quality throughout. Sub-slab drainage tests in Zones C and F have proved satisfactory.

Blockwork has continued in the basement areas and workmanship appears of good quality to date. External blockwork has continued in Zones D and G on the south and east external faces of the building with structural quality appearing satisfactory.

We have brought to Brookfield attention the fixings of the steel angle to the wall at the 1st floor suspended composite deck in the atrium area of Zone A of the Children's hospital. We have asked them to confirm they are in accordance with the

Specification and relevant current codes of practice and standards. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 111. We would note that this has not been addressed for at least 8 weeks and the concrete deck above has now been cast.

Three internal columns in the Children's Hospital Zone B Roof Steelwork do not align with the concrete bases (by approximately 150mm). We asked Brookfield to confirm that the proposed extension to the concrete bases is of sufficient structural integrity as the existing face of the base. The base is not scabbled and there is no connecting reinforcement into the existing base. Brookfield confirmed that the steelwork is in the correct location, there is however a discrepancy between the WSP and JDP drawings, and unfortunately the plinths were cast to the WSP drawing. They are currently pursuing a solution via the designer to complete the concrete works. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 117.

Two internal RHS columns in the Children's Hospital Zone B appear to be held up by adjoining steelwork. This may be work in progress, but we asked Brookfield to confirm the final detailing. Brookfield has informed us that the final detail is a connection to concrete. The concrete works and subsequent bolting up will be undertaken prior to the installation of any cladding. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 118.

Several areas of steelwork in the Children's Hospital Zone B have significant paint damage. Brookfield has confirmed that the painter will return to site (when the liner sheet is in place to offer sufficient protection) to carry out the remedial painterwork. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 119.

4.3.2 Energy Centre

Steelwork snagging appears to have been addressed, but much tidying up remains outstanding in the eastern half of the building. Externally, quality of the concrete hardstanding to the north of the building appears good.

4.3.3 Drainage

We witnessed below ground drainage tests in Zone F Pour 4/5 and Zone C Pour 3 and Zone C Pour 3. There were no issues resulting from these tests.

4.3.4 Dual Carriageway to Renfrew Road. (A&C)

The defects previously identified will be reviewed nearer to completion when they will be effectively rectified.

4.3.5 Pipework.

Installation of hot, cold, heating, & chilled water pipework in the A&C hospital is progressing and in general is being installed to a good standard. Some systems are undergoing chemical cleaN prior to testing. We have witnessed water tests for the chilled beam chilled water and heating pipework and results were acceptable.

SUPERVISOR'S REPORT NO. 26 **MAY 2013**

We are continuing to monitor all pipework installations to identify possible dead legs. The quality checking by Brookfield would appear to be identifying these before our inspections.

We have asked Brookfield to confirm the flow of water from the sprinkler head highlighted is not restricted by the adjacent section of unistrut. Brookfield has confirmed that the sprinkler head deflector appears to be under the unistrut and that the Sprinkler contractor will check this when they are installing the under services protection. If the head is shielded by the unistrut, they will turn the head pendant. Still awaiting photograph showing completed work. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 74.

During our inspections in Plant Room 21, we noted that all AHU condensate discharges are routed to gullies via low level unprotected plastic pipework. This is a potential trip hazard. We have asked Brookfield to confirm that the CDM Coordinator has considered this problem and has asked if there are any measures to address this. There is also the risk of the pipes being broken. Refer to SHTM03-01 clause

4.25. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 122).

LTHW pumps are mounted on inertia bases however, there are no pump flexes. Vibration will transmit through pipework as a result. Possible longer term leakage/ damage through pipework joints. Please confirm if this has been considered and if there any measures are proposed to address this. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 123.

4.3.6 Ventilation

The installation of ventilation ductwork in the A&C hospital is progressing well, and has been installed to a good standard. It appears that any open ends are being sealed but we have noted some exceptions and these have been highlighted to the contractor during our weekly site inspections.

An inspection was carried out in Plant Room PR21 for the AHU21 to allow this unit to set the standard for all other AHU's. A number of items were also reviewed external to the unit which will require rectification.

The comments recorded for items external to the unit were as follows and we intend to raise Communications for the following observations;

- Unistrut supports for ductwork and pipework do not have lateral restraint to prevent damage and potential collapse.
- Supply ductwork at high level near louvre is not sealed and there was evidence of gaps between duct sections which will give rise to leakage.
- We will ask if chain restraints to access hatches particularly at high level is required, to prevent covers falling from height when maintenance/ inspection is being carried out.
- Location of hatch at rear of AHU into vertical face of duct section impedes access.

We raised the following comments with Brookfield on internal AHU components during our site inspections and we await their response.

- Please confirm design criteria for AHU in relation to the following concern over location of fan discharge in relation to coil face, approx 1m between components for following reasons;
- Please confirm that the fan discharge velocity will not exceed face velocity of the coil immediately in front of the discharge
- Please confirm that location of fan discharge is offset and will provide uniform velocity across face of coil. Please confirm Coil 'off coil' conditions.
- Please confirm if this is a heating or cooling coil as this will affect parameters for face velocity and potentially cause condensate carry over if cooling coil. HTM recommendations for coil face velocities are maximum of 2m/s as SHTM clause 3.47
- Please confirm if blast plate is required after fan discharge to improve uneven velocities and air turbulence onto coil face, as per SHTM clause 4.51
- If blast plate is fitted, please confirm overall fan static pressure is still adequate for system resistance and resulting SFP's will meet assumed energy model requirements
- Please confirm borosilicate glass traps are installed to condensate drip trays. Refer to SHTM clauses 4.20 to 4.24
- Please confirm that only one motor is belted as this will cause unnecessary wear on second motor, refer to SHTM clause 4.60. Please confirm if fan control is by inverter and method of control/ switching.
- Please confirm that internal components/ surfaces are of stainless steel construction.
- Please confirm grade of filtration.
- Please confirm that the thermal wheels are fitted with purge feature.
- Please confirm that a moisture eliminator is installed downstream of the cooling coil.
- Please confirm that the AHU is compliant with SHTM03-01, or state any agreed derogation.
- Extract section fan door construction when opened, has sharp edge above head height. Please confirm what will be installed to prevent injury when carrying out maintenance.
- Final fin combing to be carried for all coils out prior to testing/ commissioning.
- Please provide pressure test certificates carried out at manufacturer's works.
- Please review generally cables crushed/ bent within some inspection chambers and MCC enclosure.

Some of the above items have now been rectified, however, we are concerned that there may be instances where the AHU does not comply with SHTM 03-01. It is important that all issues are closed out to allow this AHU to set the standard across the development.

The electrical containment appeared to be restricting access to duct access hatch adjacent to riser THE-2127. Brookfield has confirmed that the Hatch has been repositioned as shown in photograph. The sprinkler flexi is temporarily tied off, the final position of the flexi will be clear of the new hatch. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 73 is closed out.

We noted that there was restricted access to ductwork in the corridor near Atrium Void Core C. Brookfield confirmed that the tray is to be re-routed or access hatch re-positioned. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 110.

We noted that the air handling unit 21AHU16 supply duct transition does not appear to comply with HVAC DW144 clause 11.6 & 11.7 which could result in high pressure loss.

We have asked Brookfield to confirm the design philosophy in relation to this observation and any proposed remedial measures. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 121).

The duct is damage on Level 3 Plant Area at core D. We asked Brookfield to confirm when remedial measures have been completed. Brookfield has confirmed that this duct is already highlighted on the NCR (BMCE-NONC-000176) issued last week with a number of other uncapped sections of ductwork in PR31 and PR22. Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 124 is closed out, however we shall continue to monitor this through Brookfield's NCR tracker.

4.3.7 Insulation

The thermal insulation installation to the pre-fabricated sections of pipework is being completed off site, before delivery and completed after installation.

4.3.8 Pressure testing

Pressure testing of the modular pipework sections on a zone by zone or area by area basis is to be programmed through the commissioning meetings.

We await further information from Brookfield on their programme and methodology.

4.3.9 Medical Gases

Medical Gas pipework in being installed in all areas. Testing has successfully been carried out on some sections of the main distribution systems. We have witnessed these tests with the Authorising Engineer. Additional testing is programmed to take place in May.

4.3.10 Energy Centre

The A- side of the Energy Centre has been partially handed over.

We are continuing to monitor the installations in the remaining A Side areas and all B side areas.

Based on the commissioning programme issued by BM there will be more significant testing and commissioning taking place during the coming months in the roll up to handover of the A&B sides in May 2014.

The second batch of generators has been delivered and positioned on site. Test dates for these are programmed for June 2014.

Testing was carried out on the Busbar network linking switchboards 7A to 8A and 7B to 8B. We await feedback from Schneider Switchgear Service regarding the last tests on the continuity of busbars.

There are some defects/snags still to be completed andf Brookfield has confirmed that they will be completed by Friday 21st June 2013.

4.3.11 Trunking

Cable trunking is being installed as part of the offsite fabricated sections that are being installed in the A&C hospital and in general the installation is to a good industry standard.

4.3.12 Cable Trays

Cable trays are being installed as part of the offsite fabricated sections that are being installed in the A&C hospital and in general the installation is to a good industry standard.

We noted that the data cabling installed on cable basket did not appear to have capacity for future expansion.

We asked Brookfield to confirm the rationale and design philosophy and their proposals to achieve 25% spare capacity. Brookfield has provided photos showing approximately capacity in data baskets. The first photo appears to be 100% full, but the second photo shows an actual capacity of 50%. Brookfield has confirmed that this ratio appears constant to all areas checked over all floors. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 114 is closed out.

4.3.13 Cabling

Modular wiring looms are now being installed as part of the offsite fabricated assemblies and carefully tied up for protection and installation is of a good standard.

Void detection appears inadequate and inaccessible due to plasterboard ceiling. The Scotshield updated drawings following the changes by Building Control to the Fire Strategy are awaited. Once these are received by Mercury these will be issued to confirm adequate protection. These are still awaited. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 77.

The junction box appeared to be inaccessible due to the ceiling installation. We asked Brookfield to confirm if this is the case. Brookfield has confirmed that the grille shown adjacent to CCW 061 is in fact not connected to the ductwork system and is just a transfer grille (CVG). It can therefore be used as an access hatch to get to the junction box. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 79 is closed out.

4.3.14 Conduit

Solid conduit installations are well progressed in the areas being fitted out and are to a good industry standard.

4.3.15 Void Detection

There appears to be no void coverage as required within the NHS Firecode. We have asked Brookfield to confirm the void protection philosophy On Level 2, Gridlines I-H & 1.1-2.1. They have confirmed that the detection in the zone area noted above has not commenced yet. The lack of void detection now extends between gridline I & E. Currently air handling units and associated ductwork are installed, with ductwork at high level blanketing almost the entire underside of the ceiling slab.

Brookfield has confirmed that the void detection has been installed in the correct location. The Scotshield updated drawings following the changes by Building Control to the Fire Strategy are awaited. Once these are received by Mercury these will be issued to confirm adequate protection. Drawings still awaited. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 65).

Hoist cabling in CCW 051 is inadequately supported. Brookfield confirmed this has been clipped and a photograph will follow as soon as they get access back into the area. The detail shown will be that for the rest of the hoist cabling. Photograph still awaited. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 78).

There appears to be restrictive space for the void detection. The Scotshield updated drawings following the changes by Building Control to the Fire Strategy are awaited. Once these are received by Mercury these will be issued to confirm adequate protection. Still awaiting drawing. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 90).

We have asked Brookfield to confirm that the void detector above the ductwork in room AAW-381 is providing adequate protection. The Scotshield updated drawings following the changes by Building Control to the Fire Strategy are awaited. Once these are received by Mercury these will be issued to confirm adequate protection. Drawings still awaited. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 93).

We noted that there were no protective covers on the void detectors in rooms CCW-053 EQ BAY L and CCW 066 STATUS LAB on Level 1. We have asked Brookfield to confirm when the covers will been fitted to prevent dust infiltration. We have also asked them to confirm if there are any other void detectors that need to be covered that are not visible and to confirm to us when these been covered. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 112).

4.3.16 Intake Sub Station

Brookfield has confirmed that the final cables will be pulled through over the next few weeks. Last of the cables are being pulled in the Substation, the pits will be cleared and apertures sealed by mid June 2013. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 30 & 45).

4.3.17 Partitions

During an inspection on site we noted that screws had not been fitted at 200mm centres to the end of all the Assess/Treat bays in Area 522. Brookfield confirmed that this would be addressed.

We noted that the gap between the lead lined sheets fixed from the soffit and the sheet fitted from the floor had been in filled with a board which was not lead lined. Brookfield has confirmed that Knauf has approved a new detail drawing and has been given a 'B' Status by the NHS. We await a further response from Astins as to how the detail addresses the junctions at the studs and dwangs. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 108).

4.3.18 Roofs

We continue to inspect the roof work and review the QA checks.

4.3.19 Cladding/Courtyards

Cladding is substantially complete in courtyards 2, 3, & 4 and plant room 21 & 31. The "STO" system is substantially complete in courtyard 2, 3, 4 and 7. Brookfield are to carry out their final quality inspections and sign off. The standard and quality is generally to a good industrial standard.

Repairs and painting was carried out to two damaged panels and these were acceptable to the client. Brookfield await confirmation from Rukki that their Warranty is not compromised as a result of the repair/repaint. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 103).

4.3.20 Windows

Windows are progressing on the external elevations and courtyards in accordance with the specifications.

4.3.21 Fire protection

We still await dry film thickness results for the atrium steel in support of the fire proof certification. These must be for both the factory applied intumescent coating and the coating being applied on site. Brookfield has confirmed that they have been in communication with JD Pierce their sub contractor on the Steelwork and have received the following information;-

Intumescent paint logs for various components.
Steel Certs
Welding Certs

Brookfield has informed us that further works are being implemented on the above steelwork. This will require subsequent further information to be issued by JD Pierce, to supplement the information previously provided. Consequently Brookfield has confirmed that once they have this information they will be able to complete the

overall response to this item. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 54.

Following our Supervisor's Communication General Matters / Other Instruction (Cl 13.1) No 54 requesting dry film thickness results. We have asked Brookfield to provide evidence that all the steelwork on the structure that requires fire protection has been protected in accordance with the specification.

We observed on site that with external cladding panels being erected, access to some protected areas is no longer possible as can be seen in photo no 2. We have asked Brookfield that the hidden areas have been coated or will be coated. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 115).

4.3.22Equipment

Nothing to report.

4.3.23 Ducting

We have asked Brookfield to confirm that the fire damper actuator highlights in room EMC-011 can be accessed on completion of the cold water and ceiling installation. We still await a response. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 92).

4.3.24 Floors

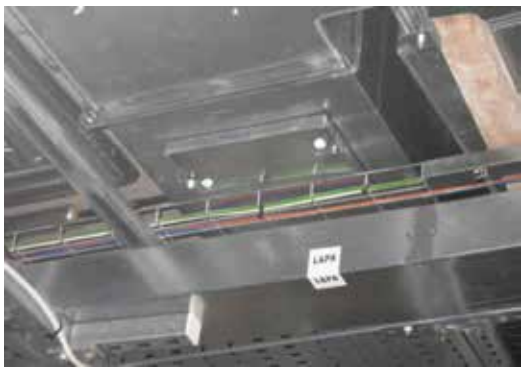
We asked Brookfield to confirm the floor flatness and levelness tolerances for the floors to the Atrium Bridge. We have also asked for the floor specification and finish to achieve the tolerances. Brookfield confirmed that the floor flatness, specification calls for an SR2 finish which is then prepared to accept vinyl. In terms of AGV's only Level 7 may be used for Transfer only (ie not carrying load) no issues with travelling over slight gradients associated with deadload deflection as long as no abrupt steps in level. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 120.

4.3.25 Blockwork

The quality and standard of workmanship of the blockwork at the curve of the south east elevations was not to a good industrial standard. Brookfield highlighted this problem and is subject to an NCR. The work is complete and Brookfield will carry out an inspection after the blockwork is cleaned.

4.4 Current Defects.

Duct access hatch blocked by chilled water pipework at ground floor area around DB cupboard AAW190. See photograph below. We have asked Brookfield to confirm when this will be rectified. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 56



SUPERVISOR'S REPORT NO. 26 **MAY 2013**

Restricted access to ductwork access hatch in corridor adjacent to Zone H near Stair Core F. Brookfield has intimated that the hatch is not restricted and access can readily be gained. We revisited the hatch and are still of the opinion that access to the hatch is not feasible as can be seen in Mercury's photograph which shows an attempt to access the hatch without the ceilings. We are still awaiting a response. (See Supervisor's Notification of Defect (CI 42.2) No 13).

Ductwork obstructed by modular frame Zone H. Brookfield is investigating this and will report. Still awaiting a response (See Supervisor's Notification of Defect (CI 42.2) No 14).

We carried out a joint inspection with Brookfield and confirm that the 'top hat flashing covers the fixings to the cladding which were previously visible. Consequently Supervisor's Notification of Defect (CI 42.2) No 16 is closed out.

BS5389 recommends that smoke detectors should not be mounted within 500mm of any walls or partitions. This does not appear to have been achieved in room AAW-384. We asked Brookfield to confirm when this has been remedied.

Brookfield has responded stating that BS5839 does recommend smoke detectors to be more than 500mm away from any obstruction, however, in some instances where the room overall size is less than 1100mm from wall to wall it is not possible to achieve this. The fire risk assessment will require that these rooms are to be protected such as electrical riser cupboards as shown in the photograph on the following page with the detector being centralized in the room. These rooms are protected but noted as a variation to BS5839 in the Fire Alarm Certificate.

Brookfield has confirmed that the functionality of the equipment is not compromised and the detector head fully functions within a 7.5 metre radius. Also, BS 5389 states that detectors should not be mounted in the way of obstructions, which would clearly be the case if it was centralized length wise in this room. The detector has been sited

as close as possible to the centre of the room to avoid obstructions. We shall continue to monitor the location of void detection but in this location Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 37 is closed out.

We noted during a joint inspection with Brookfield that insulation has been disturbed behind the boards at high level as a result of electrical installation work. If this is not corrected the acoustic quality of the partition will be adversely affected. We have asked Brookfield to confirm when this has been remedied. Brookfield intends to open up the wall to check if this has been resolved. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 39).

An AVSU penetration has been incorporated into a hazard room partition, on the corridor side of room CCW-019 Disposal Hold in accordance with drawing AST-XX-XX-DT-252-088 which does not show Kanuf board behind the AVSU. HTM 05-02 Table A1 states that the wall should have the integrity of 30 minutes and the method of exposure is to be each side separately.

We asked Brookfield to confirm that the section of partition housing the AVSU can achieve 30 minutes. Supervisor's Notification of Defect (CI 42.2) No 40 is closed, however we intend to witness an 85 point check to a similar partition on Level 2.

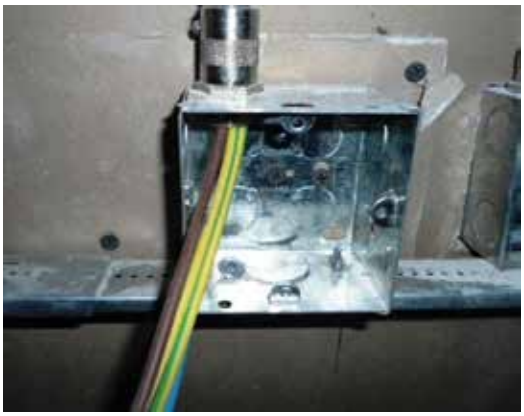
AVSU corridor side of room CCW-019

Brookfield has confirmed that the restrictive access to the ducting on Level 2 Zone D Intervention Theatre THE 228 has been resolved. The column in the room was increased in size which obstructed the route of the duct and therefore the duct was moved from the North wall to the West wall to allow suitable access to be installed. Consequently Supervisor's Notification of Defect (CI 42.2) (CI 13.1) No 42 is closed out.

Two sample areas of panels were repaired and painted. These were inspected and the finish was comparable with the original painted surface. The repair and over painting was agreed between Brookfield and NHS board at the Progress meeting on 13/05/13. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 44 is closed out.

We noted that there were gaps between lead lined noggins and vertical studs on Level 2. Following the re-issue of the drawing and rectification of the defects, a joint inspection of the work was carried out with Brookfield and found the work to be acceptable. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 45 is closed out

We brought to Brookfield's attention that a back box has been fixed by driving screws from outside to the inside leaving the sharp edge of the screws within the accessory box. Brookfield has advised us that the screws have been removed and provided us with photographic evidence. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 46 is closed out.



We have asked Brookfield to confirm the measures to address the restricted access problem to the ductwork access hatch on Level 3 Zone A near room GW1-042. See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 48).

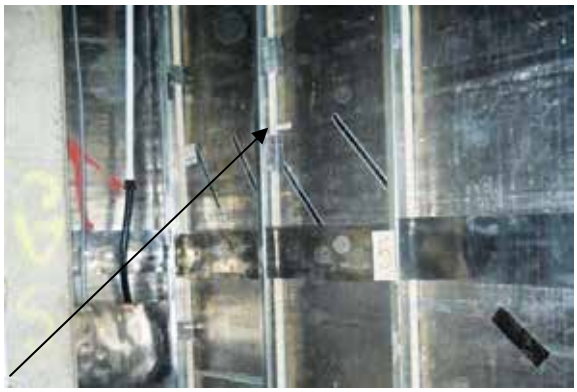
We asked Brookfield to confirm that the support to all the curtain rails will be fitted in accordance with SHTM66 and the manufactures recommendations.
After a joint inspection we can confirm that angles fixed from the suspended ceiling up to the underside of the concrete soffit has been carried out. Consequently

SUPERVISOR'S REPORT NO. 26 **MAY 2013**

Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 49 is closed out

There are numerous locations where fixings for the lead lined panels have missed the studs/batts and have punctured the lead. (See photos below). We asked Brookfield to confirm the remedial measures to resolve this situation. Brookfield confirmed that remedial measures had been undertaken as part of Astins QITP prior to closure of the lead lined partitions. We witnessed an 85 point inspection on a lead lined partition on Level 2 and noted that remedial repairs had been carried out. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 50 is closed out.

Exposed screw.



Screw covered with lead.

There are partitions on Level 0 Area 529 which have screw fixings that have been fixed too close to the edge of the board.

The Knuaf/NBS Specification states that screws to be not less than 10mm from edge of board and this is not being achieved in many locations. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 51).

The protective membrane had been punctured in a few locations on Level 4 Roof Zone E. Brookfield has carried out the repairs and these have been witnessed by us. Consequently Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 52 is closed out.

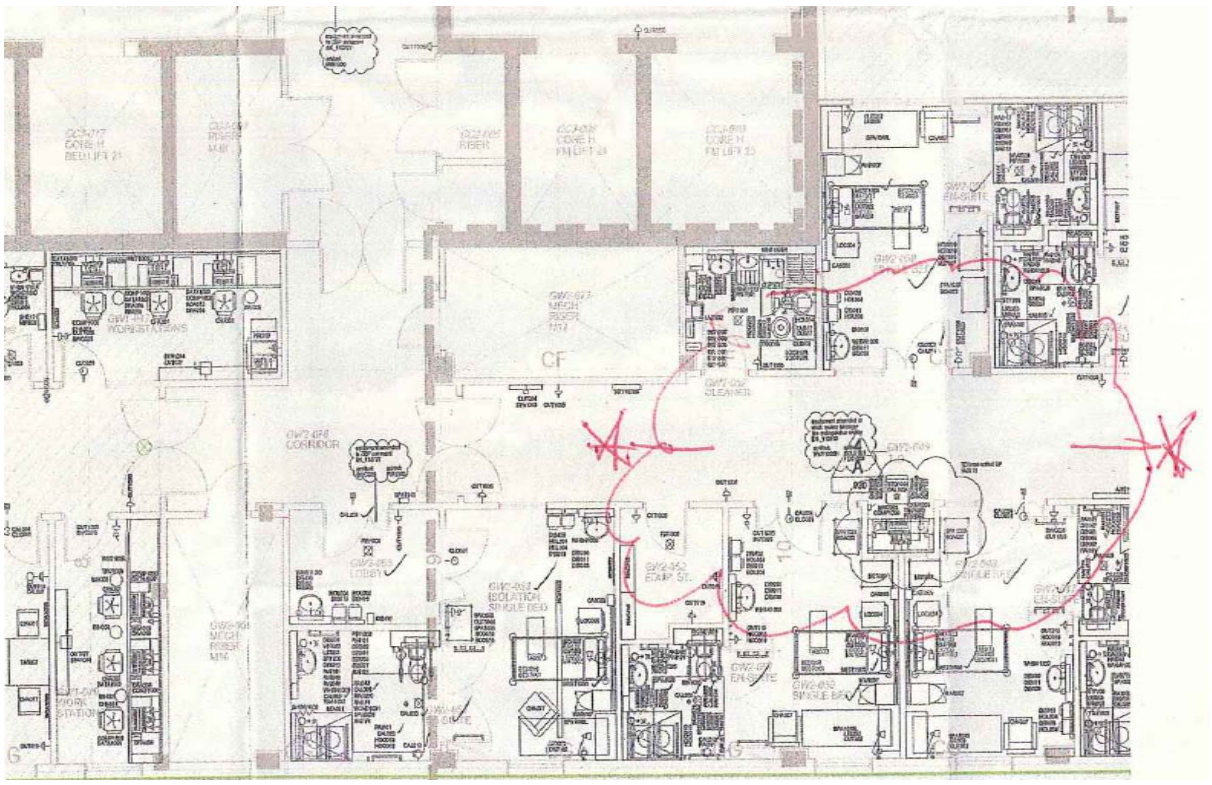
Damaged Membrane

Area Repaired

Two access hatches are blocked by containment in the corridor. See photos and location below.

We have asked Brookfield to confirm when appropriate access has been provided so that we can re-inspect the hatches. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 52).

SUPERVISOR'S REPORT NO. 26 **MAY 2013**



We have asked Brookfield to confirm when appropriate access has been provided so that we can re-inspect the hatches. (See Supervisor's Communication General Matters / Other Instructions (Cl 13.1) No 53).

We noted that the opening and closing turn handles which operates the internal blinds of the windows in Area1-528 were not operating properly. Some blinds were difficult to open and close and one turn handle at the single isolation room did not operate.

We asked Brookfield to confirm remedial measures and confirm that the operation of the blinds has been checked site wide.

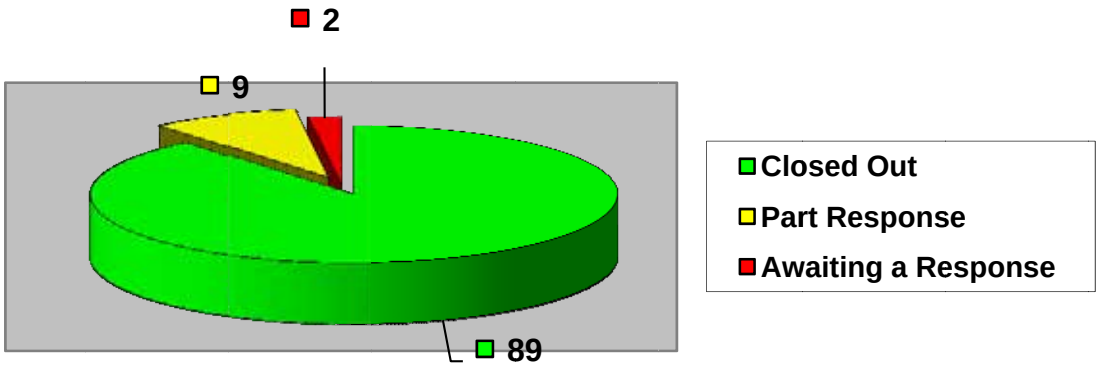
Following a meeting with TDSL and their supplier from Highline Visicom on Tuesday 4th June and subsequent viewing of the units on site the following was agreed.

Supplier confirmed the problem with the opening and closing turn handles which operates the internal blinds of the windows was an alignment issue with the glazing and operating knob on the screens. In Zone G the screens came to site with a faulty clip which was the underlying reason for the defect.

TDSL supplier will attend site w/c 17th June. During this visit all defective screens will be stripped out from the corridor side. Glazing re-aligned with the control knob and then re-fitted into the screens. Screens will then require to be redecorated. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 54).

We noted that there are areas of fire coating to the steelwork on the 11th floor Atrium Bridge which is damaged or cracked. We have asked Brookfield to confirm when the remedial work has been carried out to address these defects and to provide dry film test results for the steelwork in this area. (See Supervisor's Communication General Matters / Other Instructions (CI 13.1) No 55).

5.0 INFORMATION REQUIRED



NEW SOUTH GLASGOW HOSPITAL ADULT AND CHILDREN'S HOSPITAL AND ENERGY CENTRE

SUPERVISOR'S REPORT NO. 26 **MAY 2013**

Item No.	*Description*	*Date Requested*	*Comment*
Items 1 to 21 have been closed out			
22	Brookfield to provide us with their Air Test Procedures and Programme.	03/07/12	Response received.
Items 23 to 29 have been closed out			
30	Confirm when cabling is complete, water pumped out and batteries removed.	10/08/12	Response received.
Items 31 to 44 have been closed out			
45	See Supervisor's Communication No 30.	18/09/12	Response received.
46	Advise on proposals for preventing rain penetration	10/09/12	Closed out.
Items 48 to 53 have been closed out			
54	Provide dry film thickness results for factory applied intumescent and remedial repairs on site.	12/10/12	Response received.
55	Provide air method statement for air leakage tests.	12/10/12	Closed out.
56	Confirm remedial action to damaged steel framework.	15/10/12	Closed out.
57	Please confirm if the attached holes without bolts to the steelwork bridge connections reflects the design intent.	16/10/12	Closed out.
Items 58 to 64 have been closed out			
65	Confirm philosophy for void detection on Level 1 Gridline I-H & 1.1-2.1.	12/11/12	Response received.
Items 66 to 72 have been closed out			
73	Electrical containment appears to be restricting access to duct access hatch Adjacent to riser THE-212.	30/11/12	Closed out.
74	Confirm flow of water from the sprinkler head is t restricted.	30/11/12	Response received.
75	Confirm the access regime for sprinkler head maintenance / replacement.	30/11/12	Response received.
76	Confirm when 3m dead legs have been altered in CCW-031	30/11/12	Closed out.
77	Void detection appears inadequate and inaccessible due to plasterboard ceiling in CCW-051	30/11/12	Response received.
78	Hoist cabling is inadequately supported.	30/11/12	Response received.
79	Junction box appears to be inaccessible due to ceiling installation	30/11/12	Closed out.
Items 80 to 89 have been closed out			
90	Confirm void detector above ductwork provides adequate protection.	14/01/13	Response received.
91	Confirms access hatch shall be accessible.	14/01/13	Closed out.
92	Confirm that fire damper actuators highlights can be accessed on completion of the cold water and ceiling installation.	14/01/13	Open
93	Confirm void detector above ductwork provides adequate protection.	14/01/13	Response received.
Items 94 to 102 have been closed out			
103	Confirm on site painting of panels has the same life expectancy as the factory applied finish.	15/02/13	Open
104	Confirm safe access through the light fittings will not compromise the finished ceiling installation.	28/02/13	Closed out.
105	Provide Electronic Roof Integrity Tests for roofs on Levels 3&4. Confirm isolated area under the boiler will be finished in accordance with the manufacturers requirements and any damaged areas due to storing of materials are rectified.	11/03/13	Open

106	We have concerns materials and debris on roofs Level 2 Zone H and Level 4 Zone F will damage the membrane. Confirm all risks of damage are removed from the roof	11/03/13	Open	
107	Please investigate the crack in the ground floor, review with your designers and provide a brief summary report on likely causes, including proposed remedial action and timing.	22/03/13	Closed out.	
108	A detail in the construction of the lead lined partition on Level 1 is being used which has not been approved. Ensure that the detail has been approved.	22/03/13	Response received.	
109	Confirm when back to back electrical boxes have been repositioned.	27/03/13	Closed out	
110	We noted that there was restricted access to ductwork. Please confirm remedial measures to address this issue in the corridor near Atrium Void Core C.	27/03/13	Response received.	
111	Please check and confirm that the fixings to the steel angles to the wall at the 1st floor suspended composite deck are in accordance with the specifications/codes of practice.	28.03.13	Open	
112	Confirm when the protective covers on the void detectors in rooms CCW-053 EQ BAY L and CCW 066 STATUS LAB on Level 1 have been fitted and confirm that the other detectors are also fitted.	10.04.13	Open	
113	Confirm how you will manage the reoccurrence of insulation being disturbed or removed from partitions as a result of the installation of services.	10.04.13	Closed out	
114	Confirm that there is 25% spare capacity on cable basket.	02.05.13	Closed out	
115	Confirm all Atrium steelwork has been fire protected. Confirm that areas hidden by panels have received a protective intumescent coating.	07.05.13	Open	
116	Confirm that there are sufficient access panels in Zone D MH S4 and MH S5. Confirm that 50 mm waste pipes connecting to 100mm pipes at floor level without rodding points are compliant with Building Control.	03.05.13	Open	
117	Confirm procedures to ensure the work to the incomplete concrete base has sufficient structural integrity.	15.05.13	Response received.	
118	Confirm the final detailing to internal RHS columns which appear to be held up by adjoining steelwork.	15.05.13	Response received.	
119	Confirm measures to address areas of steelwork in the Children's Hospital Zone B which have significant paint damage.	15.05.13	Response received.	
120	Confirm flatness and levelness (including floor specification and finishes) to achieve tolerances.	16.05.13	Open	
121	Confirm the design philosophy in relation to air handling unit 21AHU16 supply duct transition does not would appear to comply with HVAC DW144 clause 11.6 & 11.7	16.05.13	Open	
122	Condensate discharges are routed to gullies are a potential trip hazard. Confirm that the CDM Coordinator has considered this problem and confirm if there are any measures to address this.	16.05.13	Open	
123	LTHW pumps are mounted on inertia bases however, there are no pump flexes. Vibration will transmit through pipework as a result. Please confirm if this has been considered and if there any measures are proposed to address this.	28.05.13	Open	
124	Confirm when remedial measures have been completed in relation to the damaged duct.	28.05.13	Closed out

NICE National Institute for Health and Care Excellence

NICE quality standard

Healthcare-associated infections

Quality standard

Published: 11 February 2016

www.nice.org.uk/guidance/qs113

Contents

This standard is based on PH36.

This standard should be read in conjunction with QS75, QS61, QS49, QS15, QS121, QS161 and QS168.

Introduction

This quality standard covers organisational factors in preventing and controlling healthcare-associated infections in secondary care settings.

Organisational factors include management arrangements, policies, procedures, monitoring, evaluation, audit and accountability. Secondary care settings include hospital buildings and grounds; inpatient, day case and outpatient facilities and services; elective and emergency care facilities; and hospital maternity units and services. Throughout this quality standard, the term 'hospital' is used for ease of reference to represent the organisation responsible for services provided in secondary care settings.

This quality standard should be read alongside NICE's quality standards on infection prevention and control and surgical site infection. Other related quality standards are listed in related NICE quality standards.

The quality statements that follow build on the Health and Social Care Act 2008: code of practice on the prevention and control of infections of practice.

For more information see the healthcare-associated infections topic overview.

Why this quality standard is needed

Healthcare-associated infections are a serious risk to patients, staff and visitors. They can cause significant morbidity to those infected and significant costs for the NHS. As a result, infection prevention and control is a key priority for the NHS.

Healthcare-associated infections cover any infection contracted:

- as a direct result of treatment in, or contact with, a health or social care setting

- as a result of healthcare delivered in the community
- outside a healthcare setting (for example, in the community) and brought in by patients, staff or visitors and transmitted to others (for example, norovirus).

The most well-known healthcare-associated infections, for which mandatory reporting is currently required, include those caused by meticillin-resistant *Staphylococcus aureus* (MRSA), meticillin-sensitive *Staphylococcus aureus* (MSSA), *Clostridium difficile* (*C difficile*) and *Escherichia coli* (*E coli*). Other gram-negative bacteria (including antibiotic-resistant bacteria) and norovirus can also cause healthcare-associated infections.

The English National Point Prevalence Survey (Health Protection Agency, 2012) identified that 6.4% of inpatients in acute care hospitals in 2011 had a healthcare-associated infection. The 6 most common types of healthcare-associated infections, which accounted for more than 80% of all healthcare-associated infections, were pneumonia and other respiratory infections (22.8%), urinary tract infections (17.2%), surgical site infections (15.7%), clinical sepsis (10.5%), gastrointestinal infections (8.8%), and bloodstream infections (7.3%).

The quality standard is expected to contribute to improvements in the following outcomes:

- hospital-acquired harm
- length of stay in acute care
- antimicrobial resistance
- avoidable morbidity
- avoidable mortality
- incidence of *C difficile* and MRSA
- patient experience
- avoidable hospital admissions
- accident and emergency department attendance.

How this quality standard supports delivery of

outcome frameworks

NICE quality standards are a concise set of prioritised statements designed to drive measurable improvements in the 3 dimensions of quality – patient safety, patient experience and clinical effectiveness – for a particular area of health or care. They are derived from high-quality guidance, such as that from NICE or other sources accredited by NICE. This quality standard, in conjunction with the guidance on which it is based, should contribute to the improvements outlined in the following 3 outcomes frameworks published by the Department of Health:

- NHS Outcomes Framework 2015 to 2016
- Adult Social Care Outcomes Framework 2015 to 2016
- Public Health Outcomes Framework 2013 to 2016.

Patient experience and safety issues

Ensuring that care is safe and that people have a positive experience of care is vital in a high-quality service. It is important to consider these factors when planning and delivering services that seek to prevent and control healthcare-associated infections.

Coordinated services

The quality standard for healthcare-associated infections specifies that services should be commissioned from and coordinated across all relevant agencies. A person-centred, integrated approach to providing services is fundamental to delivering high-quality care and preventing and controlling healthcare-associated infections in secondary care settings.

The Health and Social Care Act 2012 sets out a clear expectation that the care system should consider NICE quality standards in planning and delivering services, as part of a general duty to secure continuous improvement in quality. Commissioners and providers of health and social care should refer to the library of NICE quality standards when designing high-quality services. Other quality standards that should also be considered when choosing, commissioning or providing a high-quality services related to healthcare-associated infections are listed in related NICE quality standards.

Training and competencies

The quality standard should be read in the context of national and local guidelines on training and competencies. All health, public health and social care practitioners involved in the prevention and control of healthcare-associated infections in secondary care settings should have sufficient and appropriate training and competencies to deliver the actions and interventions described in the quality standard. Quality statements on staff training and competency are not usually included in quality standards. However, recommendations in the development source(s) on specific types of training for the topic that exceed standard professional training are considered during quality statement development.

Role of families and carers

Quality standards recognise the important role families and carers have in supporting people with healthcare-associated infections in secondary care settings. If appropriate, healthcare professionals should ensure that family members and carers are involved in the decision-making process about investigations, treatment and care and are also provided with advice and guidance on hygiene and infection prevention and control.

List of quality statements

Statement 1 Hospitals monitor healthcare-associated infections and other infections of local relevance to drive continuous quality improvement.

Statement 2 Hospitals work with local health and social care organisations to assess and manage the risk of infections in hospitals from community outbreaks and incidents.

Statement 3 Hospital staff have individual objectives and appraisals on infection prevention and control linked to board-level objectives and strategies.

Statement 4 Hospitals involve infection prevention and control teams in the building, refurbishment and maintenance of hospital facilities.

Statement 5 People admitted to, discharged from, or transferred between or within hospitals have information about any infections and associated treatments shared with health and social care staff to inform their care.

Quality statement 1: Surveillance

Quality statement

Hospitals monitor healthcare-associated infections and other infections of local relevance to drive continuous quality improvement.

Rationale

Mandatory national and local surveillance of healthcare-associated infections (such as *Staphylococcus aureus* [MRSA] and *Clostridium difficile* [*C difficile*]) provides information that can be used to assess the infection risk of people in hospital and inform the response. However, mandatory monitoring only covers a small number of healthcare-associated infections. Identification and monitoring of other infections of local relevance, including resistant organisms, contributes to a fuller understanding of the risk of infection to people in hospital. The results of monitoring can be used by staff across the organisation to help inform practice, review the effectiveness of responses, and review how well strategies to reduce healthcare-associated infections are working.

Quality measures

Structure

a) Evidence of local arrangements for hospitals to monitor healthcare-associated infections and other infections of local relevance.

Data source: Local data collection.

b) Evidence of local arrangements for the results of monitoring healthcare-associated infections and other infections of local relevance to be used across the organisation to inform and review objectives for quality improvement.

Data source: Local data collection.

Outcome

Incidence of healthcare-associated infections.

Data source: Local data collection and national data collection including NHS Outcomes Framework 2015 to 2016 indicator 5.2 (MRSA and *C difficile*); Clinical Commissioning Group [CCG] Outcome Indicator Set 2015 to 2016 indicators 5.3 (MRSA) and 5.4 (*C difficile*). National data derived from the Public Health England Mandatory Surveillance of MRSA, MSSA, E coli and C difficile.

What the quality statement means for service providers, health and social care practitioners, and commissioners

Service providers (hospitals) ensure that systems are in place to carry out mandatory monitoring of healthcare-associated infections and other infections of local relevance, including resistant organisms; and ensure that the results are shared across the organisation and used to drive continuous quality improvement.

Health and social care practitioners in secondary care (including hospital clinicians, nursing staff and allied healthcare professionals) report healthcare-associated infections, act on information provided to them about local infections to reduce infection risk, and adjust clinical practice for continuous improvement.

Commissioners (such as clinical commissioning groups) ensure that they commission services from hospitals that have systems to carry out mandatory monitoring of healthcare-associated infections and other infections of local relevance, including resistant organisms; and ensure that they share the results across the organisation to drive continuous quality improvement.

What the quality statement means for patients, service users and carers

People receiving treatment in, or visiting, hospitals can expect the hospital to monitor infection levels across all service areas to help improve services and minimise future infection rates.

Source guidance

Healthcare-associated infections: prevention and control. NICE guideline PH36 (2011), quality improvement statements 1 and 3

Definitions

Monitor healthcare-associated infections

Monitoring includes mandatory monitoring of healthcare-associated infections and also other infections that are of local relevance, including resistant organisms, within the hospital setting. Monitoring should be through a surveillance system that detects organisms and infections, and promptly registers any abnormal trends. Data from multiple sources (epidemiological, clinical, microbiological, surgical and pharmacy) need to be combined in real time, and should allow for timely recognition of incidents in different spaces (for example, wards, clinical teams, clinical areas and across the whole trust). Surveillance data in key areas should be regularly compared with other local and national data. [Adapted from NICE's guideline on healthcare-associated infections: prevention and control]

Continuous quality improvement

Improving the provision of services and practice by using a range of audit and statistical tools to assess the current situation, identify areas for improvement and measure the results. [NICE's guideline on healthcare-associated infections: prevention and control]

Quality statement 2: Collaborative action

Quality statement

Hospitals work with local health and social care organisations to assess and manage the risk of infections in hospitals from community outbreaks and incidents.

Rationale

Healthcare-associated infections are a serious risk to hospital patients, staff and visitors. Infections contracted outside a hospital setting can be brought into the hospital by patients, visitors and staff, and transmitted to others. By identifying and assessing potential risks from community outbreaks and incidents, hospitals can take action in collaboration with other local health and social care organisations, including public health services, to reduce the risk of infection.

Quality measures

Structure

a) Evidence of local arrangements for hospitals to monitor the risk of healthcare-associated infections from incidents and outbreaks in the community.

Data source: Local data collection.

b) Evidence of local arrangements for collaborative working between hospitals and other local health and social care organisations to investigate and manage the risks of healthcare-associated infection from incidents and outbreaks in the community.

Data source: Local data collection.

Outcome

Incidence of healthcare-associated infections.

Data source: Local data collection and national data collection including NHS Outcomes Framework 2015 to 2016 indicator 5.2 (MRSA and *C difficile*); Clinical Commissioning Group [CCG] Outcome Indicator Set 2015 to 2016 indicators 5.3 (MRSA) and 5.4 (*C difficile*). National data derived from the Public Health England Mandatory Surveillance of MRSA, MSSA, E coli and C difficile.

What the quality statement means for service providers, health and social care practitioners, and commissioners

Service providers (hospitals) participate in joint working initiatives with other health, public health and social care organisations beyond mandatory requirements to share information on outbreaks and incidents in the community, and assess and minimise the risks. Joint working initiatives can include agreeing a governance structure and lines of accountability between organisations; joint development of strategy, policy, pathway and shared targets; sharing information from risk assessments; and investigating and managing outbreaks and incidents of healthcare-associated infections.

Health and social care practitioners in secondary care (including hospital clinicians, nursing staff and allied healthcare professionals) participate in joint working initiatives and implement measures introduced in response to community incidents and outbreaks to minimise the risk of infections in hospital.

Commissioners (such as clinical commissioning groups) ensure that they commission services from hospitals that can demonstrate that they work collaboratively with local health and social care organisations to assess and manage the risk of infections in hospitals from community outbreaks and incidents.

What the quality statement means for patients, service users and carers

People receiving treatment in, or visiting, hospitals can expect the hospital to work with other local health and social care organisations to help prevent infections in the community spreading into the hospital. As a result of this work, hospitals may occasionally have to change the way that people receive treatment or visit hospitals. For example, a ward may be closed to visitors, or a person may be admitted to a single room to help

prevent infections spreading.

Source guidance

Healthcare-associated infections: prevention and control. NICE guideline PH36 (2011), quality improvement statements 3 and 6

Definitions

Community outbreaks and incidents

An outbreak is usually defined as 2 or more people experiencing a similar illness linked in place and time, or a single instance of a rare or particularly harmful organism. An outbreak is only declared following the identification, notification and investigation of an incident. For example, laboratory results may confirm that 2 illnesses are caused by the same organism or strain of an organism.

An incident includes events or situations needing investigation to see if action or management to reduce a risk is needed. An incident can also include a single case of a disease. In the context of this statement, an incident is taken to include any incident with the potential to expose people to infection risk. [Expert opinion]

Quality statement 3: Responsibilities of hospital staff

Quality statement

Hospital staff have individual objectives and appraisals on infection prevention and control linked to board-level objectives and strategies.

Rationale

Trust boards provide leadership in infection prevention and control, but all hospital staff have responsibility for, and are accountable for, infection prevention and control. Boards can help minimise the risk to patients and ensure continuous quality improvement by leading on and regularly reviewing all relevant infection prevention and control objectives, policies and procedures. A clear governance structure and accountability framework will allocate specific responsibilities to all staff. All staff having these responsibilities as clear objectives that are reviewed in appraisals and reflected in development plans will help ensure that board-level objectives are achieved and that the risk of healthcare-associated infection is minimised.

Quality measures

Structure

a) Evidence of local arrangements to ensure all staff have clear objectives in relation to infection prevention and control that are linked to board-level objectives.

Data source: Local data collection.

b) Evidence of local arrangements to ensure all staff have an appraisal and development plan that cover infection prevention and control.

Data source: Local data collection.

Process

a) Proportion of hospital staff who have individual infection prevention and control objectives that are linked to board-level objectives.

Numerator – the number in the denominator who have individual infection prevention and control objectives that are linked to board-level objectives.

Denominator – the number of hospital staff.

Data source: Local data collection.

b) Proportion of hospital staff who have an appraisal of their infection prevention and control objectives.

Numerator – the number in the denominator who have an appraisal of their infection prevention and control objectives.

Denominator – the number of hospital staff.

Data source: Local data collection.

c) Proportion of hospital staff who have a development plan that includes infection prevention and control.

Numerator – the number in the denominator who have a development plan that addresses individual needs for knowledge, abilities and skills in infection prevention and control.

Denominator – the number of hospital staff.

Data source: Local data collection.

What the quality statement means for service providers, hospital staff, and commissioners

Service providers (hospitals) in secondary care settings ensure that all staff have objectives in relation to infection prevention and control that are linked to the board's

objectives and strategies, that these objectives are appraised and included in development plans, and that staff are supported to carry out these objectives.

Hospital staff (including hospital clinicians, nursing staff, allied healthcare professionals, administrative staff and catering staff) in secondary care settings follow working practices and tasks on infection prevention and control described in their personal objectives; have feedback on their performance against these objectives through an appraisal; and are supported to ensure that learning, training and other development needs on infection prevention and control set out in a development plan are met.

Commissioners (such as clinical commissioning groups) ensure that they commission services from secondary care providers that appraise and support their staff to achieve their objectives on infection prevention and control.

What the quality statement means for patients, service users and carers

People receiving treatment in, or visiting, hospitals can expect that all hospital staff have the skills and knowledge needed to carry out infection prevention and control procedures in their area of work.

Source guidance

Healthcare-associated infections: prevention and control. NICE guideline PH36 (2011), quality improvement statement 4

Definitions

Hospital staff

All clinical and non-clinical staff, including support staff, volunteers, agency or locum staff and those employed by contractors. [Adapted from NICE's guideline on healthcare-associated infections: prevention and control]

Quality statement 4: Planning, design and management of hospital facilities

Quality statement

Hospitals involve infection prevention and control teams in the building, refurbishment and maintenance of hospital facilities.

Rationale

In a healthcare setting the built environment can play a significant role in the transmission of infection. The design of new buildings, as well as their refurbishment and ongoing maintenance, should allow good infection prevention and control practices. Involving infection prevention and control teams in the planning, design and maintenance of hospital facilities can ensure that needs are anticipated, planned for and met, and that the risk of healthcare-associated infections is minimised.

Quality measures

Structure

a) Evidence of local arrangements for involving infection prevention and control teams in the building and refurbishment of facilities in the hospital. Examples of evidence may include protocols covering infection prevention and control in the built environment; estate department procedures to engage infection prevention and control teams in new build and refurbishment projects; building and refurbishment project plans and schedules of work that show the involvement of infection prevention and control teams; and records of completed building and refurbishment works that show whether infection prevention and control requirements have been met.

Data source: Local data collection.

b) Evidence of local arrangements for involving infection prevention and control teams in the maintenance of facilities in the hospital. Examples of evidence may include protocols

covering infection prevention and control in the built environment; estate department procedures to engage infection prevention and control teams in maintenance works; maintenance plans and schedules that show the involvement of infection prevention and control teams; and records of completed maintenance works that show whether infection prevention and control requirements have been met.

Data source: Local data collection.

What the quality statement means for service providers, healthcare professionals and commissioners

Service providers (hospitals) in secondary care settings ensure that infection prevention and control teams are involved in planning, design and maintenance of hospital facilities, as part of managing and maintaining the whole estate to minimise the risk from infection. Providers should follow best practice guidance where available, such as Infection control in the built environment: Health Building Note 00-09 (Department of Health and Social Care, 2013), which identifies infection prevention and control issues and risks that need to be addressed at each stage of a new build or refurbishment project.

Healthcare professionals (including hospital clinicians and nursing staff) who are part of hospitals' infection and control teams are involved in the planning, design and maintenance of hospital facilities. This may include identifying design issues (such as provision of isolation facilities, decontamination facilities and hand hygiene facilities); agreeing the requirements for infection prevention and control; risk assessing the works to be undertaken and advising on the necessary measures to protect patients, visitors and staff; ensuring that control measures are implemented and adhered to; and attending estates and property project planning meetings.

Commissioners (such as clinical commissioning groups) ensure that they commission secondary care services from providers where infection prevention and control teams are involved in the planning, design and maintenance of hospital services and facilities.

What the quality statement means for patients, service users and carers

People receiving treatment in, or visiting, hospitals can expect the hospitals, and their related buildings and grounds, to be designed and looked after in a way that minimises the risk of infection.

Source guidance

Healthcare-associated infections: prevention and control. NICE guideline PH36 (2011), quality improvement statement 10

Quality statement 5: Admission, discharge and transfer

Quality statement

People admitted to, discharged from, or transferred between or within hospitals, have information about any infections and associated treatments shared with health and social care staff to inform their care.

Rationale

Potentially avoidable healthcare-associated infections can occur when people are admitted to, discharged from or transferred between or within hospitals. Sharing information on current infections, treatment and colonising organisms can result in better care and outcomes for people with, or at risk of, infections and can help to reduce the risk of infections being spread between care settings. A consistent approach to sharing information between health and social care practitioners involved in a patient's care pathway should ensure appropriate ongoing support, and minimise the risk of inappropriate management and transmission of infection. Information should be shared when arrangements are made for a person to move from the care of one organisation to another, or when arrangements are made to move a person within a hospital, while maintaining patient confidentiality and privacy.

Quality measures

Structure

Evidence of local arrangements to ensure information about any infections and associated treatments for people admitted to, discharged from, or transferred between or within hospitals, is shared with the health and social care staff responsible for the ongoing care.

Data source: Local data collection.

Process

a) Proportion of admissions to hospital, including transfers of patients from other hospitals, where information on infections and associated treatments is received.

Numerator – the number in the denominator where information on infections and associated treatments is received.

Denominator – the number of admissions to hospital of people with infections.

Data source: Local data collection.

b) Proportion of discharges from hospital, including transfers of patients to other hospitals, where information on infections and associated treatments is provided to health and social care staff responsible for ongoing care.

Numerator – the number in the denominator where information on infections and associated treatments is provided.

Denominator – the number of discharges from hospital of people with infections.

Data source: Local data collection.

c) Proportion of transfers of patients within a hospital where information on infections and associated treatments is provided to health care staff responsible for ongoing care.

Numerator – the number in the denominator where information on infections and associated treatments is provided to health care staff responsible for ongoing care.

Denominator – the number of transfers of patients between wards within a hospital.

Data source: Local data collection.

What the quality statement means for service providers, health and social care practitioners, and commissioners

Service providers (such as hospitals and social care providers) provide information about any infections, colonising organisms and associated treatments when they arrange for a person to be moved into or out of hospital, or between wards, to inform the ongoing care of that person and minimise the risk of transmission. If appropriate, information should also be shared with the providers of transport for a person moving into or out of hospital.

Health and social care practitioners (including hospital clinicians, nursing staff and practitioners in care homes) involved in hospital admission, discharge and transfer ensure that they share information with other healthcare professionals and social care practitioners to manage and support patients with an infection on an ongoing basis during admission, transfer and discharge.

Commissioners (such as clinical commissioning groups) ensure that they commission services from health and social care providers that have mechanisms in place to ensure that information about any infections, colonising organisms and associated treatments is shared as part of the transfer process and used to inform the ongoing care of patients admitted to, discharged from or transferred between or within hospitals.

What the quality statement means for patients, service users and carers

People who are admitted to, discharged from, or transferred between or within hospitals have information about any infections they have and their treatment, and any treatments they are having that include a risk of infection, shared with the health and social care staff responsible for their care.

Source guidance

Healthcare-associated infections: prevention and control. NICE guideline PH36 (2011), quality improvement statement 8

Definitions of terms used in this quality statement

Information about any infections and associated treatments

This includes information sharing to manage and support patients with existing infections – for example, transfer and isolation arrangements for them – during hospital admission, transfer and discharge. Information on infections and treatments being given for existing infections should also be shared with the health and social care practitioners who will be giving the continuing care, along with information relating to the ongoing use of medical devices (such as catheters) where there is a risk of healthcare-associated infections.

[Adapted from NICE's guideline on healthcare-associated infections: prevention and control].

Using the quality standard

Quality measures

The quality measures accompanying the quality statements aim to improve the structure, process and outcomes of care in areas identified as needing quality improvement. They are not a new set of targets or mandatory indicators for performance management.

See NICE's how to use quality standards for further information, including advice on using quality measures.

Levels of achievement

Expected levels of achievement for quality measures are not specified. Quality standards are intended to drive up the quality of care, and so achievement levels of 100% should be aspired to (or 0% if the quality statement states that something should not be done). However, NICE recognises that this may not always be appropriate in practice, taking account of safety, choice and professional judgement, and therefore desired levels of achievement should be defined locally.

NICE's quality standard service improvement template helps providers to make an initial assessment of their service compared with a selection of quality statements. It includes assessing current practice, recording an action plan and monitoring quality improvement.

Using other national guidance and policy documents

Other national guidance and current policy documents have been referenced during the development of this quality standard. It is important that the quality standard is considered alongside the documents listed in development sources.

Diversity, equality and language

During the development of this quality standard, equality issues have been considered and equality assessments for this quality standard are available.

Good communication between health, public health and social care practitioners and people with healthcare-associated infections, and their carers (if appropriate), is essential. Treatment, care and support, and the information given about it, should be both age-appropriate and culturally appropriate. It should also be accessible to people with additional needs such as physical, sensory or learning disabilities, and to people who do not speak or read English. People with healthcare-associated infections in hospitals, and their carers (if appropriate), should have access to an interpreter or advocate if needed.

Commissioners and providers should aim to achieve the quality standard in their local context, in light of their duties to have due regard to the need to eliminate unlawful discrimination, advance equality of opportunity and foster good relations. Nothing in this quality standard should be interpreted in a way that would be inconsistent with compliance with those duties.

Development sources

Further explanation of the methodology used can be found in the quality standards process guide.

Evidence sources

The documents below contain recommendations from NICE guidance or other NICE-accredited recommendations that were used by the Quality Standards Advisory Committee to develop the quality standard statements and measures.

Healthcare-associated infections: prevention and control. NICE guideline PH36 (2011)

Policy context

It is important that the quality standard is considered alongside current policy documents, including:

- Department of Health. The Health and Social Care Act 2008: code of practice on the prevention and control of infections and related guidance (2015)
- Department of Health. Infection control in the built environment: Health Building Note 00-09 (2013)
- Health Protection Agency. Healthcare-associated infection: operational guidance and standards for health protection units (2012)

Quality Standards Advisory Committee and NICE project team

Quality Standards Advisory Committee

This quality standard has been developed by Quality Standards Advisory Committee 4. Membership of this committee during the period the quality standard was produced included:

Miss Alison Allam
Lay member

Dr Harry Allen
Consultant Old Age Psychiatrist, Manchester Mental Health and Social Care Trust

Mrs Moyra Amess
Associate Director, Assurance and Accreditation, CASPE Health Knowledge Systems

Dr Jo Bibby
Director of Strategy, The Health Foundation

Mrs Jane Bradshaw
Neurology Nurse Consultant, Nationwide

Mr Derek Cruickshank
Consultant Gynaecological Oncologist/Chief of Service, South Tees NHS Foundation Trust

Dr Allison Duggal
Consultant in Public Health, Public Health England

Dr Nadim Fazlani
Chair, Liverpool Clinical Commissioning Group

Mr Tim Fielding
Consultant in Public Health, North Lincolnshire Council

Mrs Frances Garraghan
Lead Pharmacist Antimicrobials, Central Manchester Foundation Trust

Mrs Zoe Goodacre
Network Manager, South Wales Critical Care Network

Ms Nicola Hobbs
Assistant Director of Quality and Contracting, Northamptonshire County Council

Mr Roger Hughes
Lay member

Ms Jane Ingham
Chief Executive Officer, Healthcare Quality Improvement Partnership

Mr John Jolly
Chief Executive Officer, Blenheim Community Drug Project, London

Dr Asma Khalil
Consultant in Maternal and Fetal Medicine and Obstetrics, St George's Medical School

Professor Damien Longson (Chair)
Consultant Liaison Psychiatrist, Manchester Mental Health and Social Care Trust

Mrs Annette Marshall
Independent Patient Safety Nurse, Palladium Patient Safety

Dr Rubin Minhas
GP Principal, Oakfield Health Centre, Kent

Mrs Julie Rigby
Quality Improvement Programme Lead, Strategic Clinical Networks, NHS England

Mr Alaster Rutherford
Primary Care Pharmacist, NHS Bath and North East Somerset

Mr Michael Varrow
Information and Intelligence Business Partner, Essex County Council

Mr John Walker

About this quality standard

NICE quality standards describe high-priority areas for quality improvement in a defined care or service area. Each standard consists of a prioritised set of specific, concise and measurable statements. NICE quality standards draw on existing NICE or NICE-accredited guidance that provides an underpinning, comprehensive set of recommendations, and are designed to support the measurement of improvement.

Expected levels of achievement for quality measures are not specified. Quality standards are intended to drive up the quality of care, and so achievement levels of 100% should be aspired to (or 0% if the quality statement states that something should not be done). However, this may not always be appropriate in practice. Taking account of safety, shared decision-making, choice and professional judgement, desired levels of achievement should be defined locally.

Information about how NICE quality standards are developed is available from the NICE website.

See our webpage on quality standard advisory committees for details of standing committee members who advised on this quality standard. Information about the topic experts invited to join the standing members is available from the webpage for this quality standard.

This quality standard has been included in the NICE Pathway on prevention and control of healthcare-associated infections, which brings together everything we have said on a topic in an interactive flowchart.

NICE has produced a quality standard service improvement template to help providers make an initial assessment of their service compared with a selection of quality statements. This tool is updated monthly to include new quality standards.

NICE produces guidance, standards and information on commissioning and providing high-quality healthcare, social care, and public health services. We have agreements to provide certain NICE services to Wales, Scotland and Northern Ireland. Decisions on how NICE guidance and other products apply in those countries are made by ministers in the Welsh government, Scottish government, and Northern Ireland Executive. NICE guidance or other products may include references to organisations or people responsible for commissioning

or providing care that may be relevant only to England.

ISBN: 978-1-4731-1665-8

Endorsing organisation

This quality standard has been endorsed by Department of Health and Social Care, as required by the Health and Social Care Act (2012)

Supporting organisations

Many organisations share NICE's commitment to quality improvement using evidence-based guidance. The following supporting organisations have recognised the benefit of the quality standard in improving care for patients, carers, service users and members of the public. They have agreed to work with NICE to ensure that those commissioning or providing services are made aware of and encouraged to use the quality standard.

- British Kidney Patient Association
- British Association of Dermatologists (BAD)
- UK Clinical Pharmacy Association (UKCPA)
- MRSA Action UK
- College of General Dentistry

NHS GREATER GLASGOW & CLYDE

STANDARD OPERATING PROCEDURE (SOP)

FOR MINIMISING THE RISK OF *Pseudomonas aeruginosa* INFECTION FROM WATER

Applicable in all adult and paediatric intensive care units and neonatal units (Levels 1, 2 and 3)

Effective from: May 2018 Review date: May 2019 Version: 3

This SOP applies to all staff employed by NHS Greater Glasgow & Clyde and locum staff on fixed term contracts and volunteer staff.

SOP Objective

To minimise the risk of *Pseudomonas aeruginosa* infection in healthcare premises from water.

Key changes from previous version :

1. Additional comment re cleaning of humification tanks Appendix 1
2. Change from water sampling in all high risk areas to 'Those high risk areas in NHS GGC which have flow straighteners on water outlets in patient areas' on page 4 and page 10
3. Revised PA audit / checklist

Document Control Summary

Approved by and date	Board Infection Control Committee, NHS GGC Board Water Safety Group, NHS GGC

Draft 2018

NHS GREATER GLASGOW & CLYDE
STANDARD OPERATING PROCEDURE (SOP)
FOR MINIMISING THE RISK OF *Pseudomonas aeruginosa* INFECTION FROM WATER
Applicable in all adult and paediatric intensive care units and neonatal units (Levels 1, 2 and 3)
Effective from: May 2018 Review date: May 2019 Version: 3

Contents

Draft 2018

Introduction

This SOP provides direction and guidance for ward based staff to meet their responsibilities as stated in *HPS(2017) Guidance for neonatal units (NNUs) (levels 1,2&3), adult and paediatric intensive care units (ICUs) in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water.* This document refers to critical control points 2 – 4 (inclusive) only. (Critical points 1, 5 and 6 are considered in the NHSGGC Water Safety Policy and Written Scheme 2016).

All wards / departments listed in the risk assessment for additional control measures to minimise the risk of *Pseudomonas aeruginosa* infection from water should be included in this guidance.

1. Responsibilities

Senior Charge Nurses (SCNs) must:

- Follow this SOP.
- Undertake flushing of taps on clinical hand wash basins in clinical areas on days when the Facilities exception reports highlight that daily cleaning of those sinks has not been possible.
- Keep records of flushing of these taps for at least one month.
- Inform a member of the local Estates Team if this SOP cannot be followed in relation to flushing water outlets.
- Inform a member of the local Estates Team of infrequently used outlets which could be removed.
- Allow members of the local Estates Team access to complete maintenance as appropriate.

Estates must:

- Undertake actions deemed the responsibility of the local Estates Department as per the Water Safety Policy and Written Scheme.
- Keep a record of outlets reported that are deemed to be infrequently used and actions taken by them to remove this risk.
- Provide a report of maintenance actions and issues/ anomalies to the Sector Water Safety Group.
- Support staff locally to undertake their responsibilities in terms of reducing risk associated with pseudomonas.

Managers must:

- Make this SOP available to their staff.
- Support SCNs in following this SOP.

Board Water Systems Safety Group must:

- Keep this SOP up-to-date.
- Audit compliance with this SOP.
- Provide guidance via the Water Systems Safety Policy.

Draft 2018

2. Critical Point 2: Flushing Water Outlets to reduce the risk of Pipework System Contamination

Flushing of water outlets is necessary to control the build-up of biofilm in water systems to reduce the risk of transmission of pathogens via the environment and equipment to patients.

The Senior Charge Nurse (SCN) in each unit has responsibility (under current guidance) to ensure that the following recommendations are complied with in their area. The SCN should ensure that:

1.1 All water outlets are flushed in high-risk environments (patient areas and areas where clinical procedures are prepared or performed) daily, first thing in am for 1 minute at full flow (but not so that splashing goes beyond the basin). This must be recorded. In practice this will be assigned to the Facilities department as part of the local cleaning schedule. Where this has not been possible e.g. access issues, then the flushing will be carried out by the SCN and a record kept (See Appendix 2).

1.2 Any problems or concerns relating to the safety, maintenance, reduced usage, any changes in use and cleanliness of all water outlets must be identified and reported to the ICT and the Estates Department as relevant.

3. Critical Points 3 -4

The check list at **Appendix 1** should be used by the SCN as a guide and assessment tool to provide assurance that risks from contamination by *P. aeruginosa* are managed as far as possible by ward staff in high risk areas.

Where units do not meet the guidance, an action plan should be developed to remedy any risks identified through this process.

Those high risk areas in NHS GGC which have flow straighteners on water outlets in patient areas, will be subject to 6 monthly water sampling for PA as per regime outlined in **Appendix 3**

Draft 2018

4. Critical Control Point 5: Surveillance and preparedness

IPCTs will:

- Include *Pseudomonas aeruginosa* from blood culture as an alert organism from all in-patient areas and from all specimens from ICUs, NICUs, PICUs and transplant units.
- Liaise with microbiology if further water testing required (e.g. suspected / confirmed outbreak)

Clinical Managers will:

- Support IPCT to undertake an assessment of the patients and ward
- Have a contingency plan for NICUs, PICU and ICUs to continue safe patient care without use of tap water, if identified as a source.

5. Critical Control Point 6: Investigation and control measures for clinical incidents

Where alert surveillance identifies *Pseudomonas aeruginosa* bacteraemia in one of the adult high risk areas, or in any specimen from NICUs and PICU, the IPCT will undertake immediate assessment to determine if this is healthcare associated. Consideration should be given to: previous colonisation / infection with PA; review of patient's care; possible reservoirs in the clinical area and all relevant microbiology results. The following action should be undertaken:

1 isolate of PA in a high risk unit: The IPCT will undertake an audit using the PA Ward Audit Checklist (Appendix 1). If no issues, then no further action. If actions required , liaison with SCN to support remedial action. Summarise actions in SBAR for IPCT and SCN.

2 isolates of PA in 2 patients in 2 weeks
The IPCT will undertake an audit using the PA Ward Audit Checklist (Appendix 1). An incident meeting will be arranged with IPCT, clinical team and relevant staff, including estates and or microbiology to agree investigation and action required. Minutes should be kept and the incident summarised in an SBAR for IPCT and Sector Management Team.

Draft 2018

Appendix 1: PA Ward Audit Checklist / Assessment Tool:

Critical Control Point 3: Preventing Direct Water Usage Colonising / Infecting Vulnerable Patients		**Requirement met Yes/No**	**Actions required/ completed**
1.1	**Washing Babies and high risk patients:** Patients are washed (inc. face, body wash, top & tail, bed bath, nappy change and immersion bath) using clean, fresh tap water/ commercial wipes.		
1.2	**Defrosting Breast Milk:** Breast milk is defrosted either: • in a designated milk fridge • outside fridge at room temperature OR • using a warming/ defrosting device designed to ensure no direct contact with the bottle/ syringe with non-sterile water. • Using sterile water warmed in a warming cabinet NB: Discard any milk not used once defrosted DO NOT USE WARM TAP WATER		
1.3	**Warming Breast/ Formula Milk:** • Milk is taken out of fridge one hour prior to use OR • Milk is warmed using a warming device designed to ensure no direct contact with the bottle/ syringe with non-sterile water. • Use warmed (in warming cabinet), sterile water		
1.4	**Use of Ice:** • Ice is not used for direct baby care in NNUs (all levels). • Ice for consumption by severely immunocompromised patients should be made with sterile water and not taken from an ice machine.		

Draft 2018

Critical Control Point 4: Preventing Indirect Contact with *P. aeruginosa* from Colonised/ Infected Patients		**Requirement met Yes/No**	
2.1	**Hand Wash Stations:** • Clinical hand wash sinks are used for hand washing only. • Clinical Hand wash sinks are cleaned at least daily as per National Cleaning Specification. • Hand hygiene product bottles are never topped up • Hand hygiene should be undertaken as per National Infection Prevention and Control Manual (NIPCM)		
2.2	**Aseptic Procedures:** • Aseptic procedures are prepared and/ or performed in an area where there are no concurrent procedures being undertaken that generate splashing which could contaminate a sterile surface. • Decontaminate all aseptic procedure surfaces with a detergent or alcohol wipe		
2.3	**Aerosol Generating Procedures:** Existing guidance in the NIPCM for aerosol generating procedures is followed.		
2.4	**Discarding Potentially Contaminated water/ fluids:** • Small volumes of fluid, e.g. ET/ ventilator condensate, are discarded into clinical waste bags. • Larger volumes, e.g. bath water etc, are safely transported to a sink (not a hand wash sink) or sluice.		

Draft 2018

Critical Control Point 4: Preventing Indirect Contact with *P. aeruginosa* from Colonised/ Infected Patients		**Requirement met Yes/No**	
2.5	**Suction/ Chest Drain Bottles:** Disposable suction container liners are sealed and discarded in a suitable container or solidifying gel is used prior to discarding in healthcare waste.		
2.6	**Equipment Decontamination: Incubators** All re-usable equipment is thoroughly dried including mattress and all other parts, following decontamination.		
2.7	**Humidifiers:** • Humidifiers on incubators: Only sterile or distilled water is used to fill and top up. • Re-usable humidifiers are decontaminated in a Central Decontamination unit (CDU). If not able to withstand reprocessing in a CDU, then manufacturer's instructions must be followed.		
2.8	**Storage of Equipment:** Patient equipment is not stored where they may be exposed to splash contamination.		
2.9	**Non-Clinical Procedures that create a spray:** • No fluid containers are topped up • Spray bottles are not used for cleaning solutions. • Spray bottles are not used in areas where aseptic procedures are being prepared or are ongoing. • Avoid use of spray bottles where possible		

Draft 2018

Appendix 2: Example of Flushing Record for high risk areas

DAILY FLUSHING OF WATER OUTLETS

ROOM NUMBER/ BED SPACE	DATE	SIGNATURE

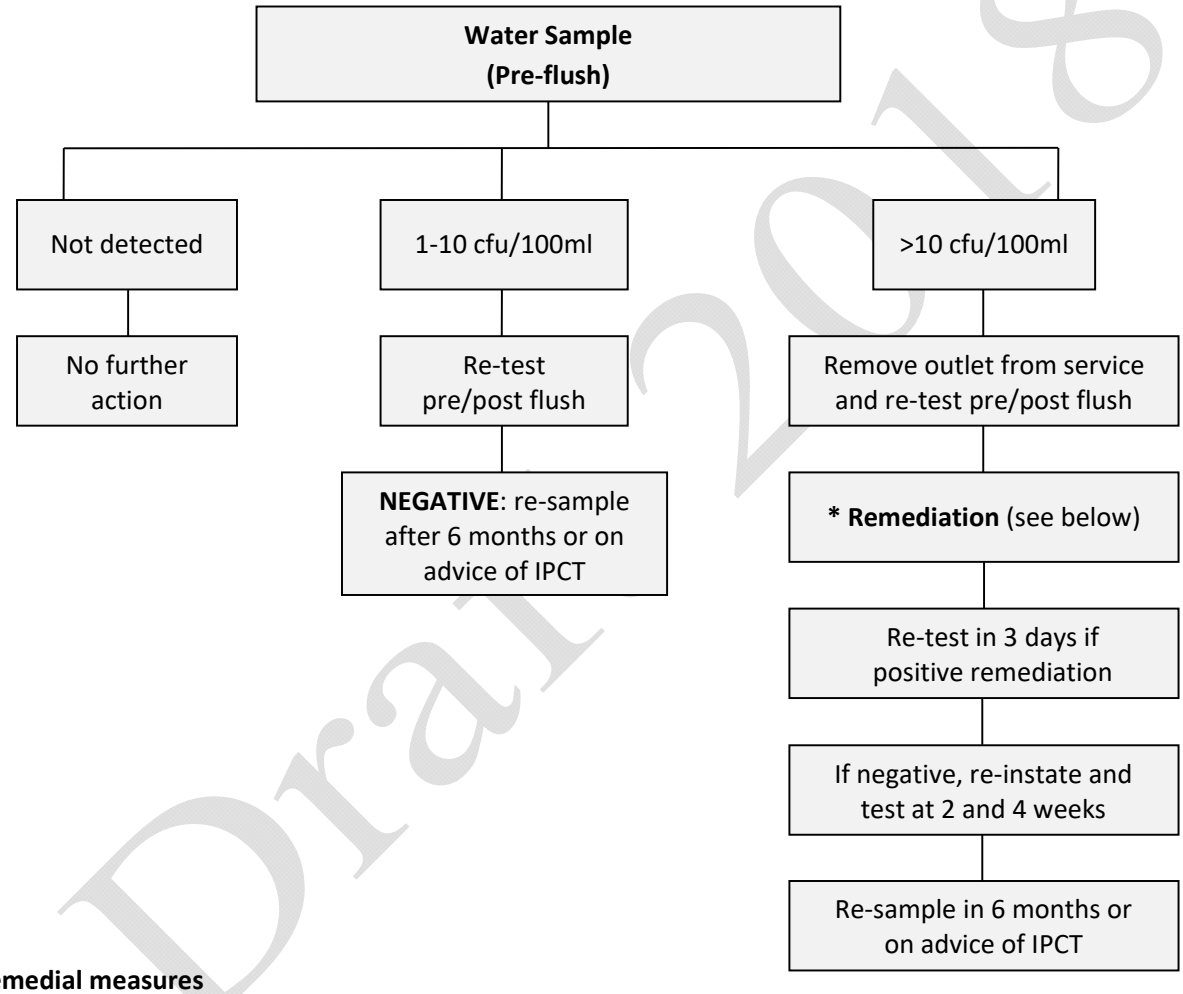
Draft 2018

Appendix 3: Water testing protocol for Pseudomonas aeruginosa in NICU

High risk areas whose water outlets in patient areas have flow straighteners should be sampled 6-monthly

Water outlets which should be sampled include those with supply water that have:

- direct contact with patients
- used to wash staff hands before and after clinical procedures
- used to clean equipment that will have contact with patients



Draft 2018

*** Remedial measures**

Consider the following:

- Continue daily flushing while out of use
- If practical consider removal of flow straighteners
- Hand washing should be supplemented by the use of alcohol gel
- Check unit for little-used outlets and if possible remove
- Check pipework for deadlegs and blind ends

- Consider disinfection e.g. chlorine dioxide
- Consider replacement taps
- Ensure best practice in relation to handwash basins
- Use bottled water for baby bathing until re-test –ve

Interpreting pre and post flush counts
High counts pre-flush (> 10 cfu/100ml) and low post flush (<10cfu/100ml) suggests local water outlet problem.

High count pre and post flush (> 10cfu/100ml) suggests wider problem with the water supply. In this situation most outlets are likely to be positive and other points in the water system should be sampled.

This year sees the bicentennial anniversary of the birth of Florence Nightingale and has been designated the International Year of the Nurse and Midwife by the World Health Organization (WHO) and the International Council of Nurses in support of the Burdett Trust's Nursing Now campaign which culminates at the end of 2020. The campaign aims to increase the profile and influence of nurses globally, emphasising the central role they have in helping to deliver the sustainable development goal of universal health coverage globally.

Florence Nightingale was born in 1820, and during her 90-year lifetime, she made an outstanding contribution to nursing, public health and the design and management of hospitals. In two articles about Florence Nightingale, Bill Newsom suggested that three of her books, *Notes on Hospitals* (1859 and 1863), *Notes on Nursing* (1860) and *Introductory Notes on Lying-in Institutions* (1871), had an enduring influence on infection control (Newsom, 2003a, 2003b). More recently, the popular romantic perspective of Florence Nightingale as the "lady with the lamp" has come under critical scrutiny. She was by all accounts a difficult person to get along with, and her privileged upbringing lead to difficult relationships with medical staff and other nursing contingents in the Crimea (Small, 2017; Williams, 2008).

However, it is apparent from the many biographies that chart her life that Florence Nightingale possessed qualities and skills that remain highly relevant to nursing roles globally. Her observation and organisation skills; a commitment to the fundamental requirements of those with health needs; a recognition of the power of collecting, analysing and using data to illustrate the need for change; and her ability to engage politicians, scientific collaborators and the media to influence opinion and change are all qualities that are critical to infection prevention and control practitioners of today.

Importance of fundamental elements of care

In January 2019, the UK Government published "Contained and controlled: The UK's 20-year vision for antimicrobial resistance" and a "5-year national action plan to combat antimicrobial resistance 2019–2024" (Department of Health, 2019a, 2019b). Both continued to advocate the centrality of infection prevention as a means of minimising antimicrobial resistance (AMR) and preserving our ability to treat infection with available antimicrobials. Infection-prevention interventions are largely focused on taking the opportunity to avert the transmission of an infectious agent from a reservoir to a susceptible host. The factors that lead to a person becoming a susceptible host are legion, but globally the socio-economic deprivation experienced by sectors of the population in low-, middle- and high-income countries is among the most frequent. In Europe, there is evidence that in the 10 years since the global financial crisis, health inequalities play a role in the transmission of infection and infectious disease (European Centre for Disease Prevention and Control, 2013) and were exacerbated by cuts in public spending on public health and healthcare provision. Wilson (2018) suggested that the marked regional variation in *Escherichia coli* bloodstream infections may be due to a range of socio-economic factors, including reductions in social-care spending.

Florence Nightingale was a follower of Edwin Chadwick, a pioneer of public-health legislation. Her experience as a volunteer at the Middlesex Hospital in London during the Cholera outbreak in 1854 convinced her that the medical interventions of the day hastened the death of patients. Nightingale's assessment of the situation on her arrival at the army hospital in Scutari was influenced by her belief that good nursing was based on ensuring that patients were well fed, hydrated, clean, warm and comfortable; sharing wash cloths was discontinued, and the cleanliness of the environment was prioritised.

Over the past five years, nursing and infection-prevention practitioners have refocused on the importance of

fundamental aspects of care such as early mobilisation (Stolbrink et al, 2014), adequate hydration (Wilson et al, 2018), nutrition (Fitzpatrick et al, 2019) and oral care (El-Rabbany et al, 2015) as being central to improving patient outcome and minimising the risk of healthcare-associated infection.

The "passionate statistician"

Florence Nightingale had the advantage of a liberal education that included mathematics, for which she showed a particular aptitude. Her use of data to drive sanitary reform in the army and later the wider public-health agenda (Kopf, 1916) resulted in her being elected as a Fellow of the Royal Statistical Society in 1858. Florence was influenced by the statistical methods and ideas of the Belgian astronomer, meteorologist and social statistician Adolphe Quetelet; throughout her early life and nursing experience in Europe and England, she collected reports, pamphlets and returns which she analysed and reported. On her return from the Crimea, Florence collaborated with William Farr, one of the foremost statisticians of the era, to analyse data provided by the army in addition to that she had collected herself. While she was aware of the high death rate at the hospital in Scutari, she had attributed it to poor nutrition, suboptimal treatment and delayed transfer to hospital from the battlefront. It was only when Farr helped her to analyse the data that she realised that more lives could have been saved if she had had a greater focus on basic sanitation. One of Nightingale's first books, *Notes on Matters Affecting Health, Efficiency, and Hospital Administration of the British Army* (1858), used statistical methods to compare the death rates of the army in peacetime with the civilian rate. Together with Farr, she showed that mortality was due to hospital conditions and concluded that "our soldiers are enlisted to die in barracks".

The National Action Plan (Department of Health, 2019b) includes the use of the WHO core components for effective infection prevention and control (IPC; Storr et al, 2017). Core component 4 focuses on healthcare-associated infections (HAI) surveillance and makes recommendations for local and national IPC surveillance. A strong recommendation (based on very low-quality evidence) indicates that local HAI and AMR surveillance and feedback to staff should be used to guide IPC interventions and detect outbreaks. Nationally, the recommendation is that national HAI surveillance programmes and feedback networks that can provide benchmarking should be established. The Public Health England Fingertips Database (Johnson et al, 2017) provides the above, but its use in driving improvement locally is yet to be evaluated. Driving improvement also requires robust design, observation and measurement skills to demonstrate and report the difference that improvement programmes have been effective. Mary Dixon-Woods (2019) comments on the lack of robust evaluation that underpins many of the improvement efforts that are undertaken in health care, and suggests that many quality-improvement initiatives are "pervaded by optimism bias. It is particularly affected by the 'lovely baby' syndrome, which happens when formal evaluation is eschewed because something looks so good that it is assumed it must work."

This links back to Nightingale's initial assumptions that delivering "clean care" (the lovely baby) would make a difference to the outcomes for soldiers nursed at Scutari when in fact they made very little difference, as she was later to realise through her analysis of the data.

Nightingale as an influencer

Florence Nightingale was an astute and perhaps manipulative influencer, having been born into a wealthy and well-connected family (Williams, 2008). The Nightingale family had three residences during the year, one in Derbyshire (Lea Hurst) where they spent the summer and early autumn, one in the New Forest (Embley) where they spent the winter, and from March to June, they were in London at the Burlington Hotel for the season. At Embley, their nearest neighbour was Lord Palmerston who held the offices of Foreign Secretary, Home Secretary and Prime Minister during his political career. Another close neighbour was Sidney Herbert who as Secretary at War was instrumental in sending Florence to the Crimea. Florence also became a media darling during and after her period at Scutari. She was a prolific writer of letters, and her sister Parthe ensured that Florence's observations were publicised in *The Times* and elsewhere. Public opinion was significantly altered by Nightingale's time in the Crimea and resulted in donations to fund the training of hospital nurses (Small, 2017).

Influencing the healthcare agenda is a political activity; Nightingale recognised this and used her connections to her advantage. Engaging with politicians and policymakers is essential if IPC practitioners are to drive change at a national and global level. The new UK AMR strategy (Department of Health, 2019a) continues to highlight the central importance of preventing infection. This provides a golden opportunity for practitioners to make clear the priorities for strengthening the evidence base for IPC and how the service is delivered across primary care, community and acute settings. This requires engagement with politicians and policymakers at a local and national level; building strong coalitions and collaborative partnerships with other professional societies creates a coherent and powerful voice for the issues that need to be addressed. These coalitions should be integrally involved in deciding on the optimal design of an IPC service and the knowledge and skills required in the workforce to prevent and address the socio-economic drivers of infection. The power of publication is obvious; Nightingale's obsession with data and its dissemination to influence change is something that IPC

practitioners should pursue. The *Journal of Infection Prevention* provides one outlet for sharing research findings and the outcome of improvement strategies with colleagues and those who make decisions about infection prevention policy. Finally, in the International Year of the Nurse and Midwife and 200th anniversary of Florence Nightingale's birth, we should not be afraid to "speak truth to power" in the pursuit of high-quality and safe care.

Foreword

Extensive experience shows that poor design and management of water systems in buildings can cause outbreaks of disease. The types of building, water uses, disease outcomes and individuals affected are diverse. The health risks are preventable and can be readily controlled. However, evidence from outbreak detection suggests that the overall trend is increasing. With increasing global urbanization, the overall exposure of the human population to poorly designed or managed water systems in buildings is increasing rapidly. Consequently, the risk of disease outbreaks is also increasing. Actions to reduce the risk of disease should be considered a public health priority.

One of the challenges is that management of building water supplies is often overlooked. In many countries and regions, management actions for water supplies in buildings may fall outside the responsibility of the drinking-water supplier. This can be influenced by a range of factors, including ownership of assets and rights of access. Water safety plans (WSPs) for managing public water supplies are not typically extended to apply within buildings. In many cases, owners, managers or maintenance personnel are responsible for management of building water supplies, but awareness and application of drinking-water guidelines is often limited.

This text is one of series of supporting documents that provide guidance on implementing the World Health Organization (WHO) *Guidelines for drinking-water quality* (GDWQ) (WHO, 2008). It is intended to support improvement of water safety within buildings.

The third edition of the GDWQ (WHO, 2008) introduced the concept of WSPs within a *Framework for safe drinking-water* (see Figure 1.1 in the introduction, below). The framework focuses attention on effective preventive management and thereby disease prevention. The GDWQ include specific reference to issues associated with large buildings, such as health care facilities, schools and daycare centres, and recommend that these buildings have their own WSPs to ensure the maintenance of safe water supplies. The intention is that such building plans should complement the WSPs of water suppliers.

The issue of water safety in buildings and the need for additional guidance was identified as a priority at the meeting of government-nominated experts who finalized the third edition of the GDWQ. This led to the development of this document. The guidance provided in this document is based on the framework from the GDWQ (WHO, 2008), as well as other supporting texts, particularly those dealing with:

- *Guidelines for safe recreational water environments volume 2: swimming pools and similar environments* (WHO, 2006a)
- health aspects of plumbing (WHO/WPC, 2006)
- heterotrophic plate counts (Bartram et al., 2003)
- *Legionella* and the prevention of legionellosis (Bartram et al., 2007)
- pathogenic mycobacteria (Bartram et al., 2004).

The development of this document was guided by the recommendation of expert meetings hosted first in March 2005 (by the University of East Anglia, Norwich, United Kingdom),

then in December 2005 (by the WHO Collaborating Centre for Health Promoting Water Management and Risk Communication, Institute for Hygiene and Public Health, University of Bonn, Germany). These meetings were followed by meetings in February 2007 (by the Instituto Superiore di Sanita, Rome, Italy), in October 2007 (by the Scottish Executive, Edinburgh, Scotland), and finally in July 2008 (by the Federal Ministry of Health in Berlin, Germany). The development of this document was also guided by a series of critical reviews by specialists in the field.

The Department of Public Health and Environment (Programme on Water, Sanitation, Hygiene and Health, WHO) led the production of this document.

This document is written for the full range of "actors" who influence the overall safe management of building water supplies. In particular, it is directed to those who design, construct, manage, operate, maintain and regulate building water systems. It is intended to be a useful resource for the development of training and information material.

1 Introduction

This document deals with all buildings where people use or are exposed to water, with a particular focus on buildings that include public use or shared facilities. Many of the principles also apply to sole occupancy dwellings and homes; however, it is not expected that management actions, such as the implementation of water safety plans (WSPs), will be applied in private homes.

Vulnerable population groups may be particularly susceptible to water-related hazards, and certain types of building are therefore of special concern. Important examples include medical and other health-care environments where the growth of a range of opportunistic waterborne pathogens, such as *Pseudomonas aeruginosa*, non-tuberculous *Mycobacteria* and *Legionella*, is a significant health concern and can lead to substantial and avoidable costs.

Outbreaks have been associated with both microbial and chemical contamination. A significant proportion of such waterborne disease is associated with contamination within buildings. This can arise from:

- direct contamination through faults in water systems (e.g. bird and small animal droppings into storage tanks) or leaching from inappropriate materials or corrosion (e.g. copper, lead, nickel, cadmium);
- indirect contamination through cross-connections between drinking-water systems and contaminated water or chemical storages;
- growth of indigenous microbes (e.g. *Pseudomonas aeruginosa*, non-tuberculous *Mycobacteria* and legionellae).

Guidance is provided for managing water supplies in buildings where people may drink water; use water for food preparation, washing, showering, swimming or other recreational activities; or be exposed to aerosols produced by water-using devices, such as cooling towers. These uses occur in a variety of buildings, such as hospitals, schools, child-care and aged-care facilities, medical and dental facilities, hotels, apartment blocks, sport centres, commercial buildings and transport terminals.

Although the focus of this document is managing water supplies within buildings, microbial and chemical hazards may sometimes also be introduced from water delivered to buildings from external sources.

The inadequate management of water in buildings has considerable health effects, as well as significant direct and indirect economic and social impacts. The World Health Organization (WHO) has identified that the benefits of all interventions to reduce risks from unsafe water outweigh costs by substantial margins (Hutton & Haller, 2004). In health-care settings, the costs of nosocomial infections, including those that are waterborne, are substantial and rising—in terms of both direct costs and reputational impacts (Anaissie et al., 2002). Travel and hotel stays are recognized as risk factors for legionellosis (Bartram et al., 2007). In Europe, approximately 20% of detected legionellosis cases are considered to be travel associated (Joseph, 2002; Bartram et al., 2007). Cases of legionellosis in

hotels have often received extensive and damaging publicity, with significant economic impacts due to reduced patronage.

The document does not deal with the management or protection of water resources, or the use of recycled water. Further detail on these aspects is provided in the supporting text, *Protecting groundwater for health* (Schmoll et al., 2006), the *Guidelines for safe use of wastewater, excreta and greywater* (WHO, 2006b) and a forthcoming text on surface water.

The guidance provided in this document is based on the *Framework for safe drinking-water*, from the WHO *Guidelines for drinking-water quality* (WHO, 2008). The framework is shown in Figure 1.1.

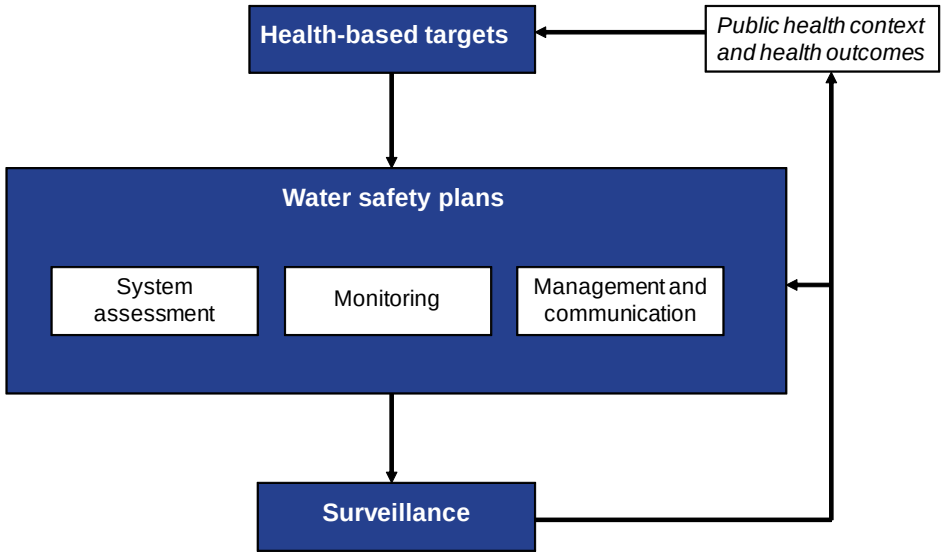

Figure 1.1 Framework for safe drinking-water

This document is divided into four sections:

- **Section 2** is made up of short introductions with principles that describe the core issues of water safety in buildings. It is organized into subsections that address hazards and risks, people and building types.
- **Section 3** deals with the role and responsibilities of stakeholders who influence the safety of water systems within buildings. Stakeholders can be involved in the planning, design, construction and renovation of buildings, as well as development of WSPs, and ongoing maintenance and operation of water systems.

- **Section 4** describes the steps in developing and implementing WSPs, and provides examples on how those key principles can be applied to buildings. This section is organized into subsections explaining how to assemble teams; understand the water system; identify hazards and assess risks; put in place control measures, operational monitoring and management procedures; and establish verification and supporting programmes.
- **Section 5** deals with the environment that supports the delivery of safe water within buildings but does not affect water quality directly. This section is organized into subsections addressing independent technical inspection and surveillance, disease surveillance and detection of outbreaks, regulatory and policy frameworks, and capacity building and training.

2 What are the issues?

This section describes the issues that confront engineers and planners when planning and implementing water safety plans (WSPs). It discusses water-system design, hazards and risk assessment, the end-users and building type.

2.1 Background

The World Health Organization (WHO) *Guidelines for drinking-water quality* (GDWQ) (WHO, 2008) describe a quality of water that is safe for a lifetime of consumption. The focus of the guidelines is the *Framework for safe drinking-water*, incorporating WSPs. This framework is applicable to all drinking-water systems, ranging from those serving the largest of cities to the smallest non-piped and household supplies. The framework is also applicable to delivery of drinking-water within buildings.

2.1.1 Purpose of WSPs

WSPs are the most effective means of consistently ensuring the safety of drinking-water supplies through a comprehensive risk-management approach that encompasses all steps, from source through treatment and distribution to consumers. The WSP approach is based on identifying all significant risks to public health, ensuring that effective controls and barriers are applied to minimize these risks to acceptable levels, and monitoring the operation of the controls and barriers to ensure that safety is maintained.

Application of WSPs and good management by those responsible for drinking-water production and distribution can assure drinking-water safety. However, management of building water systems can be complicated by a number of factors, including ownership of assets and rights of access that change on building property boundaries. Drinking-water systems in buildings are generally designed, installed and controlled independently from public water supplies. This contributes to buildings representing specific environments with specific hazards and hazardous events. Other complicating factors include:

- designated uses of buildings (e.g. hospitals, medical centres, residential care);
- use of supplementary water supplies, such as roof rainwater, greywater and water from private supplies (e.g. wells, bores and springs);
- supplementary point-of-entry treatment for water supplied from public systems;
- connection of drinking-water systems with water-using devices, such as cooling towers, evaporative condensers, boilers, swimming pools, washing machines, dishwashers, dental chairs, medical devices and industrial equipment;
- the vulnerabilities of people using buildings (e.g. in hospitals and aged-care facilities);
- the potential for multiple owners and shared assets, particularly in larger buildings.

In addition, buildings can have complex plumbing systems with at least two distinct systems for drinking-water and wastewater (sewage and greywater). In some buildings, a

third system might be installed to distribute recycled water (treated sewage or greywater) for uses such as toilet flushing. The drinking-water system is typically divided into two sections providing hot and cold water, and large buildings may incorporate a separate section conveying water for firefighting.

2.1.2 Factors that affect WSP operation

One of the consequences of the separation of ownership and oversight has been a tendency for water safety in buildings to be overlooked, or at best receive limited attention. While public water supplies are generally maintained by water utilities or agencies with particular expertise, this is often not the case with water supplies within buildings. A general perception can be that water systems in buildings connected to public supplies are safe, ignoring the potential for contamination (both chemical and microbial) and growth of waterborne opportunistic pathogens within the building water systems. This also applies to devices (e.g. cooling towers, boilers, washing machines, swimming pools, hot tub pools) and equipment. Water systems are often managed by general maintenance staff with little training or expertise in managing water quality. Regulatory authorities often establish working relationships and provide oversight of public water supplies, but this is more challenging with building managers. There may be a limited number of public water suppliers in urban areas, but many thousands of independently owned buildings.

As a result, there are many examples where faults within buildings have led to outbreaks of drinking-water-derived disease (Kuroki et al., 1996; CDC, 1997a; Blackburn et al., 2004; Robert Koch Institute, 2004; Yoder et al., 2004, 2008ab; Djiuban et al., 2006; Liang et al., 2006; Vianelli et al., 2006). These have included diverse outcomes such as outbreaks of gastrointestinal disease associated with contamination of drinking-water by *Cryptosporidium* and *Cyclospora*, legionellosis (Legionnaires' disease) associated with hot and cold water systems and cooling towers, and methaemoglobinemia from boiler fluid contamination of drinking-water. Aesthetic issues, such as taste and odours, can be caused by water stagnation and through back-siphonage from flexible hoses connected to devices such as washing machines and ice machines. Turbidity and colour can be caused by corrosion or resuspension of biofilms and sediments from storage tanks and hot-water tanks.

A common theme associated with outbreaks has been poor management of building water systems. Outbreaks can be prevented through design and application of WSPs. WSPs should deal with all sources of water, including community and private supplies (e.g. roof rainwater or groundwater) and should consider the characteristics and quality of the available sources. This includes determining whether community supplies have established WSPs. Building WSPs should be complementary to any existing plans developed by operators of community supplies. In these circumstances, drinking-water suppliers should provide assistance and information to building owners and managers responsible for developing WSPs.

Public health and regulatory authorities should provide guidance on development and implementation of WSPs. These authorities should also undertake surveillance to ensure that WSPs are operating effectively (see section 4).

2.2 System design

The basic requirements for establishing effective WSPs are good design and a sound knowledge of the physical characteristics of water systems. Water systems in buildings are often designed with limited attention to minimizing risks to public health. Retrofitting existing systems to improve management and safety is expensive. Every effort should be made in designing and constructing new systems to support the implementation of WSPs. This should include minimizing sources of hazards (e.g. stagnant water, long branch pipes and dead legs), as well as enabling access for monitoring and maintenance.

Knowledge of the characteristics of existing systems is often lacking, and in many cases there are no accurate, well-maintained maps of water systems. This is particularly true for large buildings and can be complicated in buildings that have been renovated or repaired. Pipework belonging to various networks (drinking-water, wastewater, recycled water, etc.) are often poorly labelled, which increases the likelihood of cross-connections and associated health risks. In addition, when problems arise, responses can be delayed by first having to map the system.

2.3 Hazard identification and risk assessment

Effective management of drinking-water systems in buildings requires a comprehensive understanding of the system, including the range of potential hazards, hazardous events and risks that may arise during delivery and use of water by occupants and visitors to buildings. It also requires an understanding of the quality and management of the water delivered to buildings. This can vary from high-quality, well-managed urban water supplies to poor-quality, intermittent community supplies or independent building-specific supplies.

2.3.1 Hazards

The GDWQ (WHO, 2008) describe a range of hazards that can threaten drinking-water supplies. All these hazards could enter buildings if present in external water supplies or could be introduced within buildings. Hazards include the following:

- **Enteric pathogens** (bacteria, viruses and protozoa) from faecal contamination can enter the system through faults in water supplies provided to buildings or within internal plumbing systems.
- **Environmental organisms** such as *Legionella* and *Pseudomonas* can grow in distribution systems and water-using devices, such as cooling towers and hot-tub pools. Growth is promoted by conditions such as low flow, stagnant water and warm water temperatures. In hospitals, a broader range of environmental bacteria and fungi such as *Acinetobacter* spp., *Aeromonas* spp., *Burkholderia cepacia* and *Aspergillus* have been identified as causes of nosocomial infection (Annaisie et al., 2002; Sehulster et al., 2004).
- **Chemicals** from external environmental, industrial and agricultural sources can enter the water-supply system. In addition, chemical hazards can be introduced from treatment processes, leached from unsuitable materials, or released from corrosion of pipework and fittings (e.g. copper, lead, cadmium and nickel) used in plumbing systems. Corrosion can be exacerbated by stagnation.

2.3.2 Hazardous events

Buildings represent specific independent environments that can include a wide range of conditions and situations (hazardous events), leading to the occurrence of hazards. The likelihood of hazardous events is influenced by the size and complexity of buildings and can be exacerbated by poor design, construction, operation and maintenance. These hazardous events include:

- poor flow and stagnation due to
  - poor design, including long branch pipes and dead ends
  - intermittent use or extended periods with no use (e.g. floors or wings of hotels with seasonal occupancy; schools during holidays);
- poor temperature control, including
  - inadequate heating capacity and poor design of hot-water systems, including long branch mains
  - elevated temperatures in cold-water systems due to proximity of hot-water systems and poor insulation;
- unsuitable materials used in plumbing
  - products that leach hazardous chemicals or support microbial growth
  - materials incompatible with the physical and chemical characteristics of water supplied to the building (leading to increased corrosion or scaling);
- open water-storage tanks allowing access of external contamination;
- cross-connections with independent water systems (e.g. roof rainwater), fire systems or recycled water systems, and inadequate backflow prevention from connected water-using devices (e.g. cooling towers, heat exchangers, boilers, washing machines, dishwashers) and liquid storages;
- poor management of water-using devices (e.g. cooling towers, drinking-water fountains, hot-tub pools and baths, swimming pools);
- poor management, maintenance and repair, exacerbated by inadequately mapped systems (e.g. schematic diagrams not updated following modifications) and poorly labelled pipework (e.g. distinguishing drinking-water, wastewater and recycled-water systems);
- unauthorized repairs and modifications (e.g. installation of point-of-use [PoU] devices such as carbon filters).

2.3.3 Risk assessment

Once potential hazards and hazardous events have been identified, the levels of risk need to be assessed so that priorities for risk management can be established. Risk assessments need to consider the likelihood and severity of hazards and hazardous events in the context of exposure (type, extent and frequency) and the vulnerability of those exposed.

Although many hazards may threaten water quality, not all will represent a high risk. The aim should be to distinguish between high and low risks so that attention can be focused on mitigating risks that are more likely to cause harm.

2.4 People who use buildings

Buildings represent specific environments and can provide specific services (e.g. hospitals, clinics, dental surgeries, aged-care facilities and schools). To determine the health risk associated with hazards from building water systems, it is necessary to consider:

- the vulnerability of people who work in, live in or visit the building
- the number of occupants and visitors
- the frequency and length of visits
- the types of water use and exposure.

2.4.1 Users of buildings

The types of people who use buildings will depend on the purpose of the buildings and services that are provided. Different groups can include:

- residents (e.g. of apartment blocks);
- long-term and short-term residents of hotels;
- hospital inpatients, outpatients and visitors;
- elderly residents in retirement complexes or aged-care facilities;
- dentists, doctors and nurses;
- patients at health-care centres and dental or medical clinics;
- visitors to museums, theatres, sports stadiums, shopping centres and garden centres;
- users of services (e.g. restaurants, food outlets and cafes);
- users of facilities (e.g. fitness centres, swimming pools, sporting clubs and leisure centres, ice rinks);
- workers in residential buildings;
- workers with particular exposures (e.g. lifeguards and swimming instructors);
- maintenance employees and contractors, particularly those with responsibilities relating to water systems and water-using devices;
- university and school students;
- very young children attending child-care facilities;
- prisoners.

2.4.2 Vulnerabilities

Those at greatest risk of waterborne disease are infants and young children, people who are immunocompromised, and the elderly. For most buildings, the health and vulnerability of users, visitors, residents and workers in buildings will be representative of the general population. However, some buildings will be used or visited by greater numbers of people who are more vulnerable to waterborne disease. These include very young children at child-care facilities and in hospitals; the elderly in retirement complexes or aged-care

facilities; patients attending doctors' surgeries; outpatients at hospitals and other health-care facilities; inpatients, particularly those who are immunocompromised (e.g. cancer patients); transplant patients; and those with acquired immunodeficiency syndrome. Patients with respiratory disorders may be more susceptible to waterborne organisms transmitted by inhalation (e.g. *Legionella* and mycobacteria).

Renal dialysis patients are vulnerable to microorganisms, endotoxins, toxins and chemical contaminants. This vulnerability was demonstrated in 1996 by the death of 50 patients after exposure to water contaminated by high levels of microcystin (Jochimsen et al., 1998; Pouria et al., 1998) and 10 patients from aluminium encephalopathy (Berend et al., 2001). In the latter case, a community desalinated water supply was used for dialysis without further treatment for a number of years. The deaths occurred when corroding ductile-iron pipes were coated with a cement mortar containing aluminium. Dialysis patients are also sensitive to chemical disinfectants used to disinfect drinking-water supplies (Ward, 1996; Davidovits et al., 2003; Hoenich, 2009).

Due to advances in medical care, the proportion of people in communities with greater susceptibility to disease is increasing, particularly in developed countries. Communities are ageing, and survival of cancer patients and transplant recipients is improving.

2.4.3 Exposure

Exposure will be influenced by the length of occupancy, the frequency and length of visits, the nature of the building and the type of user.

Length of exposure will range from permanent residents of apartment buildings to long-term employees and workers; regular attendees at universities, schools, fitness centres and swimming pools; long- and short-term hospital patients; occasional attendees at medical and dental surgeries; and occasional visitors to restaurants, hotels and museums.

The type and nature of exposure will vary. While consumption of drinking-water involves potentially the highest volume exposure, other transmission pathways need to be considered. Exposure could include direct ingestion of drinking-water or indirect consumption through food and beverages prepared at restaurants, food outlets, cafes, hotels and bed-and-breakfast facilities. Ingestion and contact with water could occur through normal bathing activities, as well as through the use of swimming pools, hydrotherapy pools and hot-tub pools. Aerosols from showers, hot- and cold-water outlets, hot-tub pools or cooling towers can be inhaled, as can disinfection by-products released into the air at indoor swimming centres. Aerosols can also be generated by decorative fountains, irrigation systems used in garden centres or misting devices used in food markets.

Exposure could be associated with equipment used in hospitals, such as humidifiers and nebulizers, or in dental surgeries.

Exposure could also occur though inappropriate uses of piped water supplies. For example, drinking-water supplies are generally not suitable without additional treatment to wash wounds and burns or to wash and rinse medical equipment. Water used for renal dialysis needs to be highly treated to ensure that it is microbially and chemically safe.

A48235836

2.5 Building types

Buildings can include specific environments that influence the level of risk associated with drinking-water systems. This can also be influenced by vulnerabilities of those who use and visit different types of buildings.

2.5.1 Large buildings

All buildings can represent sources of hazards and hazardous events. Large buildings can present particular challenges related to size and complexity. Drinking-water distribution systems in large buildings tend to be very long and complex, with many branch pipes. They can include large variations in flow, including very low flows at the end of long branches and dead legs. Plumbing systems are often poorly documented, particularly as buildings age and are modified or extended. Control over distribution systems in large buildings is also more difficult to maintain. Temporary or even extended periods of non-use of sections of buildings and associated plumbing systems are often poorly documented or managed.

Storage tanks can be used to maintain water pressure within the building (under-roof) or to provide buffering storage. The integrity of storage tanks needs to be maintained. In hot climates, the temperature of water—particularly in under-roof storage tanks—can increase and support the growth of environmental opportunistic pathogens.

Addition of PoU devices can occur without the knowledge of building management and maintenance staff. The potential for inadvertent cross-connections between drinking- and non-drinking- water systems increases in relation to the size and complexity of buildings. Large buildings are more likely to incorporate independent fire systems, which are prone to stagnation and the development of biofilms. Although they are generally supplied with mains water, these systems need to be kept independent through the installation of backflow-prevention devices. Ideally, fire systems should have a separate connection to the external mains water system.

The use of recycled water in large buildings is increasing; for example, greywater for toilet flushing (e.g. in environmentally friendly buildings). Recycled-water pipework and any accessible outlets should be marked to indicate that the water is not suitable for drinking. Where recycled-water systems are installed, there is a potential to lower flows and increase detention times in the drinking-water system due to reduced usage.

Large buildings are more likely to use evaporative condensers and cooling towers as part of air-conditioning systems and boilers to provide heating. Evaporative condensers and cooling towers can be sources of harmful microorganisms such as *Legionella*, while hazardous chemicals can be used to treat or condition boilers (e.g. nitrates and metaborate).

Particular types of large buildings include the following:

- **Educational facilities.** Schools, colleges, technical colleges, further education facilities and universities provide drinking-water for typical uses, as well as specialized uses in teaching and research laboratories and technical training facilities. Technical equipment using water and storages could present sources of hazards. Laboratories are also likely to include eye-wash stations and safety showers, which—like fire systems—are prone to stagnation and growth of biofilms unless flushed regularly.

Water use in educational facilities and associated buildings (residential, sport clubrooms, etc.) can be intermittent, with extended periods of stagnation possible, particularly during holidays.

- **Hotels.** Hotels can include recreational facilities such as swimming pools and hot-tub pools, and, in some cases, rooms can be provided with single-use hot-tub baths, which can be a source of environmental pathogens. Occupancy of hotels and other accommodation facilities can vary markedly depending on seasons; buildings, parts of buildings or floors may be closed during "off seasons". Associated water-using devices such as cooling towers and evaporative condensers may also be shut down for extended periods.
- **Conference centres.** Where accommodation is provided, these centres can include similar features to hotels.
- **Apartment blocks** (low rise and high rise)**.** Maintenance and management can be complicated by individual ownership or leasing of apartments. Risks in shared hot- and cold-water systems can be increased where individual apartments are used infrequently or remain empty for extended periods, and through connection of PoU treatment (e.g. carbon filters) and water-using devices such as washing machines and dishwashers, and by other modifications undertaken by tenants and apartment owners.
- **Office blocks.** Like apartment blocks, maintenance and management can be complicated by multiple ownership or tenancies.
- **Public buildings** (e.g. museums, art galleries, theatres and cinema complexes). A common concern with these buildings is maintaining hygiene and ensuring that drinking-water outlets are kept clean.
- **Shopping centres** can include decorative fountains, garden shops and fresh fruit and vegetable markets that use misting machines to keep produce fresh. These spray and mist devices produce aerosols that can disseminate organisms such as *Legionella* and *Mycobacterium* spp. if present. Centres can also include speciality shops such as hairdressing salons.
- **Factories, manufacturing industries and production centres.** These buildings can include storages of liquid chemicals and distribution systems that circulate water used for cooling or liquid coolants. Industrial buildings can include devices for worker safety, such as eye-wash stations and safety showers.
- **Transport terminals**. Transferring water at terminals to aeroplanes, ships, trains or buses needs to be managed to ensure that water safety is maintained. Specific guidance for aeroplanes and ships is provided in the WHO *Guide to hygiene and sanitation in aviation* (WHO, 2009) and the *WHO Guide to ship sanitation* (WHO, 2010). The hygiene and safety principles described in these guides should also be applied for trains and buses.

2.5.2 Hospitals

Hospitals can be very large buildings or complexes with extensive water systems. Due to the vulnerability of some patients, hospitals are more likely to provide additional treatment at the point of entry of external piped supplies. Common forms of treatment include filtration, disinfection, softeners and deionizers. Treatment is also likely where

A48235836

hospitals use private water supplies (e.g. wells, bores). These processes can represent sources of treatment chemicals (e.g. membrane de-scalants, coagulants, disinfectants and disinfection by-products). Wards and rooms are not always occupied continuously. This can provide intermittent flows or stagnation in water systems.

Drinking-water should be suitable for human consumption and for all usual domestic purposes, including personal hygiene for most patients. However, it may not be suitable for all patients or uses in a hospital, and further processing or treatment or other safeguards may be required. Patients in intensive or critical care facilities, including cancer wards, transplant wards and renal wards, can be immunocompromised and at increased risk from waterborne disease through ingestion, contact or inhalation. In wards where patients are in protected environments with filtered air and modified diets, equal attention needs to be paid to drinking-water, beverages and ice. There are many examples of legionellosis being recorded in hospitals (Bartram et al., 2007). Inhalation of aerosols from showers, hot- and cold-water outlets, nebulizers and humidifiers has been identified as a route of transmission, while aspiration from ice has been associated with infection of immunocompromised patients or those with significant respiratory impairments (WHO, 2007).

Drinking-water can contain a range of microorganisms that represent little concern through water consumption by most patients. However, some organisms (e.g. *Pseudomonas aeruginosa, Acinetobacter, Aspergillus*) can cause severe infections in those who are immunosuppressed or immunocompromised. They can also cause infections if present in water used to wash or irrigate wounds and burns; to wash medical devices, such as endoscopes and catheters; or in devices such as nebulizers and humidifiers. Water used for such purposes needs to be of a higher quality than described in the GDWQ (WHO, 2008) and may require additional processing, such as microfiltration, disinfection or sterilization, depending on use.

Renal dialysis requires large volumes of water that exceed the chemical and microbial quality requirements for drinking-water. Water used for dialysis requires special processing to minimize the presence of microbial and chemical hazards, including residual disinfectants.

Hot-water distribution systems may be maintained at lower temperatures (warm water) or have thermostatic mixing valves installed before outlets to reduce the risk of scalding (typically 41–45 °C). Warm-water systems or pipework downstream of mixing valves can provide environments for growth of environmental pathogens.

Hospitals may operate hydrotherapy pools as part of treatment regimes and include ice machines and drinking-water fountains.

2.5.3 Other medical and health facilities

Medical and health facilities include medical clinics, health centres, doctors' surgeries and dental surgeries. As in hospitals, risks can be elevated in these facilities due to the types of exposures involved and the potential vulnerabilities of some patients

Water of appropriate quality should be used in medical and dental equipment and procedures (e.g. washing and irrigation of wounds and burns). For example, dental chairs often include water systems that deliver water to high-speed equipment, de-scalers and rinsing sprays. These sprays can be inhaled and aspirated by patients. Dental water lines

can become colonized with bacteria, fungi and protozoa. Most of these organisms are of limited significance, but pathogenic species, including *Legionella*, *Pseudomonas aeruginosa* and *Mycobacterium* spp., have been detected (Sehulster et al., 2004).

2.5.4 Aged-care facilities and retirement homes

Aged-care facilities and retirement homes house elderly people who can be more susceptible to waterborne disease. In some cases, residents will have underlying illnesses that increase this susceptibility.

Like hospitals, water systems can be extensive and supply water to wards and rooms that are not always occupied. Hot-water distribution systems may be maintained at lower temperatures or have thermostatic mixing valves installed to reduce the risk of scalding.

2.5.5 Child-care facilities

Child-care facilities can cater for very young children who can be more susceptible to disease. Children's hygiene is not always well developed, and attention needs to be paid to keeping water outlets and toilets clean (Adams et al., 2009). Young children are also more susceptible to contaminants such as lead (WHO, 2008). Corrosion and leaching of metals such as lead can be exacerbated by intermittent water use, with stagnation over weekends and during holidays.

Hot-water distribution systems may be maintained at lower temperatures or have thermostatic mixing valves installed to reduce the risk of scalding.

2.5.6 Small hotels, bed-and-breakfasts, farmstays and campsites

Hotels, motels and bed-and-breakfasts provide water for drinking and bathing for guests and may use drinking-water supplies in water-using devices, such as swimming pools and hot-tub pools. In some cases, rooms can be provided with single-use hot-tub baths.

Some facilities may have private water supplies that can be potential sources of microbial and chemical hazards.

Campsites can include permanent buildings providing shared facilities (e.g. for cooking, bathing). In some cases, separate non-drinking-water supplies may be provided for bathing. These need to be appropriately marked using words as well as symbols, noting that the water is not suitable for drinking.

Like hotels, these accommodation facilities can be subject to seasonal use.

2.5.7 Sporting facilities and health centres

Sporting facilities and health centres can include sports grounds, stadiums, leisure centres, swimming pools, ice rinks, health clubs and fitness centres. These facilities can include swimming pools or hot-tub pools.

Swimming pools have been associated with outbreaks of illnesses such as cryptosporidiosis, and hot-tub pools with legionellosis and hypersensitivity pneumonitis (from mycobacteria). Indoor pools can generate elevated levels of chloramines and other disinfection by-products, which can lead to eye, nasal and respiratory irritation. Disinfection byproducts at indoor pool centres could be associated with asthma in children (Weisel et al., 2009).

At large sporting clubs, immersion pools and communal pools are used to assist recovery of competitors.

2.5.8 Garden centres and conservatories

Garden centres, greenhouses and conservatories typically use irrigation systems to water plants. In large centres, these irrigation systems can include storage tanks and sumps. Often, irrigation pipes include materials that are not suitable for contact with drinking-water.

Irrigation systems typically use spray and mist devices to produce aerosols, which can disseminate organisms such as environmental pathogens, if they are present. Water features and hot-tub pools on display in garden features may also generate aerosols. In warm environments (especially those exposed to sunlight), water in the irrigation pipes and hoses of these systems can heat up and cause microbial growth.

2.5.9 Detention centres, prisons and military barracks

These buildings can house large numbers of people in relatively confined spaces. Bathing and sanitary facilities are typically shared by groups of people, and breakdown in hygiene can be a source of microbial hazards. Due to the numbers of occupants in close proximity, the secondary spread of disease is likely.

2.5.10 Other buildings

Other buildings include restaurants, fast-food outlets, cafes, veterinary surgeries, ambulance and fire stations, beauty salons and hairdressers. Each type of building can include specific uses of water requiring appropriate management.

3 Roles and responsibilities

This section describes the roles of stakeholders and other responsible personnel to ensure that the water supply is safe. Many people are involved in water safety, from the initial water planners to ongoing operation and maintenance providers, and their range of duties is illustrated in this section.

3.1 Background

A large number of stakeholders can influence the safety of water systems within buildings. These stakeholders can be involved in the planning, design, construction and renovation of buildings, as well as development of water safety plans (WSPs), and the ongoing maintenance and operation of water systems. The specific titles of stakeholders and divisions of responsibilities will vary between different countries and jurisdictions, but the broad range of tasks will remain fairly consistent. Figures 3.1–3.3 (at the end of this section) provide examples of roles and responsibilities in one jurisdiction.

Stakeholders can include:

- building commissioners who are involved before construction of new buildings or renovation of existing buildings, such as developers, planning officers, architects, design engineers, builders, plumbers, manufacturers and suppliers;
- building operators, including building managers and owners, tenants and employers;
- employees, residents and users of buildings;
- service providers and specialist consultants who provide technical assistance, such as plumbers, maintenance contractors, water-treatment specialists, risk assessors and auditors;
- professional bodies who develop guidance and training;
- infection-control personnel in dental and medical facilities, and infection-control teams in hospitals and health-care facilities;
- regulators responsible for oversight of building and plumbing codes, public health requirements and occupational health and safety;
- public health and environmental health officials;
- standard-setting bodies and certification agencies;
- training providers;
- providers of laboratory services.

3.2 Building commissioners

A range of stakeholders can be involved in the design, construction and modification of buildings, including the installation of water systems. All stakeholders should be aware of relevant regulations, codes and standards and should implement requirements that apply to the building being commissioned. Many countries have codes and design standards that apply to water systems and devices, including cold- and hot-water systems, cooling towers, ice machines, swimming pools and hot tubs. In some cases, requirements are incorporated within building and plumbing codes, while in others codes and standards have been issued for specific components such as cooling towers. For further discussion, see section 4. Most countries have building and plumbing codes that include accreditation and approval requirements. However, these codes may not provide sufficient detail for the design of complex systems (e.g. direction on calculation of hot-water return-pipe capacities). Specific requirements for preventing the growth of microorganisms (notably avoiding long periods of stagnation of tepid water) may also not be included in these codes. Separate legislation and standards may apply to specific components of water systems (e.g. water-cooling devices, swimming pools, hot-tub pools). Where codes and standards do not provide sufficient detail, expert advice will need to be sought.

It is essential that those involved in design, construction and modification of buildings document their actions and ensure that final plans and specifications are provided to building owners and managers.

3.2.1 Developers

Developers are ultimately responsible for oversight of the entire process of construction and installation. This includes ensuring that appropriate design requirements and standards are applied.

Where buildings are intended for specific purposes (e.g. health facilities), particular requirements associated with the use should be determined through consultation with the user and from relevant legislation such as building codes and plumbing codes. Developers engage the architects, design engineers, builders, plumbers and others who design and construct buildings. Selected professionals and contractors should be familiar with the requirements associated with the intended use.

3.2.2 Planning officers

Planning officers can play a role relating to appropriate design of buildings and design and installation of water systems. Planners need to be aware of requirements relating to water systems. It is good practice for planning or development applications to be referred to health agencies for assessment of potential public health risks before approval is issued.

3.2.3 Architects

Architects are responsible for the overall design of buildings and need to have an understanding of the operation of, and requirements associated with, water supplies and devices that use water such as cooling towers. Good design can prevent or reduce many of the risks that can arise in water systems within buildings. Architects work in partnership with design engineers and other professionals who are responsible for construction details.

Designs need to take into account requirements associated with specific uses, such as:

- residential health care
- hospitals
- dental surgeries
- medical surgeries
- renal dialysis clinics
- schools
- food retailers
- hotels and guest accommodation (including specialist accommodation such as ski stations).

In the case of renovation or modification of existing and occupied facilities, architects should consult with users of the building. The extent of consultation will be influenced by the complexity of the project; however, it should include all those involved in management and maintenance of water systems. In the case of hospitals and health-care facilities, it should involve consultation with infection-control specialists.

3.2.4 Engineers

Design engineers are responsible for translating the architectural plans into building designs, taking into account structural integrity and ensuring compliance with building and plumbing standards. Project and construction engineers are responsible for completion of buildings, including installation of water systems. When buildings are being renovated, or existing structures are being modified, engineers provide a key role in establishing risk-management plans to minimize risks to people currently using the building. These risk-management plans should include instructions on how to deal with potential problems and disruptions to services, and they should ensure that technical standards and regulations are met. Risk-management plans should include education of maintenance and construction workers. Project engineers are typically responsible for final certification of satisfactory completion of building construction.

3.2.5 Plumbers

Protection of water quality and proper operation of water systems rely on plumbers. Plumbers should be appropriately qualified and have the competence and knowledge to design, install and maintain plumbing systems. Plumbers play a key role in managing risks by ensuring compliance with applicable standards and codes. In addition, plumbers and other plumbing professionals can play an important role in water conservation.

Well-designed plumbing systems are necessary to ensure that the installations are efficient, safe and appropriate for the different circumstances they serve. The design of a good plumbing service must be based on an understanding of the technical requirements and relevant regulatory restrictions. Where industry-based risk-management strategies and procedures have been established, they should be applied.

Plumbers have to ensure that water systems are intact and that intrusion of microbial and chemical contaminants is minimized. Unintended or unprotected cross-connections

should be prevented, and backflow-prevention devices should be installed where necessary. Only approved materials and devices should be used or installed.

Plumbing systems have to comply with building plans. All work has to be documented, and installations and modifications need to be included within building plans.

3.2.6 Manufacturers and suppliers

Anyone involved in the manufacture and supply of water systems components, and specialized equipment and devices (e.g. cooling towers, washing machines, water-using medical devices) should ensure that they are designed and constructed so that they are safe when used for their designated purpose. Components and devices should be designed, constructed and installed in compliance with existing codes and design standards. Systems need to be constructed from materials that are appropriate for the function of the water system and device. In addition, systems should be designed to enable ease of operation, cleaning, inspection and maintenance. Training should be provided to people who operate devices, where appropriate.

3.3 Building operators

Building operation and management can be undertaken by a range of different stakeholders, with specific responsibilities influenced by ownership and tenancy agreements. Legislative requirements may also assign responsibilities to specific parties. Requirements will generally include responsibilities relating to protecting the health and safety of residents and users of buildings. Employers have a specific duty to protect the health and safety of employees.

Building operation can be the responsibility of a building owner, leasing agency, building manager, tenants, employers or combinations of these parties. In some cases, building owners maintain control over infrastructure including water systems, but in other cases this task might be undertaken by a leasing or building management agency. Alternatively, occupiers and tenants may install and manage water devices. Regulations and codes of practice often identify responsibilities for a number of parties. For example, the Victorian Government (in Australia) has published *Legionnaires' disease: managing the health risk associated with cooling tower and warm water systems* (the Health *Legionella* Regulations) (Vic DHS, 2001), which identifies responsibilities for:

- owners of land to register certain types of water devices and to take all reasonable steps to ensure that a risk-management plan is prepared, reviewed and audited on an annual basis;
- owners or tenants of buildings to prevent conditions that may represent a risk to public health;
- owners, managers or controllers of water devices to undertake appropriate levels of maintenance;
- employers to maintain a safe workplace.

In other jurisdictions, assignment of responsibilities may be different, but the tasks remain generally consistent. The tasks and individual responsibilities should be described in a WSP. Whoever takes the lead role in building management needs to be responsible

for the design and implementation of the WSP, including ensuring completion and documentation of tasks assigned to competent employees or to specialist contractors.

Competence should be supported by training. Owners, managers or employers should ensure that those who are assigned to undertake specific tasks have appropriate levels of training. Additional training should be provided where required. In some countries, certification programmes have been established to provide evidence of training. Where such programmes have been established, owners, managers or employers should ensure that work is undertaken by employees or contractors with relevant certificates.

Building managers and employers need to communicate with residents, users of buildings and employees in relation to:

- potential risks associated with water systems;
- management plans developed for these systems;
- notification and information relating to any incidents that give rise to potential or perceived risks to public health; they should also report such incidents to the appropriate regulatory agencies.

3.4 Employees, residents and users of buildings

Employees, residents and users of buildings are often the first to detect change or faults in water systems. These could be detected due to changes in temperature, appearance, odour or taste of water; reduced flow; or leaks. Reporting of changes and faults should be encouraged, and mechanisms should be established to support reporting. Feedback should be provided on the outcome of investigations and any remedial action.

Employees and residents have responsibilities to operate and use water systems as intended and not to introduce modifications. For example, point-of-use devices should not be installed without permission from building managers. Devices and controls such as thermostats should not be altered without permission. This should be reinforced with education and communication from building managers.

3.5 Service providers and specialist consultants

Building operators may use service providers and consultants as sources of specialist skills that are not available within their own organization. Service providers and contractors can be used to undertake a wide range of services associated with water systems, including:

- installation of water-treatment devices and plumbing fittings
- routine and emergency maintenance
- risk assessments and development of WSPs
- audits.

Building operators should only engage providers who can demonstrate competence and compliance with relevant formal requirements (e.g. certification).

Service providers need to be able to demonstrate competence in undertaking tasks for which they contract. In some cases, certification programmes have been established.

In other cases, levels of service or training may be specified by industry associations. Service providers need to be able to provide evidence of compliance with established programmes and, where available, certification.

Service providers should provide evidence in the form of formal reports or certificates of completion to demonstrate that tasks have been completed in accord with requirements.

3.5.1 Risk assessors

Risk assessors need to have the expertise, knowledge and resources to undertake the task competently. Risk assessors should have expertise in:

- public health aspects of water quality;
- local legislative requirements, standards and codes of practice;
- development of WSPs;
- water systems in buildings, including water-using devices and equipment;
- identification of hazards and potential sources of these hazards;
- determination of risk;
- identification and assessment of appropriate control measures;
- operational monitoring procedures to ensure that the control measures remain effective;
- verification procedures.

In large buildings with complex water systems (e.g. hospitals), more than one risk assessor may be required to deal with the piped systems and the broad range of connected equipment and devices. Risk assessors need to comply with formal requirements, including certification and approval conditions established by regulatory agencies. If unacceptable risks are identified, they should be reported immediately to whoever commissioned the assessment. If a serious and potentially immediate risk to public health is identified, notification of the regulatory authority will be required.

3.5.2 Independent auditors

Some jurisdictions use and certify independent auditors to determine the effectiveness of WSPs and compliance with occupational health and safety requirements. Levels of knowledge and expertise, as well as the need to comply with formal requirements, are similar to those described for risk assessors. Auditors should also have expertise in assessing documentation and reporting mechanisms. Auditors may be required to submit reports of their findings to the regulatory agency.

A48235836

3.6 Professional bodies

Professional bodies (e.g. for dentists, medical practitioners, hospital engineers, nurses) can perform a number of functions, including:

- developing and advocacating for policies and codes of practice relating to water systems;
- establishing practical guidelines to support implementation of WSPs;
- training for members and their employees;
- identifying practical issues associated with implementation;
- providing mechanisms for gathering information relating to incidence of infection that may be related to water systems;
- reporting notifiable diseases and unusual or elevated incidence of disease to public health agencies;
- providing mechanisms for gathering information on successful management approaches.

3.7 Infection control

3.7.1 Infection-control coordinators

In small health facilities, clinics or surgeries, infection-control coordinators should be appointed to manage established control programmes. The coordinator could be the head of the facility or an employee trained for the task. The head of the facility is responsible for establishing the programme, ensuring that it is implemented, and ensuring that the coordinator has (or receives) appropriate training.

3.7.2 Infection-control teams

Hospitals and other health-care centres use infection-control committees and teams to prevent nosocomial infections, including those arising from water systems. The committees should include representatives from all relevant sections, including management, nursing, physicians, hospital engineers, microbiology, maintenance, cleaning and sterilization services, housekeeping and supply. These teams should contribute to ensuring that water systems are well managed, as follows:

- Management is responsible for establishing and supporting the infection-control team, and should ensure that staff have sufficient understanding of water systems and water-using devices within the building. Management should ensure that a WSP has been developed and implemented by appropriate staff.
- Nursing staff should be aware of the correct operation of relevant water-using devices and equipment and how this equipment should be cleaned and disinfected.
- Maintenance and hospital engineers are responsible for implementing WSPs, including operational monitoring; for example, monitoring temperatures in cold- and hot-water systems, monitoring disinfection residuals in water systems, and monitoring water-using devices such as hydrotherapy pools. They are also responsible for maintaining water systems and devices to ensure that they function as required at all times.

- Physicians are responsible for ensuring safe use of water systems, water-using devices and equipment. Physicians should consider the potential contribution of water systems to nosocomial infections.
- Microbiologists are responsible for monitoring cleaning, disinfection and sterilization, where appropriate, of water-using devices and equipment. They should be aware of appropriate procedures for collecting environmental samples.

Infection-control teams should contribute to internal reviews of WSPs. This should include periodic review of potentially waterborne nosocomial infections as an assessment of effectiveness of the plan. One approach could be to establish a subgroup with primary responsibility for water management. This subgroup should work with, and report to, the full team.

3.8 Regulators

A number of activities and requirements are subject to regulation. These include compliance with building and plumbing codes; occupational health and safety requirements; and codes applying to operation of devices, such as water-cooled air-conditioning plants, swimming pools and hot-tub pools. Implementation of these regulations may be administered by different agencies, including those with responsibilities for public health, environmental health and occupational health and safety. It is important that there is a shared understanding of agency responsibilities and the functions of different regulations to maintain consistency of purpose.

In some countries, the "regulator" may not be an institutional body but a public officer from an agency or authority (e.g. government agency, local health authority). The regulator will have the responsibility for dealing with specific technical issues covered by regulations. The regulator may operate through multilateral committees and expert consultants.

3.8.1 Public health agencies

Public health agencies are responsible for ensuring that public health standards are maintained. They may act in a number of areas, including surveillance and auditing of water systems; they may also help to set standards and codes, detect and investigate disease, and monitor disease trends. Public health agencies are responsible for ensuring compliance with regulations designed to protect public health, and that the actions required by regulations or by codes of practice are followed. This can include regulations and codes applying to specific devices, such as water-cooled air-conditioning plants, swimming pools and hot-tub pools. Required actions can include development of WSPs.

In the event of known or suspected disease outbreaks, public health officials are responsible for inspecting buildings, auditing WSPs and collecting water samples.

Public health officers are also responsible for issuing directions relating to remedial action, and issuing public notifications where required.

Disease surveillance

The role of public health agencies normally includes detecting and investigating disease, and monitoring disease trends (for more information, see section 5.2) Public health authorities need to establish criteria that would initiate an investigation and procedures on how such investigations will be performed. This should include procedures for identifying and confirming potential sources of disease. In the case of investigations involving illnesses associated with buildings, public health agencies should work with owners, managers and users of buildings. Advice and warnings may need to be issued to occupants and employees of buildings, as well as the general public. This should be done in a timely manner to reduce or contain public health impacts, and to provide appropriate information about the level of risk, responses and triggers for seeking medical attention.

Monitoring of disease trends can provide evidence of the need to improve management of water systems. Once a new strategy has been implemented, information on disease trends can provide evidence of the strategy's impact.

Public health agencies should establish networks with professional bodies to help detect disease, and to disseminate public health information.

3.8.2 Surveillance of water supplies

Independent surveillance of water supplies is an important element of quality assurance. Surveillance of water systems in buildings will include features similar to those applied to drinking-water supplies, but may also incorporate additional elements to deal with specific uses of the water, with water-using devices such as cooling towers, and with occupational health and safety needs. The resulting surveillance programmes may include a range of activities and agencies. For example, there could be specific surveillance programmes for cooling towers, swimming pools and other devices. Specific surveillance programmes could also involve agencies responsible for public health and for occupational health and safety.

The role of different agencies and the requirements for specific surveillance programmes should be identified and coordinated to avoid unnecessary duplication, and to ensure that appropriate levels of surveillance are applied to all parts of water systems in buildings. In some cases, surveillance could be performed by third parties such as contractors or registered auditors under programmes directed by regulators. Such programmes should include mechanisms to monitor the effectiveness of the third-party audits.

Surveillance and auditing should include processes for approving WSPs, as well as processes for verifying that WSPs are being implemented appropriately and protect public health effectively.

3.8.3 Occupational health and safety agencies

Occupational health and safety regulations can be administered by specific departments or agencies within government. In some jurisdictions, these regulations are the primary legislative mechanism applied to water-using devices (e.g. cooling towers, evaporative condensers), while in others they support or supplement public health legislation.

Administration of occupational health and safety requirements should be coordinated with other functions and regulations designed to protect public health from water systems. Administration may include either random or routine inspections of workplaces, and occupational health and safety inspectors should be aware of other requirements developed to control risks associated with water systems.

3.9 Standard-setting and certification bodies

Devices and materials used in water systems need to meet quality requirements and comply with applicable standards and codes of practice. Some countries have established standard-setting bodies and certification systems to provide assurance that, when used in accord with design specifications, devices and materials will perform as required and be safe. Standards can apply to the design, installation, maintenance and operation of devices such as cooling towers and evaporative condensers, swimming pools, hot-tub pools, hot-water systems and plumbing devices. Standards can also apply to materials used in plumbing systems, including pipework. Material standards can deal with physical attributes, and ensure that products do not give rise to unacceptable contamination of water or support microbial growth. Standards should include criteria for achieving and measuring compliance.

Certification is used to confirm that devices and materials used in water systems meet standards or alternative criteria. Certification can be undertaken by government agencies or private organizations. Certification agencies may assess data and information provided by manufacturers, undertake specific testing, or conduct inspections and audits. Certification may be issued subject to application of defined conditions. These conditions could identify specific applications and uses of certified products (e.g. where devices can and cannot be used).

Standards are typically developed in cooperation with manufacturers, technical experts, regulatory agencies, certifying agencies and consumers. Public health agencies should participate in developing or approving parts of standards that are intended to protect public health.

Standards can:

- represent technical provisions and norms to be adopted on a voluntary basis as good practice;
- be adopted as requirements by government or local government authorities;
- be adopted by reference in regulations.

Standard setting and certification also applies to sample collection and laboratory analysis. Samples need to be collected, stored and transported using established procedures and appropriate equipment (e.g. correctly prepared sample bottles). Similarly, laboratories need to be competent to perform the tests that they undertake. This includes using suitable methods, appropriate testing equipment, and qualified and capable personnel. Some countries have established standards supported by certification and accreditation systems for laboratory services.

3.10 Training providers

Design, installation and management of water systems can involve a range of personnel, all of whom must be competent to undertake assigned or required tasks. Training providers can provide courses to support competence. In some cases, course work can be combined with supervised "on-the-job" training. Training should be consistent with existing regulations, standards, codes of practice and requirements of regulatory authorities.

Training can be provided by water companies, professional associations (e.g. builders, plumbers, engineers, environmental health institutes, dental and medical associations) and specialist technical colleges and institutes. In some countries, training programmes are subject to certification and accreditation programmes. Training providers should ensure that they comply with the requirements of such programmes.

Training providers should regularly review the content of their courses. They should also consult with regulators and those seeking training to ensure that their needs are being met.

The aim of training programmes is to produce personnel with sufficient expertise and training to undertake specific tasks. However, measuring the level of competence can sometimes be challenging. Measuring competence is easier when tailor-made courses and certification programmes are available—and many countries have accreditation systems for professional and technical personnel. In some cases, requirements for accredited operators can be included in regulations.

Measuring competence is difficult when competence is based on degree of experience. A flexible approach to measuring may be needed, while ensuring that tasks are only performed by people who have sufficient expertise and knowledge. Codes and legislation that include reference to "competent persons" need to identify criteria for establishing competence, including qualifications, training requirements and relevant experience.

Figures 3.1–3.3 show an example of the roles and responsibilities of people involved in water safety.

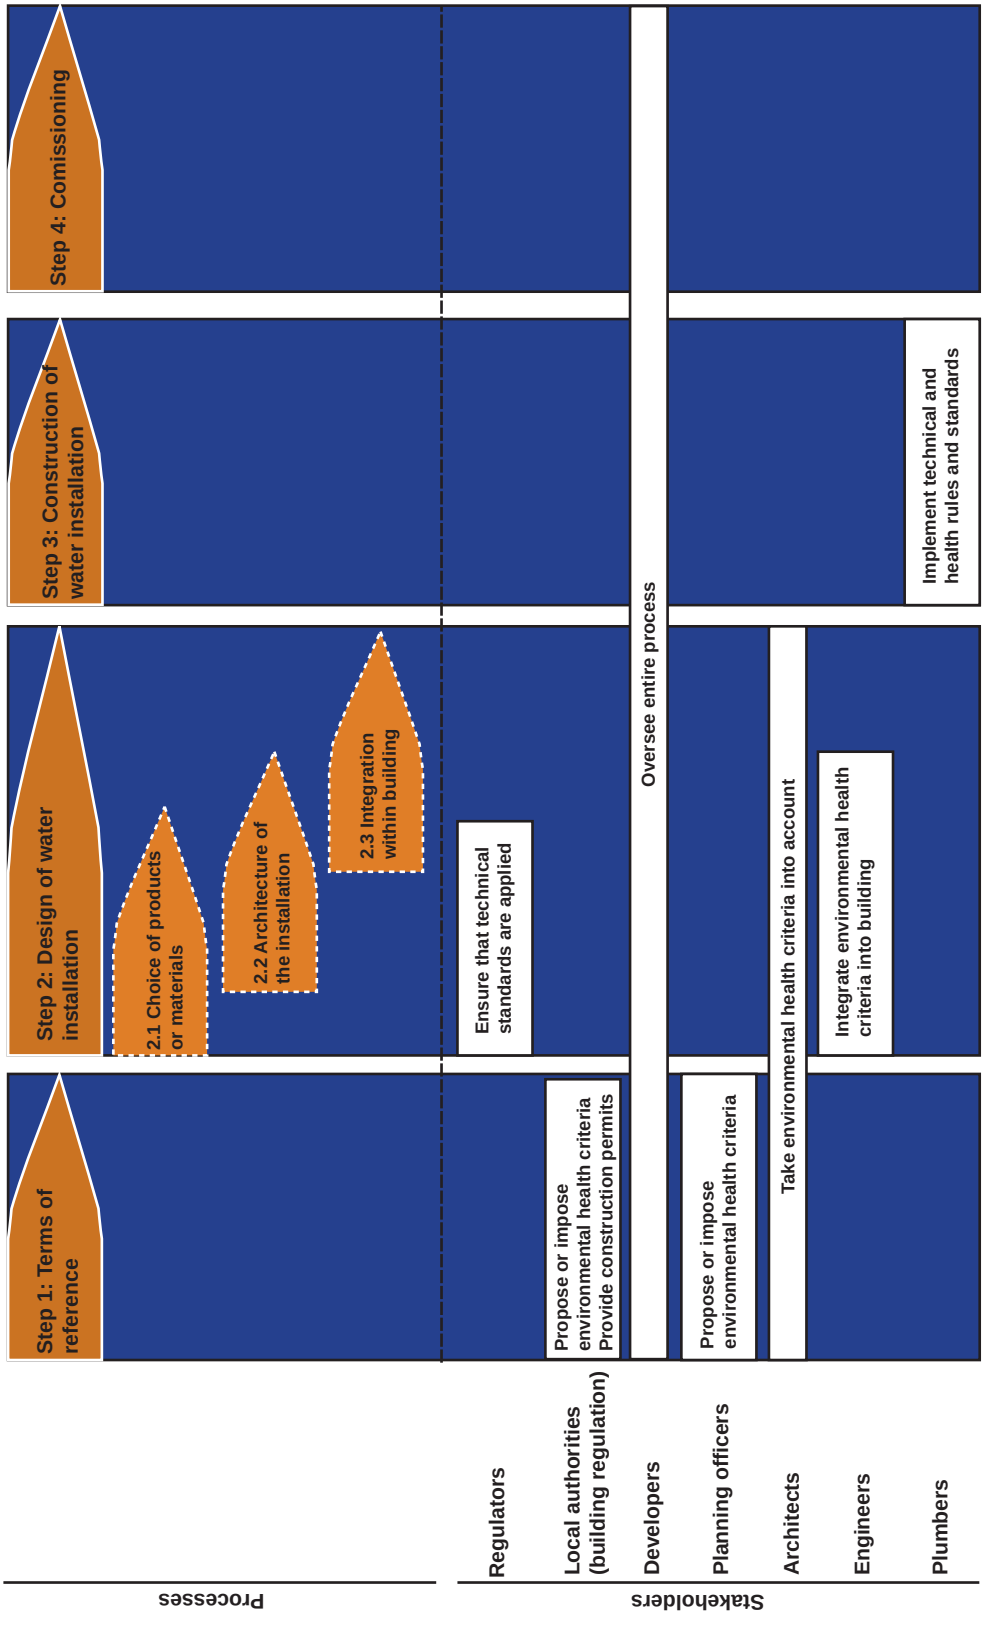

Figure 3.1 Roles and responsibilities for major projects or significant modifications

4 Water safety plans

This section describes, in more detail, water safety plans (WSPs), including the steps required to set one up, and how the key principles can be applied to buildings. Information is also provided on how to organize a WSP team, and what actions to take if a water supply becomes contaminated.

This section also explains risk assessments, control measures, operational monitoring and management procedures. Information that should be considered when designing and constructing new installation systems is also provided.

4.1 Background

The continuous delivery of safe water requires effective management and operation throughout the water-supply chain, from catchments to consumer taps and points of use. The *Guidelines for drinking-water quality* (GDWQ) (WHO, 2008) indicate that this is most effectively achieved through the *Framework for safe drinking-water*, which encompasses the following elements:

- establishing health-based targets as "benchmarks" for defining safety of drinking-water;
- assuring safety by developing and implementing a WSP to systematically assess and manage risks;
- establishing a system of independent surveillance to verify that WSPs work effectively and are capable of consistently delivering water that meets the health-based targets.

WSPs provide a preventive risk-management approach that builds on other risk-management and quality-assurance principles. They systemize long-established principles and good practices in drinking-water supply, covering both water quality and quantity management issues. These principles also apply to management and use of water-using devices and equipment. WSPs for buildings should address drinking-water networks and consider connected devices and equipment.

The development and implementation of WSPs can be the responsibility of various stakeholders: while WSPs for water treatment and distribution of public water supplies are typically the responsibility of the supplier, WSPs for buildings are the responsibility of building owners or managers, with support from various other stakeholders, as discussed in section 3. The level of detail and complexity of WSPs will depend on the size and nature of the building, including the level of risks posed by the installation, and on the population exposed to the water system inside the building. Nevertheless, the implementation of well-designed WSPs is recognized as the most effective tool to ensure provision of safe water supplies.

Development of WSPs should not be considered as overwhelming or too complicated. The aim is straightforward: to ensure consistent supply of safe water to consumers. To a large extent, WSPs document established good practice, and the most important step is getting started.

Figure 4.1 provides an overview of the steps involved in developing a WSP.

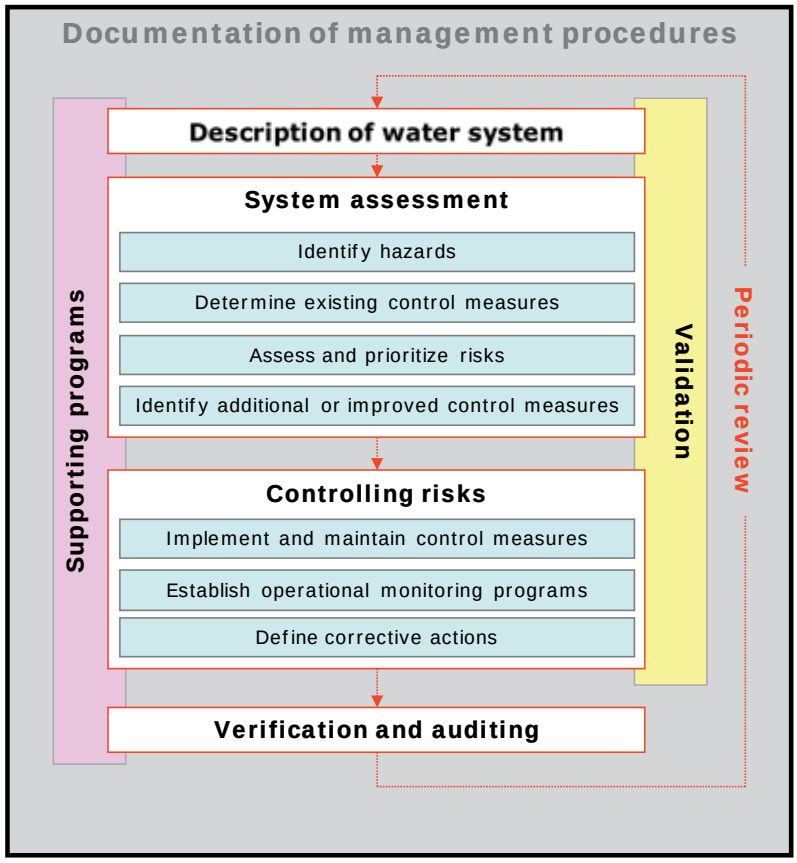

Figure 4.1 Summary of the steps involved in developing a water safety plan

4.2 Key principles of WSPs

WSPs are typically developed after the supply system has been designed and constructed. However, where possible, new or renovated systems should be designed and constructed in a way that supports implementation of WSPs. This should include identifying potential hazards, incorporating appropriate control measures (e.g. treatment processes) and considering practical aspects (e.g. ease of access for maintenance, inspection and monitoring).

Irrespective of when they are developed, WSPs should be working documents that are kept up to date and reviewed periodically to ensure that they remain current. WSPs should be reviewed if there are major changes to water supplies and uses.

The mechanisms by which WSPs are developed and applied can vary. In some cases, tasks associated with implementation could be undertaken by an owner, manager or employer. However, they could also be delegated or assigned to competent individuals employed within a building, or to specialist contractors. When tasks are either delegated

A48235836

or contracted, the owner, manager or employer retains the responsibility to ensure that those charged with performing designated functions are competent and that required tasks identified in the WSP are completed and documented appropriately.

4.3 Assembling a WSP team

Assembling a team is a core preparatory requirement for the development and implementation of a WSP in a building. The team will be in charge of developing and implementing the WSP—a role that includes identifying hazards, assessing risks, identifying and monitoring control measures, and developing incident protocols.

A responsible person (or WSP coordinator) needs to be identified to lead the team. This person should be either the building manager or a competent person delegated to this task by the manager. The WSP coordinator should have (or acquire) a good knowledge of the technical facilities in the building, and their daily work should be related to the building. Since the coordinator's primary task is to coordinate the process of WSP development and implementation, they should understand the principles associated with development and implementation of WSPs. However, a special technical knowledge in drinking-water and/or sanitation, while useful, is not necessarily required. The coordinator should have the authority to ensure that the WSP is implemented. A building manager is a good choice for the WSP coordinator.

The WSP coordinator needs to form a team of experts who will support WSP development and provide access to all relevant information needed. Team members should include the range of expertise needed for a thorough analysis of the building's water system. The team should include expertise in design, operation and management of drinking-water supplies; engineering; plumbing; and public health risk assessment. The team will include employees with relevant specialist expertise, as well as representatives of key users of the building water systems. Development of WSPs could also involve consultation with specialist contractors.

Some hazards that may compromise water quality in a building may be obvious to the building management; others may be more concealed. Therefore, it is essential that the WSP team is able to deal with all possible risks associated with delivering drinking-water. Managers of small buildings or facilities with simple water systems may not have "in-house" expertise. In this case, the manager or operators of the water system should coordinate development of the WSP and use health and water-quality expertise from external sources. This could include external agencies (e.g. health, water utilities), private consultants, or external specialists to provide expert advice. In some cases, health agencies may develop generic plans and guidance that can be applied.

4.4 Describing the water system

The first step of the WSP team is to compile available information on the design and operation of the water-distribution system in the building. This needs to be described in a comprehensive plan, starting with the nature and quality of water supplied to the building up to points-of-use (taps and outlets) by building occupants, users and visitors. The plan should document all components of the building water systems, including point-of-entry (PoE) and point-of-use (PoU) treatment, distribution systems (e.g. hot water, cold water, firefighting), water-using devices (e.g. swimming pools, cooling towers) and

specific water uses. An accurate description of the water system is essential to support the identification of hazards, allow risks to be assessed adequately and allow appropriate control measures to be identified.

4.4.1 Functions of water networks inside buildings

Drinking-water networks inside buildings have important differences from external public water-supply networks that need to be considered when analysing potential health hazards. In many buildings, at least two different drinking-water networks operate—that is, a cold-water and a hot-water system—with the following different design features and purposes:

- Cold-water networks are typically designed to deliver water under satisfactory pressure and flow rate at all taps. Parts of the system with large flow rate demands will guide the capacity of the network. Cold-water networks may also deliver water to fire-protection systems. In some circumstances, additional treatment may be provided to supply higher water quality (e.g. in health-care buildings). Cold-water networks should be designed to be efficient, with minimal stagnation, and should be insulated and separated from hot-water networks to minimize heat gain. They should also be protected against corrosion and other damage, to maximize their lifespan.
- The primary function of hot-water networks is to deliver sufficient quantities of water at satisfactory temperatures for its intended use, while limiting energy consumption. This may be achieved by storing hot water near PoUs, responding to demand peaks for large networks, and installing recirculation loops with short branch pipes to PoU to ensure supply of water on demand. Hot-water systems may incorporate temperature-reduction devices to reduce scalding. To reduce risks from *Legionella*, these should be placed close to PoUs. Networks should be designed to minimize areas with low flow or stagnation. Insulation of the piping system will minimize temperature loss.

Buildings will also generally include a wastewater network and may include other networks for delivering other types of waters (e.g. distilled water, rainwater, water for firefighting, greywater, recycled water). All networks need to be identified and labelled clearly. Networks of different water quality need to be kept separate and isolated from both the cold- and hot-water networks. Where the drinking-water system is intentionally connected to a water system, appropriate backflow prevention is needed when delivering non-drinking-water (e.g. water for firefighting).

4.4.2 Usages and water-use patterns

A good understanding of a water network includes establishing the uses of water throughout the building. Where there are multiple supplies of water (e.g. external drinking-water, roof rainwater and recycled water), the uses of each type of water should be identified.

Therefore, all water uses (planned and actual) should be established, as well as requirements for different user groups in a building. This analysis may be based on a list of different possible uses; for example, water for drinking, showering, preparing food, washing, cleaning, toilet flushing, technical uses, watering, firefighting or leisure activities. Specific uses (e.g. medical, dental) and supply to water-using devices (e.g. cooling towers, swimming pools, water coolers, water fountains) should be identified.

A48235836

Different water qualities and uses should be described clearly, using consistent nomenclature, particularly in buildings with common purposes (e.g. hospitals and health-care facilities). For example, Table 4.1 provides a description of water used in health-care facilities in France.

Water usages determine the water volume and flow rates that have to be provided at each PoU. This understanding, together with a knowledge of system capacities, is important for identifying the likelihood of low flows and areas of stagnation. Parts of buildings that have variable or seasonal occupancy rates should be identified.

Table 4.1 Nomenclature of waters used in health-care buildings in France

Quality 1. Water not submitted to any treatment within the health-care building
1.1: Water dedicated to drinking and food preparation
1.2: Water for regular care
Quality 2. Specific water treated within a health-care setting complying with defined criteria in accordance with usages
2.1: Bacteriologically controlled water
2.2: Hot water
2.3: Water from hydrotherapy pools
2.4: Water from hot tubs and shower jets
2.5: Water for haemodialysis
2.6: Purified water (drug preparation)
2.7: Highly purified water (for injection)
2.8: Drinking-water from fountains
Quality 3. Sterile waters
3.1: Diluents for injections
3.2: Water for irrigation (pouring water)
3.3: Sterilized drinking-water
Quality 4. Water for technical use[a]
4.1: Cooling network
4.2: Laundry
4.3: Boilers

[a] Water used as feed water and so on in, for example, cooling networks, boilers and laundry machines.
Note: only Quality 1, Quality 2 and Quality 3 are produced directly from the water network.
Adapted from Ministry of Health (France) (2004).

4.4.3 Understanding and documenting the design of the water system

Effective assessment of potential health hazards and risks requires a sound description and documentation of the physical structure of the building's water system (e.g. architecture, plumbing, materials, location of installations and equipment, connection to water-using devices) and its expected conditions of operation. Construction plans and any other available documentation of the building's infrastructure provide a good basis for system description. Drawing high-level, simple flow diagrams will help to capture the various elements of the building's water system, and will help to identify hazards, risks and controls.

The existing documentation and the flow diagram need to be verified by an on-site examination to confirm that they are up to date and correct. Water systems in buildings are often poorly mapped and not updated after repairs or renovations. The on-site examination should follow the delivery of water from PoE to all points of delivery or use within the building.

Elements to be examined and documented include (Figure 4.2):

- 1 point(s) of entry to the building, including possible PoE treatment;
- 2 possible building-specific sources of water and associated treatment;
- 3 water piping, storage systems and connections between drinking- and non-drinking-water systems, including intended connections (e.g. between drinking-water systems and fire systems) and unintended connections (e.g. between drinking-water systems and sewage or recycled-water systems);
- 4 devices for heating and supplying hot water;
- 5 hot-water piping systems;
- 6 equipment installed at PoU (e.g. dishwashers, washing machines, drinking- water fountains);
- 7 water treatment systems at PoU.

These elements are explained in more detail below.

1 Point(s) of entry

The most common source of drinking-water to buildings is an external piped water supply. The PoEs are often marked by a water meter on the property or building boundary. This is also the point where ownership and management responsibilities can change to the building owner. It is a critical point in terms of providing a basis for defining the physical scope of building WSPs. In some cases, buildings may have more than one PoE, and in other cases groups of buildings may be supplied through a single offtake and a shared meter. There could also be separate points of supply for firefighting. Each PoE should be identified, as well as their condition of use (permanent, intermittent, backup) and the way they are connected to the inner water system and to other entry points (i.e. whether they are interconnected or kept separate).

A48235836

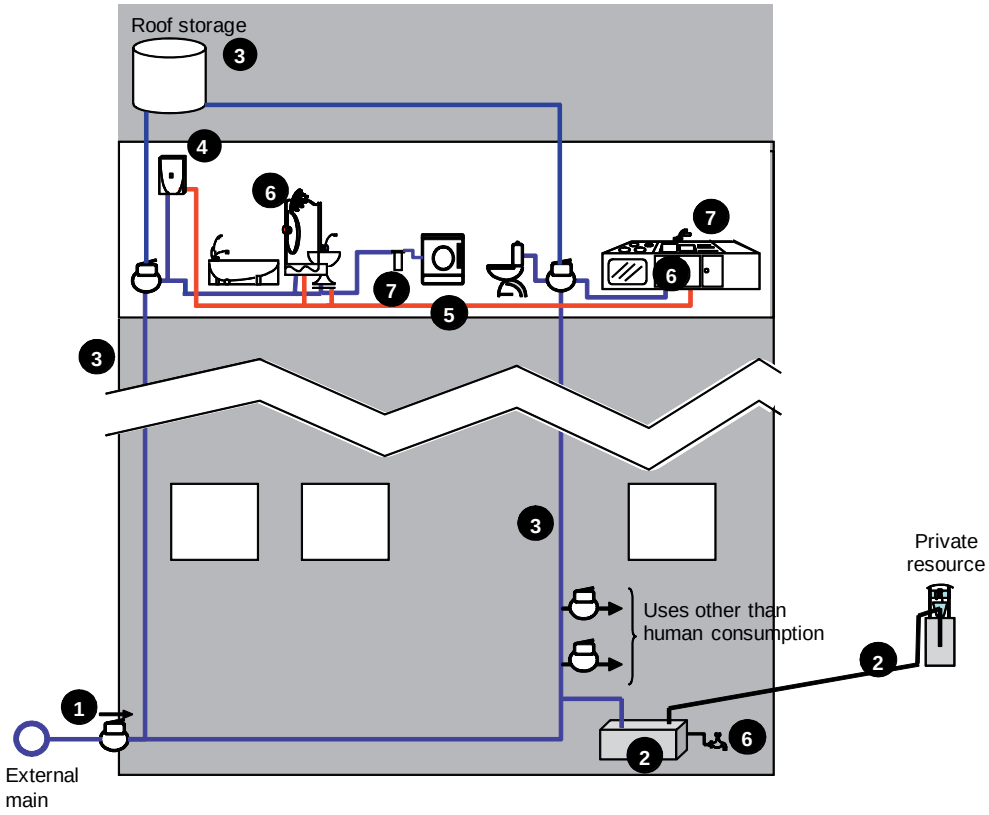

Figure 4.2 Typical components of water systems inside buildings

Issues that need to be considered include the:

- quality and composition of the delivered water (this needs to be obtained from the water supplier);
- continuity and quantity of water supply;
- conditions of accessibility to the PoE;
- presence of a water meter and of backflow-prevention systems to prevent contamination of the public network;
- responsibility of the water supplier in assuring water quality within the building; for example, it could be a requirement that the public water supply will not corrode building plumbing systems;
- treatment systems installed at the PoE (e.g. chlorinators, filters, water softeners, deionizers, activated carbon), including selection, storage, use and control of chemicals.

2 Possible building-specific sources of water and associated treatment

Buildings may use private sources of water or may augment external sources of water with building-specific sources, such as rainwater, wells, borewater and springs. If the water from the private source is not provided for human consumption (e.g. used for toilet flushing), safeguards (e.g. warning signs) must be installed to prevent this water being misused as drinking-water or being connected to the drinking-water supply.

The following questions need to be considered:

- What is the nature and location of the building-specific source?
- How is it protected from external pollution?
- How is it delivered to the building and what are the possibilities for contamination (e.g. through faults in pipework, open storage tanks, inappropriate materials in contact with water)?
- What kind of treatment is applied at the PoE?
- If the building-specific source is not used for drinking, what precautions are taken to ensure that the water is not misused or connected with the drinking-water supply?

3 Water piping, storage systems and cross-connections to non-drinking-water systems

Water piping systems in buildings vary in lengths, complexities, materials and designs. The structure of a piping system needs to be established by examining existing plans and by an on-site investigation. Plans should always be checked against reality, since they are not always updated when networks are upgraded or repaired. However, this can be difficult, particularly in large, complex buildings, because pipes are often concealed and embedded in walls or ceilings. It is important to catalogue as much of the system as possible and to document and retain all plans for future use. In particular, the following parts of the system should be identified:

- water-storage tanks (may be larger where water supplies are intermittent), including consideration of size in relation to inflow and usage requirements (total and peak flows) within the building, detention and integrity;
- points of delivery, including fixtures and connections to equipment (e.g. dishwashers, washing machines, medical equipment) and water-using devices (e.g. cooling towers, swimming pools, water fountains);
- inadvertent or unintended connections between drinking-water systems and non-drinking-water systems (lower or higher quality water);
- installation of backflow prevention between drinking-water systems and non-drinking-water systems (e.g. firefighting systems) and water-using devices;
- physical separation of cold- and hot-water systems and separation of drinking-water systems and non-drinking-water systems;
- labelling and identification of pipework;
- thermal insulation of piping systems;

A48235836

- temperatures;
- antisiphonage systems or valves;
- branch pipes and dead legs;
- areas with potential for intermittent or seasonal use;
- materials used in pipes and other components, including compliance with established certification or authorization schemes for materials used in contact with drinking-water;
- access for maintenance or disinfection.

Box 4.1 provides a case study of cryptosporidiosis associated with water shortages in a multipurpose building in Japan.

Box 4.1 Cryptosporidiosis associated with water shortage

From 30 August to 10 September 1994, there was an outbreak of cryptosporidiosis among the people who visited or worked in a multipurpose building in Hitatsuka, Kanagawa Prefecture, Japan. The multipurpose building was constructed in 1970, with six storeys above the ground and one below. There were 10 restaurants or bars, a dance studio, a clothing store, a post office and accommodation for employees in the building. An epidemiological survey revealed that 461 out of 736 people investigated complained of cholera-like or influenza-like illness. An investigation of the water system in the building found that there were two separate systems: one directly connected to the public water supply served drinking-water to the first floor, while the other delivered water from the second to sixth floors through a storage tank, which was also supplied from the public water supply. The storage tank was adjacent to a night-soil tank, wastewater tank and artesian springwater tank in the basement. The tanks were concrete and separated by a wall with holes to allow connections between the tanks. (This kind of tank design is not allowed in new regulations for buildings.) Although the purpose of the holes was not clear, they might have helped to discharge excess drinking-water from the storage tank to the night-soil or wastewater tanks. Water level in the wastewater tanks was kept below the holes by pumping to the public drain.

The epidemiological survey found that there were patients from every floor except the first. Polluted drinking-water was strongly suspected as a source of infection. According to the owner of the building, the wastewater pump was broken at the time of the outbreak. Several species of pathogenic bacteria were isolated from stool and water samples, but they were not considered to be the source of the outbreak. Oocysts of *Cryptosporidium parvum* were identified in 12 (48%) of the 25 stool samples, tap water, the storage tank and other tanks. It was concluded that the cause of this outbreak was drinking-water contaminated by *Cryptosporidium* oocysts following accidental malfunction of the wastewater drainage system.

Based on Kuroki et al. (1996).

4 Devices for heating and supplying hot water

The production of hot water is a common feature in buildings. Hot-water production may be instantaneous, or based on its storage in hot-water tanks. Buildings may be served by single hot-water systems or by multiple systems to supply individual floors, sections of buildings or living units. In large systems, hot-water production can be centralized in boiler rooms or provided by multiple units. Consideration should be given to the temperature of water in storage heaters and the capacity of systems compared with water usage.

Box 4.2 provides a case study of methaemoglobinemia (a disease characterized by a higher than normal level of methaemoglobin, which does not bind oxygen, in the blood), arising from nitrite-contaminated water.

Box 4.2 Methaemoglobinemia attributable to nitrite contamination of potable water through boiler fluid additives, New Jersey, 1992 and 1996

Two outbreaks of methaemoglobinemia were reported in 1992 and 1996. In the first outbreak, acute onset of illness was reported in 49 children from one school. Onset occurred within 45 minutes after lunch. Initial symptoms were blueness of lips and fingers, followed by nausea, abdominal pain, vomiting and dizziness. Fourteen children were hospitalized and treated with supplemental oxygen and methylene blue. All children recovered in 36 hours. In the second incident, six workers reported acute onset of blueness of the skin. Two of the workers were treated with supplemental oxygen and methylene blue. All recovered within 24 hours.
