Received 24 February 2000/Accepted 4 May 2000

Dental-unit water systems (DUWS) harbor bacterial biofilms, which may serve as a haven for pathogens. The aim of this study was to investigate the microbial load of water from DUWS in general dental practices and the biofouling of DUWS tubing. Water and tube samples were taken from 55 dental surgeries in southwestern England. Contamination was determined by viable counts on environmentally selective, clinically selective, and pathogen-selective media, and biofouling was determined by using microscopic and image analysis techniques. Microbial loading ranged from 500 to 10^5 CFU · ml^{-1}; in 95% of DUWS water samples, it exceeded European Union drinking water guidelines and in 83% it exceeded American Dental Association DUWS standards. Among visible bacteria, 68% were viable by *Bac*Light staining, but only 5% of this "viable by *Bac*Light" fraction produced colonies on agar plates. *Legionella pneumophila*, *Mycobacterium* spp., *Candida* spp., and *Pseudomonas* spp. were detected in one, five, two, and nine different surgeries, respectively. Presumptive oral streptococci and *Fusobacterium* spp. were detected in four and one surgeries, respectively, suggesting back siphonage and failure of antiretraction devices. Hepatitis B virus was never detected. Decontamination strategies (5 of 55 surgeries) significantly reduced biofilm coverage but significantly increased microbial numbers in the water phase (in both cases, $P < 0.05$). Microbial loads were not significantly different in DUWS fed with soft, hard, deionized, or distilled water or in different DUWS (main, tank, or bottle fed). Microbiologically, no DUWS can be considered "cleaner" than others. DUWS deliver water to patients with microbial levels exceeding those considered safe for drinking water.

The water obtained from dental units via 3-in-1 syringes, air rotors, and low-speed handpieces may be heavily contaminated with microorganisms and thus may be a potential source of infection for both practice staff and patients (5, 34). The range of microorganisms isolated includes both environmental organisms (e.g., *Moraxella* spp. and *Flavobacterium* spp.) and opportunistic and true human pathogens (e.g., *Pseudomonas aeruginosa*, *Legionella pneumophila*, *Mycobacterium* spp., and *Staphylococcus* spp.) (10, 14, 16, 21, 30). Such organisms may originate from incoming local water supplies, although organisms commonly found in the oral cavity have also been recovered (37, 38), suggesting that some bacteria may be derived from the patient following back siphonage. The most common cause of dental-unit water contamination is believed to be the formation and subsequent sloughing off of microbial biofilms from the surfaces of tubing within dental-unit water systems (DUWS) (22, 36). To date viruses have not been detected in DUWS (37).

Microorganisms persist in DUWS by growing as a multispecies biofilm on the inner surface of the plumbing (14, 16, 21). Biofilms may be difficult to remove from surfaces, and the bacteria within biofilms are more resistant to antimicrobial agents (12, 17, 25) than planktonic cells. This antimicrobial resistance is a result of a number of factors that may include (i) binding of the agent, (ii) a lack of penetration of inhibitors, (iii) the localization of neutralizing enzymes, (iv) the low growth rate of the microbes, and (v) the expression of a resistant phenotype due to surface growth (9). Biofilms may also enhance the survival of fastidious pathogens such as *L. pneumophila* in water distribution systems (32). Up to 25% of DUWS have been shown to be contaminated with this bacterium (8).

There are currently no rational, evidence-based guidelines available to dentists for the control of DUWS contamination. This study is the first to focus on DUWS in typical general dental practices and to compare systematically different types of DUWS (bottle, main, or header tank fed) and units supplied with deionized, distilled, soft, or hard water. Biofilms play an important role in the microbial contamination of water systems; therefore, we have investigated biofilms using conventional viable counting of bacteria, as well as microscopy and image analysis and vital staining, in parallel with equivalent (planktonic) water samples. We also assessed the nature of the microbial contamination by detecting "environmental" and oral organisms as well as a range of potential pathogens, including the hepatitis B virus surface antigen (HBsAg).

MATERIALS AND METHODS

Survey of general dental practices. Fifty-five DUWS were selected for study in 21 general dental practices in southwestern England. The units selected represented units in use and included 32 supplied by bottled water, 20 supplied by mains water, and 3 supplied by header tank systems. Of these, 33 were supplied with hard water, 11 with soft water, 9 with deionized water, and 2 with distilled water. Five of the sampled DUWS (all bottle fed) were reported to have been sanitized. The sanitization regimens in four cases consisted of a weekly 5-min addition of a 1:10 dilution of Milton sterilizing fluid (neat solution contains 2% [wt/wt] sodium hypochlorite and 16.5% [wt/wt] NaCl; Procter & Gamble Ltd., Weybridge, Surrey, United Kingdom). The other sanitized unit was treated by the continuous addition of 1:10 diluted Corsodyl (neat solution contains 0.2% [wt/vol] chlorhexidine gluconate; SmithKline Beecham, Brentford, United Kingdom).

Sampling of DUWS. Samples were taken from four points in each device at approximately mid-morning: (i) the 3-in-1 syringe's (the pistol-like device de-

signed to deliver air, water, or air/water into the mouth during dental treatment) distal outlet (the water line sample), (ii) a section of the water line tubing supplied to the 3-in-1 syringe for biofilm analysis (the water line biofilm), (iii) the air rotor water line (the air rotor water sample), and (iv) the air line (as a control sample for detection of background contamination of the tubing—the air line biofilm).

Water samples were processed in the following way. Approximately 100 ml of water was passed through a sterile nozzle into a sterile water bottle containing 0.1 g of sodium thiosulfate to remove any residual disinfectant (3) (Abinghurst Ltd., Northampton, United Kingdom). The samples were returned to the laboratory in a cool box (4 to 8°C) within 3 h and then filtered through 100-ml-capacity, 0.2-μm-pore-size analytical test filter funnels (Techware, Poole, United Kingdom) in order to recover the waterborne microorganisms. The membrane was removed from the funnel with sterile forceps and placed in a screw-cap sterile container (Elkay Products Inc., Shrewsbury, Mass.). Organisms were washed from the membrane by vortexing the container for 1 min in 10 ml of sterile phosphate-buffered saline (PBS).

Biofilm samples were taken using the following procedure. External DUWS tubing surfaces were wiped with a sterile alcohol wipe (CS Dental Supplies, Redhill, United Kingdom) and approximately 5 cm of the tubing was cut off with presterilized (121°C for 15 min) scissors. The tubing section was then placed in a bottle containing enough sterile water to cover the samples. All samples were again transferred in a cool box to the laboratory within 3 h. Tubing was sectioned to obtain a specimen representing 1 cm^2. The surfaces were rinsed in nonflowing sterile PBS to remove planktonic cells. Using sterile (121°C for 15 min) dental probes, the surface biofilm was scraped into 1 ml of sterile PBS. The scraping was checked by microscopy to determine that all the biofilm had effectively been removed from the surface.

Viable counts of selected bacteria. Total viable counts were carried out on decimal dilutions of the water and biofilm samples (in sterile PBS) and were used as the definitive measure of total microbial contamination of the water passing through the DUWS. This was compared with both the European Union standard for potable water (3) and the American Dental Association standards for DUWS (1). Samples of appropriate dilutions of biofilm and water samples were plated onto a range of selective and nonselective agar media. The media were (i) Columbia blood agar for oral streptococci, *Actinomyces* spp., and oral anaerobes (incubated anaerobically at 37°C for up to 10 days under a gas phase of 80% [vol/vol] CO_2–10% [vol/vol] H_2–10% [vol/vol] N_2) (colonies were assessed morphologically and by Gram staining); R2A agar for environmental isolates (29), incubated at 37°C for up to 7 days; (iii) CFC supplement SR103 for *Pseudomonas* spp. (27), incubated at 37°C for up to 48 h; (iv) MacConkey agar CM7 for enterobacteria (15), incubated at 37°C for up to 48 h; and (v) Sabouraud dextrose agar for *Candida* spp. (26), incubated for up to 7 days.

For the enumeration of *Legionella* and *Mycobacterium* spp., aliquots of the samples were pretreated either with heat (at 50°C in a water bath for 30 min) or with acid (1 ml of sample added to 1 ml of 1 M HCl for 15 min and then neutralized with KOH [4, 13]). Aliquots of untreated and treated samples were then plated onto BCYE agar for the enumeration of *Legionella* spp. (11), and the plates were incubated aerobically at 37°C for up to 10 days. Colonies morphologically typical of *Legionella* spp. were counted, and the serogroup was determined using a latex agglutination kit (Pro-Lab Diagnostic, Neston, United Kingdom). Similar aliquots were dispensed onto Middlebrook agar plus OADC 7H10 for *Mycobacterium* spp. (24) (incubated aerobically at 37°C for up to 30 days). Representative colonies were assessed using the Ziehl-Neelsen technique for the detection of acid-fast bacilli and examined microscopically.

Detection of viruses. Aliquots of each unfiltered water sample were frozen (−20°C) and transported frozen to the University of Liverpool. The level of HBsAg was measured by the Monolisa Ag HB Plus assay (Sanofi Pasteur, Guildford, United Kingdom). Samples (50 μl) were processed according to the manufacturer's instructions, and the resultant chromophore was read on a Dynex MR7000 plate reader at 420 and 620 nm. Positive and negative controls were included in every batch.

Microscopy and image analysis. The extent of biofouling in DUWS tubing was assessed by using image analysis. Lengths of tubing were aseptically sectioned into thin strips (approximately 2 to 3 mm wide) and stained for 1 min with 50 μl of prefiltered (0.2-μm pore size; Sartorious, Epsom, United Kingdom) propidium iodide (1 mg of stock · ml of sterile distilled $water^{-1}$; Sigma Poole, United Kingdom) before being gently rinsed twice in nonflowing sterile distilled water to remove planktonic and loosely adhered cells. The tubing surface was then examined using a Nikon Labophot 2 microscope with episcopic fluorescence and a 50× water immersion lens (33). Ten representative images were captured as computer images (TIFF) for analysis of percentage of coverage, using Optimas Software (Optimas Datacell, Finchhampstead, United Kingdom).

Viability assay. A 3-cm length of DUWS tubing was aseptically sectioned horizontally into four equal sections, with the control sample immersed in 4% (vol/vol) formalin (Western Solvents, Westbury, United Kingdom) for 10 min. Equal volumes of *Bac*Light (Molecular Probes, Eugene, Oreg.) reagents A and B were added to PBS to prepare the viability probe (final concentration, 3 μg/ml) (20). Control (killed) and test (untreated) samples were assayed with the *Bac*Light live/dead viability probe. Following a 15-min reaction, the samples were rinsed in nonflowing PBS to remove excess stain and assessed using the microscopy system described above. Microscopic counts of the stained cells were also carried out using an improved Neubauer counting chamber (Hawksley, London, United Kingdom) with the results compared against total plate counts.

Statistical analysis. Statistical analyses were carried out using Excel (Microsoft Office) and Statgraphics (STSC Inc., Rockville, Md.). Bacterial loads in different types of water (deionized, distilled, soft, and hard) and from DUWS with different water sources (main, bottle, or tank fed) were compared using a two-way analysis of variance (ANOVA) on log-transformed viable counts. Where significant differences were indicated by ANOVA, individual groups were then compared by the least-significant-difference method. Percentage coverage data were compared using the nonparametric Kruskal-Wallis test. Biofilm and planktonic counts from the same surgeries were also analyzed for correlation using the nonparametric Kendall rank correlation analysis. Statistical significance was assumed at a P value of <0.05.

RESULTS

Survey of general dental practices and sampling of DUWS. Fifty-five water line and air rotor water line fluid (planktonic) samples and 47 water line and air line biofilm samples were taken during the survey. Eleven surgeries used soft (<50 ppm $CaCO_3$) water, 33 used hard (>250 ppm $CaCO_3$) water, 9 used deionized water, and 2 used distilled water. Only 3 surgeries had tank-fed (break tank) DUWS, 32 used bottle-fed systems, and 20 had main-fed systems. Five of the 55 surgeries reported recent disinfection of their DUWS. For the purposes of clarity, each surgery was assigned a number, to which appropriate sections of the results refer.

Bacterial contamination of DUWS. (i) Water line microbial contamination. A geometric mean of 2.9×10^3 CFU of bacteria · ml^{-1} was recovered from the water of the DUWS (range, 7 CFU · ml^{-1} to 6.4×10^4 CFU · ml^{-1}). The number of bacteria recovered varied with the type of water supplied to the DUWS. Viable counts from distilled water were greater than those from hard, soft, or deionized water (Table 1). Similarly, more bacteria were recovered from units supplied by bottles than from those supplied by mains or tanks. However, the differences between DUWS types and between units supplied with different types of water were not significant at the 95% confidence level (two-way ANOVA, $P = 0.28$ and 0.58, respectively).

Surgeries 13, 14, 15, 16, and 43 had units that were reportedly sanitized (Fig. 1). Significantly greater numbers of bacteria were found in the water phase of units treated with disinfectant than in the untreated units (ANOVA, $P = 0.048$). A geometric mean of 1.6×10^4 CFU · ml^{-1} (range, 6.0×10^3 CFU · ml^{-1} to 3.6×10^4 CFU · ml^{-1}) was recovered from treated units' water, compared with a geometric mean of 2.8×10^3 CFU · ml^{-1} (range, 7.0 CFU · ml^{-1} to 6.4×10^4 CFU · ml^{-1}) from the untreated systems.

Notable bacterial species isolated from the water lines of the DUWS were slow-growing *Mycobacterium* spp. from surgeries 21, 22, and 44, *Fusobacterium* spp. from surgery 19, and fluorescent *Pseudomonas* spp. from surgeries 16, 32, 35, 47, and 48.

(ii) Air rotor water line microbial contamination. Similar numbers of bacteria (geometric mean, 3.3×10^3 CFU · ml^{-1}; range, not detectable to 9.5×10^4 CFU · ml^{-1}) (Table 1) were found in the water from the air rotor water line and the water line. The numbers of bacteria in air rotor line water were significantly different for different DUWS types (two-way ANOVA, $P = 0.04$), with the numbers of microorganisms from main-fed units being significantly greater than from the bottle-supplied units ($P < 0.05$). Higher numbers of bacteria were recovered from hard water than from deionized, distilled, or soft water (Table 1), though these differences did not quite reach significance (two-way ANOVA, $P = 0.055$).

The following specific microorganisms were detected from air rotor water line samples: *Candida* spp. from surgery 21 and fluorescent *Pseudomonas* spp. from surgeries 7, 16, 33, 35, 44, 47, and 49.

TABLE 1. Comparison of viable counts from the DUWS water samples

Sample	Viable count (CFU · ml^{-1}) from water samples taken from:						*n*
	Water lines			Air rotor water lines			
	Geometric mean	Minimum	Maximum	Geometric mean	Minimum	Maximum	
Water type							
Soft	2,590	7	31,000	1,224	0	40,000	11
Hard	3,290	32	64,000	5,063	0	95,000	33
Deionized	1,740	68	40,000	2,699	55	30,000	9
Distilled	5,970	4,400	8,100	2,013	1,350	3,000	2
Supply type							
Tank fed	1,550	480	3,700	1,881	360	7,400	3
Bottle fed	3,583	7	36,000	1,802	0	95,000	32
Main fed	2,217	32	64,000	4,914	42	40,000	20
Total	2,874	7	64,000	3,325	0	95,000	55

(iii) Water line biofilm. A geometric mean of 9.2×10^2 CFU · cm^{-2} (range, not detectable to 6.4×10^4 CFU · cm^{-2}) was recovered from the water line biofilm of the DUWS (Table 2). More bacteria were recovered from the distilled-water units than from the hard-, soft-, or deionized-water units; similarly, more were recovered from the main-fed units than from those supplied with either bottled or tank water (Table 2). However, the differences between the numbers of CFU recovered from biofilms in different DUWS types and from units supplied with different types of water were not significant (two-way ANOVA, $P = 0.89$ and 0.91, respectively). The numbers of bacteria in biofilms were significantly associated with the numbers in the corresponding planktonic phase (Kendall rank correlation; $\tau = 0.31$, $P = 0.04$).

The numbers of bacteria recovered from the biofilms in the "sanitized" units (surgeries 13, 14, 15, 16, and 43) were significantly lower than the numbers recovered from the untreated surgeries (ANOVA, $P = 0.04$). *Mycobacterium* spp. were recovered from the biofilms of surgeries 4 and 23.

(iv) Air line biofilm. Significantly lower numbers of bacteria were found in the DUWS air lines than in the water lines. A geometric mean of 5.1×10^1 CFU · cm^{-2} (range, not detectable to 3.0×10^4 CFU · cm^{-2}) were recovered from the air lines, compared with a geometric mean of 9.2×10^2 CFU · cm^{-2} from the water line (paired *t* test, $P \ll 0.0001$) (Table 2).

However, a number of medically important bacteria were detected in air line biofilm samples: *L. pneumophila* in surgery

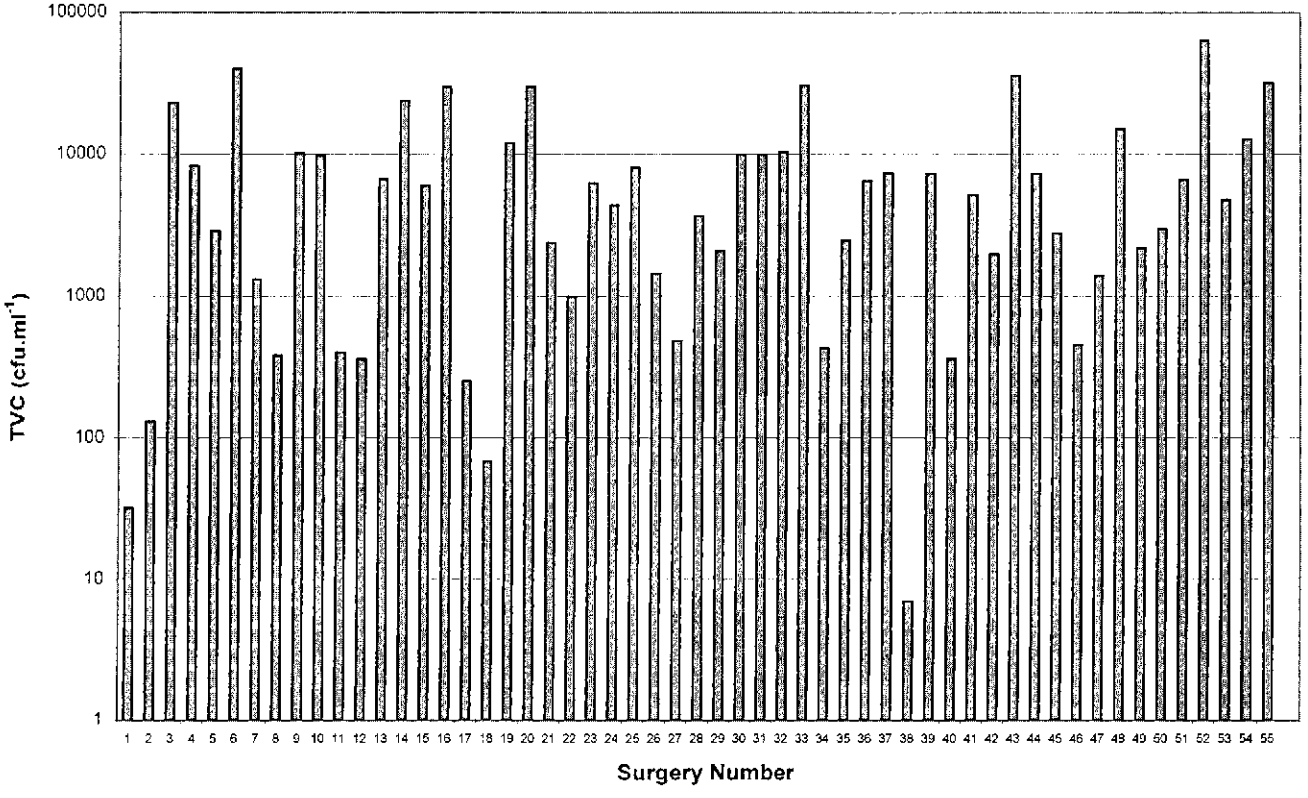

FIG. 1. Total viable counts (TVC) of water samples from DUWS in different dental surgeries.

A48235836

Downloaded from https://journals.asm.org/journal/aem on 12 March 2024 by 164.134.2.12.

TABLE 2. Comparison of viable counts from the DUWS biofilm samples

Sample	Viable count (CFU · cm^{-2}) from biofilm samples taken from:						*n*
	Water lines			Air lines			
	Geometric mean	Minimum	Maximum	Geometric mean	Minimum	Maximum

24, *Candida* spp. in surgery 30, and *Lactobacillus* spp. and *Streptococcus* spp. in surgery 19.

(v) Percentage of biofilm coverage in water and air lines. The average coverage of water line surfaces was 43% (range, 0.01 to 94%) (Table 3). Significantly less coverage was observed on the DUWS units supplied with soft water than on those supplied with hard, distilled, or deionized water (Kruskal-Wallis test, $P = 0.035$). The highest coverage was found on those units supplied with deionized water, followed by those using hard, distilled, and soft water (Table 3). There was no significant difference among units with different types of water supply, although it was observed that a higher percentage of coverage was recorded in the units supplied by water mains than in bottle- or tank-fed systems.

The results of the percent coverage analysis of the air line demonstrated that the average coverage was 5.2% (range, 0.1 to 74%) (Table 3). A higher degree of biofouling was observed on the tubing surfaces of those DUWS that were supplied with hard water than in those supplied by deionized, distilled, or soft water (Table 3). This difference was statistically significant (Kruskal-Wallis test, $P = 0.04$). In terms of the type of water supply, more extensive biofouling coverage was observed on those units supplied by mains water than on those supplied by tanks or bottles, although this difference was not significant (Kruskal-Wallis test, $P = 0.35$).

TABLE 3. Comparison of percentage of coverage from the DUWS biofilm samples

Sample	% Coverage from biofilm samples taken from:						*n*
	Water lines			Air lines			
	Avg	Minimum	Maximum	Avg	Minimum	Maximum	
Water source							
Soft	21	0.1	62	0.0	0.1	0.1	10
Hard	48	0.01	94	8.8	0.1	74	27
Deionized	54	0.5	94	1.9	0.1	6.4	8
Distilled	44	5	83	0.1	0.1	0.1	2
Supply type							
Tank fed	33	25	50	3.5	0.1	8	3
Bottle fed	41	10	94	2.9	0.1	64	29
Main fed	50	0.1	92	10	0.1	74	15
Total	43	0.01	94	5.2	0.1	74	47

(vi) Assessment of viability. Due to fluorescein binding to the DUWS tubing surfaces, viable cells could not be discriminated against the background; therefore, biofilm counts could not be assessed in situ using the *Bac*Light technique. Resuspended biofilm samples were analyzed and a mean of 68% of the total visible bacterial population was determined to be viable. A mean of 5% (three determinations) of this "viable by *Bac*Light" fraction produced viable colonies on agar plates.

(vii) Detection of viruses. None of the samples taken from the DUWS were positive for HBsAg.

DISCUSSION

Water supplied by 95% of general dental practice DUWS units failed current European Union potable-water guidelines on microbial load (i.e., loads were >100 CFU · ml^{-1}) (2), and 83% failed American Dental Association recommendations for DUWS water quality (<200 CFU · ml^{-1}) (1). The bacterial numbers reported here were comparable to those found in a number of other studies (6, 28) and lower than some (19, 35). These values probably underestimate the true microbial load to which a patient is exposed, since we also demonstrated that only 3% of the microscopically visible bacteria produced colonies on agar plates. Other bacteria may be either in a temporarily nonculturable state or may represent the large fraction of the microflora from many natural habitats which remain "as yet uncultured" (as discussed in the review by Barer and Harwood [7]).

The most common pathogens detected were fluorescent *Pseudomonas* spp. (16% of samples were positive). *L. pneumophila* was isolated on only one occasion, which was far less frequent than reported in previous studies in a dental hospital and in a mixture of institutional and private practices (25 and 6% isolation frequencies, respectively) (4, 8). Larger water distribution systems are known frequently to harbor this organism (C. L. Bartlett, J. B. Kurtz, J. G. Hutchison, G. C. Turner, and A. E. Wright, Letter, Lancet **ii:**1315, 1983). We detected *Mycobacterium* spp. in ca. 5% of surgeries, a lower detection rate than that reported by a previous study (30). These isolates were not identified, so their pathogenic potential is unknown, although several non-*Mycobacterium tuberculosis*, non-*Mycobacterium avium* species of mycobacteria are associated with a variety of infections in humans (18). Presumptive oral streptococci were identified in 7% of DUWS water samples, suggesting the failure of antiretraction devices in these systems and thus raising the possibility of cross-infec-

tion between successive patients. No HBsAg was detected in any sample.

Some dentists perceive that certain types of DUWS may be less prone to microbial contamination than others. We found no significant differences between different DUWS systems, regardless of whether these systems were main, bottle, or header tank fed or whether the water supplied to them was hard, soft, deionized, or distilled. Thus, no DUWS can be considered superior in microbiological terms to any other or can be called microbiologically "clean." Water from air rotor lines and from 3-in-1 handpieces was contaminated to a similar degree, emphasizing that air rotors should not be used as an aid in any dental surgical procedures.

The significant correlation between the numbers of bacteria recovered from biofilms and from water samples from the same units suggests that the biofilms may seed the water with bacteria and vice versa. Strategies developed for the control of DUWS contamination must eliminate both the biofilms and the waterborne bacteria in these systems (23, 31, 36). In addition, although significantly lower levels of biofilm contamination were found in the five units reported to have been recently decontaminated, more bacteria were recovered from the water phase in these systems. Decontamination with detergents or with inorganic acids (including hypochlorous acid) could increase the risk of release of organisms from biofilms and thus increase the numbers of bacteria in the water phase (J. S. Colborne, P. J. Dennis, J. V. Lee, and M. R. Bailey, Letter, Lancet **i:**684, 1987). Inadequate decontamination regimens may thus increase the hazards associated with DUWS water.

In conclusion, improved, evidence-based practical methods for controlling the microbial contamination of DUWS are urgently needed. This is particularly important in view of the increasing numbers of medically compromised and immunocompromised patients receiving regular dental treatment.

ACKNOWLEDGMENTS

This investigation was supported by the Primary Dental Care R & D Programme and National Research Register Research Grant PDC97-213 from the NHS Executive, North West, Warrington, United Kingdom.

We thank the staff and patients of the participating practices for their cooperation and support during the study.

Microbiological testing of water and environmental samples from the Queen Elizabeth University Hospital (Adults) and Royal Hospital for Children, 2015-2020

Overview of sample numbers and test results

Dominique L. Chaput (DPhil)
Healthcare Scientist in Infection Prevention & Control
Scottish Microbiology Reference Laboratories
Glasgow Royal Infirmary, Glasgow G31 2ER
2023-03-03

Table of Contents

Introduction

The Queen Elizabeth University Hospital (QEUH) campus consists of two new hospital buildings, QEUH Adults and the Royal Hospital for Children (RHC), as well as several retained buildings that were already present on the site prior to the opening of the new buildings to patients in May 2015. This report focuses specifically on the new buildings, QEUH Adults and RHC, and covers the period January 2015 to December 2020. Data from the retained buildings are summarised in a separate report, *Water testing summary for the whole Queen Elizabeth University Hospital campus, 2015-2020* (DL Chaput). Legislation and guidance applicable to water testing on the QEUH campus are outwith the scope of this report but are summarised in a separate document, *Summary of legislation and guidance for routine microbiological water tests carried out at QEUH Adults and RHC* (DL Chaput).

Section 1: Water testing gives a detailed summary of all water sampling conducted for microbiological analysis in the new buildings over this period. It includes routine and reactive test numbers and results for Legionella, Pseudomonas, potable water, fungi, Cupriavidus and other Gram negative bacteria, atypical mycobacteria, and other organism-specific tests. Water testing data were obtained from the QEUH Estates Department, from DMA Canyon Ltd, and from TelePath, the GG&C Laboratory Information Management System (see Appendices for a detailed list of data sources).

Section 2: Other environmental testing summarises additional environmental testing that was undertaken over this period in the new buildings, including swabs of drains, sinks, showers, and various dry surfaces. Environmental testing data were obtained from TelePath.

Data processing and analysis were carried out in R version 4.2.0, as detailed in the Appendices, and this report was written in Rmarkdown.

Section 1: Water testing

Protocols: Water sampling and microbiological testing

Water sampling

Collection of water samples from across the QEUH campus over the period 2015-2020 was carried out by two contractors, ALcontrol Laboratories and DMA Canyon Ltd, and by GG&C clinical staff in specific areas.

ALcontrol Laboratories (2015-2017)

ALcontrol Laboratories (hereafter referred to as ALcontrol) were a UKAS accredited water and environmental analysis service, contracted to carry out sampling and testing in the QEUH new buildings from April 2015 to January 2017. They were acquired by ALS Global in November 2016, and their website (www.alcontrol.com) now redirects to SGS Analytics.

ALcontrol collected water samples from the new buildings for Legionella testing on a monthly basis from April 2015 to June 2017. They sampled for potable water testing in April-May and Oct-Nov 2015, and again in Jan 2017. They also sampled for Pseudomonas testing every month from Nov 2015 to Mar 2016, with some additional Pseudomonas sampling in Sept 2016.

DMA Canyon Ltd (2016-2020)

DMA Canyon Ltd (hereafter referred to as DMA) are specialists in plumbing, water treatment, and water hygiene monitoring, contracted by GG&C to carry out water sampling on the QEUH campus over the period 2015-2020. They are registered with SNIPEF (Scottish and Northern Ireland Plumbing Employers' Federation), WaterSafe, and the Legionella Control Association, and hold ISO 9001 (quality management system), OHSAS 18001 (occupational health and safety), and ISO 14001 (environmental management system) certifications.

From January 2015 to August 2016, DMA conducted water sampling only in the retained buildings on the QEUH campus, while ALcontrol Laboratories sampled and tested water from the new buildings. From September 2016 onward, DMA's sampling schedule included the new buildings, but only for Pseudomonas or specific organism testing at the request of IPC/IMTs (e.g. Serratia, *Elizabethkingia miricola*, Stenotrophomonas). DMA began collecting samples on a monthly basis for routine Legionella testing in the new buildings in July 2017 (taking over from ALcontrol), and began sampling for potable testing in the new buildings in April 2018.

DMA followed industry standard methods for water sample collection, with protocols specific to the type of outlet being sampled (tap, shower, storage tank, etc., hot, cold or mixed, with or without point-of-use filter, etc.) and to the type of microbiological analysis required (e.g. potable, Pseudomonas, Legionella). Where applicable, DMA's protocols aligned with those described in the Scottish Health Technical Memoranda (SHTM), notably *SHTM 04-01 Water safety for healthcare premises Part B: Operational management (2014)*, as well as meeting the requirements set out in relevant Health and Safety Executive documents specific to Legionella control (see separate report for overview of applicable guidance and legislation).

Specialist units (new buildings)

A small number of specialist units in the QEUH new buildings had specific sampling and testing arrangements: the aseptic pharmacies in QEUH Adults and RHC, and the RHC Theatre 8, for cardiology procedures. In these areas, waters were (and continue to be) sampled routinely by GG&C clinical teams onsite. There is no involvement of Estates or external sampling contractors in this arrangement.

Testing laboratories

ALcontrol

Water samples collected by ALcontrol over the period 2015-2017 were analysed by their own UKAS accredited microbiological testing laboratory. The results were not entered into the GG&C TelePath system. Data sheets generated by ALcontrol were held by QEUH Estates.

GG&C Environmental Laboratory

The NHS GG&C Environmental Laboratory (hereafter referred to as the Environmental Laboratory) forms part of the Clinical Microbiology Department, located in the New Lister Building at the Glasgow Royal Infirmary. It is UKAS-accredited to ISO/IEC 17025:2017 for analysis of potable, endoscopy and renal waters, and air samples. Target microorganisms covered by this accreditation include *Legionella* species, coliforms and *Escherichia coli*, *Pseudomonas* species, atypical mycobacteria, as well as yeasts and moulds. Gram negative investigations are not specifically covered by the current UKAS accreditation but most of the methods involved are covered by other accredited protocols. The Environmental Laboratory has been UKAS-accredited for *Legionella* testing for many years and has therefore maintained high quality, training and calibration standards. Accreditation for the other tests was granted in April 2020 following a UKAS assessment in September 2019. Prior to this, the Environmental Laboratory was working towards UKAS accreditation for these tests and was therefore operating to these standards.

The Environmental Laboratory has had a long-standing arrangement with the clinical teams in the specialist units described above (the aseptic pharmacies and RHC Theatre 8). From 2015 onward, samples collected from these units were sent to the Environmental Laboratory for testing. Results were reported directly back to the clinical teams.

The Environmental Laboratory was also the main microbiological testing laboratory for both routine and reactive samples collected by DMA throughout the period 2015-2020. Results were reported back to DMA, who incorporated the microbiological findings into spreadsheets with sampling metadata (sampling date, location, type of outlet, etc.) and then sent the completed data sheets to QEUH Estates Department and, from mid-2018 onward, to contacts in Microbiology and IPC.

In addition to sending testing results back to the requestor (specialist unit clinical teams or DMA), the Environmental Laboratory maintained paper copies from 2015 to March 2017. From April 2017, all results from the Environmental Laboratory were uploaded to

the GG&C TelePath system, and earlier results from 2015 to March 2017 were retrospectively entered into TelePath.

Intertek

Intertek is a global quality assurance company that provides testing services for numerous industries, including water and air quality monitoring. Its water microbiology analysis service is carried out to Drinking Water Directive 98/83/EC standards (Council Directive 98/83/EC of 3 November 1998 on the quality of water intended for human consumption, European Union legislation).

From December 2018 onward, due to the large increase in the number of water samples collected from the new buildings for microbiological analysis, a subset of the routine water samples collected by DMA from sentinel outlets was sent to Intertek for testing instead of the Environmental Laboratory, who tested the remaining routine and reactive samples.

Intertek reported its results to DMA, who incorporated them into the data sheets with sampling metadata and results from the Environmental Laboratory, then disseminated to Estates and contacts in IPC and Microbiology. Since Intertek is an external contractor, its microbiological test results were not uploaded to the GG&C TelePath system, which only holds water testing data from the Environmental Laboratory.

Microbiological test types

Water testing can be broadly classified as either routine (for monitoring purposes) or reactive (for investigation). Routine water samples collected by ALcontrol, DMA, or clinical teams in specialist units underwent one or more of the standard microbiological investigations listed in Table 1. Routine Legionella, Pseudomonas, and potable testing occurred throughout 2015-2020, while other routine tests were added at various points in specific areas of the new buildings. Testing for Cupriavidus and other Gram negative bacteria (GNBs) began with a large reactive sampling effort in early 2018, followed by implementation of routine testing for these organisms from Dec 2018. Routine fungal testing began in Dec 2018, and testing for atypical mycobacterial species (AMS) in specific areas of the new buildings began in Apr 2019. Where reactive sampling was carried out specifically to assist IPC/IMTs, *ad hoc* tests for specific microorganisms were instead ordered, often in conjunction with one or more of the routine tests.

Table 1 shows the routine water tests commonly carried out in QEUH Adults and RHC. All three laboratories (Environmental Laboratory, ALcontrol, and Intertek) performed the standard potable, Pseudomonas and Legionella tests, though Intertek did not include a separate PA100 in its Pseudomonas testing, and the Environmental Laboratory and ALcontrol included it only in a subset of their Pseudomonas tests. Routine fungal testing was carried out by both the Environmental Laboratory and Intertek, whereas routine testing for other organisms, some of which was bespoke to GG&C (e.g. Cupriavidus/GNBs) was carried out by the Environmental Laboratory. The Environmental Laboratory SOP entitled *LP538 Non Legionella Water Testing: Potable Water & Endoscopy Analysis (LP538)* details its testing, control, and reporting procedures, as well as its operating thresholds for out-of-spec results. The SOP has a procedure in place for *ad hoc* investigations requested by IPC teams. Legionella testing is covered by

the Environmental Laboratory's SOP entitled *LP532 Detection & Enumeration of Legionella by Filtration*.

For the purpose of microbiological water testing and reporting, specific areas in the new buildings have been designated as high risk by the QEUH Estates Department and IPC, as detailed in the QEUH Estates Department SOP entitled *WQS-017 Procedures in the event of out of specification sample for Legionella and other monitored bacteria, moulds etc.*. High-risk areas include transplant and haematology units, intensive care and high dependency units, and others (see Supplemental Information for details on which wards are classified as high risk). Stricter water testing thresholds are applied in these areas (Table 1). In addition, the specialist units within the new buildings (aseptic pharmacies and RHC Theatre 8) that have their own testing arrangements also have different thresholds. Outwith these high-risk and specialist areas, general microbiological thresholds are applied across the new buildings.

Table 1. Routine water tests and count thresholds for out-of-spec results

Test	Type	Description	Thresholds (general)	Thresholds (high risk)	Thresholds (specialist)
Legionella	Legionella	Legionella count per 1L (any species/serogroup)	Any count	Any count	Any count
PS100	Pseudomonas	Pseudomonas species count per 100 ml	10 CFU/100 ml	Any count	Any count
PA100	Pseudomonas	*Pseudomonas aeruginosa* count per 100 ml	10 CFU/100 ml	Any count	Any count
TVC37	potable	Total viable count (37°C) per 1 ml	100 CFU/ml	10 CFU/ml	10 CFU/ml
TVC22	potable	Total viable count (22°C) per 1 ml	100 CFU/ml	10 CFU/ml	100 CFU/ml
CF100	potable	Coliform count per 100 ml	Any count	Any count	Any count
EC100	potable	*Escherichia coli* count per 100 ml	Any count	Any count	Any count
SAB30	fungi	Fungal count at 30°C	10 CFU/100 ml	10 CFU/100 ml	NA
SAB22	fungi	Fungal count at 22°C	10 CFU/100 ml	10 CFU/100 ml	NA
GNB	Gram negative bacteria incl. Cupriavidus	GNB count per 100 ml	Any count	Any count	NA
AMS	Atypical mycobacteria	AMS count per 100 ml	Any count	Any count	Any count

The thresholds shown in Table 1 are those currently applied to different areas of the new buildings. Not all of these thresholds would have been in place throughout the period 2015-2020. Routine fungal and GNB testing began in Dec 2018, whereas AMS testing began in Apr 2019, and the more stringent TVC thresholds for high-risk areas were

introduced in Dec 2018. A large amount of reactive testing specifically for Cupriavidus was carried out in March-Apr 2018, but routine testing for this organism was only described in WQS-017 in Dec 2018. An outline of the thresholds used for each routine test throughout the period 2015-2020 can be found in the report entitled *Summary of legislation and guidance for routine microbiological water tests carried out at QEUH Adults and RHC*.

Water testing numbers 2015-2020

Table 2 shows the annual numbers of water samples collected and the numbers of different microbiological tests that were carried out in the new buildings. There was a marked increase in sample and test numbers in 2019-2020 compared with the earlier years, due to the expanded programme of sampling and testing that was implemented in the new buildings in Dec 2018 to coincide with the installation of on-site chlorine dioxide dosing systems.

Table 2. Annual numbers of water samples and microbiological tests carried out in the QEUH new buildings (Adults and RHC)

Year	Number of samples[1]	Legionella tests	Pseudomonas tests	Potable tests	Fungal tests	Cupriavidus/ GNB tests[2]	AMS tests	Other specific tests
2015	2189	1280	390	637	0	0	0	0
2016	1885	1542	390	181	0	0	0	50
2017	1097	706	379	166	0	0	0	161
2018	3968	1548	547	554	400	2027	0	81
2019	4753	2916	3893	4194	3211	652	412	81
2020	6625	2926	5532	5628	2429	3504	517	124
Total	20 517	10 918	11 131	11 360	6040	6 183	929	497

[1]Samples were frequently booked in for more than one type of test.
[2]Reactive testing for Cupriavidus and other GNBs was predominantly carried out in Mar-Apr 2018, with routine testing for these organisms implemented in Dec 2018.

Samples were often booked in for more than one type of test, so there is some incomplete overlap between test numbers. A summary of all test requests is shown in Figure 1. This includes the routine tests as well as each of the reactive tests for a specific named microorganism and *ad hoc* tests, such as TVC per 100 mL. The largest number of samples underwent only Legionella testing, followed by the number of samples that underwent two or more of the standard tests (Legionella, Pseudomonas, potable, fungi). Monthly test numbers in different areas of the new buildings are shown in the following section (Microbiological test results) for each routine test.

Although a broad distinction can be made between routine and reactive water testing, in reality, over the period 2015-2020, this distinction was more nuanced due to variations in the tests ordered by IPC teams during reactive sampling, which differed among IPC doctors and also with the nature of the IMT investigation. In some instances, the reactive tests ordered were for one or two specific microorganisms, but in other cases, a broader suite of general tests was requested instead of or alongside specific microorganism tests. Occasionally, rather than requesting tests for a specific organism, IPC/IMTs requested an *ad hoc* version of a general test, notably TVC per 100 ml, which is carried out by filtration and allows subsequent identification of any colonies that grow, rather than the standard TVC per ml, carried out by the pour plate method, where colonies are embedded in agar and cannot subsequently be identified.

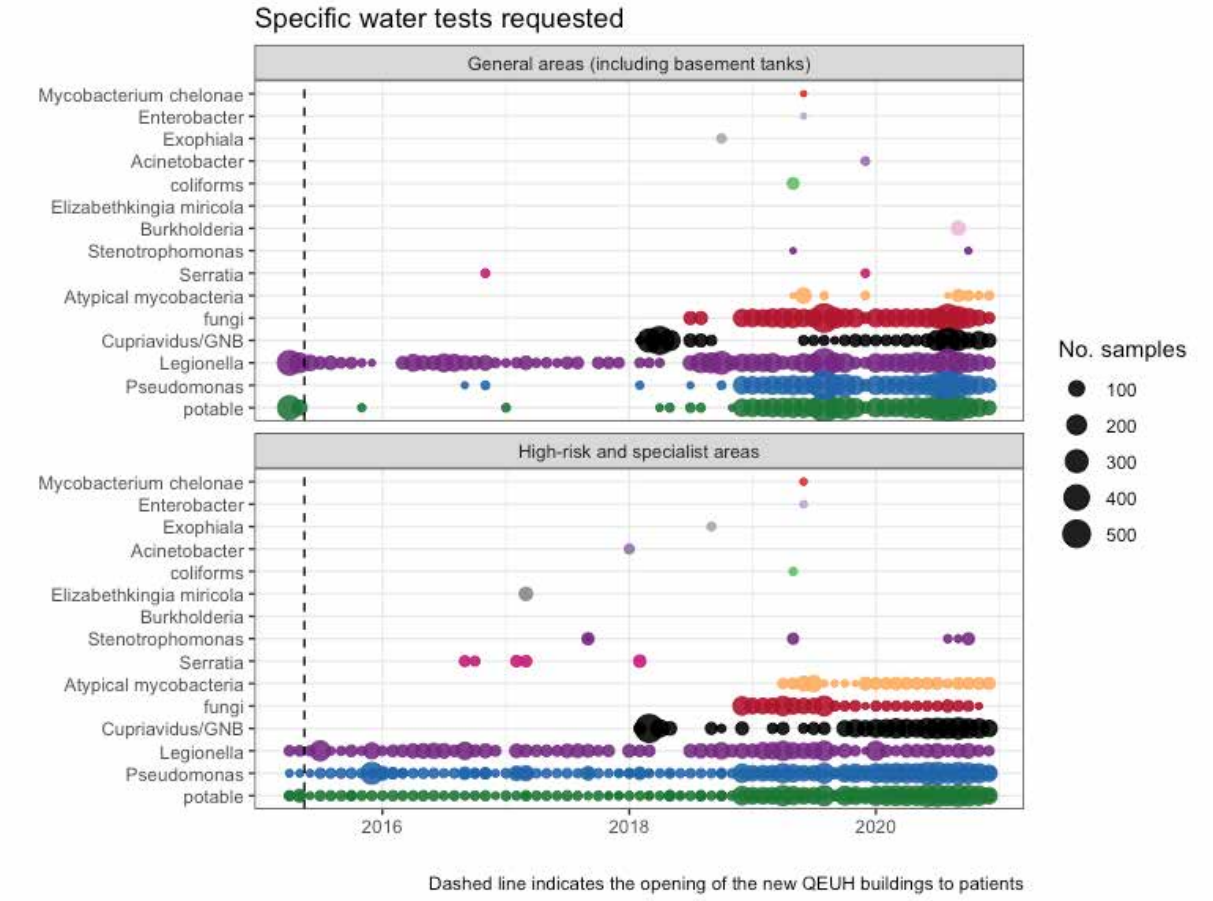

Figure 1. Types of microbiological tests requested across general and high-risk areas of QEUH Adults and RHC, 2015-2020. Specialist units are grouped with high-risk areas. Circle size is proportional to the number of tests per month.

Figure 1 shows the tests that were requested at the time of sampling, not an indication of the microbiological results that were subsequently reported (microbiological results are presented in the next section). The test(s) requested on the sample login sheets did not generally constrain the identification of microorganisms, as the Environmental Laboratory routinely identified organisms that grew in general tests, as well as non-target species that grew in specific tests (see below).

Microbiological results: Out-of-spec samples

This section shows the number of samples classified as passes or out of spec on Legionella, Pseudomonas, potable, fungal, Cupriavidus/GNB, and AMS tests over the period 2015-2020 (a sample is deemed out of spec when the microbial counts exceeded the thresholds set by GG&C, outlined in Table 1). Samples are split into four groups: general areas; high-risk areas (including specialist units); and two parts of the basement tank system that feeds both QEUH Adults and RHC – pre/intra-filtration (including any dip or drain sample from the raw water storage tanks or the sampling points within the filter units) and post-filtration (including any dip or drain sample from the bulk filtrate tanks, where water is stored after filtration but before supplementation with chlorine dioxide).

However, while this section gives a broad overview of sample numbers, it does not delve further into the nature of the out-of-spec samples or the sampling context - whether a point-of-use (POU) filter was fitted and if so, whether the sample was taken through the POU filter or after its removal, whether the sample was collected before or after outlet flushing, whether it was a repeat sampling following an earlier out-of-spec result, etc. A more detailed summary of all named organism results, including target and non-target species reported from specific tests, will be shown in the following section.

Of the routine microbiological water tests carried out by GG&C, only those for Legionella and Pseudomonas have required or recommended thresholds in applicable legislation and guidance, and the GG&C thresholds in Table 1 meet or exceed those requirements or recommendations (for more details, refer to the report entitled *Summary of legislation and guidance for routine microbiological water tests carried out at QEUH Adults and RHC*). Coliform and *E. coli* tests, included in the potable water panel of tests, also have legal thresholds for water to meet potable standards (any count is considered out of spec), but routine potable testing is not required in healthcare settings except in specific circumstances (see the summary of legislation and guidance report).

The thresholds used in this section to classify samples as passes or out of spec are those currently in place for the QEUH campus and listed in Table 1, with appropriate thresholds applied to samples depending on whether they were from general, high-risk, or specialist areas. However, it is important to note that here, in order to allow a valid comparison of water results over the period 2015-2020, the current thresholds are being applied retrospectively to samples that were collected before some of these thresholds were in place, including the more stringent high-risk TVC22 threshold (10 CFU/mL) that was implemented in Dec 2018. This will classify some samples as out of spec that would not have been considered out of spec at the time, but a temporal comparison is only valid if the same thresholds are applied throughout the period under consideration. Table 3 shows the percent of samples classified as out of spec per year (using current thresholds) on each microbiological test.

Table 3. Percent of samples out of spec for each test, using current thresholds

Year	Legionella	Pseudomonas (reported)[1]	Pseudomonas (corrected)[1]	Potable	Fungi	Cupriavidus[2]	Other GNB[3]	AMS
2015	10.70	11.54	7.95	32.18				
2016	13.55	24.36	4.87	3.31				
2017	0.42	0.00	0.00	12.05				
2018	1.42	0.18	0.18	1.44	4.50	11.05	24.72	
2019	0.17	0.85	0.85	6.08	8.13	3.22	5.52	20.15
2020	0.07	0.40	0.40	3.07	13.42	0.86	11.36	0.39

[1]Some Pseudomonas counts reported in 2015-2016 are likely transcription errors. This column is based on corrected entries, without transcription errors (see Pseudomonas section below for details).
[2]Cupriavidus (which is a GNB) and other GNBs are detected on the same microbiological test, but as they tend to be reported as two separate results, they are given separate columns here.
[3]Other GNB includes only the samples that were negative for Cupriavidus but positive for another GNB. It does not include the small number of samples that were Cupriavidus-positive and also positive for another GNB, since these are already counted in the Cupriavidus column.

The current process for dealing with out-of-spec water results on the QEUH campus is detailed in the QEUH Estates Department SOP WQS-017. Briefly, when the Environmental Laboratory and Intertek send microbiological results to DMA, any out-of-spec samples are flagged and their details entered in a dedicated spreadsheet (out-of-spec summary sheet). Full results, including the out-of-spec summary sheet, are shared with QEUH Estates, GG&C Microbiology, and contacts in IPC. Any serious issues are immediately reported to the Lead Authorised Person (LAP) in QEUH Estates. For all out-of-spec samples, the LAP logs an Incident Report, which triggers a work request for remedial action. All remedial work is logged on the out-of-spec summary sheet, and DMA continue sampling the affected outlets until a minimum of three clear results are obtained.

Legionella test results

Overall, 10 918 samples from the new buildings underwent Legionella testing over the period 2015-2020. Here, any detection of Legionella was considered out of spec, regardless of location, species or serogroup, a stricter threshold than in applicable legislation and guidance. Over the period 2015-2020, there were 378 out-of-spec samples in total (3.5% of samples). The majority of out-of-spec samples were from general areas (360 out-of-spec samples out of 5798, i.e. 6.2%) and were concentrated in the earlier part of the period, in 2015-2016. High-risk areas had 17 out-of-spec samples over the entire period 2015-2020, out of 3909 samples (0.43%). There were no Legionella detected in the 824 samples from the basement tank system (pre/intra-filtration), and one Legionella positive sample out of 387 from the post-filtration basement tanks (0.26%). Monthly numbers of Legionella samples that were out of spec versus those that passed are shown in Figure 2.

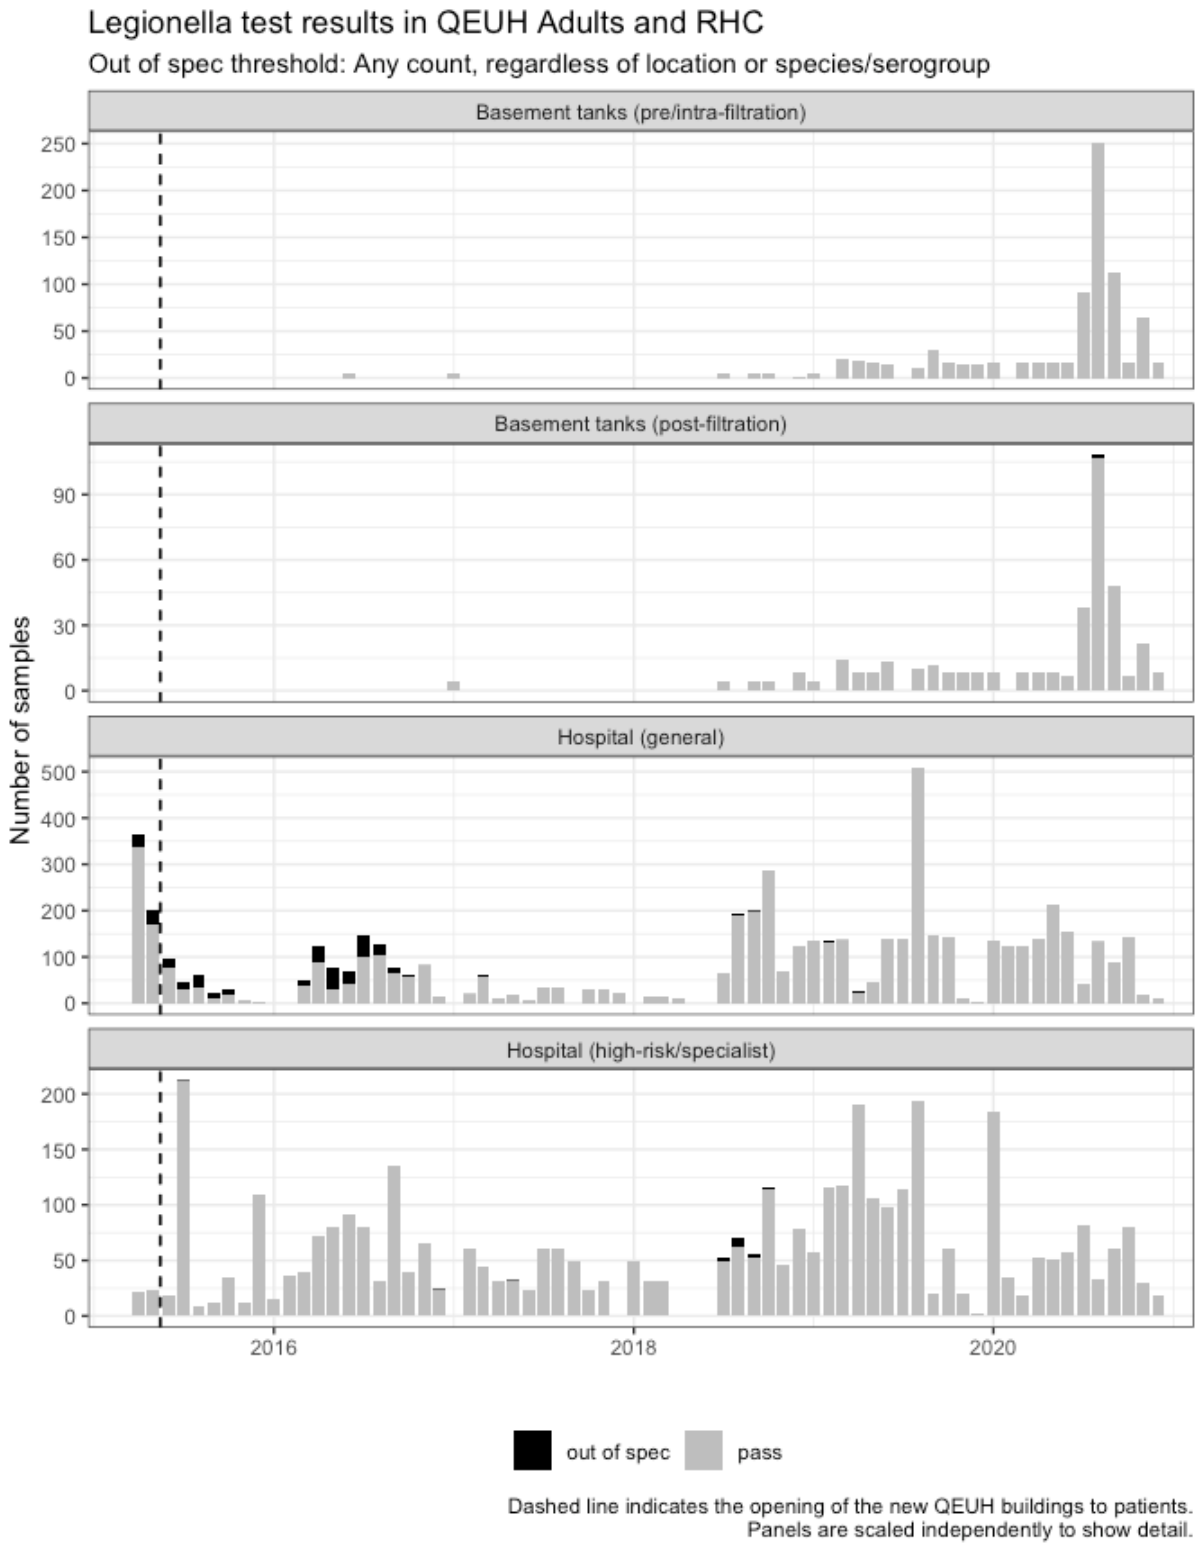

Figure 2. Number of Legionella tests out of spec per month in different areas of QEUH Adults and RHC. Panels are scaled independently to show detail.

Figure 2 gives the number and distribution of samples that had any Legionella count, regardless of species and serogroup. However, when Legionella counts are detected, the testing laboratories provide additional species and serogroup information to distinguish

between the following: *Legionella pneumophila* serogroup 1, the variant that causes approximately 95% of human cases (Lp.1), *Legionella pneumophila* serogroups 2 to 14 (Lp.2-14), or other Legionella species (L.species). Figure 3 shows the species/serogroup results for these out-of-spec samples.

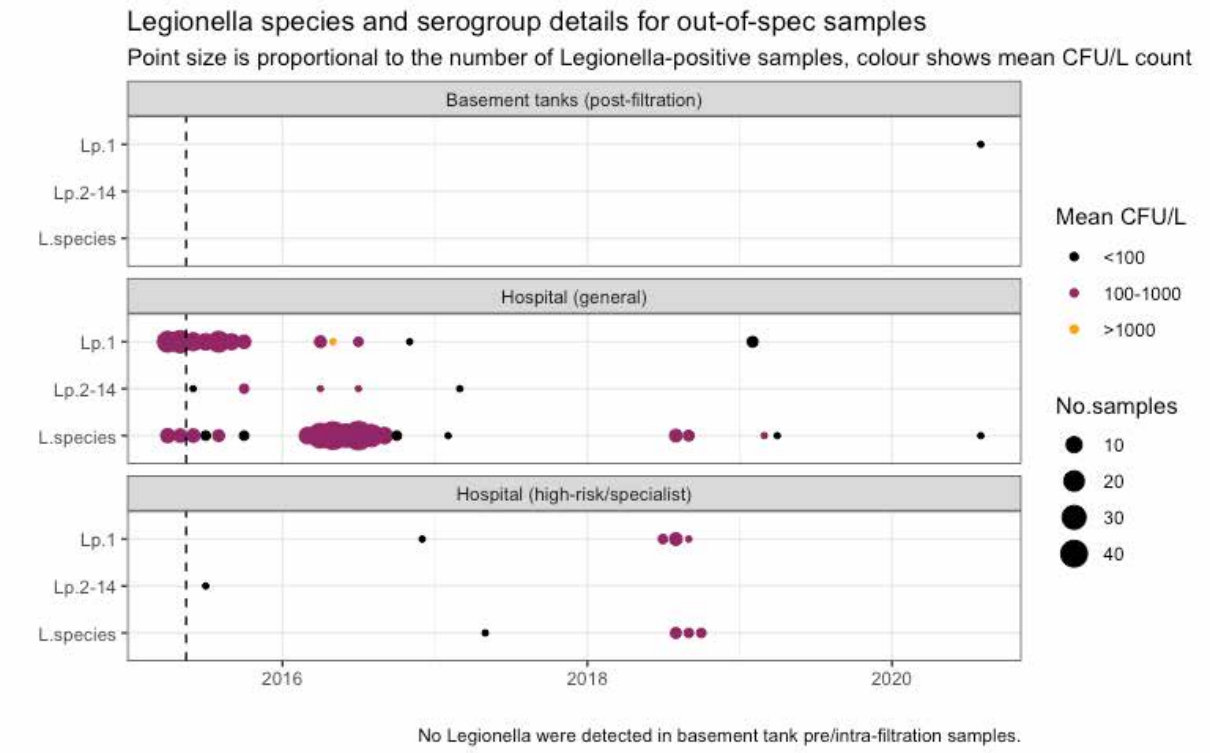

Figure 3. Legionella species and serogroup details for out of spec samples in QEUH Adults and RHC.

Legionella pneumophila serogroup 1 (Lp.1) was rarely detected in the new buildings after late 2015. Samples testing positive for Lp.1 were concentrated in the months prior to and immediately following opening. *Legionella pneumophila* serogroups 2-14 were almost absent from the new buildings over the entire period, and other Legionella species were detected only sporadically, with the largest occurrence in 2016.

Pseudomonas test results

It is important to note a possible data entry or transcription error that might be inflating the Pseudomonas out-of-spec results in 2015-2016. In the new buildings, out-of-spec Pseudomonas results were reported mostly over the period Jul 2015 to Sep 2016, with few out-of-spec Pseudomonas results after that date. Most of these samples were from the new building aseptic pharmacies, apart from the larger number of samples collected in Dec 2015 from other areas. Closer inspection of the data recorded in TelePath shows that for most of the CFU counts recorded in the PS100 column for the aseptic pharmacies and for Ward 1D (PICU) over this period, an identical number was also entered in another data column reserved for other named organisms, next to a named species (often

Cupriavidus pauculus but occasionally other species, including *Comamonas testosteroni*, *Achromobacter denitrificans*, and *Alcaligenes faecalis*). This exact duplication of counts suggests that the numbers reported in the PS100 column from Jul 2015 to Sept 2016 (excluding Dec 2015) were the total colonies on the Pseudomonas agar plates, not those that had been confirmed as Pseudomonas, and that these colonies were subsequently identified as belonging to other species. If this were the case, most of the Pseudomonas out-of-spec samples over this period would instead be passes. This section shows both the reported Pseudomonas results, including these likely transcription errors, and the corrected Pseudomonas results, where these duplicated counts are excluded.

Overall, 11 131 samples from the new buildings underwent Pseudomonas testing. Thresholds for Pseudomonas tests (PS100 or PA100) differ by location (Table 1): 10 CFU/100 mL in general areas, and no count in high-risk and specialist areas. Over the period 2015-2020, there were 196 reported out-of-spec samples in total (1.8% of samples), though this number drops to 106 out-of-spec samples (0.95%) when likely transcription errors are corrected (transcription errors only affected samples from specialist and high-risk areas - the aseptic pharmacies and PICU).

In the basement tank system, most Pseudomonas out-of-spec results were in the pre/intra-filtration samples (32 samples out of 930, or 3.4%) and not in the post-filtration tank samples (2 samples out of 401, or 0.5%). In general areas, 3 samples out of 3758 (0.08%) were out of spec, whereas in high-risk areas and specialist areas, where the stricter threshold applies, 159 samples out of 6042 (2.6%) were out of spec, though this drops to 69 samples (1.1%) when likely transcription errors are taken into account. Total Pseudomonas passes and out-of-spec results (both reported and corrected) in these four areas of the new buildings, grouped by month, are shown in Figure 4.

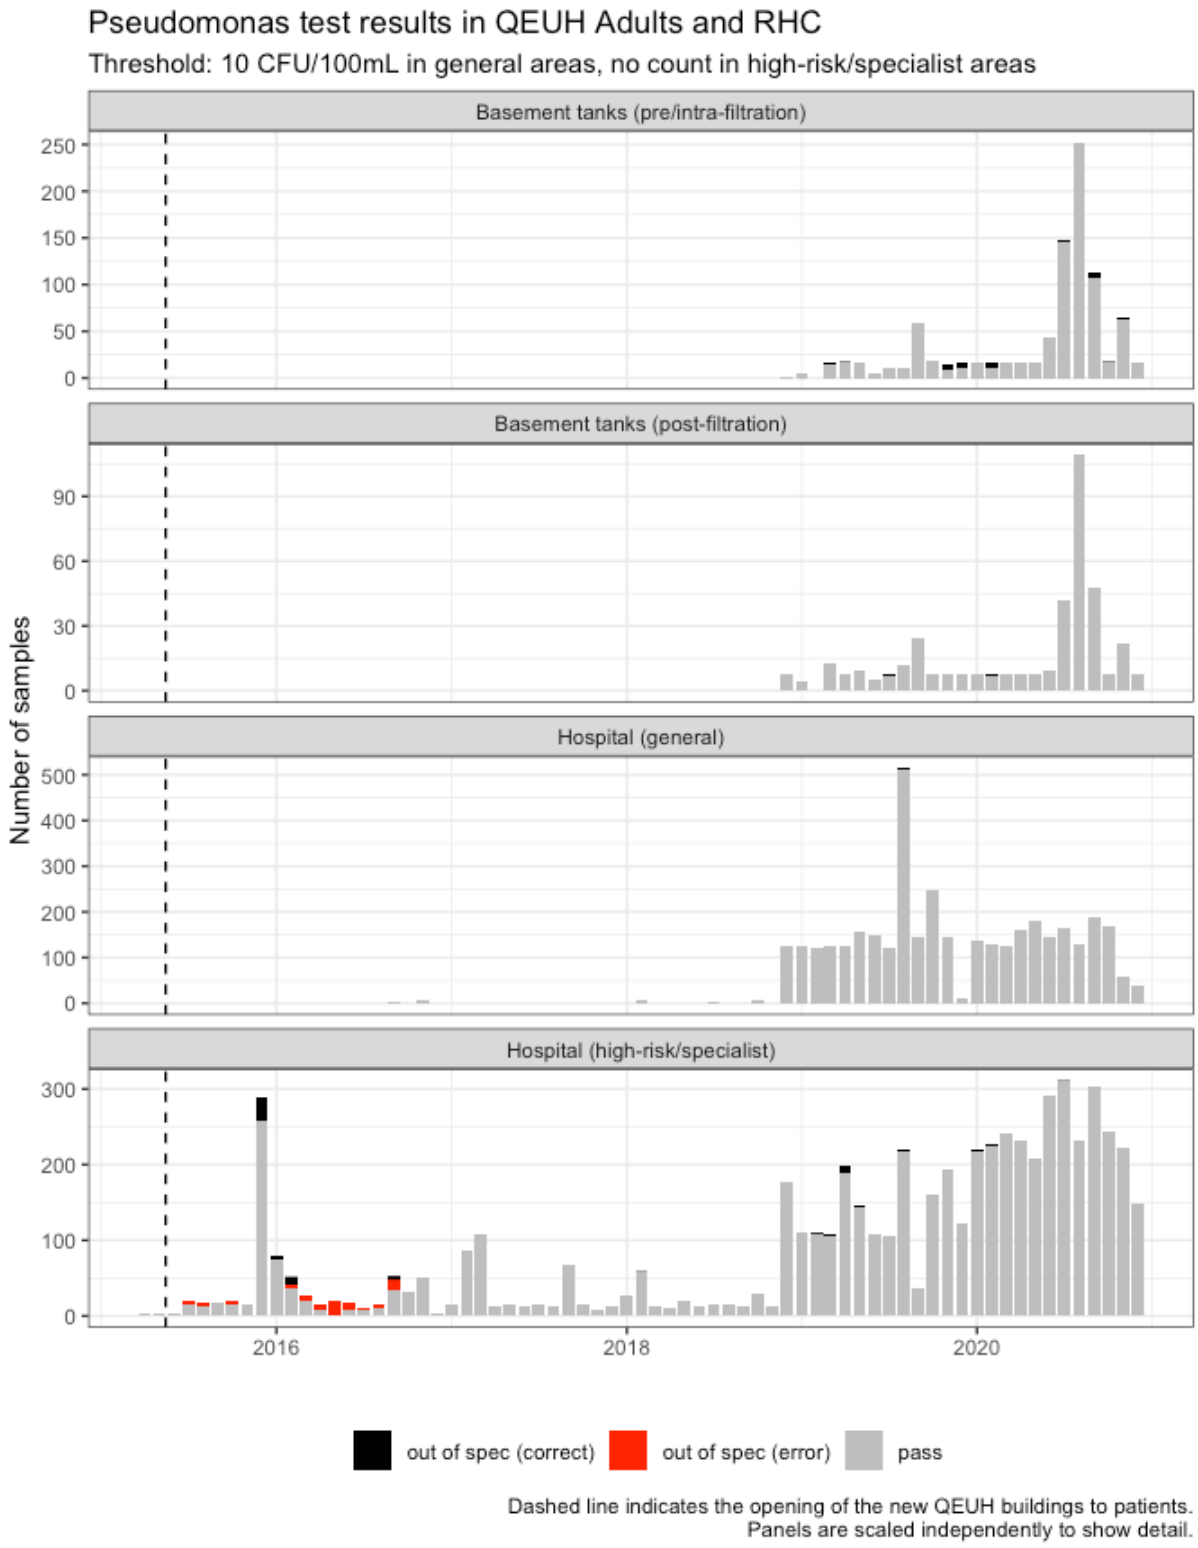

Figure 4. Number of Pseudomonas tests out of spec per month in QEUH Adults and RHC. Panels are scaled independently to show detail. Black bars show true out-of-spec samples, red bars show samples with reported counts that are likely transcription errors and should be considered passes.

Potable water tests

Potable water samples include all those with microbiological results for TVC37, TVC22, CF100 and EC100. Of the 11 360 potable tests carried out in the new buildings over the period 2015-2020, 667 (5.9%) were out of spec (using the current thresholds). The majority of out-of-spec samples were due to elevated TVC22 (476 samples in total, i.e. 4.2%) and/or TVC37 (364 samples in total, i.e. 3.2%) (Figure 5). CF100 (coliforms per 100 mL) counts were less often responsible for out-of-spec results (59 samples in total, i.e. 0.52%), and EC100 counts (*Escherichia coli* per 100 mL) were only observed in three samples (0.026%).

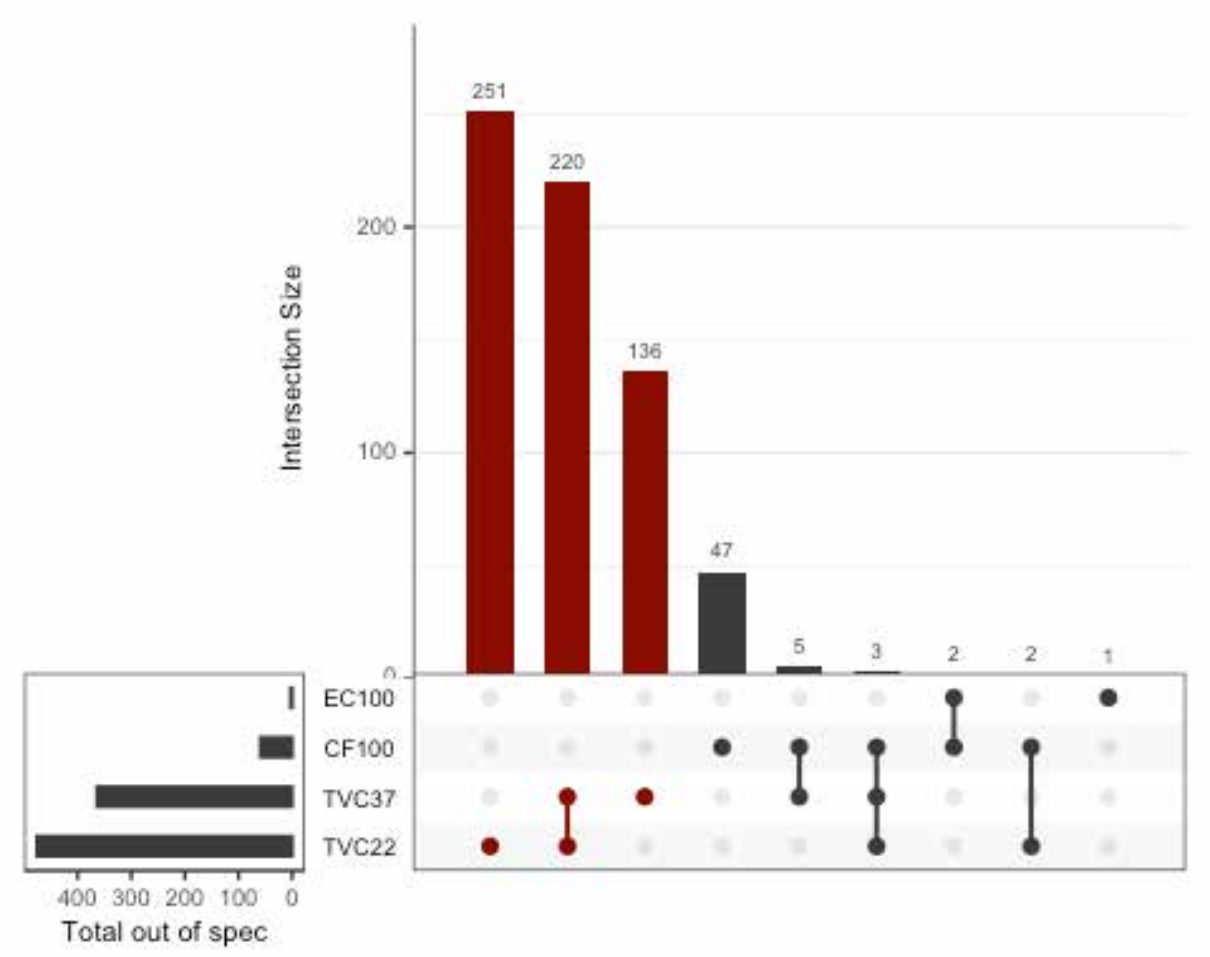

Figure 5. Specific tests responsible for potable water out-of-spec results in the new buildings 2015-2020. Red bars indicate the number of samples that were out of spec on TVCs only, black bars show number of samples with out-of-spec results in CF100 and/or EC100.

Thresholds currently in place for potable testing vary by location, with the strictest ones being applied in high-risk areas (10 CFU/mL on both TVC22 and TVC37), intermediate ones in specialist units (10 CFU/mL on TVC37, 100 CFU/mL on TVC22), and less stringent ones in general areas (100 CFU/mL on both TVC37 and TVC22). Coliform and *E. coli* counts must be zero in all areas.

The highest percentage of potable out-of-spec results was in the pre/intra-filter basement tank samples (81 out of 953 samples, i.e. 8.5%), whereas the proportion out of spec was lower in the post-filtration basement tanks (12 out of 420 samples, i.e. 2.9%). General areas had a slightly higher proportion of out-of-spec samples (268 out of 4367 samples, i.e. 6.1%) than high-risk and specialist areas (306 out of 5620 samples, i.e. 5.4%), despite the latter having stricter thresholds.

Figure 6 shows the number of potable water samples, grouped by month, that passed all four potable tests, versus the number that were out of spec according to the current thresholds (i.e. they exceeded thresholds on one or more of the four tests).

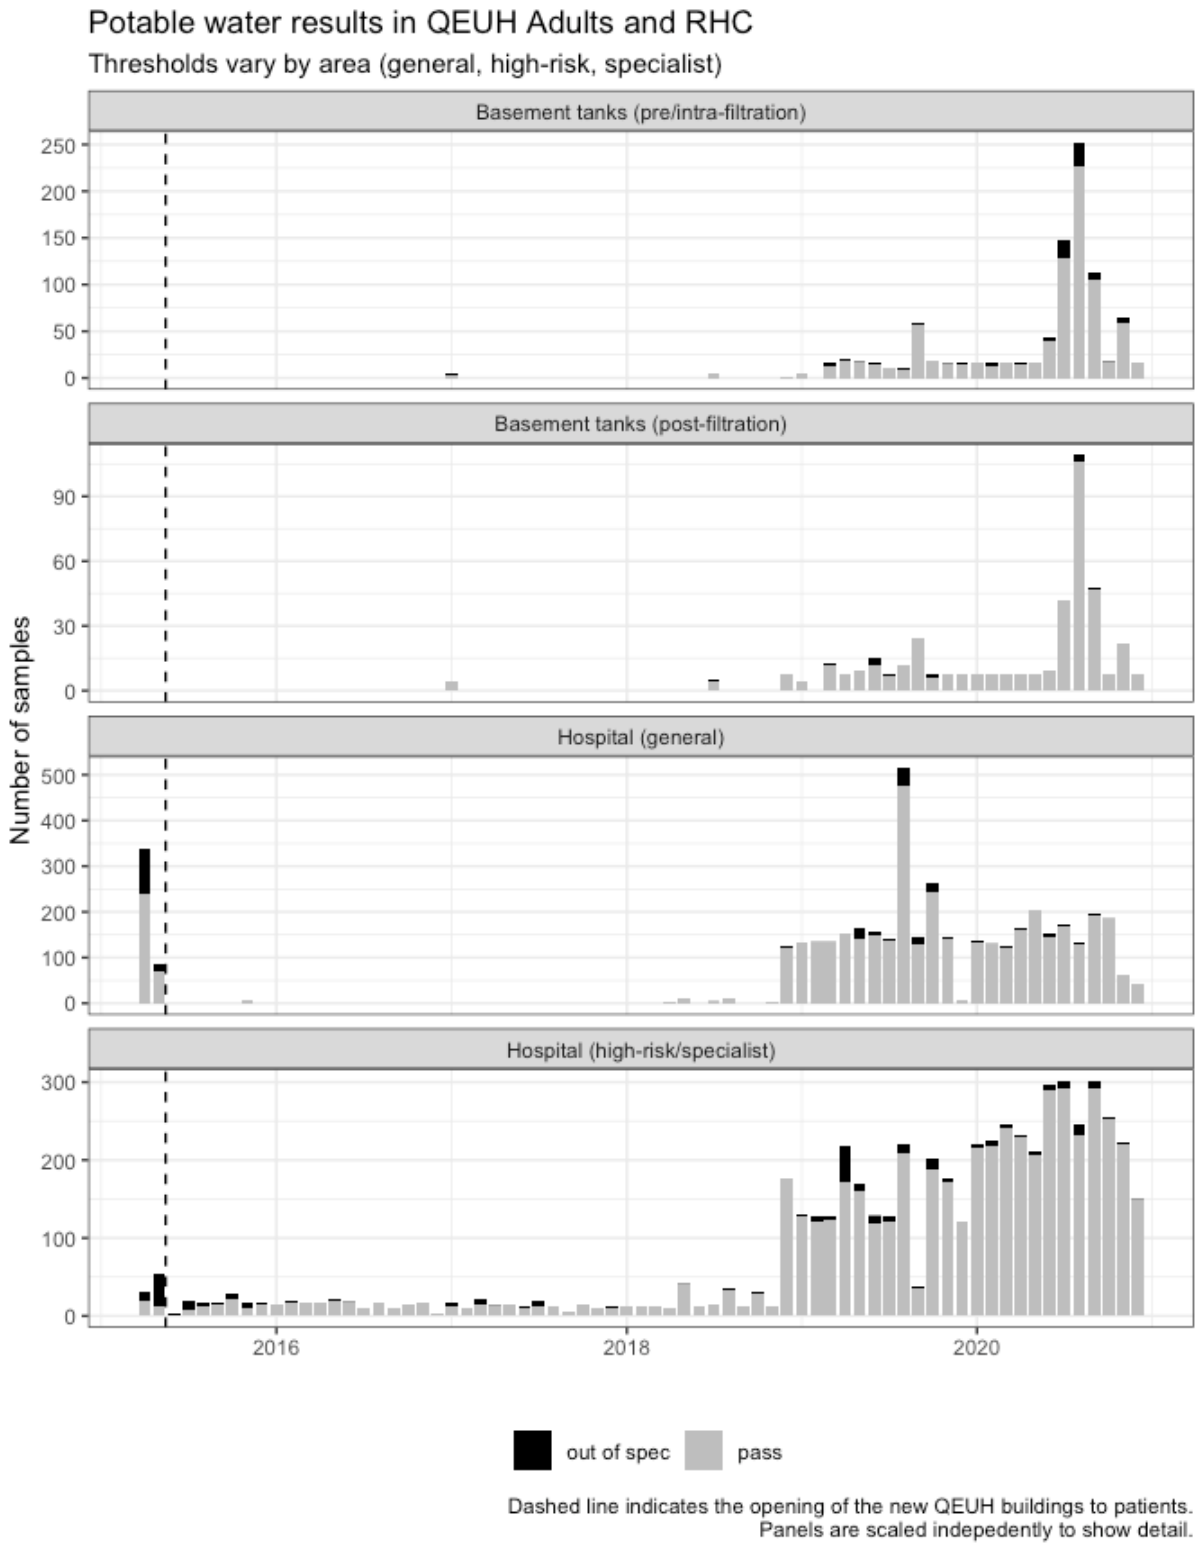

Figure 6. Number of potable tests out of spec per month in QEUH Adults and RHC. Panels are scaled independently to show detail.

Fungal test results

Routine fungal testing (SAB30 and SAB22 tests) began in December 2018. There are currently no recommended thresholds for this type of testing in guidance or legislation, so GG&C apply the threshold listed in Table 1: 10 CFU/100 mL in general and high-risk areas (routine fungal testing is not carried out in the specialist units).

Overall, 6040 samples from the new buildings underwent fungal testing over the period 2015-2020. There were 605 out-of-spec samples in total (10.0% of samples). Over half of all out-of-spec results were from the pre/intra-filter basement tank samples, where the percent out of spec was 37.5% (348 out of 927 samples). The percent out of spec dropped to 6.1% in the post-filtration basement tanks (24 out of 396 samples). Samples from the hospital areas had a lower percent out of spec than the post-filtration basement tanks, with general areas being slightly higher in proportion of out-of-spec samples (167 out of 3284 samples, i.e. 5.1%) than high-risk areas (66 out of 1433 samples, i.e. 4.6%).

Figure 7 shows the number of fungal samples, grouped by month, from each of the four areas (basement pre/intra-filtration, basement post-filtration, hospital general, and hospital high-risk).

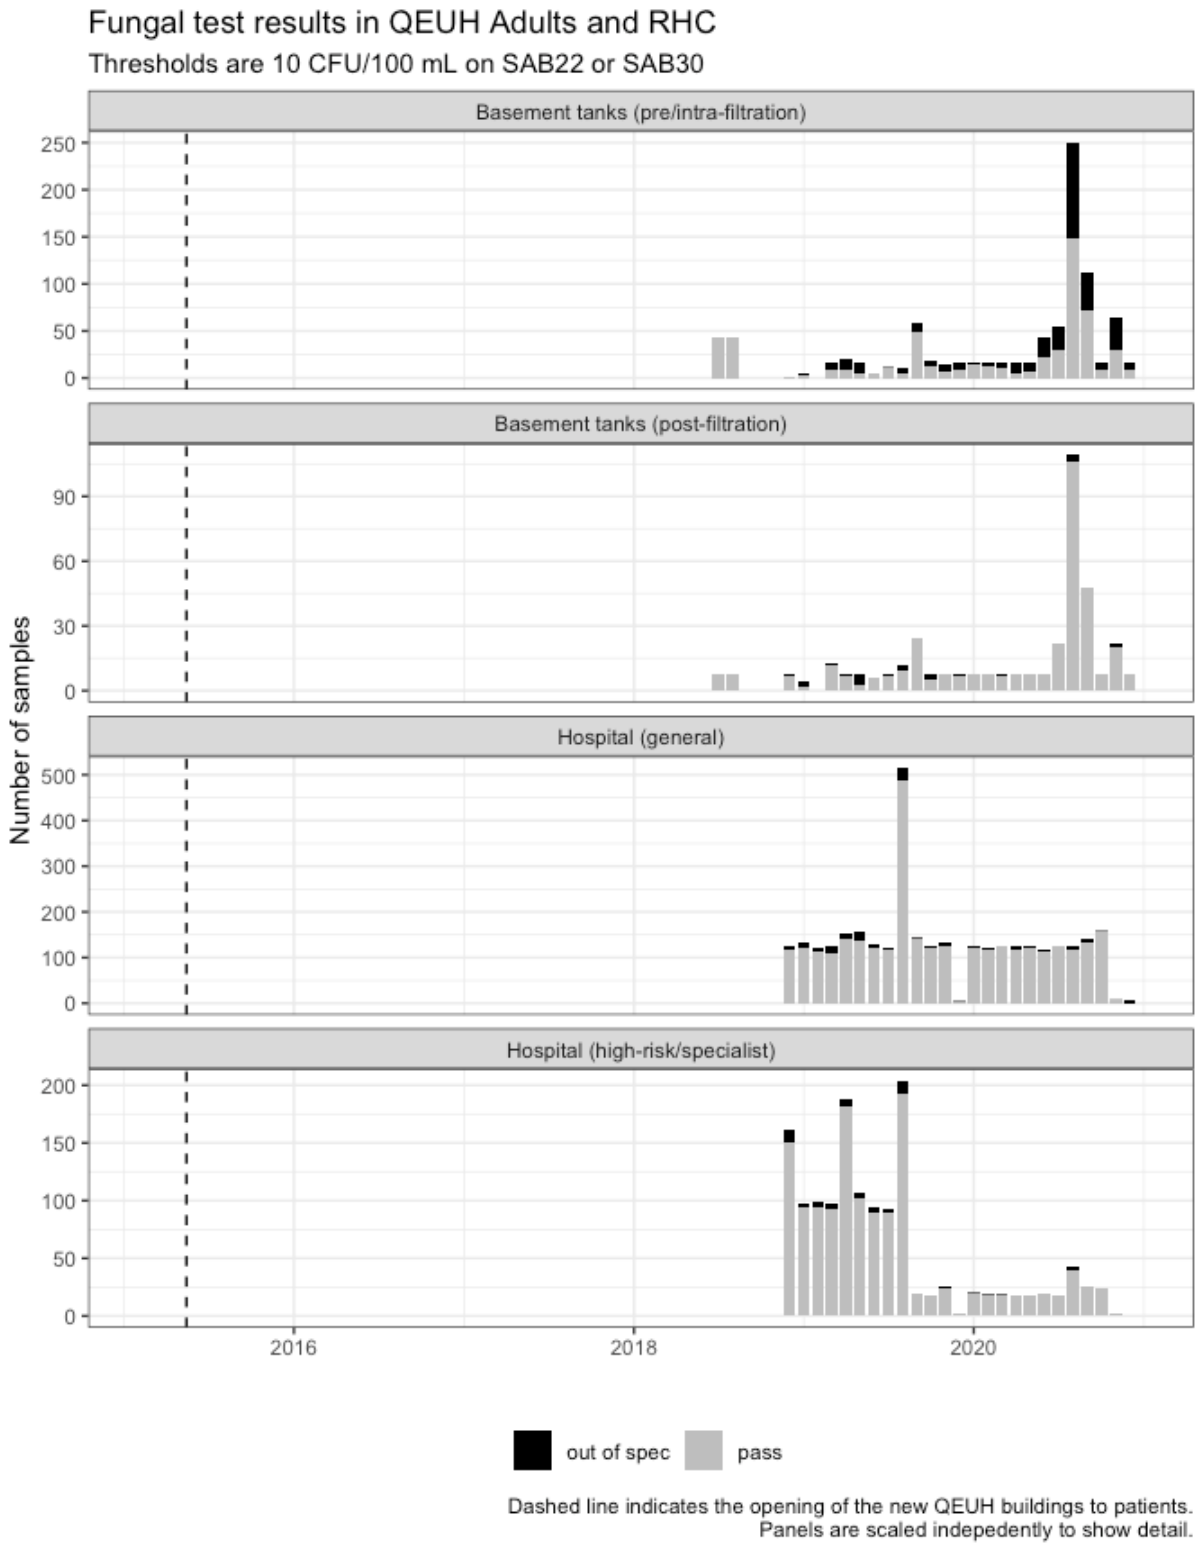

Figure 7. Number of fungal tests out of spec per month in QEUH Adults and RHC

Cupriavidus and other Gram negative bacteria

Although Cupriavidus and other Gram negative bacteria (GNBs) were occasionally noted as non-target taxa in other tests (e.g. see Pseudomonas section above), testing *specifically* for Cupriavidus and other GNBs began in February 2018 with reactive testing in RHC Ward 2A (35 samples) and in the basement tanks (five samples, exact location pre- or post-filter unspecified). While the requested test was for Cupriavidus, the Environmental Laboratory was asked to identify and report any GNB that grew (the test name was later changed to GNB to reflect this). The five basement tank samples did not grow Cupriavidus or any other GNB, but 24 out of the 35 samples from Ward 2A (68.6%) grew one or more Cupriavidus species, with three of these 24 samples also testing positive for an additional GNB. A further 9 of these 35 samples did not grow Cupriavidus but were positive for other GNBs. Only 2 of the 35 samples from Ward 2A were negative. As a result, a larger sampling effort was undertaken across QEUH Adults and RHC in March-April 2018, with 1484 samples tested specifically for Cupriavidus and other GNBs. Overall, 191 (12.9%) were positive for Cupriavidus (48 of these also grew an additional GNB), and a further 358 (24.1%) did not grow Cupriavidus but were positive for other GNBs, meaning the positivity rate for any GNB, including Cupriavidus, was 37.0%.

Including these samples and those collected from May 2018 onwards, 6183 samples from the new buildings underwent testing specifically for Cupriavidus and other GNBs over the period 2018-2020. Of these, 275 (4.4%) grew Cupriavidus and 935 (15.1%) did not grow Cupriavidus but were positive for other GNBs (giving an overall positivity rate of 19.5% for any GNB). The distribution over time of GNB/Cupriavidus test numbers, Cupriavidus-positive samples, and samples that did not grow Cupriavidus but were positive for other GNBs is shown in Figure 8, split into different areas of the new buildings. Cupriavidus-positive samples occasionally reported other GNBs as well, with 56 samples overall reporting both Cupriavidus and at least one other GNB. There was no precedent for this type of testing in GG&C prior to Feb 2018, and in the absence of recommended thresholds or interpretive criteria, GG&C currently treat any detected Cupriavidus species or other GNB as out of spec, regardless of where samples were collected. As in earlier sections, this threshold is applied retrospectively here in order to examine temporal and spatial trends.

Cupriavidus species were only rarely detected in the basement tanks, with 0.73% (7 samples out of 960) of pre/intra-filtration tank samples and 0.84% (3 samples out of 358) of post-filtration tank samples testing positive. In contrast, the proportion of samples that tested negative for Cupriavidus but positive for other GNBs was considerably higher, with 33.6% (323 samples out of 960) of pre/intra-filtration tank samples and 15.6% (56 samples out of 358) of post-filtration tank samples growing one or more GNBs.

From general hospital areas, 80 out of 1323 samples (6.0%) were positive for Cupriavidus, with a further 312 samples (23.6%) negative for Cupriavidus but positive for another GNB. This pattern was different in high-risk areas; a similar percent overall, 5.2%, was positive for Cupriavidus (185 out of 3542 samples), but the percent of samples that were Cupriavidus-negative but positive for other GNBs was considerably lower, 6.9% (244 out of 3542 samples). The Cupriavidus out-of-spec samples from high-risk areas were predominantly from the Feb-Apr 2018 sampling effort. When looking only at the 2850 samples from high-risk areas tested specifically for Cupriavidus and other GNBs from May 2018 onwards, 45 (1.6%) had any detectable Cupriavidus species, and a further 108 (3.8%) had other GNBs.

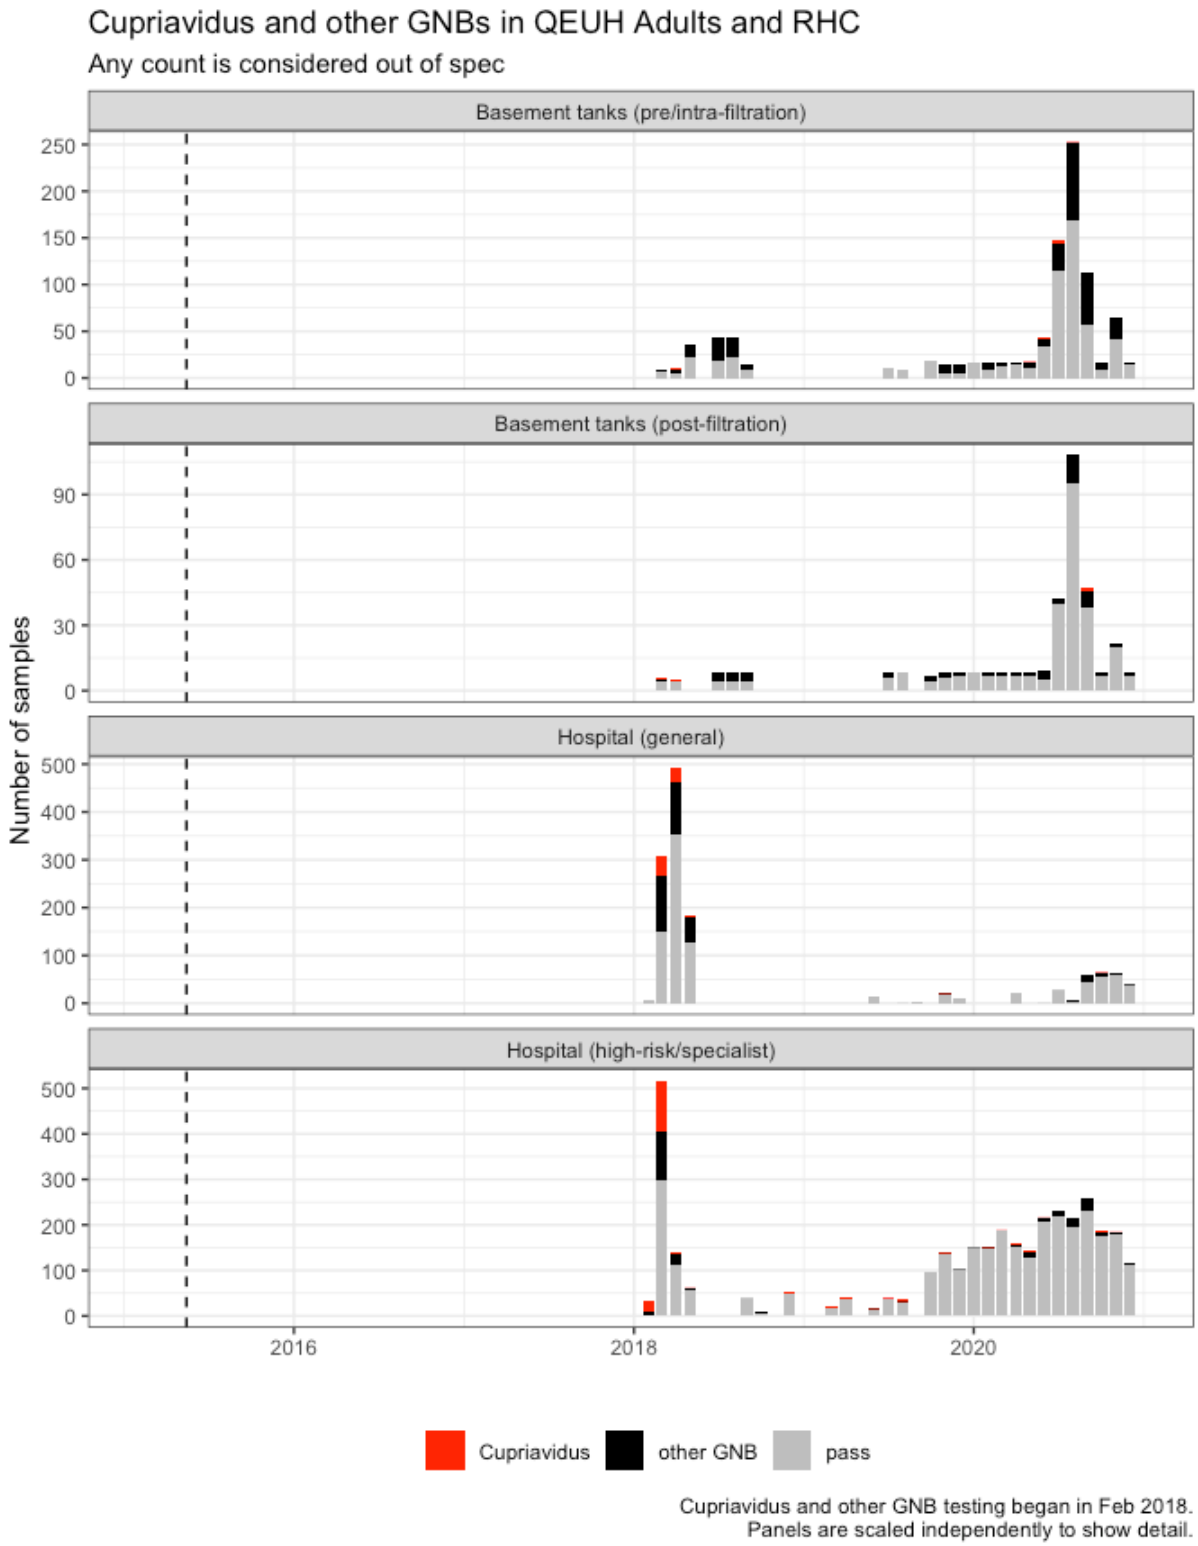

Figure 8. Number of Cupriavidus and other GNBs out of spec per month in QEUH Adults and RHC. Panels are scaled independently to show detail. The 'other GNB' category does not include the small number of samples that were positive for Cupriavidus plus one or more additional GNBs, since these are already counted in the 'Cupriavidus' category.

Atypical mycobacteria test results

Overall, 929 samples from the new buildings underwent AMS testing over the period 2015-2020, though these tests were all carried out in the latter part of the period, 2019-2020, and predominantly in high-risk areas. There were 85 out-of-spec samples in total (9.1% of samples). Sampling in the basement tanks and in general areas was limited to a handful of time points. A single sample from the pre/intra-filter basement tanks was out of spec, out of 12 samples (8.3%), and none of the 16 samples from the post-filtration basement tanks were out of spec. Samples from general hospital areas had the highest proportion out of spec, 34 out of 167 samples (20.4%). These were almost entirely from a sampling effort carried out in June 2019, with the out-of-spec samples being predominantly from the 1st floor theatres. More regular and sustained AMS testing occurred in the high-risk areas, where 50 out of 734 samples (6.8%) were out of spec. Total AMS passes and out-of-spec results, grouped by month, are shown in Figure 9.

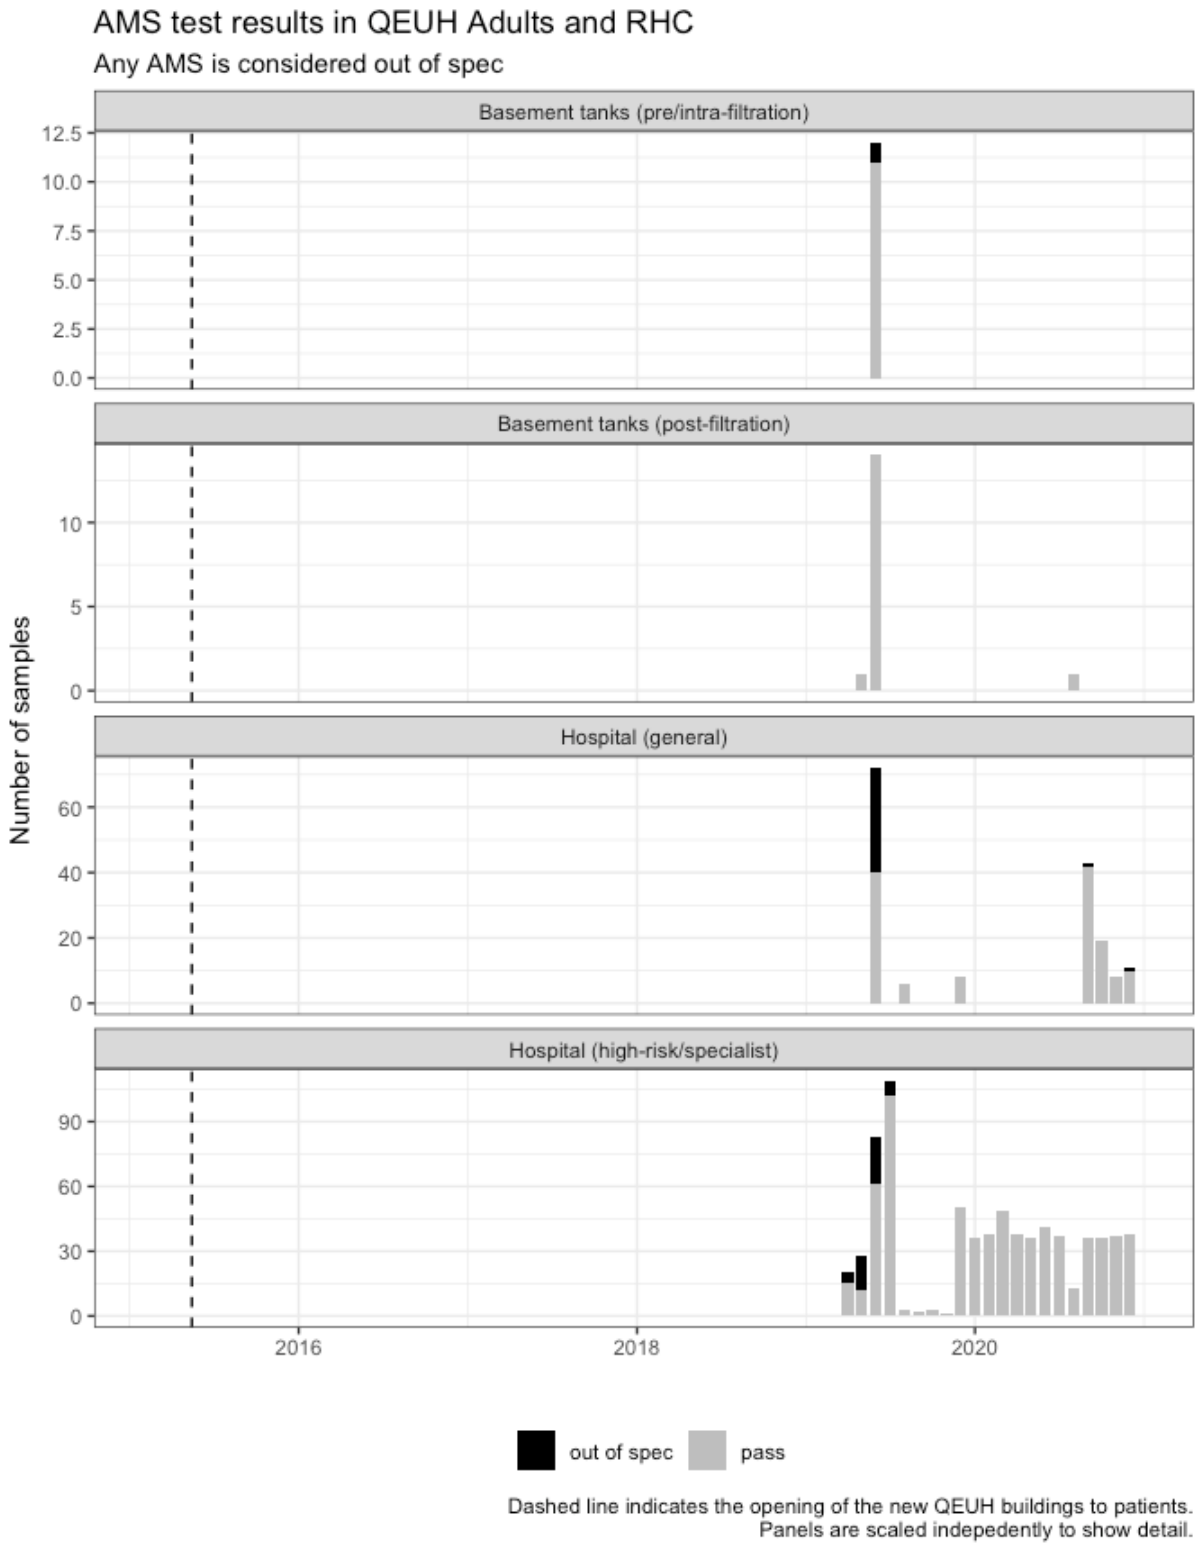

Figure 9. Number of AMS tests out of spec per month in QEUH Adults and RHC.

Results of reactive tests for other organisms

In addition to the tests described in the previous sections (Legionella, Pseudomonas, potable, fungi, Cupriavidus/GNB, AMS), water samples were occasionally booked in for other types of test, usually in the context of reactive sampling requested by IMTs/IPCTs. Numbers, locations and results of these other tests, those for specific organisms, are shown in Table 4. None of these tests were positive for the organism requested, though three of the four tests for *Mycobacterium chelonae* reported atypical mycobacteria (species unspecified).

Table 4. Organism-specific ad hoc tests requested across the new buildings

Specific test	Ward	Number of tests	Number with the target org.
Acinetobacter	1D PICU (RHC)	16	0
	other	8	0
Burkholderia	other	72	0
coliforms	other	40	0
Elizabethkingia miricola	2A/2B (RHC)	56	0
Enterobacter	6A (Adults)	3	0
	other	1	0
Exophiala	2A/2B (RHC)	1	0
	other	20	0
Mycobacterium chelonae	6A (Adults)	3	0
	other	1	0
Serratia	1D PICU (RHC)	105	0

	2A/2B (RHC)	40	0
	6A (Adults)	34	0
	other	42	0

Microbiological results: Named microorganisms

The tests listed above generally looked for specific organisms (except for TVCs and fungal tests, which counted total colonies). The microbiological growth media used in organism-specific tests are designed to encourage the growth of these organisms while inhibiting non-target species. However, this is not perfect; non-target species commonly grow in organism-specific tests, so laboratories use other methods to confirm the identity of colonies before reporting results. Depending on the laboratory, the presence and identity of non-target species may or may not be recorded and included in the final report.

ALcontrol and Intertek did not generally report named microorganisms from cultures obtained during routine potable, Pseudomonas, and fungal testing. However, the GG&C Environmental Laboratory did keep records in TelePath relating to the identification of non-target species, often in free-text data fields called 'Laboratory Comments' or 'Laboratory Comments - Not Reported'. In the earlier years, 2015-2017, these non-target species would have been found during potable, Pseudomonas, or reactive testing for other specific species (see Pseudomonas section above, where counts of non-target organisms appear to have been reported as Pseudomonas in error, indicating the growth of these taxa on the Pseudomonas plates). When the Cupriavidus/GNB and fungal tests were introduced at various points in 2018, the number and diversity of named organisms in the data sheets increased markedly, since these tests require laboratory staff to identify all growth on the agar plates.

This section focuses on the named organism data from the GG&C Environmental Laboratory, including target and non-target organisms regardless of which type of test was performed on the water sample. It is important to note that the numbers and types of test performed were not consistent over the period 2015-2020, and that the abundance and diversity of named organisms are dictated by sample numbers, test types and reporting criteria. From 2018, there was a large increase in sample numbers and in the effort taken by the laboratory to identify all organisms.

Environmental organisms with mandatory reporting

The National Infection Prevention and Control Manual (NIPCM), Appendix 13, describes the nationally agreed mandatory minimum list of alert organisms for infections to be reported to Infection Prevention and Control Teams and includes certain organisms under the heading "Environmental bacteria". The NIPCM does not mandate routine testing for or reporting of the presence of these organisms in environmental samples outwith investigations into clinical cases. The four organisms currently listed under this heading in Appendix 13 are: *Pseudomonas aeruginosa*, Acinetobacter species, *Stenotrophomonas maltophilia*, and *Serratia marcescens*, though the guidance recognises that this list is not exhaustive. These environmental organisms were added to the NIPCM on 30 June 2017, and were added to the GG&C ICNet alert list in August 2017 after going through the necessary IPC governance committees.

Across all 10 311 QEUH Adults and RHC water samples tested by the Environmental Laboratory from 2015-2020 (which does not include samples tested only for Legionella), no *Serratia marcescens* were detected, and *Pseudomonas aeruginosa* were named in a total of 8 samples (only those out-of-spec Pseudomonas tests that confirmed the identification as *P. aeruginosa* are included here, since other Pseudomonas species can grow in those test). *Stenotrophomonas maltophilia* occurred in 76 samples,

predominantly in the basement tanks pre/intra-filtration (Table 5), whereas 7 distinct Acinetobacter species were observed across 73 samples, also predominantly in the basement tanks pre/intra-filtration. *Acinetobacter lwoffii* and *Acinetobacter ursingii* were the most common Acinetobacter species detected (36 and 22 samples, respectively).

Other environmental organisms

The NIPCM guidance recognises that the list of environmental alert organisms is not exhaustive. As expected with potable water, which is not naturally a sterile environment, many more taxa were identified in all test types. Across all 10 311 samples from QEUH Adults and RHC tested by the Environmental Laboratory over the period 2015-2020, 99 bacterial taxa were identified (plus 1 non-taxonomic grouping, 'Environmental GNB', which was reported when the standard laboratory methods were unable to identify colonies), as well as 23 fungal taxa (plus 7 non-taxonomic groupings). Of these, 29 bacterial and 9 fungal groups were rare, occurring in only one sample across the entire data set.

Tables 5 and 6 list all bacterial and fungal groups detected in the new buildings, in decreasing order of abundance (number of samples with the organism). Of the 100 bacterial groups detected across all samples, 20 were found only in the basement tanks (with 14 of these detected only in the pre/intra-filtration tanks, not in the post-filtration tanks). Of the 30 fungal groups detected across all samples, 5 were found only in the basement tanks (with 4 of these detected only in the pre/intra-filtration tanks, not in the post-filtration tanks). Some of the entries are not true taxonomic groups, but broad categories that likely encompass a wide diversity of organisms (e.g. Environmental GNB, Saprophytic fungi). True taxonomic names are shown in italics, and entries ending in 'species' were resolved only to the coarser genus level.

Table 5. All bacterial taxa detected in water samples from QEUH Adults and RHC, with number of positive samples from each area.

Bacterial ID	Basement (pre-filter)	Basement (post-filter)	Hospital (general)	Hospital (high-risk)	Total[1]
Cupriavidus pauculus	9	3	67	361	440

[1]Number of positive samples out of 10 311 samples tested by the Environmental Laboratory 2015-2020, excluding those tested only for Legionella (1054 from the pre/intra-filtered basement tank system, 436 from the post-filtered basement tanks, 2085 from general hospital areas and 6736 from high-risk hospital areas).

All named bacteria and fungi present in more than five samples over the entire data set are shown in Figures 10 and 11. There is a clear increase in the diversity of identified taxa during the large peak in Cupriavidus/GNB testing effort that occurred in March-April 2018, as well as from December 2018 onwards, when sample numbers and the types of test performed routinely both increased markedly.

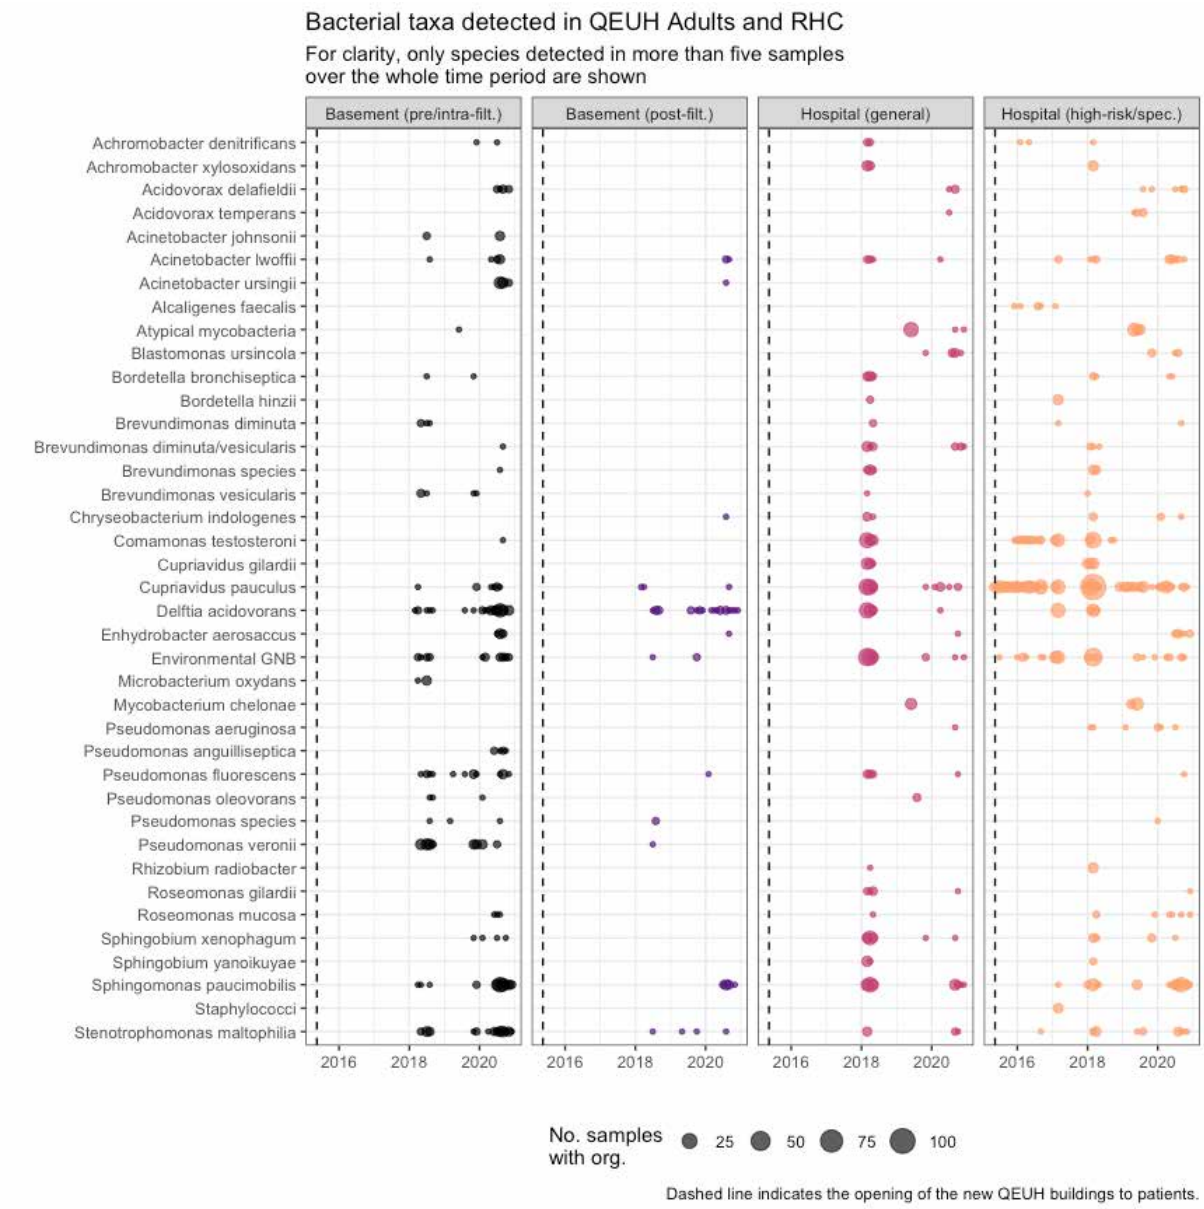

Figure 10. Bacterial taxa identified in different areas of QEUH Adults and RHC over the period 2015-2020.

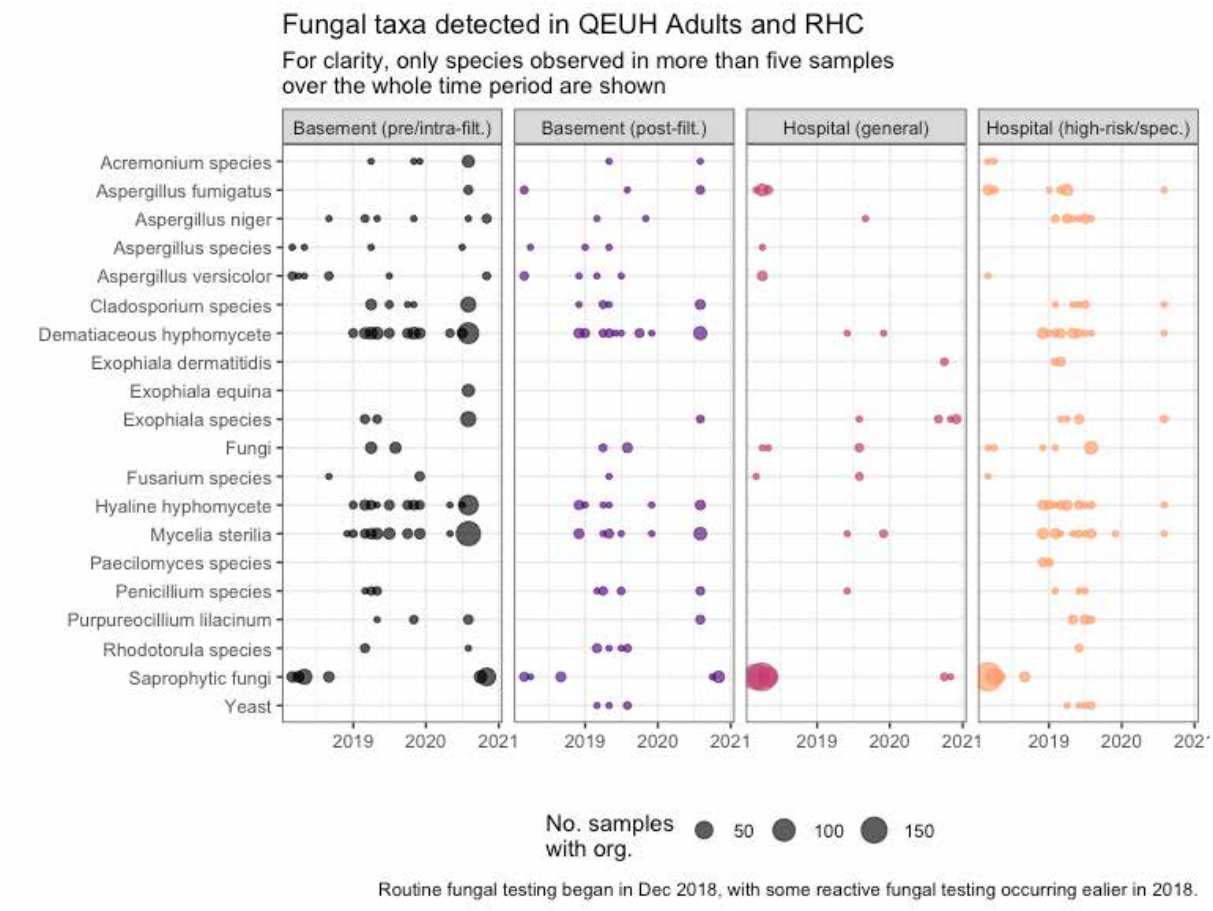

Figure 11. Fungal taxa identified in different areas of QEUH Adults and RHC over the period 2015-2020.

Named organisms were more frequently reported in high-risk than in general areas, and in pre/intra-filtration rather than post-filtration basement tanks. However, this finding could be explained by differences in sample numbers and by the suite of microbiological tests that were performed in each area. In particular, a large number of taxa were detected during the peak sampling effort in Mar-Apr 2018 - not only were samples tested in far greater numbers than usual, but the laboratory was instructed to report the identification of all colonies that grew in the Cupriavidus/GNB test performed on all these samples. Later in 2018, this Cupriavidus/GNB test became routine and was carried out more intensively in high-risk areas, resulting in more named organisms being reported.

It is important to note that identifying environmental organisms is not always straightforward, as the procedures used in routine laboratories are optimised for clinical isolates. The Environmental Laboratory identifies unknown organisms using a MALDI-TOF MS system (Biomerieux), which compares spectra obtained from unknown colonies to those in databases of reference organisms. When the MALDI-TOF system fails to identify an organism, a second system, Vitek (Biomerieux), is used, which carries out a series of biochemical tests in an automated manner to give an organism ID.

Both the MALDI-TOF MS and the Vitek perform well in a clinical laboratory setting, but as their reference databases are heavily biased towards human pathogens, they may perform less well at identifying environmental organisms that are rarely found in a

clinical context. For example, further typing by whole genome sequencing showed that numerous isolates identified as *Cupriavidus pauculus* were either other Cupriavidus species, or were not members of the genus Cupriavidus at all but belonged to other genera. Furthermore, when both systems failed to give an organism ID, the Environmental Laboratory reported 'Environmental GNB'. Table 5 shows that Environmental GNB was the third most common bacterial group detected in the new buildings over the period 2015-2020, with 193 occurrences out of 1918 reports of named bacterial taxa. This means that for 10.1% of the organisms that grew from these water samples, a reliable identification could not be obtained using the MALDI-TOF MS and Vitek platforms.

Ward-specific water sampling

The data presented above encompasses all samples collected across the QEUH Adults and RHC. This section focuses on a subset of these samples, those collected from wards 2A/2B (RHC), 4B (Adults), 6A (Adults), and 1D (PICU, RHC). These wards were all classified as high risk, so the stricter microbiological thresholds were applied.

Legionella results in key wards

Overall, 2089 samples from the key wards underwent Legionella testing over the period 2015-2020. There was a single out-of-spec sample in ward 2A and none in the other wards (0.048% of samples). Monthly numbers of Legionella samples are shown in Figure 12. A single sample from Ward 2A/2B, taken shortly after opening in 2015, tested positive for Legionella. No other sample from these key wards had any detectable Legionella over the period 2015-2020.

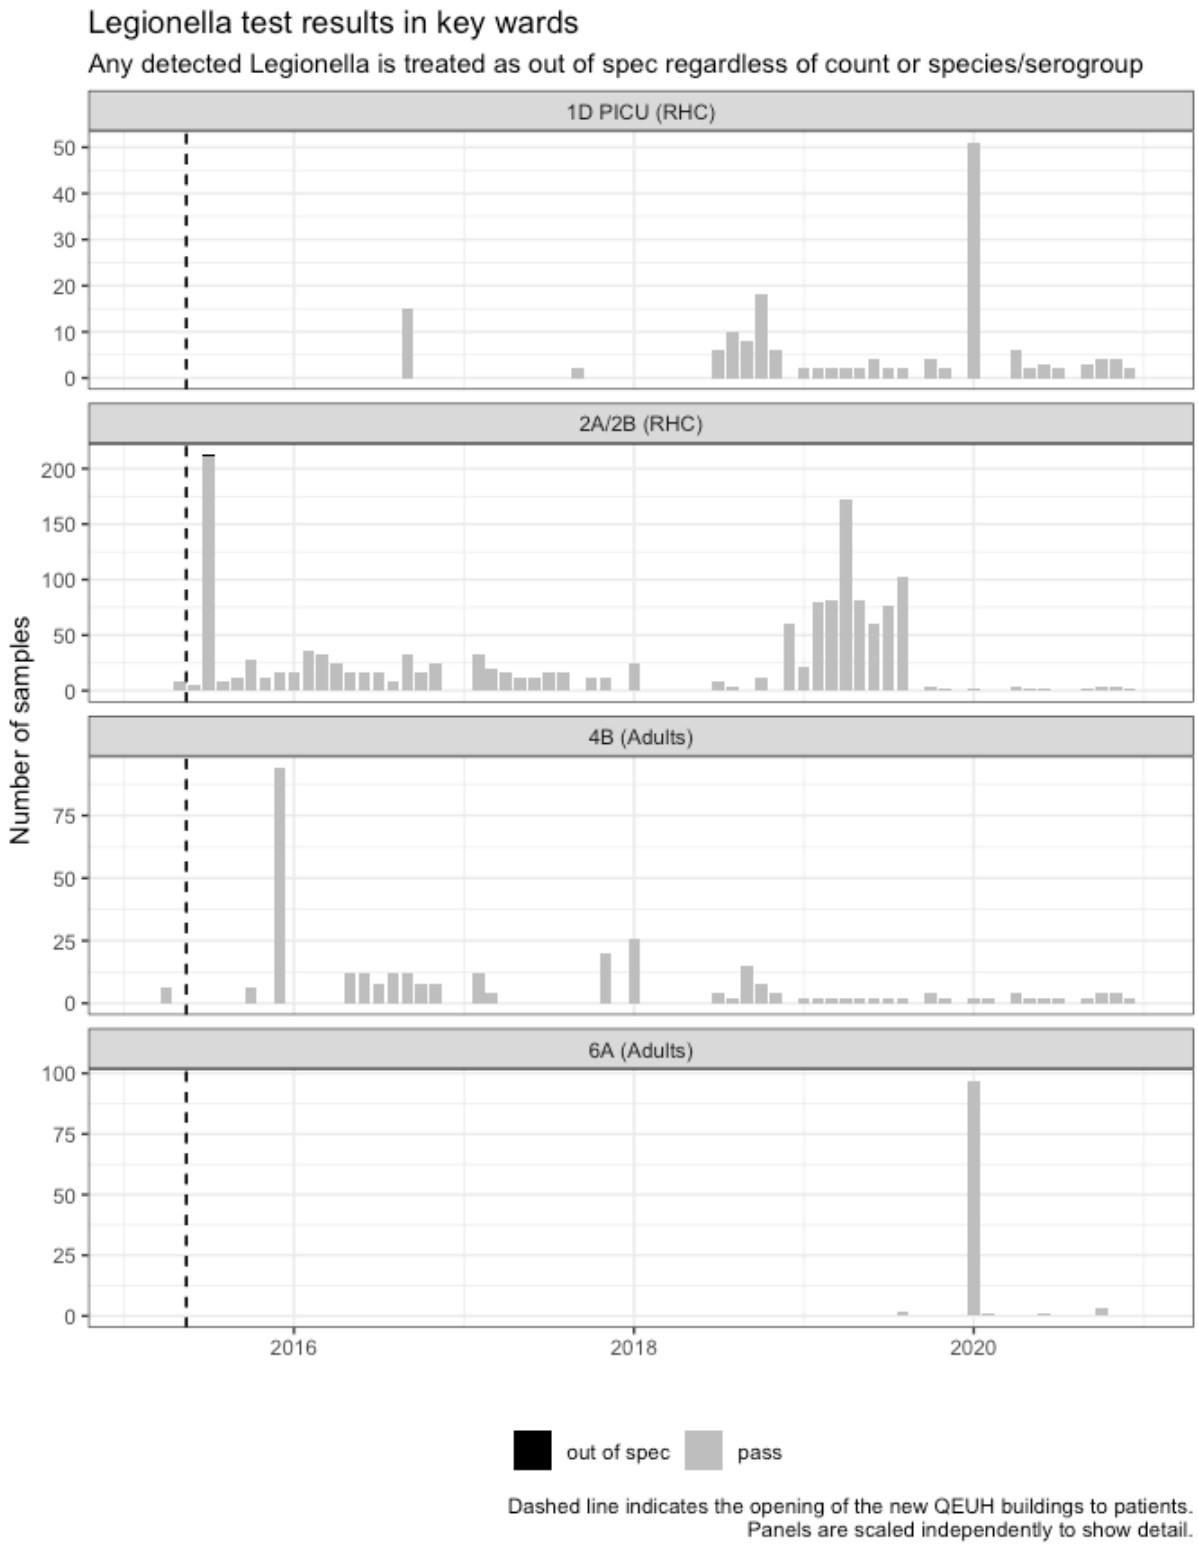

Figure 12. Number of Legionella tests out of spec per month in key wards. A single sample from Ward 2A/2B was out of spec in early 2015. Panels are scaled independently to show detail.

Pseudomonas results in key wards

Overall, 3985 samples from the key wards underwent Pseudomonas testing over the period 2015-2020. With high-risk thresholds, where any Pseudomonas count is considered out of spec, there were 75 reported out-of-spec samples in total (1.9% of samples), though this number drops to 64 out-of-spec samples (1.6%) when likely transcription errors are corrected (transcription errors only affected samples from PICU, not from the other key wards).

Ward 4B had the lowest number of Pseudomonas tests (445 samples) but the highest number out of spec (44 samples, i.e. 9.9%). These were concentrated in the earlier part of the time period, December 2015 to February 2016. The other key wards had lower proportions of Pseudomonas samples out of spec: 13 out of 1056 samples from ward 2A (1.2%), 2 out of 1565 samples from ward 6A (0.13%), and 16 out of 919 samples from PICU (1.7%), which drops to 5 samples when likely transcription errors are excluded (0.54%).

Total Pseudomonas passes and out-of-spec results in these key wards, grouped by month, are shown in Figure 13.

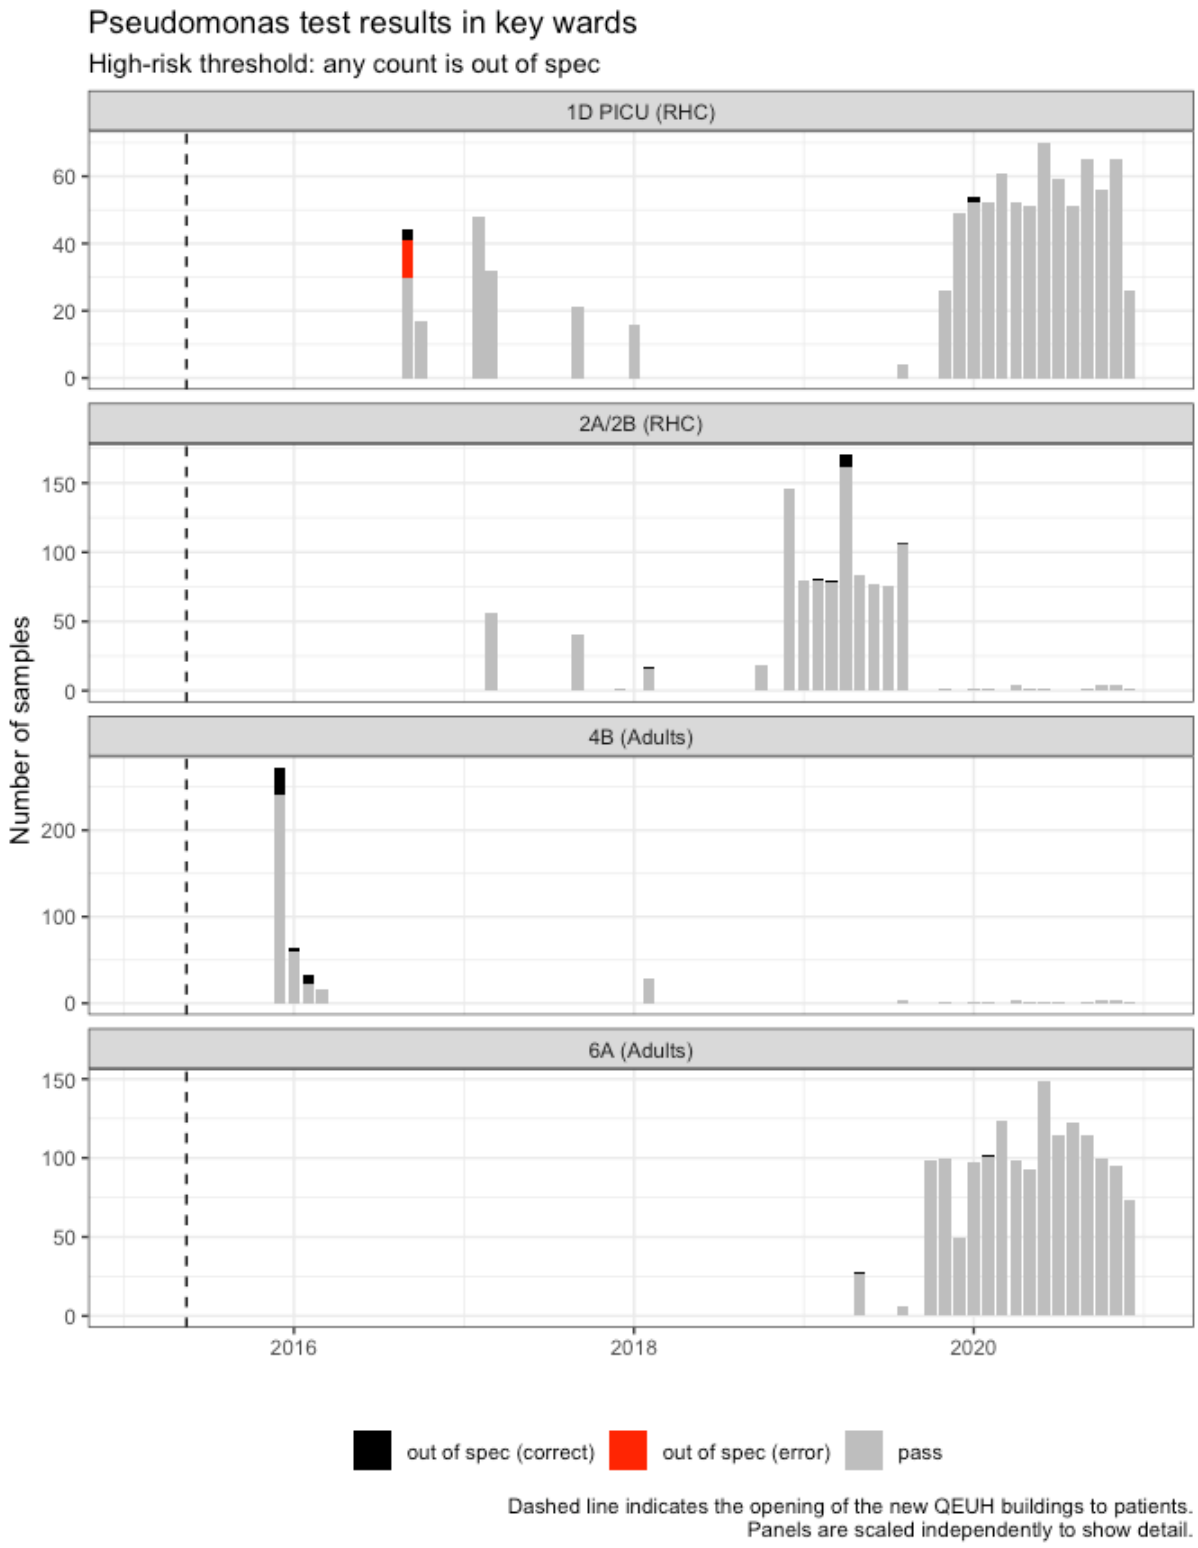

Figure 13. Number of Pseudomonas tests out of spec per month in key wards. Panels are scaled independently to show detail. Black bars show true out-of-spec samples, red bars show samples with reported counts that are likely transcription errors and should be considered passes.

Potable results in key wards

Overall, 3410 samples from the key wards underwent potable water testing over the period 2015-2020. This includes testing for TVC per mL at 22°C and 37°C, coliforms per 100 mL and *E.coli* per 100 mL. High-risk thresholds in place since December 2018 specify 10 CFU/mL for both TVC tests and no counts on coliform and *E.coli* tests. When these high-risk thresholds are applied retrospectively across the entire period 2015-2020 (to allow for comparison over time), 162 samples would be out of spec (4.8% of samples).

Like with Pseudomonas testing, Ward 4B had the lowest number of potable tests (64 samples) but the highest proportion out of spec (7 samples, i.e. 10.9%). The other key wards had lower proportions of potable samples out of spec: 97 out of 979 samples from ward 2A (9.9%), 24 out of 1574 samples from ward 6A (1.5%), and 34 out of 793 samples from PICU (4.3%).

Total potable passes and out-of-spec results in these key wards, grouped by month, are shown in Figure 14.

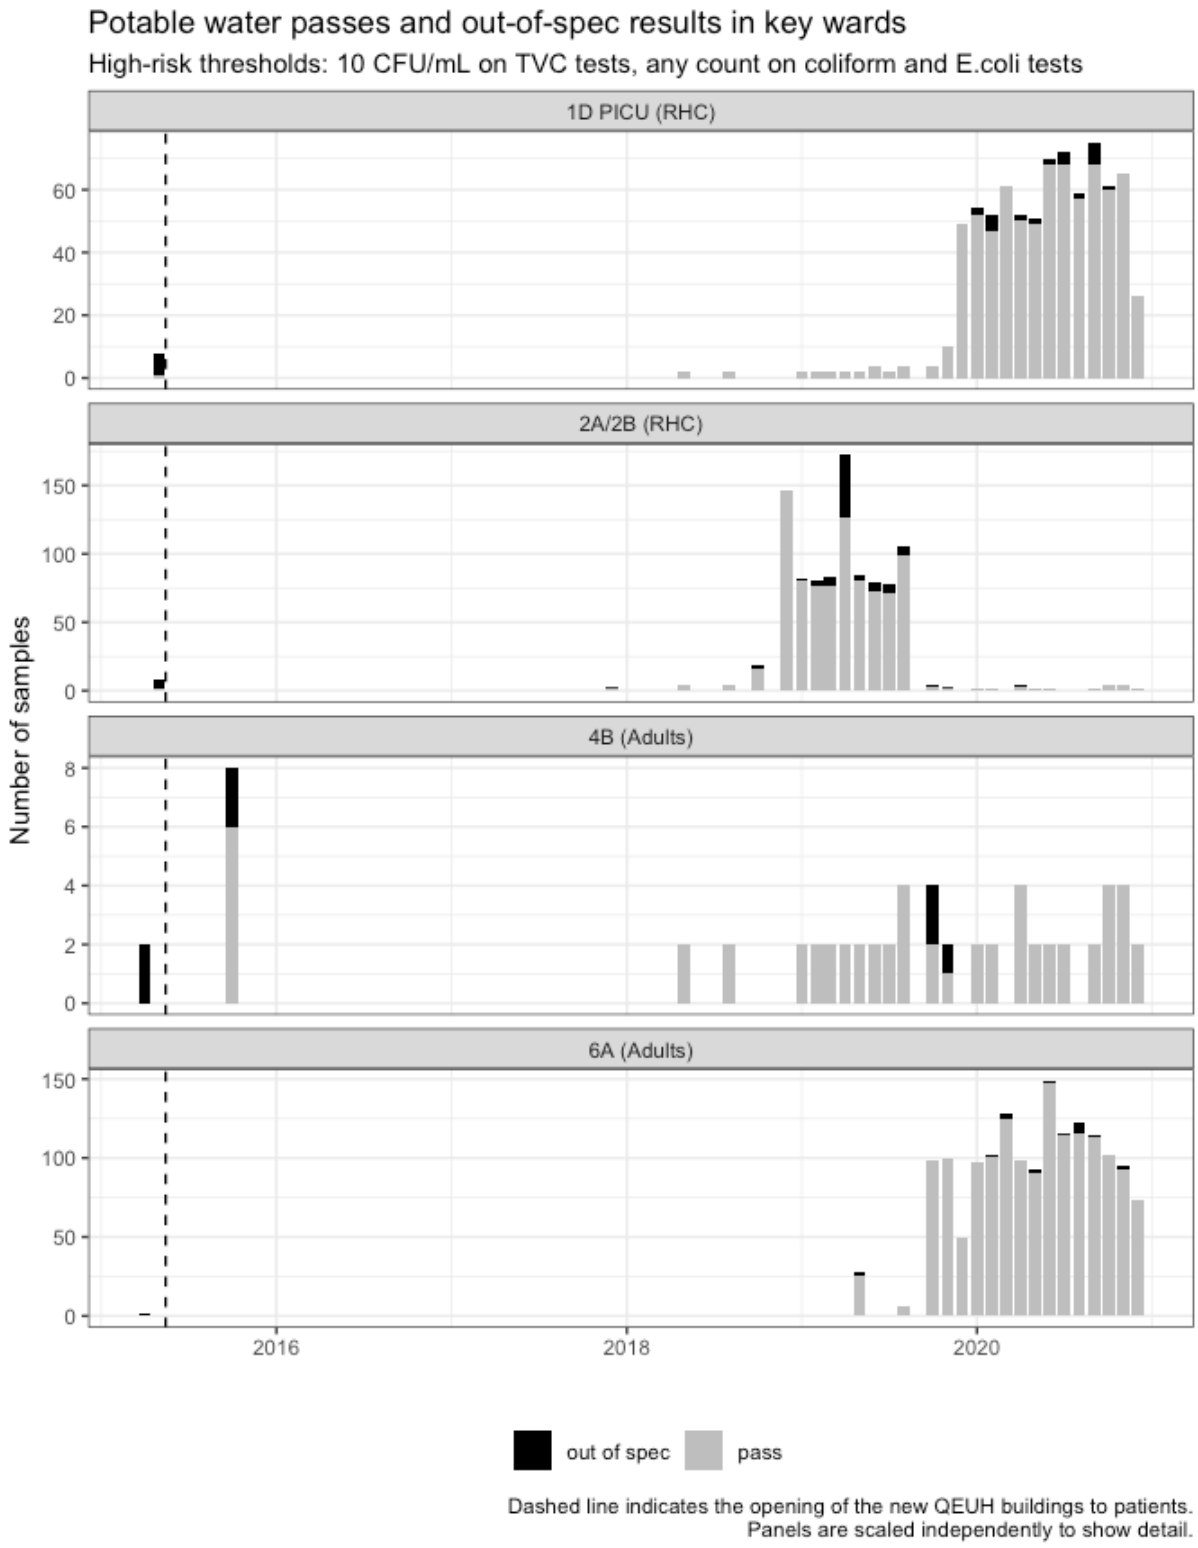

Figure 14. Number of potable tests out of spec per month in key wards. Panels are scaled independently to show detail.

Fungal results in key wards

Overall, 951 water samples from the key wards underwent fungal testing over the period 2015-2020, though this testing occurred in the later part of the time period, from December 2018 onwards. Thresholds in place since December 2018 specify 10 CFU/100mL for both fungal tests (SAB30 and SAB22). With these thresholds, 47 samples were out of spec (4.9% of samples).

However, this sampling was mostly carried out in ward 2A/2B, where 46 out of 895 samples were out of spec (5.1%). The numbers of fungal tests carried out in the other key wards were much lower: Ward 4B had only 4 fungal tests, of which none were out of spec, PICU had 20 fungal tests, with none out of spec, and 6A had 32 fungal tests, with one out of spec (3.1%).

Total fungal passes and out-of-spec results in these key wards, grouped by month, are shown in Figure 15.

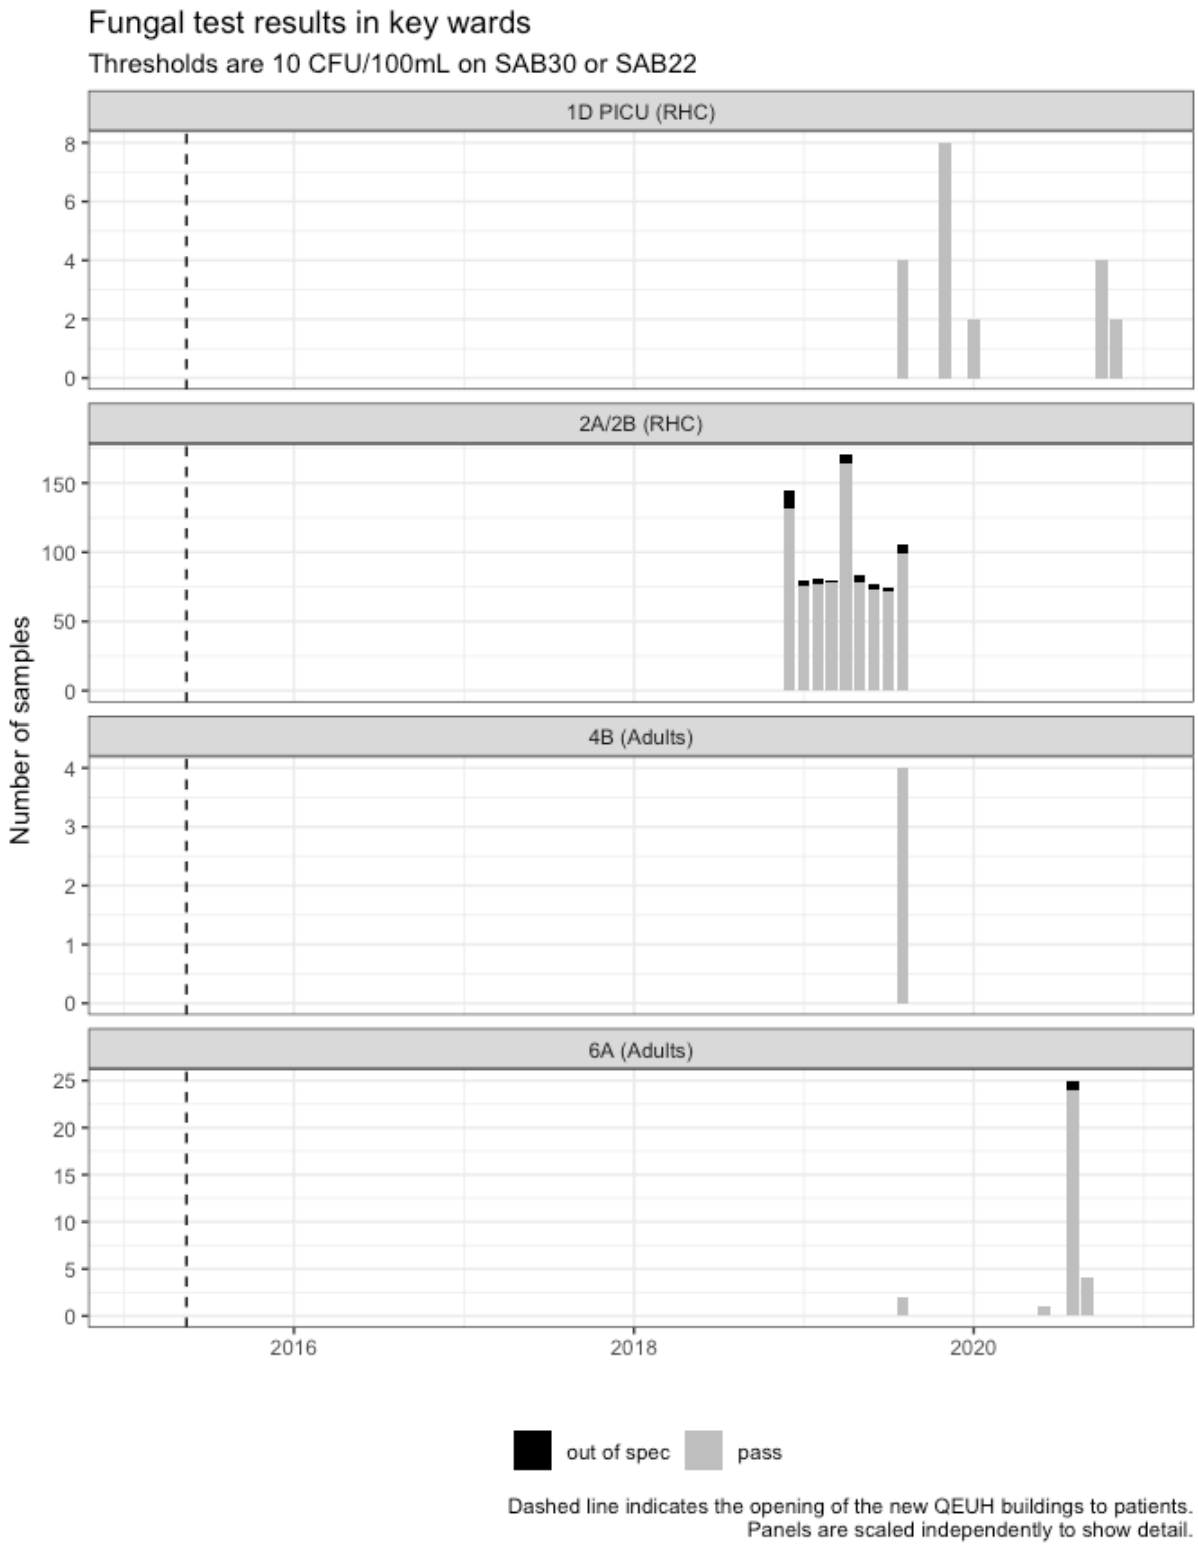

Figure 15. Number of fungal tests out of spec per month in key wards. Panels are scaled independently to show detail.

Cupriavidus and GNB results in key wards

Overall, 3254 samples from the key wards underwent Cupriavidus/GNB testing over the period 2015-2020, beginning with the reactive testing in Ward 2A in February 2018 and specified as part of the routine panel of tests in December 2018. Of these, 171 samples (5.3%) grew Cupriavidus and a further 191 samples (5.9%) were negative for Cupriavidus but positive for one or more other GNBs, giving an overall positivity rate of 11.2% for any GNB.

While these are the overall proportions across the four key wards, the proportions of Cupriavidus-positive samples and samples positive for other GNBs were markedly different in some of these wards (Figure 16). In PICU and Ward 6A, Cupriavidus-positive samples accounted for 1.6% and 0.99%, respectively (14/858 and 16/1611 samples), while samples positive for other GNBs accounted for 6.3% and 3.4%, respectively (54/858 and 54/1611 samples). In contrast, while Ward 4B had a comparable percent of Cupriavidus-positive samples (2.0%, i.e. 2 out of 101), 21.8% of samples were Cupriavidus-negative but positive for at least one other GNB (22 out of 101 samples, most of which were tested during the first large reactive sampling effort in March-April 2018). In Ward 2A/2B, 139 out of 684 samples (20.3%) were positive for Cupriavidus, and a further 61 samples (8.9%) were Cupriavidus negative but grew other GNBs. This means the overall positivity rate for any GNB (including Cupriavidus) in these four wards was 7.9% in PICU, 4.4% in Ward 6A, 23.8% in Ward 4B, and 29.2% in Ward 2A/2B.

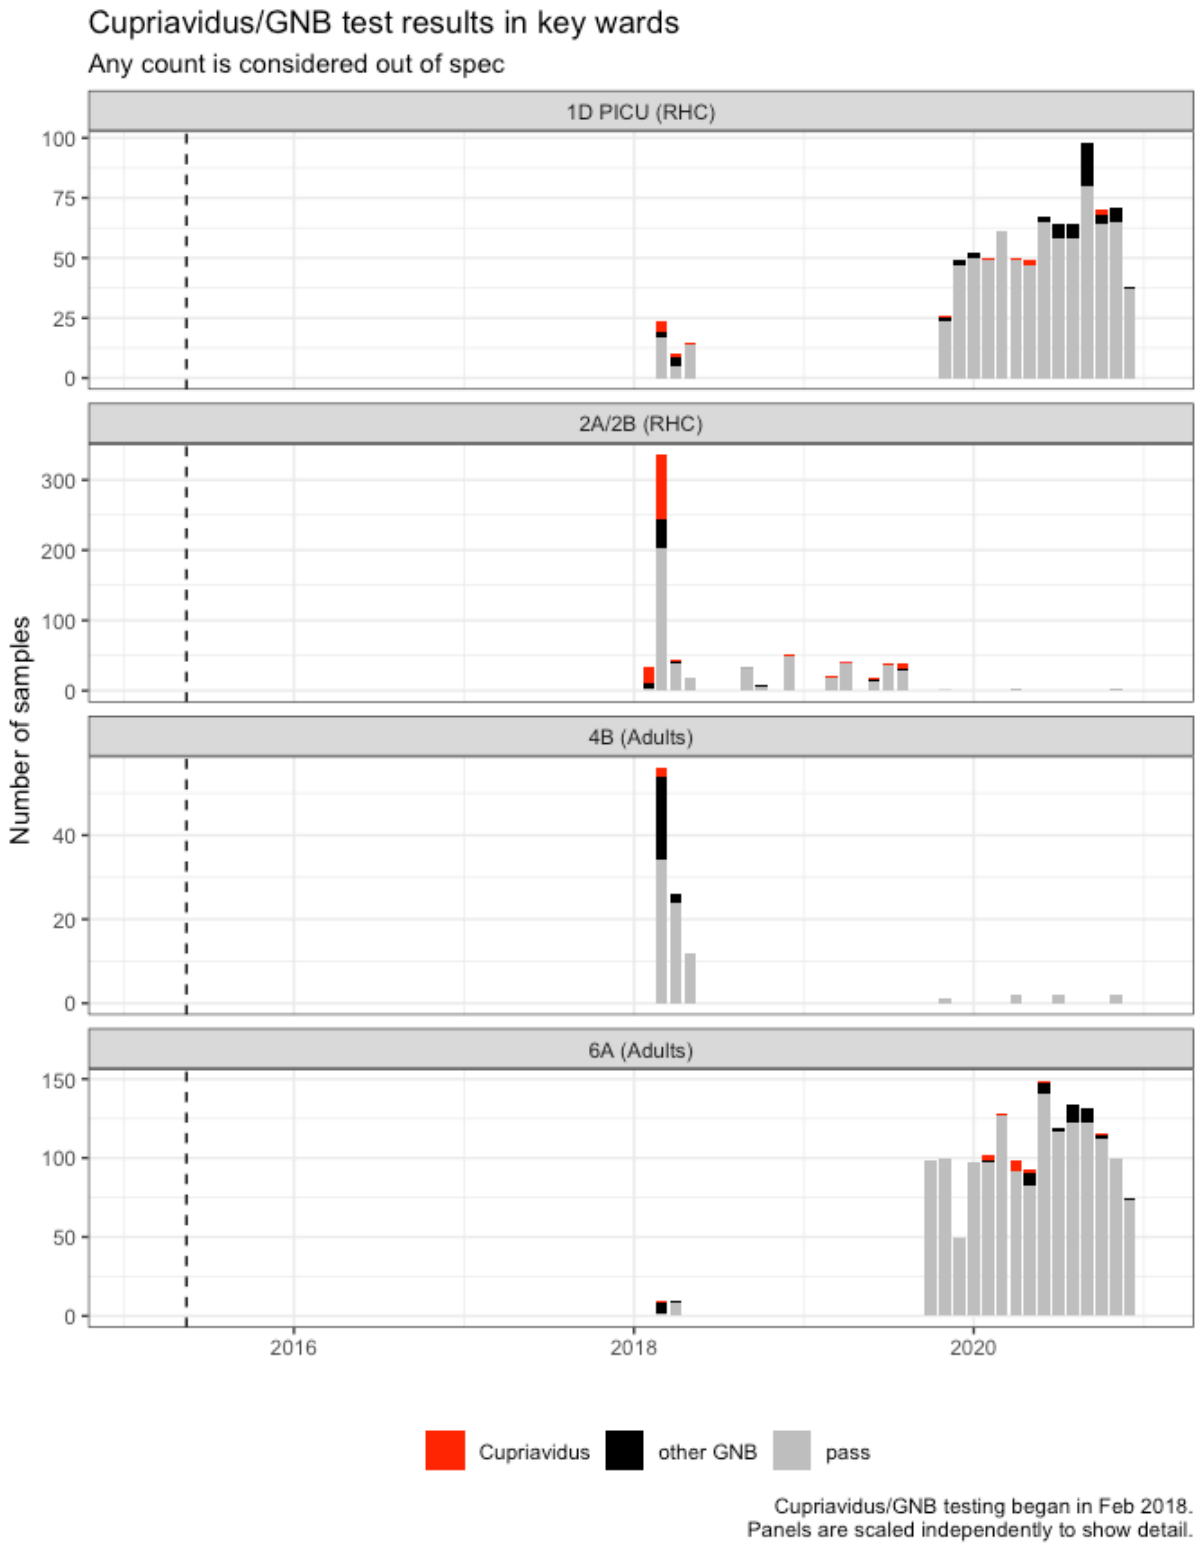

Figure 16. Number of Cupriavidus/GNB tests out of spec per month in key wards. Panels are scaled independently to show detail.

Atypical mycobacteria results in key wards

Overall, 724 samples from the key wards underwent AMS testing over the period 2015-2020, though this type of testing only began in April 2019. Any AMS count was considered out of spec on this test. In total, 50 samples from key wards were out of spec (6.9%). These were all collected during a reactive sampling effort in April-June 2019. No AMS were detected in samples collected after June 2019.

Testing for AMS was not carried out consistently across the four key wards. Ward 4B had no AMS tests, and only 20 samples from ward 2A/2B were tested for AMS, of which 5 were out of spec (25%). In PICU, 187 samples underwent AMS testing, with none out of spec. The most extensive AMS testing was carried out in 6A, where 45 out of 517 samples (8.7%) were out of spec.

Total AMS passes and out-of-spec results in these key wards, grouped by month, are shown in Figure 17.

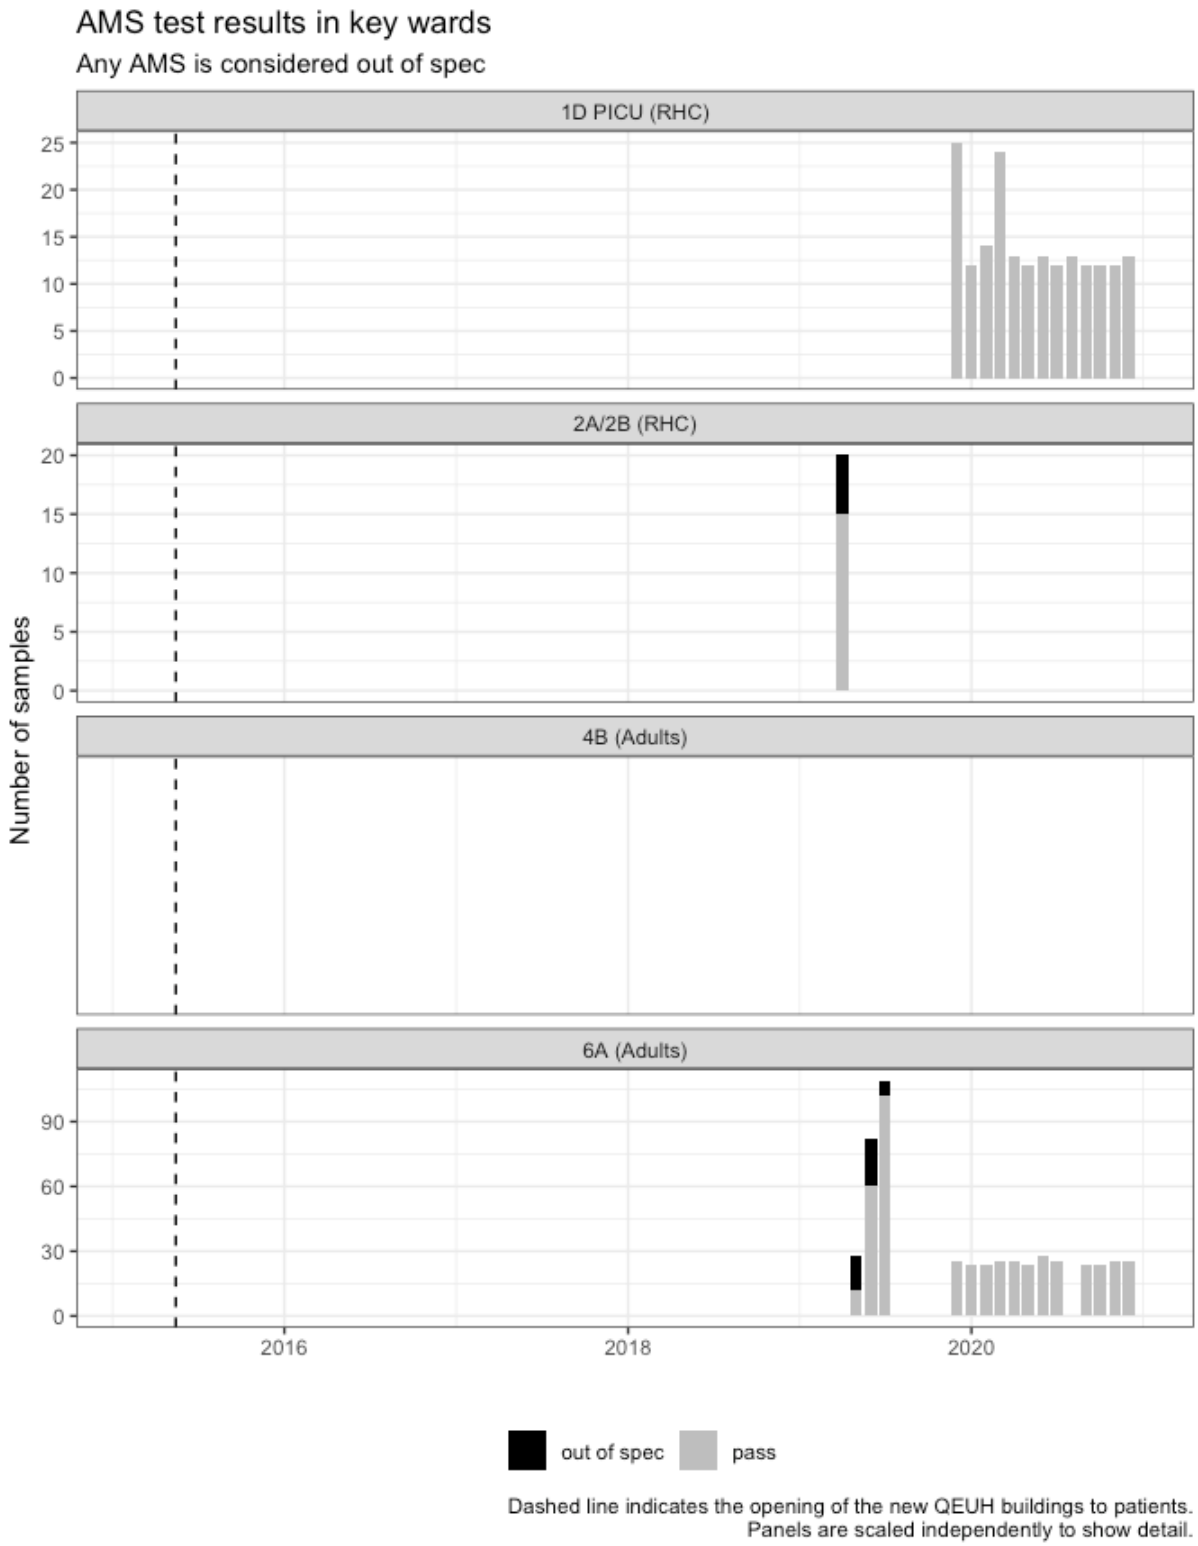

Figure 17. Number of AMS tests out of spec per month in key wards. Panels are scaled independently to show detail.

Named organisms in key wards

Named bacteria identified in all routine and reactive water samples from these wards are shown in Figure 18, and named fungi are shown in Figure 19. No named organisms were reported in 2015 or 2016. Circles show the total number of samples per month with the named organism. These are not normalised by the number of samples collected, so there are more organisms reported during the large spikes in sampling effort (notably in March-April 2018). Among the four key wards, fungal testing was predominantly carried out in Ward 2A/2B (see Figure 15 for sample numbers per ward).

Figure 18. Bacterial taxa identified in key wards in QEUH Adults and RHC.

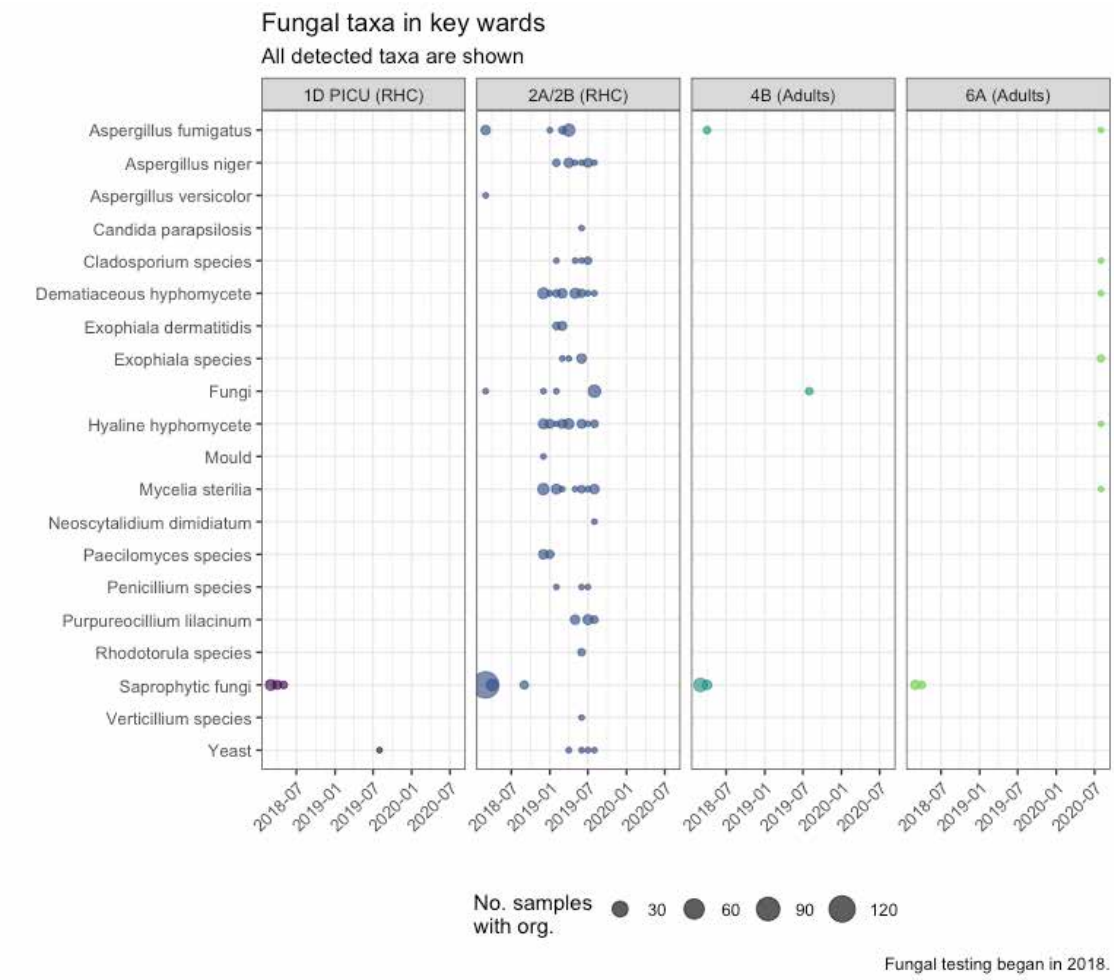

Figure 19. Fungal taxa identified in key wards in QEUH Adults and RHC.

Water data summary

1. *Sampling and testing*: Water sampling in QEUH Adults and RHC over the period 2015-2020 was carried out by ALcontrol Laboratories, by DMA Canyon Ltd, and by GG&C clinical teams, depending on the location. Most microbiological testing was performed by the GG&C Environmental Laboratory, with a subset of samples tested by ALcontrol and by Intertek.
2. *Types of test*: Water samples were either routine (for monitoring) or reactive (for investigation). Samples were booked in for one or more of the following tests: Legionella, Pseudomonas, potable water (consisting of four separate tests for TVCs, coliforms and *E.coli*), and from 2018 onward, fungal, Gram negative bacteria including Cupriavidus, and atypical mycobacterial species, as well as *ad hoc* tests for other specific organisms.
3. *Test thresholds*: GG&C set thresholds for Legionella, Pseudomonas, potable, fungal, Cupriavidus/GNB and AMS testing. Where recommended thresholds exist in applicable legislation or guidance, the GG&C thresholds meet or exceed these. For most of the tests, especially those bespoke to GG&C (e.g. Cupriavidus/GNB), there are no recommended thresholds in guidance or legislation. GG&C adapted some thresholds to the specific areas being sampled, with stricter cutoffs in wards classified as high risk. Outwith the high-risk areas and a few specialist units (aseptic pharmacies and RHC Theatre 8), general microbiological thresholds are applied.
4. *Test numbers 2015-2020*: Routine Legionella, Pseudomonas and potable water testing occurred throughout the period 2015-2020, though in the earlier years, the latter two were predominantly carried out in specific high-risk areas. An expanded programme of testing was implemented in December 2018, with additional routine tests (fungal, Cupriavidus/GNBs) and more thorough, systematic sampling across the new buildings, resulting in a large increase in monthly sample numbers.
5. *Legionella results*: 10 918 samples from the new buildings were tested for Legionella over the period 2015-2020, of which 378 were out of spec (3.5%). The majority of out-of-spec samples were from general areas (360 out of 5798 samples, i.e. 6.2%) and were concentrated in the earlier part of the period, in 2015-2016. High-risk areas had 17 out-of-spec samples over the entire period 2015-2020, out of 3909 samples (0.43%). *Legionella pneumophila* serogroup 1, the variant that is responsible for around 95% of human clinical cases, was only rarely detected after late 2015, with most occurrences clustered in the months prior to and immediately following opening of the new buildings. Across the four key wards, a single Legionella out of spec sample occurred in ward 2A/2B.
6. *Pseudomonas results*: Overall, 11 131 samples underwent Pseudomonas testing. There were 196 reported out-of-spec samples in total (1.8% of samples), though this number drops to 106 out-of-spec samples (0.95%) when likely transcription errors are corrected. Proportion out of spec was highest in the pre/intra-filter basement tank samples (3.4%), but considerably lower in the post-filtration tank samples (0.5%) and in the hospital areas (0.08% and 1.1% in general and high-risk areas, respectively). Across the key wards, 4B had the highest proportion out of spec (9.9%). The other key wards had out of spec proportions well below 2%.
7. *Potable results*: Of the 11 360 potable tests carried out in the new buildings over the period 2015-2020, 667 (5.9%) were out of spec according to current

thresholds. Pre/intra-filter basement tank samples had the highest proportion of out-of-spec samples (8.5%), whereas the proportion out of spec in the post-filtration basement tanks was 2.9%. General areas had a higher proportion of out-of-spec samples (6.1%) than high-risk and specialist areas (5.4%), despite the latter having stricter thresholds. Of the key wards, 4B had the smallest number of samples tested (64) and the highest proportion out of spec (10.9%). Proportions out of spec in the other key wards were 9.9% (2A/2B), 4.3% (PICU) and 1.5% (6A).

8. *Fungal results*: Of the 6040 samples from the new buildings that underwent fungal testing from 2018-2020, 10.0% overall were out of spec. Over half of all out-of-spec results were from the pre/intra-filter basement tank samples, where the percent out of spec was 37.5%. This percentage dropped in the post-filtration basement tanks to 6.1%, and was even lower in the general and high-risk areas of the new buildings (5.1% and 4.6%, respectively). Of the key wards, only 2A/2B underwent substantial fungal testing, with 5.1% out of spec.
9. *Cupriavidus and other Gram negative test results*: Over the period 2018-2020, 6183 samples underwent testing for Cupriavidus and other GNBs after a small amount of reactive testing in ward 2A in February 2018 showed a high positivity rate (68.6%). Of these 6183 samples, Cupriavidus species were detected in 4.4%, with a further 15.1% testing negative for Cupriavidus but positive for other GNBs. Cupriavidus were rare in the basement tanks (0.73% of pre/intra-filtration samples and 0.84% of post-filtration samples), but other GNBs were detected in a much greater proportion of basement tank samples (33.6% of pre/intra-filtration samples and 15.6% of post-filtration samples). In general hospital areas, 6.0% of samples grew Cupriavidus and a further 23.6% were Cupriavidus-negative but grew at least one other GNB. In high-risk areas, Cupriavidus species were detected in 5.2% of samples, with a further 6.9% of samples being Cupriavidus-negative but positive for another GNB. Most of the Cupriavidus-positive samples in high-risk wards were from the Feb-Apr 2018 sampling effort, as the proportion out of spec in high-risk areas from May 2018 onwards was 1.6%. Among the key wards, 2A/2B had the highest percent of samples with detectable Cupriavidus, 20.3%. In contrast, PICU, 4B and 6A had lower proportions with Cupriavidus, at 1.6%, 2.0%, and 0.99%, respectively. Samples testing negative for Cupriavidus but positive for other GNBs accounted for 6.3% of PICU samples, 8.9% of samples from Ward 2A/2B, and 3.4% from Ward 6A, but 21.8% of samples from Ward 4B, though the latter had only a small number of samples tested for Cupriavidus/GNBs during the large sampling effort in March-April 2018.
10. *Atypical mycobacteria results*: Overall, 929 samples underwent AMS testing in 2019-2020, of which 9.1% were out of spec. AMS testing was carried out predominantly in hospital high-risk areas, where 6.8% of samples were out of spec. General areas had a high percent out of spec, 20.4%, almost entirely from a sampling effort carried out in June 2019 in the 1st floor theatres. Among the key wards, PICU and 6A accounted for most of the sampling effort, with out of spec proportions of 6.3% and 3.4%, respectively.
11. *Other organism-specific tests*: In addition to the routine tests, samples were occasionally submitted for organism-specific testing at the request of IPC/IMTs. Specific organisms included Acinetobacter, Burkholderia, *Elizabethkingia miricola*, Enterobacter, Exophiala, *Mycobacterium chelonae*, Serratia, and Stenotrophomonas. None of these requested tests grew the target organism over

the period 2015-2020, though three of the four *M. chelonae* tests grew atypical mycobacteria.

12. *Number of samples with notifiable taxa*: The mandatory alert organism list in the NIPCM contains four taxa for which, when clinical cases are identified, an environmental source should be considered. Of these four taxa, Acinetobacter species were detected in 73 samples, *Stenotrophomonas maltophilia* in 76 samples, *Pseudomonas aeruginosa* in 8 samples, and *Serratia marcescens* was not detected at all, across all 10 311 water samples tested by the Environmental Laboratory from 2015-2020.
13. *Total number of bacterial and fungal taxa*: Across all 10 311 water samples tested by the Environmental Laboratory over the period 2015-2020, 99 bacterial taxa and one non-taxonomic group (Environmental GNBs) were detected as target or non-target organisms in various routine and reactive tests. In addition, 23 fungal taxa and 7 non-taxonomic groups were detected. Of these, 29 bacterial and 9 fungal taxa were rare, occurring in only one sample across the entire data set.
14. *Most prevalent bacterial and fungal taxa*: Across all 10 311 water samples tested by the Environmental Laboratory over the period 2015-2020, the most prevalent bacterial taxa were *Cupriavidus pauculus* (440 samples), *Sphingomonas paucimobilis* (206 samples), *Delftia acidovorans* (168 samples), *Comamonas testosteroni* (119 samples), and *Stenotrophomonas maltophilia* (76 samples). Most prevalent fungal taxa, excluding non-taxonomic groups, were *Cladosporium species* (60 samples), *Exophiala species* (57 samples), *Aspergillus fumigatus* (54 samples), *Aspergillus niger* (27 samples), and *Purpureocillium lilacinum* (26 samples).

Section 2: Other environmental testing

Background

The previous section focused on water samples collected from QEUH Adults and RHC from 2015 to 2020. In addition to this water testing, other environmental samples were collected over this period for microbiological testing, including swabs of sinks, drains, showers, and various dry surfaces.

This section gives an overview of numbers, dates and locations, types, and microbiological findings from these environmental samples. It is important to note that this sampling was entirely reactive and not carried out in a routine, systematic manner, nor did sampling follow a standard procedure. The findings are therefore specific to the times and locations of sampling and cannot be used to draw more general conclusions about the taxa present across the QEUH site. Samples were collected by clinical teams and not by specialist contractors like with the water samples.

Overview of sample numbers

Over the 2015-2020 period, 1463 distinct environmental samples from the new buildings were tested, with an additional 4 samples having been collected but not processed by the lab due to missing information or to the sample being sent in a non-sterile container. The distribution of samples among key wards and sample types is shown in Table 7.

Table 7. Environmental sample types collected from key wards over the period 2015-2020

Sample type	1D PICU (RHC)	2A/2B (RHC)	4B (Adults)	6A (Adults)	other wards	Total
Drain	76	31	27	148	53	335
Shower	0	8	5	48	11	72
Sink	86	14	4	58	57	219
POU filter	64	7	4	148	17	240
Wet (other)	4	5	13	2	40	64
Chilled beam	0	12	0	89	21	122
Dry surfaces	69	2	3	13	117	204
other sample types	9	47	14	34	103	207
	308	126	70	540	419	1463

The distribution of these samples over time, in each key ward, is shown in Figure 20. No environmental samples were collected in 2015. The earliest samples were collected on 2016-01-21, and the latest samples in the data set were collected on 2020-10-28.

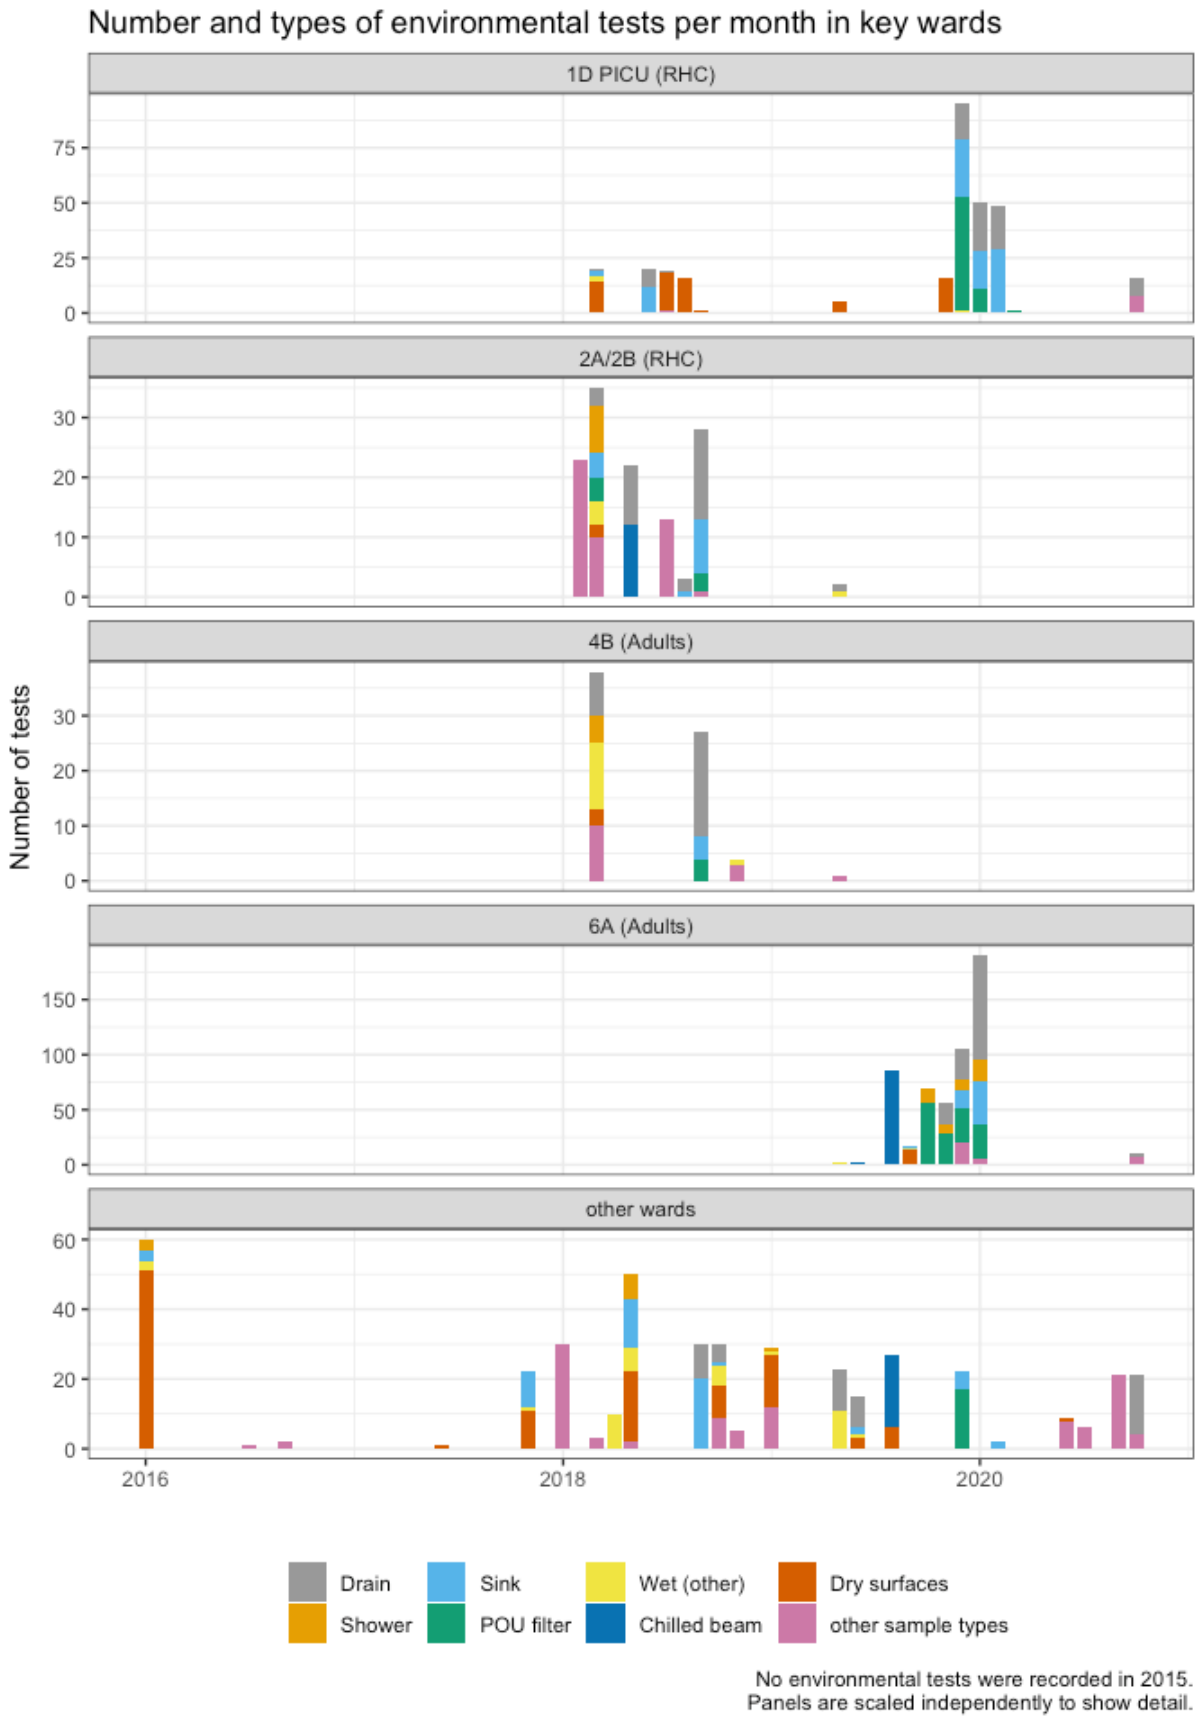

Figure 20. Number and types of environmental tests per month in key wards. Panels are scaled independently to show detail.

Sampling did not occur regularly over this period, but rather was concentrated over short intervals that coincided with IMT investigations. There was no systematic, routine environmental sampling as seen with water testing.

Microbiological results

Numbers and proportions with any detectable growth

The number of environmental samples with and without detectable growth, in each sample type category, is shown in Figure 21. Across all 1463 samples, 1074 had no reported organisms, 187 had a single reported organism, and the rest had more than one reported organism, up to a maximum of six.

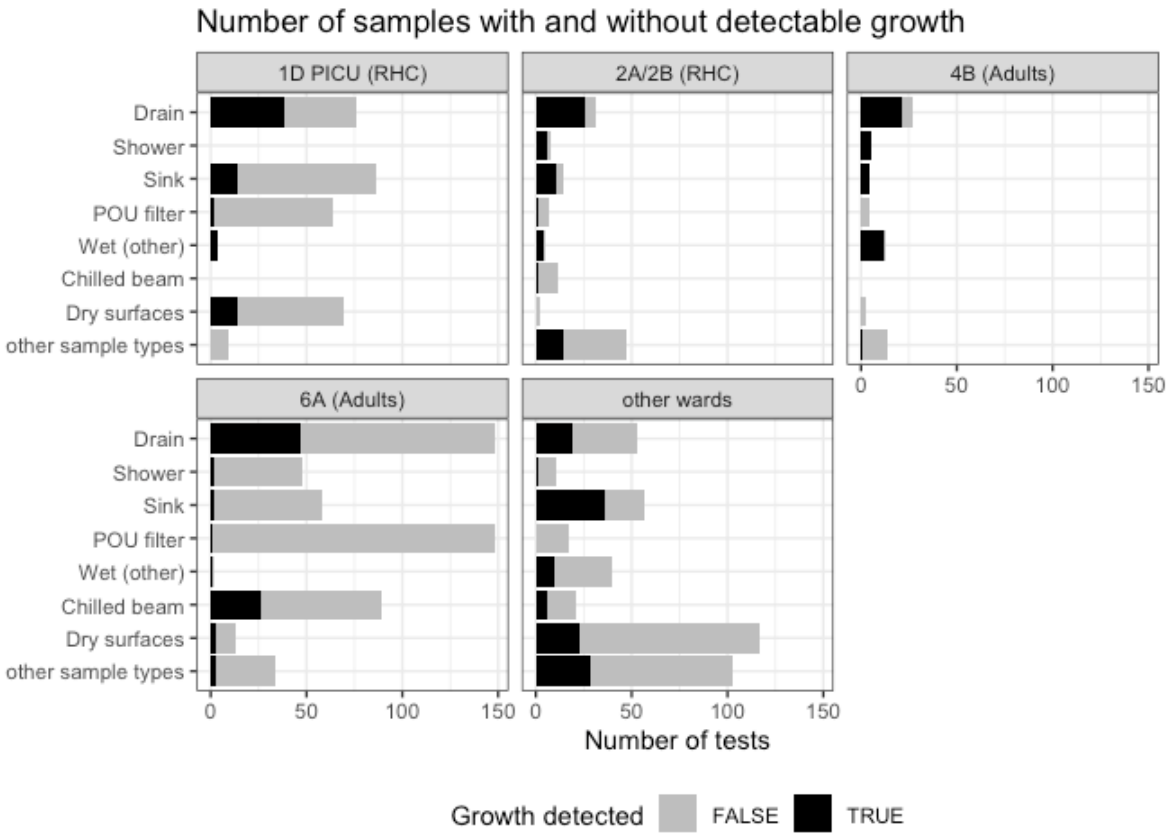

Figure 21. Number and type of environmental samples with and without detectable microbiological growth.

Named organisms

Across the whole data set, 128 distinct named organisms were detected, though 11 of these are not true taxonomic groupings but broad categories (e.g. Gram negative bacilli, mixed coliforms).

Of these 128 distinct named organisms (including non-taxonomic groupings), 57 were rare, occurring in only one sample out of 1463. All taxa detected in the environmental samples, along with their numbers in the water samples collected over the same period (see Section 1), are shown in Table 8.

Table 8. All taxa detected in environmental samples 2015-2020, and their numbers in the water data

Organism	Number in env. data[1]	Number in water data[2]
Pseudomonas aeruginosa	77	8
Cupriavidus pauculus	56	440
Fungi	54	57
Enterobacter cloacae	52	5
Stenotrophomonas maltophilia	40	76
Pseudomonas fluorescens	24	30
Staphylococcus epidermidis	23	not detected
Yeast species	21	not detected
Sphingomonas paucimobilis	18	206
Serratia marcescens	15	not detected
Delftia acidovorans	14	168
Micrococcus luteus	12	not detected

[1]Out of 1463 environmental samples.
[2]Out of 10 311 water samples tested by the Environmental Laboratory.

The distribution of detected organisms across key wards and in the main sample types is shown in Figure 22, with the point sizes indicating the proportion of samples with the detected organism.

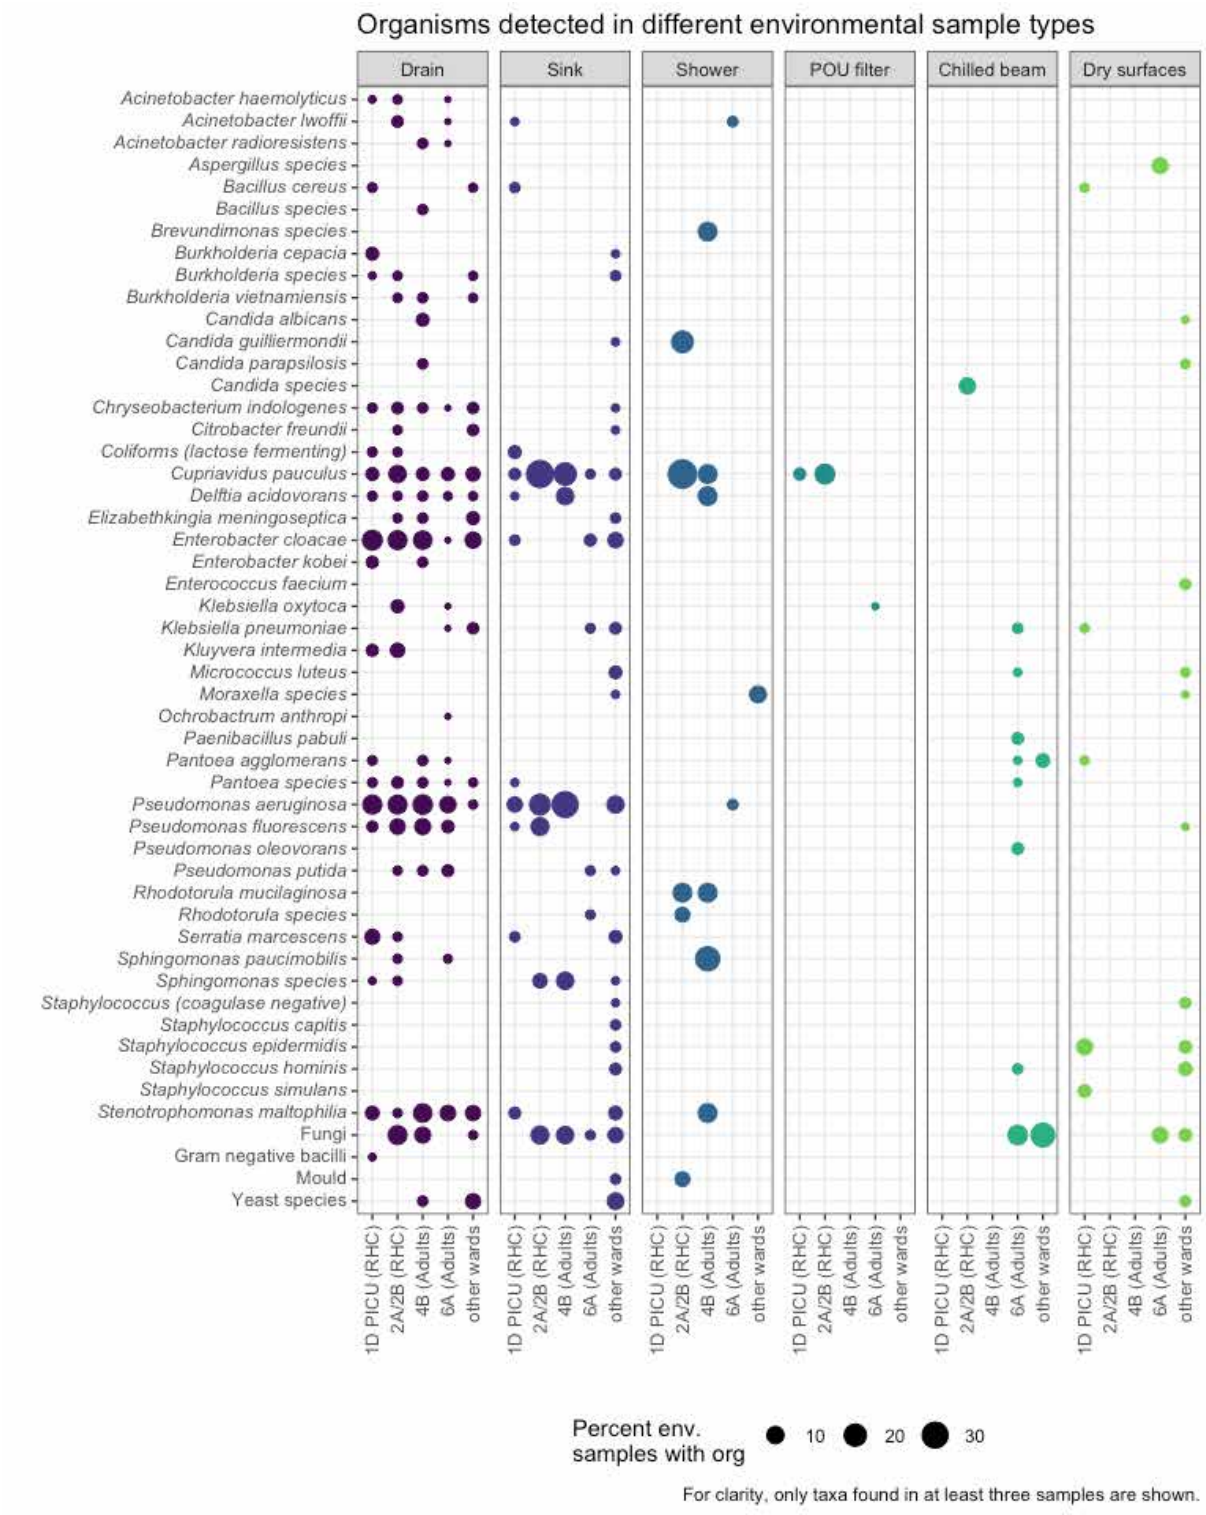

Figure 22. Organisms detected in different types of environmental samples from key wards.

Drain samples had the greatest diversity of detected organisms, and the specific taxa detected were similar in wards 2A/2B, 6A, 4B, and PICU. While many of the taxa detected in drains were also common in the water data, others were rare or had never been detected in water samples from the QEUH Adults and RHC over the period 2015-2020.

Fewer taxa were present in sink and shower samples, though the ones that were detected tended to be the most prevalent ones in water samples (*Cupriavidus pauculus*, *Delftia acidovorans*, *Sphingomonas paucimobilis*, *Stenotrophomonas maltophilia*). In contrast, the taxa found in samples from chilled beams and from dry surfaces were only rarely or never found in the water data, indicating a different source.

Swabs of the outer and inner surfaces of POU filters rarely grew any organisms. Out of 240 POU filter samples, 4 had any detected taxa - *Cupriavidus pauculus* (3 samples) and *Klebsiella oxytoca* (1 sample).

Environmental data summary

1. Environmental sampling was carried out in a reactive rather than routine manner, resulting in distinct clusters of samples collected from specific locations during short time frames rather than extensive systematic sampling at regular intervals.
2. The largest proportion of samples did not have any detectable microorganisms.
3. Samples from wet environments, especially drains, had a greater diversity of taxa than samples from dry sites.
4. There were differences between wards, with a greater proportion of wet samples from 2A/2B and 4B showing growth than from 6A. However, the sampling effort was not equal across these wards, and far more samples were collected from 6A than from any other ward.
5. Some of the most prevalent taxa in the environmental data set were also among the most common in the water data set (see Section 1), but other prevalent taxa in the environmental samples had never been seen in any water sample over the period 2015-2020.
6. The collection of taxa observed in drains was similar in 2A/2B, 6A, 4B, and PICU.

Appendices: Glossary, data sets, and processing steps

Glossary

Table 9. Acronyms and abbreviations used in this report

Abbreviation	Definition
AMS	Atypical mycobacteria
CF100	Coliform counts per 100 mL
CFU	Colony-forming unit
DMA	DMA Canyon Ltd, water monitoring contractor
E.coli	*Escherichia coli*
EC100	*E.coli* counts per 100 mL
GG&C	NHS Greater Glasgow & Clyde
GNB	Gram negative bacteria
IEC	International Electrotechnical Commission
IMT	Incident Management Team
IPC	Infection Prevention & Control
ISO	International Organization for Standardization
LIMS	Laboratory Information Management System, i.e. TelePath
Lp	*Legionella pneumophila*
MALDI-TOF MS	Matrix-assisted laser desorption/ionization time-of-flight mass spectrometer, an instrument for rapid identification of unknown organisms in the clinical microbiology laboratory
NIPCM	National Infection Prevention and Control Manual
PA100	*Pseudomonas aeruginosa* counts per 100 mL
PICU	Paediatric intensive care unit
POU	Point of use, e.g. POU filter attached to a tap
PS100	Pseudomonas counts per 100 mL
QEUH	Queen Elizabeth University Hospital
RHC	Royal Hospital for Children
SAB	Sabouraud's agar (used for selective culturing of fungi)
SAB22	Fungal counts after incubation at 22°C, which encourages the growth of moulds
SAB30	Fungal counts after incubation at 30°C, which encourages the growth of yeasts
SOP	Standard Operating Procedure
TVC	Total viable count
TVC22	Total viable count (CFU/mL) after incubation at 22°C, which selects for environmental organisms

Abbreviation	Definition
TVC37	Total viable count (CFU/mL) after incubation at 37°C, which selects for organisms that might be more adapted to human body temperature
UKAS	UK Accreditation Service

Water testing data processing

Raw data sources

Water sampling data sheets used in this report were obtained from QEUH Estates Department, from the GG&C TelePath system, and directly from DMA. All raw data files are listed below.

Table 10. Original water testing data files included in this summary report

Locations and associated out of spec threshold categories

The following location codes were used to recode and standardise location data across all samples. The associated out of spec thresholds, based on risk level, are as outlined in WQS-017 Water Management Procedure (QEUH Estates Department). Recoding of location data was based on unique outlet ID, where available, and on data in various other fields, which varied across the years and data sources. There were occasional inconsistencies among data sheets from different years, where the same unique ID was associated with entries from different wards, buildings, new vs retained, and/or risk levels. Where inconsistencies were identified, these were repaired based on the following hierarchy:

1. Unique IDs on dedicated location sheets (e.g. PICU, Ward 6A)
2. Consensus location based on numerous separate sheets
3. Clarity of entries in other fields on the same sheet
4. Most recent sheets

Table 11. Buildings, wards, and associated microbiological threshold categories

New or retained	Building	Ward[1]	Threshold category
new	Adults	4B	high risk
new	Adults	4C	high risk
new	Adults	6A	high risk
new	Adults	7A	high risk
new	Adults	7D	high risk
new	Adults	HDU	high risk
new	Adults	other	general
new	Adults RHC	basement bed wash	general
new	Adults RHC	basement tanks	general
new	Adults RHC	drains risers calorifiers	general
new	Adults RHC	external	general
new	RHC	1D PICU	high risk
new	RHC	2A 2B	high risk
new	RHC	2C	high risk
new	RHC	3A	high risk
new	RHC	3B	high risk
new	RHC	3C	high risk
new	RHC	NICU	high risk
new	RHC	other	general

New or retained	Building	Ward[1]	Threshold category
new specialist	Adults	Aseptic pharmacy	specialist
new specialist	RHC	Aseptic pharmacy	specialist
new specialist	RHC	Theatre8	specialist

[1]Wards not specifically listed as high risk were grouped under 'other'.

Water data curation and re-coding for consistency

The data sheets from ALcontrol were first processed in Excel to separate Legionella from potable and Pseudomonas test results, remove formatting and non-numeric symbols from numeric test result entries, and re-code the locations manually by cross-referencing with location data from DMA, since ALcontrol provided only outlet ID numbers with little additional information about which building or ward the sample had been collected from.

All other data sheets (those from DMA and TelePath) were locked to prevent editing, and were instead read directly into R version 4.2.0 using the readxl package, along with the processed ALcontrol data sheets. Data preparation and curation were carried out entirely in R, as detailed in the separate Rmarkdown notebook 01_Water_data_upload_and_preparation_v3_2021.Rmd.

Briefly, it involved the following:

1. Loading each Excel file, adjusting variable names so as to be consistent across the data set, and joining files into a single data object
2. Removing duplicate entries, i.e. those that were present in both the TelePath data and DMA sheets
3. Removing entries for samples that were not collected or tested, or for which results were not recorded, indicated by free text 'No sample taken', 'No access', 'Results not available', or similar character strings in one or more of the metadata columns
4. Moving character strings from numeric columns into free-text columns
5. Re-coding location data into new consistent variables (New or retained, Ward) using a series of automated string detection steps
6. Re-coding test requested data into consistent variables, based on the results in the numeric columns as well as string detection steps in free-text columns.

Named organism data were re-coded manually from the main data set into a separate Excel sheet, as there was no consistency in how these data were entered. This Excel sheet was subsequently loaded into R and joined to the main data set. Final curation steps corrected obvious errors, including duplicate Lab.Reference numbers for samples that were clearly different, mis-typed sample dates where digits were reversed or added to the year of sampling, and entries where an organism was reported using an outdated name (e.g. *Pseudomonas paucimobilis*, which is an old name for *Sphingomonas paucimobilis*).

Environmental testing data processing

Data preparation overview

All data used in this analysis are from a single file (2015 - 5.11.20 Environmental Samples Master File Complete 13.11.20.xls), which was compiled directly from TelePath, the Laboratory Information Management System used by Microbiology to report results of microbiological testing.

Location information

Most entries have information on the hospital building (QEUH, RHC, or PHILLIPSHILL) and the ward. More specific location information (room, bed, etc.) is sometimes included in one of the other free-text columns, but data entry is inconsistent and often missing. For this overview, locations will be limited to the ward level rather than specific rooms within wards, with a focus on key wards 2A/2B, 6A, 4B, PICU and NICU, and the remaining wards grouped under 'other wards'.

Sample type information

Sample type does not have a dedicated column in this data set, so it had to be deduced from free-text entries in the columns called 'Site of specimen', 'Specimen identifier', 'Specimen Ref No/identifier', and the 'Comment' columns. I created a new variable called 'Sample.type', with the following values:

- *Air* - included settle plates, air filters, vent dust
- *Env.soil* and *Env.drop* - soil and pigeon dropping samples
- *Cons* - consumables, including disinfectant wipes, creams, soaps, detergents, etc.
- *Line.site* - consumables associated with lines, including curos caps, SmartSite and Vadsite ports, etc.
- *Surf.equip* - swabs of medical equipment, including scanners, ventilators, incubators, etc.
- *Surf.fixed* - fixed surfaces, including walls, floors, bed rails, bedsite tables, call buttons, phones, etc.
- *Trolley* - trolleys used by medical, catering, and facilities staff
- *Wet.drain* - any type of drain sample, including sink and shower drains
- *Wet.pouf* - any sample from the inside or outside of a POU filter
- *Wet.sink* - any sample linked to sinks, excluding drains and POU filters, including basin and taps
- *Wet.shower* - any sample linked to showers, excluding drains and POU filters, including shower chairs and shower heads
- *Wet.toilet* - any sample from a toilet, including the seat and flush handle
- *Wet.dishwash* - any sample from inside or outside a dishwasher
- *Wet.plumb* - any sample from a plumbing component leading to a tap, including flow straighteners and flow directors
- *Wet.other* - samples from wet environments that don't fit into the other categories, including water fountains, water from leaks, baby baths, damp mops, etc.
- *Chilled.beam* - any sample from the air conditioning system linked to chilled beams

- *other* - any sample that does not fit into these categories, or that has insufficient information to determine sample provenance

Due to very small numbers of samples in some of these categories, they were further simplified to the following:

- Drains
- Sinks
- Showers
- POU filters
- Wet.other (toilet, dishwasher, plumbing, other)
- Chilled.beam
- Dry.surfaces (fixed, equipment, trolleys)
- other

Microbiological data

There are two data columns that give the results of microbiological testing, with some additional information occasionally found in the free-text 'Comment' columns.

The column called 'Growth' has the following possible values:

- *CY* for Culture yields (i.e. growth detected)
- *Enrichment* for Enrichment culture yields
- *NFI* for No fungi isolated
- *NG* for No growth
- *NSG* for No significant growth
- *NG2D* for No growth after 2 days incubation
- *NG5D* for No growth after 5 days incubation
- *NG1W* for No growth after 1 week's incubation

For simplicity, the growth column was recoded into a binary variable (Growth: TRUE or FALSE), with CY and Enrichment as TRUE and the others as FALSE.

Where growth was detected, the variable called 'Organism' gives the identification reported by the laboratory. When multiple organisms were grown from the same sample, each organism has its own entry in the data set.

Final data sets were loaded into the Rmarkdown script used to generate this report.

Purpose of Work Undertaken

Investigation into the possible contamination of flow Straighteners. Flow straighteners are commonly used in the hospital environment as an additional control for water flow. This project was done to asses the levels of contamination occurring over time and the potential of the flow straightener to become a source of contamination if not properly maintained. The flow straighteners tested in this investigation were all from a live system that had been noted for having poor water quality when compared against drinking water standards.
For this project three parameters were initially looked at:

1. Total bacterial levels.
2. Biofilm levels.
3. Visual soiling.

The flow straighteners were supplied after various times in use, from the same water system, with a time range of:

- New- unused as supplied by the manufacture
- 1 week in use
- 1 month in use
- 2 months in use
- 3 months in use
- > 3 years in use

On receipt of the flow straighteners and initial visual inspection was performed to assess for soling. The flow straightener was then placed into a sterile bag and 200ml of sterile deionised water added, this was then agitated for 30 seconds. The flow straightener was then removed. The liguid was then tested for Total bacterial count and Pseudomonas. The flow straightener was then tested for the presence of biofilm using Biofinder™.

These results were graphically plotted to give a visual representation of the levels and rate of contamination so that a potential timeline could be established. Initial results included at the end of the report.

Further analysis of the total bacteria plates was performed during testing. Ie, colony morphology was determained from the plates that where organisms were deemed to be dominant. These organisms were sent for identification and the information derived from this was used to see if the types of organisms changed with the levels of contamination.

Analysis method

An initial visual inspection of each flow straightener was performed looking for presence of soiling and potential contamination of the flow straightener. A rating was given to each flow straightener to reflect the level of soiling

Soiling assessment:
No= nNo visible soiling all holes appear clear with no ingress.
Light= Some visible soiling, no detachment during washing, >70% of holes appear clear with no ingress.
Moderate= Visible soiling, some detachment during washing, no more than 50% of holes showing indication of ingress.
Heavy= Heavy visible soiling, large fragments detached during washing, all holes show significant ingress or blockage.

Microbiological Analysis

A modified Bio-Burden test was used to analyse the flow straighteners.

a. 200ml of sterilised deionised water (SDW) was added to the bag containing the flow straightener and the bag was agitated for 30 seconds. The 200ml of liquid was then classed as the sample.

b. 1ml of the sample is used to create a serial dilution. Neat and 1:10 dilution was tested for total viable count (TVC)

c. 100ml of sample was filtered and the filter transferred to a TVC plate

d. The remainder of sample was filtered and transferred to a Pseudomonas aeruginosa specific plate

e. All plates were incubated at 35oC for 48 hours to stimulate bacterial growth.

f. After the incubation period all visible colonies were counted and recorded (any unusual growth types on the *P. aeruginosa* plates was recorded as non-typical (NT#)

Biofilm assessment

For the assessment of bioburden, a specialist product (Biofinder™) was used

Biofinder™ is a transparent yellow liquid which is sprayed onto a surface. When coming into contact with the biofilm protein structure produces a catalase reaction.

Assessment of the levels of biofilm was made based on the strength and speed of the reaction

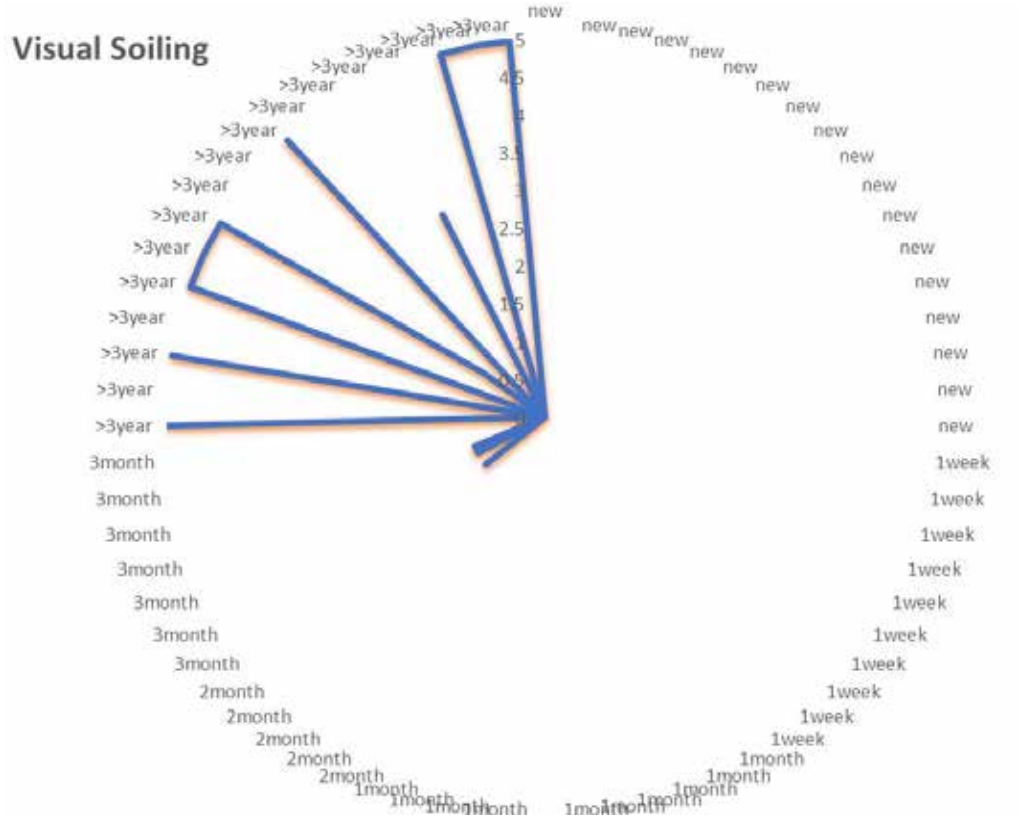
<u>Biofilm assessed on a score 0-5.</u>
0= No reaction. No biofilm presence
5= Strong instant reaction large biofilm presence/ mature biofilm

fig1 complete and dismantled flow straightener

All flow straighteners tested in this project were of the same design and from the same manufacturer. The flow straighteners are made up of 6 internal parts that fit into a grey plastic casing measuring 22mm diameter and 11mm depth. The flow straightener is made up of all plastic parts and 2 rubber gaskets. The straighteners are screwed into the spout of the tap and are used as both a strainer and to even the flow of water coming from the tap.

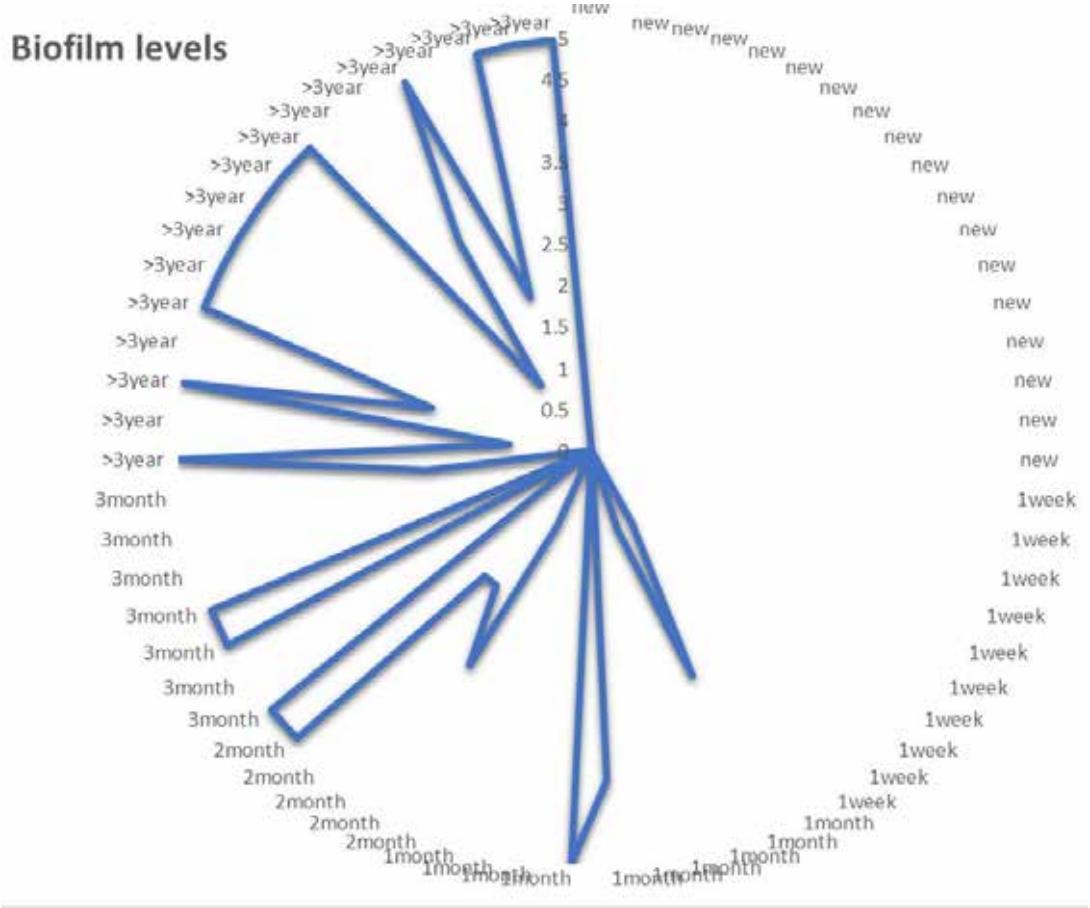
Results

Visual Soiling



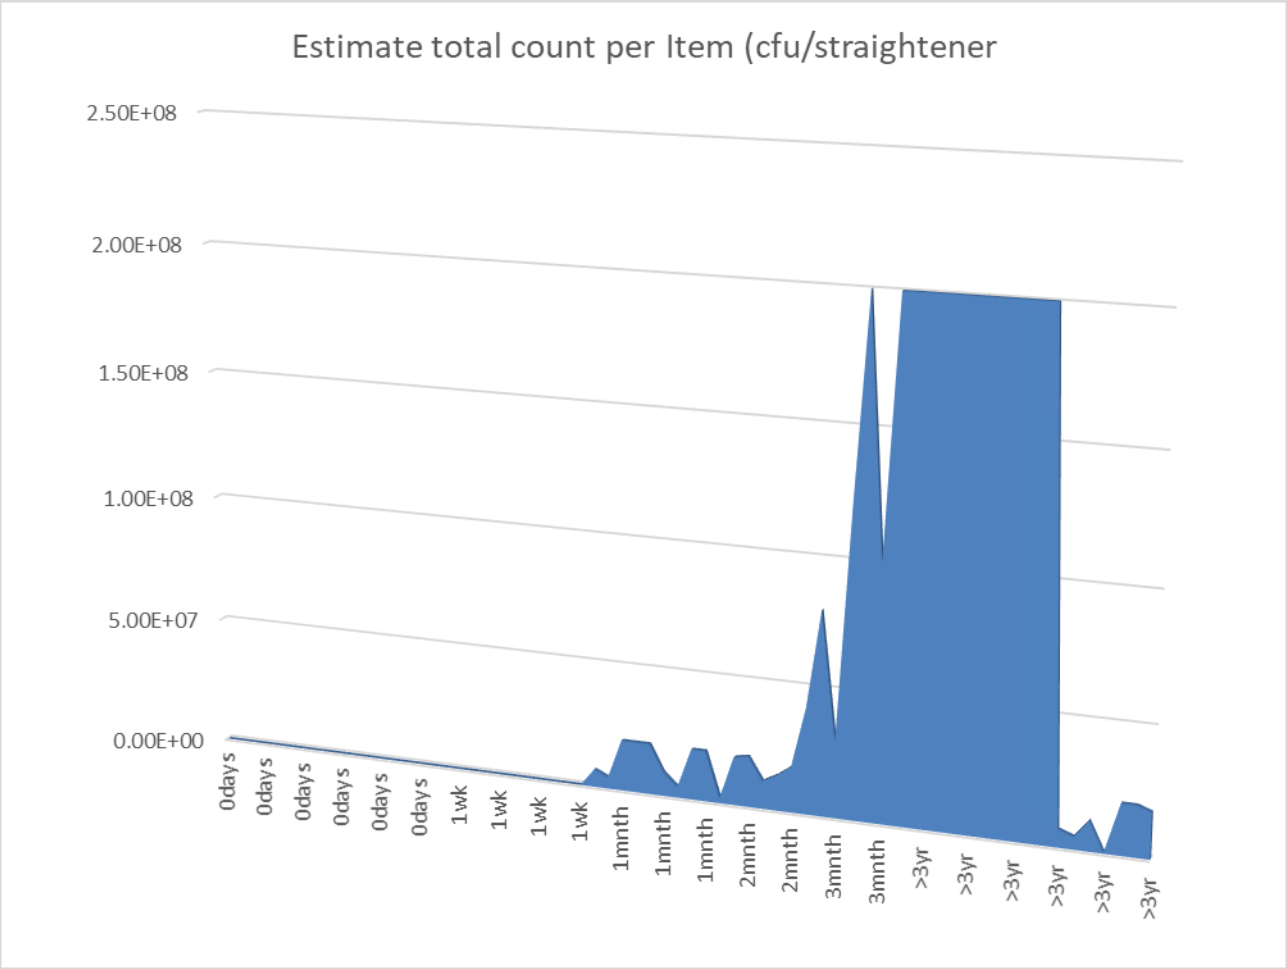
All soiling inspections were performed by the same analyst so that consistence was maintained throughout the project. No visual soiling appeared on the flow straighteners until the third month of use. On the third month of testing only light soiling was visible on the straighteners on 40% of the samples.

Biofilm Levels



The first indication of biofilm formation was detected after 1 month of inline flow straightener use. The levels of biofilm present were variable between the straighteners from no to heavy contamination and 50% of the samples returned a positive result.

Total Bacteria Levels



A larger number of samples of unused straighteners were tested so that a reliable baseline could be established for this test. All the unused samples returned similar results in the low hundreds ≈ 300cfu/unit. The increase in total bacterial levels on the flow straighteners was rapid, ie: within the first month of use these straighteners reached counts between 10*6 and 10*7. After 2 months counts often exceeded the maximum count of 2.0 10*8.

Organism Identifications

On the occasions where isolates were taken for identification a set protocol was followed.

The morphology of the colonies grown was noted and the 6 most dominant morphologies were chosen to be put forward for identification. In addition, 2 sample colonies from each set of plates that had been set up for Pseudomonas were sent for identification as the colonies did not illustrate typical Pseudomonas morphology.

After 1 month of use

Blastomonas ursincola,
Cupriavidus pauculus,
Chryseobacterium spp

After >3 years of use

Sphingomonas paucimobils,
Micobacterium laevaniformans,
Stenotrophomonas multophilia,
Acidovorax temperans,
Chryseobacterium spp,
Caulobacter

Non-Typical Pseudomonas growth

Stenotrophomonas multophilia,
Cupriavidus pauculus

Conclusion

The analysis being performed in this investigation was on a live system the number of samples provided was limited to what was available. Despite this enough data was gathered to analyse for trending and proivde some initial conclusions.

The flow straightener micro-organism analysis demonstrated that within the first month of use, the microbial contamination increased significantly from 10*2 to 10*6/7. This trend continued on the flow straighteners after 2 and 3 months and samples from flow straighteners used for over 3 years, had counts exceeding 10*8, it should be noted that the rate of increase did slow down the longer the straighteners were on the system and this may be due to the organisms reaching their optimum levels for the environment so further increase would be unlikely although small fluctuations would occur.

Visual soiling did not occur on any of the slow straighteners until they had been in use for 3 months and at this point the soiling was only light. The heavy build-up of soiling was not seen until the flow straighteners had been in use for three years. Given the micro-organism analysis, a visual inspection of flow straighteners to assess the condition would not be reliable method to determine straightener hygiene.

The presence of biofilm started to be detected on the flow straighteners as early as 1 month of use and by 3 months over 50% of the flow straighteners tested showed signs of biofilm contamination. When the flow straighteners were tested, all flow straighteners showed some level of biofilm and over 50% showed high levels (5 on the assessment scale). These results also show that biofilms can be present on the flow straighteners and not be immediately obvious when visually inspecting.

Organisms identified.

The organism identification results demonstrate that there is a change in dominant organisms over time. This may be attributed to environmental conditions changing as the biofilms mature thus creating more suitable environments to different organisms. There does appear to be a single organism (Chryseobacterium) which appears to be present in high numbers throughout the testing. Previously classified as Flavobacterium, it is well documented for its ability to form biofilms

The flow straighteners as a unit consist of 8 parts seven of which come into direct contact with the water. Given the design and number of parts each flow straightener contains these items have a large uneven surface area in contact with the water and so create ideal conditions for the formation of biofilms

Using the data derived from this work the maximum length of use for a flow straightener on this system, without maintenance should not exceed 1 month.

Result data.

D. Holloway

D. Holloway BSc (Hons) MRSPH

Background

Fourteen samples were received into the laboratory from Glasgow Queen Elizabeth Hospital. The samples comprised of parts from the portable water system and suspected contaminants taken from within the potable water system. Instructions supplied with the sample were to investigate any potential microbial contamination and identify any organisms present. To investigate overall condition of the water system parts.

Samples received

1. Water collected from inside expansion bladder
2. Holding plate from top of expansion bladder
3. Expansion bladder
4. Debris from booster set 1 from expansion vessel
5. Debris from booster set 1 pump number 5 non return valve
6. Output side of pump body from 5
7. Plant room 21 Calorifier 21/03 shunt pump
8. Plant room 33 Calorifier 1
9. Plant room 32 renal water meter soft nodules
10. Plant room 31 PRV
11. Plant room 22 non return valve
12. Plant room 31 pump
13. Plant room 41 non return valve
14. Water from pipe at 13

The investigation of these samples looked at three initial parameters:

1. Visual assessment
2. Biofilm levels
3. Bacteriological investigation

Visual Assessment

A visual assessment of water samples was not performed as this would offer very little relevant information.

Holding Plate from top of expansion bladder.

The holding plate from the expansion bladder was received with part of the rubber bladder attached. This was removed and assessed as part of the expansion bladder. Significant corrosion was observed on the internal surface of the holding plate. To properly assess the level of corrosion and any further effect on the holding plate one side of the holding plate was scraped clear of surface corrosion. The surface corrosion was found to be between 1mm and 3mm depth covering the entire surface of the holding plate. The surface of the holding plate exposed was found to

have significant pitting. The pitting continues around the edge of the holding plate and to the other side. It was noted that there was a distinct clear line where the corrosion stopped. This indicates that the seals holding the plate to the expansion bladder were intact and no water was leaking from the bladder to cause corrosion outside.

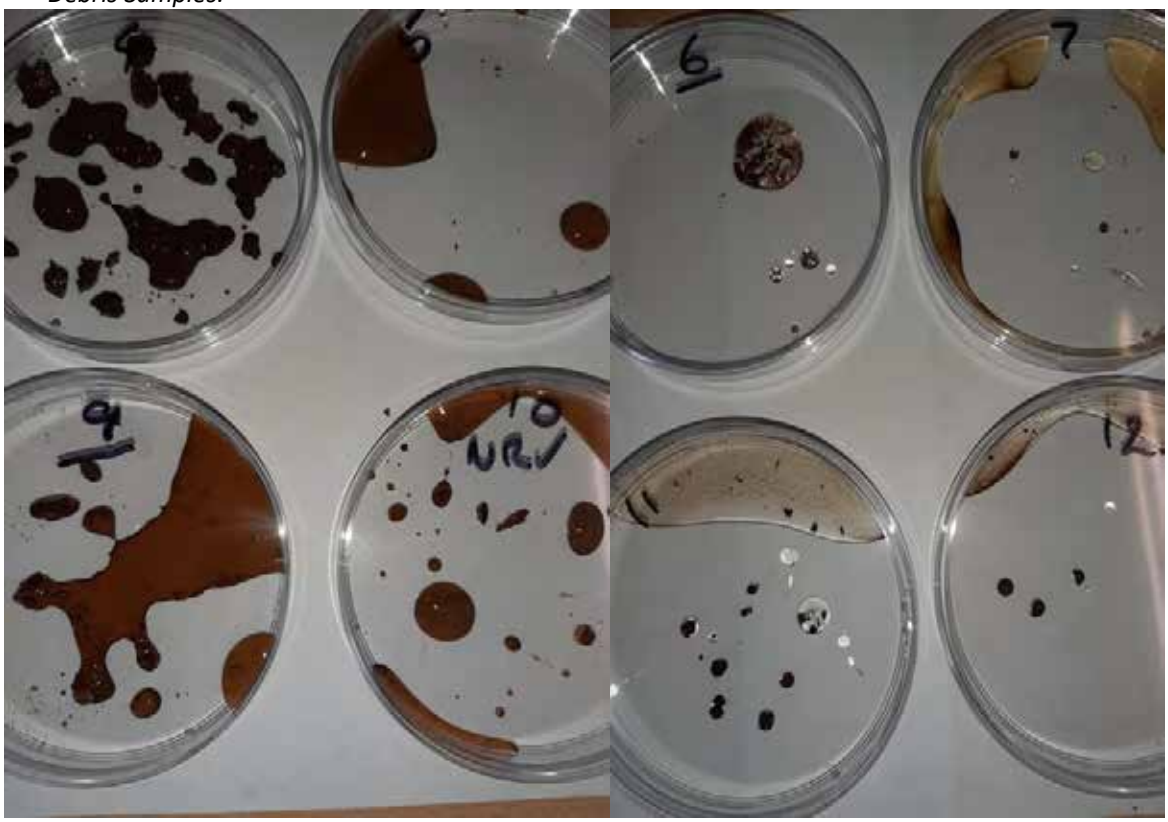
Expansion Bladder

The expansion bladder had the following manufacturer markings.

200/300 LT SE/FA EPDM Butile Made in Italy. B 7 8

The internal surface of the expansion bladder was assessed. There was no visual damage to the internal surface of the bladder observed. The internal surface of the bladder had 4 distinct visual differences. Some sections of the bladder appeared to have white/cream deposits on the surface. These had a glistening appearance and were not visible when the area was dry.
Some sections of the bladder appeared to have reddish brown deposits on the surface, these had a dry and dusty appearance and were visible in both dry and wet conditions.
Some sections of the bladder appeared to have reddish brown granular deposits on the surface. These deposits were focused around the base of the bladder.
The other sections of the bladder did not appear to have any visual deposits on the surface. These areas were observed in both wet and dry conditions with no change in appearance.

Debris Samples.



Debris samples were assessed together. All samples appeared to have fragments of various sizes. These appeared to be fragments of corroded metal, the largest fragments were found in the debris sample from booster set number 1 from expansion vessel. Given the size of the fragments it would be reasonable to assume that the corrosion on this part was significant. On samples 5 and 9 the sterile water added to the samples to maintain any bacterial content had taken on a significant amount of solids in suspension. This was enough to fully colour the liquid and change the viscosity. This indicated that the samples were not made up solely of solid fragments but also contained other particulate matter.

Biofilm Assessment.
For the assessment of bioburden, a specialist product (Biofinder™) was used

Biofinder™ is a transparent yellow liquid which is sprayed onto a surface. When in contact with the biofilm protein structure produces a catalase reaction.

Assessment of the levels of biofilm was made based on the strength and speed of the reaction

Biofilm assessed on a score 0-5.
0= No reaction. No biofilm presence
5= Strong instant reaction large biofilm presence/ mature biofilm

Holding plate.
There were two potentials for biofilm testing of the holding plate.
1/ the surface corrosion
2/ the surface area of the holding plate where the surface corrosion had been removed.

sample	BIOFILM ASSESMENT
holding plate corrosion	5
holding plate cleared	5

Biofilm was present in both the surface corrosion and the cleared surface of the holding plate. This demonstrates that the surface corrosion attachment is partly due to the presence of biofilm. It is not unreasonable to assume that the biofilm is also partly responsible for the corrosion and the pitting seen in the surface of the holding plate.

Expansion bladder

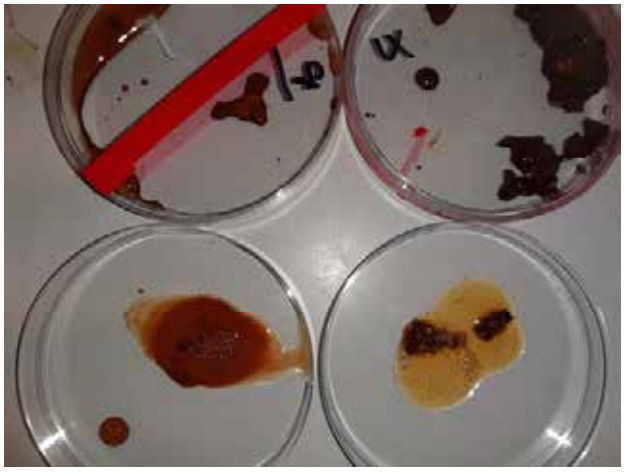
There were four sections of the expansion bladder that were chosen for biofilm assessment.

1. White/cream deposits
2. Reddish/ brown deposits with dry appearance
3. Reddish/ brown granular deposits
4. No visible deposits

A fifth section was also chosen for testing. This sample was chosen to act as a control sample. This would be from the outside surface of the bladder and cleaned using Industrial mentholated spirit prior to testing to remove any possible contamination. This was done to ensure that there was no cross reaction between the Biofinder™ and the bladder material.

sample	BIOFILM ASSESMENT
control	0
white cream deposits	5
reddish brown deposits dry appearance	5
reddish brown deposits granular appearance	5
no visible deposits	5

Debris Deposits
Samples 4 and 9 were chosen for biofilm testing as representative of the debris samples received. These contained larger fragments of debris so the potential to get a reaction was greater while allowing for the dilution of the water present in the sample.



Although the reaction from the Biofinder™ was light it was still possible to determine that a biofilm was present in these samples.

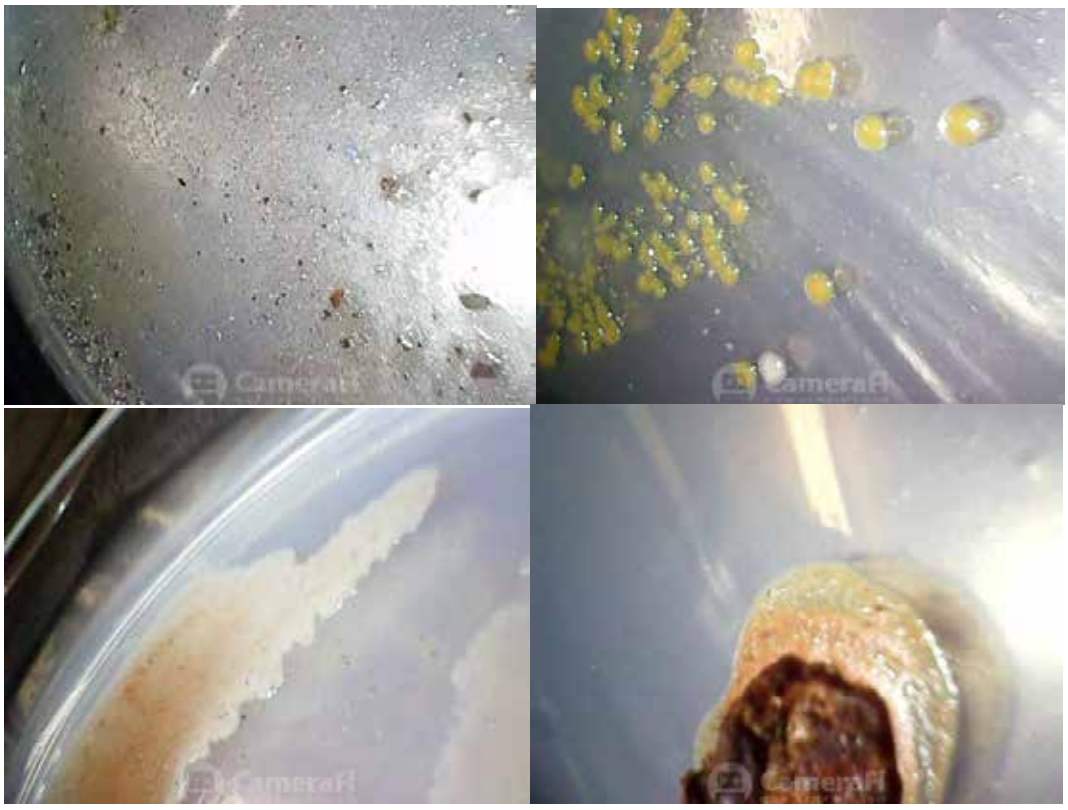
Conclusion
From the biofilm testing it is possible to state that all the water system parts, and debris samples sent to the laboratory were contaminated with biofilm.

Microbiological assessment.
Due to the amount of biofilm identified in the previous work carried out on these samples' organism levels would not be practical. On this occasion it was decided that an assessment of the types of organism's present would be the appropriate course.

To recover viable organisms from a potential biofilm is not always possible. The organisms can enter a life cycle stage where although they are viable organisms, they are not culturable.
To give the best possible chance to recover these organisms' additional steps have been added to the swabbing procedure the best possible chance of recovery.

Sections were cut from the bladder (6 areas) each section measured approximately 8cmX8cm.
These were placed into a sterile bag and a maximum recovery diluent was used to moisten the surface of the section of bladder.
The bags were closed but not sealed so as not to create an anaerobic condition a sterile straw was placed into the bag to prevent the bag sealing.
The sections were then left overnight at room temperature to allow the organisms to enter a reproductive stage therefore allowing them to be recovered on agar plates.
After the samples had stood overnight the surface of the sample was swabbed using a sponge swab this swab was then placed into 100ml of buffered peptone water and incubated at 30oC overnight. These combined steps should allow the best possible chance for the organisms to be recovered when plated. the samples were then plated onto a non-selective agar and incubated at 30oC for 48 hours. After the 48 hours the plates were inspected for growth.

After incubation the plates were inspected for growth



On inspection of the plates it was noted that all visible colonies displayed the same morphology.

Reddish/yellow in colour glistening appearance entire edge and convex shape.

It is extremely unlikely that a biofilm would be a monoculture. It was hypothesised that the most likely cause of the similarities I the morphology of the colonies was that the rust appearance of the deposits in the samples tested had resulted in staining of the colonies making them all appear the same.

In an attempt to remove or dilute the staining from the colonies multiple colonies from each plate were taken and streaked onto fresh non-selective agar and incubated for a further **24** hours to purify the colonies**.**

After the 24 hour incubation the plates were removed and inspected.

It was observed that the staining of the colonies had been reduced but not sufficiently to confidently identify individual morphologies.

The purification step was repeated to further clean the organisms to where the individual morphologies could be identified.

After the second purification step the morphology of the individual colonies could be identified.

From the purified plates a total of 15 isolates were taken to be sent for identification.
These were chosen against the following parameters

Location
Morphology
Oxidase
Dominance (where more than one morphology appeared dominant all dominant morphologies were taken)

Isolates for typing		Oxidase
A1	Holding Plate morphology 1	positive
A2	Holding Plate morphology 2	N/A
	Bladder	
B1	around fixing screw area	positive
B2	cream coloured deposits	negaitve
B3	rust coloured deposits	positive
B4	light mixed deposits	negative
B5	no visible deposits	negative
B6	cream coloured deposits	negative
	debris	
C1	Water collected internal from bladder	postitive
C2	Booster set number 2 pump number 5 - non return valve	positive
C3	Output side of pump body from (5)	positive
C4	Plant Room 32 - Renal water meter (removed nodules from both ends - very	negaitve
C5	Plant room 31 PRV	positive
C6	water from pipe at 13	negaitve
C7	Plant Room 32 - Renal water meter (removed nodules from both ends - very	positive

The full results for the typing of the organisms are due on 10th July 2019. Report certificates will be forwarded over on receipt and a second report will be sent shortly after containing background information on the organisms identified.

As the organism typing is being performed by MALDI-TOF. It is recognised that the database used is not exhaustive. Because of this a second set of isolates have been retained, frozen, by the laboratory should any further investigation be deemed necessary.

Preface

About Scottish Health Technical Memoranda

Engineering Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of SHTM guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle: Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Engineering Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

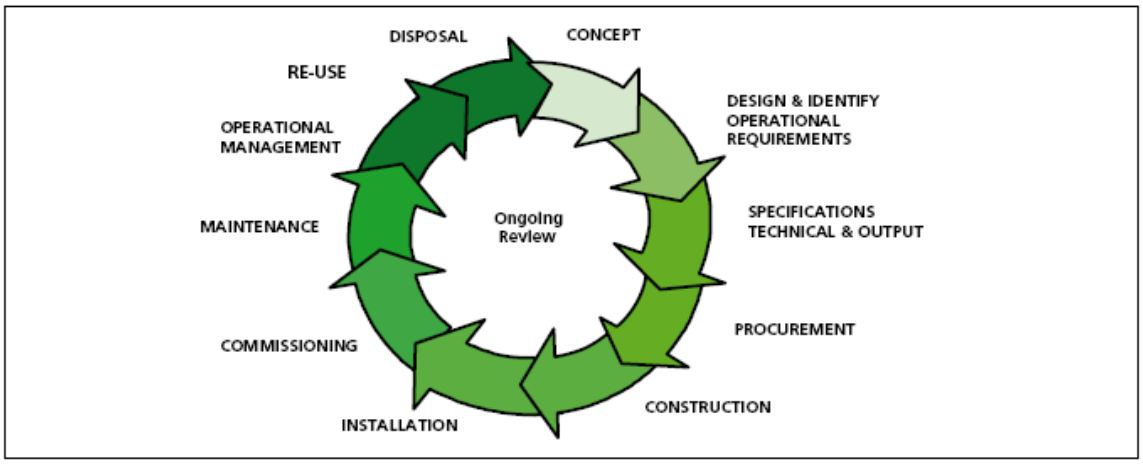
It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.

© Health Facilities Scotland, a division of NHS National Services Scotland.



Healthcare building life-cycle

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of eight core subjects:

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Scottish Health Technical Memoranda in this series).

Scottish Health Technical Memorandum 01: Decontamination

Scottish Health Technical Memorandum 02: Medical gases

Scottish Health Technical Memorandum 03: Heating and ventilation systems

Scottish Health Technical Memorandum 04: Water systems

Scottish Health Technical Memorandum 05: Reserved for future use

Scottish Health Technical Memorandum 06: Electrical services

Scottish Health Technical Memorandum 07: Environment and sustainability

Scottish Health Technical Memorandum 08: Specialist services

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent: Electrical safety guidance for low voltage systems.

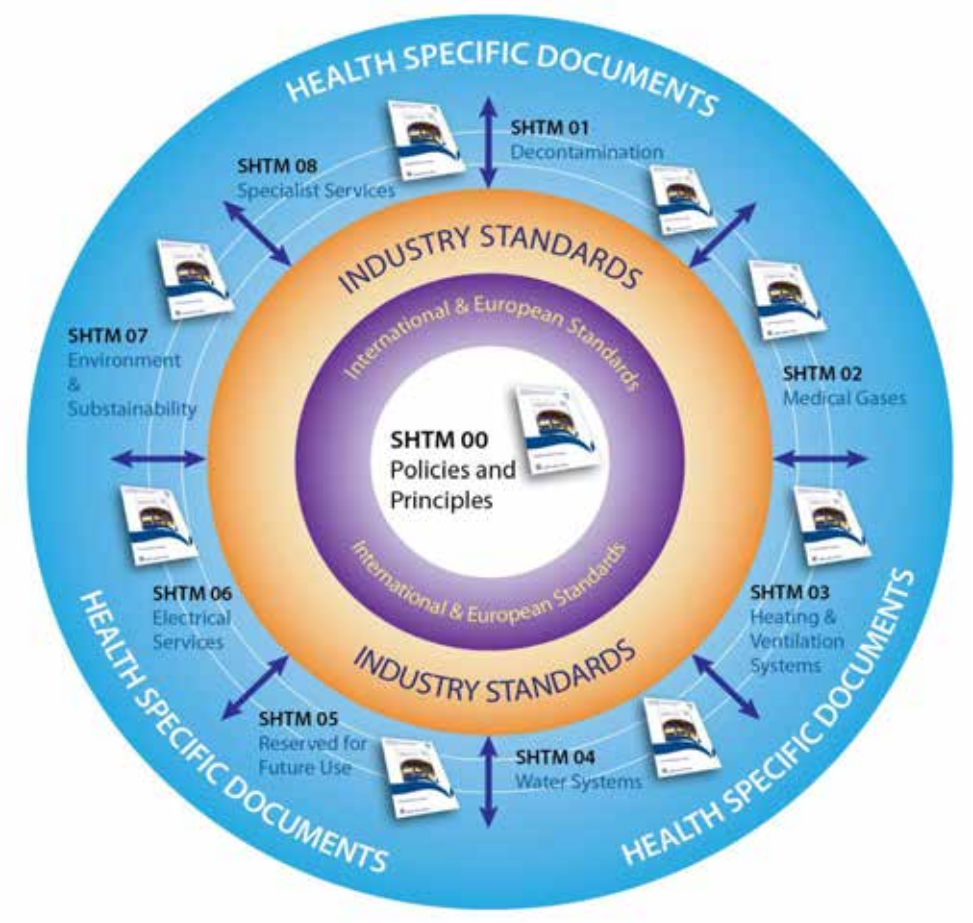
In a similar way Scottish Health Technical Memorandum 07-02 will simply represent: Environment and Sustainability – EnCO_2de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

Health Facilities Scotland wishes to acknowledge the contribution made by professional bodies, engineering consultants, healthcare specialists and NHS staff who have contributed to the review.



Engineering guidance structure

1. Introduction

Preamble

1.1 Although Scottish Health Technical Memorandum (SHTM) 04-01 Part B paragraph 9.1 states that routine quality control microbiological testing for TVCs is no longer considered to be necessary (other than where there are taste or odour problems), many estates personnel invariably have them undertaken on a regular basis after acceptance of installations as a ‘rule of thumb’ indicator by which an abnormal change assists in identifying potential problems at an early stage. This narrative sets out procedures to be followed.

© Health Facilities Scotland, a division of NHS National Services Scotland.

2. Collection procedure and location of samples

Samples collection procedure

2.1 Sampling points should be selected on the basis of risk assessments relating to system configuration or patient susceptibility.

- mark all sampling locations on up to date “As Fitted” drawings;
- allocate each sampling location a unique reference number;
- follow the procedures set out in The European Directive 98/83/EC.

Location of samples

2.2 Samples should be taken from:

- inlet and outlet at cold water storage tanks;
- incoming main, close to meter, where facilities exist to do so;
- possible stagnant areas within tanks pending rectification of any identified
- problem;
- beginning, mid-point and end of cold distribution system (i.e. sentinel
- outlets);
- special supplies to kitchens, pharmacies, etc;
- calorifier outlet;
- nearest hot water tap to calorifier;
- most distant hot water tap from calorifier (i.e. sentinel outlet);
- return to calorifier;
- typical samples from heated circulating water.

© Health Facilities Scotland, a division of NHS National Services Scotland.

3. Frequency of sampling

General

3.1 This should be carried out quarterly

- although TVCs are in themselves innocuous the testing procedures are intended to provide an early warning system whereby elevated TVCs should trigger some form of action to determine the identity of the organism and implement the appropriate treatment;
- this could inform adjustment of disinfection doses, cleaning and flushing procedures.

© Health Facilities Scotland, a division of NHS National Services Scotland.

4. Sampling organisation

General

4.1 United Kingdom Accreditation Service (UKAS) or ISO 9002 accredited laboratories should always be used for analysis.

4.2 Sampling should be undertaken in accordance with European and British Pharmacopoeia requirements to test the total number of bacteria, yeasts and moulds within water services distribution pipework.

Sampling (following BS7592: 2008 guidelines)

Sample Containers

4.3 For testing samples of Coliforms, Escherichia coli, Pseudomonas Aeruginosa, Aerobic Colony Counts and Environmental Mycobacteria 1 x sterile 500ml plastic bottle should be used containing a pre-dosed standard volume of neutraliser to neutralise any residual disinfectant in the water.

Note: The most commonly used neutraliser, which is appropriate for chlorinated or brominated water systems and those using ozone or hydrogen peroxide, is sodium thiosulphate. For mains water and hydrotherapy pools, 18 mg/litre sodium thiosulphate should be added. However, for cooling towers, 180 mg/litre (i.e. sufficient to neutralise 50mg chlorine per litre) must be used. If alternative disinfection methods are used, the laboratory should be contacted to obtain the appropriate neutraliser, if one is available.

For testing samples of *Legionella* (and other pathogenic bacteria such as Salmonella, Campylobacter and E.coli O157) 1 x sterile 1 litre plastic bottle (NB: using 2 x 500ml plastic bottles might be more practical) should be used containing standard amounts of pre-dosed neutraliser (dependent on bottle capacity) to neutralise any residual disinfectant in the water, all as above. Sampling procedures should be adhered to rigorously.

The same sample bottle is often used for *Legionella* and TVC counts testing but separate bottles for each are advised to be technically correct.

Sampling for Indicator Organisms (TVCs) should be undertaken as laid down in “The Microbiology of Drinking Water, 2010, Part 2: “Practice and procedures for sampling” published by the Environment Agency.

Sampling tap water

4.4 The following sampling procedure should be followed:

- where possible, ensure that the tap is in good condition with no leaks. Mixer taps should be avoided if possible;
- remove any internal and external fittings such as hosing;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- clean the end of the tap thoroughly with a clean disposable cloth (and detergent if necessary). Sterilise with sodium hypochlorite solution (sufficient to give 1% available chlorine) made up on the day of use, or chlorine dioxide foam. Sterilisation can be carried out by preparing a hypochlorite solution in a measuring jug and by suspending it under the tap such that the end of the tap is immersed in the solution for 2 - 3 minutes. Alternatively, use a wash bottle to spray hypochlorite solution onto the outside and inside of the tap spout. Leave for 2 - 3 minutes before rinsing;

Safety Note: Sodium hypochlorite is highly corrosive and should be handled with care. Nitrile gloves and goggles should be worn, and if contact with skin, eyes or clothes occurs, wash the affected area immediately with copious amounts of water. Contact with clothes may result in a bleaching effect.

- turn on the tap gently to avoid unnecessary aerosol production and run water to waste for two to three minutes;

Note: For initial system sampling take a Post-Flush sample (as defined in BS 7592: 2008) at sentinel points without disinfection. Where there is an initial concern with a particular outlet location – say, a combined system and outlet problem – a BS Pre-Flush sample should be taken. If concerns persist with an outlet location (typically, a known dead-leg issue or lack of, or low, water use, a further BS Pre-Flush sample should be taken followed by disinfection before a BS Post-Flush with disinfection sample. Water should be allowed to run hot for 1 minute and cold for 2 minutes by which sampling would be temperature calibrated.

- aseptically open a labelled sterile bottle (1 litre or 500ml bottle containing neutraliser; as paragraph 4.3), fill almost to the brim with water, replace and tighten the lid and shake the bottle to distribute the sodium thiosulphate;
- there is no prescriptive cooling method or temperatures but ideally, water samples should be transported as taken but stored at between 6ºC and 18ºC if a delay is anticipated prior to despatch to a (remote) laboratory. Samples should be transported out of the sun as outlined in BS6068 and ISO 11731. Most samples are transported in shopping trolleys or plastic trays as soon as possible. Guidelines do not require samples to be cooled down prior to transportation. However they should be submitted to the accredited laboratory to ensure that they can be examined promptly, ideally the same day, but always within 24 hours of collection. Where the accredited laboratory in on campus where the samples are drawn, the timescale from source to lab should be no greater than 2 hours. If there is a delay in sending samples to a laboratory, they should be stored at between 6ºC and 18ºC.

Sampling Shower or Mixer Tap Water

4.5 The following sampling procedure should be followed:

© Health Facilities Scotland, a division of NHS National Services Scotland.

- normally use a 1 litre sample which should be taken from each shower head/outlet;
- before turning on the shower/outlet, adjust the temperature setting to the midpoint for non-thermostatic taps and the normal use temperature (35°C to 43°C) for thermostatic taps;
- place a sterile plastic bag over the shower head/outlet and secure with a rubber band. Using sterile scissors cut off one of the bottom corners of the bag to form a funnel. Use this funnel to fill the bottle;
- replace and tighten the lid and shake the bottle to distribute the sodium thiosulphate;
- all water samples for *Legionella* analysis should be stored at an ambient temperature (approximately 20°C), in the dark, and returned to the accredited laboratory as soon as possible to ensure that they can be examined promptly, preferably the same day but at the latest so that processing can begin within 24 hours of taking the sample.

Sampling Swimming, Spa and Hydrotherapy Pool Water

4.6 The following sampling procedure should be followed from a number of sample points and from the balance tank (and swab samples from inside/behind any jets):

- outside shoes should be removed or plastic shoe coverings should be worn if entering swimming pool areas;
- wipe the outside of a sterile bottle (500ml sample bottle containing neutraliser as paragraph 4.3) with an alcohol wipe if not individually packed, and label with a waterproof marker or ball point pen;
- aseptically open the bottle;
- immerse the bottle, keeping the long axis approximately horizontal but with the neck pointing slightly upwards to avoid loss of the neutralising agent;
- once the bottle is immersed to about 200–400mm below the surface, tilt the bottle to allow it to fill, leaving a small headspace;
- on removal from the water, immediately replace the cap and shake the sample to disperse the neutralising agent;
- water samples should be stored between 2ºC and 8ºC, and submitted to the laboratory in a timely way to ensure that they are examined on the day of collection or at least within 24 hours of the collection;
- if both routine testing parameters and *Legionella* are required, then separate 1 litre and 500ml samples should be taken;
- it is also good practice to determine total and combined disinfectant levels and pH value from the same site as the microbiological sample. These should be determined in a separate sample collected in a bottle without any neutralising agent (e.g. a sterile plastic universal) and the tests carried out at the pool-side. These results together with information on the number of users in the pool at the time of sampling should accompany the sample to

© Health Facilities Scotland, a division of NHS National Services Scotland.

the laboratory. Also the number of bathers should be noted together with the type of disinfectant in use;

- identification information for each individual sample should be given to the accredited laboratory to confirm;
  - the specific sampling point;
  - the room/location of sampling point;
  - the premises, building block, floor etc.

© Health Facilities Scotland, a division of NHS National Services Scotland.

5. Results expected

General

5.1 Tests could take between 5 and 10 days to complete:

- an early warning can be requested by phone or email to confirm product failing to meet its specification prior to completion of testing;
- micro-organisms for which tests are to be carried out would include E coli, staphylococcus aureus and pseudomonas aeruginosa;
- written reports to be provided on completion via paper copies and email advising the number of bacteria, yeasts and moulds per gram of product;
- in smaller healthcare premises, depending on configuration of systems, it may be possible to continue functioning despite adverse readings by switching to bottled supplies for drinking water purposes.

Sampling Procedures

5.2 The Sampling and Leachate Testing should to be undertaken is detailed in SHTM 04-01 Part E.

5.3 As described in paragraph 4.4 sampling must follow that set out in BS7592: 2008 Code of Practice and BS EN ISO 5667-1: 2007 on Water Quality Sampling. Those organising sampling must make clear in advance which water quality technique is to be undertaken in order that systematic conclusion on risk can be drawn.

5.4 For initial water system sampling take a Post-Flush sample (as defined in BS7592: 2008) at sentinel points without disinfection. Where there is an initial concern with a particular outlet location – say, a combined system and outlet problem – a BS Pre-Flush sample should be taken. If concerns persist with an outlet location (typically, a known dead-leg issue or lack of, or low, water use, a further BS Pre-Flush sample should be taken followed by disinfection before a BS Post-Flush with disinfection sample. Water should be allowed to run hot for 1 minute and cold for 2 minutes by which sampling would be temperature calibrated.

Interpretation of results and further actions

5.5 Where water quality sampling in a water system confirmed (acceptable) *Legionella* results **less than 100 CFUs/Litre** – the Authorised Person (Water) would be informed and provided with copies of the samples in writing and associated record keeping. The Authorised Person (Water) would provide interpretation (with the Consultant Microbiologist when and where required) on the results and confirm if any actions are required.

5.6 Where water quality sampling in a water system confirmed *Legionella* results in **excess of 100, but less than 1,000 CFUs/Litre** – the Authorised Person

© Health Facilities Scotland, a division of NHS National Services Scotland.

(Water) and Consultant Microbiologist must be informed and provided with copies of the samples in writing. The Consultant Microbiologist would provide interpretation on the results and confirm the necessary actions prior to bringing the water system into use.

5.7 Where water quality sampling in a water system confirmed *Legionella* results in **excess of 1,000 CFUs/Litre** *immediate* action must be taken and the Consultant Microbiologist and Authorised Person (Water) must be informed and provided with copies of the samples in writing. They will immediately confirm the necessary actions prior to re-sampling and bringing the water system into use when (acceptable) *Legionella* results are reliably less than 100 CFUs/Litre.

Note: Where continued water system sampling is required, this would be undertaken on a weekly frequency.

5.8 Where the results of three consecutive weekly water system samples remained below 100 CFUs/Litre, the Authorised Person (Water) and Consultant Microbiologist would be informed and sampling would revert to a monthly sampling frequency.

5.9 Where the results of three consecutive monthly Water System samples remained below 100 CFUs/Litre, the Authorised Person (Water) and Consultant Microbiologist would be informed and sampling would revert to a 3-monthly sampling frequency.

Preface

About Scottish Health Technical Memoranda

Engineering Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of SHTM guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle: Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Engineering Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

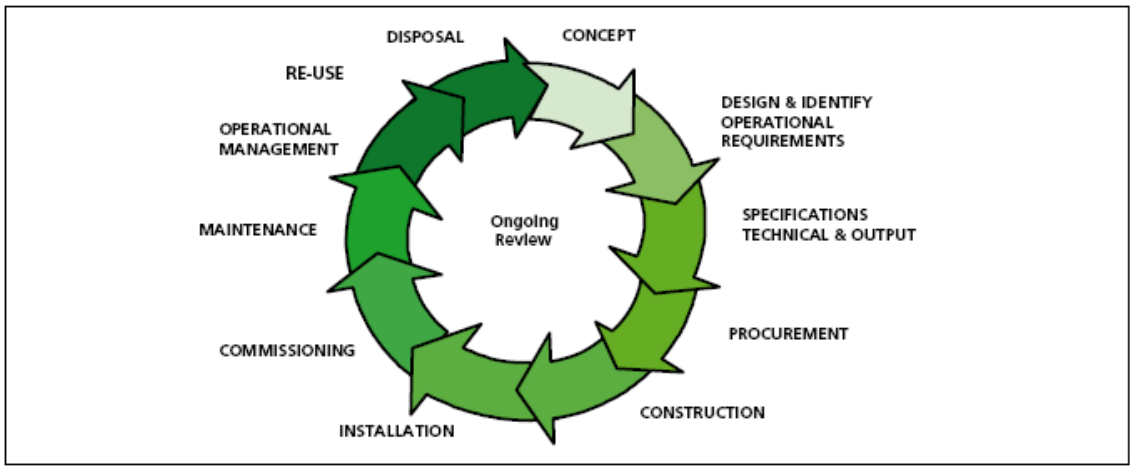
It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.

© Health Facilities Scotland, a Division of NHS National Services Scotland



Healthcare building life-cycle

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of eight core subjects:

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Scottish Health Technical Memoranda in this series)

Scottish Health Technical Memorandum 01: Decontamination

Scottish Health Technical Memorandum 02: Medical gases

Scottish Health Technical Memorandum 03: Heating and ventilation systems

Scottish Health Technical Memorandum 04: Water systems

Scottish Health Technical Memorandum 05: Reserved for future use

Scottish Health Technical Memorandum 06: Electrical services

Scottish Health Technical Memorandum 07: Environment and sustainability

Scottish Health Technical Memorandum 08: Specialist services

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent: Electrical safety guidance for low voltage systems. In a similar way Scottish Health Technical Memorandum 07-02 will simply represent: Environment and Sustainability – EnCO2de.

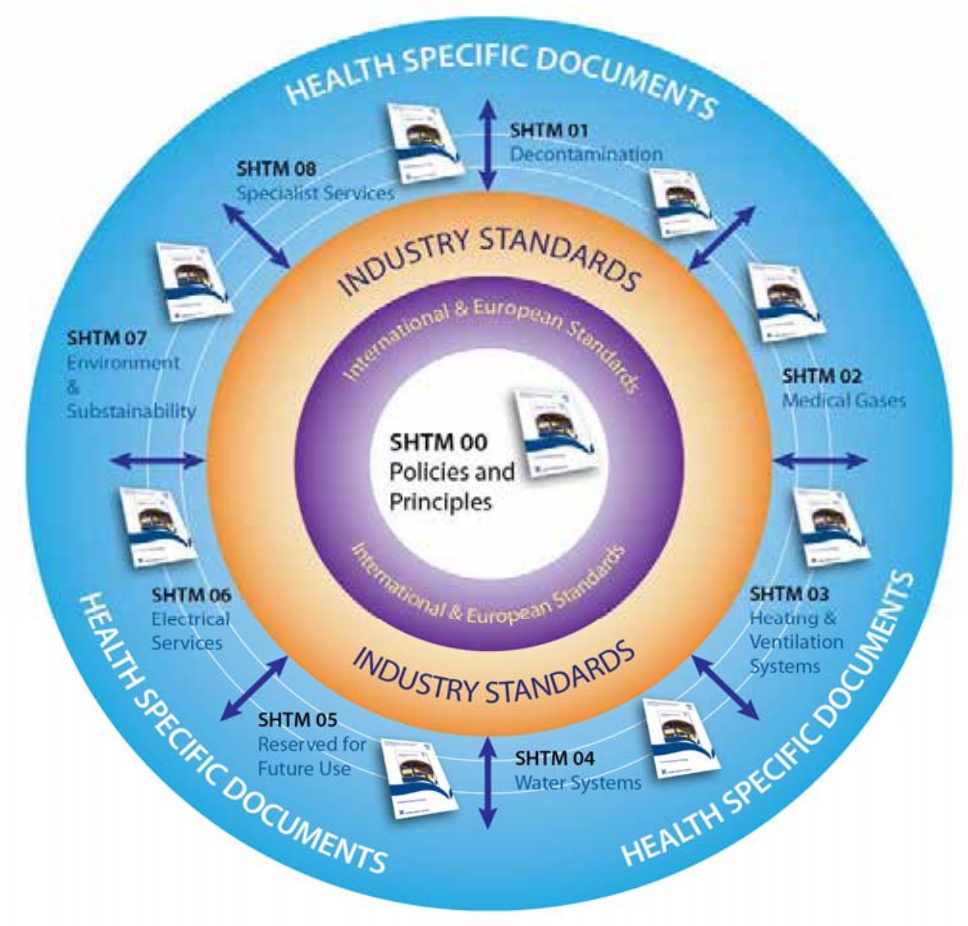
All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management

© Health Facilities Scotland, a Division of NHS National Services Scotland

and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

Health Facilities Scotland wishes to acknowledge the contribution made by professional bodies, engineering consultants, healthcare specialists and NHS staff who have contributed to the review.



Engineering guidance structure

1. Introduction

Background information

1.1 Health Facilities Scotland (HFS) Scottish Engineering and Technology Advisory Group raised concerns regarding a lack of information and guidance on the addition of chemicals to water in healthcare premises. In response to this, a Short-Life Working Group was formed and this eventually became the **National Water Services Advisory Group**. Part of the remit of this Group was to review available literature not only on the chemical treatment of water but also on processes used to treat water.

1.2 The use of any chemical in the treatment of potable water carries a risk and estates staff will need to call an independent party to review all paperwork and risk assessments before a treatment is implemented. This is of particular relevance when campaign or continuous treatment is contemplated but should also be implemented when shock treatment is proposed.

Group Membership

1.3 The group consisted of these members:

Tom Foley (Chair) NHS Tayside

Jim Alderton NHS Forth Valley

Iain McInally NHS Ayrshire & Arran

David Bennett NHS Tayside

Kenneth Walker NHS Grampian

Ged Mather NHS Borders

Alistair Johnstone NHS Dumfries & Galloway

Daniel Egan Golden Jubilee Hospital

Edward McLaughlan HFS Scotland

Ian Stewart HFS Scotland

Geraldine O'Brien HFS Scotland

Purpose of the Report

1.4 The purpose of this report has been to draw together peer reviewed information on potable water disinfection methods, in order to analyse them and identify the pros and cons associated with the use of each method

© Health Facilities Scotland, a Division of NHS National Services Scotland

Report Layout

1.5 Supplementary to this report is a quick reference guide to each method, consisting of bullet points indicating the advantages, disadvantages and safety factors to be considered when using that method. This report will ultimately provide a review of published work on each of the disinfection systems available, how these chemicals/treatments affect NHSScotland estate and its occupants, and the main advantages and disadvantages associated with their uses, in order that the most appropriate system can be selected.

- Appendix 1 provides some case studies for further reading;
- Appendix 2 comprises a decision matrix, which has been arranged for use by estates staff during the decision-making process;
- Appendix 3 is provided to assess risks associated with the content/production of this document.

2. Disinfection of water systems

General Warning Regarding Chemical Disinfection of Hospital Water:

It has been found that the renal water plants do not filter out hydrogen peroxide, copper-silver ions, chlorine, chloramines and ozone. These disinfection systems should not be used where water serves a haemodialysis treatment area (SAN HAZ (SC) 08/07, 2008). Due to the extremely sensitive nature of renal water plants, no chemicals should be added to the water going to these units. If possible these units should be kept on a separate mains supply, or at least isolated when any shock or campaign treatment is planned.

Introduction

2.1 Opportunistic pathogens colonise water systems and can cause pulmonary, wound and bloodstream infections in healthcare patients. This contributes to approximately 25% of all healthcare-acquired infections (Anaisse et al., 2002). Papers published on nosocomial outbreaks in healthcare facilities have provided evidence that the source of contamination often originates from pathogens in the water supply. Bacteria, for instance, have been implicated in an estimated 1,400 deaths each year as a result of waterborne nosocomial pneumonias caused by *Pseudomonas aeruginosa* (Anaisse *et al*., 2002). Mucoid strains of *Pseudomonas aeruginosa* have been shown to have increased resistance to chlorine as a result of being protected by a biofilm (Grobe *et al*., 2001). These strains have been found to persist in swimming pool PVC pipework.

2.2 Another example of opportunistic pathogens is mycobacteria, which can survive in potable water systems for several years due to having a moderate resistance to chlorine. These bacteria have been implicated in serious nosocomial outbreaks (Reyn et al. 1994), and *Mycobacteria avium* has been shown to be resistant to chloramination, chlorination, chlorine and ozone disinfectants (Taylor et al. 2000). Mycobacteria are common in the natural environment and can colonise water distribution systems (Wright et al., 1985). Taylor *et al*. (2000) state that *Mycobacterium avium* can be found in public water supply and can be the cause of infection in hospital patients. Some studies have shown mycobacteria colonizing only parts of hospital water systems (Fox et al., 1992; Fujita et al., 2002). This suggests that the source of the contamination in these cases is not necessarily the public supply. Fujita et al.'s (2002) results also show that the colonisation affected directly connected parts of the distribution system, suggesting that contamination can occur at a water outlet, and then travel throughout the system. Mycobacteria is one of the most common opportunistic infections in AIDS patients, and it has been reported that 20% to 40% are infected by mycobacteria (Horsburgh, 1991).

2.3 Other pathogens that may contaminate healthcare domestic water systems are Aeromonas, which are found in many types of water and have been shown to inhabit biofilms in distribution systems. Aeromonas symptoms include diarrhoea that can last a few days or weeks (Vila *et al*., 2003), and is generally not life

© Health Facilities Scotland, a Division of NHS National Services Scotland

threatening. However, high risk groups such as immuno-compromised, young, and old patients' lives may still be at risk from such an infection. Protozoa such as Cryptosporidium and Giardia can also be present in the domestic water system and although the main symptoms again include diarrhoea, they can present a more serious threat to patients (Freije, 2005).

2.3 A paper produced by Yu (2007), indicated that researchers have found 70 percent of hospital water systems tested in the US to be positive for *Legionella* species. Many of the standard hospital disinfection methods involve the use of chlorine, however Kuchta (1983) states that *Legionella* can survive low levels of chlorine for relatively long periods of time. Another factor that may promote the growth of *Legionella* is the temperature of the system, although Scottish guidance - SHTM 04-01 Part A, (2011) - specifies the flow and return temperature of a domestic hot water system in a healthcare environment should be no less than 60°C at the calorifiers with a return temperature of 55ºC, the minimum allowable return temperature is 50ºC. This temperature of 50ºC should not be designed for as it will not kill off, only inhibit *Legionella* growth. The optimum temperature for multiplication of *Legionella* strains in culture media is approximately 37°C (Kramer and Ford, 1994); this temperature should never be reached in a system unless there is a malfunction. However, contrary to common belief a healthcare institution's cold water supply may also be contaminated with *Legionella* (Hoebe 1998). Colbourne & Trew (1986) maintain that *Legionella* occurs in 52 to 54% of domestic and cooling water inside commercial, industrial and health care buildings, these types of water systems are now regarded as a normal habitat for *Legionella. Legionella* is commonly found in the public water supply, the public is not aware that *Legionella* is a common inhabitant of man-made water distribution systems (Stout and Yu, 2001).

2.4 The reason treated water systems continue to be colonised by these pathogens, is due to an inappropriate treatment regime. *Legionella* is ubiquitous in water systems unless treated, however, Zhang *et al*., (2009) states that infection can be prevented through using an appropriate water disinfection system. Chlorination, the traditional method, as mentioned above may not be the most efficient technique and, following growing evidence of a link between chlorination and mutagens in drinking water (Gopala *et al*., 2007), alternative disinfectants continue to be investigated. There are many disinfection systems currently available, examples of which include

- heat and flush;
- continuous chlorination;
- chlorine dioxide;
- Ultra Violet light (UV);
- copper silver ionisation;
- silver catalysed hydrogen peroxide;
- ozone and chloramines.

All of these decontamination processes have advantages and disadvantages and work at their optimal performance within different parameters. The main

© Health Facilities Scotland, a Division of NHS National Services Scotland

aim of this report is to investigate the different methods, analyse their advantages and disadvantages and determine the factors needed to ensure optimal results when using each system.

Physical Parameters

2.5 When considering the most suitable method of disinfection for a healthcare facility a number of parameters have to be taken into consideration, factors to be considered include the condition of estate, the health of the occupants, the quality of the public water supply, finance, and the availability of resources to implement a particular regime.

Parameters of Incoming Water

2.6 There are many factors concerning the incoming water supply that should be taken into consideration when selecting the most suitable disinfection method. These include aspects such as:

- pH - has no effect on Ozone or UV, however the disinfection power is reduced with a higher pH than 8 for continuous chlorination (See Appendix 2 for more details);
- temperature – has no effect on Ozone or UV, however the residual effect decreases for continuous chlorination and chlorine dioxide when temperature increases;
- taste and odour – if this is already a problem, chlorine dioxide can neutralise these odours. However some disinfectants may contribute to taste and odour, such as chlorination if used at a high dose (See Appendix 2 for more details);
- if systems or parts of systems are unused for long periods of time then it is essential that a full flushing regime is instigated. If the water is not used on a regular basis then a residual disinfectant will be required, the volume and pipework design should also be considered as this may also determine if a residual effect is required. Disinfectants such as UV and Ozone have no residual effect, whereas chlorine dioxide, copper – silver ionisation and silver catalysed hydrogen peroxide have a long-lasting residual effect.

Heat and Flush

2.7 This process is one similar to pasteurisation and is distinct from normal temperature control applied to DHWS; this is used as a means of disinfection causing the destruction of disease-causing microorganisms. Increasing the temperature of hot water was the first method used to control *Legionella* in a hospital distribution system (Fisher *et al*., 1981). This chemical-free method requires no additional equipment and is commonly used, particularly as an emergency decontamination procedure in hospital outbreak scenarios.

Method

2.8 As stated in L8, and SHTM 04-01 Part A this disinfection is carried out through raising the temperature of the entire contents of the calorifier, or hot water

© Health Facilities Scotland, a Division of NHS National Services Scotland

heater, followed by circulating the water throughout the system for at least an hour at 75ºC. The calorifier/heater temperature must be sufficiently high to ensure that the temperature in all parts of the circulating system, and at the return connection, do not fall below 75 C (Zacheus and Martikainen, 1996). This can be used as a continuous process in a hot water system only but has a significant cost to sustain the high temperatures required. This form of disinfection can only be used as a shock treatment for an outbreak in a cold water system; therefore, it is not suitable for continuous disinfection. It must also be noted that when utilising this method for a cold water system particular attention must be made to the thermal expansion of the system and this must be accounted for.

Advantages

2.10 The main advantages to this form of disinfection are that it requires no specialist equipment and therefore can be implemented immediately after an outbreak has been detected. If also used to disinfect the cold water system an additional connection from the calorifier is required, this must be disconnected after flushing and any branch connections must *not* result in extended dead legs being formed.

Disadvantages

2.11 One of the main disadvantages to using this method of disinfection for treatment of a water distribution system is that disinfection may not eradicate *Legionella* fully and recolonisation may occur. This disinfection method is also labour intensive and numerous personnel are required to monitor water temperatures and flushing times. It can also prove ineffective for long-term *Legionella* infestation management (Zhang et al., 2009). Furthermore, the energy costs of maintaining a hospital hot water system above 60ºC are substantial and may not reliably prevent persistence at parts of the system where there is infrequent use and a lower temperature (Farr *et al*., 1998).

(See Appendix 1 on Case Studies for further information)

Continuous chlorination

2.12 Chlorination was the primary method of disinfection for drinking water from the early 1900s, however in the 1970s, it was discovered that chlorination caused a number of disinfection by-products that are known to be hazardous to human health (Moudgal *et al*. 2000). Also due to the risks inherent in the handling of chemicals to producing chlorine gas it is no longer as prominent in systems within UK healthcare facilities and has been replaced with Chlorine Dioxide.

Method

2.13 Chlorination is the process of adding chlorine to water as a means of water purification. This is accomplished by continuous injection through calcium hypochlorite, sodium hypochlorite, or gas chlorination. The effectiveness of chlorine as a disinfectant is determined by the chlorine concentration, contact time, the pH level, temperature, the concentration of organic matter, and the number and types of microorganisms in the water.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Advantages

2.14 Continuous chlorination provides a residual disinfectant concentration throughout the entire distribution system (Fass et al., 1998). Nearly 100 years of chlorination for the disinfection of drinking water has demonstrated the effectiveness of this process for the inactivation of microbial pathogens, with the notable exception of *Cryptosporidium* where very high concentrations of chlorine are required (Korich *et al*., 1990).

Disadvantages

2.15 There are several disadvantages to using chlorine as a disinfectant:

- it is highly corrosive and causes damage to pipework (Lin *et al*., 1998);
- needs monitoring due to the fact that once added and circulating freely within the water the chlorine combines with organic compounds and produces carcinogenic chloroform and carbon tetrachloride. It is the combination of chlorine and organic materials already in the water that produces cancer-causing by products. The more organic matter in the water, the greater is the accumulation of Trihalomethanes (THMs) (Waller *et al*., 1998). Also studies in Belgium have related development of malignant melanoma to consumption of chlorinated water (Douglass, 1994). The residual chlorine levels should be below 5 mg/litre as stated in the drinking water quality guideline (WHO Drinking Water Guidelines, 2004);
- Chlorine may only suppress *Legionella* and not kill it and rarely can *Legionella* be eradicated from a system using this method alone. Moreover, the inactivation of *Cryptosporidium* requires high chlorine dosages, thereby resulting in higher by-product concentrations and increased rates of corrosion. One of the main side effects to using chlorination as a disinfectant is that it reacts with natural organic matter to produce halogenated disinfection by-products i.e. THMs;
- Chlorine reacts with organic materials and creates carcinogenic by-products called (THMs), and numerous studies have linked the consumption of chlorinated water with cancer (Lin *et al*., 1998). This in turn has led to guidelines by international organisations such as the World Health Organisation to be revised to lower the THMs in drinking water;
- Chlorine has no detergent cleansing powers; therefore it is essential that slime and debris are removed by thoroughly cleansing before chlorine is used. However, chlorine should not be used with some other biocides, since they may neutralise each other unless they are known to be compatible. Such as ammonia which reacts with chlorine to form harmful THMs.

Chlorine Dioxide (ClO_2)

2.16 Chlorine dioxide must be manufactured on site because it decomposes readily and presents toxicity hazards when stored (Kim *et al*., 2002).

© Health Facilities Scotland, a Division of NHS National Services Scotland

Method

2.17 The chemical is a gas that is generated mechanically or electrolytically from a sodium chlorite solution which is then introduced into the water distribution system.

Advantages

2.18 Chlorine dioxide is a very selective oxide, allowing lower dosages to be used to obtain the same results as chlorine or ozone (Gates, 1998). Radziminski et al. (2002) state that chlorine dioxide is superior to chlorine in the destruction of spores, bacteria, viruses, protozoan cysts, biofilm, and waterborne pathogens. There are also only minimal corrosion issues associated with using chlorine dioxide, and although biofilm in the pipework can protect *Legionella* from disinfection system such as heat and flush and chlorine, chlorine dioxide can remove biofilm and kill these bacteria, spores and viruses. ClO_2 is also an effective biocide over a wide pH range and is useful for removing iron and manganese to control taste and odour (Zhang *et al*., 2009). However taste problems can become an issue from chlorine dioxide at high dosage levels.

Disadvantages

2.19 There are some dangers to using this disinfectant in potable water, as chlorine dioxide and its by-products, (THMs), chlorate and chlorite ions, do have toxic properties and pose health risks to consumers (Zhang et al., 2009). Chlorine dioxide generally forms less THMs, haloacetic acids (HAAs), and total organic halogen (TOX) than free chlorine. However, chlorine dioxide forms more iodinated DBPs when iodide is present in the source water. The WHO's recommended guideline for chlorite in drinking water is less than 0.2 mg/litre, while the Secretary of State for the Environment's legal requirement is that the combined concentration of chlorine dioxide, chlorite and chlorate should not exceed 0.5 ppm.

(See Appendix 1 on Case Studies for further information).

UV light

2.20 Disinfection using UV light differs considerably from chemical disinfectants such as chlorine and ozone, which inactivate microorganisms by destroying or damaging cellular structures, interfering with metabolism, and hindering biosynthesis and growth (Snowball and Hornsey, 1988). UV on the other hand, inactivates microorganisms by damaging their nucleic acid, thereby preventing the microorganism from replicating.

Method

2.21 This disinfection method involves exposing contaminated water to radiation from UV light. The most efficient and widely used device for this purpose is the mercury arc lamp, as approximately 85% of its energy output is of the 253.7 nm wavelength, which is within the optimum germicidal range of 250–270 nm (Chen *et al*., 2006). This can be used at the entry to the domestic water system where all of the water is disinfected or can be used as a point of use system which Kim

© Health Facilities Scotland, a Division of NHS National Services Scotland

et al. (2000) suggest is the most effective use of this type of filtration system. The use of a point of use system may not be feasible in a healthcare setting as this would not be economical on a large scale system.

Advantages

2.22 UV light can inactivate pathogenic microorganisms without forming the by-products that other chemical treatments create, and it has proven effective against some pathogens, such as *Cryptosporidium*, that are resistant to commonly used disinfectants like chlorine (USEPA, 2003). In particular, several studies have confirmed the efficacy of UV light for disinfecting *Legionella* in laboratory water settings (Muraca *et al*., 1987).

2.23 Some other advantages of ultraviolet light include its easy installation, and its lack of adverse effects on water or plumbing systems. Studies suggest that the efficacy of UV light is only minimally affected by high water temperature (Severin *et al*., 1983; Malley, 2000). Studies also indicate that UV disinfection at doses of up to 200 mJ/cm^2 do not change the pH, turbidity, dissolved organic carbon level, UV transmittance (UVT), colour, nitrate, nitrite, bromide, iron, or manganese of the water being treated (Malley *et al*., 1995).

2.24 Lin *et al.* (1998) state that if UV light is used to disinfect an entire system, as it is only effective immediately after disinfection, and it should be combined with another systemic disinfection method such as hyperchlorination or thermal eradication. Filters are also required prior to UV filtration to remove particles from the water system (Kim *et al*., 2002). The recommended pre-filter for each UV model depends on the turbidity of the local water supply this filter size can range from 20-5 microns.

Disadvantages

2.25 The main disadvantage to this form of disinfection is its lack of residual protection. If used at the point of entry to a domestic water system, levels of contamination would have to be measured at outlets, as *Legionella* re-growth in the biofilm layers of scale and accumulated debris still allows for recolonisation. Maintenance of the water system is necessary and important to reduce this biofilm formation and *Legionella* recolonisation (Franzin *et al*., 2002).

2.26 As discussed above, another way UV treatment can be utilised is as a point of use system. Although this system seems to be effective, in the case of a large hospital it would be uneconomical as there are many points of use. Another possible drawback to using UV light as a disinfectant is that some of the microorganism cells damaged by the UV light can be repaired, either in the presence of light, termed ‘photoreactivation’, or through a ‘dark repair’ in the absence of light (Jagger, 1967). As a result, the strategy in UV disinfection has been to provide a sufficiently high dosage to ensure that nucleic acid is damaged beyond repair. UV disinfection costs will vary depending on size and difficulty of installation. The Water Research Foundation carried out a case study on a water treatment works in Arizona, and found that running costs were $0.004 per 1,000 gallons. (http://www.waterresearchfoundation.org/research/TopicsandProjects/Resource

© Health Facilities Scotland, a Division of NHS National Services Scotland

s/caseStudies/caseStudyFlagStaff.aspx. It is impossible to convert this into a UK equivalent figure, but this illustrates the relatively low cost of treatment by volume. Small scale systems are available from several manufacturers. One example of these is a 430 litres/minute system costing £4,499, with lower priced systems for lower water demand, going down to 40 litres/minute (http://www.eastmidlandswater.com/products2.asp?CategoryID=18&SubcategoryID=30).

The intensity of the lamps declines over time; therefore they need to be replaced in most units every 8,000 to 9,000 hours for optimum unit performance (Srikanth, 1995).

Copper-Silver Ionisation

2.27 Metals such as copper and silver ions are known as bactericidal agents. Most studies on the use of copper-silver ionisation as a disinfection method have suggested good efficacy for *Legionella* control in water systems (Liu *et al*., 1994). A laboratory study by Huang *et al*. (2008) of copper and silver ions in combination provided evidence to suggest that bactericidal efficiencies are greater than 99.99% against the most significant clinical waterborne microbes; *P. aeruginosa*, *Acinetobacter baumannii*, and *S. maltophilia*, including *Legionella*. Silvestry-Rodriguez et al. (2007) summarises the disinfectant properties of copper-silver ionisation for large building water distribution systems, stating that this method has an appreciable impact on levels of coliform bacteria, iron-related bacteria, sulphate-reducing bacteria and slime producing bacteria. This has led to the conclusion that copper–silver ionisation may have the potential to eradicate major waterborne pathogens in hospital distribution systems. However the eradication efficacy of ionisation under field conditions in UK institutional water systems and its significance in reducing hospital-acquired infections are still to be determined. Studies in the United States have shown copper-silver ionisation to be effective at controlling *Legionella* in hospitals (Lin *et al*., 1998; Stout *et al*., 1998).

Method

2.28 This disinfection method is brought about by electrolysis, positive copper and silver ions are created from electrodes made of copper and silver, these ions are then distributed throughout water systems to eradicate bacteria. Copper ions penetrate the cell wall and as a result they will create an entrance for silver ions. Silver ions bond to various parts of the cell, such as the DNA and RNA, causing all life support systems in the cell to be immobilized. The ions remain active until they are absorbed by a microorganism.

Advantages

2.29 Copper-silver ionisation systems have many advantages in that they are easily installed and maintained, and their efficacy is not affected by high water temperature, unlike chlorine and ultra-violet light (Lin Yu *et al*., 1998). Additionally, *Legionella* is killed through this disinfection method rather than suppressed, which minimises the possibility of recolonisation (Lin *et al*., 1996). This was demonstrated in Liu Z *et al*'s study in 1994 where recolonisation was

© Health Facilities Scotland, a Division of NHS National Services Scotland

delayed by six to twelve weeks, even after the ionisation was shut down in one hospital. This factor provides a safety margin if the system malfunctions, unlike chlorination through which *Legionella* can rapidly re-appear.

Disadvantages

2.30 Some of the disadvantages to copper-silver ionisation are that silver ions react easily with chlorines and nitrates that are present in the water, causing them to no longer be effective, therefore to ascertain the level of ionization required the levels of chlorines and nitrates present in the water must be established. This may cause a problem if the water has very high levels of chlorines and nitrates as a very high level of copper and silver ions would be required to disinfect the entire system properly. Furthermore, some microorganisms can become resilient to silver and it is suggested that *Legionella* could develop resistance to copper and silver ions (Mietzner *et al*., 2005). This form of disinfection is also expensive to install, and the electrodes must be cleaned regularly to reduce scale build up, and replaced annually to give optimal performance. High concentrations of silver in the water can also stain porcelain (Lin *et al*., 1998). The only obvious sign of silver overload to humans is Argyria, a condition in which skin and hair are heavily discoloured by silver in the tissues. The amount of silver required to develop Argyria is estimated (by the EPA) to be 3.8 grams per day.

2.31 The pH of water is an important factor in the efficacy of copper and silver (Lin *et al*., 2002), as elevated pH levels (>8.0) reduce the effectiveness of copper ions against *Legionella*. Although pH has little effect on silver ions, a higher pH can alter the positively charged copper ions to become negatively charged, and therefore less effective at eradicating *Legionella*. Sensors would have to be provided in order to maintain accurate concentrations throughout the system. In terms of these concentrations in water, the European Union does not dictate any standards concerning silver. However copper has a maximum value of 0.02mg/litre (EU Drinking water directive, 98/83/EC1998).The WHO also does not dictate any standards; they believe the available data is insufficient for recommending a concentration limit (WHO Guidelines for Drinking Water Quality, 2004). The United States however, dictates a maximum value of 1 mg/litre for copper and a maximum value of 0.1 mg/litre for silver (EPA National Secondary Drinking Water regulations, 2002). Industry leaders who manufacture copper silver ionisation technology recommend a copper concentration of 0.4 to 0.8 mg/litre and a silver concentration at 40 to 60 µg/litre, to be compliant with EPA drinking water standards (Shields, 2002).

2.32 The Health and Safety Executive issued an Approved Code of Practice and guidance on the control of *Legionella* bacteria (L8, 2000) in water systems, below is the statement made in clause 176 of the document:

"The application of ionisation will need to be properly assessed, designed and maintained as part of an overall water treatment program. The Water Supply (Water Quality) Regulations and Private Supply Regulations prescribe a maximum value for the level of copper and silver ions in drinking water supplies. It is important that installers of ionisation systems are aware of the need to avoid any breach of these Regulations and maintain copper and silver levels

© Health Facilities Scotland, a Division of NHS National Services Scotland

below the maximum allowable concentration. The local water company may need to be consulted to check that the installation complies with the requirements of the Water Regulations. "

http://www.hse.gov.uk/pubns/priced/l8.pdf

2.33 The Scottish Government issued a formal document stating that silver is not to be used continuously as a disinfectant for a public water supply. Below is what the Drinking Water Quality Division - List of Approved Products, December 2007 states:

*"C*urrent approval for the use of products containing silver salts in relation to emergency disinfection of water intended for human consumption is subject to the following conditions of approval:

- the concentration of silver in the water does not exceed 80 µg/litre; and
- consumers are exposed to water containing silver for only as long as necessary to restore conventional treatment, and for no more than a total of 90 days in any period of a year.

These conditions ensure that there is only a limited exposure of the consumer to silver". http://www.scotland.gov.uk/Publications/2008/03/04152957/9

2.34 For a public water supply indicated by The Water Supply (Water Quality) (Scotland) Regulations (2001), the inclusion of silver is not contained in the document as no product has been approved for this application and would have to be assessed for this purpose.
http://www.opsi.gov.uk/legislation/scotland/ssi2001/20010207.htm

2.35 In contrast to this if a hospital has its own private water supply then, The Private Water Supplies (Scotland) Regulations (2006) should be adhered to, schedule 3 in these regulations state that:

"Silver may be used in some water treatment devices where it is used for disinfection purposes"

Table B part II states that a concentration of 10µg/litre is allowed and if used in a water treatment process, 10µg/litre may be substituted for 80µg/litre.

http://www.opsi.gov.uk/legislation/scotland/ssi2006/20060209.htm#4

2.36 The above Scottish regulations do not imply that silver is any safer to be used in a private supply than a public supply, only that silver is more likely to be used in a private water supply due to the smaller quantities involved, for public supplies the economics of using silver would not stand up against cheaper alternatives such as chlorine.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Note: It can be concluded that there is no clear decision to be made on the use of silver in domestic water systems, however the Opinion of Counsel have put forward ANY form of treatment to domestic water systems that causes a change to the condition supplied by the Water Authority leaves the User of that Treatment open to legal challenge. Due to this, the Counsel recommends that an independent assessment is carried out of all Risk Assessment and Method Statement documentation prior to treatment being initiated. This documentation should be supplied to Scottish Water and to the Drinking Water Inspectorate.

Silver Catalysed Hydrogen Peroxide

2.37 There is very little research within the UK on the use of silver catalysed hydrogen peroxide as it is a relatively new form of decontamination and at present is only implemented in a small number of water distribution systems within the UK (it is widely used in Europe). Available research suggests that combined Sliver and Hydrogen Peroxide has a moderate bactericidal effect on *E. coli* and only a mild virucidal effect (Pedahzur *et al*., 2000).

Method

2.38 A silver catalysed hydrogen peroxide solution is added to a water system by injecting it directly into the water.

Advantages

2.39 In some instances, the combined bactericidal effects of silver and hydrogen peroxide are 1,000-fold higher than the sum of them being introduced on their own. Another benefit to using this disinfectant is that the biocidal action of silver catalysed hydrogen peroxide generally increases with rising temperature and pH levels (Pedahzur *et al*., 2000). In addition, the slow and moderate bactericidal effect, and the prolonged stability and efficacy at relatively low concentrations, point to its use as a secondary long-acting residual disinfectant for good quality drinking waters (Pedahzur *et al*., 2000).

Disadvantages

2.40 One area of concern is the level of silver contained in the water. As discussed previously in this document under the copper-silver ionisation section. There are Scottish Government guidelines indicating levels of silver allowed in a water supply, which should be adhered to in this instance. As also stated in the previous section on Copper/Silver ionisation, the Private Water Regulation Act (2006) allows the use of silver for disinfection. However there is no mention of Hydrogen peroxide in this document. The Drinking Water Quality Division - List of Approved Products, December 2007 states in relation to Hydrogen peroxide:

"Hydrogen peroxide containing silver or its compounds should not be used continuously as a disinfectant for public water supply".

http://www.scotland.gov.uk/Publications/2004/02/18931/33327

© Health Facilities Scotland, a Division of NHS National Services Scotland

Levels of silver must also adhere to the documents produced by Scottish water as stated in the previous section on copper-silver ionisation.

Ozone

2.41 Ozone is a similar disinfectant to UV light as it decomposes quickly in potable water and is therefore normally used as a secondary disinfectant at point of use. Ozone is an unstable compound and because of its instability, it cannot produce a persistent disinfectant residual in distribution systems (Singer, 1994).

Method

2.42 Ozone disinfects water by damaging the DNA of microorganisms (Kim et al., 2002). Ozone in aqueous solutions may react with microbes either by a direct reaction with molecular ozone or by an indirect reaction with the radical species formed when ozone decomposes.

Advantages

2.43 Ozone is one of the strongest and fastest acting disinfectants, and its high efficiency may have significant advantages in water treatment processes (Wojtenko, 2001). The bactericidal activity of ozone is much less prone to variation in pH and ammonia content than chlorine, and is more effective at low temperatures (Ingrams & Barnes, 1954), however ozone does react with ferrous and manganous salts to produce a scum that must be filtered off. The use of ozone in the removal of colour and odour has been well documented, and this use may be combined with the disinfection process (O'Donovan, 1965).

Disadvantages

2.44 One of the main disadvantages to using ozone as a disinfectant is that it has been shown that mutagenic and possibly carcinogenic by products may be produced under certain conditions of ozonation (Charmichael et al., 1982). Ozone is not a widely used disinfectant mainly due to its cost, and many hospitals choose to use chlorine, chloramines and chlorine dioxide which are cheaper to set up and run. Kim *et al*. (2002) state that one of the main reasons ozone on its own is not suitable as a disinfectant is that it has a very short life and carries no residual disinfectant into the water mains. This confirms previous reports in which ozone alone was found to be inefficient for controlling *Legionella* in water systems (Blanc *et al*., 2005). Charmichael *et al*. (1982) state that a more effective disinfection method would be to disinfect water by ozonation and then add small amounts of another disinfectant to give a residual effect in the piped supply. Chlorine would form (THMs) when combined with ozone which also carry risks; these are discussed in the section on Continuous Chlorination.

Chloramines

2.45 There has been an increasing interest in using chloramines as a secondary disinfectant to maintain a residual disinfectant effect throughout the distribution system (Seidel *et al*., 2005). Chloramines provide a similar protection to

© Health Facilities Scotland, a Division of NHS National Services Scotland

Chlorine and, although they have weaker bactericidal properties, they are more persistent in the water supply, lasting from 10 – 14 days.

Method

2.46 Adding ammonia to water containing free chlorine, hypochlorous acid (HOCl) and hypochlorite ions (OCl-), can, depending on the pH, produce chloramines. The ideal pH value for this reaction is 8.4, at which point the water is slightly alkaline.

Advantages

2.47 There are advantages to using this form of disinfectant. Primarily, chloramine technology is easily installed and maintained and it is among the less expensive disinfectant alternatives to chlorine that has a residual effect (USEPA, 2007). Chloramine is also not as reactive as chlorine, and forms fewer disinfection by-products, which, as discussed previously (Continuous Chlorination), may be harmful to humans (Hua, 2007). However, it should be noted that chloramines form more iodinated DBPs when iodide is present in the source water (Hua, 2007). In addition, as chloramine is more stable and longer lasting than chlorine, and provides better protection against bacterial re-growth. Chloramine is also effective in controlling biofilm, as shown by a study conducted by LeChevallier (1988) in which chloramines were more effective at inactivating biofilm organisms than free chlorine.

Disadvantages

2.48 There are some drawbacks to using chloramines, mainly because it can lead to the production of excess ammonia present in the water and leads to taste and odour problems. This can however be prevented by maintaining a pH level above seven which must be tested for prior to implementation for this disinfection system to be deemed suitable, and keeping the chlorine to ammonia ratio at 5:1 (USEPA Water Disinfection, 2007) these levels must be continually observed and the dose rate must be constantly adapted to maintain the specified ratio. Additionally, there are some potential problems with chloramines in relation to the corrosion of copper pipes and elastomer gaskets (USEPA Water Disinfection, 2007). Estates staff have also found that in the UK and the rest of Europe, this disinfection system is only available on large scale installations and at present it is not accessible to most NHSScotland healthcare settings.

3. Disinfecting agents: Pros and cons

Chlorine

H&S: Chlorine gas - Very dangerous

Hypochlorite liquid, etc - Dangerous/Moderate

Chlorine release tablets - OK

Cost: Low

Advantages: Well-established technology.

Readily available as gas, liquid or powder.

Inexpensive.

Relatively simple and flexible dosing control.

Well-known taste, if present.

Can eliminate certain noxious odours during disinfection.

Liquid chemical can be prepared off or on site.

Available as tablets for ease of handling.

Can be generated from salt and electricity.

More cost-effective than either UV or ozone disinfection.

The residual that remains in the water can prolong disinfection even after initial treatment and can be measured to evaluate the effectiveness.

Reliable and effective against a wide spectrum of pathogenic organisms.

Effective in oxidising certain organic and inorganic compounds.

Toxic to most microorganisms.

Disadvantages: May dissipate quite rapidly (12 to 24h), especially in distribution due to reacting with organic matter and other oxidizable contaminants. For this reason it may not reach the end of the water system, even if high doses applied.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Dosing equipment requires regular maintenance.

Can create taste and odour problems in poor quality water.

Can create carcinogenic compounds Trihalomethanes (THMs) in poor quality water. When considering the water from the utility provider, although it is of a potable standard there is still organic matter in the water that reacts with Chlorine to create THMs.

Simple neutralisation may be required before discharge to the environment. Any chemical discharge to a drain needs to be sanctioned by the Water Authority, who may then impose conditions on the discharge.

Long-term effects of discharging dechlorinated compounds into the environment are unknown.

Does not penetrate into centre of established biofilms.

All forms of chlorine are highly corrosive and toxic. Thus, storage, shipping, and handling pose a risk, requiring increased safety regulations.

Some parasitic species have shown resistance to low doses of chlorine, including oocysts of *Cryptosporidium parvum*, cysts, of *Endamoeba histolytica* and *Giardia lamblia*, and eggs of parasitic worms.

Potentially dangerous in case of a leak of chlorine gas.

System corrosion causes pipe leaks.

Workers must have access to a wash down hose, chemical eyewash, and shower. Operators must also wear the proper safety equipment, including carrying an Acid Gas escape respirator.

Must be removed from water prior to dialysis.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Chloramine (monochloramine)

H&S: Chlorine: Gas - Very dangerous

Liquid - Dangerous/Moderate

Tablets - OK

Ammonia: Gas - Very dangerous

Solutions - OK

Cost: Low

Advantages: Less potent disinfectant, but more persistent (residual can last 10 to 14 days).

Less prone to creating taste or odour problems, if correctly applied.

Low residuals can be effective.

Will generally not create carcinogenic compounds (THMs).

Some effect on biofilms.

Chloramines may provide a less obnoxious taste and smell than chlorine.

Few disinfection by-products are formed.

Chloramines remain active for a long time, longer than chlorine.

Disadvantages: Weak disinfectant and oxidation agent compared to chlorine. Ineffective against viruses and cysts (*Giardia, Cryptosporidium*).

High dosage and prolonged contact time required in comparison to the other disinfectants. Must be removed from water prior to dialysis.

Requires careful, precise mixing and dosing regime. Can create bad tastes, due to creation of dichloramine or trichloramine, if dosing is inaccurate or if pH unsuitable.

Has to be mixed and dosed on site. Not available as package plant. Dosing equipment requires regular maintenance. More difficult to remove from water than chlorine or chlorine

© Health Facilities Scotland, a Division of NHS National Services Scotland

dioxide, needs to be removed using active carbon. May not penetrate into biofilm. Can cause corrosion to copper. Workers must have access to a wash down hose, chemical

eyewash, and shower. Operators must also wear the proper safety equipment, including carrying an Acid Gas escape respirator.

Must not be used in water systems supplying dialysis machines.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Chlorine Dioxide

H&S: Dangerous - When chlorine dioxide concentrations reach 10% or more in air, chlorine dioxide becomes explosive.

Cost: Moderate

Advantages: Chlorine dioxide is more effective than chlorine and chloramines for inactivation of viruses, *Cryptosporidium* and *Giardia*.

Required contact time and concentration is low.

Generally good at controlling bad tastes and odours.

Available as package plant.

More effective at a high pH level.

Will remove biofilm, over a period of time.

Oxidizes iron, manganese, and sulphides.

May enhance the clarification process.

Is easy to generate. Provides residuals.

No formation of bromides from bromates.

At the concentrations required for disinfection, chlorine dioxide is not corrosive.

Must not be used in water systems supplying dialysis machines.

Disadvantages: Unstable, generally must be dosed immediately after manufacture - has to be made on site.

Requires careful, precise mixing and dosing regime, low pH needed.

May cause precipitation of iron and manganese.

Dosing equipment requires regular maintenance.

Can lead to production of noxious odours in some systems, may need to be neutralised before discharge to the environment. Any chemical discharge to a drain needs to be sanctioned by the Water Authority, who may then impose conditions on the discharge.

© Health Facilities Scotland, a Division of NHS National Services Scotland

The chlorine dioxide process forms the specific by-products chlorite and chlorate.

Costs associated with training, sampling, and laboratory testing for chlorite and chlorate are high.

Cost of the sodium chlorite is high.

Chlorine dioxide decomposes in sunlight.

Workers must have access to a wash down hose, chemical eyewash, and shower. Operators must also wear the proper safety equipment, including carrying an Acid Gas escape respirator.

Chlorine dioxide is generally effective for the deactivation of pathogenic microorganisms. It is less effective for the deactivation of rotaviruses and E. coli bacteria.

5 to 10 times more expensive that chlorine.

Can form THMs at lower levels than chlorine, forms more iodinated DBPs in relation to the other disinfection methods when iodide is present in the source water.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Ozone

H&S: Dangerous

Cost: High

Advantages:

Rapid and strong disinfectant and oxidation agent.

Been used for several decades for disinfection, colour elimination, taste and odour control.

Does not form Trihalomethanes (THMs).

Very effective against Giardia, Cryptosporidium and any other pathogenic microflora.

Facilitates removal of turbidity from water.

Can improve the palatability of the water.

Package plants are available.

Disadvantages:

Disinfects only at the point of injection.

Specialised equipment required to generate ozone.

Decomposes quickly.

Hard to hold effective concentration.

Ground level ozone is an air pollutant with harmful effects on lung function.

Bromite mutagenic and carcinogenic by-products may be produced under certain conditions.

Must use biologically active filters to remove by products.

No residual disinfection.

Expensive for initial equipment.

May cause precipitation of iron.

Plant and equipment require regular maintenance.

When reacting with organic compounds, ozone disintegrates them into smaller components, which could become a feeding media for microorganisms growth in water distribution systems.

Requires high voltage equipment.

Training and installation support required.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Silver Catalysed Hydrogen Peroxide

H&S: Dangerous

Cost: Moderate

Advantages: Hydrogen peroxide is catalysed with silver for increased activity.

Rapid and effective disinfectant.

Will remove biofilm.

Works in all temperatures.

Silver has curative properties against disease.

Disinfects drinking water for long periods of time.

Will not corrode pipes.

Easy to install and maintain.

Disadvantages: Residual Silver may need to be neutralised before discharge to the environment. Any chemical discharge to a drain needs to be sanctioned by the Water Authority, who may then impose conditions on the discharge. Expensive chemicals but overall system is cost effective. Not approved for continuous dosing, except in emergencies. See http://www.scotland.gov.uk/Publications/2008/03/04152957/9

Maintenance of plant is simple and straightforward but there is a need to maintain close control over the sensor used to monitor dosage rates.

Requires the inclusion of a filter on the inlet to the sensor and regular inspection of it to ensure a clean sensor electrode.

Biocidal efficacy of silver may be compromised by high concentrations of chloride.

High pH may affect efficacy.

Not equally effective for all pathogens.

Must not be used in water systems supplying dialysis machines.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Silver/copper ionisation

H&S: Can be dangerous to dialysis patients

Cost: Low

Advantages: Works in all temperatures. High doses will remove biofilm. Silver has curative properties against disease. Disinfects drinking water for long periods of time. Will not corrode pipes. Easy to install and maintain.

Disadvantages: Monitoring the silver levels is difficult and expensive. Can stain porcelain. May need to be neutralised before discharge to the environment. Any chemical discharge to a drain needs to be sanctioned by the Water Authority, who may then impose conditions on the discharge.

High pH may affect efficacy.

Biocidal efficacy of silver may be compromised by high concentrations of chloride. Level of silver required for effectiveness is eight times greater than for silver catalysed hydrogen peroxide. Not equally effective for all pathogens. Must not be used in water systems supplying dialysis machines.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Ultra Violet

H&S: UV radiation is not suitable for water with high levels of suspended solids, turbidity, colour, or soluble organic matter. UV light can cause serious damage to the retina if viewed directly through the viewing port.

Cost: High

Advantages: Requires no chemical handling. Effective in clean, low turbidity waters. No special requirements for storage and transportation. No formation of by-products. Not effected by pH or temperature.

Disadvantages: Only works at point of entry. Leaves no residual disinfectant in the water. Can be ineffective in turbid waters. Expensive in equipment and maintenance. Actually, the UV generator is quite inexpensive, relatively speaking. The cost increases, though, when serious filtration is needed to allow the process to work.

Power supply deviations effect wavelength. Requires pre filtration. May require frequent cleaning of tubes and chamber. Water velocity is critical so may require special chamber to provide appropriate dwell time. Poor penetrating power of UV light in established biofilms. Turbidity makes it difficult for radiation to penetrate water. These materials can react with UV radiation, and reduce disinfection performance.

Appendix 1

Case Studies

Heat and Flush

Colville *et al* (1993) stated that following a heat and flush treatment at Nottingham University Hospital, new cases of hospital-acquired Legionnaires' disease were reported. Chen *et al*., (2005) also reported recolonisation in a Taiwanese hospital where heat and flush was used for the treatment of Legionella. It should be noted that when adhering to the recommendations of two authoritative bodies, namely the Centers for Disease Control and Prevention (CDC) and the American Society of Heating, Refrigeration, and Air-Conditioning Engineers (ASHRAE), the heat and flush method was shown to be ineffective in eradicating *Legionella* from this hospital's water system. The paper puts forward that this failure may have been due to the flush time, which is recommended by ASHRAE to be greater than five minutes. The author suggests that a flush time of thirty minutes would have been required to eliminate Legionella in this system. Zhang *et al*. (2009) maintains that the heat and flush method is labour intensive and numerous personnel are required to monitor water temperatures and flushing times and can prove ineffective for long-term Legionella infestation management.

Chlorine Dioxide

Pavey and Roper (1997) have published results indicating that chlorine dioxide concentrations of 0.1 ppm to 0.2 ppm were shown to be effective in decontaminating a cold water system, whilst higher concentrations up to 0.35 ppm were needed for the hot water system.

Other studies have shown that temperature and high levels of total organic carbon in drinking water would cause deterioration of the chlorine dioxide levels in the water, therefore affecting the efficiency to control contaminants (Zhang *et al*., 2008). Maintaining a sufficient residual level of chlorine dioxide in the hot water system is a difficult task as an elevated water temperature accelerates the conversion of chlorine dioxide to chlorite, through reactions with organic compounds in the water distribution system. This finding is consistent with Zhang et *al*'s. (2007) study observation where the mean chlorite concentration in hot water was higher than that in cold water. Additionally, results from Pavey and Roper's (1997) study showed that more chlorine dioxide was used in the soft water than hard water systems to achieve the same concentration.

Zhang *et al*'s. (2007) study also showed that chlorine dioxide did not completely eliminate Legionella organisms from a hospital's hot and cold water system, given a target feed concentration of 0.5-0.7 mg/litre in the cold water.

UV

Abbaszadegan *et al*. (1997) completed an experiment to evaluate the microbial disinfection efficacy of a point-of-use water treatment system comprised of a

© Health Facilities Scotland, a Division of NHS National Services Scotland

pressed activated carbon block filter followed by an ultraviolet (UV) light reactor. This method of filtration was found to effectively remove and/or inactivate more than 99.9999% of the bacterial pathogens, more than 99.99% of the viruses and more than 99.9% of the protozoan cysts and oocysts, tested to 150% of the water treatment capacity of the point of use water treatment system. These findings suggest that a properly designed and operated point of use water treatment may be adopted as an approach to removing microbiological waterborne pathogens from potable water (Abbaszadegan *et al*., 1997). This system would probably not be considered on a large scale as it has a high capital and revenue costs compared to other disinfectant methods as many disinfection points would be required as UV has no residual effect. Also there may be problems in retro fitting a UV system if there is limited space.

Appendix 2

Traditional forms of water treatment for the disinfection of potable water systems in healthcare premises

Biocide comparison chart

Parameters	Heat and flush	Continuous chlorination	Chlorine dioxide	Ultra violet light (U.V.)	Copper – silver ionisation	Silver catalysed hydrogen peroxide	Ozone	Chloramines
Concentration required at outlets during continuous use	Continuously above 55°C	2-4 mg/l as free chlorine (Zhang, 2007)	0.5 mg/l as CL02 (Zhang, 2007)	300 nm (Chen *et al*., 2006)	Cu=0.2-0.4 mg/l	H202=15 mg/l	0.1 to 5.0 mg/l over a contact time ranging from 5 minutes to 15 minutes	WHO maximum allowable concentration is 3.0 mg/l based on the NOAEL level
	70-80°C for 30 min (Zacheus and Martikainen, 1996)				Ag=0.02-0.04 mg/l (Kim *et al*., 2002)	Ag=0.008 mg/l (Pedahzur *et al*., 2000)	(Kim *et al*., 2002)	1.0 mg/l for design purposes (Kim, 2002)
On-site efficacy documented in literature	Yes (Zacheus and Martikainen, 1996)	Yes (Korich et al., 1990)	Yes (Gates, 1998)	Yes (Maraca *et al*., 1987)	Yes (Blanc, 2005)	Yes (Kim *et al*., 2002)	Yes (Kim *et al*., 2002)	Yes (Kim *et al*., 2002)
Residual effect	No	Yes (WHO, 2004)	Yes (Thomas, 2004)	No (Chen et al., 2006)	Yes (Blanc, 2005)	Yes (Kim et al., 2002)	No (Kim et al., 2002)	Yes (Kim et al., 2002)
Time to re-colonisation after treatment stopped	Varies but usually a few months (Zacheus and Martikainen, 1996)	1-2 Weeks (Fiehn & Henriksen, 1988)	Some residual protection until biofilm is re-established (Gates, 1998)	Only works at point of entry (Maraca *et al*., 1987)	6-12 weeks (Liu *et al*., 2004)	Long lasting residual effect in water (Pedahzur *et al*., 2000)	No residual disinfectant (Kim *et al*., 2002)	A few days, far less effective than chlorine (Kim et al., 2002)
Temperature	N/A	Residuals decrease as temperature increases (Kim *et al*., 2002)	Residuals decrease as temperature increases. Bacterial kill rate increases with increase in water temperature (Kim *et al*., 2002)	Temperature effects are minimal (Mally, 2000)	Residuals unaffected by high temperature (Lin *et al*., 1996)	No reported degradation at up to 90 degrees, centigrade. Poor disinfectant below 10 degrees (Pedahzur *et al*., 2000)	Unaffected by temperature (Kim *et al*., 2002)	Unaffected by temperature (Hua, 2007)
PH	No effect (Neurener, 2002)	PH>8 Disinfection power is reduced (Neurener, 2002)	Effective over normal range of PH values for drinking water below pH of 10 (Kim *et al*., 2002)	No effect (Mally, 1995)	Elevated pH (>8) may effect efficacy (Blanc, 2005)	Biocidal action generally increased with increased pH (Pedahzur *et al*., 2000)	No effect (Kim *et al*., 2002)	Quantities of ammonia and chlorine depend on the acidity of the water (USEPA, 2007)
Disinfection by-product	None (Neurener, 2002)	Trihalomethane (THMs) (Hua, 2007)	Can form (THMs) lower levels than chlorine. Forms more iodinated DBPs when iodide is present in the source water (Hua, 2007)	Ozone (Jeong, 2005)	None known but residual levels of Cu and Ag (Neurener, 2002)	Residual levels of Ag. Primary compound breaks down into water and oxygen (Pedahzur *et al*., 2000)	Bromite mutagenic and carcinogenic by-products may be produced under certain conditions (Charmichel *et al*., 1982)	Can form (THMs) lower levels than chlorine. Forms more iodinated DBPs when iodide is present in the source water (Hua, 2007)

Preface

About Scottish Health Technical Memoranda

Scottish Engineering Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of SHTM guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle. Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Scottish Engineering Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

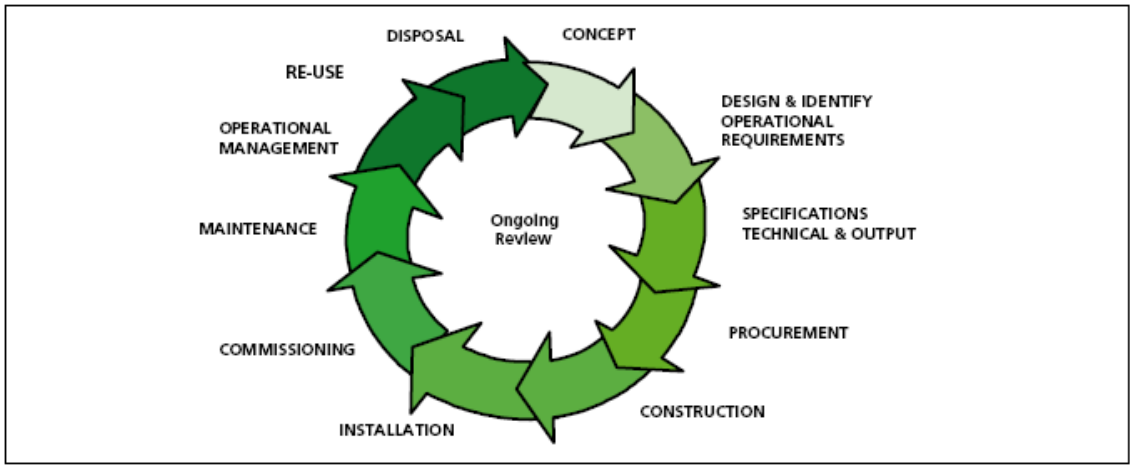
It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.

© Health Facilities Scotland, a Division of NHS National Services Scotland



Healthcare building life-cycle

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of eight core subjects pending a re-assessment of Firecode SHTMs 81-86.

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Scottish Health Technical Memoranda in this series)

Scottish Health Technical Memorandum 01: Decontamination

Scottish Health Technical Memorandum 02: Medical gases

Scottish Health Technical Memorandum 03: Heating and ventilation systems

Scottish Health Technical Memorandum 04: Water systems

Scottish Health Technical Memorandum 05: Reserved for future use

Scottish Health Technical Memorandum 06: Electrical services

Scottish Health Technical Memorandum 07: Environment and sustainability

Scottish Health Technical Memorandum 08: Specialist services

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent Electrical Services - Electrical safety guidance for low voltage systems.

In a similar way Scottish Health Technical Memorandum 07-02 will simply represent Environment and Sustainability – EnCO_2de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management

© Health Facilities Scotland, a Division of NHS National Services Scotland

and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

Health Facilities Scotland wishes to acknowledge the contribution made by professional bodies, engineering consultants, healthcare specialists and NHS staff who have contributed to the review.

Executive summary

Background information

Chloramine is increasingly replacing chlorine as the secondary disinfectant in water treatment systems primarily because it produces fewer dangerous disinfection by-products. Chloraminated water is already being introduced within some regions of Scotland and it is envisaged that most NHS Boards in Scotland will soon confront a change in their water supply disinfection regime.

This guidance provides information on the likely impact of the change backed up by relevant case studies.

© Health Facilities Scotland, a Division of NHS National Services Scotland

1. Methodology

Aim of this SHTM

1.1 The aim of this SHTM is to assess the impact chloramination may have on patient safety and infrastructure within healthcare facilities provided by NHSScotland.

Factors examined

1.2 Following an outline of the relevant background detail, numerous factors have been examined including:

- those which will directly affect patients;
- those which may impinge upon the general populace;
- those which could concern estates staff.

Case studies undertaken

1.3 A series of case studies has been used to examine which lessons can be learned from water utilities which converted to chloramine disinfectant. The information contained within this SHTM was sourced from published technical papers and reports authorised by regulatory bodies in addition to material available online. The SHTM concludes with a series of observations and recommendations which have arisen from an appraisal of the relevant data and review of the literature.

Review questions

1.4 This SHTM seeks to verify if the introduction of chloramine into the common water supply enables a different maintenance regime to be developed in healthcare facilities without impacting on patient safety. Answers have been sourced to the following questions:

- what is chloramine?
- what is chloramination as it relates to water disinfection?
- what are the benefits and risks of using chloramine for water disinfection within a healthcare environment when compared with chlorine?
- are there any negative impacts that could occur when converting from chlorine to chloramine water disinfection and, if so, how can these be minimised?
- what has been the experience of other healthcare organisations which have changed to chloramine for their water disinfection needs? What can be learned from these past experiences?

Abbreviations

1.5 The following abbreviations have been used throughout this SHTM:

AWWARF	American Water Works Association Research Foundation
DBP	disinfectant by-product
HAA	haloacetic acids
HPC	heterotrophic
MWUA	Maine Water Utilities Association
NDMA	N-nitrosodimethylamine
NWSAG	National Water Services Advisory Group
PEFEx	Property & Advisory Forum Executive (Predecessor of Health Facilities Scotland)
SEDWQU	Scottish Executive Drinking Water Quality Unit
SFPUC	San Francisco Public Utilities Commission
THM	trihalomethane
USEPA	United States Environmental Protection Agency
UWRAA	Urban Water Research Association of Australia

2. Introduction

General

2.1 Reference is made in this SHTM to lead and copper pipework. It is believed that all lead pipework has been removed from NHS premises in Scotland and copper pipework is no longer routinely specified. Lead service pipes were phased out in the 1960s and proscribed in 1969, with lead-soldered joints being prohibited in 1987. Many existing installations still use copper pipework whereas some fittings may use alloys containing lead, therefore issues raised in case studies are still relevant.

2.2 Chloramination, whilst reducing the levels of *Legionella* in the water, may give rise to increased levels of other contaminants. Therefore, NHS Boards that are supplied with chloraminated water should be aware of the potential for incoming water to have increased levels of other contaminants; the types of contaminants likely to arise from this process are discussed within this document.

2.3 However, it should be noted that when water is supplied to Dialysis Units, Hydrotherapy Units and Manufacturing Pharmacies additional action should be taken at point of use. Further details on how to manage these areas are described in Parts A & B of this SHTM.

Secondary disinfection

2.4 The final step in water purification schemes within most developed countries involves the addition of disinfectant intended to persist within the distribution system. Known as 'secondary disinfection', this practice is intended to maintain water quality by inactivating pathogens or bacteria that may have entered the distribution network and is usually distinguished from a 'primary disinfection' stage which targets source water.

2.5 For many years chlorine was the most widely used secondary disinfectant, although other substances were viewed as suitable (and in some cases preferable) alternatives. In one such instance, water authorities in Australia concerned with controlling the prevalence of the pathogenic amoeba *Naegleria fowleri* realised that chloramine was much more effective as a counter-measure (Urban Water Research Association of Australia [UWRAA], 1990).

2.6 However, the discovery that natural organic matter in water could react with chlorine to produce hazardous compounds known as disinfection by-products (DBPs), prominent among which were trihalomethanes (THMs) and haloacetic acids (HAAs), constituted the principal motivation for the use of chloramine.

2.7 During the 1970s and 1980s concern grew in the United States that exposure to THMs at high concentrations might increase the risk of some cancers. As a result, the United States Environmental Protection Agency (USEPA) began regulating THMs and developed the Stage 1 Disinfectants and Disinfection By-Products Rule, lowering the permissible total THM concentration to 80 µg/litre in

© Health Facilities Scotland, a Division of NHS National Services Scotland

December 2001, with HAAs limited to 60 µg/litre (San Francisco Public Utilities Commission [SFPUC], 2004; Edwards *et al*., 2005).

2.8 It was known that using chloramine as an alternative to chlorine reduced the formation of these potentially carcinogenic THMs, ostensibly making the water safer for human consumption. Although chloramine had been used for disinfection in a small number of facilities within the US since the early 1900s, its popularity in recent years has soared, principally because it is a low-cost means of complying with the USEPA regulations (Edwards *et al*., 2005); 30% of water utilities in the US already used chloramine as a secondary disinfectant by 2004 (Flannery *et al*., 2006).

2.9 Notwithstanding Spain and Sweden's long established use of chloramine, European nations were generally slower to respond to the DBP issue (Lenntech, 2009). However, the number of water treatment plants in the EU using chloramine is expected to increase as utility companies seek to comply with more stringent regulatory requirements.

2.10 Scotland is bound to the EU Drinking Water Directive (98/83/EC) which limits total THM concentrations to100 µg/litre but does not specifically mention other DBPs. As part of its long term investment programme to improve water quality for customers, Scottish Water is gradually increasing the number of areas within Scotland that are supplied with chloraminated water (Scottish Water, 2010).

2.11 While chloramination appears to have several advantages in comparison with chlorination (these terms will be used henceforth to denote the relevant secondary disinfectant), its associated risks are still being determined. For example, a claim by Dr Michael J. Plewa of the University of Illinois that only 17% of DBPs associated with chloramination have been identified (see Barlow (2004)) has been given much publicity by campaign groups (such as 'Concerned Citizens about Chloramines') anxious about the purity of water supplies and companies which sell domestic purification equipment (exemplified by Aquavantage (see www.buyaquavantage.com/av-learnmore-epa.htm)).

Chloramination – possible risks?

2.12 Recent studies have found possible links between chloramination and blood lead levels (Miranda *et al*., 2007), nitrification, increased bacterial growth and the degradation or corrosion of pipe fittings (see, for example, Kirmeyer et al. (1993)). In addition, chloramine is known to be toxic in the bloodstream, thus posing significant risks for dialysis patients (Arrowsmith, 2002). Despite the well-known susceptibility of babies to nitrified water supplies (see, for example, Florida Department of Health, 2010), little detailed research work has focused on the impact chloramine might have on the healthcare environment and patient safety. In particular, there are no directly related literature surveys.

2.13 There exists a considerable body of literature that addresses chloramination from various other perspectives. A particularly comprehensive review of the topic was carried out by Kirmeyer et al. (1993) on behalf of the American Water Works Association Research Foundation (AWWARF) and this report draws heavily on the case studies contained therein. The AWWARF study was in fact

© Health Facilities Scotland, a Division of NHS National Services Scotland

supplemented more recently with the results of further research and practical experience of chloramination (Kirmeyer et al., 2004). Research focusing on some of the potential risks of chloramine is reasonably extensive (see, for example, Edwards *et al*. (2005), Miranda *et al*. (2007) and Weintraub et al. (2006)). While information on chloramine within a healthcare setting is sparse, Arrowsmith (2002) and Walker (2004) provide some foundation and several studies have associated chloramination with a *decreased* risk of Legionnaires' disease (Heffelfinger *et al*., 2003; Flannery et al., 2006; Kool *et al*., 1999). Additionally, there is anecdotal evidence that some NHSScotland Boards have had no reports of *Legionella* since their incoming water supplies were altered to being treated with chloramine.

Chloramination – advantages and disadvantages

2.14 This SHTM examines chloramination and discusses the various advantages and disadvantages of using chloramine as a disinfectant. It has also attempted to garner information from organisations that have converted from chlorine to chloramine and to determine the lessons that were learned in the process. Ultimately, it seeks to establish which problems Scotland's NHS Boards may encounter when faced with a changeover to a chloraminated water supply.

2.15 Following a detailed description of the chemical reactions and water treatment processes entailed, this SHTM discusses the advantages and disadvantages of chloramination. Attention subsequently focuses upon the main findings in respect of the impact chloramination may have, particularly with reference to patients and staff within NHSScotland healthcare facilities. The various issues involved are separated into

- those which have a direct impact on the NHS (dialysis, nitrification and the inactivation of pathogens);
- those which affect the populace, some of which may have a long-term impact upon the NHS (chloramine ingestion, cancer, disinfection by-products and aquatic life);
- those which will be primarily of concern to NHS estates staff (lead-leaching, metal corrosion and the degradation of rubber).

2.16 This SHTM proceeds to examine the experience of numerous water utilities following a conversion to chloraminated water. Finally, in light of the knowledge acquired in the literature survey, it concludes with a summary of the main observations and a list of recommended actions NHS Boards should consider.

© Health Facilities Scotland, a Division of NHS National Services Scotland

3. Preparation of this SHTM

Sources of information

3.1 The initial review was carried out primarily as a literature survey with as systematic an approach as possible adopted given time and resource constraints. Information was obtained both from online sources and books, journals and guides. The researchers aimed to gather a wide range of information from many different sources, mostly from outside the UK. However, the case studies were as representative as possible.

3.2 In order to determine the key organisations in this field and the main sources of information, searches were carried out via general search engines such as Google. Search terms used included:

> Chloramine, chloramination, monochloramine, … + potable water, … + drinking water, + risks, … + benefits, … + healthcare, … + hospitals, … + pathogens, … + DBPs, … + toxicity, … + corrosion, … + materials degradation, … + lead-leaching, … + dezincification + bacteria.

3.3 Journal papers and articles were obtained from NHS libraries and databases, either online or in hard copy. Databases searched included Science Direct, MEDLINE and Cochrane. Several books on the topic were also sought from the NHS Library.

3.4 Source material which was deemed acceptable fulfils one or more of the following criteria: peer-reviewed scientific papers and articles, reliable information from reputable organisations, work carried out by or on behalf of governments and comprehensive case studies. Information from unknown organisations or agenda-driven websites was excluded as were case studies with insufficient details.

3.5 In published form as this SHTM it is expected to be used by NHSScotland managers, facilities management providers, designers and decision-makers to assist them in determining how chloramination could affect healthcare procedures and patient safety and enable them to take the steps necessary to minimise any negative impacts.

Note: This would include those responsible for home dialysis equipment.

Risk of bias

3.6 The information used in this SHTM came from a variety of sources, although there was a clear bias towards those from the United States. This has been largely unavoidable because the US has led the world in chloramination and possesses most expertise and experience. Nevertheless, there is not necessarily a bias within the US *per se*, since a wide spectrum of perspectives is reflected in the literature.

© Health Facilities Scotland, a Division of NHS National Services Scotland

3.7 As chloramination becomes more widespread, particularly within United Kingdom, Europe and Australia, more case studies and information will become available. However, it will take time for lessons to be learned and shared. It is therefore anticipated that future updates of this SHTM will have a wider international slant.

4. Chemistry of chloramination

Basic Chemistry

4.1 This section follows UWRAA (1990) in describing the chemical reactions involved in the formation of chloramine.

- when gaseous chlorine is added to water it is said to hydrolyse or disproportionate as shown below:

$$Cl_2 + H_2O \rightarrow HOCl + H+ + Cl- \quad (1)$$

- a dissociation of the relatively weak hypochlorous acid HOCl into hypochlorite and hydrogen ions follows:

$$HOCl \rightarrow ClO- + H+ \quad (2)$$

- the hypochlorite ion ClO- very rapidly establishes equilibrium with hypochlorous acid. The reaction between HOCl and ammonia NH_3 forms monochloramine NH_2Cl:

$$HOCl + NH_3 \rightarrow NH_2Cl + H_2O \quad (3)$$

- the reaction between monochloramine and hypochlorous acid forms dichloramine NHCl2:

$$HOCl + NH_2Cl \rightarrow NHCl_2 + H_2O \quad (4)$$

- while the reaction between dichloramine and hydrochlorous acid forms trichloramine NCl_3:

$$HOCl + NHCl_2 \rightarrow \quad NCl_3 + H_2O \quad (5)$$

Definitions

4.2 Monochloramine, dichloramine and trichloramine are sometimes collectively known as combined chlorine (or combined available chlorine). However, depending on whether the context involves water treatment or chemistry, the term 'chloramine' is used to denote both the compound monochloramine alone as well as the mixture of compounds, monochloramine, dichloramine and trichloramine. Monochloramine predominates at ratios of chlorine to ammonia-nitrogen of 3:1 to 5:1, while the formation of dichloramine and trichloramine are favoured by higher ratios (Hankin, 2001).

4.3 Collectively, Cl_2 (the chlorine molecule), HOCl (hydrochlorous acid) and the hypochlorite ion (ClO-) are known as free chlorine or freely available chlorine.

Chloramination – a Brief Summary

4.4 Chloramination is a water management practice that uses chloramine to treat and deliver public water supplies in compliance with water supply regulations

© Health Facilities Scotland, a Division of NHS National Services Scotland

(Flannery et al., 2006), while apparently producing fewer potentially dangerous DBPs than chlorine (SFPUC, 2004).

4.5 Municipal drinking water disinfection generally occurs in two phases, the first being an initial disinfection to kill organisms in the water, while a residual disinfection agent maintains biocidal activity throughout the water distribution system (Kool *et al*.,1999). Chloramination is known to provide a lasting residual disinfectant in the water system (Flannery *et al*., 2006) and, consequently, a typical chloramine water treatment plant uses chlorine for the initial disinfection and monochloramine for the residual disinfection (Kool *et al*., 1999).

4.6 The process of chloramination usually introduces chloramine at a concentration of 1.5 to 2.5 mg/litre, although it can be as low as 0.2 mg/litre and as high as 3.0 mg/litre based on World Health Organisation (WHO) recommendations (Hankin, 2001). It is known that because chloramine is a weaker agent a higher disinfectant residual will be needed to produce the same results as chlorine (MWUA, 2010). Therefore, a residual of 2.0 mg/litre of chloramine is relatively equivalent to a residual of 0.5 mg/litre of free chlorine.

4.7 Monochloramine is the most active chloramine compound and forms preferentially at the ratios of chlorine to ammonia-nitrogen defined above and at a pH value in the range 7.5 – 9.0 (Kim et al., 2002). At ratios of chlorine to ammonia-nitrogen between 5:1 and 7:1 and a pH ranging from 4 to 7 dichloramine tends to form, while the corresponding values favouring trichloramine are 7:1 and above and pH levels lower than 3.0.

4.8 Both trichloramine and dichloramine can cause taste and odour problems (Lenntech, 2009; Kool et al., 1999). It should be noted that the chloramine compounds can be broken down into free chlorine relatively easily and have a half-life ranging from one minute to 23 days (Lenntech, 2009). One major reaction leading to chloramine loss is initiated by the disproportionate of monochloramine, namely (see UWRAA (1990)):

$$NH_2Cl + NH_2Cl \rightarrow NHCl_2 + NH_3 \qquad (6)$$

The subsequent decomposition of dichloramine results in the loss of chloramine:

$$NHCl_2 + NH_2Cl \rightarrow N_2 + 3Cl^- + 3H^+ \qquad (7)$$

4.9 Although it will ultimately decay, chloramine is more stable than free chlorine and persists for longer periods, thereby enabling the disinfectant to reach more remote areas of a distribution system (SFPUC, 2004) and facilitating a potential reduction in costs (Kool et al., 1999). However, it is also a less effective (Kim et al., 2002), less reactive (American Society of Microbiology, 2007) and slower disinfectant (Kool et al., 1999) than chlorine and is weak at inactivating certain viruses (Hankin, 2001). Its slow reaction means that if there is contamination after water leaves a treatment plant, monochloramine may not be as effective as chlorine, since there is little control over its contact time with the contaminant (American Society of Microbiology, 2007). On the other hand, chloramines provide antibacterial activity with lower total chlorine (namely, the chlorine

© Health Facilities Scotland, a Division of NHS National Services Scotland

content of free chlorine and combined chlorine) levels (Arrowsmith, 2002) and seem to penetrate biofilm more thoroughly than free chlorine, enabling them to kill sessile biofilm bacteria (Kool *et al*., 1999). According to Walker (2010), a distinct benefit of chloramines in comparison with chlorine is that they have no significant odour or taste provided the levels of dichloramine and trichloramine are insignificant, which water utilities usually can ensure by the appropriate manipulation of variables such as pH and chlorine: ammonia-nitrogen ratios.

4.10 It is believed that monochloramine produces fewer dangerous DBPs (such as THMs and HAAs) since the contact time of the initial chlorine is shorter (Hankin, 2001) and this is the main factor driving the changeover in the US and elsewhere.

4.11 The USEPA states that THM reductions of 40-80% are usually experienced when a utility company switches from free chlorine to chloramines (Water Research Foundation, 1999). The THM by-products are chemical compounds that form when chlorine mixes with naturally occurring organics in source water. Many THMs are carcinogenic in laboratory animals and therefore expected to be so in humans (Kool et al., 1999). It is also suspected that they are associated with reproductive problems (Guay, Rodriguez & Serodes, 2004), although more research is needed to confirm this possible finding.

4.12 The EU currently has set a standard of 100 parts per billion as the safe level of THMs in drinking water although Scottish Water aims to reduce THM levels significantly lower. Since monochloramine produces fewer DBPs and is in contact with the water for a longer period, thereby shortening the time that free chlorine is in the system, it is believed that a chloramination regime poses less of a cancer risk than disinfection by free chlorine (Kool *et al*.,1999).

5. Issues Arising from Chloramination

Factors Directly Affecting NHSScotland Healthcare Staff:

Dialysis (including home dialysis)

5.1 Chloramines are known to be particularly harmful when they directly enter the bloodstream and because they persist in a water system longer than chlorine they pose a particular danger during dialysis. However, dialysis patients can use chloraminated water for drinking, cooking and bathing (Hankin, 2001).

5.2 The Renal Association currently sets limits of 0.1 mg/litre for chloramine (and 0.5 mg/litre for total chlorine) in dialysis water because excess amounts can cause haemolysis in patients (Arrowsmith, 2002).

5.3 Many dialysis patients also suffer from anaemia or methaemoglobinaemia, since they lack the natural hormone erythropoietin (EPO) which stimulates bone marrow to produce red blood cells. In these patients EPO is not produced in sufficient quantities and although synthetic EPO can be provided it is accompanied by unpleasant side effects. When chlorine or chloramine exist in dialysis water the need for EPO increases and transfusions may be necessary in severe cases (Hankin, 2001). Consequently, it is important to ensure that all chlorine and chloramines are eliminated from water used for dialysis treatment in order to minimise required EPO dosages (Arrowsmith, 2002). Furthermore, during the dialysis process the water comes into contact with the blood through a permeable membrane. This membrane does not remove the chloramines but can be damaged by them and therefore the chloramines need to be removed before the water passes through any reverse osmosis membrane system (Hankin, 2001).

5.4 Chloramine removal can be achieved through several processes. One possibility is deionisation, although this practice is inconsistent. Another is chemical reduction by the use of ascorbic acid (Vitamin C); a concern in this case is the acid's toxicity for dialysis patients.

5.5 The most common solution is to use filters containing granular activated carbon (GAC) which is made mostly from bituminous coal. The resulting charcoal is pulverised and activated by exposure to superheated steam which increases its surface area for absorption and provides filtration down to 2 µm (Arrowsmith, 2002). In order that the life of the carbon filters is optimised, monitoring of the water is essential and sampling must be carried out using the DPD test or a simple drop test for total oxidant. Small photometers are also available as an alternative (Arrowsmith, 2002).

5.6 Currently, all NHS equipment used for renal care treatments is required to be modified with GAC filtration in compliance with SAN (SC) 03/10. The size of carbon filter required in chloraminated systems, however, is approximately 10 times that required for chlorine systems, implying an increase in cost. Although an economic solution might save on testing and monitoring costs by having a

© Health Facilities Scotland, a Division of NHS National Services Scotland

central facility serving the renal dialysis unit, this would conflict with NHS policy which encourages patients to dialyse at home (Scottish Executive Drinking Water Quality Unit [SEDWQU], 2002).

5.7 The main issue with respect to home dialysis equipment is 'chloramine-proofing' the units since a substantial number of carbon filters would be required and protocols introduced to ensure that patients test and monitor their own water. While it was proposed by NHSScotland that Scottish Water contributes to the cost of chloramine-proofing the units, there is currently no provision in the Scottish Water investment plan for this funding (SEDWQU, 2002). In order that the home dialysis units are monitored adequately, one solution would be a programme that includes routine visits to change carbon filters.

5.8 Arrowsmith (2002) suggests that dialysis filtration can be continued based on the assumption that the carbon filters can remove 1.0 mg/litre total chlorine (free chlorine or monochloramine). Levels of total chlorine in the water supply remain relatively constant aside from a small reduction in winter or during public water mains work where disinfection is carried out afterwards. It is essential therefore that the water authority is notified of dialysis patients in its area so that they can be included on the 'sensitive client' list and notified when chlorine or chloramine levels will be high. It is noted that this process is the NHS Boards' responsibility (Arrowsmith, 2002).

Nitrification

5.9 Another potential problem with the use of monochloramine is nitrification, which is caused by a reaction between ammonia-oxidising bacteria and excess ammonia from an incorrect dosing (MWUA, 2010) or from the decay of chloramine due to water ageing and temperature increases. The nitrifying bacteria can be found on the inside of water pipes, protected by biofilms, and nitrification can occur if there are low disinfectant residuals to combat it. Currently two-thirds of medium and large water distribution systems in the US that use chloramines experience nitrification to some degree (MWUA, 2010).

5.10 During the nitrification process, the bacteria oxidise the ammonia and produce nitrite, which is subsequently converted to nitrate and organic carbon in the form of biomass and soluble microbial products. The health concerns of excess nitrate in water relate to the capacity of blood to carry oxygen; short-term exposure to excessive levels of nitrate or nitrite can lead to potential problems, the most serious of which in a healthcare context is 'blue baby disease'.

5.11 Consequently, drinking water standards for nitrite and nitrate have been set within the United States at 1 mg/litre and 10 mg/litre, respectively (MWUA, 2010). In comparison, the permitted concentration values in Scotland are 0.5 mg/litre (nitrite) and 50 mg/litre (nitrate) in accordance with the EU Drinking Water Directive 98/83/EC.

5.12 There appear to be no studies that address the use of chloraminated water within maternity wards and as a result no definitive relevant conclusions or recommendations can be made within this survey. Nonetheless, it might be reasonable to suggest that caution should be the watch-word. The presence of

© Health Facilities Scotland, a Division of NHS National Services Scotland

nitrification in water is relatively straightforward to ascertain and several manufacturers sell test strips at low cost which can detect the relative level of both nitrates and nitrites.

5.13 With regard to chloramine, it must also be considered that the levels of organic carbon created by nitrifiers may be sufficient to support the growth of heterotrophic (HPC) bacteria. In one study (MWUA, 2010), the levels of HPC bacteria were 1,000 times more than they would have been had chlorine been used as the disinfectant. A significant advantage of chlorine is that it does not release nutrients for bacterial growth.

5.14 During nitrification, chloramine residuals are consumed faster than those of nitrate due to an increase in demand and a system with no chloramine residuals is vulnerable to future bacterial contamination. The numbers of nitrifying bacteria increase markedly during periods of accelerated chloramine decay, although the causality of this relationship is not fully clear (UWRAA, 1990).

5.15 Nitrification is also usually accompanied by a reduction in pH and dissolved oxygen; under certain conditions nitrifying bacteria can potentially accelerate lead and copper corrosion due to the release of nitric acid (Kirmeyer et al., 1993). It should be noted that Scottish Health Technical Memorandum (SHTM) 04-01 Part E 'Alternative materials and filtration' states copper is no longer routinely specified for use in NHSScotland premises (HFS 2011). This repeats the statement in the superseded Scottish Hospital Technical Note (SHTN) 2 (PEFEx, 1999). However, these publications have not gone as far as to state that existing copper within systems had to be removed. As a result some older healthcare premises still contain large amounts of copper pipework.

5.16 The Water Research Foundation (1999) states that nitrification and its methods of control depend on water quality factors:

- pH;
- temperature;
- chloramine residual;
- ammonia concentration;
- chlorine-to-ammonia ratio;
- concentrations of organic compounds and distribution factors;
- detention time;
- reservoir design and operation;
- sediment;
- tuberculation in piping;
- biofilm;
- the absence of sunlight.

© Health Facilities Scotland, a Division of NHS National Services Scotland

5.17 There is no consensus within the literature concerning the relative significance of nitrification in relation to chloramination. According to MWUA (2010), nitrification alone may negate the benefits of using chloramine, although full consideration of its suitability should include the source water type and quality and the overall treatment process required to produce potable water.

5.18 The UWRAA (1990) report into chloramination asserts that nitrification is the major problem facing operators of chloraminated systems. On the other hand, SFPUC (2004) states:

'nitrification is more of a nuisance and operational a health issue since nitrification is due to metabolism and growth of harmless non-pathogenic nitrifying bacteria that are ubiquitous in soils and water'.

5.19 To minimise nitrification, treatment plants must ensure that sufficient disinfection residual is maintained at all times and particularly during the winter months. Additionally, free ammonia entering the system should be limited and the distribution network flushed periodically to prevent water ageing in areas of low circulation. In the US, several utilities have rid their systems of nitrifying bacteria by temporarily converting to chlorine (Kirmeyer *et al*., 2004). Lastly, booster stations should be established and supplemental treatment applied at storage and pumping stations to increase monocholoramine concentrations (MWUA, 2010).

© Health Facilities Scotland, a Division of NHS National Services Scotland

Note:

Piping Materials

Feedback obtained during the preparation of this SHTM raised the topic of the effect different piping materials might have on biofilm formation and thereby nitrification. There is thus a link other than corrosion between the issues of chloramination and piping material, albeit indirectly.

Kerr *et al*.(1999) carried out a lengthy experiment which examined the relative resistance of cast iron, Thermanox (a trademark name for a polymer widely used in laboratory equipment), medium-density polyethylene (MDPE) and unplasticised polyvinyl chloride (PVC-U) to biofilm accumulation. Potable water was pumped at a rate of 3 ml/minute past specimens of the various materials and measurements taken of the numbers of viable heterotrophs (organisms that cannot fix carbon and use organic carbon for growth). Bacteria built up exponentially during an initial phase of 2-3 weeks and then tended to level off, with the exception of cast iron which showed a slower, but steady, increase. A year or so later, it was apparent that the plastics resisted biofilm formation to a much greater extent than cast iron, with both MDPE and PVC-U superior to Thermanox in this regard. Park et al. (2007) performed a similar experiment and discovered little difference between stainless steel, galvanised steel and PVC in resisting biofilm formation.

Yu *et al*. (2010) analysed the capability of 6 different piping materials (copper, chlorinated PVC, (PVC-C), polybutylene (PB), polyethylene (PE), stainless steel and zinc-coated steel) in resisting biofilm formation in drinking water, a mix between drinking water and river water and drinking water inoculated with *E. coli.* This experiment differed from those above in not simulating water flow. The material which exhibited the most resistance to bacteria formation was copper with the steels faring worst while the plastics were fairly indistinguishable. Silhan et al. (2006) was concerned with the formation of biofilm in galvanised steel, PEX (cross-linked polyethylene), MDPE and copper. These researchers were also looking at the survival of *E. coli* in both biofilm and water within each of these piping materials. Once again, steel fared less well with copper being most resistant to biofilm formation. *E. coli* was not detected within biofilm on any material. It was noted that biofilm formation was very significantly increased at very warm temperatures (35ºC) in the plastics but relatively unaffected in the metals.

There are some discrepancies between results within the literature and the papers referred to above only report a series of experiments. The general picture appears to be that plastic piping is increasingly favoured by water utilities which view the rough surfaces of old cast iron pipes as encouraging biofilm growth (Water Quality and Health Council).

5.20 Recent research has investigated the role nitrification may have in the corrosion of plumbing systems (Zhang *et al*., 2008). The research group concerned has also been examining whether pipe corrosion may induce or exacerbate nitrification. This work was motivated by fears of copper and lead dissolution

© Health Facilities Scotland, a Division of NHS National Services Scotland

caused by nitrification, the risk of which is considered likely to increase with a chloraminated water supply. It is important to note that the experiment was laboratory-based and no recommendations were made with respect to piping materials.

Inactivation of Pathogens

5.21 Chloramine is a less effective biocide than agents such as hypochlorous acid, hypochlorite, ozone or chlorine dioxide. This was verified in Kirmeyer *at al*. (1993) which tabulated research by Olivieri *et al*. (1985) recording CT values (dosage concentration x time taken to inactivate various percentages of pathogens present) for a variety of biocides in relation to *E. coli* and Poliovirus1. The same source also records data obtained by the USEPA that established the CT values of chloramine and other agents for various inactivation levels of *Giardia lamblia* and what were known generically as 'viruses'; again, the values associated with chloramine are very much larger than those of other agents, including chlorine. It is also known that chloramine is ineffective in removing *Cryptosporidium parvum*, although this applies to chlorine too.

5.22 Nonetheless, it is important to note that chloramine is intended to be a secondary disinfectant and its comparatively large related CT values should not preclude it from this role. The Australian experience of a changeover from chlorine to chloramine (UWRAA, 1990) was positive in terms of microbiological quality. One paramount concern was to control the growth of *Naegleria fowleri*, the causative agent of an invariably fatal disease which attacks the central nervous system.

5.23 In this regard, chloramination was found to be highly successful, with only 1 sample out of a total of 580 containing this amoeba after chloramination – the corresponding figure before the changeover was 40 positive samples from a total of 701. The Australian authorities also carried out surveys at various locations to ascertain the impact on the traditional indicators of microbiological quality: total coliforms, *E. coli* and plate count organisms; HPC iron bacteria, *Aeromonas* spp. and fungi were also examined.

5.24 UWRAA (1990) reports that by each of the aforementioned criteria, chloramination of a previously chlorinated supply improved microbiological quality. For example, in two river systems the frequency of isolation of total coliforms was reduced from values of 45.9% and 32.3% to 1.7% and 4.8% respectively. Kirmeyer *et al*. (1993) confirms that chloramine has been very successful in practice in terms of reducing coliform organisms. Moreover, as mentioned previously, chloramine also seems to be more effective than chlorine for controlling biofilm in pipes (LeChevallier et al. as cited in Kirmeyer et al. (1993)). While chloramine's mechanism of action make it a weak primary disinfectant, Kirmeyer *et al*. (1993) describes research suggesting that the very same properties may account for its ability to penetrate biofilm. A detailed discussion of the processes involved is beyond the scope of this SHTM.

5.25 One key advantage of chloramination in a healthcare context may be a reduced risk of the outbreak of Legionnaires' disease, a community-acquired and nosocomial type of pneumonia caused by the inhalation of aerosols or the

© Health Facilities Scotland, a Division of NHS National Services Scotland

microaspiration of water containing *Legionella* bacteria (see, for example, Flannery *et al*. (2006) and Heffelfinger *et al*. (2003)). Each year in the US there are 8,000 to 18,000 cases of Legionnaires' disease, of which 10-20% occur from outbreaks (Kool *et al*., 1999).

5.26 Prevention of this disease currently focuses mainly on preventing or limiting the colonisation of *Legionella* bacteria in water pipe systems by increasing temperature in hot water pipes and employing 'heat and flush' to cold water pipes or supplementing with extra chlorine. However, both of these treatments are generally unsuitable, due to practical constraints in the former instances while extra chlorine may quicken the development of corrosion and leaks in plumbing systems (Heffelfinger *et al*., 2003).

5.27 In one study (Flannery *et al*., 2006), a two-year trial during which water and biofilm were collected from 53 buildings during six intervals, it was found that *Legionella* colonized 60% of the hot water systems before chloramine was introduced, at which point colonization decreased to only 4%. These authors therefore concluded that "increasing use of monochloramine in water supplies throughout the United States may reduce *Legionella* transmission and incidence of Legionnaires' disease".

5.28 Another study (Heffelfinger *et al*., 2003) was conducted through a survey of 459 members of the Society for Healthcare Epidemiology of America that addressed hospital features, endemic- and outbreak-related, hospital-acquired Legionnaires' disease, water supply sources and methods of disinfection used by the hospitals and water treatment plants. Results from the 166 hospitals that responded found that hospitals supplied with drinking water disinfected with chloramine were less likely to have sporadic cases or outbreaks of hospital-acquired Legionnaires' disease.

5.29 Kool *et al*. (1999) also discovered that hospitals supplied with drinking water containing free chlorine were more likely to have a reported outbreak of Legionnaires' disease than those which used chloraminated water. In Kool's study, 32 hospitals that had experienced outbreaks of Legionnaires' disease were compared with 48 control hospitals selected for their hospital characteristics and water treatment factors. It was suggested that 90% of the outbreaks associated with drinking water may not have occurred had chloramine been used for disinfection rather than free chlorine, although these authors recommended that further studies be conducted to confirm this finding.

5.30 In addition to research in the form of case studies, an in vitro experiment that measured the effect of disinfectants on *Legionella* growth showed monochloramine to be more effective at killing the bacteria in biofilm than chlorine (Donlan *et al*. as cited in Heffelfinger *et al*., 2003).

5.31 Finally, another study of a hospital's water system indicated that monochloramine generated on site and used as a supplemental disinfectant could lead to the rapid and sustained reduction of *Legionella* growth (Shelton et al., as cited in Heffelfinger et al. 2003). The relative ability of monochloramine to inactivate *Legionella* bacteria is thought to arise from its property of penetrating biofilm more aggressively than free chlorine. Nevertheless,

© Health Facilities Scotland, a Division of NHS National Services Scotland

although these studies suggest that monochloramine reduces the risk of Legionnaires' disease, it cannot be concluded that monochloramine will kill *Legionella* bacteria in all instances.

Factors Indirectly Affecting NHSScotland:

Chloramine Ingestion

5.32 Surprisingly little data exist on the health effects of monochloramine ingestion despite its long history in water disinfection. According to Hankin (2001), ingested monochloramine would reach the stomach intact and rapidly decay in stomach acid. No studies were found that suggest chloramines could have any negative impact in respect of stomach ulcers, although this is an area that warrants more research. It can be only tentatively suggested that chloramine is not expected to enter the systemic circulation intact.

5.33 In one past study, the short-term exposure to a maximum of 24 mg/litre of monochloramine in drinking water did not produce any adverse effects (Lubbers *et al*., 1981). International guidelines for drinking water quality suggest that no short-term or long-term health effects have been associated with chloramines in water (Hankin, 2001).

Cancer

5.34 Hankin (2001) states that to date the International Agency for Research on Cancer has not fully evaluated the cancer-causing potential of chloramines. Although a number of studies have found chlorinated drinking water to be associated with bladder and colon cancer, few of these involved chloraminated drinking water. In research conducted by Zierler *et al*. (as cited in Health Canada, 1995), it was found that the incidence rate of pneumonia and influenza leading to deaths in a Massachusetts community was slightly higher among those who had their water disinfected with chloramine rather than chlorine. On the other hand, the bladder cancer mortality rate was more excessive among residents using chlorinated water in comparison with those supplied with chloraminated water.

5.35 There is little other information available indicating any link between cancer and chloramine. The USEPA (1992)) has not classified chloramine/monochloramine as carcinogenic because there are inconclusive human data and equivocal evidence from laboratory animal assays. However, Edwards *et al*. (2005) states that '*the switch to chloramine immediately reduces the concentration of potentially carcinogenic disinfectant by-products in water*' (p.2). Bull and Kopfler (as cited in Kirmeyer *et al*. (1993)) believe this reduction in cancer risk could be as much as 80%, assuming that the chloramine used produces similar by-products to chlorine, but rather at lower levels. In conclusion, further research is needed to determine if any associations may exist between chloramine and cancer.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Disinfection By-Products

5.36 As stated previously, chloramine is known to produce fewer dangerous DBPs in comparison with chlorine, (see, for example, SFPUC (2004)). However, there are two particular DBPs produced to a greater degree during chloramination than chlorination which give cause for concern: cyanogen chloride and N-nitrosodimethylamine (NDMA). NDMA in particular can develop at higher concentrations in areas where precursor amines exist in the water from man-made sources, thereby necessitating enhanced monitoring and controlling of existing amines. Further research is being conducted on this by-product and progress has been made within the United States to limit its formation.

5.37 In 2004, there was another worrying development when iodoacid, the most toxic and DNA-damaging to mammalian cells of DBPs discovered to date, was discovered in chloraminated water within Texas. This may have been a rare occurrence due to the area's high levels of bromide and iodide (Barlow, 2004). It has been claimed that scientists currently have only been able to identify 50% of the DBPs in chlorine-treated water and only 17% of those in chloramine-treated water. In addition, the Water Research Foundation (1999) states that DBP formation decreases as the pH increases and the chlorine-to-ammonia ratio decreases and that a change in either of these variables can significantly impact DBP formation, suggesting that there is still a long way to go in determining the full effects and impacts of chloramination (Hankin, 2001).

Factors Affecting NHSScotland Estates Staff:

Lead-Leaching and Corrosion

5.38 Some research has revealed that the conversion from chlorine to chloramine can cause an increase in blood lead levels due to corrosion, a new and unexpected finding both for regulators and the water industry (SFPUC, 2004). In general, most childhood lead uptake occurs from exposure to degrading lead paint, although 14-20% of childhood lead exposure in the United States is estimated to originate from drinking water (USEPA, as cited in Miranda et al., 2007). Surprisingly, Edwards et al. (as cited in Edwards *et al*., 2005) state that there are no maximum contaminant levels enforced 'at the tap' in the United States, although an 'action level' of lead concentration is given as 15 µg/litre. In comparison, in accordance with the EU Drinking Water Directive (98/83/EC) Scotland imposes an upper limit on lead concentration of 10 µg/litre.

5.39 Several studies have proved that the introduction of chloramines to water systems containing lead-based pipes, fixtures or solder may increase the amount of lead in the water due to changes in the resulting water chemistry (Edwards & Dudi; Mass *et al*.; Schock; Shock *et al*.; Switzeret *et al*.; as cited in Miranda *et al*. (2007)).

5.40 Miranda *et al*., (2007) also discovered that a change to chloramine disinfection in the Goldsboro Water System in North Carolina was associated with an increase in children's blood lead levels. However, this particular study noted that the impact of the change was progressively mitigated in newer housing and in houses built after 1950, with the age of the house constituting a stronger

© Health Facilities Scotland, a Division of NHS National Services Scotland

influence on blood lead than the use of chloramines as a disinfectant (Miranda *et al*., 2007).

5.41 Variables such as the location of a potential lead source, the timing of sample collection and small changes in water chemistry can affect measured water lead levels considerably. In addition '*numerous factors can contribute to metal corrosion including water quality, biofilms, the pipe manufacturing process, and the design and installation methods of piping systems*' (SFPUC, 2004, p.15). In two studies (North Carolina and Washington, DC) this unpredictability caused the increased levels of lead as a result of chloramination to remain undetected until almost a year after the conversion had taken place (Miranda *et al*., 2007). It has been suggested that the dissolving of lead from pipes into water following chloramination may only be a transient process as a new film may subsequently develop inside the pipe, thereby creating a barrier between the water and lead source (Miranda *et al*., 2007). Evidently, there is still much to learn about the association between chloramine and lead-leaching.

5.42 Lead piping within Scottish houses and infrastructure is highly unusual nowadays and the main problem is likely to stem from lead-tin solder or degradation of brass fittings. Brass components can also experience dezincification, although the correlation between this phenomenon and chloramination is as yet unclear. Ideally, brass in taps and other appurtenances should be of a composition that is dezincification-resistant (DZR) and relatively immune to the leaching of copper (and lead, if present at all).

5.43 Miranda et al. (2007) summarised the current state of knowledge on general metal corrosion from chloramine by stating that 'the details of all the related environmental chemistry are not fully understood and are highly dependent on the particular chemical interactions found in each water treatment and distribution system'. The most comprehensive field study covering the impact of chloramination and materials deterioration is contained within Kirmeyer et al. (2004). This report confirms that both chlorine and chloramine can increase water's corrosiveness towards copper and its alloys (brass, bronze, cupronickel, etc), especially at low pH levels. There are two distinct manifestations of copper corrosion: a uniform, gradual thinning and a more destructive form, known as 'pitting'. Kirmeyer et al. (2004) details a survey of 31 utilities which converted from chlorination to chloramination after 1980. 13 of the respondents found there had been no increase in pipe erosion, 17 did not know and only 1 thought there had been an increase in the corrosion of galvanised pipes. Biocorrosion of copper piping was mentioned by Kirmeyer et al. (2004), although an evaluation of the influence of water disinfectant in controlling it requires further investigation.

5.44 There is little available data on the relative degradation of plastic piping fittings and associated equipment by chlorinated and chloraminated water. Kirmeyer et al. (2004) reports only one issue related to the possible impact of chloramination on plastic components, namely, hot water propylene dip tube heaters in Chesterfield, Virginia, and does not confirm that this was a result of the changeover. Chung *et al*., (2006) carried out a series of tests on ½" standard SDR-9 PEX tubing and found no discernible difference between the

© Health Facilities Scotland, a Division of NHS National Services Scotland

degradation induced by water containing representative concentrations of chlorine, chloramine and chlorine dioxide.

5.45 Carrying out research for the Urban Water Research Association of Australia (UWRAA), Moore (1998) concluded that the long term testing of a variety of materials at chloramination levels of 4 mg/litre and lower indicated:

- increased de-alloying of copper-based alloys, particularly in non-DZR materials (DZR alloys showed some corrosion but well within limits);
- increased corrosion of copper;
- negligible effect on stainless steel and plastic materials.

Moore (1998) accordingly recommended that the use of DZR materials in Australian water supplies should be mandatory.

Effect on Rubber

5.46 According to SFPUC (2004), the use of chloramine in a water system can have deleterious effects on distribution system plumbing fixtures, particularly natural rubber products and their derivatives commonly used in household appliances. Indeed, Kirmeyer et al. (2004) places this factor (after concerns about dialysis patients and aquaculture and ahead of those related to nitrification) as the second most serious hazard related to chloramination.

5.47 Practical experience has revealed that the severity of the effect of chloramine exposure on rubber has varied widely and is dependent on the material used, the amount of chloramine present and the temperature of the operating environment (Kirmeyer et al., 2004; Ashtabula Rubber Co., 2010). For example, one study found that 23% of utilities surveyed experienced an increase in the materials degraded after chloramination. In another case, after Austin, Texas, converted a portion of its water system to chloramine a number of complaints were received from customers concerning black specks in the water which were the result of the degradation of nitrile rubber material within the system (SFPUC, 2004). Moore (1998) stated that both natural rubber and neoprene suffered from significant attack in chloraminated water.

5.48 To examine the impact of chloramine on rubber products, the American Water Works Association Research Foundation (AWWARF) – see Kirmeyer et al. (1993) – studied seven elastomer formulations including natural rubber, nitrile, Styrene Butadiene Rubber (SBR), Neoprene, Ethylene propylene butadiene Monsoner (EPDM), silicone, and fluorocarbon and subjected them to a number of tests to determine their life cycle when exposed to chloramine. It was found that natural rubber subjected to chloramine exposure tended to crack, exhibit severe swelling and lose elasticity and tensile strength; chloramine attacked the polymers which significantly degraded rubber's physical properties. Furthermore, it was verified that the rate of decay was positively associated with increased temperatures.

5.49 Nitrile, SBR, neoprene and EPDM fared better in these tests but still showed significant degradation, whereas the considerably more expensive options

© Health Facilities Scotland, a Division of NHS National Services Scotland

silicone and fluorocarbon performed well. Custom, chloramine-resistant EPDM and nitrile materials are now available and are increasingly being used within the US potable water industry (Ashtabula Rubber Co., 2010). NHSScotland should therefore ensure that any rubber components within their facilities, which can be found in kitchen fixtures, bathroom shower heads and taps, bathroom toilets, drinking fountains, irrigation, systems, ice makers, fire suppression systems, sprinklers, water pipes and water meters contain chloramine-resistant components.

Notes:

Safety Action Notice:

A Safety Action Notice published by Health Facilities Scotland in 2009 looked at the risk of flexible hoses harbouring Legionella and other potentially harmful micro-organisms, it stated that HFS had received reports that high levels of Pseudomonas and *Legionella* bacteria had been found in water samples taken from water outlets fed by flexible hoses, this was confirmed by testing of the hoses which revealed colonisation of the lining. The lining material in these reports was EPDM. However, it is possible that other lining materials (and washers within the couplings) could have been similarly affected. Due to this, in situations where flexible hoses must be used they should be lined with an alternative to EPDM and be WRAS approved.

Aquatic Life:

Chloramines are harmful to fresh and saltwater fish and aquatic reptiles and amphibians, easily passing through the gills and directly entering the bloodstream (SFPUC, 2004). Here the compounds bind to iron in red blood cell haemoglobin and reduce each cell's capacity to carry oxygen. Care must therefore be taken to ensure that water courses are discharged neutrally or water-conditioning agents are added to remove the ammonia and chlorine (Walker, 2010). Specifically, SFPUC (2004) suggests that to remove or neutralise chloramine, a GAC filtration system or an additive that contains a dechloraminating chemical for both ammonia and chlorine, should be used. In addition, water tests should be completed frequently to ensure that chloramine has been sufficiently reduced (SFPUC, 2003). Consultation with the Water Authority may be required to ensure that any WRAS arising from processes introduced by them are not unreasonably borne by the consumer as they can be underwritten by savings achieved by the utility company.

Conversion from Chlorination to Chloramination

5.50 An appreciable body of information has now been established documenting the experiences of water authorities which have converted from chlorine to chloramine disinfection. A study conducted by Flannery *et al*. (2006) in California showed that the conversion to a monochloramine disinfection system resulted in higher concentrations of total chlorine and lower concentrations of THM components. While the average temperature and pH measured in building water samples remained relatively constant, the conversion resulted in a 10-fold increase in total chlorine concentrations in the hot-water systems.

© Health Facilities Scotland, a Division of NHS National Services Scotland

5.51 As a result, it was concluded that monochloramine in drinking water provides better control of Legionella growth in building plumbing systems than free chlorine, although the Group also state that the potential use of supplemental monochloramine in hospitals to prevent Legionnaires' disease still needs to be evaluated. In addition, the increased stability of monochloramine ensured higher disinfectant concentrations in potable hot water systems, since chlorine dissipates rapidly at higher temperatures.

5.52 Another conversion from chlorine to chloramine, completed by the Regional Municipality of Ottawa-Carleton in Canada in 1992, resulted in an average chloramine concentration of 0.92 mg/litre (95% of which was monochloramine) leaving the plant and 0.71 mg/litre in the distribution system. The changeover to chloramine produced no observable changes in the bacteriological quality of the drinking water (Health Canada, 1995), although the municipality has increased its average concentration to 1.0 mg/litre in order to achieve higher residual amounts at the end of the distribution system. According to SFPUC (2004), many water agencies that have converted to chloramine from chlorine have reported that customers note an improvement to taste and odour of the water.

Scottish experience

5.53 In a Scottish context, NHS Dumfries & Galloway recently completed a pilot scheme to measure and assess the impact of the changeover to chloramine, and noted no observable changes during or after the process, although it did start with a 'clean' water system in a new facility. NHS Lothian has also converted and likewise reported little noticeable change to water quality and operational maintenance (Walker, 2010). However, NHS Grampian, which has been supplied with chloraminated water for 7 years, noticed a considerable improvement in quality much cleaner water pipework and tank systems. Moreover, laboratory personnel who have been unable to culture Legionellae in supply and secondary system samples suggest that chloramination has the potential to reduce operational maintenance requirements.

5.54 On the other hand, NHS Grampian observed that the conversion introduced manganese in granular form, most likely originating from leaching of Scottish Water pipework (Walker, 2010). Anecdotally it has been suggested that differing distances from the reservoir to the point of use may account for differences in quality of water, this has not been proven.

Findings from the Case Studies

5.55 The case studies reviewed for this report are restricted to North America. Nevertheless, the experiences they provide are diverse and, as such, they still represent a valid basis for determining the possible effects of chloramine disinfection in other situations. The key point emerging from the case studies is that the impact of chloramination depends very much on the raw water quality, surrounding soil, pipe fittings and combinations of other chemicals.

5.56 Most of the case study organisations experienced one or more of the negative characteristics associated with chloraminated water and, consequently, the

© Health Facilities Scotland, a Division of NHS National Services Scotland

successful implementation of chloramination may rely heavily on the experimental abilities of individual water treatment plants to manipulate variables such as pH levels or the ratio of chlorine to ammonia-nitrogen appropriately.

5.57 However, bearing in mind the strict requirements of healthcare facilities, the risks already highlighted in this report warrant a degree of caution before chloramine can be recommended as a completely safe choice for NHSScotland and its patients. Some thoughts with regards to these case studies, in conjunction with relevant findings from the literature, are given below:

- the theoretically-oriented literature states that, being a more stable and persistent disinfectant than chlorine, chloramine has associated cost reductions. This principle was borne out by the case studies, with Brown Deer finding chloramine to be the best cost/benefit option and Massachusetts being able to eliminate booster stations by using a 5:1 chloramine to ammonia-nitrogen ratio, thereby saving $100,000 each year. However, when used, chloramine booster stations decreased service pipe failures for Brown Deer;
- a decrease in DBPs after switching to chloramine was observed by Gulf Coast, Massachusetts, Ann Arbor, Hackensack and Tampa Water Departments, indicating that this is also a reliable benefit of chloramine use. Moreover, the use of chloramine provided increased residual in water distribution systems for Brown Deer, Massachusetts, Vancouver and Tampa, thereby helping to decrease HPC and coliform bacteria levels. In Ann Arbor, however, where a decreased residual resulted in increased HPC levels in dead-end areas, free chlorination was used for control measures before re-conversion to chloramination;
- taste and odour results were more mixed: Philadelphia found chloramine to decrease taste and odour effects, whereas Vancouver found the opposite occurred. Vancouver attributes this result to chloramine residual being more widespread within the test area and its presence more detectable to customers than the chlorine previously used;
- of the 14 case studies, lead corrosion from chloramine was evident in Brown Deer, North Carolina, Washington and Maui, while in Massachusetts chloramination actually helped to decrease iron corrosion. Affecting 29% of the case studies in this report, lead-leaching is a dangerous characteristic and its possible link with chloramine requires substantial future analysis;
- Nitrification is described alternatively as ‘more of a nuisance and operational problem than a health issue’ (SFPUC, 2004, p.8) and a factor that may negate the benefits of using chloramine (MWUA, 2010). Reports of nitrification in the case studies were not very common although when they did occur they were dealt with by experimenting with different solutions. Ann Arbor, for instance, managed to decrease nitrification by changing its ratio of chlorine to ammonia-nitrogen and increasing pH before temporarily switching to free chlorine. Portland, however, employed the use of booster stations to decrease its nitrification;

© Health Facilities Scotland, a Division of NHS National Services Scotland

- although chloramine is known to have increased residuals and reached outer-most areas of their distribution systems, Washington and Maui both noticed that during stagnation periods there was an increase in bacteria levels. In Maui's case, the chloramine was being mixed with phosphate and causing a slime-forming bacteria at a pH of 7.7;
- nitrification falls within the remit of water utility organisations and NHSScotland has little leeway in controlling the amounts of excess ammonia within a water distribution system. As noted in the recommendations, however, it is possible to take action to minimise the formation of nitrification within NHS facility water systems by ensuring through the regular flushing of pipes and the avoidance of dead-legs that no stagnation of water occurs. Provided UK and NHS regulations and procedures concerning these practices are complied with, stagnation and its possible associated bacterial growth should not prove a significant issue within Scottish healthcare premises;
- the link between chloramine use and general health is still not known with absolute confidence. North Carolina experienced a number of health complaints after conversion to chloramine, although none of the skin disorders discovered was found after investigation to be fully attributable to chloramine;
- several of the case studies, including Vancouver and Tampa, noted the importance of a public education and notification programme when implementing chloramine treatment. Philadelphia in particular worked to understand customer perceptions and sensitivities with regard to chloraminated water and realised that direct communication with the public was the best option. Through its education programme, the organisation also attempted to develop a link between chloramine and safe, clean water, so that if the public detected a change in the taste of their water when the system converted from chlorination to chloramination, they would make this educated association rather than complain or panic. The water department noted that a public survey was a useful tool for gathering the required information and the populace can provide reliable information on water-related concerns;
- the Hackensack Water Authority initially avoided the public notification and education stage, believing that since it had already used chloramine in the (relatively distant) past the changeover would be trouble-free. However, the conversion caused substantial problems with aquatic life and several dialysis patients required transfusions. The conversion to chloramine was conducted successfully four years later following the launch of a proper information campaign;
- in the case of Scotland, an educational program on chloramination would generally be the responsibility of Scottish Water. However, if needed, a smaller campaign could be developed by the NHS Boards in Scotland to inform staff about the changeover;
- a monitoring programme before, during and after a change to a chloramine system is an important component for success. In particular, Portland states that an understanding of chloramine chemistry is vital for a monitoring strategy to be useful. It continued a monitoring programme with

© Health Facilities Scotland, a Division of NHS National Services Scotland

the objective of limiting free ammonia and ensuring high residuals in their system;

- several of the organisations in the case studies reported the use of chlorine to treat particularly difficult cases of bacteria, even though they may have implemented a chloraminated system; these include Ann Arbor and Maui. (Gulf Coast successfully combined chloramine with chlorine dioxide.) In all cases, the use of chlorine was successful, whether the aim was to decrease lead concentration, bacteria or nitrification. However, in Maui the chlorine residual decayed significantly while in Ann Arbor, there was an increase in HPC, coliform bacteria and THMs. The eventual outcome was that chloramine remained the preferred choice for these organisations, with chlorine simply on hand in future if needed for temporary treatments. Ann Arbor stated that future chlorination treatments would need to be accompanied by improved measures to minimise any negative effects.

6. Conclusions and Implications

6.1 This SHTM has investigated the advantages and disadvantages entailed in a changeover from chlorinated to chloraminated water supplies, with particular focus on the bearing this might have on healthcare facilities. Chloramination is being adopted by water utility companies primarily because of the requirement to find a cost-effective means of complying with increasingly stringent regulations covering quality.

6.2 There are certainly advantages associated with using chloramine as a disinfectant, especially in terms of its long-lasting presence within the supply network and its generation of fewer dangerous by-products. Nevertheless, it is clear that the addition of chloramine to water is not entirely risk-free and, given the American experience, there are concerns over possible nitrification and materials degradation.

6.3 Scottish Water supplies the vast majority of Scotland's healthcare facilities, although a small number have their own private water source. Consequently, most NHS Boards have little control over the water within their domains and must adopt a reactive policy based on planning and monitoring. This review has identified the chief areas of concern in a medical context to be the safety of dialysis patients and small babies, while materials degradation in water distribution systems may become a problem in respect of physical infrastructure. It is important that these issues are addressed and there are some steps that can be taken by NHS Boards in regions of Scotland where chloramination is envisaged.

© Health Facilities Scotland, a Division of NHS National Services Scotland

7. Recommendations

Communication

7.1 Direct communication should be developed between NHSScotland Health Boards, healthcare and estates staff and Scottish Water (or the relevant water treatment organisation) to ensure all are fully briefed on issues concerning chloramination and aware of the actions needed from their side to ensure a successful change and the maintenance of patient safety. It is essential that unilateral changes from chlorination to chloramination of incoming water supplies do not occur without consultation. This has happened in the past.

Monitoring Water

7.2 NHSScotland Health Boards must give serious consideration to monitoring for possible nitrification the water supplied to wards with young babies and relatively inexpensive testing kits are available for this purpose. NHS Boards should also have an action plan in place to account for any sudden increase in nitrate levels. Additionally, a line of communication must be established between Scottish Water and NHSScotland Health Boards which would raise an early alarm in the event of a problem arising in the water supply. This will also help to ensure that unilateral decisions are not taken (see paragraph 7.1, above).

Dialysis Equipment

7.3 In advance of chloramination, NHS healthcare and estates staff must ensure that provision is made for the supply, installation and regular replacement of the appropriate granulated activated carbon (GAC) filters for dialysis machines. Previously, Safety Action Notice (SAN) (SC) 03/10 recommended that a notice of 12 months was required before changeover.

Distribution Infrastructure

7.4 The estates staff responsible for overseeing water networks within healthcare facilities must be informed as to the possible impact of chloramination on pipes and appurtenances. In particular, components containing rubber or vulnerable elastomers should be replaced when necessary by equivalents which are chloramine-resistant. In certain cases, it may be necessary to effect these changes in advance of chloramination.

7.5 Additionally, when pipes and fittings are being replaced they should be inspected for corrosion and other problems. Brass fittings should be dezincification-resistant (DZR). Due attention must be given to the need to avoid stagnation and dead-ends, although this is standard practice.

© Health Facilities Scotland, a Division of NHS National Services Scotland

Education and Notification

7.6 All staff should be informed of the changeover to chloraminated water beforehand. This will hopefully prevent any unnecessary alarms over unfamiliar tastes and odours and encourage vigilance.

Introduction

Submission Reference:

SECTION 3.1: ARCHITECTURAL DESIGN STRATEGY 3.1

Submission Response:

The following is an illustrated narrative which explains the key aspects that have informed the architectural, masterplanning and landscaping proposals. This narrative should also be read in conjunction with the relevant Wayfinding (Volume 3 Section 3.2) and Arts strategy (Volume 3, Section 3.3) proposals.

Introduction

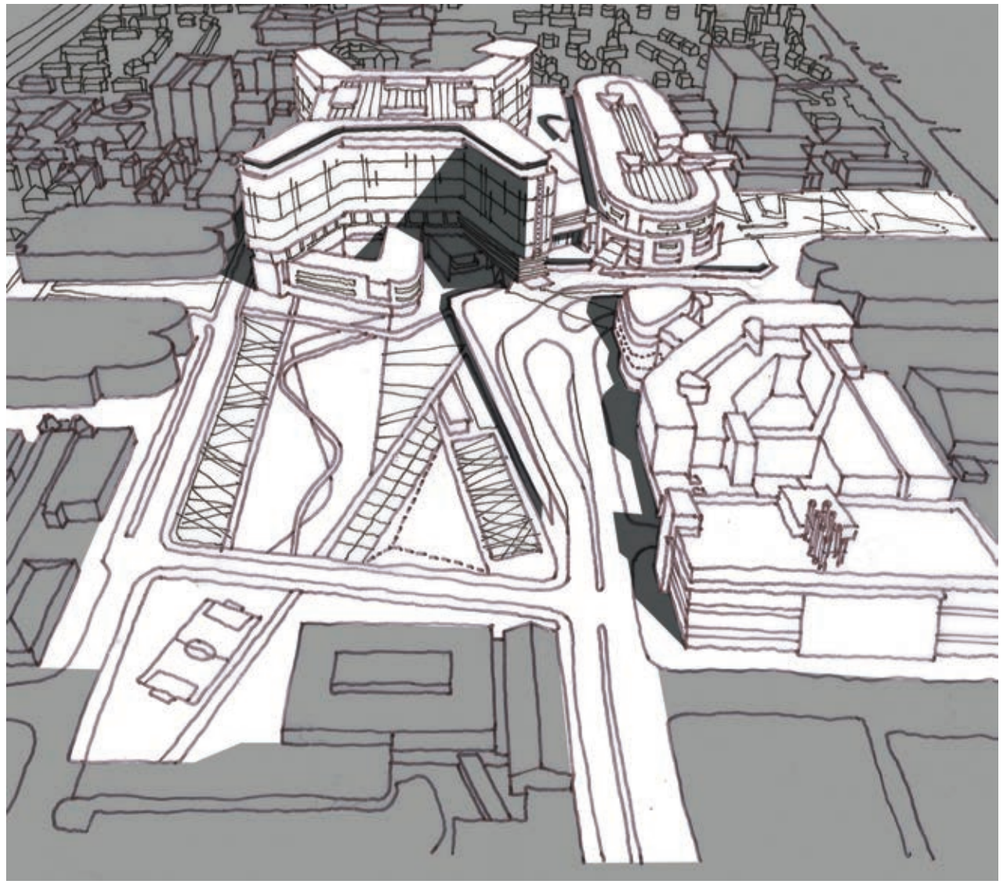
We have pursued an integrated approach to our masterplanning, design and clinical planning for all elements of the new hospital. This has influenced the way we have structured our team, our working methods and engagement with the Board over the past few months. Our goal is a hospital that is a fine piece of architecture - an elegant simple solution to a complex problem.

Hospitals are by virtue of their arrangement and multiplicity of services complex buildings. The big challenge to designers is to create a positive patient environment that also helps staff deliver complex clinical processes in a non-institutional environment. Our answer is simplicity - a building that can be easily understood by all of its users- both in its form and layout.

We have also sought to create an appropriate building for Glasgow with a sense of ‘wow’. We have done this through a process of honing and refinement of form and finishes, with some carefully considered grand gestures - the curved Children’s building, the two storey main entrance space and the central atria. These buildings will be a place of wonder and discovery for patients and visitors. A well designed hospital will improve staff retention and recruitment. Staff will want to work in this new hospital, feeling that it is a supportive environment in which they can pursue and develop their particular vocation or speciality.

We have endeavoured to capture and make real the aspirations of the Board, reflecting the heritage of Glasgow whilst rising to the challenge of current and future demands in a changing healthcare culture. We are confident that our proposals, informed by dialogue with the Board and its advisors, offer a simple elegant solution to a complex challenge, one that has enduring qualities that will stand the test of time.

This design statement is arranged in two sections in order to explain the key aspects of the scheme: Masterplan and Architecture.



Brookfield

Masterplan

The Masterplan for the New South Glasgow Hospitals presents a cohesive design based upon function, clarity and the creation of an approachable environment of high quality. The masterplan has sought to make the best possible use of the site and the opportunities presented by the requirements of the brief. The arrangement of the buildings, routes and public spaces has been defined to create a user-friendly setting for this significant new landmark healthcare development for Glasgow. The design and layout of the site seeks to underpin very positive experiences of a high quality site for patients, staff and visitors. The masterplan is based upon the establishment of a durable parkland character which will enable the campus to evolve and grow over time in response to healthcare demands and opportunities for redevelopment of particular areas of the existing NHS estate. The masterplan provides the platform and a robust identity for the future.

Key Opportunities

Some of the key opportunities explored during the early stages of the masterplanning were as follows:

- Excellent legibility of main entrances upon arrival, through the definition of effective sight lines to aid orientation
- Definition of a very clear and unobstructed blue light route to A&E
- The creation of an expansive and influential green setting for the campus, which extends into and sets the scene for the hospital buildings
- The definition of a high quality arrival plaza as a significant new public space, to create a setting for the three main entrances
- The clear distribution of pick up and drop off facilities for specific modes of transport, to enable efficient and safe use of the public spaces to be defined for all
- The creation of a range of clear, safe and effective pedestrian routes into, through and around the site
- Realignment of the western car park to create enhanced space for a new Children's park and to enable disabled parking to be moved closer to the main entrance
- The establishment of distinct identities and high quality landscape settings for the Adult & Children's hospital buildings
- A sensitive and appropriate response to the listed buildings and the existing areas of the site which are to be retained
- The definition of a site structure based upon approachable public spaces as a setting for the new healthcare campus
- The continuation of the public spaces well into the internal areas of the buildings, which share a similarly approachable design ethos

Design concept sketches to illustrate an expansive green character and early exploration of opportunities

Brookfield

Masterplan Development

The Masterplan has been developed with flexibility in mind, creating spaces which can be easily added to or altered in the future without compromising the overall integrity and design of the landscape. Careful consideration has been given to the placement of buildings to create appropriately scaled spaces and ensure that routes between buildings are clear, safe and approachable. The various areas of the site are well connected and served by a range of routes for pedestrians, cyclists and vehicles. A transport hub is located at the heart of the site as a clear and logical point of arrival. Entrances are positioned around this large public arrival space and there is direct access for pedestrians from the drop off points from cars, taxis or buses.

Brookfield

Public Space & Landscape Design

The new campus masterplan offers extensive grounds, delivering abundant green space for patients, staff and visitors throughout the day and night. The central park provides the setting for the Adult hospital. The Children's park provides the setting for the Children's hospital. The main entrances to both are located within the arrival space, which connects the two parks. Secondary entrances connect the buildings to the surrounding public areas and parks. The landscape can be easily read, is visually appealing and appropriately scaled to complement the architecture, with a clear hierarchy of external environments. Vehicular drop-off points are clearly located close to the main building, with parking set further away to promote pedestrian circulation as the dominant means of traversing the campus. Pedestrian facilities will ensure access for all through minimal level changes and high quality surface materials that reinforce movement towards the entrances. Vehicular speed will be controlled via traffic calming elements and pedestrian crossings, creating a more comfortable environment for pedestrians. The transport hub is centrally located, allowing for easy connections with public transport systems and designated cycle routes and shelters further promote the use of sustainable transport.

Brookfield

Public Space & Landscape Design

The new campus masterplan offers extensive grounds, delivering abundant green space for patients, staff and visitors throughout the day and night. The central park provides the setting for the Adult hospital. The Children's park provides the setting for the Children's hospital. The main entrances to both are located within the arrival space, which connects the two parks. Secondary entrances connect the buildings to the surrounding public areas and parks. The landscape can be easily read, is visually appealing and appropriately scaled to complement the architecture, with a clear hierarchy of external environments. Vehicular drop-off points are clearly located close to the main building, with parking set further away to promote pedestrian circulation as the dominant means of traversing the campus. Pedestrian facilities will ensure access for all through minimal level changes and high quality surface materials that reinforce movement towards the entrances. Vehicular speed will be controlled via traffic calming elements and pedestrian crossings, creating a more comfortable environment for pedestrians. The transport hub is centrally located, allowing for easy connections with public transport systems and designated cycle routes and shelters further promote the use of sustainable transport.

Key Spaces and Places

The Central Park within the campus provides a functional retreat for patients, visitors and staff. The masterplan extends the soft landscape from ground level up the buildings, through the external courtyards and on to the roof, creating physical links between the hospital buildings and the surrounding landscape. These courtyard gardens provide therapeutic retreats for recovering patients, utilising level changes for rehabilitation where appropriate. The roof areas provide amenity whilst also supporting a wide range of vegetation types from sedum mats to shrubs and trees, reflecting the native species found at ground level for continuity.

The Masterplan recognises the opportunity presented by the expansive greenspace to optimise the use of the landscape, not only for the enjoyment of patients but also those who use the space on a regular basis, providing a focus for passive and active recreation, including the prposed 5-a-side pitch and an informal running track within close proximity to the hospital buildings. Informal lawns and a meandering path provide for use of the park as a thoroughfare as well as a place to relax, whilst the wildflower meadow and woodland vegetation establish a wildlife fringe with great habitat potential, increasing the overall campus biodiversity.

Children's Park

The New Children's Hospital will dock with the main building connecting the two whilst retaining a feeling of separation. The external environment for this hospital is focused towards delivering a stimulating space with low key play for a variety of age groups. The Children's Park and interactive play area is delivered with a playful use of colour, texture and creative design, easily accessed by all.

Hard and Soft Landscape

The campus-wide soft landscape strategy has been carefully considered through study of the supporting ecological reports and BREEAM requirements as well as a study of local flora and complementary 'exotic' species, which have been chosen for their low maintenance requirements. The softscape palette delivers year round visual interest, which achieves an appropriate sense of scale, softening the architecture rather than competing with it. The design remains mindful of the variable local climate, building aspect and success of desirable local flora. Such consideration is particularly important for the roof garden, which may be subject to extreme climate conditions. Widespread use of locally sourced native and exotic species will further the chances for successful plant establishment and will also create more habitats for local fauna.

Vegetation is used creatively to both screen undesirable views and frame important ones, whilst also acting to reinforce the wayfinding strategy for creating spatial hierarchy. Larger trees line the avenues and main access routes, whereas squares and gathering points are complemented by more intimate vegetation, formally arranged at a lower level, providing variety through foliage color, scent and flowers. Informal arrangements of wildflower meadows will provide an annual profusion of color across the Central Park, linking back to the main buildings and extending to the roof terrace, strengthening the green corridor. Such species will survive on poor quality soil and require minimal maintenance.

The development will result in a loss of protected tree species, which cannot be avoided. The Masterplan looks to replace any vegetation lost with suitable native alternatives and seeks wherever possible to further the variety of the naturalistic environment.

The palette of hard landscape material will create a cohesive and legible public realm to facilitate circulation. It will achieve this through the use of a range of surfacing materials which reinforce the character of particular areas. Hardscape treatment will act to differentiate as well as unify destination hubs and transition zones, responding to the environmental conditions, be it by providing pedestrian, shared or vehicular surfaces. Variety is desirable and will ensure visual interest and richness as well as providing a clear hierarchy of spaces. Hardscape materials will remain consistent within defined areas, providing a clear transition from one space to another whilst creating a sense of arrival. Level transitions, pedestrian ramps and service covers are carefully considered to avoid clumsy transitions between surfaces.

The hardscape environment has been designed to minimise the environmental impact. Permeable gravel surfaces permit surface water infiltration, whilst granite and paving slabs help to reduce the carbon expended on supply. Hard wearing surfaces delay the need for replacement materials and are used where the greatest level of activity is anticipated. Sustainable drainage systems are accommodated with surface run off being directed towards surface level drainage which is filtrated through a reed bed system. All materials will accord with the relevant British Standards and will meet BREEAM standards for 'Excellence'.

Brookfield

Furniture Strategy

The furniture strategy is designed to respond to the variety of environments experienced across the campus, to provide robust, practical, comfortable and attractive features. Some seating is to be constructed on site, in the form of low seating walls faced with reclaimed dressed stone from site demolition, and other elements supplied as individual pieces of furniture. Design will vary according to the locality but quality will not be compromised. A complementary palette of bins, bollards, railings and cycle stands all add to the character and identify of the space.

Illuminating the Campus

Lighting within the hospital campus will create an environment which is as welcoming and accessible during the night as it is by day. Functional lighting to routes is to be used in conjunction with feature lighting in key areas. The lighting strategy will help to identify the New South Glasgow Hospitals as a unique location whist also delivering seamless integration with the surrounding environment. The scheme will allow for the use of power efficient luminaires with appropriately low maintenance requirements. Fittings will limit light pollution by providing a variety of light levels appropriate to the locality. Stronger lights affixed on lamp posts will delineate the primary routes and entrances where high visibility is of greatest importance. Subtle use of lower intensity light fixtures, uplighters and illuminated bollards will create a more intimate and relaxed environment for secondary pedestrian destinations, whilst still providing sufficient light to permit ease of use and without disturbing wildlife which may inhabit the area.

Architecture

Overview

The challenge for this development has been the provision of two different hospitals together on one campus, both requiring a different approach architecturally whilst maintaining both legibility and identity as a whole. The solution is the formal composition of the building as an expression of its principal functional parts, the wards, the Children's hospital and the podium levels (comprising the diagnostic and treatment services). These three elements each have their own specific character, albeit derived from a unified concept for the whole building. The façade treatment of each piece has been informed by material selection and detail with the design responding to aspect, functional content, as well as life-cycle and maintenance considerations.

Internally the challenge has been to maximise clinical adjacency whilst minimising circulation and maintaining a simple and robust wayfinding strategy. We believe we have achieved this as well as a strong robust, iconic architectural design.

References and Inspiration

We believe that the redevelopment of the Glasgow Southern General Hospital site should recognise and reference the importance of the history of the city. The Clyde as it meanders through the city with history steeped in shipbuilding offers ample opportunities for reference to materials, scale and form.

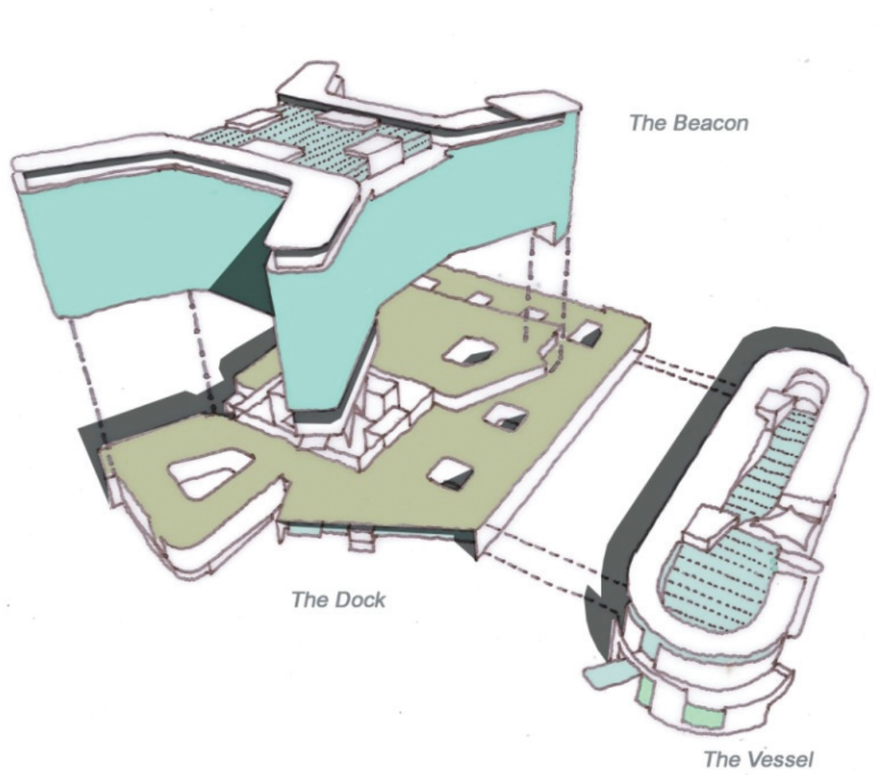
The building is large, yet it is evident that this scale when set within the surrounding shipyards along the Clyde is not only appropriate but necessary to relate to such imposing structures.

The Children's hospital takes its inspiration directly from the ships that once and still do glide down the Clyde. Rounded at both ends, with funnels references on the lift cores, the building reflects the shape and form of a ship. Further reference to the Clyde's history is evident in the roof gardens whose canopied play areas make reference to the decks on the majestic liners that once cruised the nearby river.

Brookfield

Building Architecture

Three blocks of accommodation of strikingly different geometry come together around the podium. The three principal elements are the ‘Beacon’ (Ward Tower), the ‘Dock’ (Podium) and the ‘Vessel’ (Children’s Hospital)



1. The Beacon (Tower)

The ward tower comprises 8 floors of ward accommodation with plant space in an interstitial layer and at roof level. Designed as a continuous free-flowing plan formation around a central atrium, maximum views and flexibility for all inpatients without overlooking any other patients is ensured.

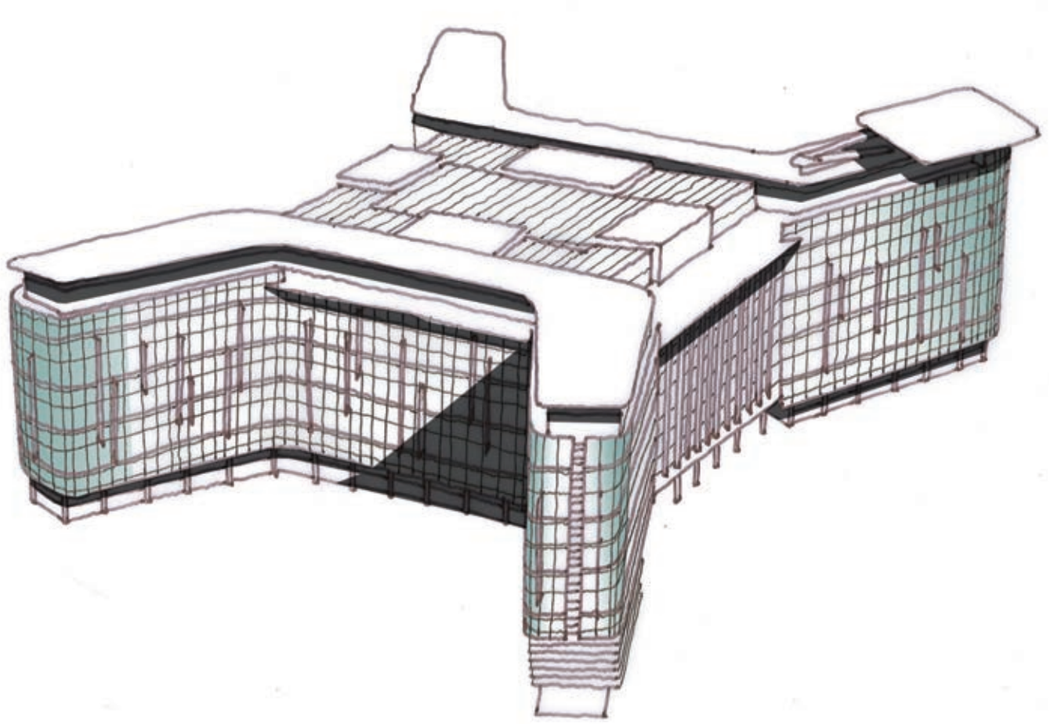
The external expression of the ward tower remains consistent with this continuous planning approach and embraces and emphasises this free-flowing aspect through a distinct horizontal emphasis. This approach assists in mitigating height and any potential over-bearing effects.

Other subtle details are employed to vary the expression and respond to aspect and scale. A horizontal emphasis is proposed for alternate floors thus reducing the perceived height of the development whilst embracing the horizontal planning approach of the wards. On the longer east and west elevations, this horizontality is broken down in the central area of the elevation through the application of regularly spaced vertical aluminium fins which as well as providing some relief from oblique solar gain also allow a subtle hierarchy to be introduced. These fins are also proposed to be added to the tower ‘wings’ as a device to add subtle colour and relief from the smooth free-flowing skin of the

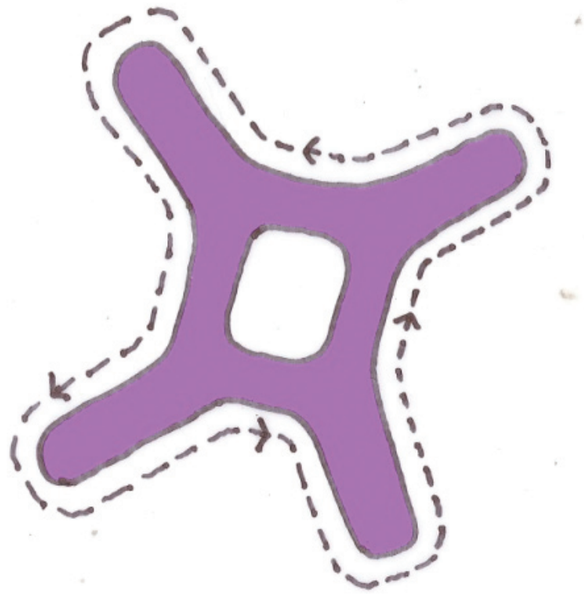
Brookfield

2. The Dock (Podium)

The podium varies in height between three and four storeys, responding to the varying scales of existing facilities around the perimeter of the site. It also accepts and exploits the difficulties often presented in attempting to adopt a legible compositional strategy that can respond to a myriad of small cellular spaces within. Our strategy is designed to deal with this and also to allow flexibility during the detail design phase, where the inevitable development of functional content requirements will impose change. Ensuring that the internal clinical plan is not compromised through a desire to achieve an external aesthetic/ compositional effect is critical in our view and our strategy is designed to prevent this



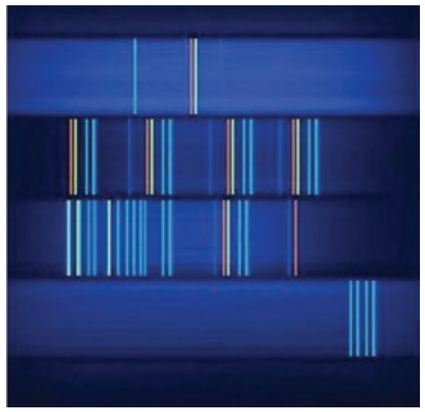
Sketch View of Tower

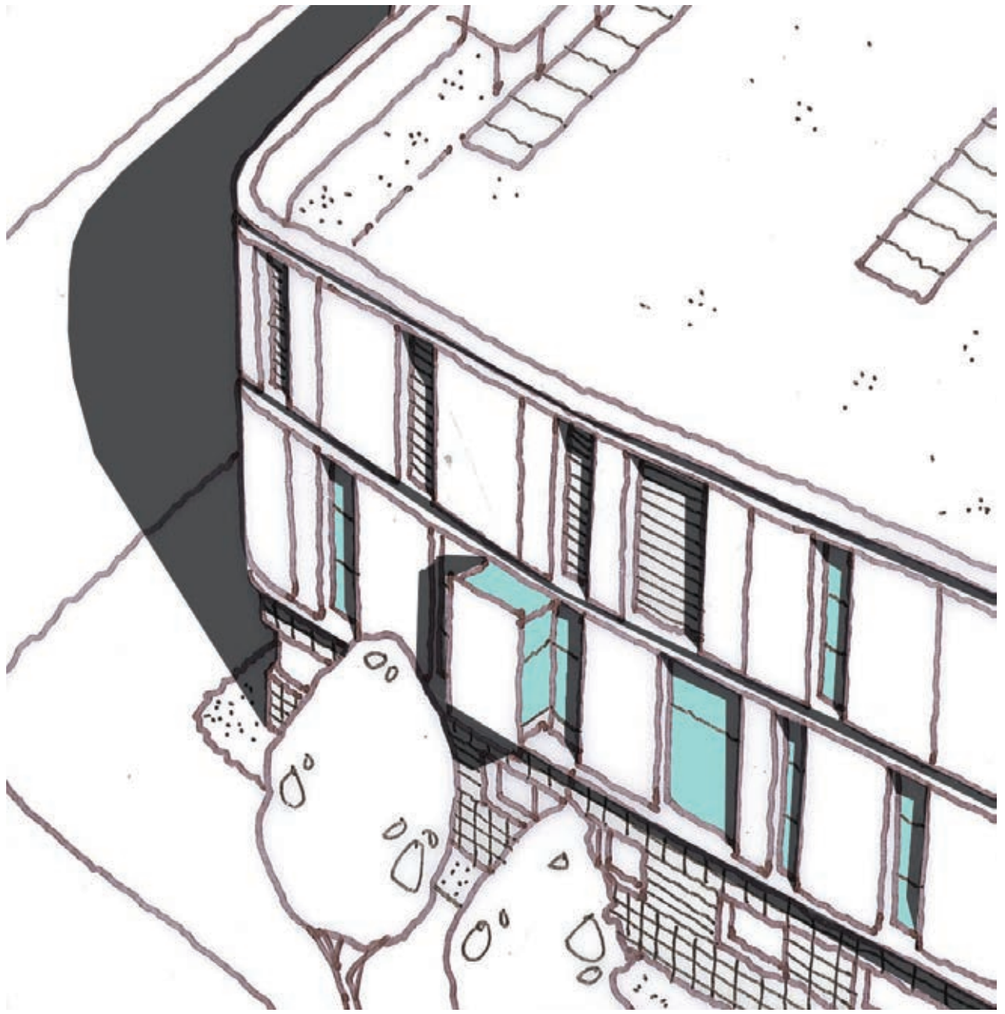


Free-form ward tower arrangement

Brookfield

The podium takes its visual references from medical imagery and in particular the DNA strand. The strategy for fenestration and modular panel systems follows the principle of a DNA strand with the placing of varying width full-height solid or transparent panels, in a seemingly random manner. The perceived height of the podium is also mitigated by a horizontal emphasis, highlighted through the use of a separating floor level steel channel. Horizontality and a dynamic expression of the individual floor plates is also emphasised through the curving of corners, which allow views to continue around corners rather than terminate.





Sketch View of Podium

Brookfield

3. The Vessel (Children's Hospital)

The Children's hospital has been designed to reflect the patient group it is dealing with, who are generally very nervous about attending hospitals. With this in mind we have tried to make the building feel playful and colourful as well as light and airy. The theme of a vessel mooring alongside the dock, in this case the podium has been taken. The curved form of the building and the internal lift towers rising up to roof level providing expression as ship 'funnels' further add to this theme. The idea of the Children's hospital 'docking' with the Adult hospital providing support and security is an integral part of the overall composition. As such, the Children's hospital is treated as a more transient form which takes some cues from the acute building, in order to ensure an integrated approach, but also is treated as an individual piece with its own strong identity.

To further enhance the Children's hospital's identity and to ensure an appropriate response to human scale, the front of the building fragments to form an expressed screen/'arch' which assists in breaking down the mass and scale of the five storeys of accommodation. The 'arch' structure also encloses and protects a second floor terrace/play-deck, accessed from the Schiehallion ward and also provides a springing point for the main entrance canopy.

Sketch View of Children's Hospital from Children's Park

Further references have been considered to reduce any potential institutional effects whilst being mindful not to ignore other users. As well as maritime references, other sources of inspiration have been introduced in order to assist the external compositional strategy, to reinforce the building's individual identity and, above all, to engender a feeling of fun and relaxation. Accordingly, the use of colour through a study of imagery from areas ranging from medical (tablets, pills etc.) to confection (jelly beans, sweets, etc.) is proposed.
The building fenestration employs a simple strategy which groups pairs of windows with coloured panels. This grouping is then offset between adjacent floors, introducing a sense of random playfulness which mitigates formality and institutional feelings.

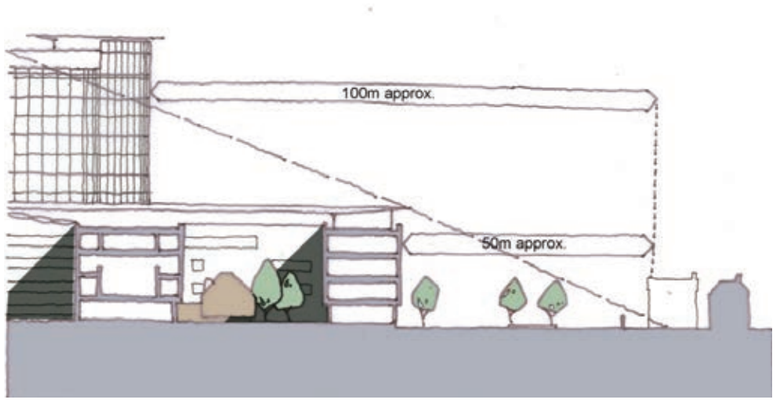
Entrances and Building Approach

The hospital has three significant entrances. The main entrance for both the Children's and the Adult facility are expressed such that as people arrive at the site, they are guided intuitively to the entry points, and are not dependant upon detailed signage. Both entrances overlook the central square and vehicular drop zones. It is the scale and presence of the building that gives our proposals a truly civic impression. The entrance canopies have been ideally placed to create both civic impact and to clearly present themselves to visitors approaching along the main boulevard. The third entrance, to the rear of the building, serves only as an entrance for the Adult and Children's Emergency Centre. This is not a grand entrance but no less important. It is necessarily functional and will be obvious due to the canopied drop areas along the length of this façade.

Scale

The overall scale of the building is the result of compact planning together with a desire to offer the potential to create landmark views for patients, staff and visitors over the surrounding hills as part of the healing environment. The tower will also act as a wayfinding beacon and landmark for the population of Glasgow. The placement of the building concentrates the mass and height to the centre of the site away from the adjacent terraced houses and smaller scale hospital facilities avoiding an over bearing building mass. The podium fixed at either 3 or 4 stories is a scale felt appropriate for the surroundings and includes a floor of plant accommodation which is set back where possible to further reduce its impact.

The scale of the courtyards allows sufficient daylight into the spaces between the 3 – 4 storeys of the podium or the Children's hospital. These courtyards will support a variety of therapies as well as contemplation and repose.



Schematic Section at Southern Perimeter of Site

Perspective View towards Main Entrance

Brookfield

Permeability/Views

The importance of the building connecting with the surrounding landscape and the inside/outside functionality has been fundamental to the basic concept of this scheme. Maximising natural light and views to and from the hospital are not only important for orientation and the therapeutic recovery of the patients but also staff moral and easy wayfinding. To that end we have sought to ensure where possible there are strong links with the external environment.

The main entrances do not build barriers between the inside and outside rather they encourage you into them with continuity of floorscape, scale and permeability and use of materials. The Children's hospital maintains the link to the outside further by opening up the ground and first floor areas with a glass wall overlooking the proposed Children's park. This along with the 4 storey atrium will provide light and views over the park providing an exciting entrance space for children and visitors reducing stress for all.

On the Adult hospital both the café and restaurant are located to ensure they maximise the benefit of the therapeutic nature of the landscape park. Set at the front of the building on two floors behind floor/ceiling glass they will not only provide a visual link for people as they approach but also relaxing zones with access outside should weather permit.

The main atria to the Adult hospital within the ward tower has been designed not simply as a top lit space, but rather as a space which maximises opportunities throughout its vertical height to gain light and views over the surrounding city. The central space breaks through to the outside at the ground floor and levels 3 and four on both the East and West facades to ensure natural daylight permeates the entire height of the space whilst allowing patients and visitors the opportunity to orientate themselves with their surroundings.

We have created an environment that will be perceived as a destination for the local community and people of Glasgow, one that is non-institutional, innovative and breaks down the common perception of healthcare environments.

Hierarchy of Space; Therapeutic Approach to Design

Although clinical adjacency issues are key to a successful hospital which are evident in our 1:200 drawings, we believe that by using a truly 'evidence based design' approach to the hospital as a whole can bring wider ranging benefits, including staff moral and retention, reduced patient treatment times by 14-21%. The evidence based approach is based on the concept of a health building as a hierarchy of spaces from public to social to private emphasis with different character as well as function. A number of simple principals are evident in this approach to design.

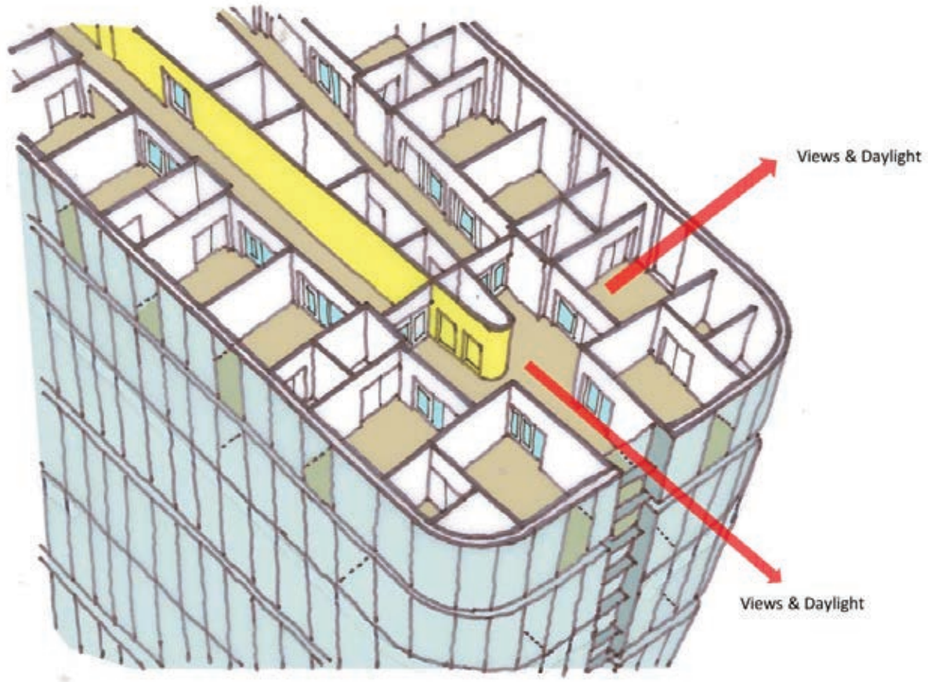
- Give patients privacy and dignity.
- Design to give patients, staff and visitors views within and from the building.
- Create spaces that have spatial legibility. Design so that there is a hierarchy of space, clearly demarking public / private with entrances clearly evident.
- Use art to define spaces but also to distract the patient / visitor.

Our design has used these design principles to produce what we believe is a truly holistic approach to the final design proposal. Firstly we have approached the Board's schedule of accommodation to create a space hierarchy within all departments which range from:

- Public space
- Social space
- Private space
- Intimate space

Our proposals encompass this approach across both hospitals with their differing levels of both private and intimate spaces readily accessible from the more lively public / social areas of the atria and main circulation cores.

We have attempted to create a sense of place rather than simply achieve functional requirements. All spaces make the best use of orientation, daylight, views, providing visual stimulus and spatial variety. Some spaces provide a sense of wonder such as the Adult hospital atria and the Children's central concourse with views out to the park, Radio Lollipop and the circular medi-cinema. Whilst others such as the multi faith centres and the consult / interview areas respect the privacy and dignity of patients and visitors.



Bedrooms areas in the Children's and Adult hospitals are designed to have all bedrooms outward looking over the landscaped parks and the wider views of Glasgow. Due to this clear design strategy there are no instances where a bedroom overlooks another bedroom. The use of interstitial bathrooms helps provide a shallow plan and regular shaped rooms but as each room has a window and glazed screens for observation it also ensures that light and views through into the corridors is maximised. Nurse bases are areas where natural light is further maximised for the benefit of patients and staff and on the Adult ward tower a connection with the inside and outside is continued with floor/ceiling glazing at the end of the ward corridor

Brookfield

Entrances

Adult Hospital Atrium

The entrance may be the starting point for your journey but the atrium is the place where you really start to orientate yourself, to contemplate, to experience a sense of wonder. The atrium is the centre of the Adult hospital. Its internal form not only provides the primary circulation routes for patients and visitors but in its style and form act as the canvas for the interior design strategy which with the use of specialist lighting will change throughout the day and seasons. At the lower levels the area will act as a hub providing routes to and from departments or circulation cores as well as areas for retail and dining. We have designed different levels of social space with both interactive and quiet spaces. If it is dull outside it will never be dull inside and it provides the perfect opportunity for exhibitions, community events and generating a sense of occasion.

Children's Concourse / Atrium

This is designed as an internal street linking both the inside and outside and the vertical circulation cores. Think of it more as the yellow brick road rather than a clinical street. Three-four storeys in height and top lit throughout its length it terminates at the second core opening out into the central courtyard. At a minimum of 15m wide the ground floor space is kept interactive by integrating the OPD waiting spaces. The floor plates above are curved to provide interest and will be coloured along their leading edges either with physical colour or imaginative lighting which, like the Adult atrium, can change with the time and seasons. Flooded with light and artwork on different plains this will be a magical space for visitors and children to recuperate.

Brookfield

Finishes - Building Envelope

The materials for the external envelope of the hospital have been chosen for their looks and contribution to the whole, for durability and for the ability to maintain a high quality of appearance with very low maintenance for the desired lifespan of the building. The design team have investigated several alternatives for elevational materials. As the design has developed it was clear it was not necessary to generate overt animation and interest in the facade rather a less is more approach. A carefully chosen palette of high quality, familiar materials will provide a calm, sophisticated supporting texture to the building forms.

The proposals are divided into three distinct elements, as already stated and as such, the material strategy varies for each as follows:

The tower is conceived as a glazed element, with a smooth continuous 'skin'. This approach is consistent with the continuous ribbon-like layout of the ward templates and also ensures that varying lighting/daylight/weather conditions can be exploited. A unitised curtain walling system is proposed offering advantages in construction and programme but also in consistency of detail.

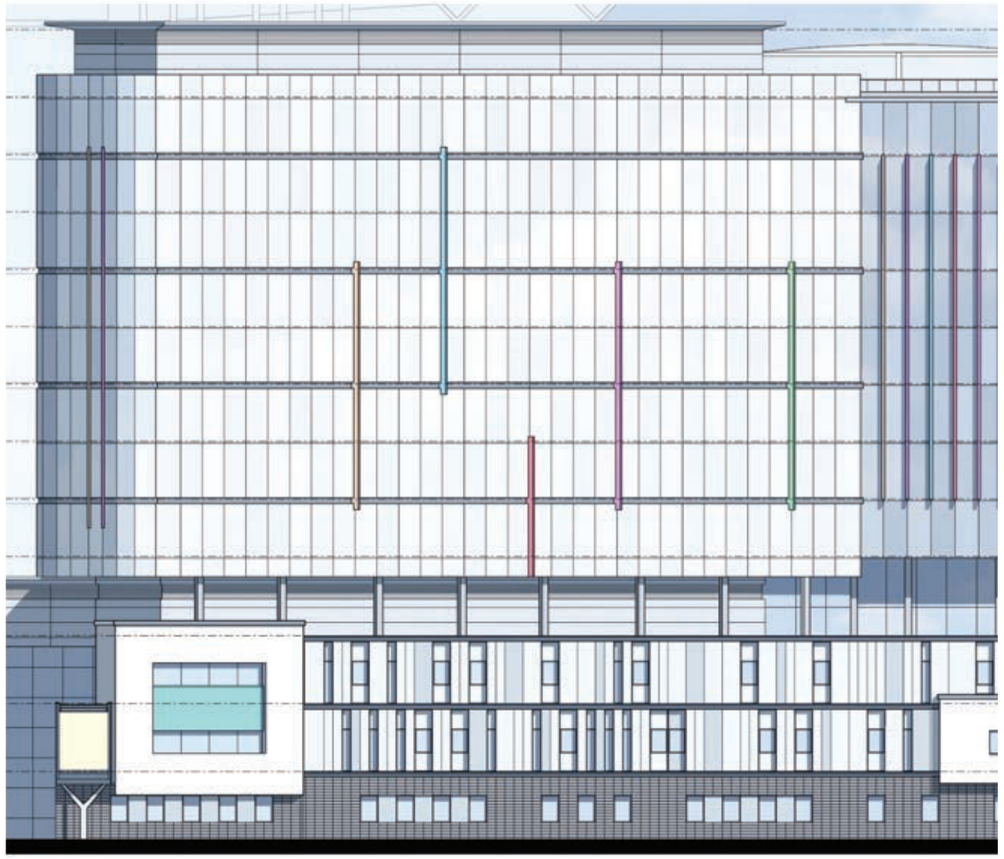
The podium is conceived as a vertically layered form consisting of a lightweight, panelled upper section sitting upon a solid, robust masonry plinth. The plinth is treated in a manner that will accept a higher degree of public contact and interaction and allow ease of maintenance. The upper floors shall be either full height high pressure laminate panels or full height double glazed units (obscured with opaque glazing where necessary). Floor/roof parapet steel channels separate the floors and reinforce the horizontal emphasis. Interest and variety is introduced by occasional small bay projections and expression of plant/ ventilation elements.

Given it will be viewed by the majority of the occupants of the Adult ward tower, the expression of the podium roof is critical. Large areas of roof planting is proposed – either as sedum or as a more fully landscaped, accessible roof terrace adjacent to the Children's hospital (third floor), providing a dedicated therapeutic amenity space. Other roof areas will consist of high-performance single-ply membranes, ballasted/paved as necessary.

The drive to ensure a separate identity for the Children's hospital suggests a similar approach to material selection. The Children's hospital is conceived as either a large, white vessel or a giant piece of confectionary. Accordingly, the simple use of white through-colour render is suggested as appropriate. A more robust masonry element is proposed for the base with a range of window sizes and heights introduced offering views for all age ranges of building users.

The roof of the Children's hospital will also be visible from the tower. The intention is not to introduce over-elaboration to the roof purely for aesthetic purposes and hence it is treated as a simple continuous form. Ribbed single ply membrane in a subtle colour, plus the expression of lift cores and ventilation cowls mentioned previously, will provide adequate rhythm, pattern and interest when viewed from above.

Courtyards are also proposed as simple, white rendered spaces in order to maximise the potential for reflected daylight. Careful detailing and consideration of aspect and wind direction will ensure that the potential for staining to render is eradicated.



Partial Elevation of Tower/podium

The glazing is proposed to extend past the uppermost roof level and the soffit of the lowest tower floor, forming a balustrade at roof level and reinforcing the impression of cladding as 'skin' at lower interstitial level. This detail stops at the junction of the tower wings with the main body where at roof level a small eaves is introduced. These measures help to sub-divide the form and scale of the tower, introducing a hierarchy whilst remaining consistent with the concept of a continuous horizontal ward-planning approach.

Brookfield

Infection Control

Research and investigation have consistently confirmed that the healthcare environment is a secondary reservoir for organisms with the potential to infect patients. As such we have ensured that infection control principles are incorporated in our design, drawing on national guidance – particularly 'infection control in the built environment: design and planning (HFN30).

The key control of infection features of our scheme are outlined below:

Sizing, Space and Innovation

- Bed spaces of at least 3.6m in multi bed bays (our cruciform beds have minimum 6m spaces), with a maximum of 4 beds per multi bed bay.
- Provision of 100% single beds in the Adult Hospital including critical care and assessment wards.
- Provision of adequate sanitary facilities. En-suite shower/wc/wash per single bedroom: separate en suite facilities per multi bed bay.
- Single bedrooms are sized to ensure a variety of treatments can be undertaken at the bedside and these rooms and wards are generic so that patients movement is not required other than if critical care facilities are needed.

Partial Elevation of Children's Hospital

Isolation Rooms, Single Rooms

- Provision of a high proportion of ensuite single bedrooms as identified above.
- Provision of isolation rooms within each ward.
- Isolation rooms have lobbies with integral clinical hand wash facilities.
- The design of isolation lobbies complies with the latest HBN04 (supplement 1), eliminating the need for positive and negative pressure switching.

Sanitary Facilities, Clinical Sinks, Hand Cleanliness

- Quantities of clinical handwash basins complies with HFN30 (one per single bedroom, two per four-bed bay, one per critical care bedroom, one per consult exam.
- Procedure rooms as a rule have, as a minimum, a clinical handwash basin, or- where appropriate a scrub trough.
- Clinical wash basins are equipped with thermostatically controlled, single lever action taps; spray taps are not to be used.
- All areas where clinical activity are undertaken are provided with hand rub solutions, positioned at the point of care and within all staff utility rooms.
- Glove and apron and antibacterial solution dispensers will be provided outside any room which accommodates a patient bed, trolley or reclining chair.
- Clinical hand wash basins located so they are clearly visible when entering a room.
- Provision of clinical hand wash basins at entrance to each ward.
- All doors used by visitors and patients for personal hygiene are provided with doors capable of release from outside in case of collapse behind the door.

View of Adult Acute Single Bedroom

Brookfield

Ancillary Areas

- Separation of clean and dirty processes within clinical areas.
- Ledges and ridges will be minimised in the design to avoid dust traps.
- All hot water will be delivered within safe working temperatures (i.e. Maximum of 43 degrees centigrade), and complies with ‘safe’ hot water and surface temperature guidance.
- All generic sanitary ware will utilise pre plumbed units.
- Theatres are designed with ultra clean ventilation and engineered to ensure air pressures are managed to minimise the risk of airborne contamination.

Storage

- Patient bedrooms are provided with locker and wardrobe space.
- Domestic cleaning equipment, laundry and clinical waste is always stored in purpose-built spaces to prevent cross contamination.

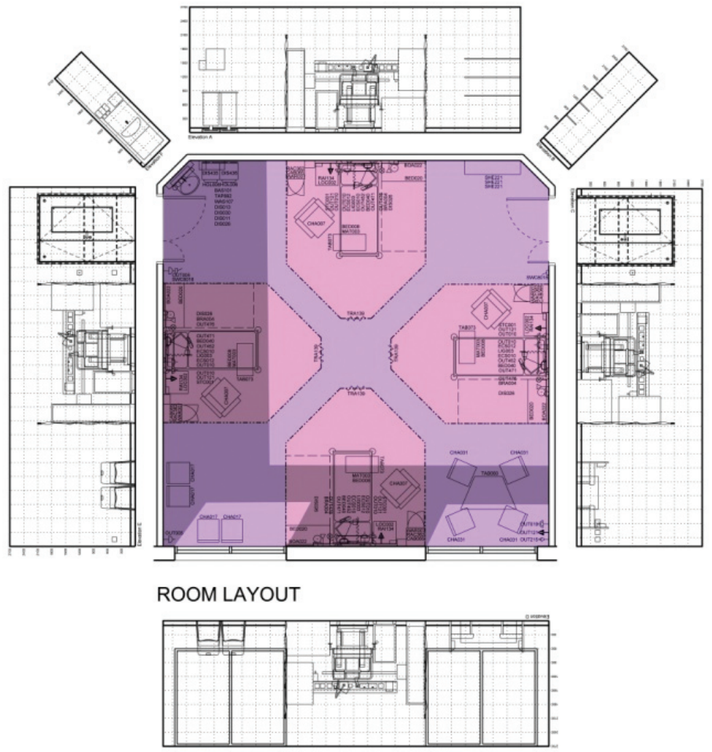
Finishes

- Finishes comply with HTM56 guidance and facilitate easy cleaning. In clinical areas, all finishes are seamless and impervious. In areas where joints are permitted, these are sealed/welded to prevent water egress, skirting boards are sealed.
- Where appropriate all details and fixtures and fittings will be designed and reviewed to ensure dust traps are kept to a minimum.

The Board’s brief has encouraged an innovative approach to the design of the new hospital. We believe we have responded to this by including many innovative design features covering a wide spectrum of disciplines.

Inpatient Wards

- The inpatient block epitomises the innovative approach to the hospital design. Each ward is built around the fact all bedrooms for Adults are single with interstitial bathrooms all outward looking giving the following benefits:
- Regular shaped room for maximum efficiency and the ability to incorporate ‘H’ shaped ceiling mounted patient hoists if required
- Excellent observation from corridors through glazing, plus optimised views and natural daylight.
- Short travel distance from bed to bathroom with access via double doors to aid patient access in any difficulty.
- Flexibility, all wards can be flexed in terms of size upwards or down from 28 beds as required as each ward abuts an adjacent ward with nothing in between.



Plan of 4-bed bay

Brookfield

4 Bed Bays to the Children's Centre – an Innovative Approach

- Off set bays for improved privacy.
- A separate Ensuite adjacent to the ward providing privacy.
- Good staff observation into the bedroom.
- Maximum bedhead separation well in excess of the HTM for control of clinical infection.
- The cruciform arrangement allows for inclusion or privacy for all patients should they desire.
- Integral day spaces for teaching or rest periods.

Facilities Management

Our proposals have been designed for optimum functionality across a range of conventional and more innovatory systems for distribution and disposal, giving the Board a high degree of flexibility in the delivery of FM support. Automated Guided Vehicles will be used to deliver and collect various items to predetermined locations throughout the development. Whilst AGV technology is not new it has rarely if ever been used in UK hospitals. Requiring no fixed track and fitted with collision detection systems the AGV systems can be easily expanded if the Board deem them beneficial.

Perspective View of 4-bed bay

Automated Guided Vehicle

Brookfield

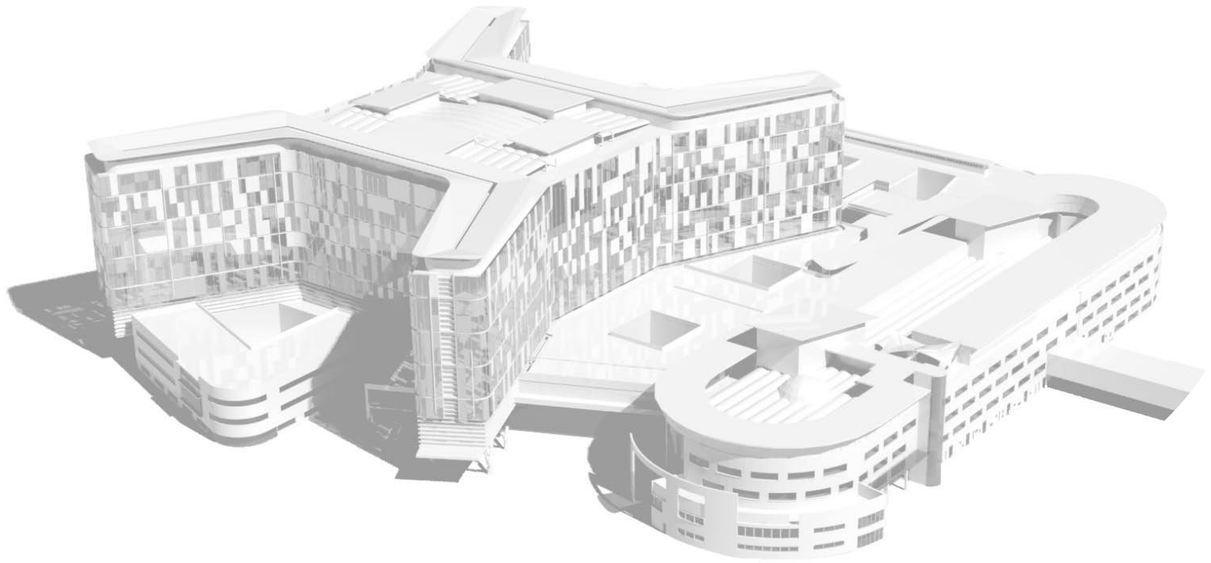
Summary

The resolution of our proposals has only been possible through the dialogue and engagement that has been offered to us by the Board. We have listened, we have understood and we have responded. Such close dialogue is critical in the success of any project and in this case has been instrumental in our ability to arrive at the solutions presented. We thrive on such dialogue and see this as an ongoing activity through the life of the design phases to come. There are many opportunities to enhance the already successful features of the design proposals and we would relish further engagement.

The conception of our design is based on a simple approach: a strong master-plan upon which a simple architectural proposition is imposed. We have designed from the inside out. Clinical effectiveness, flexibility and innovation is married with, but not dominated by architectural flare and expression.

This perfectly balanced building will deliver exemplary healthcare facilities, enhance the Board's profile and provide a lasting legacy of which the whole community and Glasgow can be proud for many years to come.

WAYFINDING STRATEGY

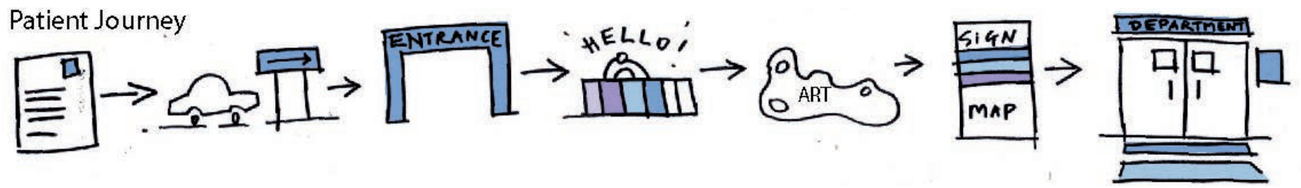


Brookfield

Contents

Brookfield

Introduction to Wayfinding



The design proposal for the New South Glasgow Hospitals is underpinned by the need for effective wayfinding to facilitate the diverse functions of the new facilities. The design process has been tested at each stage to ensure that design decisions support operational demands. Wayfinding refers to the movements around the hospital which will be made by staff, patients, visitors and for servicing and equipment.

The goal of the design process is to deliver a high quality healthcare environment which is as user-friendly as possible for people to use, whether for the first time or all the time. This means that journeys to particular parts of the hospital should be as easy to understand as possible and that regular journeys should involve the shortest practical distances for travel. The wayfinding strategy addresses orientation and movement at a variety of scales and ensures that movements can be based upon logical but ultimately intuitive decisions. Clear wayfinding has underpinned the design process in order to make the design as clear and robust as possible.

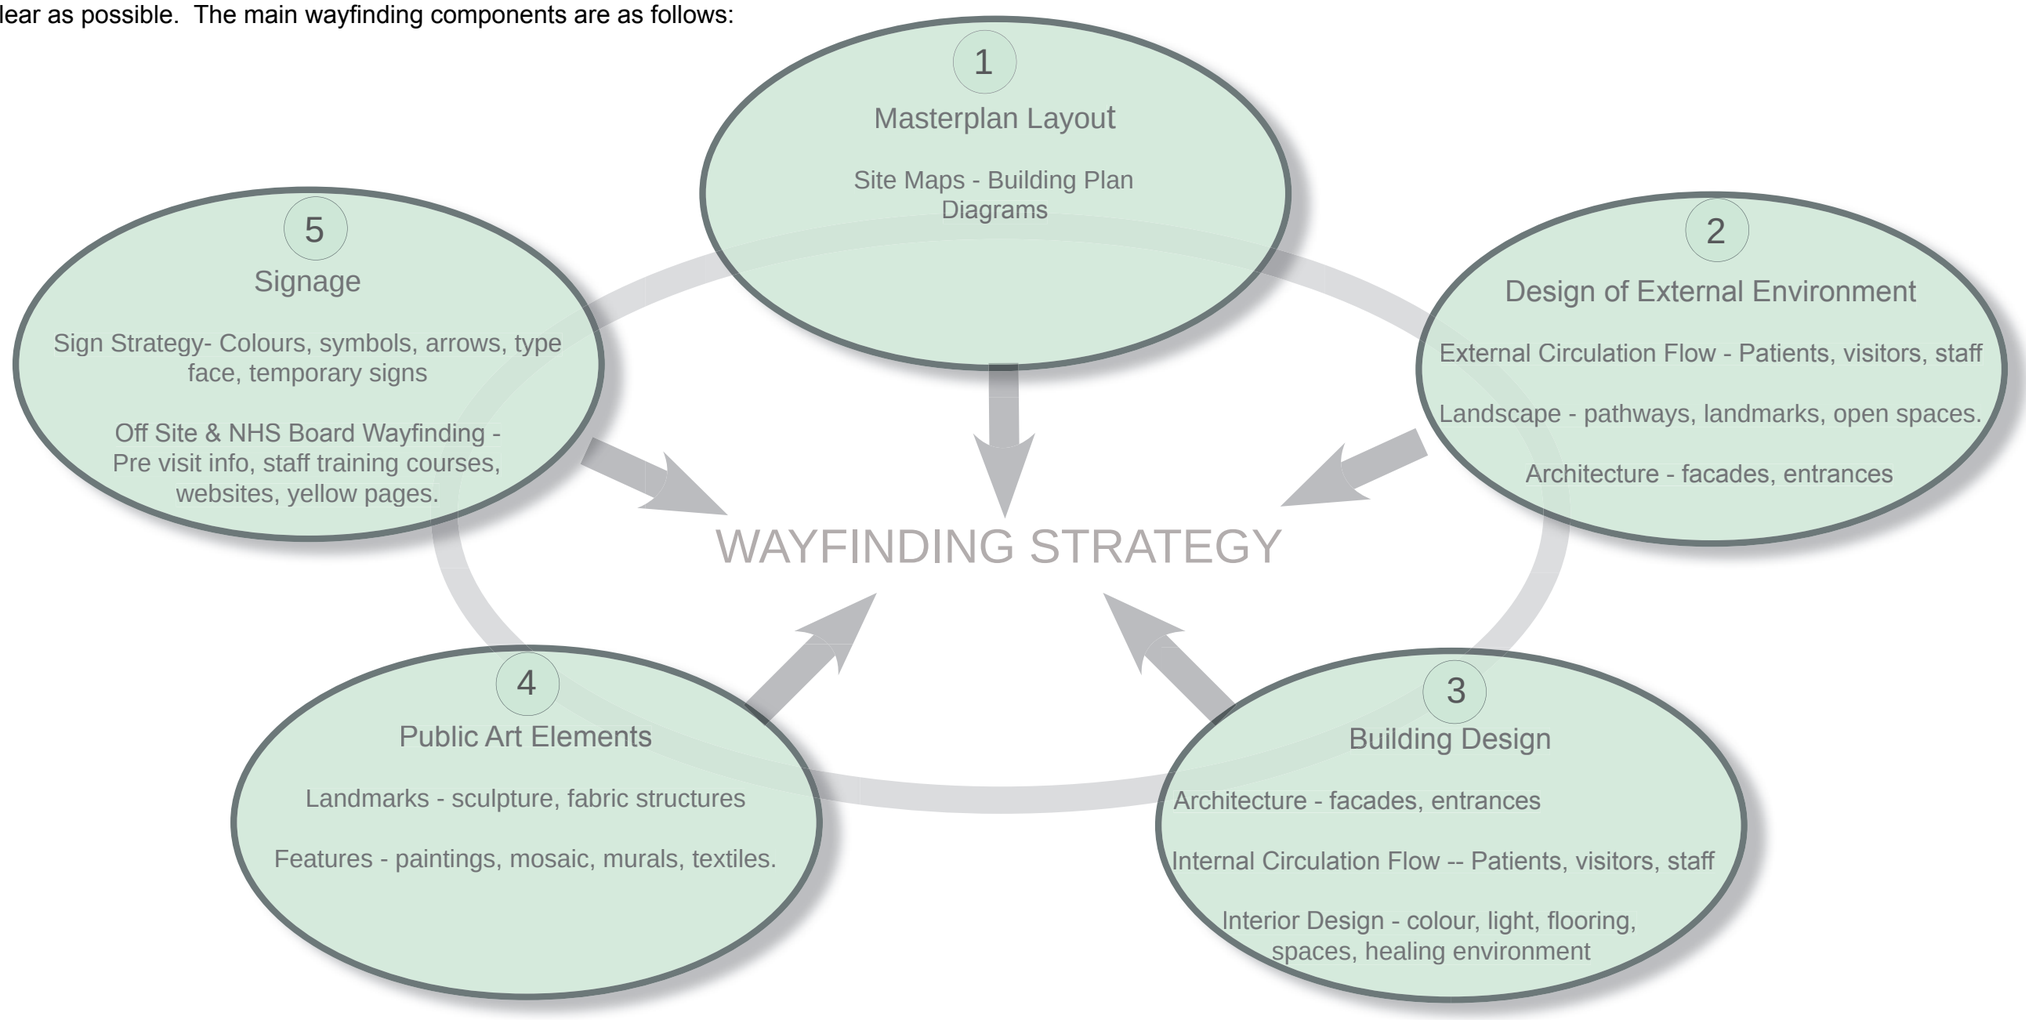
Brookfield

Principle Components & Hierarchy of Wayfinding

Wayfinding within the new hospital environment has been considered in response to a recognised hierarchy of movements and orientation decisions. It is the effectiveness of the decisions made by visitors (or other hospital users) during their journey(s) which will determine the success of the wayfinding. Wayfinding decisions are related to the following hierarchy, which captures the key decision points in hospital visits:

- Sub-regional location, profile and identity
- Access to location from within the city & local environment
- Site entrances
- Access to the various building entrances
- Site circulation
- Orientation within buildings
- Departmental orientation

A number of elements within the design process influence the effectiveness of the wayfinding and many of these overlap in the ways in which they strengthen the legibility of primary routes and make destinations as clear as possible. The main wayfinding components are as follows:



Brookfield

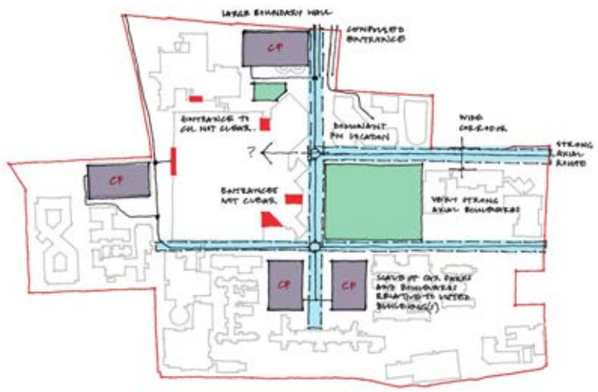
(1) Masterplanning

The masterplanning process has defined the layout of the site and established the position of the various buildings and the routes between them.
The position of the building entrances has been defined in response to the main approach along the entrance boulevard from Govan Road.

This means that the position of the entrances is clear as soon as possible within the site. Cars, buses, taxis, cyclists and pedestrians all have simple and direct access to the entrances.
The design of the entrances to each building makes them clearly identifiable and user-friendly.

The masterplan has also defined clear routes to entrances from car parks and other buildings. With the exception of accident and emergency, the building entrances for the new hospital are all sited within a new arrival square. This provides a clear and distinctive point of arrival which is clearly identifiable and is different from the approach roads. The masterplan has defined a clear separate route to the dedicated entrance for accident and emergency.

1. Exemplar Design



2. Site - Exemplar Evaluation & Critique

3. Re-Massing for better masterplanning & Wayfinding

4. Circulation & Spatial Analysis & Refinement

5. Urban Design, Green Space Potential

6. Masterplan Defined

Brookfield

(2) Design of the External Environment

The core wayfinding principles which underpin the definition of the site layout (the masterplanning) are robustly supported by the design objectives for the external environment.

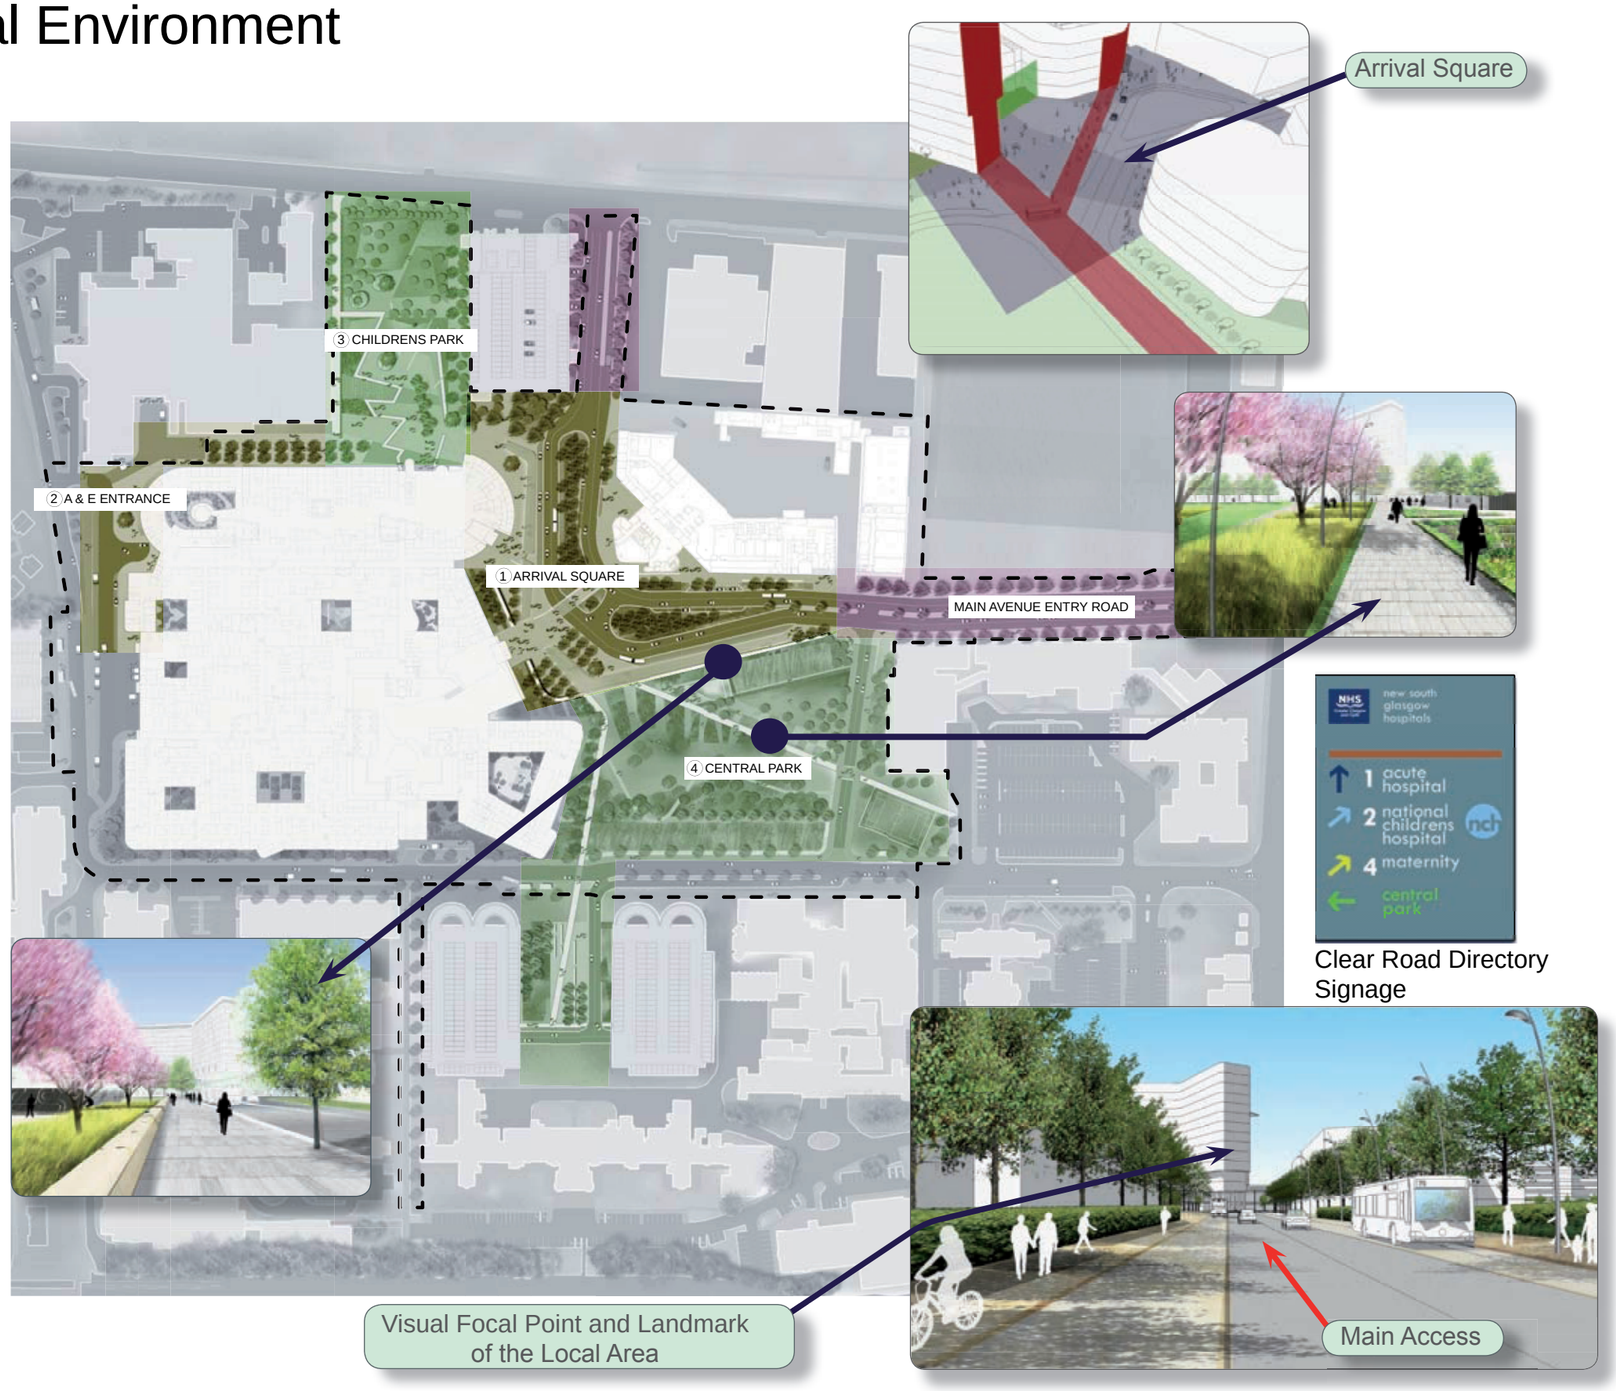
The masterplan structure is represented in the design of the external spaces as a clear hierarchy of open spaces. These include the arrival square, central park, children's park and main boulevard.

The core objectives of the public space design are the creation of a cohesive high quality green campus environment for the new hospital facilities and definition of a diverse range of well considered public spaces to establish an approachable and identifiable high quality character for this significant civic resource.

The new parkland campus environment is arranged around the hub of the arrival square, with clear and legible connections provided to all areas from this logical point of arrival.

This square functions as a transport hub as well as being a designed heart to the campus.

Within a short distance of the arrival point there is access to primary entrances, car parking, park and play areas, seating areas, the external cafe and public transport.



Clear Road Directory Signage

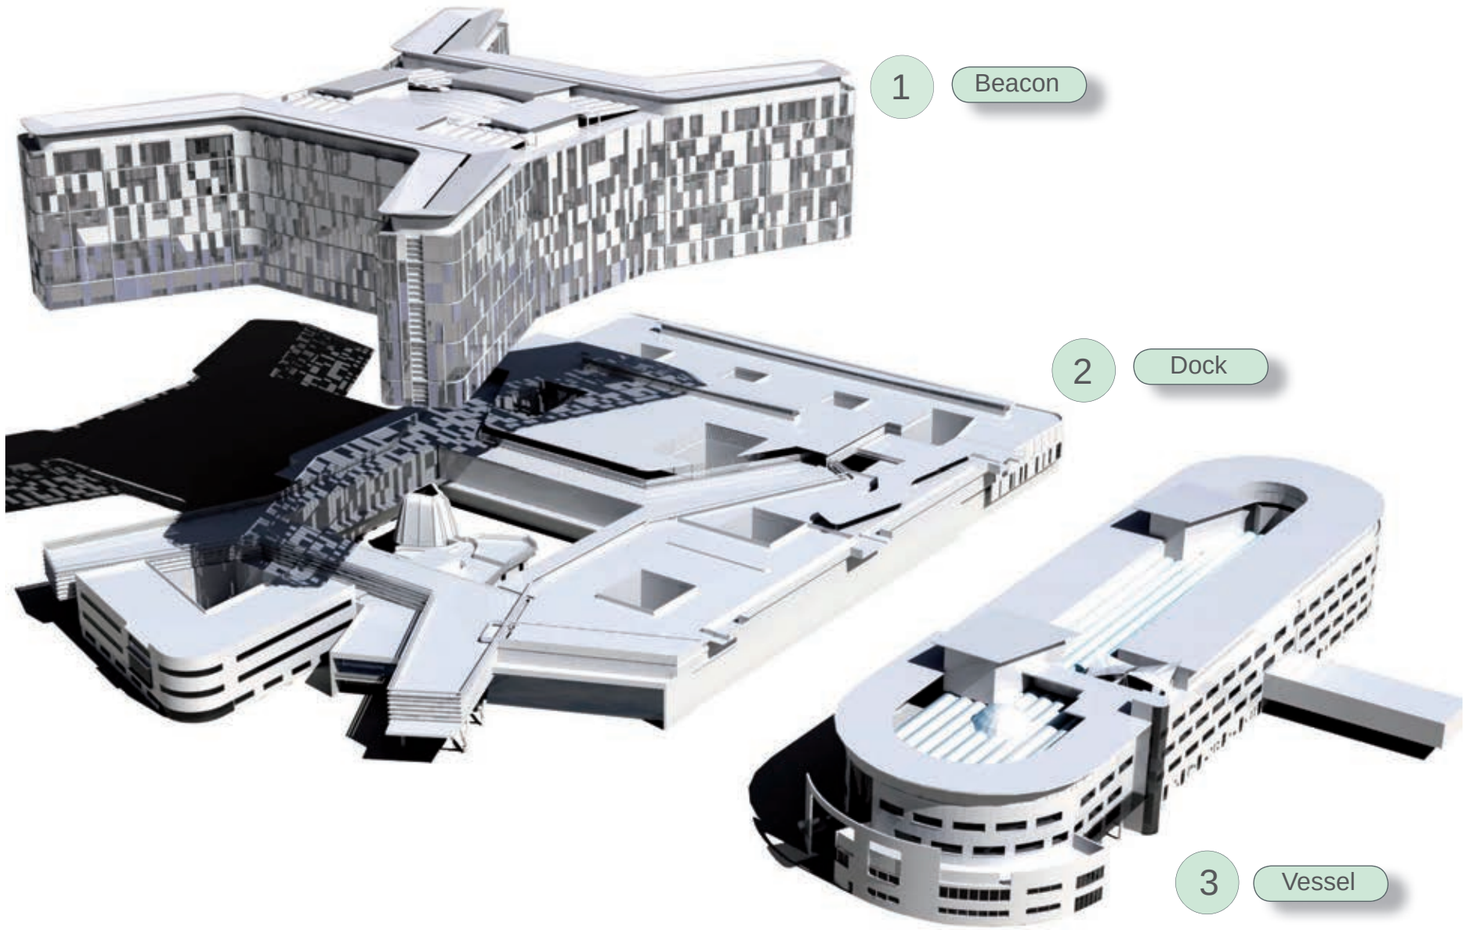
Brookfield

(3) Building Design & Central Theme

The design of the form of the buildings is a significant tool to aid wayfinding and make orientation as intuitive as possible.
The beacon character of the ward tower will create a local landmark. The form of the tower and its relationship with the arrival square provides a clear link between the form of the building seen from beyond the site and the journey to the main entrance.

The design of the New Children's Hospital is based upon the creation of a distinctive building within the site. The design provides this building with a unique identity and an appropriate character and this supports effective wayfinding. Elements of the building design, in the form of materials, colours and motifs are also to be used within the external environment and as a key to internal wayfinding.

The effectiveness of internal wayfinding is a driver for the design of the buildings and a wide range of operational movements are supported by the layout of the public and clinical areas and their relationships. Internal wayfinding is supported by a range of public art interventions which create a sense of place and identity within the buildings.



The Beacon or tower is reminiscent of a wharf building. The tower design also references the propeller of a boat.

The Podium, whilst taking visual cues from medical sources such as DNA also makes reference to the many fine Glasgow parks with its sensitive use of green & landscapes roofs and pockets of naturally lit courtyards.

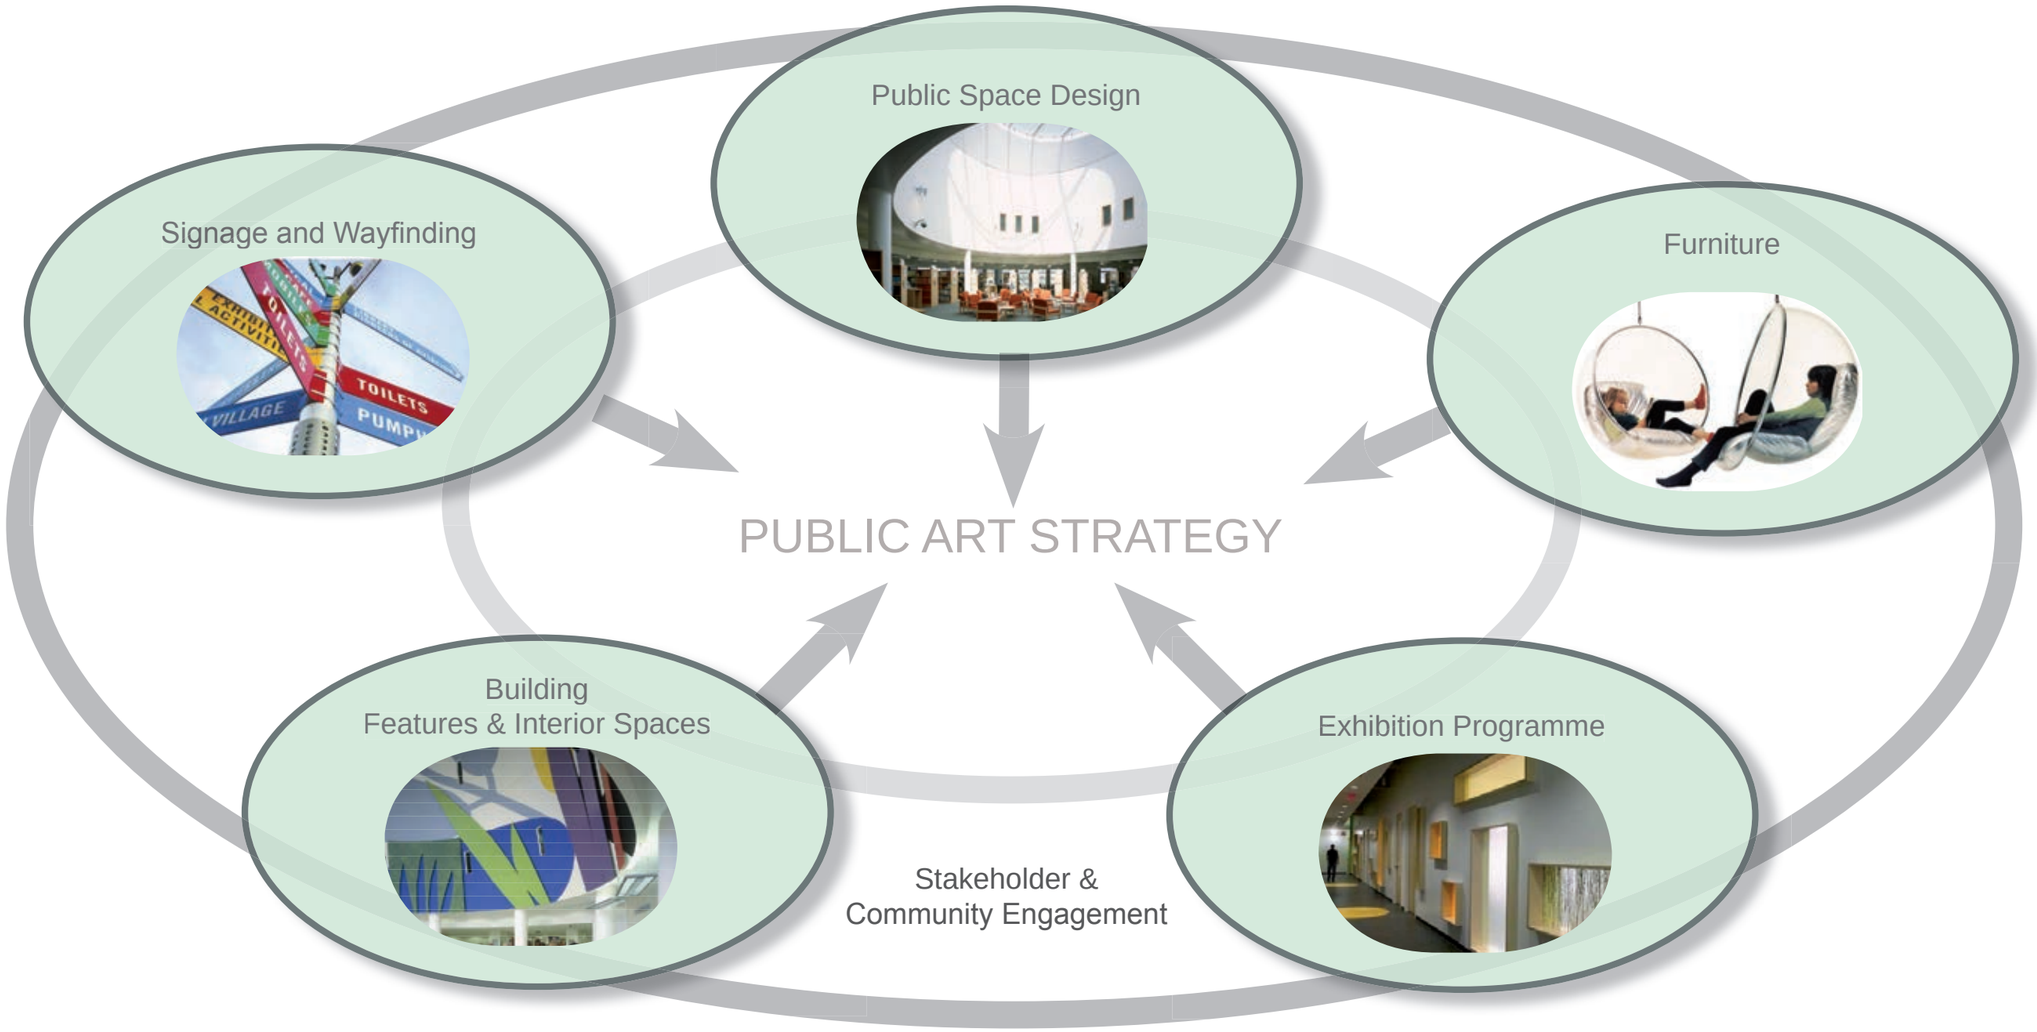
The Childrens Hospital can be related to a vessel hugging the dock. It is treated as an independent form and references a range of influences including maritime, medical and even confectionary.

Brookfield

(4) Public Art

Public art will play a significant part in defining a distinctive character for the hospital and in creating an approachable centre of excellence. Creative expression is an established part of the design process which has already influenced the masterplan and the design of the external spaces. Creativity will add richness, colour and fun to the wayfinding process through the use of themes and motifs derived from community engagement.

The distinctive character of the New Children's Hospital offers particular opportunities for engagement with specific user groups and local schools to define a unique place with functional wayfinding elements developed as creative elements. Creative expressions within the design of the building fabric will create distinctive features which in turn are recognisable and create landmarks to aid orientation. Some examples which have been proposed include the main reception desks, structural elements and canopies within the building entrances, elevated coloured pods and lighting within the main atrium, creative design touches embedded within the design of ward rooms, external furniture and the design of internal walls. Signage will also be treated creatively and is intended to be defined with community input. Many of these proposals will be developed further during stage 2 when firm community engagement can be developed.



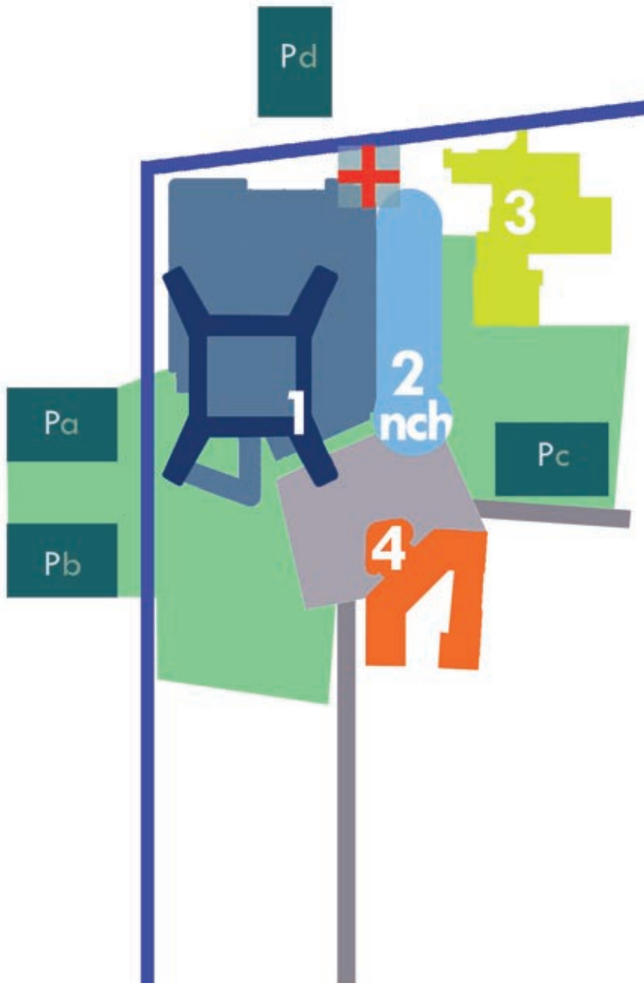
Brookfield

(5) Signage

There is a considerable overlap between public art and signage, but effective functional signage will also be provided to support the core functions of the hospital facilities.
This functional information will be supported by the creative use of colours, forms and imagery internally and externally and with specific regard to differentiating between different areas and moderating the significant scale of the hospital buildings.

The character of the wayfinding components has a big impact upon the quality and the feel of the environment. A legible place is much easier to use and this creates a better and more successful environment for staff and for visitors. The setting of the buildings, the use of colours and familiar forms communicates a favourable character for the hospital.

Example of Branding and Identity



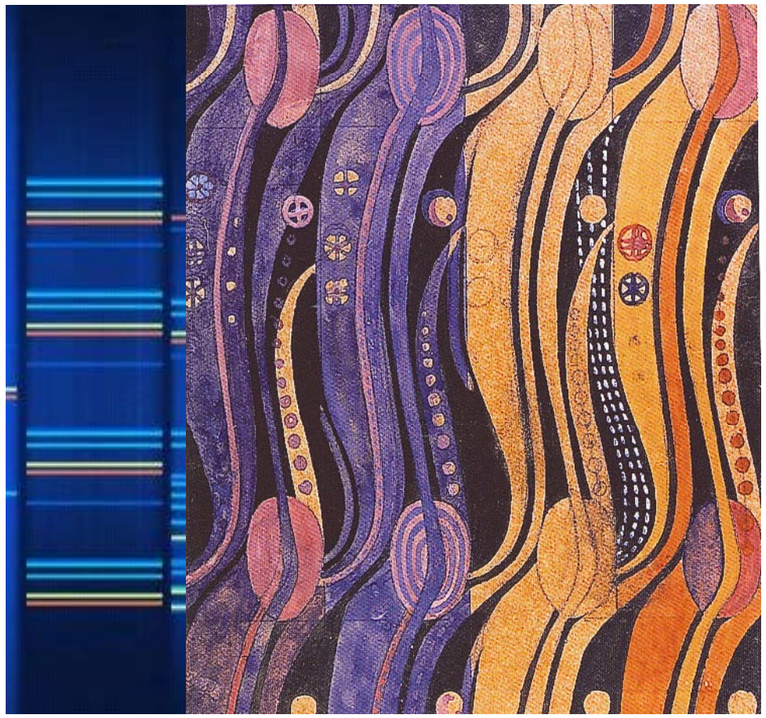
Example of External Building Location Map

Brookfield

Design Inspiration For Wayfinding

The aim of the wayfinding and interior design strategy is to create a positive and therapeutic environment for patients, visitors and staff. This is achieved through careful consideration of materials, lighting, colours, art, views and space.

- **Materials** will be chosen carefully to offer a range of textures and hues to help create subtle back drops and a strong identity to each level and/ or department.
- **Lighting** not only provides general illumination to assist way finding and security but also highlights features and art.
- **Colour** is one of the key aspects used in the way finding strategy. Colour will also be used to help evoke feelings of calmness, tranquility, energy and healing in the appropriate spaces.
- **Views** link the inside of the building to the outside landscaping and surrounding area. A view from inside a room promotes wellbeing, helps locate people and brings in natural light. Views also provide wayfinding by informing people of their location relative to natural light via atrium space, courtyards and lightwells which occur in hospital streets and public spaces.
- **Spaces.** Throughout the building spaces range from intimately scaled rooms and zones to large public areas. Courtyards and large atrium spaces punctuate the main body of the building and draw daylight into key patient rooms and corridors.



Brookfield

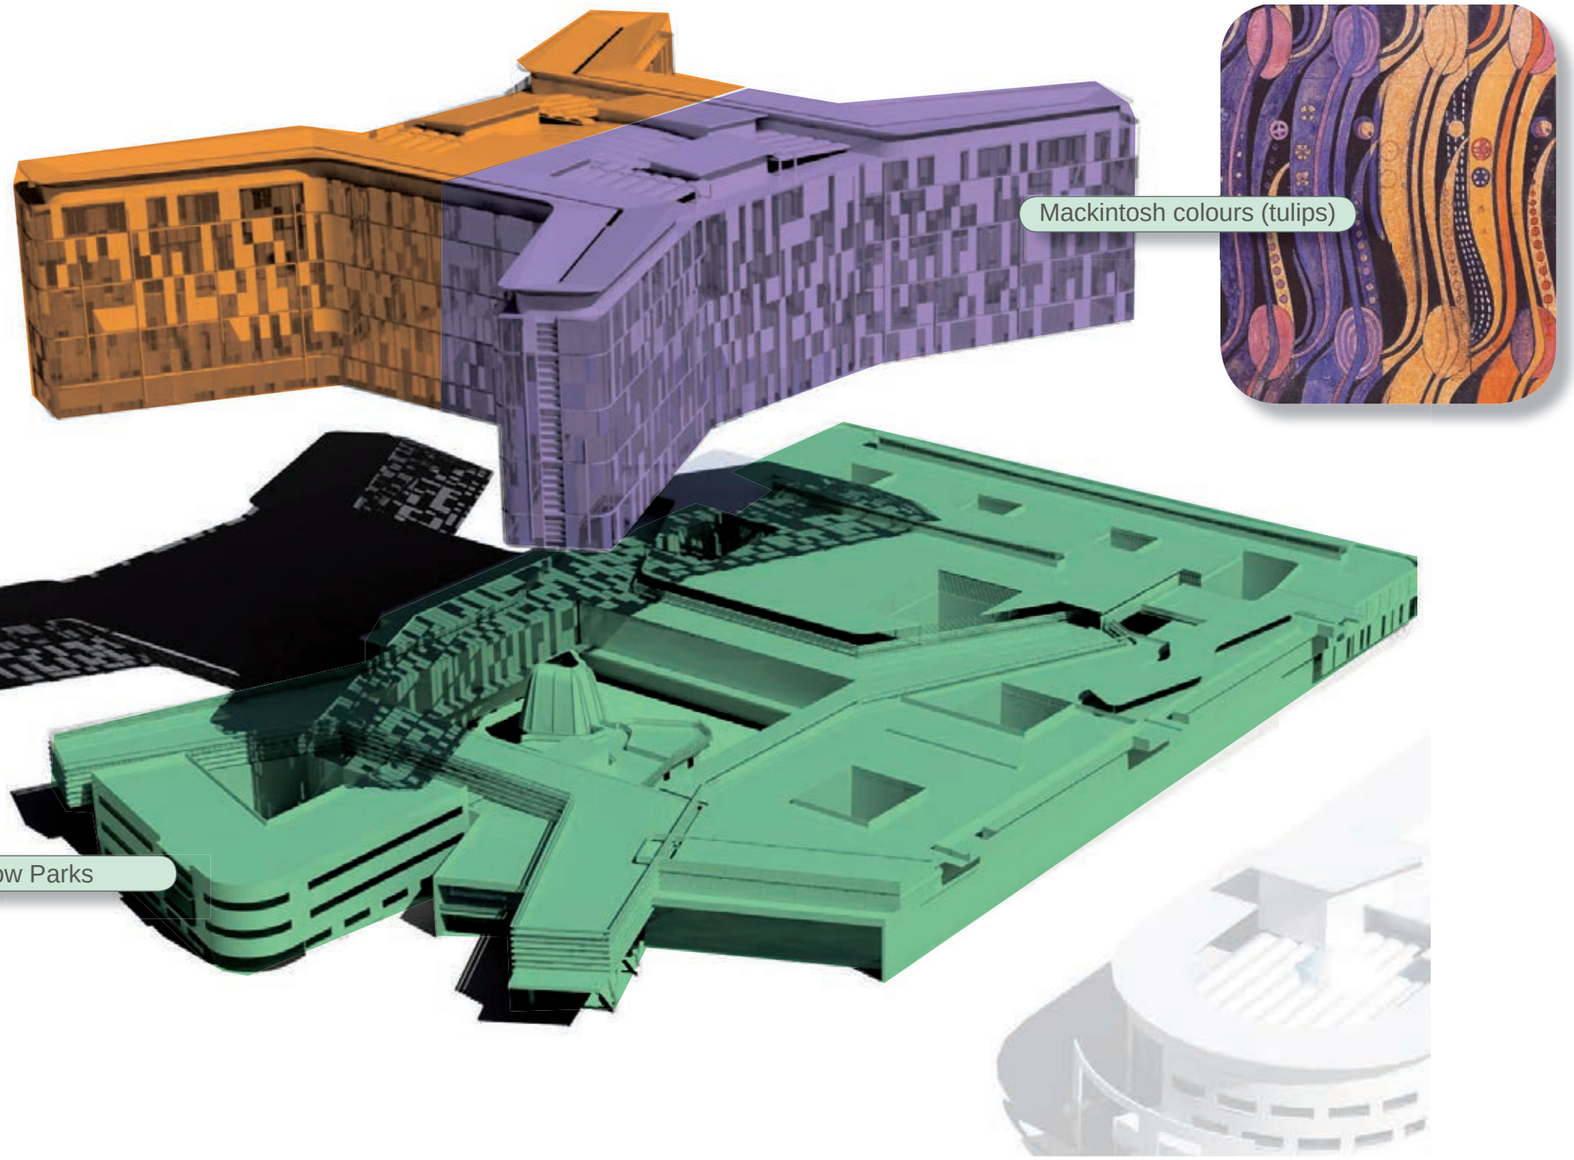
Internal Colour & themes - Adults

The Adult Acute Hospital based on the large dock buildings and the plan of the city and it's parks.

The colours that have been chosen for the internal zoning of the tower reflect those of Mackintosh's Tulips.
The colours for the Podium reflect that of the parks and landscapes of Glasgow.

The colours are carried out throughout each zone via interior design and wayfinding. The colours are also used externally drawing the outside into the building and form part of the way finding strategy.

Each inner public core of the building has it's own colour which can be easily identified. One orange core and one purple core.



Mackintosh colours (tulips)

Glasgow Parks

A48235836

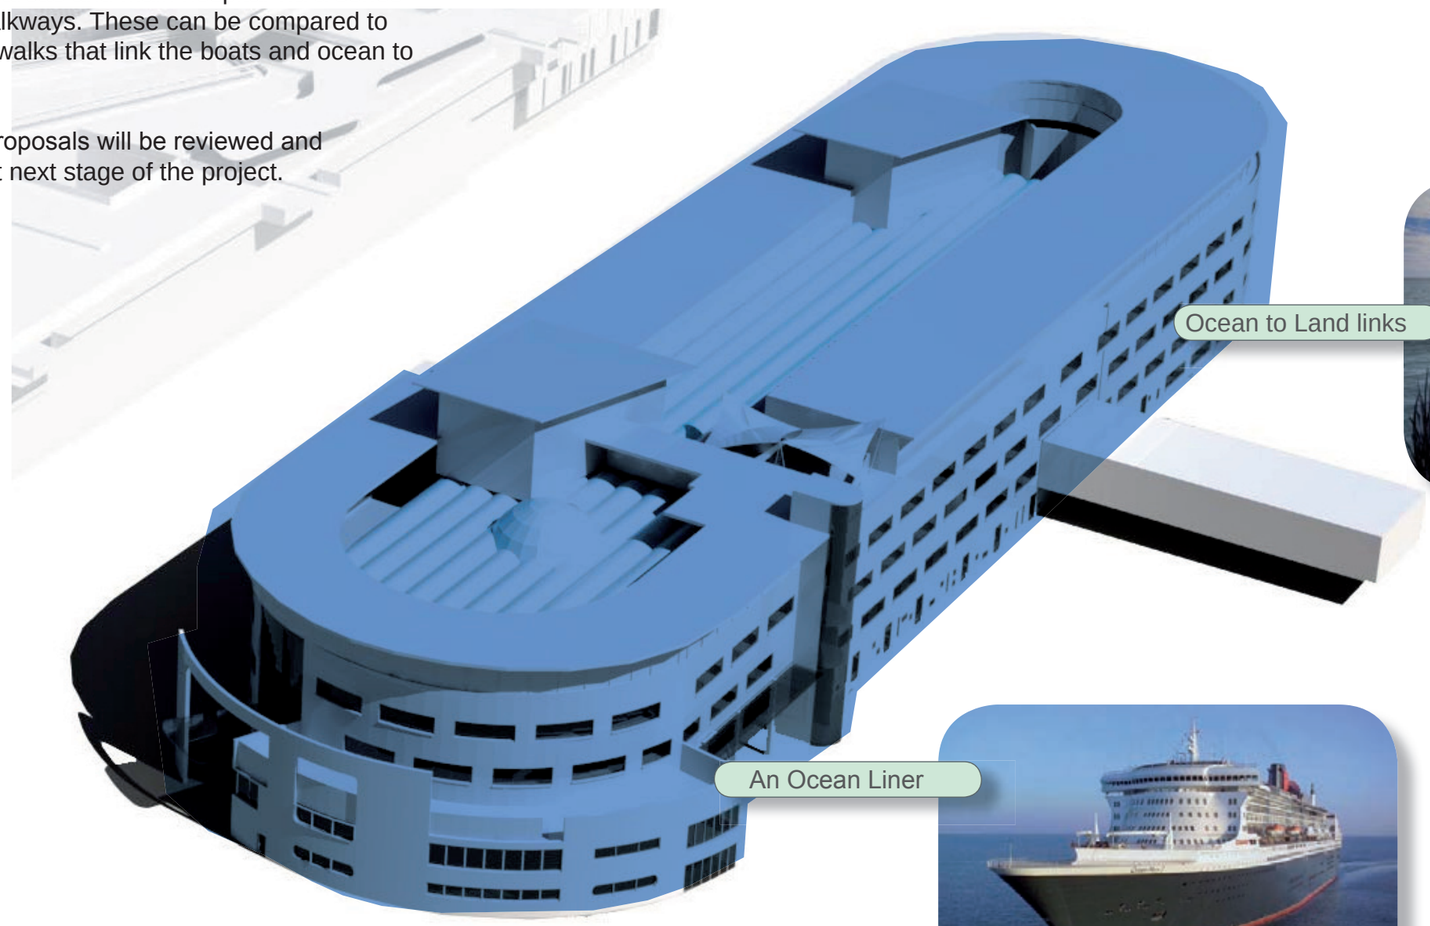
Brookfield

Internal Colour & themes - Childrens

The theme of the ocean, boats & Glasgow ship industries are carried through the interior of the building via the wayfinding colours: blues, whites and greys.

The childrens hospital is linked to the surrounding spaces eg. carparks, green areas and main hospital via a series link bridges and walkways. These can be compared to the piers and boardwalks that link the boats and ocean to the land.

These wayfinding proposals will be reviewed and developed further at next stage of the project.



Ocean to Land links

An Ocean Liner

Brookfield

Building Entrances

There are 3 entrances to the building, the main adult hospital entrance, the main children's hospital entrance and the emergency centres entrance.

Each entrance has its own identity and will have clearly marked signage throughout the hospitals campus and on all main vehicle routes to the hospital.

Patient Journey - Generic

I need to visit the hospital. I have not been before.
What time do I need to arrive?
Which mode of transport shall I use to get there?
How long will each one take?
How much time should I allow for the journey?

I am unwell, so will be taken by a friend.
I have decided to travel by car. I know I can park at the hospital, but as I have not been before I do not know where to park.

I can see the hospital from a distance as it is a recognisable and distinctive landmark.
I can see the hospital from a distance as it is a recognisable and distinctive landmark. I can also follow the road signs.
Where is the entrance to the site? I follow the signs and the entrance is easy to find.
The hospital entrance is clearly visible from the entrance road. My friend follows signs to the entrance to drop me off at the front door.

We drive beside a park and the road is lined with lovely trees. Shadows flicker over the car. I enter through the adult hospital entrance.
I have noticed that buses also come to the front door, so I may come by bus next time.

Inside the entrance there is a big reception desk and also signs to some of the main areas. The lifts are nice. They are different colours and the music is relaxing.

The hospital is a huge building. I have no idea what happens in all those rooms. The part that I am familiar with is a friendly place, with really colourful walls. There is always something different to look at on the walls.

After my treatment I am due to meet my friend in the café in the park (which we passed on the way to the main entrance). If it is raining we will meet in the café in the entrance area (the one in the big space with the coloured pods and interesting lights). I can look out of the window and watch people walking through the park.

I have dropped my friend at the front entrance to the hospital. In have helped her inside and I am now going to park my car. I can see the car park signs and the walking route from the car park to meet her goes through the park. I will wait for her in the café as I can see the new pictures from the local primary school. A couple of months ago my grandson painted a picture of me and it was displayed here for a while. I also prefer to wait here and enjoy the park on a nice day.

I need to visit A&E. There is a clear entrance for this and I can drive straight to the door. I can then park my car. I can see the signs to direct me to accident and emergency

Masterplan External Wayfinding Strategy & Interactive Information Points

Interactive Information Points
wall mounted and/or freestanding

2D Intelligent wayfinding technology which offers a choice of agreed languages. Department/Ward list in A-Z format appears in preferred language on request and the department route highlighted on a ground floor plan from the location of specific pod being used when touch screen is activated. (The plan on screen will be identical to the plan on the main A-Z wayfinding guide for continuity). The highlighting will indicate either the route to a department if on ground level or to lift/stair core if on upper floor. If upper floor is requested then the appropriate floor will superimpose on the screen indicating use of lift/stair, and then the final destination is highlighted on the upper level plan.

Brookfield

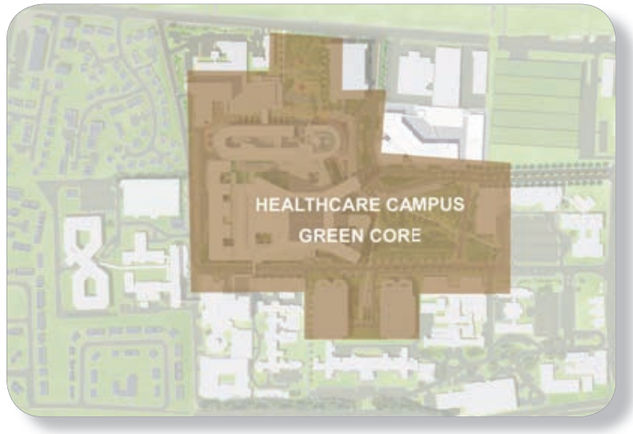
Wayfinding & Identity

Wayfinding is greatly assisted by the creation of identifiable features within the hospital campus as an aid to orientation. For this reason the integrated design process - from the initial masterplanning stage to the more considered design of the architecture, public spaces and external areas - has defined a strong and durable identity for the campus and the various built elements, spaces and places. These identities are considered further in the architectural design strategy.

This approach immediately gives specific identities to physical places within the campus. The large campus environment of the New South Glasgow Hospitals can then be understood as an identifiable whole, consisting of a series of smaller places. This clear hierarchy delivers significant benefits for wayfinding as well as giving a strong sense of place to the hospital.

The same identity principles apply within the hospital buildings and further architectural design features and public art will be used to articulate the character and identity of interior spaces.

A hierarchy of placemaking and identity has been defined to enable the form of the campus to be clearly understood as an aid to wayfinding. The hierarchy is summarised as follows and illustrated on the accompanying plans:



The New South Glasgow Hospitals – whole campus

The creation of a strong campus identity with a green heart has been defined to unify the retained areas of the site with the new buildings. This single healthcare campus will evolve and develop over time and the establishment of strong green infrastructure in the form of approachable public parks and incidental spaces is intended to establish ‘design for the future’. Design for the future has been a significant consideration in the design process to date and during stage 2.

To make the significant scale and potential complexity of the site legible further areas have been defined to simplify understanding of the place through the creation of internal areas with an equally strong identity

Brookfield

Acute Hospital

The tower presents a strong regional landmark for the new acute hospital facilities and this building is strongly associated with the central park as its setting. The tower has been designed to establish a clear contrast with the Children's hospital. The main hospital entrance addresses the arrival square and the tower is primary landmark within the sequence of three key buildings.

Children's Hospital

The new children's hospital has a unique identity derived from the architectural design. The masterplan and the design of the external spaces have also defined a specific environment as the setting for the new children's hospital, thereby creating a strong identity which will be augmented by a naming strategy for key streets and spaces. The setting for the Children's hospital encompasses maternity and neo-natal services to create a meaningful heart for the provision of exemplary services for children and young people focussed around the children's park and the connecting street. There is a strong connection between internal and external public spaces.

The creation of identifiable places will serve to create a user-friendly and personal feel to the campus. Descriptions applied to journeys can include defined places, such as 'Lollipop Lane' and 'Central Square'. Places within the campus provide identifiable landmarks at a human scale and this process will be augmented by additional wayfinding components and public art.

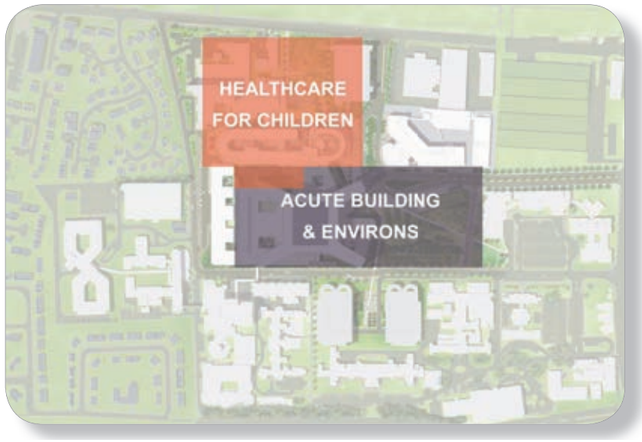
The creation of an identifiable personality for the scheme is an important step in communicating an approachable character for the project.

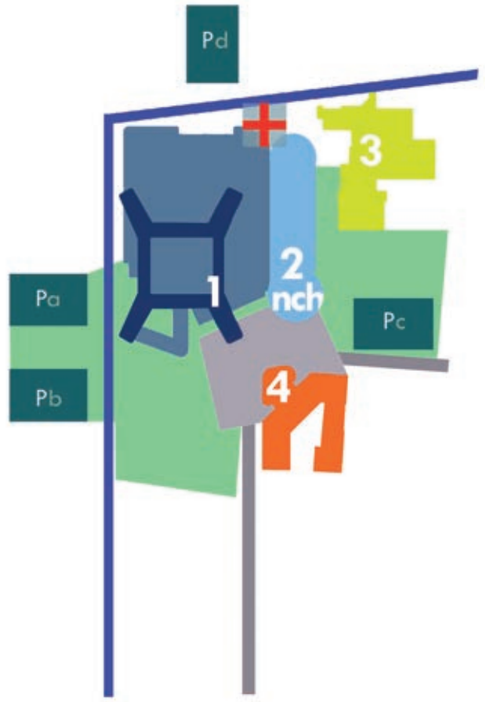
First tier identity – New South Glasgow Hospitals Healthcare Campus
Second Tier Identity – Differentiation between Acute & Children's Areas
Streets and smaller places – Parks, streets and public spaces

Some of the key identifiable public places within the campus are as follows:

Arrival Square
Central Park
Children's Park
Entrance Boulevard
Lollipop Lane

Names for each of these key areas are to be considered as part of the stakeholder engagement during stage 2.





Art and Therapeutic Design Strategy

Vision

The aim of this strategy is to outline the vision and identify the guiding principles for the role of art within the new South Glasgow Hospitals that Brookfield would like to develop in conjunction with the Board.

The Board wishes to introduce an art and therapeutic design strategy for the benefit of patients, staff, visitors and the local community. The programme will use art and design to de-institutionalise and energise the hospital environment, creating a sense of place, culture and identity.

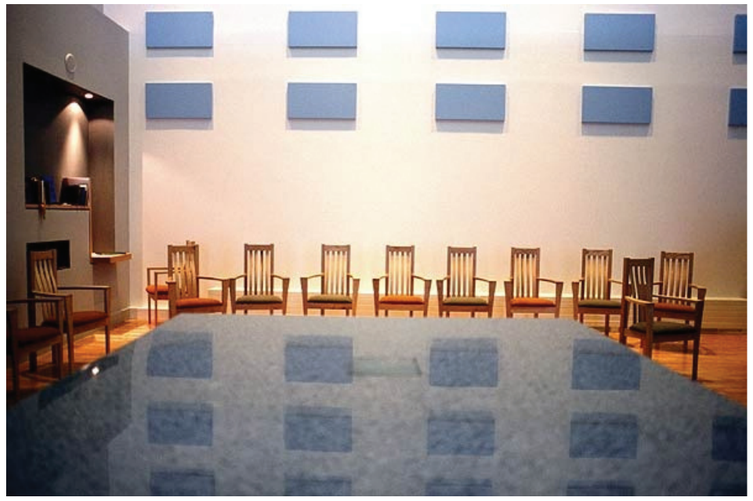
This section provides a strategic context for the relevance, expectations and outcomes of artists' work within the new hospital environment. Developed without a working process with surrounding communities it should be seen a starting point for an arts development process and it would be expected that a further developed strategy and commissioning framework will be produced during Stage 2 that will be able to specifically respond to the working environment and ambitions of the Board.

The main ambitions for the art programme are to:

- help create a positive healing environment in the hospitals' clinical and non-clinical areas
- aid the physical and emotional recovery process
- provide aesthetic enhancement to the hospital environment
- meet the spiritual and emotional needs of patients, staff and visitors
- personalise and de-institutionalise the experience of visiting and staying in hospital
- strengthen the relationship between internal and external spaces
- celebrate and support the hospital's strong cultural relationship with the surrounding community
- increase access for the public to experience high quality contemporary art, craft and design
- enhance the prestige and reputation of the NHS trust during the redevelopment process
- form visual/textural connections around the site to aid wayfinding and orientation
- build on the work to date of by the hospital community.
- The art programme will largely promote the role of visual artists, craft practitioners

and designers within the hospital environment exploring different aspects of the hospital experience; visual, tactile and aural. The role of art forms including performance, dance, music and literature should be encouraged as part of an ongoing programme of commissioning and temporary art provision.

An overall ambition for the strategy is to 'normalise' the role of art within the hospital treating the contribution of artists in the same way as that of other designers and contributors to the hospital environment. Art should not be set on a pedestal. Development and resourcing mechanisms should be developed to allow for this, especially on such a large scale important project for the city. This is a chance for the Board to demonstrate that it is in the forefront of hospital reprovisioning through creating an environment based on supporting wellbeing and health.



Brookfield

Background

The planning and building of the new hospitals will create an opportunity for a fresh and innovative approach to working with artists within the healthcare environment. This approach will develop a commitment to an art programme focussed around key stakeholders: patients, staff, visitors and the local community.

Underpinning the strategy, it is assumed that:

- The Board aims to create a high quality new hospital that improves the environment for patients, respecting their privacy and dignity
- There is ground level support for arts in hospital from departmental staff and associated art partners
- The overall internal environment of the hospital is important in the healing process and the art programme shall address fundamental ways of influencing this environment rather than just adding another layer of decoration
- Art can significantly contribute to the journey of the patient recovery process and be a spiritual support for visitors
- There is a particular willingness to work with artists on the themes of orientation, wayfinding, placemaking and the connection with the external environment
- The cultural context of the hospital in relation to its community is very important
- The concept of the provision of a hospital gallery or programmable space(s) is important
- That existing cultural activities should be reviewed and if appropriate, incorporated into the new hospitals so as to build on current activities and working relationships
- There is potential for artists to create links with surrounding local, city and sub regional communities especially in the development of creative skills to be applied to the hospital environment
- There are opportunities via the art plan to make links to existing local art programmes and identify areas or establish initiatives where these can be brought into hospital life. These may be participatory arts projects or performance groups, offering an opportunity to work on an ongoing basis with patients and staff.

How Arts Add Value

"People say the effect is on the mind. It is no such thing. The effect is on the body, too. Little as we know about the way in which we are affected by form, colour, by light, we do know this, that they have a physical effect. Variety of form and brilliancy of colour in the objects presented to patients is the actual means of recovery."

Florence Nightingale. 'Notes on Hospitals', 1863

Over a century later than Florence Nightingale's publication, the positive role which art plays in the healthcare environment is now widely acknowledged and documented.

It has been recognized by the Scottish Executive in their document "A policy on design quality for NHS Scotland 2006." This document states that:

"Scotland can benefit in many ways from the adoption of arts in healthcare programmes including better patient environments and an improvement in staff morale."

"There is growing evidence that patient recovery rates and stress levels are improved by the adoption of appropriately selected art in healthcare programmes. An extensive piece of research with the Kings Fund, published by NHS Estates demonstrates:

"The impact of the hospital environment on the patient experience and staff recruitment and retention."

The report illustrates that:

"Where time and attention has been tailored to meet patient needs, the resulting environments have had "therapeutic impact". ….

These environments, which encourage patients to feel looked after and cared for, and for staff to feel valued, demonstrate that public art projects have an impact beyond the physical environment."

Assessment of the Kings Fund public art programme (Evaluation of the King's Fund's Enhancing the Healing Environment Programme. NHS Estates, 2003.) reported that public art engendered the following:

- feelings of calmness and wellbeing
- patients feeling more respected and valued
- a reduction of vandalism and aggressive behaviour
- a perception by patients of receiving better treatment.

The Achieving Excellence Design Evaluation Toolkit (AEDET) developed by The Centre for Healthcare Design, NHS Estates, recommends that design be evaluated under three basic headings: Functionality, Excellence and Impact.

The arts have a significant contribution to make in creating impact. In particular, the arts can be used to:

- Create local distinctiveness
- Ensure that the built environment reflects individual human scale
- Meet the spiritual and emotional needs of patients and staff
- Support and improve wayfinding, for example by creating landmarks at entrances and in key public spaces
- Enhance landscaping and interior design through creative use of materials and finishes
- Enhance the prestige and reputation of the NHS trust during the redevelopment process

Brookfield will develop, in collaboration with the Board, a programme that is the forefront of good practice and will be an exemplar for Glasgow and Scotland.

APPROACH TO DEVELOPING THE ART PROGRAMME

Guiding principles

This art strategy is based on the fundamental belief in the ability of art and artists to help create a healing environment. In order to achieve the most effective integration of art in this environment, artists need to be involved at the earliest stage in the planning and build of the hospital. Therefore the art programme needs to be initially aligned in synergy with the building and public realm programme. Provision has been made to allow for artists to be commissioned for key commissions during Stage 2.

A holistic approach is required, integrating the art programme with the landscape and with the building, thus linking the interior with the exterior coherently.

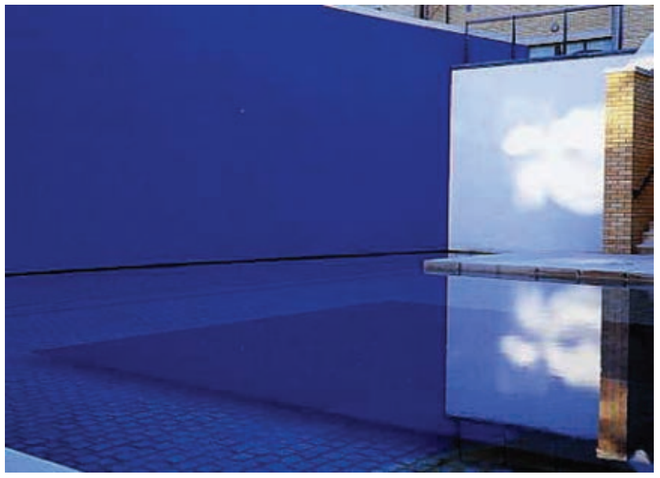
By adopting the practice of an integrated art programme it is possible to create value added, high quality elements through creatively accessing existing building budgets.

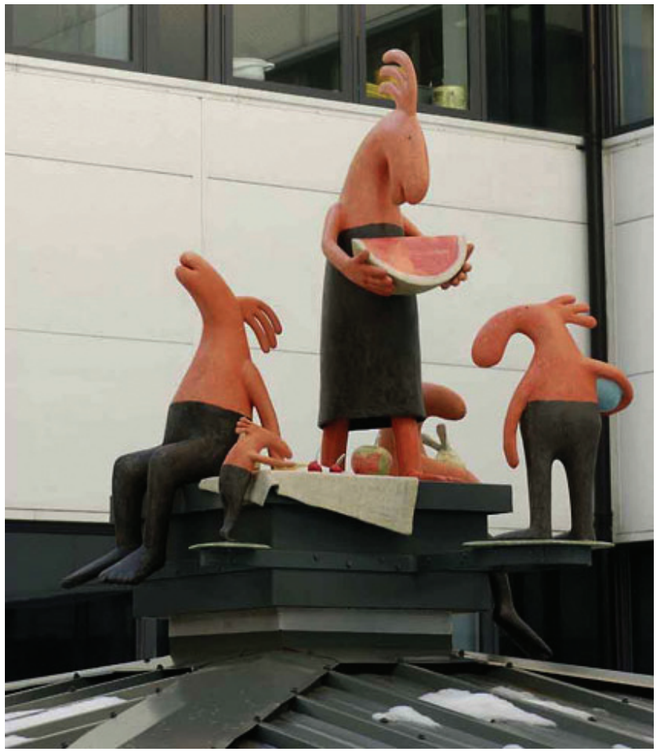
The art programme will be guided by recent research into therapeutic practice, the field of behavioural science that explores the idea of healing patients through contact with their surrounding environment and particularly nature. It will also be guided by information gathered from the field of environmental psychology and from research into the efficacy of Health Care Arts.

If supported by the Board, it is proposed that a partnership with a design based research institution (such as the OPENspace programme at the Heriot- Watt University of Edinburgh, although a Glasgow based relationship would be further encouraged) is established to help guide and frame how the art programme can respond to, and support good practice in the relationship between people, environment, movement and space.

The art programme will seek to add to Scotland's body of research through participation in good practice, innovation and evaluation.

Proposed principles that the detailed art strategy shall develop over Stage 2:





Brookfield

Principle 1:

Create a positive healing environment focusing on user experience

- Ensure that the built environment reflects individual human scale, providing a positive, healing and therapeutic environment that meets the spiritual and emotional needs of patients, visitors and staff. It shall help to de-institutionalise the hospital environment, creating domestic and comforting public and ward areas.
- Provide high quality visual links between the interior and exterior of the hospital, encouraging and supporting access to nature and the outdoors.
- Support and improve wayfinding and orientation, for example by creating landmarks at entrances and in key public spaces.
- Enhance landscaping and interior design through creative use of materials and finishes, innovating uses of colour, surface and light for the improvement of patient, staff and visitor experience.

Principle 2:

Recognise cultural context and cultivate community links

- Recognise the cultural strengths and opportunities of the region whilst creating local distinctiveness.
- Implement education and outreach programmes that fully extend the programme to a broad audience and make genuine and sustainable links with the community.
- Be informed by a practical and open dialogue between the artists, patients, staff and community.
- Where possible and relevant use local crafts people and skills.
- The strategy will identify physical and cultural characteristics and activities which are unique to the area so as to provide rich source material for artists to investigate and use within their commissions.

Principle 3:

Integrate the role of the artist into the working life and design of the hospital in a fundamental and supported manner.

- Undertake professional and accountable project management procedures developing and implementing projects that evolve with the total confidence of both the artist and the Arts Development Group. Ensure that commissioned work and management procedures are fitting, appropriate and safe for a healthcare environment.
- Work with artists, designers and craft practitioners from the very early stages in all project development, creating the maximum opportunity for work to integrate into its context.
- Foster research and collaboration within different fields such as science to enhance and support the development of the arts in healthcare.

Principle 4:

Uphold artistic quality and contemporary practice.

- Commission artwork that is innovative and of high quality.
- Commission artwork that is sensitive and apt for its environment.
- Create the maximum opportunity for work to integrate into its context and provide a variety of ways for users to access the work of artists.

Brookfield

PROGRAMME DEVELOPMENT

The role of artists

The role of an artist shall be as examiner and questioner, creator and facilitator.

Artists have a crucial role to play in the humanisation of the newly created internal and external environment, particularly in ensuring that the hospital environment relates to its social, cultural and physical context. This will relate especially to the areas of wayfinding, social spaces, gallery spaces and sanctuary spaces. By allowing artists to engage with the hospital environment and communities, strongly grounded and researched works of art will be created.

Brookfield will work with the Board and artists through a commissioning process that will allow for proper research and development of project ideas and proposals. The role of the programme will be to develop an environment for commissioning where artists are able to interact with the new spaces, patients, staff and visitors to develop projects that can be rooted in the new site. The main emphasis of the programme will be to create new permanent and temporary commissions that reflect and enhance the caring values of the NHS. The programme will be orientated towards the production of works of art that respond to their context.

Where possible, although not exclusively, the skills of local and city artists and craftspeople shall be drawn upon.

The role of staff and patients

The input of patients, staff and visitors will be key to the success of the project. Working processes should be developed to allow for staff participation so as to develop the role that arts can play within the hospital. This involvement is a key aspect to the project's success and this should feed into the art programme.

Patients and visitors will benefit from the programme, however acute patients are unlikely to play a significant role in the creation of work. Within the art programme we will seek to find alternative strategies through which patient experiences and preferences can be fed into the creative process.

An education and outreach programme should be developed for staff and patients where possible, in order that they might learn new skills and build their engagement in the arts programme as it progresses.

The role of the local and city communities

The detailed art strategy will specifically identify methods to involve the local and city communities. This may be through active contribution to artists' consultation, residencies and participatory projects.

Andy Scott, well known for his work throughout Glasgow will be invited to assist in developing an aesthetic and grounded approach to developing an accessible programme.

Design collaborations between landscape architects and artists and the local community will ensure that the building and grounds fit within the local landscape and provide an accessible destination that relates to the cultural context of the area. This will be through careful consideration of the landscape around the hospital and to the form, colour and texture of external spaces and as well as internal spaces. Areas for collaboration might include sensory gardens, children's play within the Children's Park, and development of communal/social spaces such as the chapel/sanctuary.

It is proposed that a dedicated gallery space is considered for the benefit of hospital patients, staff and visitors. Such programmable spaces lead to a sense of vibrancy connecting the hospital to its communities. By introducing the wider community to the hospital via an exhibition programme, such a space will help to reduce the sense of isolation or loss of self often associated with spending time within a healthcare setting.

Potential linkages to city based cultural initiatives and organisations will be researched with the aim of connecting the new hospital to its sub regional and city communities through culture. Many cultural organisations now have to engage audiences out of their normal working areas and this project will offer significant opportunities for new partnerships to be established.

A48235836

Brookfield

The role of Brookfield

Brookfield will continue to work with the specialist arts agency Ginkgo Projects during Stage 2 to develop a detailed arts strategy in collaboration with the Board. Further details are set out under 'Programme development and resourcing'. Brookfield's aims will be to develop, manage and facilitate the development and delivery of the art programme, reporting to the Boards Art Development Group.

Programme development rationale

Concept

The concept of providing a seamless Patient Care Pathway is now promoted at the core of patient care. It is proposed that as a starting point, the art strategy is positioned around providing a core rationale to which the guiding principles above can be applied through the notion of journeys.

The notion of 'journey' can be explored in a number of ways, including:

1. Physically:

The provision of well designed and provisioned articulated routes and places is integral to this bid. Artists have a critical role in further helping to provide relief, distraction, humour, orientation and integral design as part of the patient experience of visiting hospital. Priority will be placed on the main points of patient and visitor interaction with these routes and spaces.

2. Emotionally:

Artists have a valuable role to play in helping to reduce the anxiety around visiting hospital and helping to deinstitutionalise the environment. Process and participatory based projects have a significant role to play in developing a working environment that connects people to place through activity based work. Such projects can provide research and resource material for permanent commissions, but often have a critical role in providing change and vibrancy to the hospital environment. Areas for consideration for example include oral history projects, work based on creative play and cross art form work including poetry and literature based projects.

This type of work is often developed through artist residencies developing long term relationships between staff and artists to work with patient groups, both on and off site. The outcomes in themselves can be made visible, but they also provide solid research and inspirational material for permanent art commissions.

In the development of the art strategy it will be important to develop ways of working that support both human relationships and the physical environment.

Brookfield proposes that a long-term commitment is given to incorporating the work of artists within the hospital, and those projects are developed through a phased approach. The intention is to develop art projects along both the routes and the activity places, but it is suggested that initial priority is given to areas that are shared by the majority of user groups, namely staff, patients and visitors/community, working with spaces that have most influence on all users.

Two initial research and development projects are proposed during Stage 2, both of which will result in later physical projects for implementation within the initial stage of the art programme, this work will also provide a platform for further artists commissions.

Firstly, it is proposed that an overall concept for a first project, Way Marking and Orientation is established, and this will be achieved through considering the whole site and the various routes and interactions between activity areas contained within it and the role that artists have supporting wider signage and orientation initiatives.

A48235836

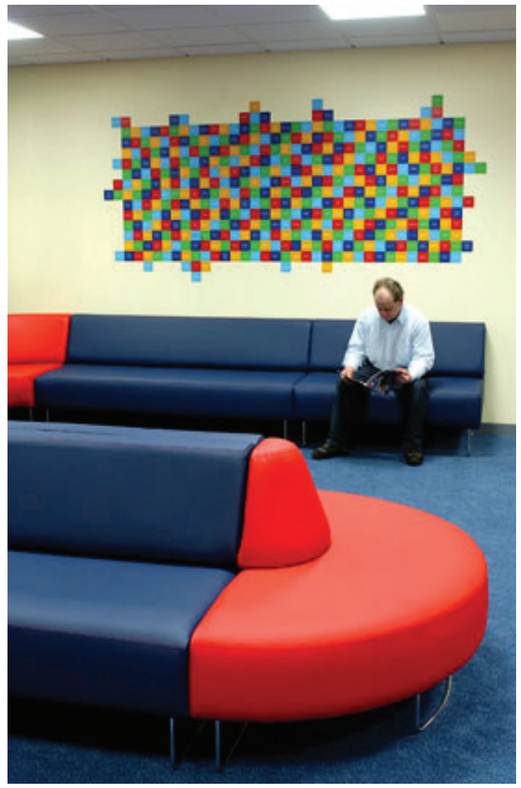
Brookfield

Secondly, it is proposed that a research project, The Healing Environment, is undertaken which will set out to question a number of factors within the hospital environment that might contribute to the healing process and to de-institutionalise the experience of living, visiting or working within the hospitals, it is proposed this project will initially concentrate on areas of relaxation, although this should be agreed with the Arts Development Group. The subject is diverse but will enable a focussed approach to improving the hospital environment. Relaxation is critical to the Care Pathway and recovery process and the spaces associated offer great scope for artist contributions.

Two artists partnered with a research led element (e.g OPENspace or similar) will be commissioned to work with the project teams to develop a framework for further development. Key areas of early artist involvement will be identified, and if appropriate further artists commissioned to develop concept designs for these areas.

The graphic below sets out an overall framework for development, setting out an approach which is research led, leading to projects that clearly relate to the patient experience of the care pathway.

It is proposed that the environmental research project, education and outreach and evaluation programmes feedback into the programme development process providing a means to ensure that the art programme will continue to reflect Board and patient aspirations as it develops.



Brookfield

ARTIST RESEARCH AND DEVELOPMENT PROGRAMME: projects delivered through artists' residencies working with staff and communities feeding into projects below. Two initial projects are proposed during Stage 2: 1. the Healing Environment and 2. Waymarking and Orientation

ARRIVAL	ENTRANCE	WAITING	TREATMENT	RECOVERY	RELAXATION
Main entrance Car parks Bus stops	Main entrance and atriums to Main building and Children's Hospital Department entrances	Departmental waiting areas Assessment rooms Wards Treatment rooms	Assessment rooms Wards Treatment rooms	Wards External areas Courtyards	Staff/Public restaurants Courtyards Children's park Roof gardens Chapel/Sanctuary Incidental spaces
Gateway works, perhaps incremental on approach. Orientation works Car park lighting	Integrated /standalone commissions Reception areas Thresholds and decision points Hospitals Colour projects Corridor works	Ward furniture/ fittings Furniture Lighting Floorscapes Gallery/ showcasing spaces	Lighting Ceiling photography Sound projects Art trolley Cinema project	Colour projects Furniture and fittings gardens / grounds Sanctuary Personal space furniture	Staff sanctuary Childrens play Planting design e.g sensory planting Gallery/ Showcases Cultural studio/workspace?

ENVIRONMENTAL RESEARCH PROJECT: providing a solid basis for commissioning and prioritisation of projects

EDUCATION / OUTREACH PROJECTS: supporting activities connecting people to projects

EVALUATION AND FEEDBACK MECHANISM:

Brookfield

Programme Devlopment And Resourcing

It is important that a flexible and appropriate approach is taken to developing the art strategy and programme in line with the Boards expectations.

During stage 2 Brookfield will work with the Board to:

- produce a detailed arts strategy
- consult with key hospital, community and cultural stakeholders
- Initiate two research/development projects: 1. The Healing environment and 2. Waymarking and Orientation. Undertake if required further artist concept design commissions as agreed with the Board.
- develop a community engagement programme
- develop a costed, phased action plan for programme delivery.
- ensure that art enabling works are accommodated within the construction programme
- set out management structures for programme delivery and post build activity
- develop (as an additional activity) a register/audit of exist artworks and cultural assets, if none exists at present.
- develop a donations policy
- work with the Arts Development Group to help promote its own activity and profile as required.

It is anticipated that Brookfield will have the responsibility for delivering the art strategy during the construction phase as directed by the Boards Art Development Group.

As an integral member of the Boards Arts Development Group, during design and construction, Brookfield will provide the specialist advice to (scope to be refined during stage 2):

- ensure that the art strategy is updated and maintained as a live document.
- consult with key hospital, community and cultural stakeholders
- maintain the costed, phased action plan for programme delivery
- develop artist briefs
- develop artist selection and project procurement procedures
- select artists for identified projects
- ensure that art enabling works are accommodated within the construction programme
- manage the development of artist concept and detailed designs, including artist residencies
- maintain a detailed programme for programme development and delivery
- manage the delivery of the art programme up to completion of the construction phase.
- provide advice on specialist arts contracts and procurement
- develop a programme for community engagement and participation
- development of maintenance, management and decommissioning plans
- in collaboration with the Board identify potential external funding sources, (if required)
- develop, with others, a register of existing cultural assets for relocation (if not existing)

Andy Scott has participated in the Competitive Dialogue process and has accepted the role of Local Champion for the art strategy. During Stage 2 Andy will be invited to contribute to the development process to participate in the process of ensuring that a broad range of grounded art opportunities are developed.

Brookfield

Commissioning practice

The value and professional status of artists shall be respected and the selection, commissioning and contracting of artists shall follow recommended models of good practice as promoted by the Scottish Arts Council. Artists may be selected though direct selection, limited competition and open competition.

It is recognised that research and project development forms a significant part of the contribution that arts programmes make to the hospital environment.

It is suggested that the engagement of a part time or seconded Hospital art coordinator would facilitate the successful delivery of the art programme post construction. This post could be funded through the art programme.

Development Priorities

The level and extent of resourcing of the programme needs to be determined during stage 2 and decisions for investment will be led by the Board. It is recognised that a tiered or staged approach is requested for development to enable budgets to fit with the Boards aspirations.

Resource allocation for Activity undertaken during stage 2:

Stage	Activity	Resourced by
Stage 2	Art strategy production	Brookfield/ Board
	Research projects: 1. The Healing Environment 2. Waymarking and Orientation	Brookfield
	Selected art design concept design work development as agreed	Board / Brookfield

A set of criteria for project priority will be developed during Stage 2 to enable the Board to decide on project benefit and desirability.

First level priority projects

Priority should be placed on projects that:

- can only be delivered as part of the construction phase and are integral to the fabric of the buildings
- are located in areas which have the maximum public benefit e.g. entrances, atria, parks/green space
- Research and development programme to support grounded commissioning

Second level priority projects

- Stand alone artworks
- Integrated works in areas of lower pubic interface e.g treatment areas, waiting areas, corridors
- Education and outreach programmes
- Gallery / programmable spaces

Third level priority projects

- Gallery programming
- Temporary projects

Evaluation

Criteria for evaluation in relation to the art programme shall specifically relate to:

- An overview of how well the art plan incorporates the requirements of the Board and a clear response to the relevant ER's
- Clear evidence of how the art strategy will support the well being of patients, staff and visitors through the four guiding principles as referred to earlier in this documents and as set out below:

Principle 1: Create a positive healing environment focusing on user experience

Principle 2: Recognise cultural context and cultivate community links

Principle 3: Integrate the role of the artist into the working life and design of the hospital in a fundamental and supported manner.

Principle 4: Uphold artistic quality and contemporary practice.

Brookfield

Public Art Elements

Stakeholder & Community Engagement

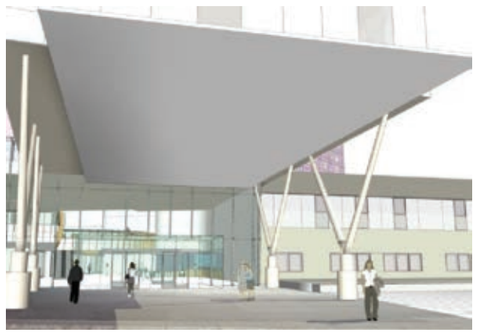
Stage 2 of the design process will enable full engagement with stakeholders to be commenced in support of the significant ambitions for the development of an influential public art programme for the New South Glasgow Hospitals. It has been noted that this will build upon the existing activity of the Board. It has been noted that the NSGH project offers the potential to create a benchmark for creative input into the provision of healthcare and the establishment of excellence in the new healing environment.

Public Art at New South Glasgow Hospitals

A number of elements within the design of the hospital environment will make a significant contribution to the delivery of creative features and community activities. It is intended that public art will be embedded within the fabrication of the buildings and external spaces and will be delivered within the same programme. Artists will therefore continue to be represented within the integrated design team to ensure that opportunities for creative expression are captured during the design process. In this way the delivery of the hospital buildings will include art features which have been firmly embedded within the form and fabric of the building to safeguard delivery and capture the opportunities.

During the design process up to the point of the ITPD submission a range of opportunities have been identified for further development and as a platform for stage 2 design. These are grouped under the following headings, which are briefly explored below:

- Signage & Wayfinding
- Public Space Design
- Building Features & Interior Spaces
- Furniture
- Exhibition Programme



A48235836

Brookfield

Signage and Wayfinding
There is a clear requirement for functional signage to respond to the appropriate standards and guidance for NHS sites. In addition to this signage there are additional opportunities to create unique creatively conceived features which forge identity, assist with wayfinding and serve as landmarks. Examples of these include entrance gateway features, sculptural forms in key locations, site maps, design motifs along primary routes, play elements and the use of colour within signage elements, both internally and externally.

Public Space Design
The design of public spaces has created a range of complementary places which provide variety and varying seasonal character. The stage 2 design for these places will include the definition of paving and other features through engagement with artists and the community, under the guidance of the art development group. Paving motifs can also aid wayfinding and public spaces will also offer flexibility for a range of uses, including occasional events. The heritage of the city and the Clyde-side location offer potential for creative interpretation applied to features such as the entrance canopy. Play areas within the Children's Park will also be designed as an expression of local creativity and innovation.

Building Features & Interior Spaces
A number of building features within the ITPD design proposal have been influenced by the desire for creative expression and innovation to shape the character and vitality of the built environment for patients, visitors and staff. The input of artists will continue and be expanded in stage 2 through stakeholder and community engagement. Elements of note for creative expression include reception desks, the atrium pods and aspects of the structure of the building in key locations.

Special building features include the chapel spaces, children's radio station, roof gardens, wall treatments and furnishings. The creation of unique and special places will be a feature of the stage 2 design process. Many of these opportunities are considered further in the wayfinding strategy.

Furniture
Internal end external furniture offers potential for creative design input, balanced with the need for function, cost-effectiveness and minimal maintenance. The integrated design team will work during stage 2 to enhance the scheme through a range of opportunities for identity to be enhanced through the use of appropriate suites of internal and external furniture and special unique features.

Exhibition Programme
The scale of the hospital buildings presents a range of opportunities for the creation and display of works of art. Strategic partnerships will be explored with existing bodies to maximise the potential for the display of artworks. The potential café within the park and the extensive catering areas internally offer additional potential for creative use of building spaces.

Brookfield

Acoustic Report

Submission Reference:

Section 3.4 Acoustic Report indicating the following information:-

- Specialist Acoustic Engineer's report providing a clear demonstration of compliance with HTM 08-01
- Outline principles adopted underlying bidder approach to acoustics with particular regard to issues around items such as rooftop helipad, atrium etc

Submission Response:

Acoustic Logic has been engaged by Brookfield to provide specialist Acoustic Engineering service. The report as prepared by Acoustic Logic is contained herein.

TABLE OF CONTENTS

Brookfield

INTRODUCTION

This document presents the acoustic design report for the Brookfield - New South Glasgow Hospital bid submission. All acoustic aspects of the hospital have been design to fully comply with the requirements of Health Technical Memorandum (HTM) 08-01: Acoustics. The issues discussed include all aspects of the design covered by HTM 08-01 including:

- Acoustic treatments to the atriums and public spaces
- External noise control including traffic and the rooftop helipad
- Treatment proposed for plant rooms and the energy centre

In addition, the report provides indicative treatment to typical areas within the building to ensure an acceptable environment is provided. It is noted that although the final selection of the plant and equipment will take place in due course, their treatments in principal are outlined.

2. NSGH AND THE APPLICATION OF HTM 08-01

The design of all acoustics aspects of the New South Glasgow Hospital (NSGH) will be guided and determined by the criteria and guidelines set out in HTM 08-01. In order to maintain the intent and standards set out in HTM 08-01, it is proposed to generally maintain these criteria except in cases where the NSGH briefing documents have varied these or it is warranted on the basis of rationalising acoustic performances verses other functional requirements. In all cases, aspects such as hygiene, functionality, space relationships and practicable building outcomes are considered.

Acoustically, hospitals are unique buildings and due to their function do not closely model other buildings which may operate in similar modes. Acoustics becomes an important issue as control of intrusive noise from a range of sources (waste pipes, impact noise, wall transmission, and mechanical services) is essential for peace of mind and amenity.

Hospital buildings combine a number of functions more so than any other building type, and combines aspects such as residential commercial, educational, hostel and retail buildings. Hospitals operate differently to and generally their acoustic requirements are function based. Hospitals combine a number of functions from accommodation of patients in wards, ICU's CCU's, day patients, medical imaging, medical treatment, therapy areas and specialist functions. As such, hospital buildings overlap acoustically with a number of building types, residential, commercial, retail, education and specialist medical.

When selecting acoustic standards for hospitals a number of factors require consideration, including the space relationships, the requirement for general and quick access to the majority of areas, patient monitoring, the large area over which most spaces are planned, in particular ward layout in comparison to residential apartments. There may be 30 to 40 beds on a ward, which all generally require open doors for access by staff and others, whereas in apartments, the space is closed off to all but those within the immediate ownership. Hence, assigning a hospital the acoustic standards that would be used in residential, commercial, education buildings (et al) is not strictly correct, as it does not recognise the unique functions of a hospital.

For NSGH, all acoustic measures will be considered in this light and where adjustment are required to strike a balance between the varying requirements, these will be enacted.

2.1 GENERAL PHILOSOPHY

The acoustic advice for this project has been developed to encompass the broader requirements of the facility. The consulting rooms, counselling offices, executive offices, birthing suites and specialised areas of the hospital such as psychiatric observation are seen as the most critical, requiring adequate acoustic isolation to maintain speech and acoustic privacy. Other associated spaces such as waiting areas, patient wards, general treatment and medical areas will require acoustic standards which provide speech privacy under normal conditions. That is when people are talking at normal volume, these conversations will not be clearly audible in adjoining spaces. Loud events such as screaming or shouting are not seen a normal and hence do not require consideration in these space.

The location of the space is also important in determining the required Rw rating. For example a tutorial or consulting room located in the middle of a corridor and adjoined by storage areas should require a lower Rw rating than the same room type adjoining a patient ward or another consulting room. Note corridors are transitory spaces, where people either pass along or spend short periods of time, and differ greatly from spaces where people are stationed and are in a position to hear or be disturbed by sound in an adjoining area.

2.2 ACOUSTIC DESIGN APPROACH

A suitable acoustic standard for the different space types was determined by evaluating space function against specific acoustic requirements. Accordingly, the required acoustic environment for a space can be seen as a composite of four elements, namely;

1. The perceived sound privacy requirements.
2. The ambient acoustic environment (background noise levels); this is a direct function of the activities which occur and mechanical services noise.
3. The acoustic character of the space.
4. The levels of noise which are likely to be generated within a space, and how they will affect adjoining spaces.

This evaluation process was carried out to determine the acoustic requirements of the various spaces within this development.

Brookfield

2.3 IMPORTANCE OF SPACE CHARACTER TO PERCEPTION OF SOUND

The acoustic character of a room will determine the quality of the sound and may lead to a space being perceived to be noisy. Acoustic character specifically refers to the sound absorption properties of the room finishes and the resulting nature of sound. A space with little acoustic absorption will sound reverberant and hollow. Noise heard in such a space tends to sound loud and sharp. Where adequate acoustic absorption is provided, sounds tend to be more natural and intelligible. This also makes the space sound quieter and therefore aurally more comfortable. For this development, it is proposed to provide a room character which is suitable for a heath facility environment, i.e. quiet and comfortable.

3. NOISE INTRUSION FROM EXTERNAL SOURCES

The NSGH project brief requires that the façade be designed to comply with the standards given in HTM 08-01 under normal conditions. The design criteria adopted in the Brookfield bid submission are those nominated in HTM 08-01 and are outlined in Table 1 below.

TABLE 1 - HTM 08-01 CRITERIA FOR NOSIE INTRUSION FROM EXTERNAL SOURCES

room type	examples	Criteria for noise intrusion to be met inside the spaces from external sources (dB)
Ward – single person	Single – bed ward, single-bed recovery areas and on-call rooms, relatives' overnight stay	40 LAeq, 1hr daytime
		35 LAeq, 1hr night
		45 Lmax, fast night
Ward – multi-bed	Multi-bed wards, recovery	45 LAeq, 1hr daytime
		35 LAeq, 1hr night
		45 Lmax, fast night
Small office type spaces	Single – bed ward, single-bed recovery areas	40 LAeq, 1hr
Open clinical areas	A& E	45 LAeq, 1hr
Circulation spaces	Corridors, hospital streets, atria	55 LAeq, 1hr
Public areas	Dining areas, waiting areas, playrooms	50 LAeq, 1hr

Brookfield

room type	examples	Criteria for noise intrusion to be met inside the spaces from external sources (dB)
Personal hygiene (en-suite)	Toilets, Showers	45 LAeq, 1hr
Personal hygiene (public and staff)	Toilets, Showers	55 LAeq, 1hr
Small food-preparation areas	Ward kitchens	50 LAeq, 1hr
Large food-preparation areas	Ward kitchens	55 LAeq, 1hr
Large meeting rooms (> 35m2 floor area)	Lecture theatres, meeting rooms, board rooms, seminar rooms, classrooms	35 LAeq, 1hr
Small meeting rooms (≤ 35m2 floor area)	Lecture theatres, meeting rooms, board rooms, seminar rooms, classrooms	35 LAeq, 1hr
Operating Theatres	Operating theatres	40 LAeq, 1hr
		50Lmax, fast
Laboratories	Laboratories	45 LAeq, 1hr

4. INVESTIGATION OF HELICOPTER NOISE INTRUSION

This section details our review of potential helicopter noise and regenerated structure borne noise impact to the future occupants of the proposed New South Glasgow Hospital.

4.1 HELICOPTER NOISE

HBN 15-03 “Hospital Helipads”, references Planning Policy Guideline 24 which urges caution in measuring and applying noise exposure categories when absolute levels of noise are balanced by an infrequent occurrence and a short duration of such noise. The occasions when ambulance helicopters cause disturbance are likely to be irregular, few in number and short in duration.

Notwithstanding the new proposed helipad is an improvement over the existing helipad, thus reducing the potential for noise impact inline with the mitigating measures proposed in HBN 15-03 as follows;

- New proposed helipad is located on top of the Ward tower, which represents the highest point on the estate (HBN 15-03),
- Elevated helipad reduces air time on approach and takeoff, and enables planning of the flight path to avoid unnecessarily low transits over sensitive areas. High flight path for as long as possible to maintain maximum distance attenuation to receivers.
- Minimising ground idling time.
- Improvement to existing ground pedestrian paths of current hospital by locating helipad on roof.

4.2 HELICOPTER FLIGHT PATH

The helicopter serving NSGH will be landing or taking off on the rooftop of the new building. It is assumed that suitable flight paths will be determined to avoid sensitive receiver locations.

To determine suitable noise levels for the various space types with regards to the helicopter landing pad the following information was examined and evaluated:-

1. The proposed location of the helicopter landing pad.
2. Typical frequency of use of the landing facility.
3. Recommended design sound levels for different areas of occupancy for standard aircraft movements.

4. Extensive experience with hospitals and helipads.

It has been assumed that helicopter movements will be limited to emergency situations. Based on this assumption an acceptable noise level for rare and short term occurrences such as helicopter arrival and departures would be the recommended design levels plus 20 dB(A).

The nominated noise levels for the various spaces types selected following the methodology described above are shown in the table which follows.

Nominated Helicopter Noise Levels

SPACE TYPE	NOISE LEVEL OBJECTIVE Lmax dB(A)
Wards	70
Theatres	65
Treatment rooms	70
Consulting rooms	70
Laboratories	75
Service Areas	85
Private offices, conference areas	70
Offices - general	75

4.3 EVALUATION OF NOISE INTRUSION

Noise intrusion into the habitable spaces within the proposed development was predicted. The calculations were based on the worst case that helicopters pass directly over the development. A façade receiver distance of 20m was taken relative to the helicopter based on the distance to the helipads and expected passing height of the helicopter over the subject development.

Noise levels used for assessment were obtained from measurements taken of a Sea King Helicopter during the following activities;

- Starting up
- Running hard during starting up
- Taking off
- Various approaches

It is noted that Jet Ranger represents the type of helicopter which would arrive at the hospital more frequently. It is acknowledged that Sea King Helicopters may use the hospital helipad. However the difference in design requirements within practicable means for both helicopter types will be equivalent especially based on frequency of the Sea Kings. Hence the design is considered conservative.

Of the above activities, taking off was the loudest and thus this level was used for assessment purposes. Calculations were performed taking into account the orientation of windows, the total area of glazing, facade and roof transmission loss and room sound absorption characteristics. In this way the likely interior noise levels can be predicted. The roof construction is concrete over the Adult hospital.

4.4 TOP THREE FLOORS OF THE HOSPITAL WING WHERE THE HELIPAD IS LOCATED

Glazing:	6mm glass /12mm air gap /10mm glass
Windows:	Not open-able
Facade	To perform a minimum of 10dB above glazing

4.5 STAFF RESOURCE (REMAINING FLOORS)

Glazing	6mm glass /12mm air gap /6mm glass
Windows:	Not open-able
Facade	To perform a minimum of 10dB above glazing

4.6 OTHER CONSIDERATIONS TO SURROUNDING RESIDENTS

As a reference, the Royal London Hospital offered secondary glazing for noise control to residents living nearby. The factors to be considered for NSGH prior to taking this approach would include the fact that the existing helipad and that the proposed helipad location will effectively represent same flight path and that currently the helipad operates without upgraded glazing to surrounding residents. This is an emergency service, thus the proposition to offer secondary glazing like Royal London Hospital may be a premature measure.

Prior to moving forward with this proposition, it is proposed that a review be conducted of the existing operations and then any variations from existing to new hospital operations is evaluated. If it is determined that the new helipad will seriously increase the impact upon existing residences, then suitable amelioration can be considered.

In the case of the temporary operating helipad, a similar study is proposed, if it is found that significant impact is generated, then suitable treatments need to be formulated.

5. TRAFFIC NOISE

Based on the location of the new hospital building being away from the major roadways which surround the site and the results of a cursory noise survey, conducted around the site, and the criteria presented in HTM 08-01 reproduced in this report the following general glazing system is recommended for the NSGH.

Typical Façade based on traffic noise intrusion:

Glazing	6mm glass/ minimum 12mm airgap (greater for integrated venetian)/ 6mm glass

Brookfield

6. PLANT AND BUILDNG SERVICES NOISE

The specified levels are generally in accordance with HTM 08-01. This is consistent with the normal practice in UK. In the absence of criteria in HTM 08-01, the NSGH bid documents have nominated suitable criteria. In general, these criteria are adopted for the Brookfield bid submission.

The adopted criteria relate to the total noise resulting from simultaneous operation of all plant and building services including structurally transferred noise. Noise from toilet flushes is excluded as per the NSGH bid document notification.

The proposed criteria are set out in tables 2 and 3 below.

TABLE 2 – SERVICES NOISE CRITERIA FOR INTERNAL SPACES COVERED BY HTM 08-01 (For note 1 see section 6.1 below)

Area	HTM 08-01	Proposed in NSGH PROJECT BRIEF	BROOKFIELD CRITERIA	COMMENTS
Single bed wards	NR 30	Nr 30	NR 30	Complies with HTM 08-01
Consulting rooms	NR 35	Nr 35	NR 35 – NR401	Complies with HTM 08-01
Operating Theatres	NR 40	Nr 40	NR 40	Complies with HTM 08-01
Privates Offices, small (≤ 35m2) meeting rooms	NR 35	Nr35	NR 35- NR401	Complies with HTM 08-01
Privates Offices, large (> 35m2) meeting rooms	NR 30	Nr30	NR 30-nR351	Complies with HTM 08-01
Multi bed wards	NR 30	Nr 35	NR 35	Complies with NSGH project brief
Waiting rooms	NR 35	Nr 35	NR 40	Proposed NR40 to increase privacy as NR35 creates a low background environment
Staff rooms	NR 40	Nr 40	NR 40	Complies with HTM 08-01
Relatives' overnight stay	NR 30	Nr30	NR 35	Background sound level increased to improve privacy.
General Office	NR 35	Nr 35	NR 40	Background sound level increased to improve privacy. It is noted normal background from human activity in general offices is NR43
Corridor, Laboratory	NR 35	Nr35	NR 35	Complies with HTM 08-01
Toilet, shower (en-suite)	NR 30	Nr30	NR 351	Background sound level increased to improve privacy.
Washroom, toilet	NR 30	Nr 35	NR 351	Complies with NSGH project brief
Ward kitchens	NR 35	Nr 35	NR 35- NR401	Complies with HTM 08-01

TABLE 3 – SERVICES NOISE CRITERIA FOR INTERNAL SPACES NOT COVERED BY HTM 08-01 (For note 1 see section 6.1 below)

Area		Proposed in NSGH PROJECT BRIEF	PROPOSED BROOKFIELD CRITERIA	COMMENTS
Sports Hall, Gymnasium		Nr30	NR 351	Increased background see note 1
Music room		Nr 35	NR 35	Complies with NSGH project brief
Activity / Group work room / Multi-purpose room		Nr30	NR 35	Complies with NSGH project brief
TV room		Nr35	NR 35	Complies with NSGH project brief
Observation & Recording		Nr 35	NR 35	Complies with NSGH project brief
Recreation rooms, cafeteria		Nr40	nr40	Complies with NSGH project brief
Recreation rooms, cafeteria	Bedroom	nr25	NR301	Complies with standard night-time residential criteria
	Lounge	NR30	nr351	
Residential Living Area / Living Unit	Bathroom	Nr 40	NR40	Complies with NSGH project brief
	Kitchen / Corridor	NR40	Nr40	

Brookfield

1.1 BACKGROUND NOISE LEVELS AND PRIVACY

Although the selection of background noise levels which are too low may seem a conservative and correct practice, it can lead to excessively quiet spaces which highlight other issues. A quiet waiting room, means that every sound made can be heard and may lead to annoyance and irritation. Also selection criteria for specialised areas such as wards, which are too low means that there is a greater audibility of noise

The Employer's Requirements (Hospitals) Volume 2/1, stated: "The contractor shall endeavour to minimise and mask ambient noise sufficient to preserve patient privacy, confidentially and maintain a calming atmosphere in public and private areas "

Based on the requirements outlined above, the first principle which needs be considered is that if the background is too low, then minimal speech masking will occur and the above objectives will not be met. Furthermore, it is noted that if the background is too low then the patient will be more aware of general sounds which would otherwise be masked by an appropriate level of background or ambient noise.

Hence all services noise criteria need to consider the balance between noise levels that are required for patient well being and those required to provide speech privacy and masking for patient dignity and aural comfort.. In some case the noise levels criteria were marginally increased.

Furthermore HTM 08-10, states: "Sound insulation between rooms – allows rooms to exist side by side. Noisy activities should not interfere with the requirements of adjacent rooms, and private conversations should not be overheard outside the room."

This statement calls for a balance between adjoining spaces, activity generated noise, ambient noise levels and internal partitions. The degree of audibility or inaudibility for each space type will vary depending on the planning or spatial relationships with other parts of the hospital/rooms. This will be further discussed below, but more importantly at this stage is what factors contribute to audibility and inaudibility.

1.2 PROPERTY BOUNDARIES

Noise levels emitted by the mechanical plant at all property boundaries and nearby buildings on adjacent properties shall meet the requirements of:

1. Local Council

2. Environment Protection Authority.

3. Any other relevant statutory authority.

1.3 HOSPITAL ACCOMMODATION

Noise levels emitted by the mechanical plant incident on hospital accommodation are to meet noise intrusion targets with open/closed windows.

1.4 NOISE DURING A FIRE EMERGENCY

Noise from all plant during a fire emergency shall comply with the requirements of HTM 08-01. Noise levels inside the fire control room shall not exceed 65dB (A) during a fire emergency. Anywhere else in the hospital they shall not exceed the background + 10dB (A).

1.5 OUTDOOR AREAS ON THE DEVELOPMENT SITE

Noise levels emitted by the mechanical plant to outdoor public and private areas on the development site shall not exceed the A-weighted background noise level or any level agreed with the local authorities

1.6 VIBRATION PRODUCED BY PLANT

Tactile structure vibration levels produced by the plant should not exceed the criteria given in BS 6481. Where the standard recommends a range of criteria for a particular occupancy, the low end of the range shall be used.

The following measures shall be adopted for mounting of mechanical plant:

- Isolation mounts and connections shall be adopted for all reciprocating and rotating equipment, pipe work and ductwork.
- Selection of suitable vibration system shall be made based on the design minimum isolation efficiency, floor static deflection, and plant/ equipment mass, rotational/ reciprocating speeds and power requirements etc.

The method of vibration mitigation shall be selected for each particular application. The following minimum isolation spring defections are applicable:

- Pump/ motor sets 25mm deflection
- Air handling plant 10mm deflection
- CPEF and CPSF 25mm deflection

Other means included providing a minimum clearance of 50mm between vibrating equipment and nearby building structure and 25mm between the underside of a concrete inertia block or machine base and the top of a concrete slab.

1.7 SERVICES RISERS

Internal services risers shall be selected to meet both acoustic and fire rating requirements. Typically, risers constructed of masonry or Shaft wall or similar are acceptable.

1.8 PLANT ROOMS GENERALLY

Treatment cannot be confirmed to these rooms until equipment and noise levels for that equipment are selected. Typically it is assumed that the slabs in the plant rooms are at least 180mm thick.

Brookfield

1.9 DIESEL GENERATOR

The proposed diesel generator room will require specific acoustic treatment which is to be finalised once the unit selection is available. Indicatively a suspended 16mm thick plasterboard ceiling below the roof structure spaced 300mm on resilient hangers equal to Embelton RHD series shall be installed. A layer of 75mm thick 11 kg/m^3 glasswool will also be required in the ceiling void. Plant room walls shall be lined with 50mm thick perforated metal faced insulation. Silencers will be required to the air intake/discharge. 45mm thick solid core doors with full perimeter seals will be required. It is recommended that the plant room walls be nominal 190mm masonry block.

1.10 DOORS

It is recommended that plant room doors be min 40 mm thick solid cores with full perimeter acoustic seals. It is noted that the diesel generator room should be min 45mm thick.
All other doors shall be solid core with all gaps minimised. It is noted that door seals to meeting rooms/interview rooms etc will not be required. However there are a few minor instances where consulting offices are located opposite waiting areas and as such in these locations acoustic seals are recommended. Doors shall meet a minimal rating of Rw35, as set out in the NSGH project specification

7. HYDRAULIC SERVICES

The principal requirements for noise from the hydraulic services is that all waste soil pipe passing through the various spaces of the hospital development comply with satisfactory noise levels. The actual treatment of the waste pipe work will be dependant of the receiver space configuration, the ceiling construction system, the material from which the pipework is constructed and the hydraulic practices adopted on the project.

For the purpose of this schematic design report a series of design criteria is presented, these criteria are based on the maximum design levels presented in Table 2 and 3 above.

8. INTERNAL ROOM ACOUSTICS

A hospital is an amalgamation of different spaces with varying hygiene, security and aesthetic requirements. In the determination of suitable acoustic absorption/reverberation control mechanism and materials, the above factors were taken into consideration.
Room acoustics character specifically refers to the sound absorption properties of the room finishes and the resulting nature of sound. A space with little acoustic absorption will sound reverberant and hollow. Noise heard in such a space tends to sound loud and sharp. Where adequate acoustic absorption is provided, sounds tend to be more natural and intelligible. This also makes the space sound quieter and therefore aurally more comfortable. For this development, it is proposed to provide a room character which is suitable for a heath facility environment, i.e. quiet and comfortable.

HTM 08-01 in Section 21.06 nominates that sound absorption should be provided in all areas including corridors except in areas where cleaning and infection control, patient safety, clinical and maintenance requirements do not allow.

The general acoustic philosophy of the Brookfield bid is to fully comply with the intent of Section 21.06. To this end, a general acoustic system has been developed for the hospital to meet the requirements of room to room noise transmission, whilst providing the required level of acoustic absorption. The propose system make use of a high density ceiling tile to achieve the ceiling attenuation from room to room and provides an NRC rating in all allowable areas of ≥ 0.55 on the ceilings. This means that all areas in the hospital that are allowable will have good room acoustic character, and comply with HTM 08-01.

These areas include:-

- Department corridors
- Wards
- Treatment rooms
- Consulting rooms
- Utility rooms
- Open Clinical areas
- Meeting rooms
- Offices
- Entrance areas
- WC’s
- Hospital streets

This design approach will provide a quiet and peaceful environment thought the hospital. This will also assist in reducing externally transmitted noise for spaces located on the building façade and reduce services noise throughout the hospital. The room correction or reverberate noise level difference in a standard room with an absorptive ceiling is between 3 to 5 dB quieter than a room with a hard or non-absorptive ceiling. Hence it can be stated that in general all room is the NSGH will be 3 to 5 dB quieter because of this Brookfield initiative.

In the case of more specialised areas the treatments will vary according to the function. A brief outline is provided below for a few of the more important areas:

Brookfield

8.1 ATRIUM ACUTE HOSPITAL

This is the principal space in the hospital most people arriving will transit through and hence it can be stated that this is one of the critical area to be addressed. The Architects have formed a grand, light filled voluminous space, which extend to some 11 storeys and is full of various architectural features, the chapel, sky bridges, glass walls etc.

Acoustically, this space is divided into a number of zones; there is the main space and special/peripheral space. The peripheral spaces (reception desk, retail, cafeteria etc) will be treated with localised systems such a ceiling tiles or panel absorbers. In the main spaces, consideration is given to the vast volume where a room correction of – 20dB has been calculated due to sound dissipating into the space. This will provide significant acoustic benefit in controlling room character. Further sound absorption will be provided to available surfaces where it can be applied (glass and windows are excluded) in the form of dense fibreglass (40kg/m3) faced with acoustically transparent material. In addition, any surfaces which may cause echo or strong reflections will be acoustically treated when the final form of the atrium is derived.

Based on the current design of the atrium, normal speech levels will be reduced by approximately 20 to 25dB(A). This will provide an aurally comfortable environment in which people can meet, stand and speak or quietly wait.

8.2 LECTURE THEATRES, SEMINAR ROOMS

These rooms have an important roll and their acoustic design is important for speech intelligibility and general function. A general approach for these rooms will be to have carpeted floors, acoustic treatment on the side wall and rear walls, with approximately 100% of the rear wall covered and 40 – 60 % of the side walls. The ceiling will be evaluated to control strong reflection and diffuse sound.

8.3 PUBLIC SPACES

Other than the atriums, the principal public spaces will be waiting areas, retail (cafeteria) and hospital corridors. The acoustic strategy for these areas has been covered above.

9. INTERNAL AIRBORNE SOUND INSULATION (PARTITIONS)

The sound insulation ratings of the partitions strictly follow the requirements of HTM 08-01. In accordance with HTM 08-01, the walls are designed to comply with the DnTw ratings shown in Table 5 of HTM 08-01. This is the same table title as Figure 1 in the Volume 2/1 Appendix S of the NSGH bid documentation. This table provides a matrix showing the sound insulation performance required (dB DnTw).

In addition and as indicated in the NSGH bid documentation, BB93 has been reviewed for teaching spaces and the Scottish Building Standard Authority (SBSA) Techinal Handbook in living areas. It is noted that the DnTw ratings presented in Table 5 which is reproduced above are on-site performance to be achieved in the completed building. The Rw ratings were and if indicated are laboratory ratings and not equivalent to DnTw, but are approximately 10 to 20% higher.

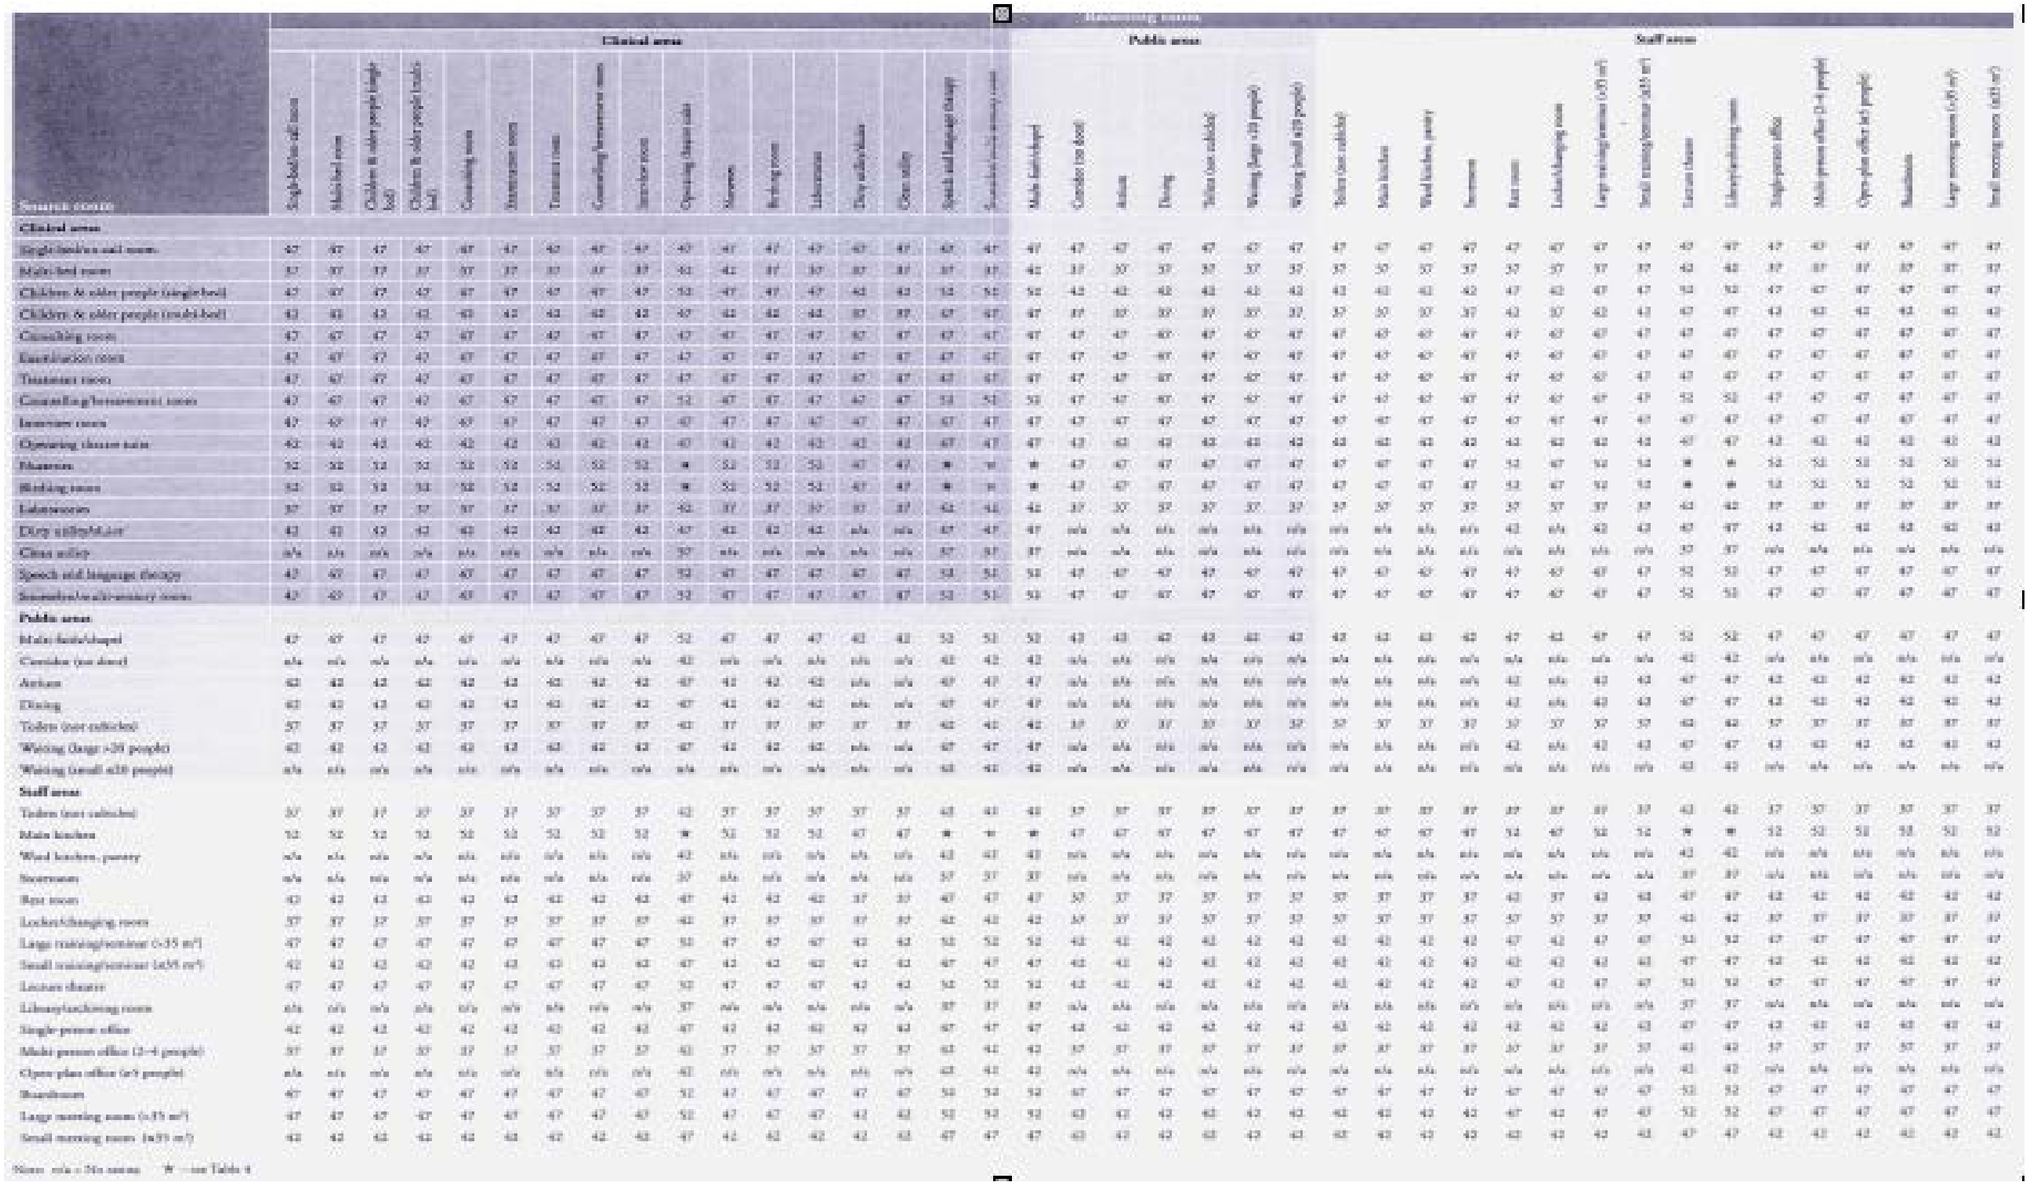
The proposed wall details are attached in Appendix A. The details are labelled with the appropriate acoustic rating and colour coded to be referenced from the marked-up architects drawings in Appendix B.

The design of the partitions considers all penetrations and joints and flanking paths, required backing boxes, above ceiling treatments, light boxes and plenum boxes to mechanical systems.

In the case of toilet walls to corridors, where there is no door, the walls are rated at a minimum of Rw43.

It is noted that the DnTw ratings used in this report strictly comply with HTM08-01. It is also noted that in the NSGH project brief, one change is made to Table 5 in the Arups' report, namely; the single ward to single ward criterion appears as DnTw 50, as opposed to the DnTw 47 rating shown in Table 5. In the Arup document which is Appendix S of Volume 2/1 (on the second page of Appendix A), they provide a definition of 'Perceived Change in Decibel Level" for 3dB - they noted: "A just noticeable difference "or in other words a barely noticeable difference. The guidance of HTM 08-01 is strictly followed for the selection of all partition ratings.

Brookfield



A48235836

Brookfield

10. DOORS

The sound insulation ratings of the doors strictly follow the requirements of HTM 08-01. The door rating requirements are set out in table below.

room type	DOOR SOUND INSULATION RATING	COMMENTS
Wards and Duty rooms	Rw30	Proprietary acoustic door with seals to head and jambs
Treatment rooms	Rw30	Proprietary acoustic door with seals to head and jambs
Consulting rooms/Control rooms	Rw30	Proprietary acoustic door with seals to head and jambs
Offices/Seminar rooms	Rw30	Proprietary acoustic door with seals to head and jambs
Plant rooms	Rw35	Proprietary acoustic door with seals to head, jambs and thresholds
Rooms where seals can not be fitted for hygiene, functional or and cleanliness reasons	Rw20-25	Proprietary acoustic door minimal gaps

In section 2.72 of HTM 08-01, it is recognised that doors are an inevitable weakness in partitions and will reduce the overall acoustic performance of most partitions. Reasonable acoustic performance can not be achieved without seals being fitted around the whole door perimeter. In hospitals there can be restrictions on fitting doors seals and they are to be fitted where it is possible. The principal reasons doors seals can not be fitted are:

- Opening force under emergency conditions
- Infection control
- Patient safety
- Ventilation regimes

In the case of the NSGH where door seals cannot be fitted and the room is required to have high noise sensitivity, the door sets will be designed to optimise performance and designed to rating of Rw 20- 25.

In case of non-noise sensitive rooms such as store rooms, no seals are to be fitted.

The acoustic selection of doors for all spaces in the NSGH is shown in the Architects Door Schedule (refer to Volume 2 Section of the bid deliverables).

11. INTERNAL IMPACT SOUND ISOLATION

The weighted standardised sound pressure level will meet L'nTw 65 dB(A) which is the criterion nominated in HTM 08-01 for floors over noise or acoustically sensitive spaces.

12.

13. VIBRATION

Tactile structure vibration levels produced by the plant should not exceed the criteria given in BS 6481. Where the standard recommends a range of criteria for a particular occupancy, the low end of the range shall be used.

13.1 CONTINUOUS VIBRATION

Continuous vibration will be assessed in terms of RMS value (1sec) of the frequency weighted acceleration on the floors of occupied areas. The frequency weighting shall be Wg as specified in BS6481, with the base value frequency weighted acceleration of the being 0,005m/s. Multiplying factors are as per the standard.

13.2 INTERMITTENT VIBRATION

This is to be assessed as continuous to comply with BS6841 and BS6477.

13.3 VIBRATION SENSITIVE EQUIPMENT

All environments around vibration sensitive equipment will be evaluated to ensure that they comply with manufacture specifications for specific equipment. All potential sources of nearby vibration will be considered, including;

- Footfall
- Plant
- Speed humps
- Helicopter
- Vehicle traffic
- Loading docks etc.

Brookfield

14.

15. AUDIOLOGY / AUDIOMETRIC TESTING

Audiology tests booths will be provided to allow for the following audiometric testing;

- Sound field tests
- Bone Conditions
- Any other requirements of the Board

16. CONSTRUCTION NOISE AND VIBRATION

Construction noise and vibration will be a critical issue on the NSGH due to the surrounding hospital campus being operational during the construction works and the nearby residential premises. This section sets out an outline of proposed construction noise and vibration management strategy.

A demolition, excavation and construction noise and vibration plan will be developed to manage noise and vibration from the construction works. The objectives of this management plan are the minimisation of noise and vibration emissions and to assist in maintaining a satisfactory environment around the site.

To develop this plan, an advanced evaluation of all work to be performed during the demolition, excavation and construction phase of the project will be undertaken to forecast the potential impact of noise. This noise forecasts will be used to formulate and streamline effective controls and mitigation measures. As a part of this process, an on going testing will be used to evaluate the noise regulation strategies and ensure that they are effective.

The principal issues which will be addressed in this plan are:

- Identification of the noise and vibration standards which will be applicable to this project.
- Formulation of a strategy for construction to comply with the standards identified in the above point.
- Development of a monitoring programme to measure and regulate noise and vibration at all potentially affected locations.
- Establishment of direct communication networks between affected groups, the local Authorities, the Hospital Board, Brookfield and Acoustic Logic Consultancy (UK) Ltd.

16.1 POTENTIALLY AFFECTED RECEIVERS

The Potentially affected noise sensitive receivers include the following:

- All operating buildings within the hospital grounds
- Neighbouring residential buildings surrounding the hospital site

16.2 ASSESSMENT CRITERIA

16.2.1 Noise Goals

The guidance contained in British Standard BS 5228 “Noise Control on Construction and Open Sites” does not extend to providing criteria against which to assess construction and demolition noise. This Standard presents an overview of the legislative background to the control of environmental noise and vibration. The Standard is limited in only providing guidance on the importance of community relations, training site personnel, protecting people in the work environment, neighbourhood nuisance, project supervision and the control of noise and vibration. In addition, the Control of Pollution Act 1974, will also be considered.

16.2.2 Vibration Criteria

The British Standard BS 7385 “Evaluation and Measurement for Vibration in Buildings” considers the potential effects of vibration upon buildings. This Standard defines criteria for two different types of building structure - brick-built residential and more heavily-built industrial buildings. The Standard advises that there is a minimal risk of cosmetic damage (i.e. the formation of hairline cracks on drywalls, plaster or in mortar joints) at the specific guidance levels.

For residential buildings, the limit for cosmetic damage varies with frequency: 15mms-1 at 4Hz rising to 20mms-1 at 15Hz and to 50mms-1 above 40Hz. These limits apply to all three orthogonal directions individually.

Limits for transient vibration, above which cosmetic damage to buildings could occur are presented in the table below.

	Peak component particle velocity in frequency range of predominant pulse	
	4Hz to 15Hz	15Hz and Above
Reinforced or framed structures industrial and new commercial buildings	50mms-1 at 4Hz and above	
Un-reinforced or light framed structures residential or light commercial type buildings	15mms-1 at 4Hz increasing to 20mms-1 at 15Hz	20mms-1 at to increasing to 50mms-1 at 15Hz at 40Hz and above

NOTE: The values apply to vibration levels measured at the base of the building.
The above criteria should be halved for continuous vibration.

Brookfield

16.3 NOISE ASSESSMENT

Noise generated by plant and equipment throughout the duration of the project will be managed to generally comply with the noise level objectives set out in this report.

Predictions of internal noise levels at the sensitive receivers identified above will be undertaken. All such predictions will be made internally within the buildings (given that for all the buildings openable windows are normally closed or facades have fixed windows) and taking into account the expected façade reductions, barrier effects (where applicable), distance losses and using the equipment noise levels tabled above. The process of assessment are summarised below.

16.4 NOISE AND VIBRATION CONTROL METHODS

The determination of appropriate noise control measures will be influenced by the particular activities and construction appliances. This section provides an outline of available methods.

16.4.1 Selection of Alternate Appliance or Process

Where a particular activity or construction appliance is found to generate excessive noise levels, it may be possible to select an alternative approach or appliance. For example; the use of a hydraulic hammer on certain areas of the site may potentially generate high levels of noise. By carrying this activity by use of pneumatic hammers, bulldozers, ripping and/or milling machines lower levels of noise will result.

16.4.2 Acoustic Barriers

Barriers or screens can be an effective means of reducing noise. Barriers can be located either at the source or receiver. The placement of barriers at the source is generally only effective for static plant. Equipment which is on the move or working in rough or undulating terrain cannot be effectively attenuated by placing barriers at the source. Barriers can also be placed between the source and the receiver.

The degree of noise reduction provided by barriers is dependant on the amount by which line of sight can be blocked by the barrier. If the receiver is totally shielded from the noise source, a reductions of up to 15dB(A) can be effected. Where only partial obstruction of line of sight occurs, noise reductions of 5 to 8dB(A) may be achieved. Where no line of sight is obstructed by the barrier, generally no noise reduction will occur.

As barriers are used to provide shielding and do not act as an enclosure, the material they are constructed from should have a noise reduction performance which is approximately 10dB(A) greater than the maximum reduction provided by the barrier. In this case the use of a material such as 10 or 15mm thick plywood would be acceptable for the barriers.

16.4.3 Silencing Devices

Where construction process or appliances are noisy, the use of silencing devices may be possible. These may take the form of engine shrouding, or special industrial silencers fitted to exhausts. In certain cases, it may be possible to specially treat a piece of equipment to dramatically reduce the sound levels emitted.

16.4.4 Silencing Devices

Where construction process or appliances are noisy, the use of silencing devices may be possible. These may take the form of engine shrouding, or special industrial silencers fitted to exhausts.

16.4.5 Treatment of Specific Equipment

In certain cases it may be possible to specially treat a piece of equipment to dramatically reduce the sound levels emitted.

16.4.6 Establishment of Site Practices

This involves the formulation of work practices to reduce noise generation. A noise plan will be developed for this project outlining work procedures and methods for minimising noise.

16.4.7 Noise Monitoring

Noise monitoring can be undertaken to determine the effectiveness of measures which are been implemented. The results of monitoring can be used to devise further control measures.

16.4.8 Combination of Methods

In some cases it may be necessary that two or more control measures be implemented to minimise noise.

Brookfield

16.5 ESTABLISHMENT OF DIRECT COMMUNICATION WITH AFFECTED PARTIES

In order for any construction noise management programme to work effectively, continual communication is required between all parties concerned including the regulatory authority. This establishes a dynamic response process which allows for the adjustment of control methods and criteria for the benefit of all parties. The objective in undertaking a consultation processes is to:

- Inform and educate the groups about the project and the noise controls being implemented.
- Increase understanding of all acoustic issues related to the project and options available.
- Identify group concerns generated by the project, so that they can be addressed.
- Ensure that concerned individuals or groups are aware of and have access to the Brookfield Complaints Register which will be used to address any construction noise related problems should they arise.

To ensure that this process is effective, regular scheduled meetings will be required for a finite period, until all major issues have been addressed and the evidence of successful implementation is embraced by all parties.

16.6 DEALING WITH COMPLAINTS

Should ongoing complaints of excessive noise or vibration criteria occur; immediate measures shall be undertaken to investigate the complaint, the cause of the exceedance and identify the required changes to work practices. In the case of an exceedance of the vibration limits, all work potentially producing vibration shall cease until the exceedance is investigated. The effectiveness of any changes shall be verified before continuing. Documentation and training of site staff shall occur to ensure the practices that produced the exceedances are not repeated.

If a noise complaint is received the complaint should be recorded on a Noise Complaint Form. The complaint form should list:

- The name and address of the complainant (if provided).
- The time and date the complaint was received.
- The nature of the complaint and the time and date the noise was heard.
- The name of the employee who received the complaint.
- Actions taken to investigate the complaint, and a summary of the results of the investigation.
- Required remedial action, if required.
- Validation of the remedial action.
- Summary of feedback to the complainant.

A permanent register of complaints will be kept by Brookfield. All complaints received should be fully investigated and reported to management. The complainant should also be notified of the results and actions arising from the investigation.

The investigation of a complaint shall involve where applicable, noise measurements at the affected receiver, an investigation of the activities occurring at the time of the incident, inspection of the activity to determine whether any undue noise is being emitted by equipment and whether work practices being carried out either within established guidelines or outside these guidelines. Where an item of plant is found to be emitting excessive noise, the cause is to be rectified as soon as practicable. Where work practices within established guidelines are found to result in excessive noise, then the guidelines should be modified so as to reduce noise emissions to acceptable levels. Where guidelines are not being followed the additional training and counselling of employees should be carried out. The results of any corrective actions arising from a complaint shall be validated by measurement or other method where applicable.

16.7 STAFF TRAINING

Responsibilities and reporting requirements of all members of management and staff responsible for the implementation of each element of the plan shall be defined. Training to introduce the Noise Management Plan and explain details of noise sources, noise level targets, personnel roles and responsibilities, communication and complaint handling procedures shall be undertaken for all relevant employees upon commencement.

16.8 NOISE AND VIBRATION MONITORING

Noise and vibration monitoring would be undertaken for the duration of the construction process to provide historical verification data and to determine the effectiveness of measures that may be implemented or to respond to complaints. Attended vibration monitoring would be undertaken at the commencement of any new process to establish “safe” working distances.

17. COMPLIANCE TESTINGS

Compliance testing will be conducted in accordance with the standards nominated in this document and in full acknowledgement and compliance with the requirements of the Board. It is assumed for the purpose of this document that the minimal testing regime will be that set out in NSGH bid documents Volume 2/1 , Appendix S - Acoustics.

Facilities Management Strategy

Submission Reference:

Section 3.5 Facilities Management Strategy

Submission Response:

3.5.1 Introduction

Brookfield through our own experience as building owners and operators recognise the importance of ensuring a good design is complemented with efficient operational design issues being duly considered. Our design for the New South Glasgow Hospitals Project appreciates that additional to providing first class clinical patient services, there are other very important activities necessary to permit the hospitals facilities management team to deliver their operations in an efficient and effective manner that matches the delivery of health services.

In this section we cover the following:

- Goods In and Out proposals for deliveries and removal off site
- Distribution proposals (hospitals and to lab building) from delivery to site to end user stations and back to location of removal off site.
- Separation of flows
- Systems and technologies
- Interface of systems
- Resilience of systems and proposals
- External façade access (cleaning and maintenance/replacement) solution

We understand that after Completion, the facilities management services will be delivered by a combination of NHS GG&C Health Board staff and specialist service providers working under contract to the Hospital's FM Department. Whilst they may be considered to be 'back of house' they are very necessary to support the delivery of clinical services. These services should be kept separate from patient or public activities and we have sought to meet this wherever possible. Our strategy for the delivery of Facilities Management Services reflects the 'back of house' principles and supports the separation from patient and public flows wherever practical

Key elements of our Strategy include:

- The inclusion of the service tunnel between the hospital and FM areas (particularly the goods in and out locations)
- The separation of vertical transportation routes, not only front and back of house but also clean and dirty FM functions
- The use of an automated movement system for the delivery of many bulk services
- The recognition that plant and equipment will over time need to be overhauled or replaced (refer to Volume 3 Section 3.23)
- The provision of specialised access systems to ensure that the external façade in particular can be cleaned and maintained.

The automated movement system incorporates the use of Automated Guided Vehicles (AGV) manufactured by Swisslog Healthcare (UK) one of our Supply Chain Partners and is a key aspect of our offer. Further detail is contained in subsequent paragraphs.

Brookfield

3.5.2 Goods In and Out - proposals for deliveries and removal off site

All goods in and out will be managed via the designated areas within the Facilities Management Department. Separate and dedicated areas are provided for goods received, the back loading of empty containers and waste. Refer to Volume 2 Section 2.8a for 1:200 FM departmental drawings for the proposed locations within the Facilities Management Department and details of the service tunnel and basement.

There was much debate during the dialogue stage on the pros and cons and cost of incorporating a service tunnel into the design. We listened! Brookfield see this tunnel as fundamental. Our design incorporates a service tunnel linking the basement and the FM area where all goods are received and waste is collected by specialist contractors. All FM traffic, both pedestrian and AGV will use this tunnel and this is the primary 'structural' means of separating FM traffic from other users of the hospital. Movements to and from the mortuary and the hospitals will also use the service tunnel.

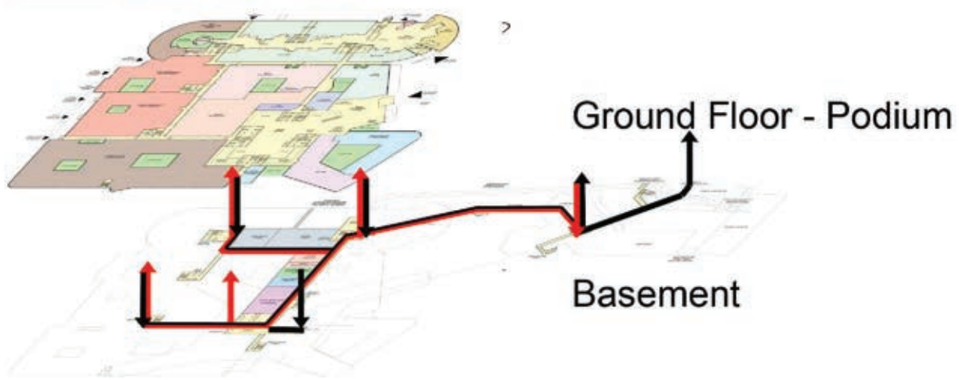
For vertical FM movement through the hospital, our design incorporates dedicated clean and dirty FM lifts. In addition, for the peak FM travel routes through the podium levels, the adult wards and in the FM area (both the main goods in/out and waste disposal areas), we have provided pairs of lifts for both the clean and dirty functions with one dedicated AGV lift within each pair. These lifts are integrated into the AGV Control System and will be 'called' automatically as an AGV approaches. In the event of a temporary failure of an individual lift, operation of the remaining clean or dirty lift in the pair will be converted to shared operation until the repairs are completed.

The FM lifts servicing the children's hospital will be shared between AGV and pedestrian traffic while still maintaining the split between clean and dirty operations.

3.5.3 Facilities Management Distribution Routes and Separation of Flows

The following table summarises the movement of materials, waste and staff into and around the hospital. As it is common to all FM traffic, the graphics contained in the table do not show the tunnel or FM area but focus on the traffic flows through the hospital. The following graphics are indicative only. More detailed sketches are contained in Volume 2 Section 2.2. As requested (updated ITPD volume 3 issued 19/8/09) the FM routes through the wards and other areas are included in Volume 2 Section 2.2.

First Floor - Podium



Brookfield

Activity	Description	Normal delivery method from / to receipt / pickup area
Catering – Deliveries to Central Kitchen	Deliveries to central kitchen including chilled food, milk, bread, general provisions, chilled dairy, other items AGV will deliver these items directly to holding areas in the main kitchen on Level 3. Vertical movement via the dedicated Clean FM Lift (AGV).	
Brookfield

Activity	Description	Normal delivery method from / to receipt / pickup area
Catering – Deliveries from Central Kitchen	Deliveries of prepared food to regeneration kitchens Adult Wards Children's Wards Meals will be despatched from the central kitchen via AGV to the intended destination. The AGV will deliver the meals to holding areas adjacent to each regeneration kitchen. For the delivery to the adult wards, the AGV will use the dedicated Clean FM Lift (AGV).	
Activity	Description	Normal delivery method from / to receipt / pickup area
	For delivery to the children's' wards the AGV will move to the basement via the dedicated Clean FM Lift (AGV) and then use the Clean Shared FM Lift servicing the Children's Hospital. Note that the diagram only shows one lift core being used for this function. This has been done for clarity of the diagram. The clean lift within both cores will be used for this purpose.	Catering – Deliveries from regeneration kitchens	Deliveries of prepared meals from regeneration kitchen to bedside.	The meals will then be delivered manually from the Regeneration Kitchens to patients under the normal hospital arrangements.

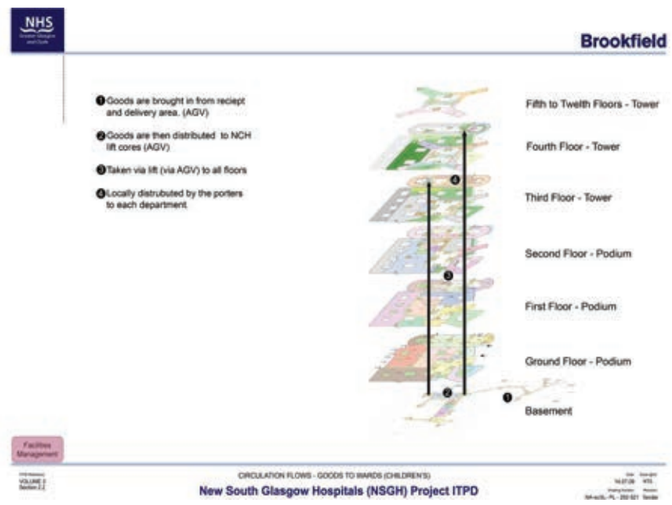
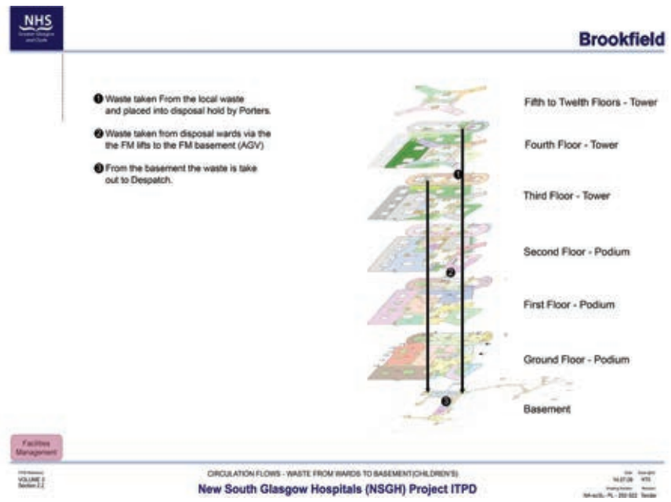
Brookfield

Activity	Description	Normal delivery method from / to receipt / pickup area
Stores and Materials	Medical goods, general stores including NDC deliveries Stores and supplies are transported via AGV compatible carts from the receipt area to the holding area adjacent to the FM lifts on the floor where it is required. Porters will complete the delivery from the holding area to the final destination. For stores delivered via the main lift core, the AGV will use the dedicated Clean FM Lift (AGV) Empty stores carts will be handled in a reverse manner with the cart placed in an outgoing buffer storage area in the FM area to await collection for transport off site For stores for the children's hospital, the AGV will use the shared Clean FM lifts.	
Brookfield

Activity	Description	Normal delivery method from / to receipt / pickup area
		


Brookfield

Activity	Description	Normal delivery method from / to receipt / pickup area
Waste	Including clinical, domestic, recycling, WEE, furniture and equipment site special waste Porters will collect full containers from locations around the hospital and deposit them in the holding area adjacent to the Dirty FM lifts. These are then collected by AGVs and transported to the waste handling centre. For waste moved via the main lift core, the AGV will use the dedicated Dirty FM Lift (AGV). Empty waste containers will be handled in a reverse manner and exchanged by the porters in the holding areas on each level. For waste from the children's hospital, the AGV will use the shared Dirty FM lift.	
Activity	Description	Normal delivery method from / to receipt / pickup area
		


Brookfield

Activity	Description	Normal delivery method from / to receipt / pickup area
Linen	Clean linen, soiled linen	Linen is transported by AGVs in a manner similar to goods in and waste out described previously except that porters will collect clean linen from the holding area adjacent to the Clean FM lift and deliver it to the appropriate clean linen stores in the wards. Similarly, soiled linen is collected by the porters from the disposal hold and moved to the holding area adjacent to the Dirty FM Lift where they are collected by AGVs and transported to the collection points in the FM area.
Other Products.	Includes retail, mail, drug, laboratory products, retail waste	All items will be moved by porter, other FM staff or retail tenants. These items will be collected from source and delivered directly to the final destination. For movements to and from the main podium and adult, they will used the appropriate dedicated Clean or Dirty FM lift (pedestrian).
Specialist Services	Bed management, medical gases	All items will be moved by porters or FM maintenance staff. For vertical movement within the hospital, dedicated bed lifts have been provided. Medical gases will use the optimum FM route which may include a Dirty FM lift.
FM Staff	Maintenance staff, domestic staff	All vertical FM pedestrian movement will use the appropriate Dirty FM lift. All FM staff will use the service tunnel to move between the FM Department and the hospital.
Mortuary	Movements between Hospitals and Mortuary	All movements between the Hospitals and Mortuary will be via the service tunnel.

Brookfield

3.5.4 Systems, Technologies and Integration

3.5.4.1 Automated Guided Vehicles (AGV) Strategy

Introduction

By reference to the ITPD Volume 2/1 Employer's Requirements (Hospitals) Appendix M&E 7 identifies the requirements for an Automated Material Transfer System. We understand that the provision of the medical treatment and patient-care core processes at the New South Glasgow Hospitals will generate substantial logistical workloads. Without an automated system, this requirement can only be met by a large number of porters thereby making it operationally inefficient and with it significantly higher costs.

To meet the requirements of an Automated Material Transfer System, Brookfield proposes the use of an Automated Guided Vehicle (AGV) system manufactured by Swisslog Healthcare (UK). We know this solution will streamline the movement of goods, linen and laundry and catering services around the hospital as well as improving the overall efficiency and effectiveness of the these 'back of house' FM functions. AGVs are currently in use in hospitals in Germany, where as you would expect efficiency is at the core of these operations. If appropriate and requested by NHS GG&C Health Board, Brookfield can arrange through Swisslog to facilitate a visit to some existing facilities to witness first hand how these AGV's operate and discuss end users experiences.

Swisslog Healthcare (UK) Ltd has been closely associated with key aspects of the design development and as a consequence our design incorporates the requirements of this system including the appropriate sizing of corridors, the service tunnel, doors and lifts. The AGV system has been fully integrated into the lift operation which will ensure a smooth and seamless operation.

One of the key advantages of this system is the minimisation of the requirement to install fixed infrastructure and the ability to allow both pedestrian and AGV traffic in the same spaces thereby reducing capital expenditure. We are confident that the Automated Guided Vehicles will significantly improve the movement of goods within your hospitals. Furthermore, our analysis indicates that the system provides a lower whole of life cost when compared to a fully manual distribution solution because of the annual savings in manpower costs that can be achieved through a reduced number of porters.

Brookfield

Design Philosophy

We have sought to optimise the utility of the AGV system by using it for all elements of the service until loads become too small to be carried on an AGV cart. As far as possible the AGV's will be used to carry full loads between major nodes within the hospital.

- Distribution of goods requires decision making on the part of the deliverer.

We anticipate that porters will continue to distribute goods beyond the major nodes particularly when some decision making is required by the person moving the load. For example, we anticipate that porters will continue to distribute linen from the holding areas on each floor to storage locations in each ward.

- Potential for interaction between patients and robots

While the AGV's are safe to use around humans, we have sought to minimise the potential for contact between AGV's and patients/members of the general public. By restricting the use of AGV's to 'back of house' locations and movements between major nodes using the dedicated FM routes, we have ensured the potential for contact with patients and the general public is unlikely. We understand that this principle was generally agreed during the final dialogue session.

Key assumptions

This proposal is based on the following assumptions:

1. All carts for NHS stores, linen, meals and sterile goods will be AGV compatible and details of which will be provided by NHS GG&C Health Board during the Hospital build and procurement programme.
2. Special drop side carts to meet the Swisslog specification will be provided by NHS GG&C Health Board to allow non-AGV compatible stores trolleys and cages to be loaded and transported via the special active buffer system provided by Swisslog as part of the works.
3. Waste carts will be either AGV compatible or will be configured such that they can be transported on drop-side AGV carts. Further discussion and consultation will be required to confirm the particular solution appropriate to the New South Glasgow Hospitals and its waste contractors.

Whilst it is assumed that AGV compatible carts will be provided through the usual NHS procurement channels for use by NHS-controlled distribution centres, Swisslog are able to provide carts to all specifications on request. Swisslog will provide the necessary data and specification for AGV compatible carts. Modifications required to standard manual handling cart designs are minor and do not significantly increase the unit cost over a standard cart at the time of manufacture.

By way of information AGV compatible carts have the following specification requirements:

- 360mm ground clearance to allow the LTC2 AGV to manoeuvre underneath.
- Swivel wheels with magnetic or similar mechanical locking device to ensure wheels are aligned fore-aft when the cart is being carried.
- Specific cart width with a small side overhang to allow the carts to be handled by the active buffer conveyor systems and automatic cart washing machine.
- Fixed magnets on the chassis to allow accurate cart positioning on the AGV.
- Pocket/holder for the RFID tag that identifies the cart's intended destination.
- Optionally, specific door mechanisms if the cart washer is to be fitted with automatic door opening and closing devices.

3.5.4.2 AGV Operations

The general FM traffic flows through the hospital is described in section 3.5.3. This section expands on that concept with particular reference to how AGVs are integrated into those traffic flows.

The identification of individual loads and destinations will be through Radio Frequency Identification (RFID) technology.

Linen

Linen will be ordered electronically and packed at a remote facility (depending on the requirements of specific departmental locations) and loaded onto an AGV compatible cart for transport to site. Following delivery it will be placed in a buffer holding area in the FM area prior to collection by AGV and delivery to the holding area adjacent to the FM lifts on the relevant floor. Porters will complete the delivery process to the final destinations within the wards.

Soiled linen will be handled in a reverse manner with the cart of soiled linen placed in an outgoing buffer storage area in the FM area to await collection for transport off site.

NHS stores & supplies

NHS stores and supplies will be ordered electronically, packed at a remote facility (depending on the requirements of specific departmental locations) and loaded on to an AGV compatible cart for transport to the Hospital. Following unloading in the FM area, it will be placed in a buffer holding area for collection by AGV and delivery to a holding area adjacent to the FM lifts on the relevant floor. If necessary, porters will complete the delivery.

Empty stores carts will be handled in a reverse manner with the cart placed in an outgoing buffer storage area in the FM area to await collection for transport off site.

Stores and supplies from other suppliers

Stores and supplies from other suppliers will be delivered to site in standard (non AGV compatible) cages and trolleys to the FM area. Here they will be loaded directly onto a special AGV compatible cart via an active buffer system that will present the special cart at ground level to allow trolleys and cages to be wheeled straight on. These will be collected by AGV for delivery to the intended destinations as described previously

Waste

Waste may be handled directly by AGV compatible carts, but where this is not possible, empty standard Euro bins will be loaded on to special AGV compatible carts and delivered by AGV to the intended destination as described previously.

Full waste carts will be collected from holding areas on each floor by the AGV and transported to the waste handling centre where the Euro bins will be removed from the AGV cart for transport off site.

Catering

Food deliveries from off site will be managed in a similar way to other stores and materials except that the AGV's will deliver these directly to holding areas in the main kitchen on Level 3.

Meals will be despatched from the kitchen via an active buffer system that ensures that meal carts are handled in a first in, first out manner to ensure timely delivery of the meals by AGV to the intended destination.

The AGV will deliver the meals to holding areas adjacent to each regeneration kitchen where the final preparation activities will be completed. The meals will then be delivered to patients under the normal hospital arrangements.

Cart Cleaning

We recognise that carts must be cleaned regularly as such have included an on-site washing facility with a capacity of around 20 carts per hour.

Brookfield

3.5.4.3 AGV's The Proposed System

Equipment

Our proposal includes the following elements:

- 22 x LTC2-LC vehicles with NICAD batteries
- 15 x NICAD charging stations
- 2 x control server PC installed with TCMS2 software (Live + backup unit)
- Service laptop installed with TCMS2 software
- 10 bus controllers (PLC interface for doors etc)
- 2 x active buffer units:
- One is located at goods in/out in the FM area to handle special drop side carts for transporting stores on non-AGV compatible trolleys and cages. This buffer fitted with a horizontal diverter to make a loop configuration and also a lifting mechanism to enable carts to be loaded at ground level.
- The second is located in the kitchen to handle outbound meal carts.
- 221 passive cart stations made up of 78 send only stations, 73 receive only stations and 70 combined send/receive stations. These will be located at the FM hub area on ward floors and in passive buffer areas within goods in/out and also the Energy Centre.
- 56 x arrival signal units and 20 AGV approaching warning beacons.
- A two-chamber automatic cart washer.

Interface with other systems

Lifts

The AGV System interfaces directly with the various FM lifts. Our plan shows two lifts (one clean, one dirty) dedicated to AGV use in each FM cluster in the main building core. To service the Children's hospital the lifts will be shared between pedestrian and AGV traffic.

Lifts are automatically called by the AGV traffic management system. After the individual transportation of an AGV is complete the lift is released either for subsequent AGV traffic or manual operation as required.

Doors

All doors on the route of the AGV System will be automated. Fire doors, held open, will be slightly delayed from shutting until any AGV in the immediate area of door operation is clear.

Fire Alarm System

The AGV installation will be connected to the fire alarm system so that in the event of an alarm, AGV movement is controlled in an appropriate and programmable manner to suit the circumstances.

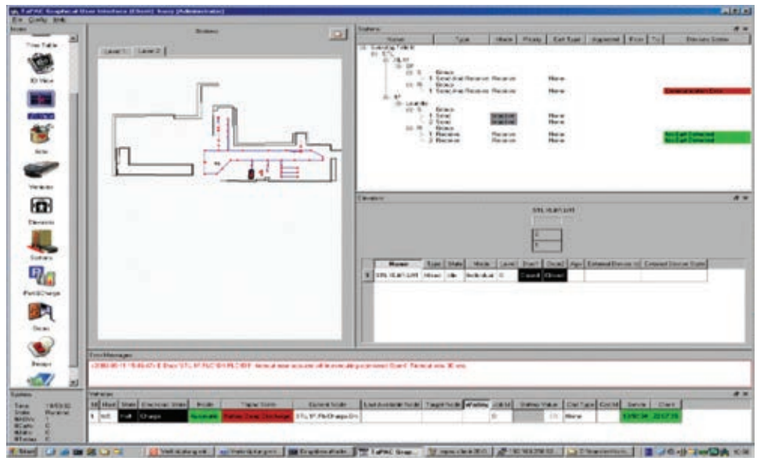
Additional requirements

To be able to provide an operational installation, a compatible network with comprehensive WiFi will be provided. In addition, suitable network connections including provision for Power Over Ethernet will be provided adjacent to all locations required by the peripheral equipment of the AGV installation e.g. sending station transponder readers, charging stations, PLC interfaces for lifts and doors.

We will provide suitable interfaces to connect to lifts, doors, fire alarms and communication systems (BMS etc). The suppliers of this equipment will provide compatible interfaces to ensure appropriate interaction.

Control systems

Swisslog's LTC2 AGV and its Traffic Control & Management System software (TCMS) have been specifically designed for healthcare applications. The compact vehicle design and small turning space is ideally suited for operation in a hospital environment. The bi-directional vehicle minimises manoeuvring space requirements around lifts and send/ receive stations. The AGV's navigation and guidance system does not require any modification or attachments to the building fabric, and hence the scope of the Swisslog AGV's operational routes can be easily altered or extended at any time. TCMS2 is designed for ease of operation with both 2D and 3D visualisations of AGV activity and location. Programming and control functions are easily configured, and the system may be operated with minimal training.



Brookfield

3.5.4.4 Resilience of Systems

Warranty

We note that at the Commercial Dialogue Meeting No 3 on 15th July 2009, NHS GG&C Health Board confirmed that Bidders should allow for an extended Defects Liability Period of 24 months for all elements post completion of each Stage. The equipment included within the AGV system will be provided with an additional 12 months defects liability warranty period by Swisslog in addition to the 24 months DLP provided as part of the construction contract. During this period the equipment will require servicing procured by the hospitals FM department according to the manufacturer's schedules.

Maintenance

In addition to the system supply and installation, we are pleased to advise Swisslog will also offer a comprehensive service and maintenance for the Swisslog AGV installation including all parts and labour over a five year period for a sum of approximately £300,000 (to avoid doubt this figure is excluded from the Target and Maximum Price). As a comprehensive maintenance offer, this includes all routine maintenance, ad-hoc repairs and consumable items but excludes batteries. Maintenance on the cart washers and active buffer conveyor/lifters is excluded from this estimate.

A comprehensive maintenance agreement with Swisslog will provide NHS GG&C Health Board with confidence that the manufacturer is standing behind its product and that this innovative system will continue to provide operational savings year on year.

3.5.5 External Access Systems

Safety is at the core of Brookfield and we are extremely conscious of the need to provide safe external access to the façade of both the podium and the tower for both cleaning and maintenance activities. We have assessed each facility and set out are proposals to that affect.

Laboratory Building

Our proposal anticipates that the laboratory building will be cleaned externally using an articulated boom lift (commonly known as a "cherry picker").

Podium Levels

We have allowed a 2m wide perimeter to permit access via elevating platform or articulated boom lift (cherry picker) to most of the podium levels and Children's Hospital. The only exception to this is at the Children's Accident and Emergency ambulance entrance as we have allowed a soft border for privacy/screening adjacent to the building (Observation Ward). For work above these locations an articulated boom lift will be necessary to provide sufficient horizontal travel to reach the façade above this area. By way of example, the Nifty Heightrider 17 4x4 lifting platform provides a 17m lift with 9.6m outreach and a working ground width of 2m.

Tower (Adult Hospital)

Our design proposes the use of Manntech Type 1 Building Maintenance Unit supplied and installed by Cento to provide safe access to all sides of the Tower façade.

The Manntech Type 1 Building Maintenance Unit (BMU) is a proven design with over 400 examples installed in the UK between 1972 and 2009 and in excess of 3,500 world wide. This equipment is ideally suited to buildings where a roof level perimeter track system can be installed. The imposed roof loadings are minimal and will allow the use of a non-anchored and non roof penetrating 'freely laid' track system. The freely laid track system is cost effective to produce and fast to install. It reduces associated construction cost and the non-anchored track support detail eliminates the need for weathered fixing details.

This BMU and Track system design is the preferred option for many PFI and other hospital projects for example, Lewisham, UCLH, RVH Belfast, Addenbrookes, and Hull RI. With proper maintenance it will provide a service life of 30 years.

The system is fully powered and is available for use within minutes of maintenance or cleaning staff arriving at the garaging location. Cleaning and maintenance staff will access the roof the building through doors to the roof areas, Safety barriers will be installed to permit access from the door to the BMU 'rest' location.

In the event of emergency service helicopter using the roof landing pad when the BMU is in operation, we propose to install a communication system between the cradle and roof car that can be used to warn BMU occupants of a helicopter approach. Operational procedures will need to be established to resolve interface issues between BMU and helicopter operations. These procedures should be repeated in the 'helipad operations manual'.

Maintenance.

The system must be maintained and tested in accordance with BS 6037: 2003, LOLER 1998 ACoP and PUWER 1998. The manufacturer recommends routine inspections are advised at 3 month intervals and a more thorough inspection at 6 month intervals. Weight test & re-certification is required every 12 months. An estimate from the manufacturer for the annual maintenance and certification of this equipment will be provided.

Training

This system is simple to use and operator instruction is provided by Cento. The manufacturer can provide operator training to permit FM staff to use the equipment. One day's training is sufficient to train six operators. Instruction is always site specific Refresher instruction is not compulsory but is recommended depending on how frequently an operator is using the equipment. This is a client decision. Cento can deliver instruction at the Hospital's request.

Brookfield

Main Incoming Utilities Design/Connection Strategy

Overview

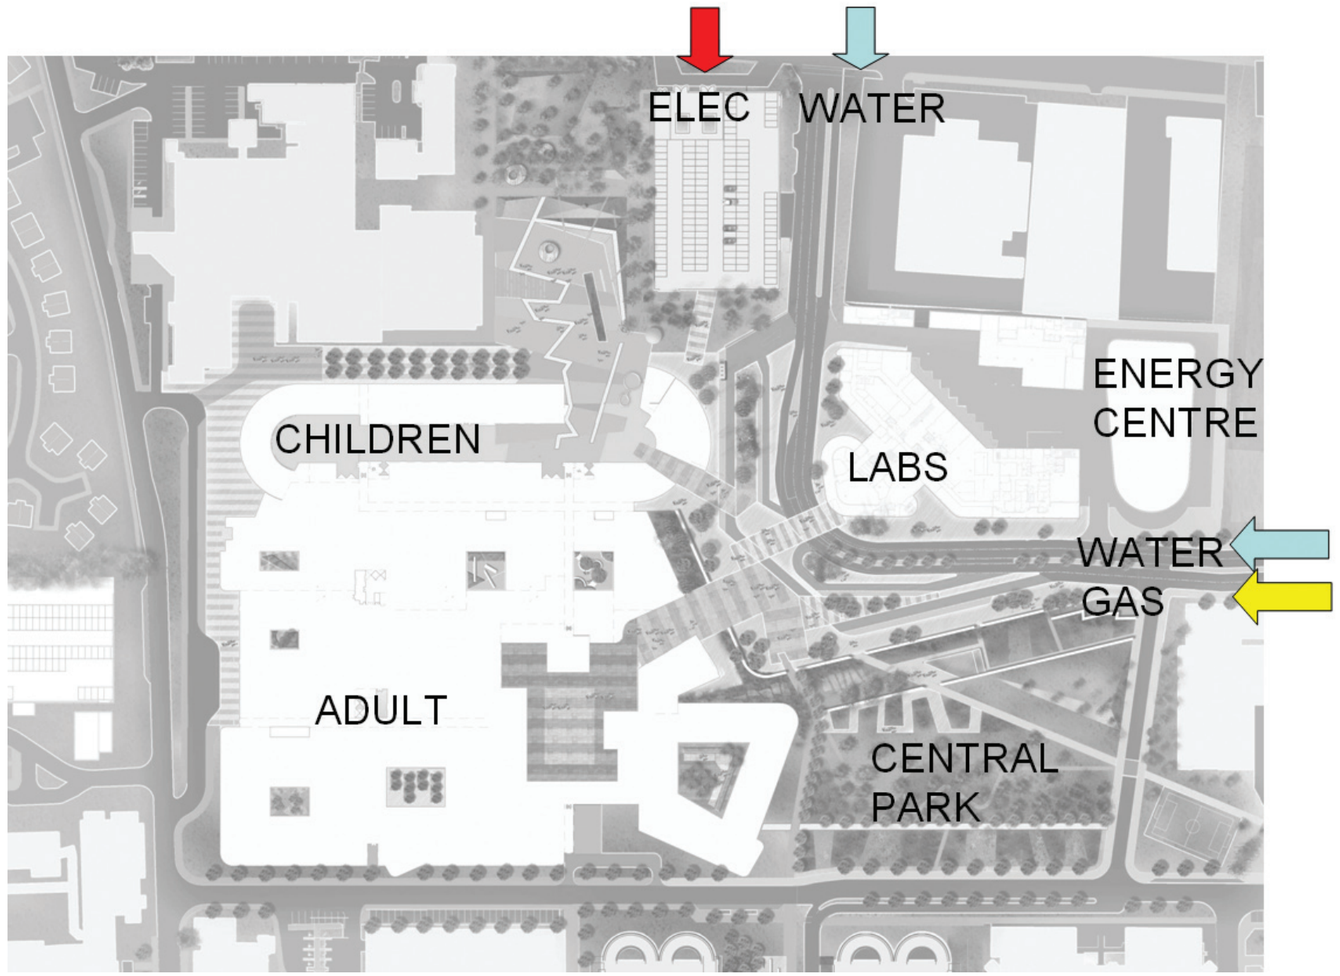
The diagram illustrates the location of the incoming utilities, the water and electricity being taken from the Hardgate road, the gas and a second water supply being taken from the Govan Road.

Electrical Utility

The site will be supplied by Scottish Power at 33,000 Volts, their substation being located off Hardgate Road.

It is estimated that the site load will be in the order of 21.5 MVA, including 25% growth and including the retained estate.

This figure exceeds the estimate in the Employer's Requirements by 1 MVA, however, it is noted that the figure in ITPD of 20.5 MVA is based upon an area for the exemplar scheme of 140,000m_ whereas the measured area of the examplar is approximately 166,000m_. If corrected, the load stated in the ITPD would become approximately 22.5 MVA.



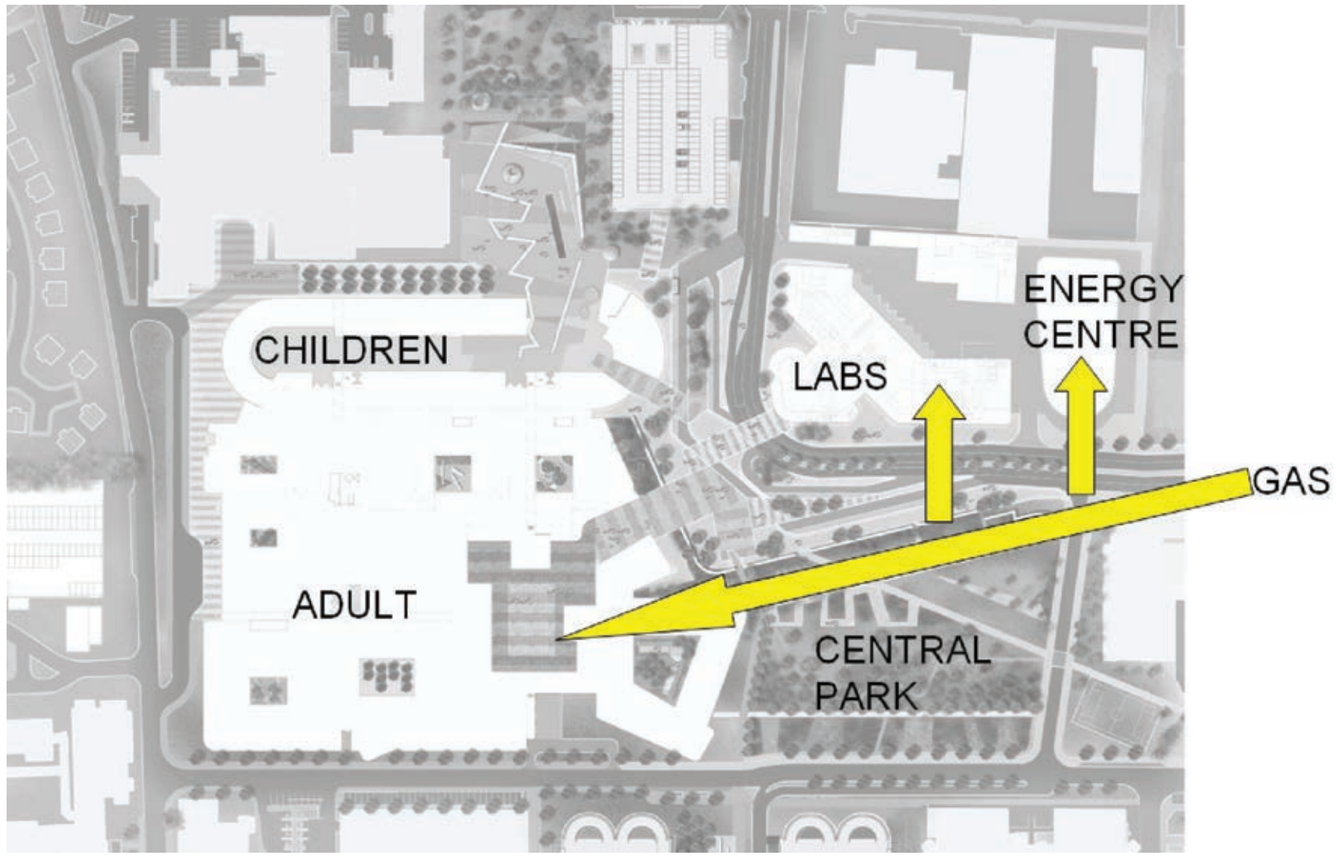
Brookfield

Gas Utility

The gas supply for the Adult Hospital and Children's Hospital will run from a new meter housing and booster station at the boundary of the site on Govan Road and run as a medium pressure supply to the Energy Centre and with a branch to serve the Laboratory Building.

The medium pressure gas main will continue to the Acute building to serve the kitchen/catering.

Whilst the current solution is based on gas supply being brought to the site at Low Pressure, consideration will be given to bringing in a medium pressure supply to avoid the need for onsite boosters.



Brookfield

Water Utility

Potable mains cold water will be derived from two separate street public water mains with a separate water main entering the site from each main.

The two 150mm respective site water mains will run in a shared trench with the fire and gas main.

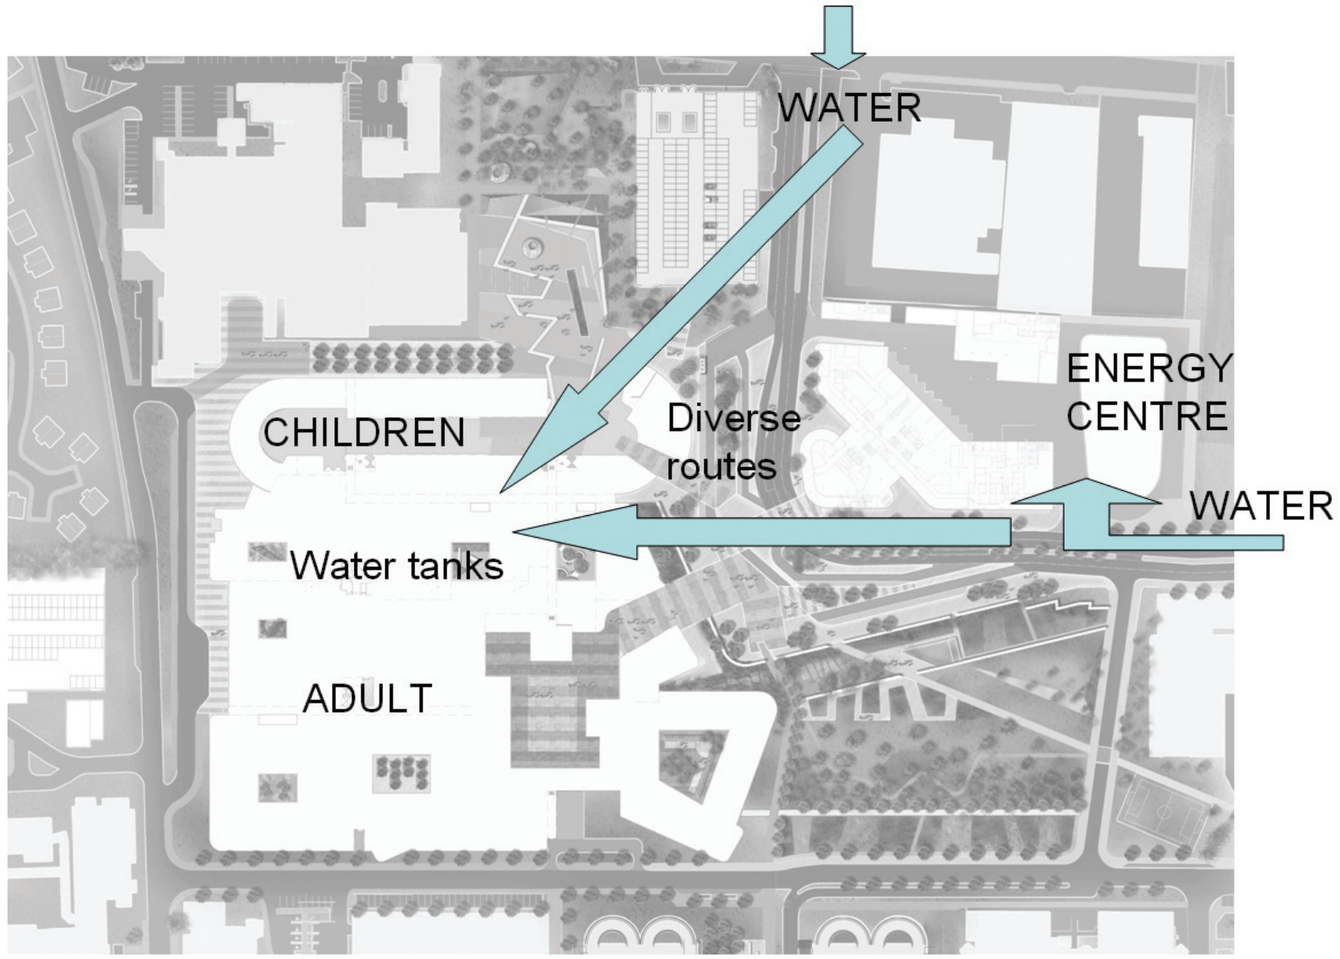
To safeguard against the event of a mains failure from either public street main and ensure resilience to the hospital site water supply the two site mains will be linked by a valve chamber with a normally closed valve for sole use by Scottish Water if and when required.

Fire Mains

The two separate water main connections from Govan Road and Hardgate Road will each have branches to run as fire mains around the site to serve fire hydrants.

The fire mains will form a ring around the building and be interlinked by a normally closed Fire Brigade valve to ensure resilience to the site fire main network.

The fire mains will be unmetered unless specifically requested by the local water authority.



A48235836

Brookfield

Energy Centre

The Employer's Requirements Proposal is for two energy centres in separate locations on the site. This has been reviewed and an alternative is proposed.

The proposed energy centre is to be located adjacent to the laboratory block. The single building will be internally separated into two separate compartments each containing half of the required plant and separated by a 4 hour fire wall. This effectively provides for two energy centres within one building envelope.

Each half of the energy centre will be capable of independent operation and together will incorporate the N+I requirements for resilience and maintenance.

The energy centre plant will include generator and boiler capacity for the laboratory block to reduce plant space requirements in the laboratory building and to provide a level of resilience consistent with the rest of the site.

It is proposed that the energy centre will be built at the same time as the laboratory building and fitted out with services to enable the laboratory block to be fully operational in advance of the full fit out of the energy centre.

The energy centre will also house fuel oil for the emergency generators and boiler standby fuel for the retained site.

Brookfield

Water Services and Drainage Design Strategy

COLD WATER SERVICES

The two incoming potable cold water mains will supply the filtration and storage plant located within the hospital basement.

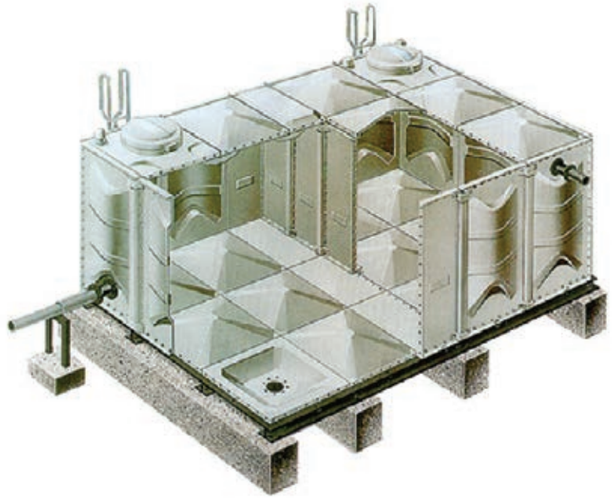
The incoming mains water will supply break tanks before passing through water filters to supply the bulk storage tanks. The water will be stored in a ‘wholesome’ condition and distributed to all sanitary fitting points, thus avoiding the need for a separate drinking water distribution system.

Cold water will pass through electronic water conditioning devices to reduce the build up of scale within equipment and distribution systems.

Water booster sets will pump the filtered water from the basement to the cold water distribution systems throughout the hospital and also supply the domestic hot water systems.

At each floor distribution branch a pressure regulating valve will be provided to maintain similar water pressure at all levels in the building providing convenience of use and minimizing water consumption.

All distribution systems will be capable of being chemically cleaned and disinfected.



Sectional water storage tank

Booster set

Brookfield

DOMESTIC HOT WATER

The boosted cold water systems will supply the domestic hot water (DHWS) systems therefore they will be pressurised. A number of systems will be provided for the various areas of the hospital. The DHWS will be generated and stored within the building utilising high efficiency semi-storage calorifiers comprising buffer vessels linked to rapid recovery plate heat exchangers. The calorifiers will be located within the plant rooms generally related to the location of the heating stations.

The DHWS distribution system will be configured with a pumped return to maintain temperatures within the system. The pumped return system will minimise “dead legs” and reduce water consumption by providing the correct temperature of water at the outlet with minimum delay.

The storage system will be capable of achieving higher storage temperatures for carrying out a pasteurising process to minimise contamination from Legionella bacterium within the storage vessel. Each storage vessel will be isolated from the distribution system while the process is carried out.

The distribution system will be arranged to minimise conditions of low flow within pipework. The hot and cold water system pressures will be equalised at each service outlet for successful blending of hot and cold water through anti-scalding devices prior to use.

The anti scalding devices will be used throughout the hospital where service outlets provide water for personal hygiene washing.

At each floor distribution branch a pressure regulating valve will be provided to maintain similar water pressure at all levels in the building providing convenience of use and minimizing water consumption.

Packaged HWS plate heat exchanger/buffer vessel

Brookfield

Heating Design Strategy

Selection of system

The choice of heating medium has been considered and the use of Medium Temperature Hot Water (MTHW) is proposed for the following reasons:-

- There is considerable transmission distances involved on the Southern General Hospital site. MTHW operating at 120oC flow and 90oC return temperatures will reduce the mass flow rate circulated and thus pumping power required.
- Most building on the site will use Low Temperature Hot Water (LTHW) as the final heating distribution medium. Therefore, to maintain adequate temperature at the extremities of the site a high temperature is required at source. MTHW is most suitable for this purpose.
- There is little requirement for process steam on the site, for example laundry and CSSD. Steam systems are generally a more inefficient source of heating due to higher operating temperature, blowdown and other losses, and complications with return condensate back to the plant. Therefore, central steam system has been ruled out. Any steam requirement such as humidification will be met by either local gas fired plant or direct electric units, depending on the size and location of loads.
- In order to reduce the carbon emissions of the development it is proposed to incorporate Combined Heat and Power (CHP) units as part of the heating source. CHP units operate more efficiently at lower temperatures. Whilst LTHW is preferable, incorporation of CHP into MTHW systems is still very beneficial. If operating with a steam system their operation can be severely affected.

Location of Boiler Plant

The Exemplar scheme indentified two separate energy centres on the new development site; a main energy centre to the North of the new acute hospital and a second centre to the East adjacent to car park 1B. This arrangement provided resilience in the event of a catastrophic failure in one of the buildings.

It is proposed to utilise a remote energy centre to concentrate noisy and ‘dirty’ plant away from the main hospital buildings. The energy centre will house not only the central boiler and CHP plant, but also 11kV switchgear, standby generators, oil storage and main hospital cooling plant.

To avoid the need to provide two energy centres the single energy centre building will be divided into two with heating and cooling plant, and standby generators spread across the halves, with four hour fire separation between. The plant will be designated A and B and essentially work as independent systems to provide resilience.

The building will be three storey with accommodation arranged as follows:-

- Ground Floor – oil storage for standby generators, boilers and retained site. Oil fill points for tanker deliveries will be located on the Western face of the energy centre
- First Floor – standby generators and 11kV switchgear
- Second floor – MTHW heating boilers and CHP units, absorption cooling plant
- Roof – main chillers and associated transformers, absorption chiller dry air coolers, wind turbines

A multi-core chimney will collect flue discharges from the standby generators, boilers and CHP units to discharge products of combustion.

Multi core chimney

Brookfield

Boiler Plant Sizing

The heating load for the site has been assessed for fabric, ventilation and hot water service loads. Loads for the retained estate and proposed developments have based on the information given in Appendix M&E.2 of the Employer's Requirements.

The heating load for the new hospital as discussed above has been established as follows:-

- Fabric heating is based on similar projects and has been taken as 20W/m2
- Ventilation heating has been assessed using the volumetric flow rates calculated from the proposed scheme and are described in section 3.9. An allowance for heat recovery on ventilation plants has been assumed.
- Hot water has been assessed based on the number of sanitary fittings within the hospital and selections made of suitable calorifiers.

MHTW Boiler

The total heating load can be summarised in the following table:

Heating (kW)										
Description	Total AHUs	Heat Recovery	Total AHUs	Duct Heaters	VT Circuit	Misc CT	Total heat load	Pipe Losses 2%	Total HEX Duty	HWS
Plantroom 21	1800	-340	1460	85	300	100	1945	39	1984	300
Plantroom 22	1895	-380	1515	95	100	100	1810	36	1846	300
Plantroom 31	4395	-880	3515	220	440	100	4275	85	4360	1000
Plantroom 32	3320	-660	2660	165	1200	100	4075	80	4155	450
Plantroom 33	-	-	-	-	-	-		-	-	450
Plantroom 41	1700	-320	1380	80	350	100	1910	38	1948	450

Total	14293	2950
Diversity	10%	10%
Load Diversity	-1430	-295
Mains losses 1%	143	-
Corrected loads	13006	2655
New build total		15661
Retained Estate(1)		5670
Future Developments(1)		5700
Total Boiler Load (kW)		**27031**

Heating loads taken from ITPD Volume 2/1 App. M&E.2 Base Building Loads

Therefore, the total heating load for the new hospital will be in the order of 28,000kW, which equates to 120W/m^2. The compares favourably with similar projects as noted below;

Princess Royal University Hospital	157 W/m^2
Barnet Hospital	120 W/m^2
Peterborough Hospital	110 W/m^2 (Designed to 2006 Building Regulations)
Kings College Hospital	189 W/m^2

The total site load to be met by the boiler plant in the energy centre is 28,000kW.

Boiler Plant Arrangement

As described earlier, for resilience, the boiler plant will be divided into two. The total load to be supported by each part will therefore be some 14,000kW, which will be met by three boilers at 5,000kW. Allowing for standby capacity on each half (N+1) gives four boilers, and a total installed load for each side of 20,000kW. Therefore, each boiler plant can meet 66% of the total site load, which should be sufficient to allow the hospital to continue to function in the event of a catastrophic failure on one system. This allowance will also include for a service reserve capacity.

For further resilience connections will be made available on each system header to allow a temporary trailer mounted boiler to be connected to boost the capacity of the heat source.

The boiler plant will be dual fuelled using natural gas as the primary fuel and 35 second gas oil as the emergency fuel. Automatic changeover between primary and emergency fuels will be automatic to prevent disruption in operation. The arrangement of the natural gas and fuel oil systems are described later.

Combined Heat and Power System

In order to reduce carbon emissions from the Southern General Hospital, a number of Low and Zero Carbon strategies are proposed. One of these strategies is to use combined heat and power (CHP) plant to generate electricity on site and use the waste heat from the generator cooling jacket and exhaust gases to provide heating and cooling, via absorption chiller plant, to the building.

An analysis of the use of CHP is further described in Section 3.20.

Heating Distribution

From the energy centre MTHW will be distributed to the main hospital to serve the various major plant zones. It is proposed to employ buried underground heating mains to avoid the need for a major tunnel system, with the associated complications of access, ventilation and fire protection, etc.

The two heating systems (A & B) will be replicated in the heating distribution between the energy centre and the main hospital building, thus providing resilience in the event of a pipework problem necessitating the shutdown of one circuit. At the main hospital the two circuits will be brought together for final distribution to the main load centres.

The final heating medium for fabric heating and ventilation systems will be LTHW to provide safe operation of plant. MTHW will be used for hot water service calorifiers to give rapid heating and recovery.

To separate MTHW and LTHW heat exchange stations will be formed at load centres.

Whilst the Exemplar Design utilized a constant volume pumping distribution arrangement with 3-port bypass valves at the load centres this does mean that the pumps have to run at constant speed and offer no facility to reduce pump power across the site. It has been estimated that this could consume up to 1.4GWh across all pumping systems more than is necessary equating to 4kg/m^2 of CO_2, which with such a stringent carbon and energy target needs careful consideration.

It is therefore proposed to employ variable volume pumping arrangements and 2-port valve control to maximise pumping efficiency, with the pump speed being varied automatically as the heating load changes.

Retained Estate

Allowance has been made in the boiler capacity to serve the retained estate together with future developments, such as the laboratory/FM building. Separate pumped circuits from the A and B sides are allowed for the laboratory/FM building and connections have been allowed on the B side plant for future provision for the retained estate and other buildings.

This will allow the CHP heating capacity to be further utilized and therefore increase system efficiency and reduce site carbon emissions further.

It is envisaged that when it is planned for the retained estate to be linked to the central system a new pumped circuit will be established and heating mains run out from the energy centre using a buried pipework system, similar to that used for the new hospital buildings. Connections would be left at each load centre on the heating mains and then the decentralised boiler plant sequentially decommissioned and fed via plate heat exchangers from the central system. As with the new buildings it is proposed that variable volume pumping is employed to reduce pumping power.

Brookfield

Ventilation and Air Treatment Design Strategy

Purpose of ventilation

Ventilation in the healthcare environment can be naturally or mechanically driven and serves a number of purposes which can be summarised as follows:

Providing fresh air for normal respiratory purposes
Diluting the level of CO^2 in the space
Removal of odours and pollutants
Control of temperature and humidity
Control of infection
Specialist process requirements
Occupants experience a feeling of wellbeing

The use of natural ventilation will minimise the need for energy to drive fans. However many clinical requirements, in for example Operating Theatres, necessitate the use of mechanically driven ventilation for close environmentally controlled spaces and departments having high equipment heat gains. Furthermore, despite carefully considered planning, building constraints invariably lead to spaces that do not have access to natural ventilation.

The other major consideration with regard to the ventilation strategy for the building is the construction. The thermal mass and 'u' values or thermal characteristics of the structure have been carefully selected as they determine the optimum thermal lag of the building which controls the rate of heat transfer into the space and therefore how quickly the space may overheat.

Studies have been carried out into particular areas of the hospitals – wards, for instance, which make up a significant proportion of the hospital – to determine whether natural ventilation can be employed to achieve the purposes as set out above, within the targets set down by the Board in the ITPD documents.

Use of natural ventilation

As indicated above the main benefit of employing a natural ventilation strategy in a hospital building is the reduction in energy consumption. Windows aid a feeling of connection for the occupant with the outside world and manual opening can increase the perception of control over their internal environment.

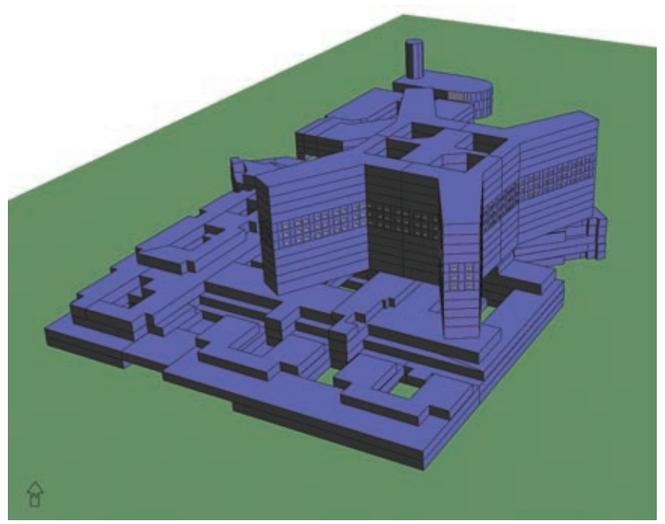
However there are a number of situations in which natural ventilation may not be suitable or desirable. The ventilation solution needs to take into account a number of local factors, which include, but are not restricted to, the following:-

- Air permeability - Building Regulations now legislate for the airtightness of buildings in order to help reduce heating requirements by minimising the uncontrolled infiltration/exfiltration of external/conditioned air.
- Outdoor air quality – The quality of outdoor air needs to be considered when determining the use natural ventilation where treatment of the incoming air is not available.
- Indoor air quality – Natural ventilation from windows on the external face of the building will only be effective internally for a zone of 5-6m from the openings.
- Pollution – In addition to common airborne pollutants, the site is susceptible to other sources of pollution including the noise and downdraft from the emergency helicopters landing on the helipad and the odour from the nearby sewage works.
- Thermal comfort – The disadvantages of natural ventilation include the increased risk of overheating in summer and low external temperatures in winter may discourage the opening of windows. Both situations will lead to poor air quality if insufficient ventilation is provided.

As stated above the new hospital building will contain departments or some rooms within departments that have to be mechanically ventilated however consideration has been given to naturally ventilating the maximum possible number of areas. The analysis below has concentrated on the option of naturally ventilating the wards as they form a large proportion of the building.

Analysis of the ventilation strategy for the building

The Building Regulations recommend acceptable limits for overheating based on the number of hours experienced per year over a limiting temperature. However, the analysis has been based on an amendment to the ITFD documents which stated that the overheating threshold was to be set at '50 hours per year above 26°C'. A virtual 3-dimensional thermal model has been produced, as shown below, based on the floor layouts and the thermal mass and properties of the selected constructions. Using the model extensive thermal dynamic modelling has been undertaken to determine the rooms in which overheating is likely occur.



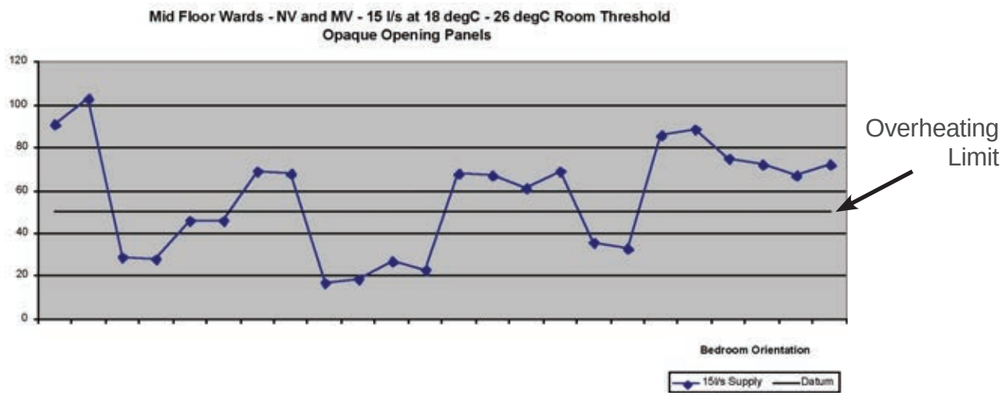
The thermal modelling has concentrated on the typical ward layouts on the 3 mid-tower floors and three top-floor wards and specifically considered two adjacent ward bedrooms located on each face of the tower. In association with the thermal modelling, daylight simulation calculations have been undertaken as part of a strategy to achieve a BREEAM 'Excellent' rating for the new hospital. These calculations determined the optimum window sizes required for the daylighting percentage. Due to the low envelope air permeability mechanical make-up ventilation

Brookfield

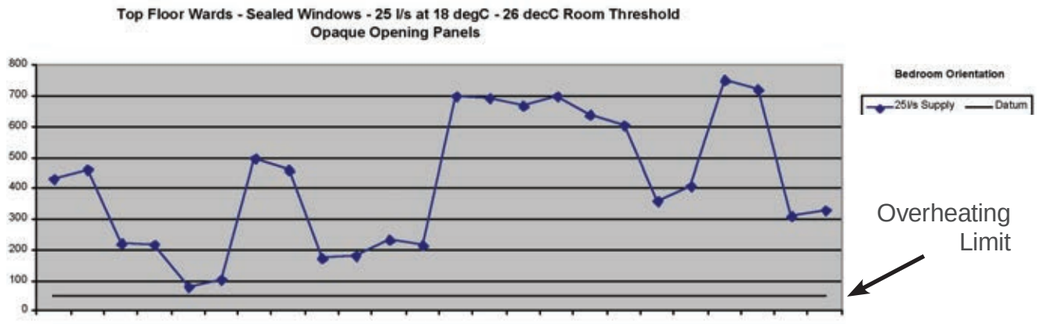
is provided to the bedrooms to match the extract from the adjacent bedroom en-suite toilet/ shower rooms. This adds the benefit of being able to condition this air, particularly in warm weather, to assist in reducing overheating.

Below are two examples of simulations that were carried out to reach a final solution, however, these are the culmination of many other simulations carried out using differing design criteria and options.

A simulation for the three mid-tower floors was undertaken with the bedroom mechanical ventilation set to 15 litres per second at 18ºC supply air temperature to provide only sufficient make-up air for the en-suite extract together with natural ventilation provided via an opaque 200mm high opening louvred panel. A full height section of high performance glazing was used on all the elevations. The results in the graph below show that overheating would be experienced on approximately 60% of the elevations:



A similar simulation of the three top-floor wards was undertaken with mechanical ventilation set to 25l/s at 18ºC supply air temperature. There is no natural ventilation provided via the full height section of high performance glazing or the opaque section as all the windows were sealed to avoid nuisance from helicopter noise and downdraft. The results in the graph below show that overheating would be above the threshold on a 100% of the elevations:



Odour Control

The issue with the problem of odours from the adjacent sewage works in association with the design of the mechanical ventilation has been addressed with the provision of carbon filters on the fresh air side of the air handling units.

Conclusion

Both sets of results show that in the wards a mixed mode, natural and mechanical ventilation combination, together with optimising the glazing area and type does not provide the solution to meeting the overheating criteria in the majority of the rooms. It is proposed that all ward rooms be provided with a means of mechanical cooling in the form of an active chilled beam as pictured below. The active chilled beams operate most effectively with the windows sealed as this reduces the likely hood of condensation.

It is envisaged that generally only small perimeter non clinical rooms with low occupancy and low heat gains will be able to be solely naturally ventilated. Other similar but larger more densely populated rooms will employ a mixed mode system. Then as stated above the majority of the clinical spaces will be mechanically ventilated or mechanically or air conditioned.

With the overheating design target set at ‘50 hours per year above 26ºC’ and the summer external design temperature also 26°C the target is an onerous one to achieve with natural ventilation. In progressing the ventilation design strategy a number of calculations have been carried using ‘50 hours per year above 28ºC’ (in accordance with the guidance in SHTM 03-01) as the target and it has been found that the mixed mode method is a feasible solution in the majority of the ward rooms.

Mains Power Distribution Design Strategy

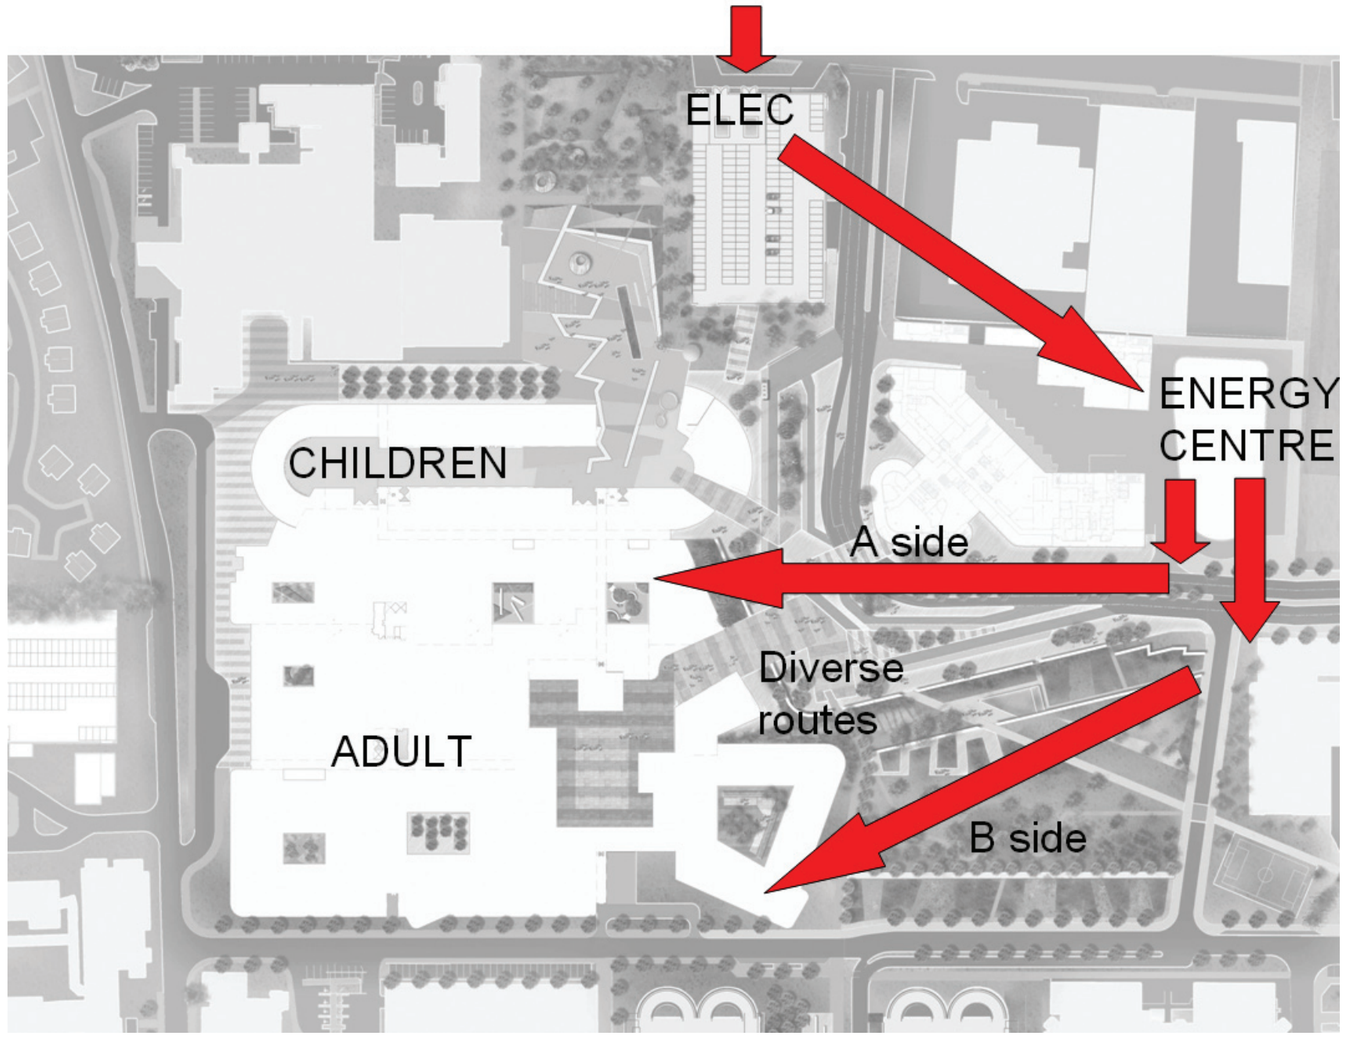
The Incoming Utility supply will be derived at 33kV from the Govan Grid Connection Point. The11kV supply up to and including the Utility Primary 11kV switchboard will, under normal supply conditions, provide two independent incoming 11kV supplies to the Hospital's 11kV system. The configuration of Utility 33kV and 11kV feeders and switchgear will allow the Utility Company to maintain or rapidly restore the 11kV supply to the hospital under most scenarios of a planned outage, or during any unplanned failure, of part of a leg of the Utility 33kV/11kV supply system. This will be achieved by the Utility switching the 33kV and 11kV feeder and bus section switchgear.

Two main incoming 11kV Utility supplies from the Utility Primary 11kV Switchboard are proposed, entering the site routed via diverse routes. Each of these will be terminated into one of the two NSGH 11kV main intake switchboards, each located within one of the two Energy Centre generator halls. Under normal supply conditions the supply arrangement will provide two independent incoming 11,000V supplies to the Hospital's 11,000V system. The two separate sections of the Energy Centre, and the equipment contained in them, will be designated A and B respectively.

The segregation of the two parts of the Energy Centre will provide a high degree of fire separation between the two sections.

In the event of a loss of supply from either section of the Utility Primary 11,000V switchboard, or one of the metered services from it, the lost Utility service will be replaced by automatic switching of the incoming and interconnector 11,000V switches on both NSGH Main Intake Switchboards to isolate the failed service and replace it with a feed from the remaining service. This will be done via the automatic controls for the NSGH 11,000V distribution system.

The overall arrangement will provide an incoming 11kV supply having an inherently high degree of resilience. This incoming supply will also be backed up by the Standby generator provisions; refer to the later section of this specification, "Standby Generators", for a description of this system.



Brookfield

The switchboards will be equipped to supply 4 new 11kV rings, two for the new hospital building and two for the retained site.

From the energy centre, the mains power distribution will follow the principles of a dual-unified distribution network as described in SHTM 06-01 whereby primary and secondary circuits are provided, each fully rated to provide a resilient distribution network and routed by diverse routes as illustrated in the diagram.

To achieve this, the HV network will be formed of open rings, each limb of which is effectively a radial circuit.

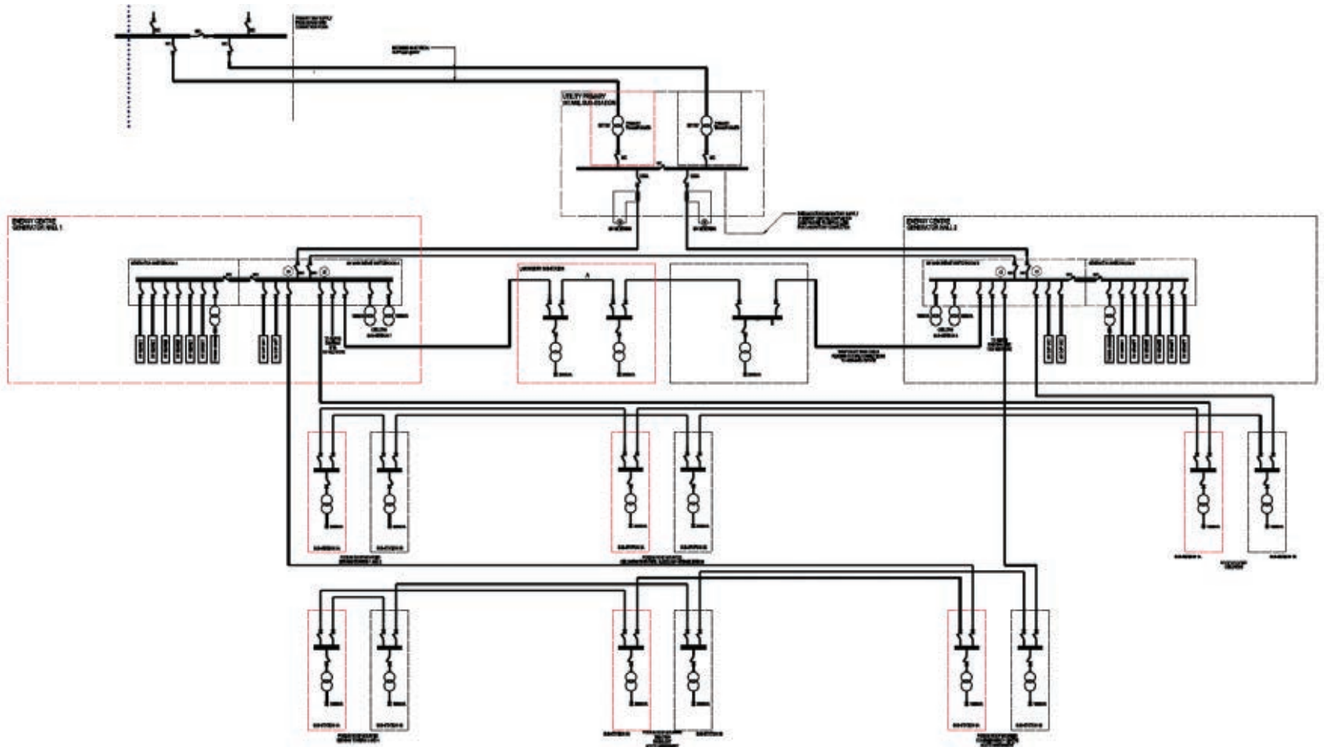
The cables will be selected to carry the whole load, this will enable the open point position to be changed in the event of a fault thereby isolating the fault. Refer to specification section 4.55 for further technical details.

The laboratory building will be fed from one of the rings which will later be extended to serve the retained estate. Provision will be made for connection to the retained estate as follows:-

- Adequate cable ducts and access pits from the energy centre to the opposite side of the main access road
- Cable ducts from the laboratory building for extension of that ring to the edge of the retained estate
- HV switchgear arranged in laboratory for safe extension of ring to serve retained estate

The schematic diagram illustrates the principles described so far.

- Two rings are illustrated serving the childrens and adult hospitals and two rings for the retained estate, one of which serves the laboratory building.
- The building is divided into 6 electrical zones with one substation per zone and a pair of transformers per substation.
- The transformers are connected in sequence so that they are allocated to the A side and B side of the HV ring.

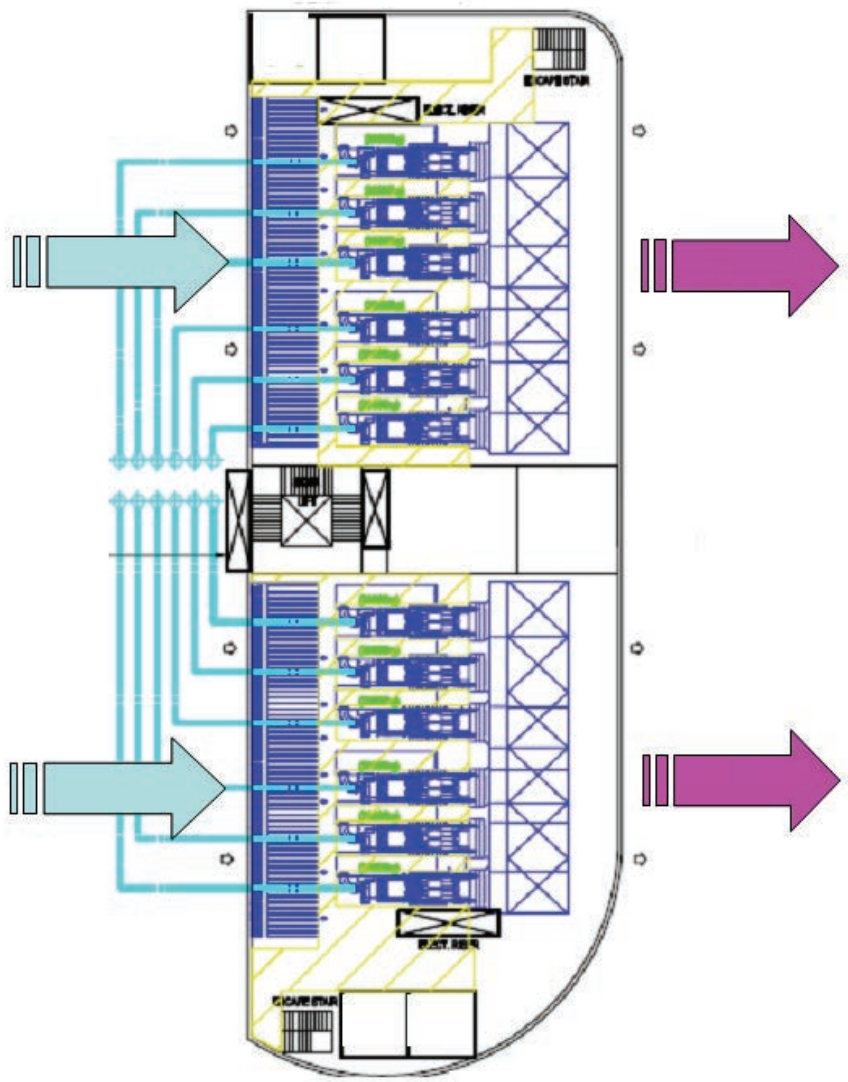


The Energy Centre will accommodate the standby generators. The estimated site load will be 21.5 MVA / 20MW (at a high power factor). The generators must be rated for Watts, thus 2 MW/2.5MVA Generators will be provided in an N + 1 configuration, hence 12 generators will be provided in total.

The generators will operate at 11,000 volts. Step up transformers will be included for future connection of mobile low voltage generators.

The generators will be housed in two fire separated generator halls as illustrated in the diagram.

The energy centre will be located to allow free flow of combustion and cooling air to the generators.



Mains failure

A load management control system will be provided to schedule the reconnection of power on mains failure in accordance with the principles laid down in Appendix 1 “Maximum interruption times to the primary supply” of SHTM06-01. Automated motorised switchgear will be provided controlled by an automated load management control system. Each main LV switchboard will incorporate Power management System controls.

Refer to section 4.55 for a more detailed description of the mains failure and reconnection scenario and details of the Power Management System.

Refer also to section 3.11 for a description of the strategy adopted in the event of failure of LV components.

Brookfield

Brookfield

Sub-mains Power Distribution Design Strategy

The high voltage network is described under 3.6 and 3.10. This document covers the LV distribution network within the building.

The sub-mains power distribution will follow the principles of a dual-unified distribution network as described in SHTM 06-01 whereby primary and secondary circuits are provided, each fully rated to provide a resilient distribution network.

The principle adopted is that the first single point of failure will be as close as possible to the point of use. Thus the possibility that the failure of a single component will cause a major power outage has been removed as far as is practicable.

In simple terms, there will be two of everything: two transformers per substation, two main LV switchboards linked by an automatic bus coupler, two submain feeds to sub switchboards and two distribution boards per department (minimum).

The Adult Acute and Children's Hospitals will be served by six substations, each comprising two transformers, one fed from what is termed the A side of the 11,000V ring the other fed from the B side.

Each transformer will serve a 400/230V LV switchboard which in turn will serve sub switchboards within the electrical zone served by that substation.

The main LV switchboards and the sub switchboards will be provided with automatically operated bus switches so that on loss of the A side supply the switch will close and the switchboard will be entirely supplied from the B side, and vice versa. The transformers will each be rated to support the entire load in an electrical zone, thus during normal circumstances each transformer will support half of the load.

Submains cables from the main LV switchboards will be contained in electrical riser cupboards, A side cables will be segregated from B side cables within the risers.

Departments requiring specialist or heavy loads (Imaging Departments, Catering etc.) will be provided with their own LV panel fed directly from the respective main LV panel.

The sub switchboards will feed local distribution boards, a minimum of two per department, one from the A side sub switchboard and one from the B side. Distribution boards will serve lighting and power.

Fixed items of equipment will not be provided with dual supplies, in risk category 3, 4 and 5 areas such supplies will be derived from sub switch panels which themselves have a dual supply.

Each Ward Tower will be provided with two risers each accommodating local distribution boards fed from a rising bus bar. Two bus bars will be provided per tower, one fed from the A side and one from the B side.

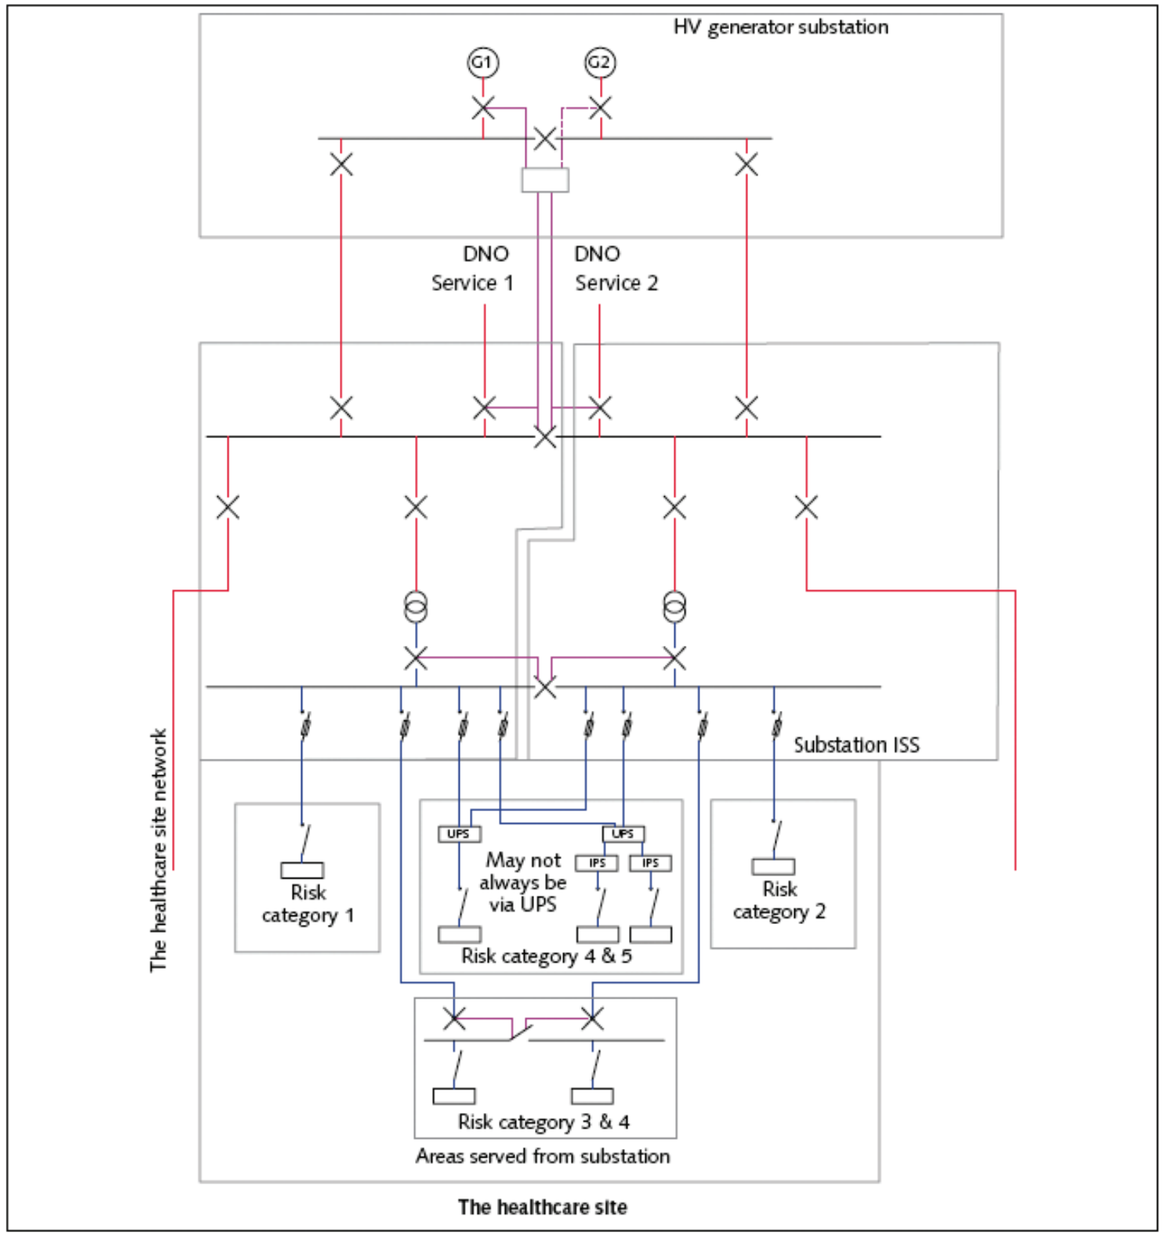
The Ward Towers will each be provided with two rising bus bars feeding two distribution boards per ward.

Final circuits in departments will be interleaved so that each room, so far as is practicable, will be provided with circuits from diverse sources.

A and B side submains cables will be housed in separate electrical risers.

Brookfield

The diagram below is reproduced from SHTM 06-01, and illustrates the general principles adopted, with the exception that the Employer's Requirements state that dual distribution boards are required to all departments, regardless of risk category.



Brookfield

The following sequence of diagrams illustrates the resilience of the distribution network and its operation during failure of its component parts.

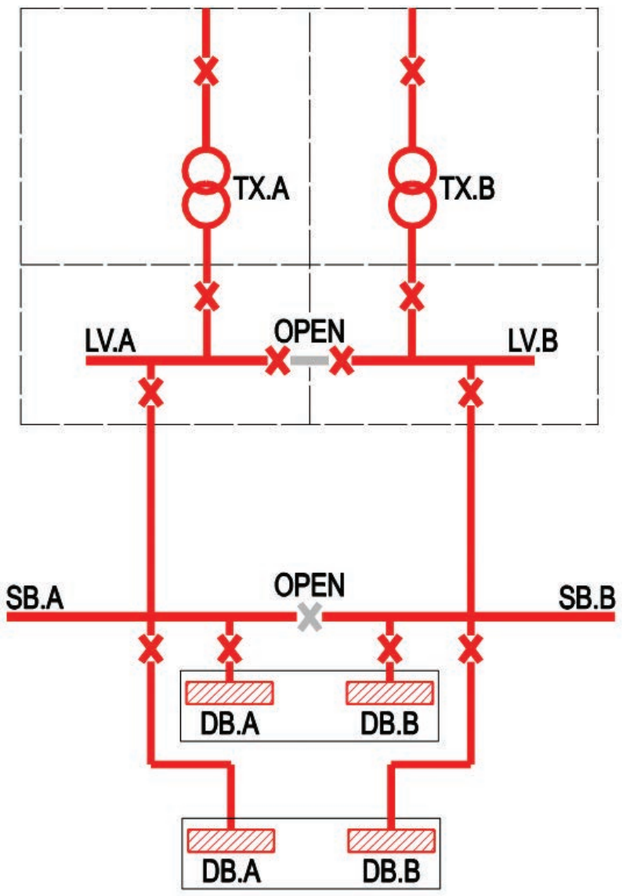
Consider a substation comprising two transformers, fed from different legs of an open HV ring, termed ‘A side’ and ‘B side’.

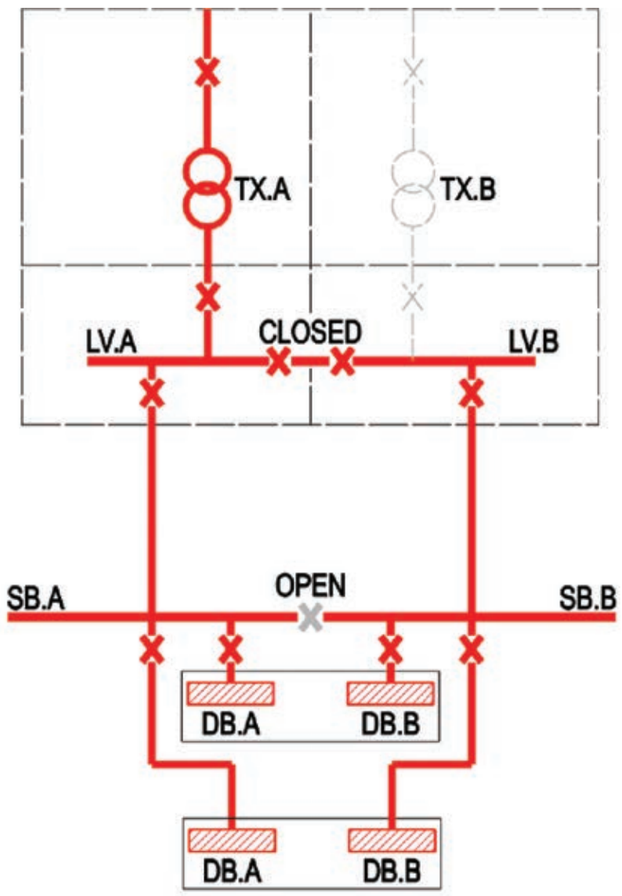
On mains healthy the low voltage distribution will be divided into two sides, A and B, one side being fed from one transformer and the other side being fed from the other transformer.

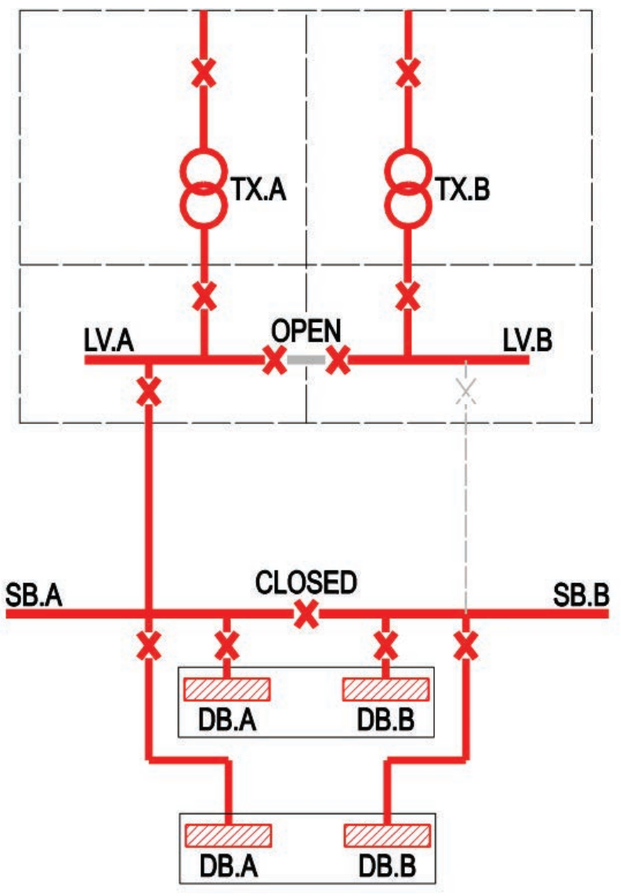
The transformers and main low voltage switchboards will be located in fire rated compartments so that an incident in one room will not affect the others.

On the failure of one transformer the automatically operated bus coupler in the LV switchboard will close. The remaining transformer will support the whole load.

On the failure of a submains cable to a sub switchboard, or a fire in one of the main LV switchrooms, or during maintenance of one of the main LV switchboards, the bus coupler on the affected sub switchboards will close and the A and B side submains cables to the switchboard will be capable of supporting the total load on that switchboard.





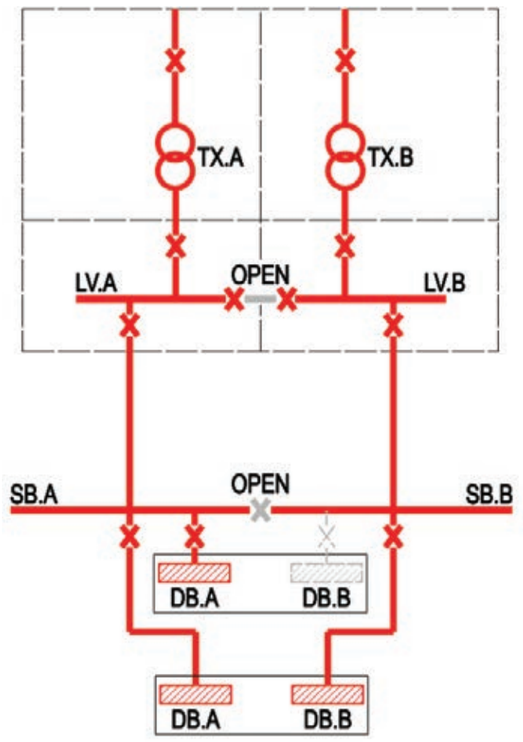


Brookfield

Each department will be fed by at least two distribution boards. Distribution boards will be three phase, fitted with miniature circuit breakers and RCBOs as appropriate. Failure of one distribution board will lead to the loss of 50% of the lighting and power to that department. To mitigate against this, final circuits will be interleaved so that 50% of the light and power to a room will be maintained.

These distribution boards will be contained within electrical cupboards within each department. Adjacent to each of these electrical cupboards will be located an equipment cupboard for ancillary components such as power supplies to nurse call panels, fire alarm interface units, security control equipment and door hold equipment.

To limit the quantity of distribution boards to a manageable and economic number, each board will feed lighting and small power final circuits (otherwise there would be at

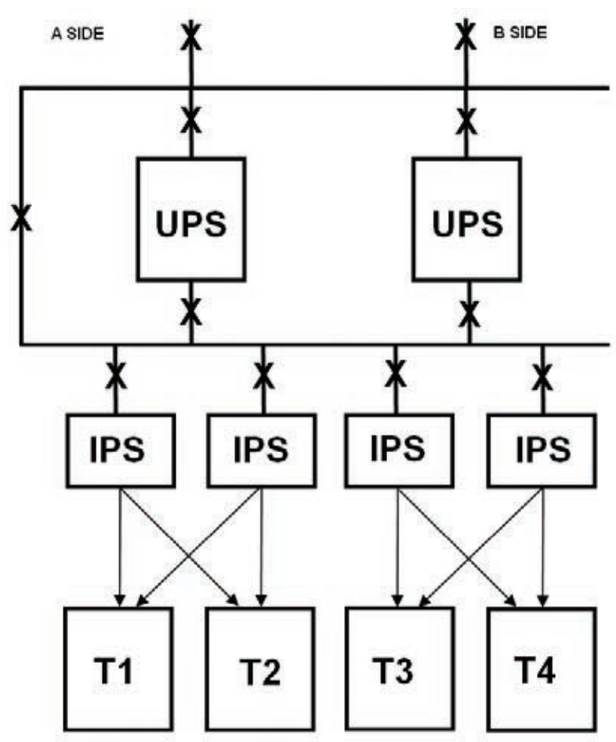


Power Supplies to Plant

It is proposed that horizontal bus bars will be run around plant rooms to provide power to plant. Duplicate bus bars will be provided (A and B side) to minimise disruption due to power failure. Plant will be provided with integral motor starters/inverter controls and will be plugged in to the nearest plantroom bus bar.

Uninterruptible Power Supplies and Isolated Power Supplies

Isolated Power Supplies will be provided as required by IEE Guidance Note 7, Chapter 10 and MEIGaN Annex “Health Care Interpretation of IEE Guidance Note 7 (Chapter 10) and IEC 60364-7-70 for Electrical Installations in Medical Locations”. The quantities of IPS units included in the bid are detailed on the accompanying LV schematic diagrams.



Socket outlets in Group 2 locations, as defined by IEE GN7 and MEIGaN will be IPS protected where serving medical electrical equipment and medical systems which are intended for life support and equipment located in the patient environment. Non critical / non life support electrical equipment in Group 2 locations will be RCD protected.

Socket outlets in Group 1 locations will be RCD protected but not IPS protected, including at patient bedheads.

The Employer’s Requirements state that Isolated Power Supplies should be supported by Uninterruptible Power Supplies.

The diagram illustrates the principles to be adopted in the theatres. Each pair of theatres will derive supplies from a pair of IPS units, the final circuits being interleaved.

UPS serving IPS units and two main server rooms will be configured in an N+1 arrangement, generally in pairs, each capable of supporting the full load for 50% of the required autonomy. Dedicated UPS rooms will be provided in the plantrooms so as to reduce plant space in the occupied areas.

Batteries or UPS will be provided to support:-

- Engineering hub cabinets, 2KVA, 10 minute autonomy
- FM office engineering hub, to suit load, 1 hour autonomy
- BMS front end, to suit load, 1 hour autonomy
- BMS outstations, to suit load, 1 hour autonomy
- Generator/HV network control and monitoring system
- Central UPS for Server Rooms, 15 minutes autonomy
- Central UPS for IPS units, to suit load, 15 minutes autonomy, except for theatres 60 minutes
- ICT nodes, 15 minutes, rack mounted
- Emergency lighting luminaires will incorporate self contained battery packs
- Battery back up will be integral to security, access control, fire alarms and nurse call (central data logger)

Final Circuits

Final circuits will generally be LSF insulated copper conductors run in concealed steel conduit and trunking. Modular wiring systems will be used in non clinical areas.

Power Quality

Provision will be made for future harmonic filters (space for free standing filters to be provided in each switchroom)

Miscellaneous Systems

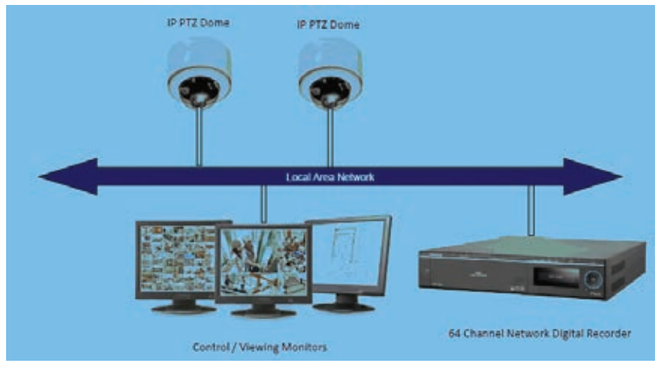
CCTV System

The system will comprise of a number of external PTZ colour/mono change over dome cameras, internal PTZ colour dome cameras and internal fixed colour dome cameras to provide coverage of external car parks, building entry/exit points, internal entry/exit points and general public areas and corridors.

The proposal will utilise PoE CAT6 cabling to central IT equipment rooms and a dedicated TCP/IP network infrastructure which will be provided by others.

All cameras will be streamed direct to Network Video Recorders located within central IT equipment rooms throughout each floor level and full control and viewing capability will be provided at the central security control room and other main reception areas within the building.

The choice of an IP based CCTV system with a graphical front end will provide the platform for full flexibility and future growth throughout the hospital buildings.



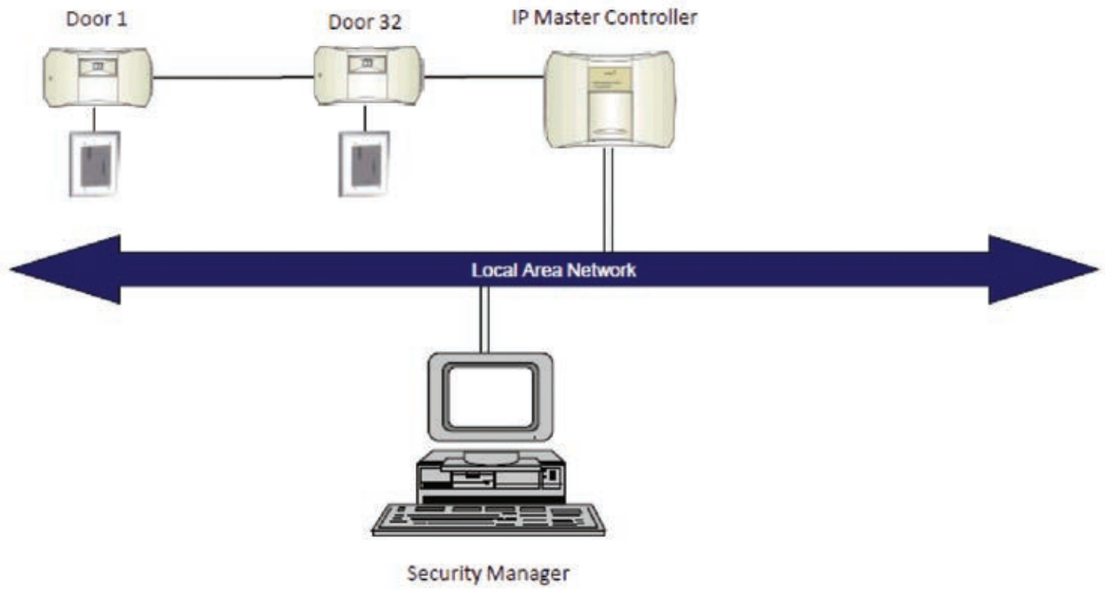
Access Control System

The system will comprise of a number of proximity access control readers along with push to exit egress buttons to allow for controlled access and egress for authorised staff throughout the hospital building. Typically this will cover building entry/exit points, internal entry/exit points and general ward areas and corridors not authorised to the general public.

The proposal will utilise dedicated CAT6 cabling from each off the door controllers to the master controller located within the central IT equipment rooms and a dedicated TCP/IP network infrastructure which will be provided by others.

The access system will be based on Mifare reading technology which will also allow interfacing with other systems such as cashless vending etc.

A management PC complete with software and Mifare enrolment reader will be located at the central security control room.



A48235836

Brookfield

Lighting Design Strategy

Introduction

The design of internal lighting installations is paramount and will greatly influence the aesthetics along with patients, visitors and the staff's perception of the building and therefore its importance should not be undervalued.

The first aim of lighting design in a hospital is to meet the required service illuminance for each area in the building.

Secondly, the design will create a lit environment which is visually appealing and compatible with the healthcare environment.

Design Considerations

The lighting design will take into account a number of considerations including:

- provide illumination levels and select luminaires which are appropriate for the task being carried out,
- select and arrange luminaires which are sympathetic, co-ordinate with and compliment the overall interior design concept,
- minimize ongoing maintenance costs by selecting luminaires and lamps from a limited number of sources and types,
- available daylight,
- glare,
- the lit appearance,
- illuminance at task areas,
- lamp colour,
- colour rendering,
- energy efficiency.

Brookfield

Service Illuminance

The target service illuminances will be as given in the ADB Sheets and where not defined they will be as scheduled in CIBSE Lighting Guide 2, 2008.

Given available lamp lengths and lamp configurations within luminaires it is not possible to exactly match the required service illuminances. It is proposed that design illuminances will be no lower than 10% below the target and no more than 25% above the target. (Refer to the section on energy below for further comment on the upper level.)

The Lit Appearance

The lighting design will aim to promote a sense of well being in the patients and an air of competence and quality throughout the building.

In public areas the emphasis will be on creating a pleasing environment with gentle but deliberate contrasts. Consideration will be given to the use of LED luminaires in public spaces.

Computer modelling will be employed to illustrate the lit appearance of sensitive areas. The image above is a 3D model of the entrance mall of an Acute hospital. The lighting creates interest and contrast and highlights architectural features such as the glass roof and suspended artwork.

Glare will be controlled and luminaires positioned so as not to cause discomfort to patients who may be in a prone position.

The selection of luminaires will be carefully considered so as to be aesthetically appropriate to the area.

The lighting design in public areas will be developed in tandem with the art component.

Lighting will be used as part of the way-finding strategy to highlight landmarks, reception desks and enquiry desks.

The image on this page is a 3D model of a waiting area.

AREAS OF KEY INTEREST

Typical Single Bed Ward Room

Lighting to the single bed ward room should be treated with care and thought since the patient will identify it as their own space; where they will spend the most amount of time and which will contribute the most to the overall healing process – both physically and mentally.

Our general approach to Ward Room lighting is to develop a strategy that will provide a comfortable and domestic level of lighting that will differentiate it from other more institutional areas that the patient may experience during their stay in the hospital. This can be achieved through careful selection of luminaire types and lamp selection.

Luminaires:

- Selected based on performance and function to suit medical uses that include features such smooth and simple finishes which are wipe-clean and snag-free to minimise the build-up of dust and other particles, are relatively sealed, are of sufficient build and material quality so as to provide a long-term lighting installation.
- Selected based on appearance and finishes to achieve the desired aesthetic design, we look at the type of trim type and finishes, colours, quality of detailing, user comfort and appearance (ie. louver or opal diffusers) Lamp selection tends to favour fluorescent or compact-fluorescent lamps for their long service-life, efficiency, colour-rendering properties and instant-switch/dimming capabilities. Being a large area lamp source they are ideal lamps for general lighting applications where uniform lighting levels are desired to all room surfaces.

Corridor lighting should be clear, concise and economic. Our lighting approach is a surface mounted or semi-recessed linear fluorescent fitting running parallel to the line of the corridor and off centre to one side. A surface-mounted or semi-recessed fitting can spill light further horizontally minimising high-level shadow marks on the walls, as well as putting some light onto the ceiling which would otherwise be directly unlit. This will help give the corridor an overall feeling of brightness. Orientating the luminaires to run parallel with the line of the corridor helps to fill the corridor out with light as well as give a strong perspective to the line of travel down the corridor. The luminaires are placed off centre to minimise strobing for bed-ridden patients being transported to other areas of the hospital. In specific single patient ward corridors the lighting may respond to the architectural layout of the rooms and doorways similar to a hotel corridor. This can still achieve the required light and uniformity levels demanded while contributing to create a less institutional environment. Major intersections or nodes along corridors can be marked through a change in lighting or the use of a different luminaire (size, shape, proportion). This assists way-finding through internal corridors and creates an identifying, repeating pattern throughout the building.

Brookfield

Communal Spaces

Communal and social areas should benefit from interesting lighting, not just in the form of interesting luminaire selection, but also of differing lighting intensities within the space that add interest and life into it. An effective tool is the use of spotlighting wall hung artwork as well as wall washing. Staff/nurse bases can be made more visible though increased lighting onto counter surfaces and through wall-washing vertical surfaces behind them to increase their lit presence. Illumination of vertical surfaces plays just a vital role as horizontal illumination and helps create interest and visible markers within a space.

Colour Rendering and Colour Temperature

Generally all lamps will have a colour rendering index of Ra≥80 except where identified in table 1 of LG2 as requiring Ra≥90.

The colour temperature of fluorescent lamps will generally be 4000K; except in certain circumstances identified in LG2, e.g. ophthalmology test rooms where the CCT will be 6500K.

Energy

The lighting design will be compliant with Section 6 of the Building (Scotland) Regulations 2007. The philosophy to be employed will be to utilise high efficacy lamp/gear combinations, luminaires with high light output ratios and to minimise use by means of automatic controls and use of available daylight.

A “DEER” value of level A will be achieved, i.e. minimum of 66 luminaire lumens per circuit watt.

Lighting control methods will be employed to maximize the potential for energy saving. In all cases the Building Regulations Part ‘L’ requires that switches should be no more than 8m away from the luminaire it controls. Whilst this will be achieved and users will have good access to switches as required, energy saving measures, which rely solely on users remembering to switch lighting off will not maximize their potential. Most often smaller spaces such as Store Rooms, Consultation Rooms, Laboratories and the like, which are out of use overnight and weekends may have lighting left on only because no one person is designated to switch lighting off. Therefore it is proposed to investigate automatic switching systems to maximize energy savings.

We propose the following simplified lighting control strategy:

A mixture of automatic ‘absence’ and ‘presence’ detection will be provided.

Presence detection: detector switches lighting on and off.

Extent of provision: intermittently occupied areas such as WCs, en suites, corridors, ward kitchens, stores, plant rooms, services risers, hospital streets, bathrooms etc.

Absence detection: lights manually switched on, detector extinguishes lighting in unoccupied room.

Extent of provision: offices, consulting rooms etc.

In addition, in rooms benefiting from daylight, luminaires near windows will be dimmable, regulated by the amount of daylight available.

Daylighting is an incredibly important factor for all buildings, but more importantly for hospitals. It has been proven to improve patient healing and greatly adding to their sense of well-being, mood and general health.

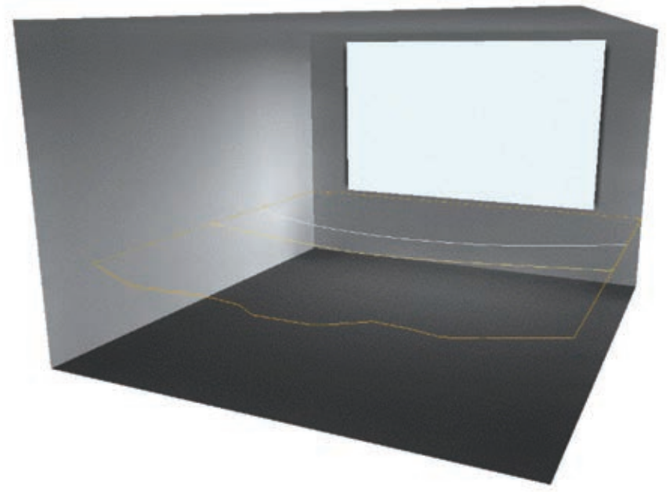
It connects people with the larger cycles of day and night and that of the seasons, which can help alleviate the stress of having to spend most of the day bed ridden inside. Daylight is also free, therefore having the added advantage of energy-savings in rooms that receive adequate amounts of daylighting through the reduced need for electric lighting during daylight hours. A dimmable control system can take advantage of this through smart monitoring of daylight presence within individual rooms.

A function of daylighting in hospital ward rooms is also the view that may be provided through the window and helps to further create a connection between the patient and outside world. Being a tower block, the rooms for New South Glasgow Hospital have a greater potential for increased natural daylighting and can benefit from longer views over the city below.

The ERs require lighting in corridors to be dimmed when unoccupied and scheduled by BMS. We do not believe that this will be necessary as the detectors will extinguish lights in unoccupied areas regardless of the time of day.

Dimmable lighting throughout has not been included, except where specifically required by the ADB sheets.

Automatic control of lighting in rooms which have plenty of natural light will be regulated by means of a photocell within the space to ensure the required LUX is achieved by the combination of ambient and artificial light. The image illustrates the graphical output of a daylighting calculation for a single bedroom.



Brookfield

General Lighting Installation

General lighting will be provided throughout the new development in accordance with the design criteria as issued through the NHS but summarised briefly as follows:-

- DHSS Engineering Reference Data “Standard Reference Luminaires for Hospital and Health Building Use”.
- SHTM 2007, SHTM2011
- CIBSE Guide 2.
- ADB sheets.
- “Designing for the Disabled”

Generally lighting will be by fluorescent tubes with recessed fittings.

Luminaires will be manufactured and tested in accordance with the requirements specified in the relevant sections of BS 4533. Their location will afford ready access for lamp changing and maintenance, but with the overriding requirement that the recommended standard of illuminance is provided to the task area. Many areas, however also require a domestic ambience, i.e. non-clinical and the design will reflect this requirement.

In areas where computer terminals are to be used, the lighting will be designed to avoid bright light reflections on the screen and to ensure that the contents of the screen are legible. Specific guidance is available in CIBSE Lighting Guide LG03 entitled “Areas for Visual Display Terminals”.

Patient’s bedroom lighting, other than high dependency and recovery, will be switched from the door and the bedhead unit: a watch light with dimmer controlled from the door, and an overbed light.

Dimmable night lighting is provided at Nurses Stations and in patient bedrooms and corridors. Care will be taken in design to ensure that night lighting does not spill into patient bedrooms, thereby causing discomfort to patients.

The lighting design will incorporate a flexible switching arrangement to allow for varying activities within each room and for cleaning. Where more than one luminaire is to be provided in a room a minimum of two switches will be provided. Switches for public areas will be positioned so that lighting cannot be switched by unauthorised persons.

Alternative circuits and two way/intermediate switching at all doors and corridor direction changes will be provided for lighting in corridors and circulation areas.

Kitchens and areas in which food is prepared or handled are to have food factory type luminaires. Clinically clean areas, eg all rooms requiring theatre level environment, will have recessed, sealed luminaires as required for the area.

Emergency and Standby Lighting

Maximum interruption times to the primary supply will be as scheduled in Appendix 1 of SHTM06-01.

Only fixed medical lighting and escape lighting will be supported by standby batteries. This will include operating theatre lamps and fixed examination lamps in clinical risk category 3, 4 and 5 areas. General lighting will not be battery supported. Power to general lighting will be restored within the times required by Appendix 1 of SHTM06-01.

A complete Emergency Lighting System covering all internal and external areas as required by BS 5266: Part: 1988 and the Building Control and Fire Officers requirements will be provided.

The emergency lighting will comprise self-testing addressable lighting units which will be connected to an addressable emergency lighting, testing and monitoring panel.

A software control package will be provided to monitor and manage the system.

Brookfield

Lift Engineering Design Strategy

General Preambles

Consideration has been given to efficient reliable and secure vertical transportation throughout the site.

The elevator systems proposed are all Machine Room Less technology and will feature energy efficient equipment .

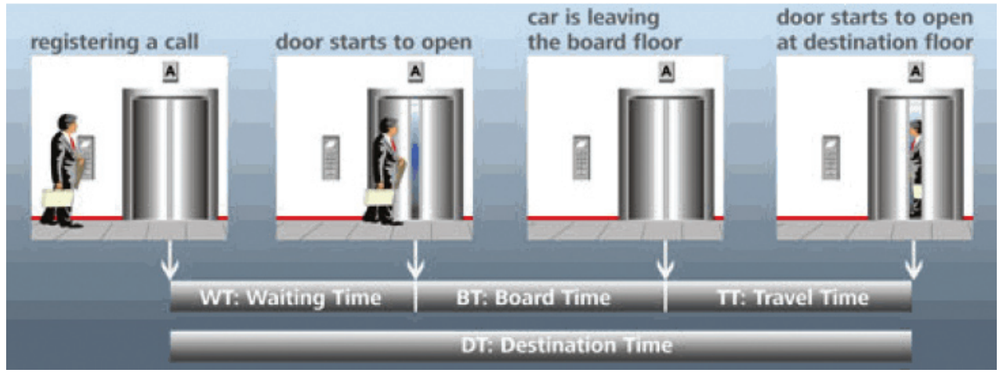
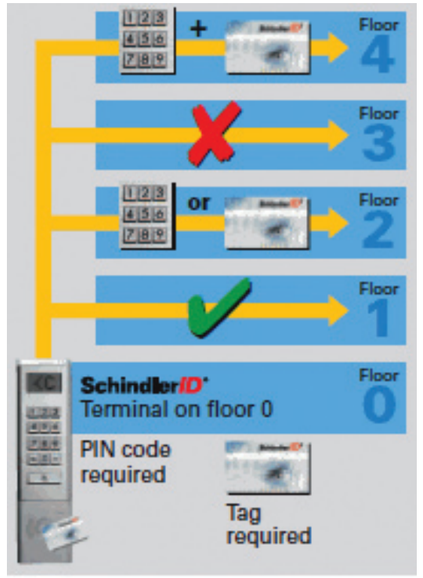
Traffic Simulations have been carried out on the main lifts in the Main Hospital Tower and the Children's Hospital which are appended to this section. The results of these simulations generally reflect the requirements of the exemplar report.



In some areas of the hospital we are proposing the use of ID technology and Destination Control Systems to provide efficient service and levels of personalised security and individualised access



A48235836

Brookfield

Main Hospital

The Main Hospital features six Visitor and six Bed Passenger lifts serving all floors. These lifts feature additional security and lift control specifications

The traffic simulations show that these lifts will provide good lift service to visitors, patients and staff.

To provide adequate access for FM four dedicated lifts have been provided, these lifts are integrated in to the Automated Vehicle System.

There are also various other lifts within the podium area which provide access to all levels for passengers and patients.

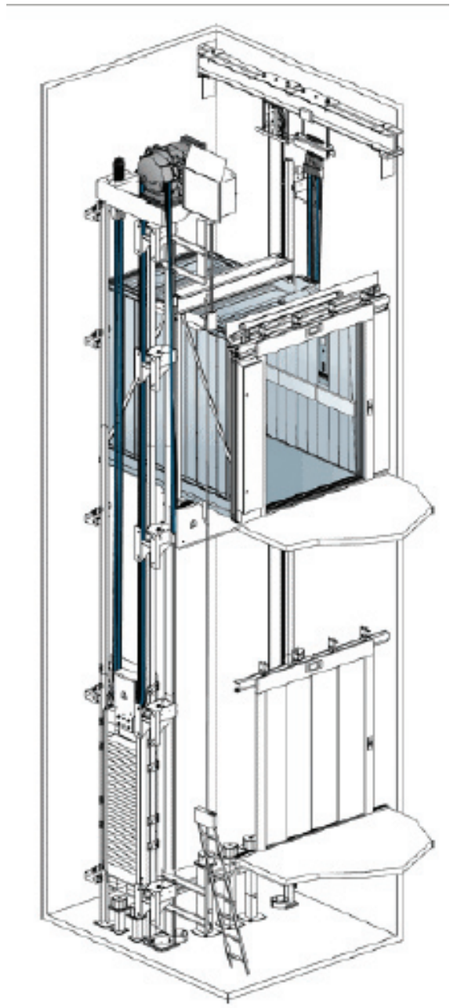
A dedicated lift is allowed for serving the Helipad.

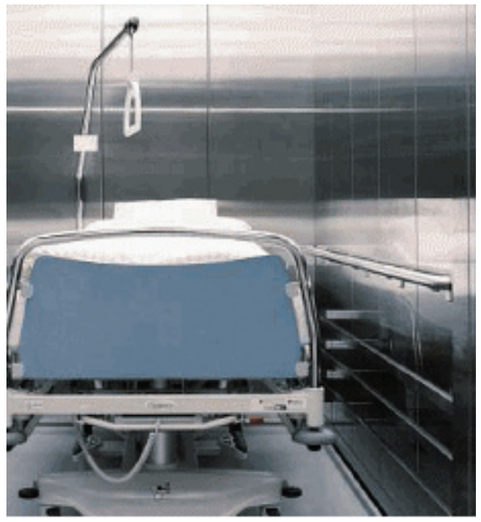
Three escalators will take visitors from the main entrance to reception level.

Children's Hospital

Traffic simulations have indicated that four visitor and 4 bed passenger lifts will provide excellent service to The Children's Hospital, again special security and control features are envisaged.

Facilities Management will be provided with three dedicated lifts.

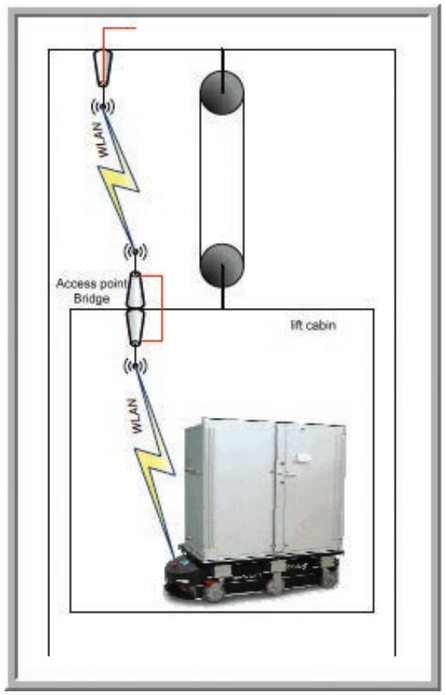




Brookfield

Laboratory Block

The proposal allows for sixteen lifts of various specifications, these include four FM lifts which will be linked to the Automated Vehicle System.



The freight lifts proposed are purpose designed for goods lift application and feature a traditional sling and platform car design together with heavy duty lift car and landing doors and tracks to ensure robust and reliable FM lift service.

Energy Centre

One purpose designed Goods Passenger Lift is proposed.

Technical

All lifts proposed will comply with the relevant EN Code Requirements.

The lifts will comply with EN81-70 which relates to lifts suitable for use by disabled passengers.

Certain lifts will comply with EN81-72 Fire Fighting application.

The HTM2024 NHS Design Considerations for Lifts is met in principle in so far as it reflects current industry standards ,engineering and manufacturing innovations.

A48235836

Brookfield

Whole Life Costs and Maintenance Proposals

The submission includes 7 years maintenance which commences on Practical Completion of each phase.

The maintenance is fully comprehensive and includes 24 hour cover.

Communication Links to the manufacturers call centre are included.

The maintenance covers all replacement parts other than those damaged thorough misuse.

Whole Life Cost proposals are indicated, these reflect the efficient technology and energy saving features that the lift and escalator systems provide.

BREAAM Credits are also available with the equipment proposed.

Consideration has been given to the environmental impact of manufacturing, installing and operating the lifts and escalators and considerable data can be provided to provide more information if required.

System electricity consumption in 20 years	
Operation [kWh]	68107
Stand-by [kWh]	37104
Total [kWh]	105211

System electricity consumption per annum	
Operation [kWh]	3405
Stand-by [kWh]	1855
Total [kWh]	5261

Impact category	Unit	Material supply[1]	Usage phase[2]	Ratio usage/material
Global warming potential	[kg CO_2-eq.]	16001.0	62005.6	3.9
Acidification potential	[kg SO_2-eq.]	238.6	455.2	1.9
Ozone formation potential	[kg Ethene-eq.]	24.9	87.6	3.5
Eutrophication potential	[kg PO_4-eq]	4.7	15.4	3.3
Ozone depletion potential	[kg CFC11-eq.]	0.015	0.04	2.7

Innovation

The lifts proposed utilise the latest lift drive and control technology all lifts feature Permanent Magnet Gearless drive with VF Drive and Control Strategy

Various groups of lifts will utilise Hall Call Destination and ID control.

These features allow for the most efficient method of handling passenger traffic and provide the best lift service to visitors, staff and patients.

Of particular benefit is the facility to consider disabled use via the wheelchair button, this allocates a lightly loaded lift to a wheelchair bound passenger, it also activates a audible signal leading partially sighted passengers to the appropriate lift, in all cases it allows the lift doors to remain open longer to provide time to access the lift.

The ID Control feature will provide personalised lift service to staff and allow for the following features:

- Restricted Security Access to certain floors via data held on ID cards
- Dignity Trips – allowing bed bound passengers to travel in dedicated lifts
- Code Blue emergency response.
- Personalised Elevator Service

The integration of building management and emergency systems has been considered and together with the incorporation of the automatic vehicle systems off site proving and commissioning of the lift control systems has been allowed for.

The flexibility of the ID control system will allow for on site programming of staff data to allow for personalised service

Building +Lift Monitoring Systems

A dedicated Elevator and Escalator Monitoring System is proposed to allow for instant access to performance and operational date.

Summary

The Preliminary Traffic Simulation Analyss have been carried out for both the Visitors and Bed Passenger Lifts.
The Data is based on the Population for Lift Assessment included in the exemplar report.
Traffic Paterns have been generated to reflect a two way flow of passengers.
Schindler ID control has been proposed for the Bed Passenger lifts .

NSGH VISITOR 6 LIFTS. LF 1 6 elevators		Miconic 10 control			1.6 m/s		1600 kg	
Traffic Situation	Floors	Population	Rating		HC5	WT	DT	IS
Two-Way Hotel	0..1,4..11	1984	3.4	★★★☆☆	11.8 %	35.9 s	92.5 s	1.7

NSGH BED LIFTS (6 Lifts). LF 1 only 1 pers per	6 elevators	Schindler ID control			1.6 m/s		2500 kg	
Traffic Situation	Floors	Population	Rating		HC5	WT	DT	IS
Lunch (Single Tenant)	0..11	565	3.0	★★★☆☆	11.0 %	39.9 s	60.3 s	0.0

In both situations the recommended 6 lifts will provide excellent lift service to the Hospital visitors and patients

A48235836

Standards and Recommendations

Depending on the type of building, one or two of the following traffic situations are analysed:

Traffic Situation	Incoming	Outgoing	Inter-floor	Type of Building
Up-Peak	100 %	0 %	0 %	Office (all)
Lunch Single Tenant	40 %	40 %	20 %	Office (single-tenant)
Lunch Multi-Tenant	45 %	45 %	10 %	Office (multi-tenant)
Two-Way Hotel	50 %	50 %	0 %	Hotel
Two-Way Residential	50 %	50 %	0 %	Residential

For other types of buildings, an Up-Peak situation and optionally one of Lunch Single Tenant, Lunch Multi-Tenant, or Two-Way Hotel are analysed.

Every analysis covers a full range of arrival rates, reporting handling capacity HC5 and average waiting time WT as main criteria. As a general guideline, Schindler defines a rating in the range of 0.0 (worst) to 6.0 (best) based on these criteria. Recommended ratings are 3.0 or higher:

Schindler Traffic Analysis Ratings 2008

	Rating >= 3.0		Rating >= 4.0		Rating >= 5.0	
Traffic Situation	HC5	WT	HC5	WT	HC5	WT
Up-Peak	>= 12 %	<= 30 s	>= 14 %	<= 20 s	>= 16 %	<= 15 s
Lunch Single Tenant	>= 11 %	<= 40 s	>= 13 %	<= 30 s	>= 15 %	<= 20 s
Lunch Multi-Tenant	>= 11 %	<= 40 s	>= 13 %	<= 30 s	>= 15 %	<= 20 s
Two-Way Hotel	>= 11 %	<= 40 s	>= 13 %	<= 30 s	>= 15 %	<= 20 s
Two-Way Residential	>= 6 %	<= 80 s	>= 7 %	<= 60 s	>= 8 %	<= 40 s

Ratings are also displayed by a corresponding number of stars and may be interpreted on a global basis as follows:

Rating	Stars	Office	Hotel	Residential
>= 3.0	★★★☆☆	Standard office buildings	Up to approx. 3-star hotels	Basic segment
>= 4.0	★★★★☆	Mid-to-higher requirements	Up to approx. 4-star hotels	Medium segment
>= 5.0	★★★★★	Premium sites	Up to approx. 5-star hotels	Premium segment

How Schindler Undertakes Traffic Analyses

4.1 Introduction

A traffic analysis studies the performance of a group of elevators, based on assumptions about the expected traffic situation. The main performance measurements are handling capacity and waiting time. Reliable and comparable performance results are found by means of benchmark simulations which reflect the expected real behavior of a group of elevators under a wide range of traffic situations.

4.2 Measures and Definitions

The elevators' main task is to manage the traffic, i.e., the transportation needs of passengers and goods, in such a way that the highest possible density of arriving passengers and goods can be transported in the building at the highest possible perceived service quality.

4.2.1 Arrival Rate and Handling Capacity (P5, HC5)

For a specific elevator group, the arrival rate describes the density of arriving passengers in an observed time period. In contrast, the handling capacity is the number of passengers transported in an observed time period. As long as the elevator group is able to transport all the arriving passengers without building up waiting queues, the arrival rate and the handling capacity are equal.

Handling capacity is measured by P5 and HC5:

- P5 is the number of persons that is transported on average within 5 minutes.
- HC5 is the percentage of the population on the floors served by the elevator group that is transported on average within 5 minutes:
  HC5 = P5 / (population on floors served by elevator group).

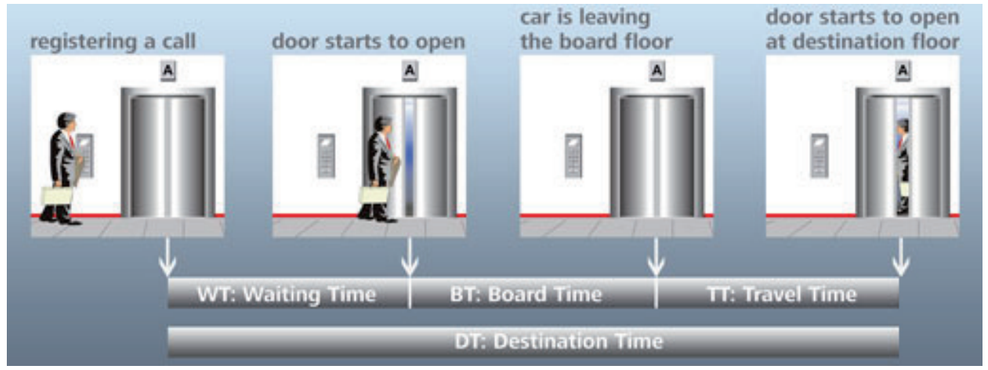
Example: Consider an elevator group which serves floors with a population of 1000 people. By observation, there are 600 passengers transported within 30 minutes, therefore:

- P5 = 600 persons * (5 minutes / 30 minutes) = 100 persons,
- HC5 = 100 persons / 1000 persons = 10.0 %.

4.2.2 Waiting Time (WT) and Destination Time (DT)

Waiting time and destination time for an individual passenger are defined as follows:

- waiting time: time from when the passenger registers a landing call (or joins a queue) until the door of the serving elevator begins to open on the boarding floor (zero if the door is not closed when the passenger arrives)
- destination time: time from when the passenger registers a landing call (or joins a queue) until the door of the serving elevator begins to open on the destination floor



For a number of served passengers in an observed period of time, the average waiting time WT and the average destination time DT are defined in the usual way as mean values of the passengers' individual waiting time and destination time, respectively.

4.2.3 Number of Intermediate Stops (IS)

The number of intermediate stops for an individual passenger is the number of times an elevator stops with the passenger between boarding floor and destination floor. For example, for a passenger with a direct (non-stop) trip from boarding floor to destination floor the number of intermediate stops is zero.

For a number of served passengers in an observed period of time, the average number of intermediate stops IS is defined in the usual way as mean value of the passengers' individual number of intermediate stops.

4.3 Methods of Traffic Analysis

A traffic analysis should cover a variety of important traffic situations, especially when planning new buildings. Reported values should be as reliable and comparable as possible. However, performance values depend on the methods of the traffic analysis and the basic traffic assumptions.

4.3.1 Simulation vs. calculation methods

In *simulation methods,* a real passenger flow is being replaced by a virtual one, which was created with the help of a random generator and loaded into the same control algorithm as used in a real elevator controller. Thus the results can be measured under different traffic conditions and reflect the expected reality to a very large extent.

In contrast, *calculation methods* are based on formulas which only cover a very limited range of traffic situations (usually, only up-peak traffic). The formulas reflect theoretical assumptions rather than a realistic behavior of elevator groups, and results are usually too optimistic. Therefore, calculation results should not

Brookfield

be compared with simulation results.

Schindler Traffic Analysis Reports are based on simulations in order that the reported results are the most reliable and realistic achievable.

4.3.2 Wide Range of Traffic Assumptions

The traffic flow in a building keeps changing all the time; no two days are the same. As a rule, traffic depends on many factors (such as location of building, tenant structure, etc.) and may vary considerably during operation of the building. A traffic analysis should take such factors into consideration and try as far as possible to cover future traffic situations.

In a complex building, a single traffic assumption is not sufficient. E.g., it is not sufficient to apply a traffic pattern measured in some other existing building for the design of a new building. In particular, the limits of the handling capacity of the elevators cannot be found by such "spot light" examinations.

Predictions about the range of handling capacity of an elevator group can only be made by actually simulating a wide range of traffic situations. A benchmark method applies a reference traffic situation from low to very high traffic intensity; by this, the limits of the elevators' handling capacity can be detected. Schindler uses a benchmark method which gives a neutral system assessment.

Schindler Traffic Analysis Reports are based on different traffic situations (see Section 2) tested by benchmark methods. This ensures that the traffic analysis covers a full range of applications and reports reliable and comparable performance predictions.

Summary

The Preliminary Traffic Simulation Analysis have been carried out for both the Visitors and Bed Passenger Lifts .
The data is based on the Population for Lift Assessment included within the exemplar report.
The simulations have been based on the folowing:
Visitor Lifts:
Simulation 1 Visitors only - conventional control
Simulation 2 Visitor and Staff populations - conventional control
A two way traffic flow has been considered.
Bed Passenger Lifts
Simulation 3 - Based on Staff Numbers and single occupancy levels within the car - Schindler ID Control

Visotor Passenger Lifts - Childrens Hospital (includir	4 elevators	Conventional control	1.6 m/s	1275 kg

Traffic Situation	Floors	Population	Rating	HC5	WT	DT	IS
Two-Way Hotel	0..3	723	5.5 ★★★★★	18.3 %	9.0 s	37.9 s	0.7

Visitor Lifts - Childrens Hospital (1)	4 elevators	Conventional control	1.6 m/s	1275 kg

Traffic Situation	Floors	Population	Rating	HC5	WT	DT	IS
Two-Way Hotel	0..3	465	5.6 ★★★★★	18.8 %	7.5 s	31.2 s	0.5

Bed Passenger Lifts - Childrens Hospital (3	4 elevators	Schindler ID control	1.6 m/s	2500 kg

Traffic Situation	Floors	Population	Rating	HC5	WT	DT	IS
Two-Way Hotel	0..3	264	5.4 ★★★★★	17.5 %	11.5 s	26.1 s	0.0

The traffic simulations for both the Bed Passenger and Visitor/Staff Lifts show the proposed arrangements will provide excellent lift service.

Brookfield

Standards and Recommendations

Depending on the type of building, one or two of the following traffic situations are analysed:

Traffic Situation	Incoming	Outgoing	Inter-floor	Type of Building
Up-Peak	100 %	0 %	0 %	Office (all)
Lunch Single Tenant	40 %	40 %	20 %	Office (single-tenant)
Lunch Multi-Tenant	45 %	45 %	10 %	Office (multi-tenant)
Two-Way Hotel	50 %	50 %	0 %	Hotel
Two-Way Residential	50 %	50 %	0 %	Residential

For other types of buildings, an Up-Peak situation and optionally one of Lunch Single Tenant, Lunch Multi-Tenant, or Two-Way Hotel are analysed.

Every analysis covers a full range of arrival rates, reporting handling capacity HC5 and average waiting time WT as main criteria. As a general guideline, Schindler defines a rating in the range of 0.0 (worst) to 6.0 (best) based on these criteria. Recommended ratings are 3.0 or higher:

Schindler Traffic Analysis Ratings 2008

	Rating >= 3.0		Rating >= 4.0		Rating >= 5.0	
Traffic Situation	HC5	WT	HC5	WT	HC5	WT
Up-Peak	>= 12 %	<= 30 s	>= 14 %	<= 20 s	>= 16 %	<= 15 s
Lunch Single Tenant	>= 11 %	<= 40 s	>= 13 %	<= 30 s	>= 15 %	<= 20 s
Lunch Multi-Tenant	>= 11 %	<= 40 s	>= 13 %	<= 30 s	>= 15 %	<= 20 s
Two-Way Hotel	>= 11 %	<= 40 s	>= 13 %	<= 30 s	>= 15 %	<= 20 s
Two-Way Residential	>= 6 %	<= 80 s	>= 7 %	<= 60 s	>= 8 %	<= 40 s

Ratings are also displayed by a corresponding number of stars and may be interpreted on a global basis as follows:

Rating	Stars	Office	Hotel	Residential
>= 3.0	★★★☆☆	Standard office buildings	Up to approx. 3-star hotels	Basic segment
>= 4.0	★★★★☆	Mid-to-higher requirements	Up to approx. 4-star hotels	Medium segment
>= 5.0	★★★★★	Premium sites	Up to approx. 5-star hotels	Premium segment

How Schindler Undertakes Traffic Analyses

4.1 Introduction

A traffic analysis studies the performance of a group of elevators, based on assumptions about the expected traffic situation. The main performance measurements are handling capacity and waiting time. Reliable and comparable performance results are found by means of benchmark simulations which reflect the expected real behavior of a group of elevators under a wide range of traffic situations.

4.2 Measures and Definitions

The elevators' main task is to manage the traffic, i.e., the transportation needs of passengers and goods, in such a way that the highest possible density of arriving passengers and goods can be transported in the building at the highest possible perceived service quality.

4.2.1 Arrival Rate and Handling Capacity (P5, HC5)

For a specific elevator group, the arrival rate describes the density of arriving passengers in an observed time period. In contrast, the handling capacity is the number of passengers transported in an observed time period. As long as the elevator group is able to transport all the arriving passengers without building up waiting queues, the arrival rate and the handling capacity are equal.

Handling capacity is measured by P5 and HC5:

- P5 is the number of persons that is transported on average within 5 minutes.
- HC5 is the percentage of the population on the floors served by the elevator group that is transported on average within 5 minutes:
  HC5 = P5 / (population on floors served by elevator group).

Example: Consider an elevator group which serves floors with a population of 1000 people. By observation, there are 600 passengers transported within 30 minutes, therefore:

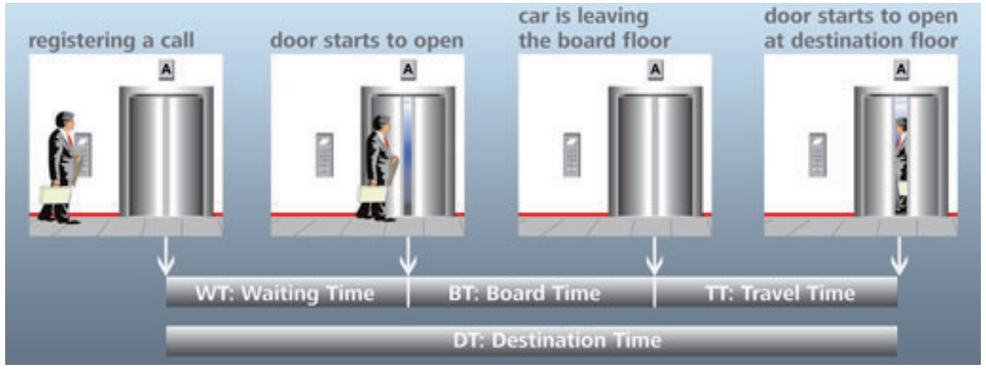
- P5 = 600 persons * (5 minutes / 30 minutes) = 100 persons,
- HC5 = 100 persons / 1000 persons = 10.0 %.

4.2.2 Waiting Time (WT) and Destination Time (DT)

Waiting time and destination time for an individual passenger are defined as follows:

- waiting time: time from when the passenger registers a landing call (or joins a queue) until the door of the serving elevator begins to open on the boarding floor (zero if the door is not closed when the passenger arrives)
- destination time: time from when the passenger registers a landing call (or joins a queue) until the door of the serving elevator begins to open on the destination floor

Brookfield



For a number of served passengers in an observed period of time, the average waiting time WT and the average destination time DT are defined in the usual way as mean values of the passengers' individual waiting time and destination time, respectively.

4.2.3 Number of Intermediate Stops (IS)

The number of intermediate stops for an individual passenger is the number of times an elevator stops with the passenger between boarding floor and destination floor. For example, for a passenger with a direct (non-stop) trip from boarding floor to destination floor the number of intermediate stops is zero.

For a number of served passengers in an observed period of time, the average number of intermediate stops IS is defined in the usual way as mean value of the passengers' individual number of intermediate stops.

4.3 Methods of Traffic Analysis

A traffic analysis should cover a variety of important traffic situations, especially when planning new buildings. Reported values should be as reliable and comparable as possible. However, performance values depend on the methods of the traffic analysis and the basic traffic assumptions.

4.3.1 Simulation vs. calculation methods

In *simulation methods,* a real passenger flow is being replaced by a virtual one, which was created with the help of a random generator and loaded into the same control algorithm as used in a real elevator controller. Thus the results can be measured under different traffic conditions and reflect the expected reality to a very large extent.

In contrast, *calculation methods* are based on formulas which only cover a very limited range of traffic situations (usually, only up-peak traffic). The formulas reflect theoretical assumptions rather than a realistic behavior of elevator groups, and results are usually too optimistic. Therefore, calculation results should not

be compared with simulation results.

Schindler Traffic Analysis Reports are based on simulations in order that the reported results are the most reliable and realistic achievable.

4.3.2 Wide Range of Traffic Assumptions

The traffic flow in a building keeps changing all the time; no two days are the same. As a rule, traffic depends on many factors (such as location of building, tenant structure, etc.) and may vary considerably during operation of the building. A traffic analysis should take such factors into consideration and try as far as possible to cover future traffic situations.

In a complex building, a single traffic assumption is not sufficient. E.g., it is not sufficient to apply a traffic pattern measured in some other existing building for the design of a new building. In particular, the limits of the handling capacity of the elevators cannot be found by such "spot light" examinations.

Predictions about the range of handling capacity of an elevator group can only be made by actually simulating a wide range of traffic situations. A benchmark method applies a reference traffic situation from low to very high traffic intensity; by this, the limits of the elevators' handling capacity can be detected. Schindler uses a benchmark method which gives a neutral system assessment.

Schindler Traffic Analysis Reports are based on different traffic situations (see Section 2) tested by benchmark methods. This ensures that the traffic analysis covers a full range of applications and reports reliable and comparable performance predictions.

Brookfield

A48235836

Communication Design Strategy

Introduction

For the New South Glasgow Hospitals Project, Brookfield knows the Telephone Distribution Systems and Information Technology (IT) Equipment and Distribution Systems are critical to the success of the hospital and operation. This section sets out an overview description on the telephone distribution systems and information technology description and distribution systems (TDS and ITEDS) infrastructure for consideration by the NHS GG&C Health Board.

The strategy document highlights the key components of TDS & ITEDS systems proposed for the project including distribution networks.

Brookfield have included for all requirements as stated in the ITPD Volume 2/1 Employer's Requirements section 8.3.5 to 8.3.20 The Telephone Distribution And Information Technology Equipment and Distribution Systems design strategy has been developed by the Brookfield team to comply with these requirements and key points discussed during the design dialogue process with the NHS GG & C Health Board.

Brookfield strategy includes for the development using of the latest technologies for each system to ensure optimum future proof systems that will be determined at the time of final design during stage two of the project.

Detailed information about network technology (active equipment, including PABX, switches routers fire walls etc.) is not included in this section as the design and provision of these active items were confirmed to be procured by NHS GG&C Health Board.

TDS and ITEDS spaces such as the main communications room (MCR) located with in the Adult and Children's hospital area will contain all main servers and core switches, a secondary communications room (SCR) containing only duplicate critical servers will be located in another fire compartment within the hospital to provide a level of resilience. The main communications systems will be connected to a system of communications rooms located throughout each floor via a backbone network system.

Each communication room will contain various communications and control systems equipment such as; patch cabinets, interface modules etc that support the hospital services serving a specific area to ensure optimal performance of each system are described in this section.

Connections between these rooms are also outlined with details on the containment dedicated to the TDS and ITEDS infrastructure and electrical risers within the various buildings.

The route for the incoming TDS ducting is to be provided from the Govan and Hardgate Roads up to each hospital entrance on the hospital campus. The two alternate routes ensure resilience via providing physically diverse routes. The two entrance facilities for the purposes of these ducts are designated Entrance Facility 1 (EF1) and Entrance Facility 2 (EF2). These shall be used as termination points by the various Service Providers (SP).

EF1 and EF2 termination points will be located in close proximity to the main communications room.

Data and Voice will be run in a combined services trench with connections to the new Adult Hospitals, Laboratories, Energy Centre and existing hospital buildings.

NHS GG&C Health Board shall be responsible for engaging the Service Provider(s) to provide telecommunication services into the new facilities.

A network of underground PVC ducts will be routed in a resilient fashion from the main control room in the Adult and Children hospital to the Laboratory, Energy Centre and existing hospital buildings. This network of ducts will facilitate the TDS and ITEDS infrastructure cabling (optic fibre and copper) that will service the buildings around the hospital campus.

Brookfield has included to consider new technologies and systems that maybe able to use modern wireless network

It is envisaged that in the future new hospitals will use wireless technology for public, staff data, patient monitoring, equipment tracking and automated transfer system connections, this will require the design and implementation of strategically located wireless access points to meet reliable robust performance and maintain the efficient operation of the hospital.

Facilities Management systems require a cabling infrastructure to enable effective communication between the various buildings. There is a requirement to provide an Independent Protocol network to support communication, interaction, data transfer and data retrieval from and between the various engineering systems that provide service to the buildings. The Building Management System will be fully integrated with this network and will provide control over the engineering plant and facilities to enable management of maintenance and to monitor energy usage. Systems such as metering, pressure monitoring status, general lighting controls and presence detection will use the Facilities management backbone network. The network will be totally independent of the clinical network except for an interface, which will be engineered into the final solution via the server.

Brookfield

Telephone Distribution Systems and Information Technology (IT) Equipment and Distribution Systems Room Allocations

Spaces distributed across the hospital to enable an efficient resilient network include:

- EF1 - Termination point for Service Providers
- EF2 - Termination point for Service Providers
- MCR and SCR.
- Communications rooms on each floors.

Networks

The voice and data clinical network will use a combination of optic fibre, category 6A (10G) copper cabling and copper multi-core telecommunications cable. NHS GG&C Healthy Board advised they will source and install all active network equipment, including the PABX and all associated telephone equipment.

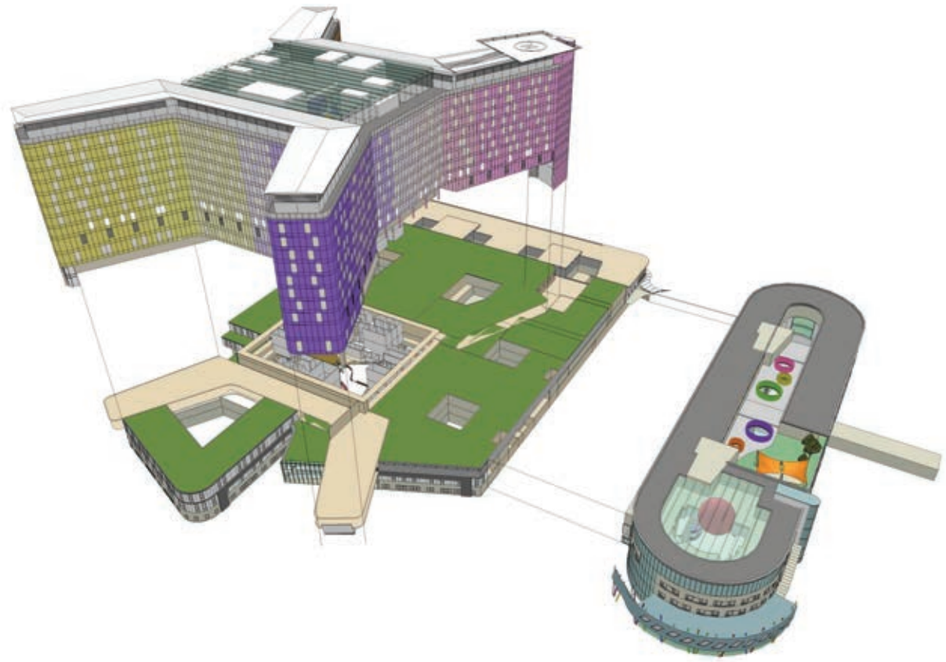
The core of the voice/data network will be located in the two main communication rooms located with in the Adult and Children's Hospitals. These rooms will contain all core routers and switches, as well as all server equipment to drive services delivered across the Structured Cabling System (SCS).

Local communication rooms will be distributed on each floor, the quantity of these rooms will be dependant on maintaining optimum performance of each system such as 90 metre cabling loops for fire alarms etc. These rooms will have connections back to the main communications rooms in a meshed configuration.

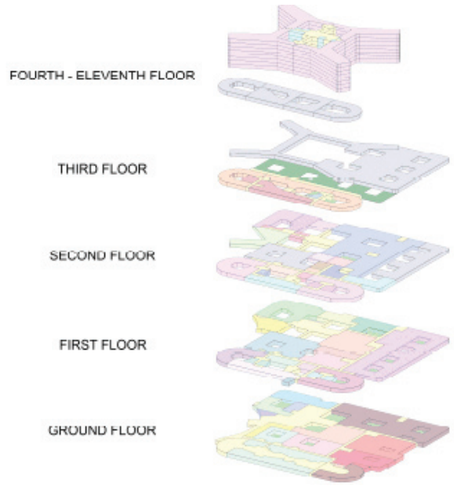
The first image shows a structural overview of the Adult and Children's Hospitals with the 3 distinct elements:-

- Podium
- Tower
- Children's Hospital

The next image outlines the different levels in the hospitals where we will now identify where the potential communications rooms will be located.



Brookfield



For the Adult Hospital, we would envisage having the main communication room at the Podium Level, where a level of security can be provided given the type of equipment that will be located here and a secondary communications room located in an alternate fire compartment. Access to each room will be required frequently.

Local communication rooms will be provided on the Podium and Tower levels, Children hospital, Laboratory, Energy Centre, Facilities Management areas and will be based on maintaining optimal performance of each system such as limiting to 90 metre maximum loop distance. The maximum distance limitation will dictate the number of communication rooms required. The majority of the communications rooms will be located in mechanical and electrical plant rooms where possible or located in dedicated riser rooms etc.

Access to these communication rooms will be less frequent than the main communication rooms (MCR & SCR) All rooms will be design with sufficient to house all equipment and allow future space for new technology or some additional future systems.

Users

We envisage that the number of users that will require access to the voice and data clinical network will include; consultants, nurses, administration staff, doctors, visiting medical personnel, maintenance and operations staff. Each user will be managed by setting up appropriate level of access authorisation controlled by a designated hospital IT manager. The Brookfield training program will provide all necessary training to use the system to set up each system with levels access and authorisation. However it is imperative for security that there is a physical and logical separation between internal users and external users. NHS GG&C Health Board will have sole control and management of the physical and logical patching of the network.

Ducting

Ducting has been designed to deliver internal & external communication network services across the site. The routes for the underground ducting will be provided from the Govan and Hardgate Roads up to each EF1 and EF2. We have calculated that a total of six ducts will need to be provided to each Entrance Facility, two ducts will be provided to the new Laboratory and two ducts to the current Estates Department. It is envisaged that at least four Service Providers will have connectivity to the new Hospitals.

Electrical risers facilitate the routing of the incoming cables and also aid the distribution of network cables within the building. All cables will be supported and fixed to proprietary containment and it should be noted that there will be no active or switching equipment in these locations. Riser access will be secured with lock and key.

Cable routes have been designed to ensure the internal networks are coordinated appropriately within each new building.

Copper network cabling and other various systems lengths will not exceed 90m from patch panel to socket or device. This requirement has been considered throughout the design.

Outlet provision

The voice/data outlet provision is based on the ADB Room Data Sheets. These ADB sheets define the location and quantity of the service types defined earlier in this report. Different colour patch leads will be used to distinguish the various services. In the bedrooms, outlets will be provided on the medical trunking where they will cater for data applications, voice applications, telemedicine applications and patient entertainment applications.

Outlets serving critical elements such as emergency phones will be clearly coloured and labelled. Outlets will be provided in the various rooms ensuring that all applications are served with an adequate quantity of these outlets.

Wireless Network Installation

Brookfield has included to consider new technologies and systems that maybe able to use modern wireless network

It is envisaged that in the future new hospitals will use wireless technology for public, staff data, patient monitoring, equipment tracking and automated transfer system connections, this will require the design and implementation of strategically located wireless access points to meet reliable robust performance and maintain the efficient operation of the hospital.

We are cognisant of the changing technologies in the wireless arena and note the widespread use of the “n” standard.

During stage two Brookfield will liaise with manufacturers such as Cisco and Trapeze to review wireless technologies and provide the NHS GG&C Health Board with a detailed proposal for a first class wireless infrastructure.

Noting the Employer’s requirement to provide an Independent Protocol network, this is to support communication, interaction, data transfer and data retrieval from and between the various engineering systems that provide service to the new buildings. The Building Management System (BMS) will be fully integrated with this network and will provide control over the engineering plant and facilities to enable management of maintenance and energy usage. Systems such as metering, pressure

A48235836

Brookfield

monitoring status, general lighting controls and presence detection will use this Facilities management backbone network.

The network will be totally independent of the clinical network except for an interface, which will be engineered via the server.

Public Address Systems (PA)

PA system will be provided that allows zoned emergency messaging throughout the hospitals, lifts, building link tunnel, facilities management and energy centre together with mustering areas, supplemented with voice and background music to entrances, main reception, atria, changing rooms, waiting areas, coffee shop and at each remote reception including nurse base for radiology, outpatients, pharmacy, A&E etc, inline with Clinical Requirements.

A vibrating disc or pager based system will be provided to indicate to patients that their appointment is available. This system will be operated via the wireless access system. Three separate systems will be provided, with power supply, data connection to the wireless system, each with twenty pagers.

Background music for the comfort of patients and visitors and public address facilities to main and sub-waiting area entrances and hospital streets are provided by input devices, amplifiers, distribution cabling and loudspeakers. Local volume control to each area, waiting or sub waiting etc will be provided with full volume on PA announcement.

The emergency messaging shall be controlled from two locations and the system shall incorporate pre-coded messages.

Audio Induction Loop System

Comprehensive Audio Induction Loop Systems (fixed or portable) will be provided:

- Reception areas.
- Bedded bays.
- Single room.
- Treatment rooms.
- Consulting rooms.
- Counselling rooms.
- Interview rooms.

The system shall be provided in compliance with the Disability Discrimination Act, the final locations and provisions will be agreed with the board.

Each induction loop will comply with the requirements of BS 6083: 1981 and in particular Part 4: Magnetic Field Strength in Audio Induction Loops for Hearing Aid Purposes.

A vibrating disc or pager based system will be provided to indicate to patients that their appointment is available. It is considered that this system may be offered via the wireless access system.

Patient Entertainment

Adult Hospital Patient entertainment provisions will be in accordance with the guidelines and include provision for local bedside TV, Radio, and telephone facilities with the capability of integration to satellite TV, local hospital radio, chapel services, internet services Brookfield have included to provide the latest technology that allows the patient entertainment system to interface with the hospital data communication system. The patient entertainment system will comprise Free-to-view Digital TV signals and shall be decoded in the Patient Entertainment Room server and shall be extended to each of the TV's located throughout the hospital building.

Brookfield acknowledge the differing requirements for the Adult and Children's hospital (ITPD 8.3.19.1/2 and 8.3.19.3/4) and has included to the design to meet those requirements accordingly.

Cabling and infrastructure provisions will be in accordance with the chosen suppliers requirements. Consideration will be given to procurement rather than renting of such system to enable greater flexibility to extend the functionality of the services and for patient charges and tariffs.

Cabling Infrastructure

The main TV signal shall be extended in coaxial cable to the Patient Entertainment Room where the signals shall be decoded for transmission over copper 4pair twisted pair cables. Multicore copper cables shall extend from the Patient Entertainment communications room to each of the CWP's. The Patient Entertainment TV distribution shall be via category 6 copper twisted pairs extending from patch panels within the CWP's to RJ45 Outlets at the TV points.

Nurse Call, Alarm Systems

Nurse Call system and emergency alarm services will provide a comprehensive system integrated within the BMS networking system at all bed locations (and en-suites), Nurse stations, Toilets, showers, TV rooms and all other areas frequented by patients in accordance with S/HTM's and S/HBN's. Brookfield will agree with the Board all enabled on-screen alerts and their locations.

The system will be capable of emitting both audible and visual warnings for the following situations:

- To summon a nurse (Patient to Nurse)
- To highlight a medical emergency (Nurse to Nurse)

The nurse call system will be part of the bed head service. A patient hand unit with a call button will linked to an indicator panel in the ward nurse station.

The system shall include:

- Ensuite protection.
- Over-door indicator lights.
- Ability to link calls between adjacent wards.
- Cardiac arrest or ‘crash’ call alarms taken back to a 24 hour manned point to allow the “crash” team to be paged

All equipment and materials to provide fully operational independent monitored Nurse Call Systems will be provided as described below to facilitate the summoning of nurse assistance throughout the areas by a ‘follow lamp’ system and separate nurse paging.

Resetting of each system will be carried out at the initiating point of the call by means of reset pushes either located in or separate from the call panels generally as detailed on the appropriate drawings.

Once the call has been initiated the system will remain operational both audibly and visually until the system is reset. A linked automatic paging system will be provided and interface with the ward call system, send ward, room No, call type etc to a central encoder transmitter via a wired network to provide the information to individual nurses mobile pagers.

Each bed system shall be transferable to adjacent and remote nurse stations via a hierarchical password control system to meet Nursing requirements of the flexible ward configuration.

Cardiac Alarm Systems

Cardiac Arrest facilities will be provided for use by patients and staff that can be operated by the telephone system and a dedicated alarm button located within certain areas to call adjacent staff.

Personal Attack Alarm System

Personal Panic and Attack Alarm System will be provided and installed in each ward and department in accordance with S/HTM’s S/HBN’s that will be based on a system using:-

- Portable transmitters carried by staff to initiate an alarm via the wireless connection points.
- An audible alarm installed within the various indicator panels located in security rooms and agreed locations that until the call is cancelled will continue to sound alarm.
- Local indicator lights that will signal alarm until the emergency call has been cancelled.
- All pagers will respond to the priority alarms.

In circumstances where staff could be at risk of attack whilst travelling across external areas of the hospital, suitable portable transmitters using modern digital technology will be provided linked to the security system. Upon activation, calls will be indicated visually and audibly at the various security panels until the call is cancelled.

External areas are provided with security lighting and CCTV that can be used to view areas where the alarm has been raised.

Staff Location Paging System

Staff pager and patient to staff message system will provided that will enable communication between staff to staff.

All Nurse Call Equipment will be as manufactured by the named firms in the Schedule of Specified Equipment and Materials.

The pagers will be integrated in the BMS and Telephone Systems to suit the Board requirements.

Clinical Equipment Alarms

Each clinical drug cupboard shall be alarmed as follows:

- Light externally over door to room.
- Back to Nurse station.
- Back to office to warn of unauthorised access.

Clinical equipment alarms such as blood fridges located as defined on the ADB sheets will be provided with an alarm and will have audible and visual remote alarms and auxiliary contacts wired back to the local BMS outstation. The remote alarm panels will have a mute button fitted.

The system provided by Brookfield by which clinical equipment alarms can be annunciated at designated locations during working hours, however out of hours alarms can be directed to a designated staff member off site.

Asset Tagging System

An asset tagging system will be provided based on RFID technology and have a system interface that will define the rules for particular assets and will provide a reporting facility.

The main benefits of this system are:

- Lowers acquisition costs
- Reduces lease expenses
- Trims asset shrinkage
- Increases asset utilization
- Boosts staff productivity
- Enhances work flow
- Reduces equipment hoarding
- Advances Accredited maintenance & calibration compliance
- Cuts risk & litigation exposure

Brookfield has included a digital web based asset management system that will be developed from the start of the project phase 1 and used as the main hand over process. The result is a complete comprehensive asset management system.

Further details of the electronic handover asset management system are contained in document 3.24.

Brookfield

Brookfield

Protective Systems Design Strategy

Submission Reference:

3.15 Protective Systems Design Strategy

Submission Response:

The protective systems described below comprise the design strategy for the hospital and the installation of these provides the following benefits:

- Saving lives of, and preventing injuries to, occupants and fire fighters.
- Preventing fire spread.
- Reducing property damage.
- Reducing environmental impact.
- Reducing water damage compared with water used during fire-fighting activities.
- Reducing social impact e.g loss of community facilities, loss of employment.
- Reducing financial losses.

This protective systems design strategy should be read in conjunction with the fire safety design strategy (Volume 2 Section 2.10).

The provision of the protective fire system described below will be monitored and controlled from a central fire control room which will be sited adjacent to the main service entry point into the building.

Fire Detection and Alarm System

The fire detection and alarm system will comply with BS 5839-1 2002 and SHTM 82 and be a category L1 installation.

The primary purpose of the system is for staff alert and the activation/warning design will consider a voice alarm system to be audible throughout the hospital, a coded message system for staff alert in certain areas and/or the use of indicators at staff bases to ensure the intelligibility of phone conversations during an alarm scenario.

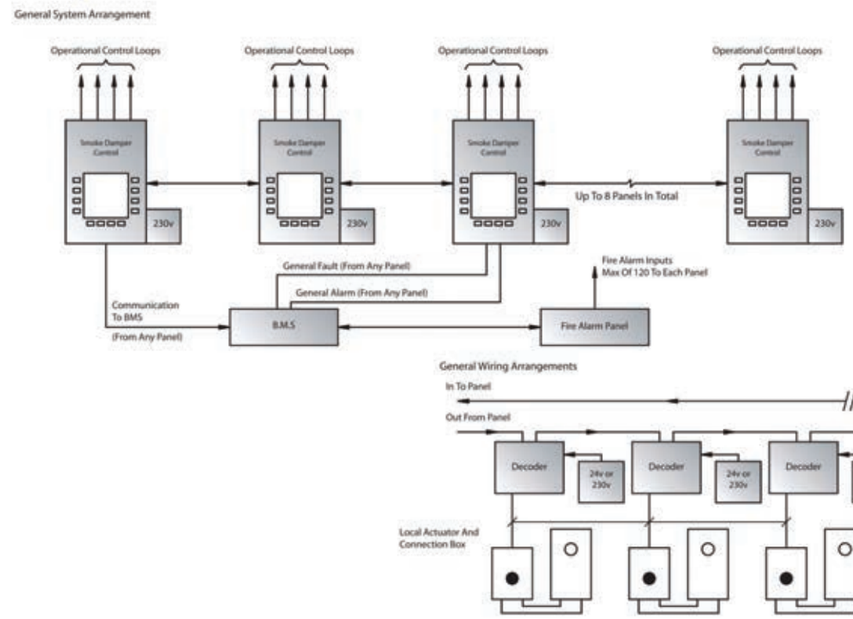
The system will comprise multiple analogue fire panels located throughout the building. The fire panels will be networked. Repeat indicators will be distributed throughout the hospital to provide local indication. Repeat panels will display any fire fault and disablement information. A mimic diagram will be provided adjacent to each fire alarm and repeat indicator panel. The main fire alarm panel will be located at the main reception and the repeater panels at certain staff bases.

An administration PC will be provided to give full administration facilities for the fire system.

Detection devices will be a mix of optical and heat sensors as appropriate to the area protected. Sensors will be provided with a number of different states of operation to enable configuration suitable for the area protected.

Sounders to BS EN54 will be incorporated into the sensors or separate units as appropriate. Manual call points will be provided.

General Wiring Arrangement
Addressable Damper Control



Brookfield

The system will be interfaced with the other fire protection systems and the ventilation system fire/smoke dampers which will prevent the spread of smoke and fire. These will be wired and controlled by a fully addressable damper control system incorporating local and master control panels with fireman's override facilities.

The damper control system shall be programmed to operate in accordance with the cause and effect strategy that will be developed for the New South Glasgow Hospitals. The damper system control panels will display the operating status and report faults on a continuous monitoring basis. The main fire alarm panels will have the facility to manually operate either collectively or individually the dampers

Gaseous Extinguishing Systems

Aspirating detection will be provided in the two main server rooms, interfaced with the fire alarm system. The server rooms will also be provided with gaseous extinguishing systems operating a 'double knock' confirmation facility. The system will comprise a zone control panel adjacent to the protected space which interfaces with the alarm system, ventilation and air conditioning systems, power supplies and the extinguishing system. The panel will control the shut down of these power, ventilation and air conditioning systems in the event of a signal from the fire alarm system and then activate the extinguishing system.

Sprinkler Installation

The automatic sprinkler installation for the hospitals will comply with BS EN 12845, LPC standards, SHTM 82 and, due to the height of the building, with the high system requirements layout in accordance with BS EN 12845:2004 Annex E. The system will protect the building from serious fire damage. The water supply for the system will comprise two multistage electric pump sets drawing water from tanks located in the basement of the building.

The design of the system will use the Ordinary Hazard Group III classification. Sprinkler protection will be installed at ceiling level throughout the protected areas from Level -1 to Level 12 in the adult hospital and Level -1 to Level 4 in the children's hospital, with the pipe work concealed in the ceiling void. The installation will be subdivided into zones in accordance with Annex D and Annex F of the BS EN12485. Each zone valve arrangement will comply with the Life Safety requirements and each zone will not exceed 2,400 m^2.

Sprinkler protection will be provided throughout the building apart from optional permitted exceptions, so that if a fire starts at any location in the building it is suppressed and controlled and /or extinguished quickly and efficiently, preventing fire spread to other parts of the building.

All the monitored sprinkler equipment such as pumps valves and flow switches will be wired to an addressable panel. A flow alarm switch will be provided on the alarm valve riser to give remote alarm indication.

Wet Risers

A wet risers system will be provided in the Adult and Children's hospital with a landing valve at each floor and each staircase. The water supply for the system will be from an electric booster pump set drawing water from a tank. Four wet risers will be installed in the Adult hospital and two in the Children's hospital. The booster pumps will act as duty and standby with automatic changeover.

A landing valve will be provided at each floor level where personnel can connect and fill hose lines in relative safety before entering the fire compartment. Each landing valve will be sited in the stairway enclosure and will be protected and installed within a box in accordance with BS 5041-2.

Escape Lighting

The hospitals will be provided with emergency lighting to aid the escape and therefore protection of staff and patients. The systems will be in accordance with BS5266: Part 1: 1999 and SHTM 2007. Further details on lighting are provided in Volume 3 Section 3.12 (Lighting Design Strategy) and Volume 4 Section 4.36 (Electric Lighting Specifications).

Kitchen Fire Suppression systems

Localised kitchen extract fire suppression systems will be installed within the kitchen extract canopies.

Fire Extinguishers

Fire extinguishers will be provided and installed throughout the hospital building in accordance with BS5306: PART 8

Appropriate types of extinguishers will be incorporated in order to cover varying types of potential fire risk.

Fire Hydrants

A system of water fire hydrants, with a sufficient incoming water supply, will be located externally to the building and distributed around the building so that every external elevation of the hospital is within 60m of a hydrant. The hydrants will be at least 6m from the building and be constructed in accordance with BS 750: 1984.

Helipad

The helipad located on the roof of the Adult hospital will be supported by a fully equipped foam extinguishing system in compliance with NFPA 418, CAA guidance and Health Building Note 15-03: Hospital helipads design. The foam extinguishing system will be connected to the nearest wet riser.

In addition, the fire protection system for the helipad will be supported by two 50Kg Multipurpose Dry Powder Chemical Wheeled Fire Extinguishers located at the same level. Further details are provided in the Helipad M&E services design strategy in Volume 3 Section 3.22.

Brookfield

Medical Gases Design Strategy

Central gas storage

A medical gas storage compound will be located on the southern perimeter road adjacent to the multi-storey car park as indicated on the external services layout drawing.

The positioning of the compound provides the required safe separation distances as required by HTM02-1. Access for tanker and bottled gas deliveries will be provided so as not to cause obstruction of the roadways.

Oxygen supply plant

Oxygen will be supplied from two separate VIE compounds. The VIE (Vacuum Insulated Evaporator) units will be arranged as main supply and emergency reserve.

The VIE oxygen supply equipment will be sized and installed by B.O.C under direct leasing arrangements with the Board; a valved connection being left in each compound for continuation by the medical gas specialist.

From each VIE unit an oxygen supply will be taken underground to enter the main Acute Hospital and then connect to the oxygen ring main running at ground floor level. The ring main will connect to the major risers serving the upper floors of the Acute and Children's Hospitals. The risers will be cross-connected at roof plant level to provide additional resilience to the distribution system.

Manifold supplied services

Nitrous Oxide will be provided from manifold rooms in the medical gas compound. Separate manifolds will be provided for the Acute Hospital and Children's Hospital theatre departments.

A single pipeline for each service will run below ground from the manifold room to enter the main Acute Hospital where it will run to rise within ventilated service risers to the various departments to be served.

Central compressor plants

Central Plant will be located at roof plant room level for the following systems:-

(a) *Medical Air*

- Medical Air 4bar plant be installed within plant room 121/122. This supply all wards on level 4 through to level 11. There be two risers each riser supplying two wards on each level.
- Second air compressor be installed within plant room 41 on the fourth floor to supply the children's block.
- The third air compressor be installed within plant room 31 above the main theatres this plant cover ground, first, second & third floors of the main building.

Emergency reserve bottle manifold to supply each of the 4bar plant will be installed in plant rooms 121/122, 31 & 41

(b) *Medical Vacuum*

- The vacuum pumps be located in plant room 121/122 to serve the wards on level four through to level 11, there be two risers each riser supplying two wards on each level.
- The second vacuum plant be installed in plant room 41 to serve the Children's Building.
- The third vacuum plant to be installed in plant room 31 to serve the main block levels ground, first & third floors.

(c) *Surgical Air*

- One 7bar plant to be installed in plant room 41and one 7bar plant to be installed in plant room 31 supply the requirements of all Ultra Clean Theatres, Cardiac department and General Theatres.

Emergency reserve bottle manifolds to supply each of the 7bar plants will be installed in plant rooms 41 & 31

Plant Noise

The sound pressure level within the compressor plantrooms need to be carefully considered. It is, therefore, intended that screw compressors will be used whenever possible to reduce the sound pressure levels.

Anesthetic gas scavenging systems (agss)

Anesthetic Gas Scavenging Systems will be provided for wherever Nitrous Oxide is used for anesthetic purposes and pumped to local exhauster sets within the roof plantrooms.

Within the departmental areas wherever AGSS terminal outlets are provided, local starter panels with plant run/fault indications will be provided.

Terminal units

Terminal units will be single outlets, wall mounted or part of a horizontal medical trunking or part of a ceiling pendant.

Brookfield

Area valve service units (AVSUs)

These will be generally located for both departmental isolation units located within the hospital street adjacent to departmental doors and local area isolation units located adjacent to nurses stations etc.

Medical gas alarms

Medical gas alarm systems will be stand-alone systems and only give status and alarm facility to the central BMS via volt free contacts on the Main Alarm Panel.

All central panels will have audible and visual alarms for all remote plant conditions and visual pipeline pressure fault conditions. Repeater panels will show all the alarm conditions on the control panel.

Main alarm panels will be located in the main hospital switchboard room with a repeater panel within the Facilities Management office.

At the main alarm monitoring panel and repeater panels, the pipeline status in critical care areas will also be indicated, e.g. Theatres, and Intensive Care Areas

AGSS alarms will local to the area served.

Brookfield

Design Strategy for Pneumatic Tube System

General

A PC controlled pneumatic tube system (PTS) will be installed in the Acute and Children's Hospitals with links to the Laboratory building via the service link tunnel.

The preliminary plan for the PTS is a ten zone network to serve around 92 stations within the hospital buildings, with four zones covering the Ward Tower itself. A dedicated zone between A&E and Pathology will be provided to maintain a high priority service, three dedicated systems will be provided between the network hub and specimen reception to maximise traffic handling capacity with automatic empty carrier return using transponder fitted carriers.

The system will be capable of supporting 300 (carriers) per hour on the power assisted links and 40 (carriers) per hour on the direct link from A&E. A proposed layout is illustrated on the schematics drawings accompanying this document

A front end PC will be provided complete with dedicated printer and modem for remote operation and analysis.

The system will incorporate an advanced platform software control package with full automatic dual control redundancy to provide optimal flexibility, performance and convenience in the management and maintenance of the pneumatic tube system.

The controller will have battery backup for system memory and status, and be capable of being remotely controlled through the PC.

Tubing will be 160 mm diameter solvent welded rigid UPVC, with intumescent fire sleeves when passing through firewalls or floors.

The equipment will be supplied and installed in accordance with SHTM2009, utilising optical carrier detectors, safety extra low voltage cabling to the stations, electronic positioning sensors, volt free contacts for BMS alarm status and fire alarm interface at the controller.

Stations

The stations will generally be of front-loading design with a wipeable membrane type keypad.

A 'spare carrier' rack holding up to four carriers will be wall mounted adjacent to the station.

The stations are to be designed to comply with the latest Health & Safety Regulations. Access to the station mechanism is to be protected by an electronically controlled opening/closing guard door with full mechanical interlock.

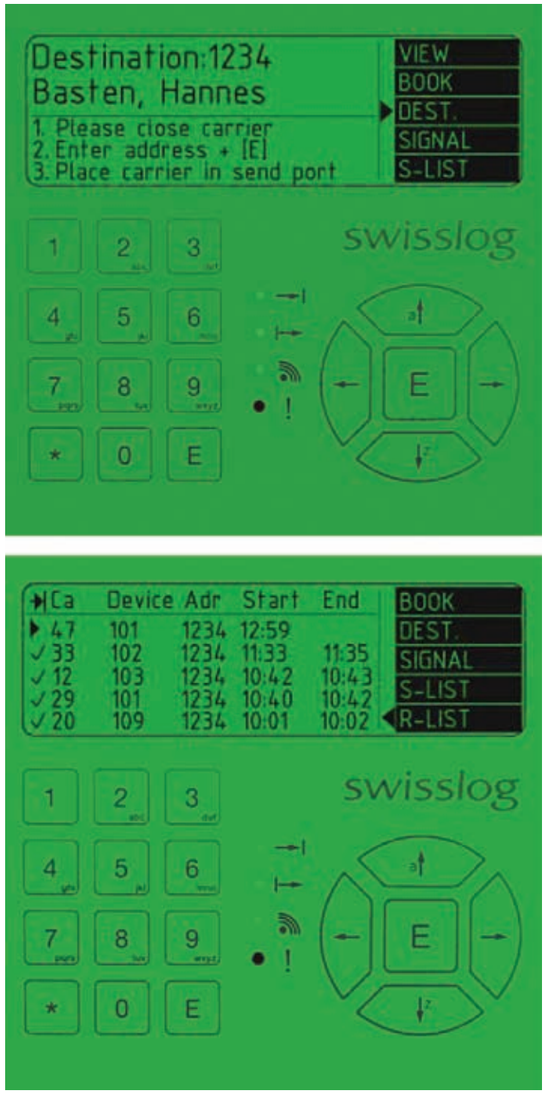
The stations in-built LCD display will show:

- Time and date
- Carrier destination
- The station the last carrier arrived from
- Station status - ready, selection OK, out of use, maintenance, faulty, basket full, invalid address and purge

The display will also have a directory of all system station names and numerical addresses.

The stations indicators display will show:

- Carrier being despatched
- Carrier incoming
- Carrier arrived at destination
- System busy
- System faulty



Station display information

A48235836

Brookfield

Stations will be fully automatic and capable of accepting a carrier when another carrier is incoming to that station.

Destinations will be addressed by the use of the 4 digit number or by accessing the station name through the directory.

Destinations may be restricted if required.

The destination setting can be optionally set to return to 1 of 3 settings after a carrier

has been sent:

- Force new address input
- Default to a pre-set address
- Default to “last number re-dial”

Wrongly addressed carriers will not be accepted by the system. A code reader at the station will allow only carriers to be introduced into the system, e.g. objects such as cans will not be accepted.

Incoming carriers will be able to be re-directed to another station.

All stations will be fitted with air control to ensure carrier soft arrival. This system will provide total safety of even delicate glass samples.

The station will automatically clear and eject a blocked carrier exit by agitating the station mechanism.

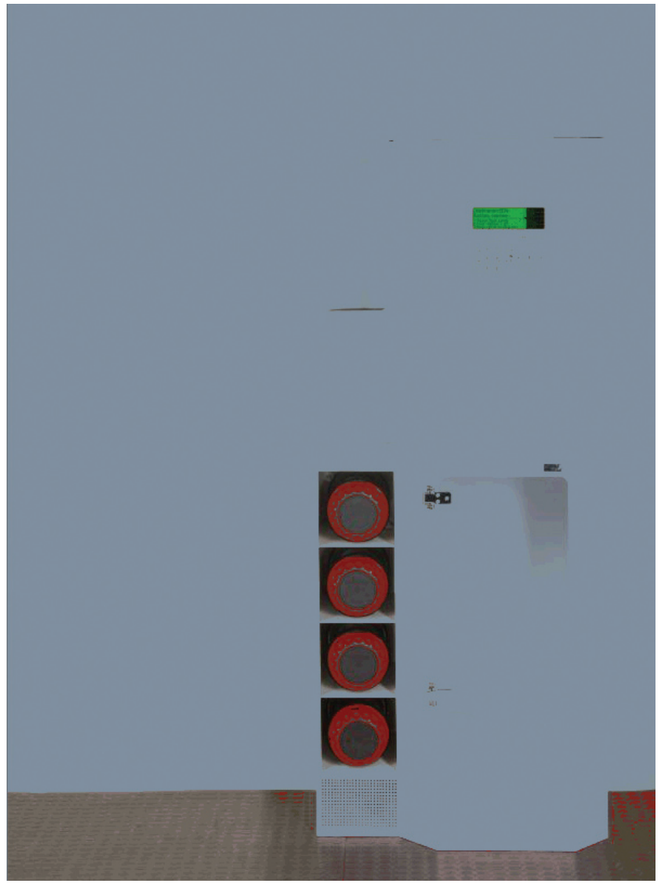
The station will be set to automatically return a carrier to the station from where it has been received by use of a single keystroke.

Carriers will be received into a cabinet below the station. The cabinet will be either an open type, or secure, accessible only by the use of a swipe card. Arrival signal units will be able to be programmed to discriminate to different user addresses, thereby allowing urgent full carriers to be immediately notified to the user, whilst allowing no alarm for empty returns.

The use of the station will be restricted by a user identifiable touch key and security card.

The station will include an in-built carrier arrival indicator consisting of a warning bleep and light. The bleep is to be enabled or disabled as required at the station by the user.

Remote indicators will be provided in some locations to indicate the arrival of a carrier at the station, as indicated in the schedule. These are generally from the Clean Utility Rooms to the appropriate Staff Base, and indicate on the Nurse Call Panel.

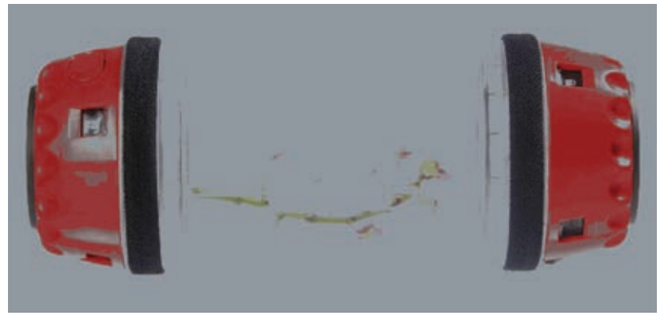


Carriers

Carriers will have transparent bodies with coloured ends and are available in various lengths The coloured ends can be used for different purposes, for example red for pathology or green for Pharmacy.

Each carrier will come complete with transponder technology that allows automatic redistribution and allow only correct carriers to be sent from any station.

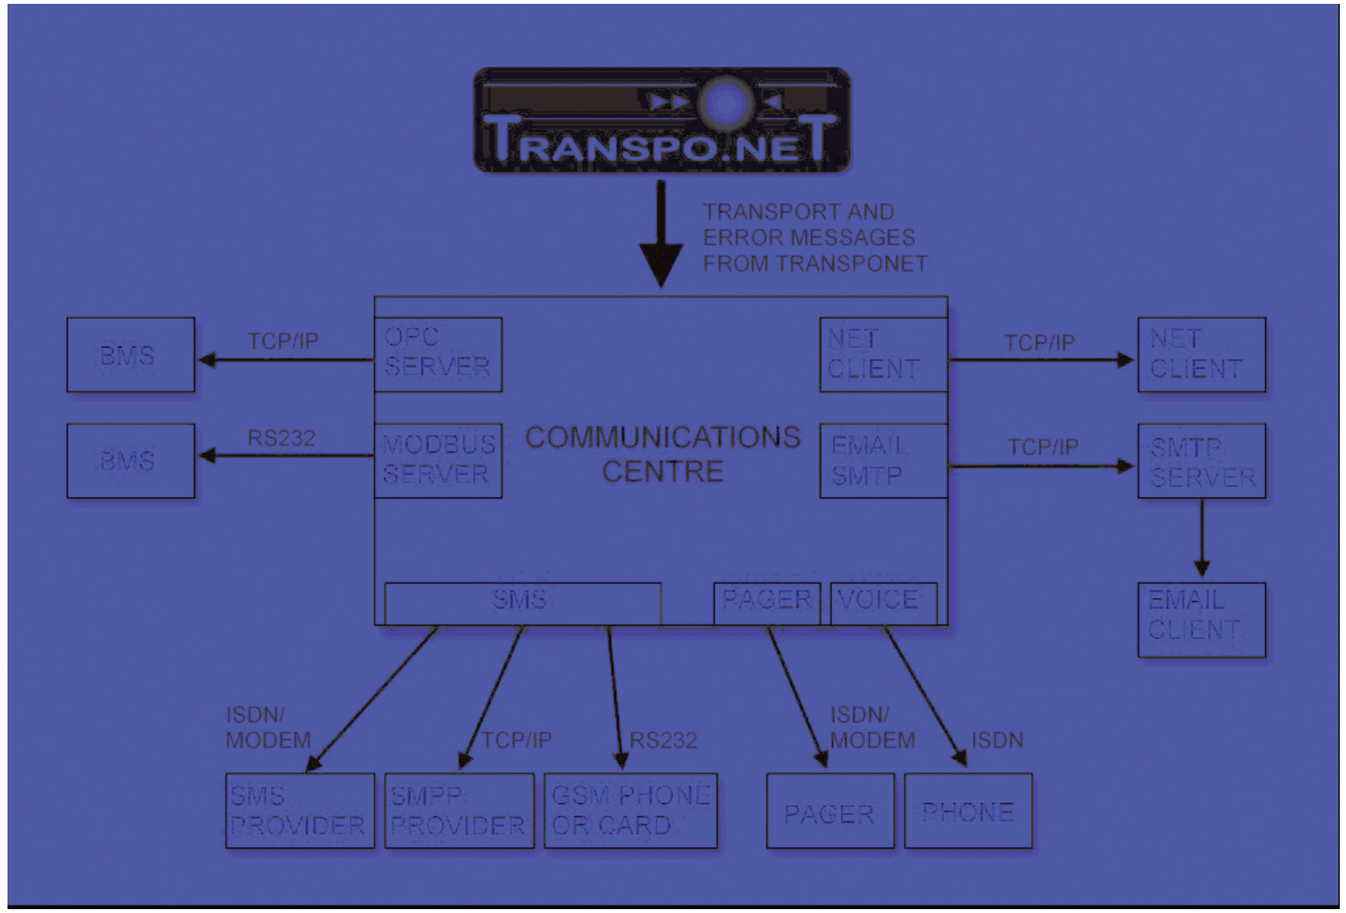
Carriers will be secured during both the send and receive operations.



PC & Printer

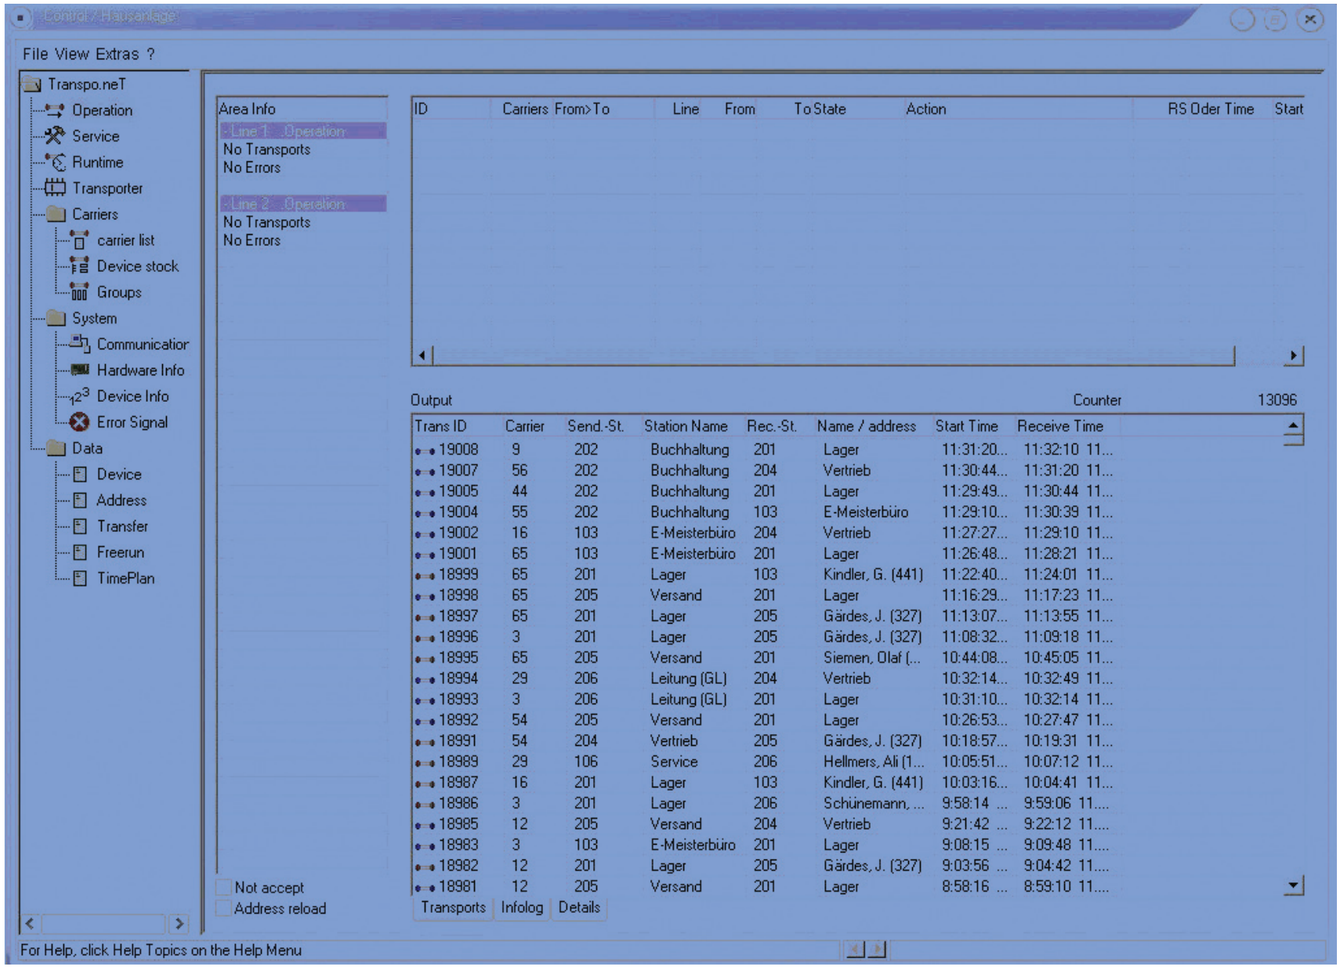
A PC based maintenance System Control Center will be provided for use by the hospital engineering and operations departments to configure the system, monitor system operations, schedule system operations and troubleshoot system errors, and to run a remote facility management PC and Communications Centre which will provide all external communications interfaces as illustrated below.

The supervisor terminal will be positioned in allocation to be agreed with the Board, and be used to monitor the activity of the system, all carrier movements plus the status of all of the equipment.



Brookfield

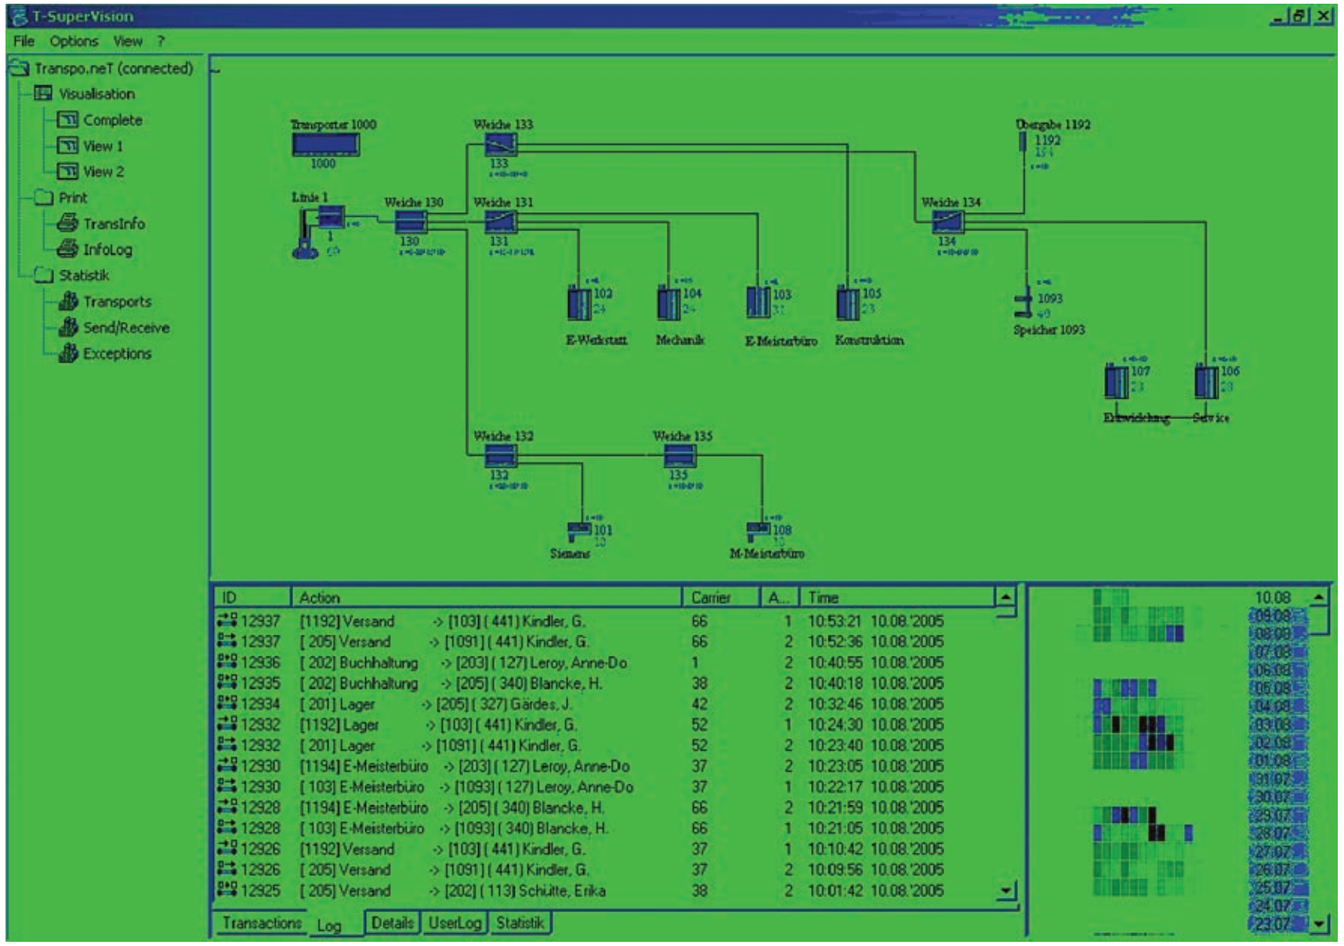
In the event of the requirement to track down individual sending of carriers from particular stations on the network it will be possible to interrogate the PC to display all transactions between a particular requested timeframe between any 2 stations. This function can be repeated right across the network.



Brookfield

For historical information the PC will be able to produce the last 20,000 transactions.

In addition the monitoring PC will identify the load time of each carrier into the load / despatch tube of each and every single station on the network. The time that the carrier is accepted into the station ready to be transported will also be registered. The PC will also log the time that each carrier is discharged from the network. In the event of a localised power failure to the PC the system will continue to operate.



A48235836

Brookfield

Additional Features

Follow Me / Redirection Facility.

Each station on the network will have this ability, and will be controlled by the user. This will allow users to divert their station address to any other one within the network, enabling them to still receive carriers even if they are working within another area of the hospital.

Automatic Isolation of stations

Stations can be isolated electronically on a ‘timed’ basis if required.

This facility will be programmed at the central processor unit PC.

Manual Operation of Station

Any station nominated by the user can be closed locally without affecting any other station or diverter on the network, thus giving the user full control of their station.

Alpha Numeric Address

The system will include Alpha Numeric address facilities. Once an address code is inserted the user has the opportunity to check it before accepting the displayed, programmed target address. If satisfied then the confirmation key can be pressed.

Modem

This will enable external connection to allow remote technical support from the Facilities Management Department or any other external point.

Carrier Monitoring

All carrier transactions through the network will be monitored in real time.

Power Failure

In the event that a power failure occurs, the system will automatically be reinitiated and any carriers that are contained within the system will be removed and taken to their pre-programmed destination or to the assigned ‘dump’ station.

Fire Alarm

In the event that the fire alarm system is activated (either in a real event, by accident or a planned test) then the system will close down following completion of any transaction in progress. As and when the Fire Alarm is reset then the system will be reinstated. This can be carried out either manually or automatically. A manual ‘test’ key will be provided to override and disable this facility for fire alarm testing, so as to avoid disruption to the system operation. This is to be positioned at the main control location (to be agreed).

The system will be linked to the BMS via volt free contacts within the main control unit. In a fault condition the system will activate the alarm.

Fire Engineering Design Strategy

Selection of system

The choice of a fire fighting strategy has been considered and the use of automatic sprinkler for the main parts of the buildings is proposed following for the following reasons:

- Saving lives of, and preventing injuries to, occupants and fire fighters.
- Preventing fire spread
- Reducing property damage
- Reducing business interruption
- Reducing environmental impact
- Reducing water damage compared with water used during fire-fighting activities
- Reducing social impact,e.g loss of community facilities, loss of employment
- Disincentive to arsonists
- Reducing financial losses

Standards

Sprinkler systems will be designed, installed and maintained to a recognized standard to ensure the effective performance of the system in the event of a fire and to satisfy insurers and /or approving authorities.

In the UK, the current recognized principal standards relevant to design, installation and maintenance of sprinkler in buildings are:

- BS EN 12845: Fixed firefighting systems – automatic sprinkler systems – design, installation and maintenance.
- The LPC rules for automatic sprinkler installations incorporating BS EN 12845. These rules are for property protection purposes and contain the text of BS EN 12845 and a series of technical bulletins, which amplify the requirements of standard or cover additional requirements for insurers.

In the UK, the recognized principal standards that cover requirements for components of sprinkler systems in buildings are:

- BS EN 12259: Fixed firefighting systems, components for sprinkler and water spray systems. This is a companion standard to BS EN 12845.

Key elements of the system

The key elements that need to be considered for the design, Installation and Maintenance of sprinkler systems are:

- Documentation
- Extent of sprinkler protection ,including permitted exceptions
- Classification of occupancies and fire hazards, including protection of special hazards
- Hydraulic design criteria, including design density and area of operation
- Water supply and type
- Pumps
- Installation type and size
- Spacing and location of sprinklers
- Pipe sizing and layouts
- Sprinkler design characteristics and uses
- Valves
- Alarms and alarm devices
- Pipework
- Signs, notices and information
- Commissioning and acceptance tests, periodic inspection
- Regular maintenance
- Special requirements for property protection systems or life safety systems.

Sprinkler protection and hazard classification

Sprinkler protection will be provided throughout the building apart from optional permitted exceptions, so that if a fire starts at any location in the building it is suppressed and controlled and /or extinguished quickly and efficiently, preventing fire spread to other parts of the building. All exceptions to sprinkler protection will be agreed with the relevant Jurisdictional authorities.

Limitations of automatic sprinkler systems

Automatic sprinkler systems, like other fire protection systems, have limitations. Sprinkler systems are designed to protect a particular hazard and therefore will not be suitable for protecting special hazards that are not allowed for in the design for example:

- Greater hazards than the system is designed for
- Saving people in contact with flames
- Unprotected areas in a building, i.e. Areas with no sprinkler protection
- Fires with a great degree of shielding
- Compartments with very tall ceilings
- Electrical fires
- Explosions
- Exposure fires with rapid spread (fire originating externally to the sprinkler protected building)
- Extreme events resulting in mechanical damage, e.g. earthquakes and impacts
- Small fires, producing insufficient heat generated by the fire to operate a sprinkler head that can be extinguished promptly by other means.

Brookfield

WET RISER

Location
Wet rising mains will not be located against or near external walls unless they are adequately insulated or otherwise satisfactorily protected against frost.

Landing valves
A landing valve will be provided at each floor level where personnel can connect and fill hose lines in relative safety before entering the fire compartment. When selecting the position of landing valves, consideration will also be given to ease access; exposure to fire from the accommodation if a door is open; obstruction of fire doors by the hose line; and the risk of unintentional discharge of water hitting the lift doors or controls.

Each landing valve will be sited:

1. within a ventilated lobby of a lobby approach stairway, where this is provided; or
2. in a stairway enclosure; or
3. in any other position as agreed with the appropriate authority

In all cases a landing valve will be installed with its lowest point about 750 mm above floor level.

Landing valves for fire mains will preferably be protected by, and installed within, a box accordance with BS 5041-2. Landing valves will also be protected against interference and attack by thieves and vandals as far as possible to do so without adversely affecting operational capability.

Adequacy of basic supply
In all cases where town's mains supply is involved, the capacity of the mains is important and will be checked. Generally a water supply capable of provided a minimum of 1500 L/min at all times will be required.

Supplementing the basic supply for wet mains
We are assuming that the towns main supply will not provide sufficient pressure and capacity to provide the necessary supply, each fire main should be fed from two interconnected tanks of nominal equal capacity and having a total minimum capacity of 45 000 l.

The tanks will be automatically supplied from a towns main's controlled by ball valves and the capacity of these mains together with the contents of the tanks should be such as to maintain a flow of water capable of supplying two fire fighting jets for 45 mins when water is being used at a total rate of 1 500 1/min. Each tank will be fitted with isolating valves to enable one tank to be taken out of service for maintenance or repair.

Pumps for wet fire mains
Two automatic pumps will be installed to feed the wet fire main, one of which should act as standby, and be arranged so that when acting as duty pump it will operate automatically, i.e. on a flow of water or a fall in pressure on the installation. The secondary pump will be so arranged that it will operate automatically on a failure for any reason of the duty pump. Both pumps will be primed automatically at all times. This will be affected if the pumps are sited so that at least two thirds of the effective capacity of the suction tank is above the level of the top of the pump casings. The pumps will be driven by electric motors.

They will be driven from the same supply with an automatic changeover to a completely independent secondary supply in the event of failure of the primary supply.

All pumps will be capable of being started and stopped manually.

An audible and visual alarm should be provided at an agreed position to indicate that the equipment and the pumping plant have operated.

Each pump will be capable of providing a flow of water of at least 1 500 L/min in the fire main, i.e. sufficient to serve lines of hose from two separate landing valves simultaneously. A running pressure of 8 bar will be maintained at each landing valve when fully opened.

Helipad
The helipad located on the roof of the Adult hospital will be equipped with a Foam extinguishing system in compliance with NFPA 418. This foam extinguishing system will be connected to the nearest wet riser.

Also the fire protection will be completed by two 50Kg Multipurpose Dry Powder Chemical Wheeled Fire Extinguishers located at the same level.

Extinguishers
Fire extinguishers will be provided and install throughout the hospital building in accordance with BS5306: PART 8

Various type will be fitted in order to cover all types of fire risk.

Fire suppression system
A localised kitchen extract fire suppression system will be installed within the extract canopies.

Plantroom Design Strategy

The plantrooms have been located so that plant is positioned close to the areas and departments served. Thus, the majority of the plant space will be directly over the most heavily serviced areas, for example theatres, critical care, radiology and A&E.

Plant will also be located above the adult and children's wards.

The plantrooms will accommodate air handling units, extract fans, circulation pumps, pressurisation units, medical gases plant, calorifiers, heating and cooling plate exchangers, and water treatment plant as well as transformers, LV switchgear and UPS systems.

The plant will be laid out to allow safe access for maintenance and commissioning, and components that require regular access, such as valves, will be positioned at low level avoiding the need for step ladders. Adequate draw out space has been allowed for items such as withdrawable switchgear, coils, motors, fans and so on. The plantrooms have been planned with plant replacement and maintenance in mind; refer to the plant replacement strategy (Volume 3 Section 3.23) for further details.

Air handling plant will introduce outside air via louvres around the face of the plantrooms. Deep plan or 'land locked' plantrooms will also be provided with louvred 'turrets' on the plantroom roof.

Plantroom floors will be tanked to prevent spillage passing to the areas below.

Services will be distributed horizontally within plantrooms to vertical riser shafts which will be optimally positioned to deliver the services as close as possible to the final point of use, thus reducing system pressure drops and hence pump and fan power energy consumption. Plant items will be positioned so that horizontal distribution runs are as short as possible.

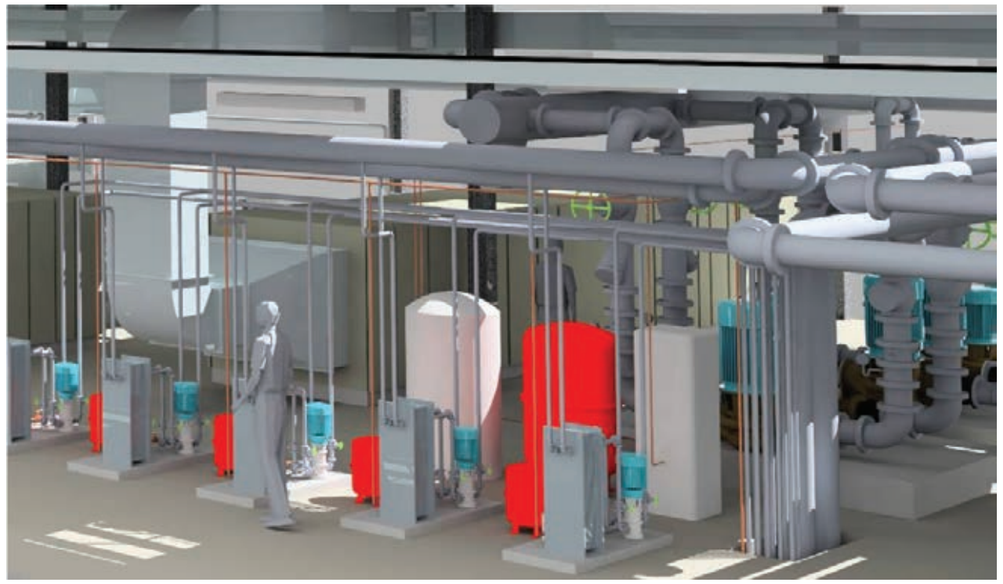
A valve room will be located at basement level of the hospital to receive incoming chilled water and medium temperature hot water generated in the energy centre. The basement will also accommodate domestic water storage and sprinkler water storage tanks. With the tanks being located as close as practical to the points of use temperature 'pick up' will be minimised.

Brookfield

The electrical services for the plantrooms has been designed to facilitate a quick installation and easy maintenance. Motor control centres for mechanical plant will not be used; power to plant will be distributed by means of high level plug-in bus bars, a method very commonly employed in industrial applications. Plant will be delivered with on-board controls and power wiring for simple 'plug and run'.

Transformers and main LV Switchboards will be segregated in 4 hour rated fire compartments. Refer to the Electrical Services design strategies for further details on the approach taken to resilience and redundancy.

The central energy centre for the hospital and laboratory buildings will be located to the north of the new development and will house major plant items which can be considered as noisy and dirty, and requiring fuel deliveries and major cranage, in the event of plant replacement. These operations will therefore take place well away from the main clinical operations reducing disturbance and potential hazards to patients and staff. The energy centre building will be constructed and engineering in a different form to allow noise, etc to be better controlled than if it were part of the hospital building.



The energy centre building will be three storey with accommodation arranged as follows:-

- Ground Floor – oil storage for standby generators, boilers and retained site. Oil fill points for tanker deliveries will be located on the Western face of the energy centre
- First Floor – standby generators and 11kV switchgear
- Second floor – MTHW heating boilers and CHP units, absorption cooling plant
- Roof – main chillers and associated transformers, absorption chiller dry air coolers, wind turbines

Oil tanker deliveries are noisy and potentially hazardous

Brookfield

Design Strategy for Engineering Systems Reserve Capacity

In respect of Clause 8.1.3.2 of Volume 2/1 of the ITPD documents the following reserve capacity is proposed for each of the major engineering services systems:

System	Proposed Reserve Capacity	Description
Electrical substations/ transformers and switchgear	25% reserve capacity	In addition to the provision made for emergency resilience, electrical distribution systems will incorporate 25% reserve capacity, for example, cable capacity, distribution board spare ways, etc.
Ventilation plant	25% reserve capacity	All air handling plant includes 25% reserve capacity for future expansion with inverter drives fitted to motor for capacity adjustment. All heating and cooling coils will by default incorporate this reserve capacity. *It should be noted that oversizing plant in this way will result in poor control performance and increased energy consumption.*
Boiler plant	Reserve capacity incorporated from terminal loads	Systems being served from the boiler plant incorporate 25% reserve capacity, e.g ventilation plant, which is accounted for in the sizing of boiler plant and distribution systems. Therefore no additional reserve capacity is included. However, with the arrangement of A & B boiler systems additional capacity has been included.
Cooling plant	Reserve capacity incorporated from terminal loads	Systems being served from the cooling plant incorporate 25% reserve capacity, e.g ventilation plant, which is accounted for in the sizing of chiller plant and distribution systems. Therefore no additional reserve capacity is included. The provision of N+1 on the plant, which is unusual in healthcare premises, will give an additional 15% reserve capacity.
Cold water storage	Nil reserve capacity	The provision of spare capacity in cold water systems is discouraged as this can lead to increased risk of Legionella. Water storage volume should not exceed 24 hours usage and ideally be less.
Hot water storage	Nil reserve capacity	The provision of spare capacity in hot water systems is discouraged as this can lead to increased risk of Legionella. However, a standby calorifier is provided in each location which for the vast majority of time will achieve reserve capacity
Pneumatic tube	25% reserve capacity	The pneumatic tube system will be able to accommodate an additional 25% traffic movement over and above that anticipated from the traffic analysis
IT/telephone installation	25% reserve capacity	Distribution containment will incorporate space for 25% additional cabling. The hub room racks will be sized to accommodate a 25% reserve capacity, but active equipment will only be provided as and when the capacity is required.

Brookfield

Brookfield

Energy Strategy, Including Approach to Renewables and Sustainability

Introduction

The New South Glasgow Hospital, to be located to the west of the city centre, will include both a general acute hospital and the National Children's Hospitals. The hospital will be formed from a four storey podium, housing acute treatment areas and ward areas, and an eight storey tower, accommodating ward areas.

The net occupied floor area for the new hospitals, as defined in EnCO$_2$de, will be approximately 136,000m^2 (gross 165,000m^2).

It is the aim of this report to provide an estimate of the total energy consumption for the New South Glasgow Hospital at the present stage of design, and to determine the measures required so that the design, and ultimately the constructed hospital in operation, complies with the required energy targets.

Objectives

The Board has committed through its Carbon Management Programme and Carbon Management Plan to reduce CO_2 emissions by a minimum of 25% by 2016.

This objective is supportive of Scottish Government Planning Policy 6, which states the following:

"…all future applications proposing development with a total cumulative floor space of 500 square metres or more should incorporate on-site zero and low carbon equipment contributing at least an extra 15% reduction in CO_2 emissions beyond the 2007 building regulations carbon dioxide emissions standard."

"The Scottish Ministers have set a target of generating 40% (since quantified as 6GW) of Scotland's electricity from renewable sources by 2020 and confirmed that this target should not be regarded as a cap."

The new hospital development must therefore encompass these objectives and strive to provide the lowest practical energy and carbon footprint possible.

It is also a requirement for at least 0.5% of the building's CO_2 emissions to be met by a visible renewable energy source, such as solar thermal, photovoltaics or local building mounted wind turbines.

Energy and carbon targets

The new hospital will achieve the following targets:

Energy consumption below	55 GJ/100m^3/year
Carbon emissions below	80 kg CO2/m^2/year
EPC asset rating less than	40

Analysis of energy and carbon targets

While the energy consumption target is equal to the mandatory Department of Health target, the target for CO_2 emissions and the required EPC rating reflects the drive for low carbon design within the building.

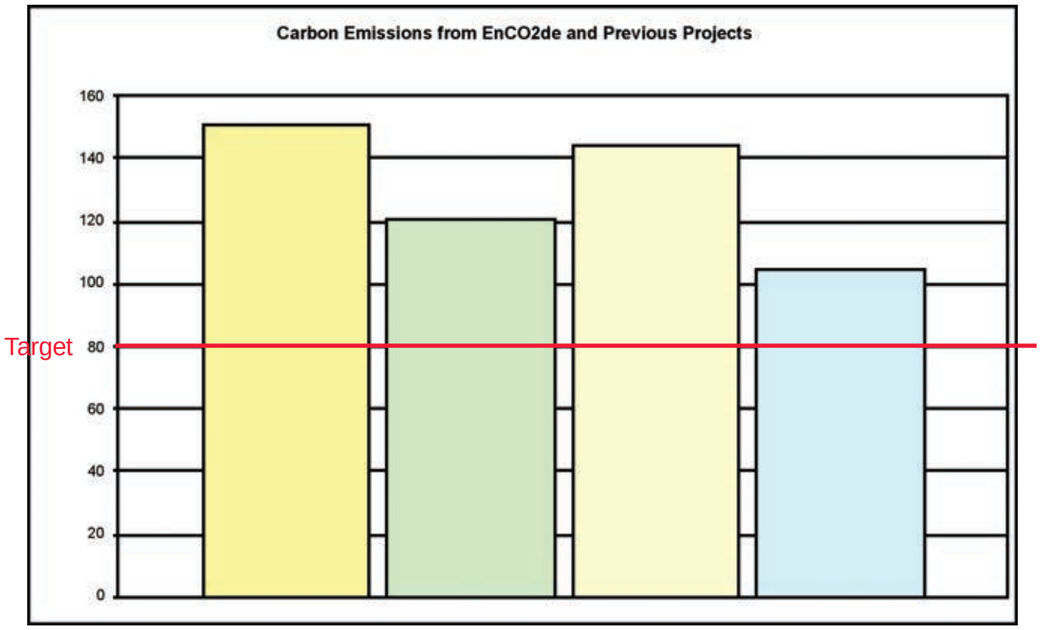
SHTM 07-02: 'EnCO$_2$de – Making Energy Work in Healthcare' gives details of average CO2 emissions from existing general acute hospitals as well as good practice benchmarks for new general acute hospitals:

Average emissions from existing sites	145 kg CO_2/m^2/year
Good practice benchmark	<105 kg CO_2/m^2/year

The target for CO_2 emissions is well below the published benchmark figure, and when compared with the calculated CO_2 emissions of other recent projects, the scale of savings required within the new design becomes apparent.

Peterborough Hospital (completion 2010)	151 kg CO_2/m^2/year
Kings College Hospital Jubilee Wing (2002)	121 kg CO_2/m^2/year

Brookfield



Graph showing CO_2 emissions from EnCO_2de and previous projects

When attention is turned to the other two targets set for the new hospital, both the examples given above meet the energy consumption target of 55 GJ/100m^3/year.

In addition, Peterborough Hospital, the more recent of the two, achieves an EPC asset rating of 28, comfortably below the minimum requirement of 40 for the new hospital.

As a result of this analysis, priority has been given to the reduction of carbon emissions in order to meet the target of 80 kg CO_2/m^2/year. Previous projects had satisfied the remaining targets while displaying relatively high calculated carbon emissions. As such it can be assumed that a reduction in carbon emissions would lead to a consequential improvement in the overall building energy performance.

Methods to both reduce energy consumption and improve energy efficiency within the building have been considered, as have low and zero carbon technologies. An energy performance model of the building has been created in order to assess the impact that these methods and technologies have.

In order to assist is monitoring the overall a low carbon design development and operation the Low Carbon Design Tracker has been developed. The tracker has been completed for this stage of the project and is included in Volume 8, Section 20.

Energy model

To assess the new hospital building' energy consumption and hence carbon emissions footprint the development has been modeled within a Microsoft Excel based model. The energy model also details the assumptions made within the model, and the outputs obtained. The full version of the energy model is contained in Appendix A.

The model has been developed using a number of similar projects, and incorporates real data based on past experience to estimate the building's energy consumption.

The model calculates the energy consumption from the use of both electrical systems and fossil fuels. General power, lighting and all mechanical plant are used to produce a total for the energy consumption for electrical energy. Fabric heating, air heating and hot water services are used to provide a total for the energy consumption for the fossil fuel systems.

In order to inform the overall energy model the hospital has been modeled within IES Virtual Environment, a dynamic thermal simulation program. The simulations have been used to carry out provisional predictions of heat gains within rooms and summer time temperatures within the ward towers and sample podium spaces. The simulations also support the solar shading study, and are used to obtain a provisional EPC rating.

The energy model is intended to be a live document and will be regularly updated as the detailed design progress and final information becomes available. This allows the Team to monitor the targets and make any adjustments necessary to the designs to ensure the targets are maintained. The criteria used in the model will be based on real data available from the supply chain, for example heat recovery efficiencies, and will form the basis of the final construction specifications, thus giving a link between procurement and the energy model, which will be regularly monitored throughout the construction period.

External Cladding

Energy reduction and efficiency measures

Before considering low and zero carbon technologies, measures to reduce energy consumption and improve energy efficiency within the building have been explored. By reducing the overall energy consumption of the building, the task of achieving the emissions target of 80 kg CO_2/m^2/year through the use of low and zero carbon technologies becomes less onerous.

The following technologies have been assessed and implemented within the energy model to reduce consumption and/or improve efficiency:-

External Fabric By improving the U-value of the external fabric and glazing of the building, the amount of heat lost to outside can be reduced. This in turn reduces the amount of energy required to heat the building.

The cladding proposed for the hospital building has a calculated U-value less than the minimum requirements set out in the Building Regulations, which will help to minimise the energy required to heat the building.

Natural Ventilation

Wherever possible, natural ventilation will be used within the building. This will be by means of openable windows and reduces energy consumption associated with mechanical ventilation.

The use of mechanical ventilation has been analysed and is discussed in Section 3.0 ‘Ventilation and Air Treatment Strategy’.

The studies conducted to compile the report concluded that it is likely that non-clinical areas with low occupancy and heat gains could be naturally ventilated.

Brookfield

Lighting Energy

Lighting Energy efficient lighting is proposed to reduce the overall electrical demand from the hospital. Automatic controls will ensure that the lighting is only used when required in many areas.

The proposals for automatic lighting control are described in Section 3.12 ‘Lighting Design Strategy’.

Hospital Lighting

Mechanical Ventilation

Mechanical Ventilation Heat recovery on the majority of air handling units will allow potentially wasted heat energy to be recovered from the exhaust air by transferring it to the supply air. Thermal wheels, which offer the highest efficiencies, will be used in most non-ward areas. Plate heat exchangers will be used in wards to remove any potential cross-contamination.

Thermal wheel for ventilation heat recovery

Brookfield

Cooling

Cooling High efficiency chillers, using magnetic bearings within the compressors are proposed, as described in Section 3.27 ‘Cooling Design Strategy’.

A High Efficiency Indigochiller

Pumps

Pumps Variable volume circulation systems for heating and cooling using two port control valves and variable speed pumps are proposed. When demand for heating or cooling is reduced, the fluid flow required within the system is reduced, allowing the pumps to slow down and save electrical meter energy.

Variable Volume Pump

Brookfield

Overall energy consumption

Following the inclusion of all the energy reduction and efficiency measures within the energy model, the overall energy consumption and carbon emissions from the building were calculated. The model can be found within Appendix A.

As anticipated, the drive to reduce energy consumption and improve energy efficiency within the model helped reduce the overall energy consumption comfortably below the required 55 GJ/100m^3/year.

The calculated carbon emissions rate of 123 kg CO_2/m^2/year is higher than the target of 80 kg CO_2/m^2/year. In order to reduce the emissions rate below the target, a number of low and zero carbon technologies have been considered.

Strategy to meet CO2 target

To meet the target of 80 kg CO_2/m^2/year, low and zero carbon technologies must offset 43 kg d carbon emissions rate of 123 kg CO_2/m^2/year is higher than the target of 80 kg /year.

In order to determine which technology has the best potential for meeting the emissions target, the split between emissions from electricity and fossil fuel sources has been taken from the energy model as:

Fossil fuel	37 kg CO_2/m^2/year
Electricity	86 kg CO_2/m^2/year

It can be seen that the CO_2 emissions caused as a result of electrical use within the building are 70% of the total building CO_2 emissions, with 30% from the use of fossil fuels. This shows that, in order to meet the target, electrical generation through low carbon or renewable means must be a major part of the carbon reduction strategy.

The available technologies for carbon reduction have been considered and their contribution to achieving the target analysed. These assessments are shown in Appendix B and can be summarized as follows:-

Photovoltaic Panels

Photovoltaic panels convert light energy in to electrical energy. Photovoltaic panels are an established technology and can be integrated within the building fabric. Once installed, panels are low maintenance. However, panel efficiencies are low and a large area is required to generate a reasonable quantity of power.

For example, a 200m2 array of photovoltaic panels will reduce the CO_2 emissions by only 0.11 kg CO_2/m^2/year. Whilst this is a very small contribution to the target and cannot provide a practical solution, a small area of photovoltaic panel in a prominent position will demonstrate the Board's commitment to carbon reduction.

Solar collection systems

Solar Thermal Hot Water

Solar collectors use the suns energy to heat water for use within the building. Unlike photovoltaic panels, solar thermal systems require regular maintenance. Solar thermal systems are effective during the summer months; however efficiency significantly reduces during the winter.

For the main hospital 200m^2 of collector panels would reduce the CO_2 emissions by 0.13 kg CO_2/m^2/year. Whilst this is a relatively small contribution to the main hospital's carbon reductions, there may be a more significant impact for the laboratory building, and if positioned on the roof would be visible and appreciated from the upper levels of the acute hospital.

Groundwater Cooling

Cool ground water is extracted from the water table via vertical boreholes drilled into the ground and used to cool the building. Once used, it is returned to the ground. Generally, due to the water temperature available from ground water cooling is limited to use with chilled beams rather than primary air handling plant. In the case of the new hospital there is a requirement for chilled beams, mainly in the ward areas, which could make use of ground water cooling. Although the groundwater provides 'free' cooling, energy is required to extract it from the ground, and site ground conditions need to be appropriate.

Assuming that ground water can be used for the chilled beam circuit serving the ward tower, it has been assessed that a carbon reduction of 0.76 kg CO_2/m^2/year will be achieved.

Borehole rig

Brookfield

Wind Energy

Wind turbines convert use energy from the wind velocity to produce electricity. The output from turbines depends largely on the rotor size, wind speed and wind quality. Economics of scale currently favor turbines with a capacity of 1MW or greater.

Considering a large scale 2MW wind turbine this could meet 49% of the overall CO_2 emissions reduction target. Therefore, in order to meet the target by means of wind alone, three turbines of this size would be required.

A 2MW wind turbine is relatively large, standing at approximately 80m tall. As a result of this, it is unlikely that the turbine could be practically located on or close to the hospital site, particularly as helicopters regularly land at the hospital, and it is relatively close to Glasgow Airport.

Alternative available methods of securing electricity from a larger wind turbine include locating the turbine off site, or investing in an existing or proposed wind farm.

A wind turbine located off site would be owned by the hospital and the electricity generated would be fed in to the national grid. By feeding electricity generated by a renewable source in to the grid, the hospital can claim this electricity to offset CO_2 emissions from the building.

However, whilst it would not be practical to install a large wind turbine on site, smaller vertical axis wind turbines could be installed on the hospital's energy centre. Despite making a very small contribution to the target reduction in CO_2 emissions (0.03 kg CO_2/ m^2/year each), their presence would act as a visible statement of the Board's low carbon commitment.

The installation of twelve small vertical axis wind turbines would meet the Board's requirement to generate 0.5% of the building's CO_2 emissions by means of a visible renewable energy source.

A Vertical Axis Wind Turbine

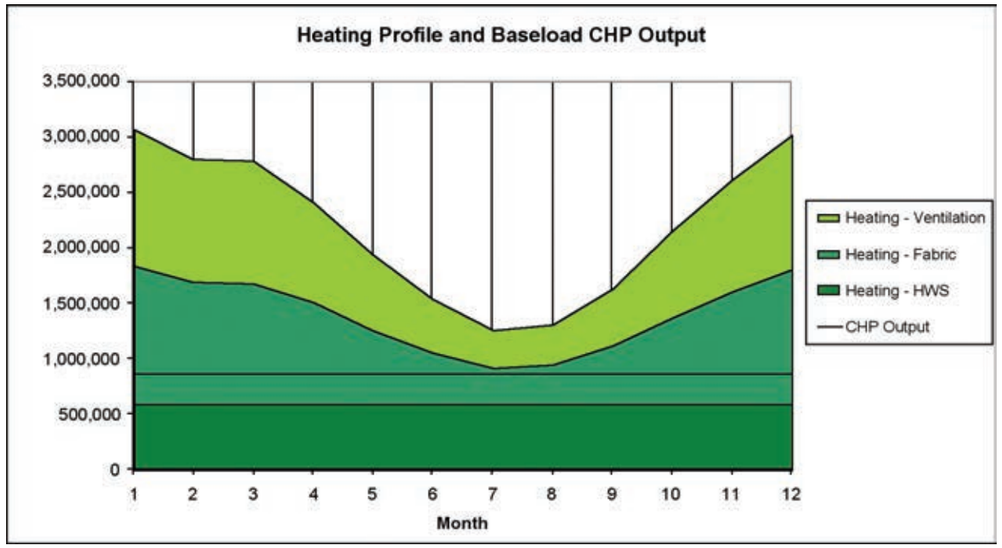
An 80m Turbine

Combined Heat and Power

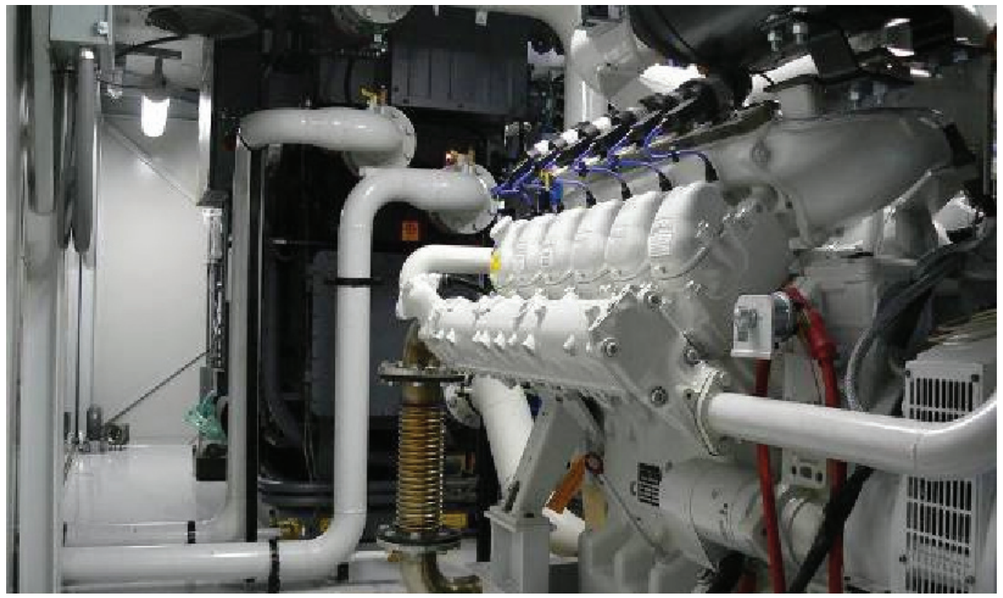
Combined heat and power (CHP) units generate both electricity and heat. An engine drives an electric alternator and the engine's exhaust and jacket heat are used to produce hot water. This technology provides a more efficient method of generating electricity compared to grid electricity and thus reduces overall CO_2 emissions.

CHP units are well suited to hospital buildings due to the relatively large and constant demand for heat, allowing the units to operate at peak efficiency. The engines are generally fired with natural gas, although diesel and biofuel units are available.

CHP units are generally sized to meet the base heat load of the building, as shown in the graph below. The graph shows the building's projected annual heating load and the heat output from the CHP unit. For example, a 1.25MWe unit that is sized on this philosophy, as displayed in the graph below, would achieve 49% of the target reduction.



Graph showing the heating profile and the output from a CHP matched to the base load



CHP Unit

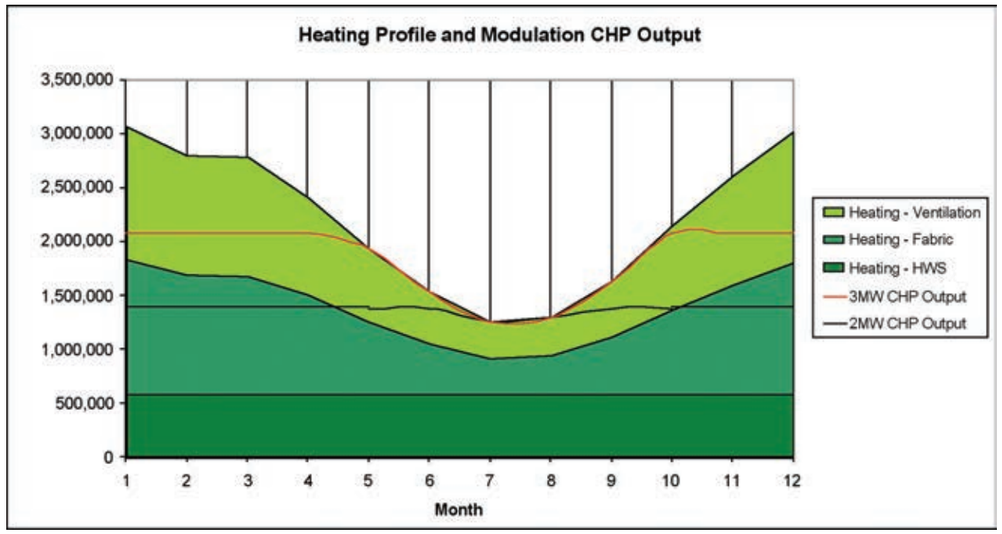
Brookfield

As a result of the limited CO_2 savings, methods of increasing the CHP capacity within the building have been investigated to determine the maximum potential CO_2 savings achievable from this technology

It can be seen from the previous graph that, as expected, the building's heat load throughout the year is not constant, and reduces in the summer months. As the number of CHP units increase, the likelihood of generating an excess quantity of heat during these months increases. Simply dumping the excess heat during these months whilst generating electricity is not an economic solution. Therefore, in order to avoid this scenario, the units could modulate to match the heat load, or chiller units that utilise heat to produce chilled water could be installed. These chillers are known as absorption chillers and operate in this manner.

By modulating multiple CHP units, as shown in this graph, up to 100% of the total target savings could be met. The units turn down when the building's heat load reduces during the warmer months.

By adding absorption chilling, 100% of the target could be met. The heat required by the absorption chiller fills the gap left by the reduction in heating demand from the hospital. The absorption chiller operates during the summer months as the demand for cooling also increases at this time. This allows the CHP units to run constantly at peak efficiency throughout the year, avoiding drops in efficiency associated with modulating.



Graph showing the heating profile and the output from two sets of CHP units modulating to match the load

All results for CHP units thus far have been based on a natural gas fired engine.

In order to increase CO_2 savings generated by a CHP unit an alternative low carbon yielding fuel could be considered, usually referred to as a biofuel.

Alternatively, the output of electricity generated by the CHP units can be increased. By increasing the electrical output of the units, the CO_2 savings are increased considerably, as the CO_2 savings made through the generation of electricity are much greater than the savings made through the generation of hot water.

Alternative Fuels

A feasibility study has been conducted on the potential for the use of biodiesel fired CHP units. A bi-fuel CHP unit, fueled by a combination of biodiesel and natural gas, has been considered for this study, as this combination of fuels gives the lowest input CO_2 emission rating when compared with other fuels, for example a diesel and biodiesel blend.

Biofuels sourced from sustainable or waste materials, have a lower CO_2 emission rating than natural gas. CHP engines can be modified to operate on both biogas and biodiesel. However, the use of biodiesel requires storage and transportation to site from the producer.

Using biodiesel fired units can achieve 100% of the target when used to track the building's heat load. Further savings are achieved when using this type of unit with an absorption chiller.

On a practical side there are problems associated with the security of the fuel, its storage and distribution, as well as its delivery. Biodiesel is also generally more expensive than other available fossil fuels. For this reason a biodiesel option has been discounted.

The use of biogas as a fuel has also been considered. Modifications to the sewage works adjacent to the hospital site, currently being explored between the Board and Scottish Water, would allow the production of biogas, which could be used to fuel CHP units within the hospital. Further investigation of the use of biogas will be carried out during stage 2 design phase.

Increasing electrical output

Increasing the electrical output from the gas fired CHP units can result in greater CO_2 savings being achieved.

CHP units, when supplied, are tuned to meet the application required by the purchaser. By altering the outputs from the units, additional electrical output is achievable; however there are limits to the maximum electrical output from a CHP unit.

The ability to adjust the output ration will very much depend on the manufacturer of the unit and the precise electrical load on the CHP unit. Therefore, this could only be confirmed once a detailed analysis is carried at a later stage in the design.

Additional electrical output can also be generated by an ORC turbine generator in tandem with the CHP unit alternator. An ORC (Organic Rankine Cycle) turbine generator is driven by waste heat and uses a refrigerant driving fluid in the system.

The generator uses heat to vaporise the refrigerant, which drives a turbine to generate electricity. The process is similar to that used in power stations, where steam drives a turbine to generate electricity. An ORC turbine generator would use the surplus heat in the CHP exhaust to generate additional electricity.

However, there are technical complications and major maintenance issues associated with an ORC system and uncertainty of the ability to modify the CHP output ratio.

As such, the use of an ORC generator is not considered viable for the project.

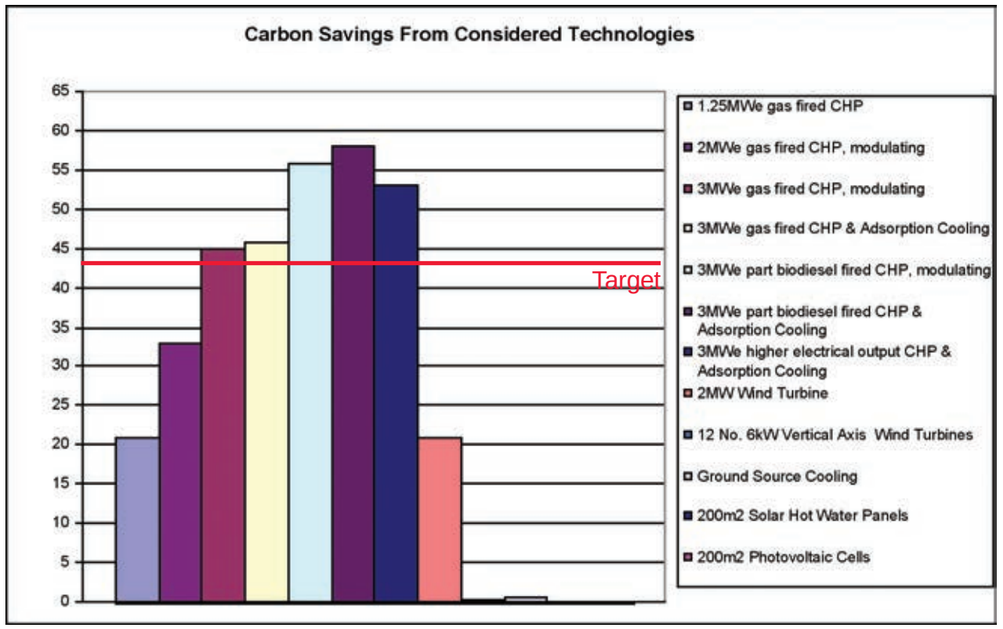
Whilst increasing the electrical output from the CHP units by 6% has the potential to achieve 100% of the CO_2 reduction target, further investigation in to potential modifications to the CHP output ratio is required, and will be carried out during stage 2 design phase.

As a result, modifications to the CHP output ratio to increase electrical output has not been considered as a potential solution to meeting the CO_2 reduction target at this stage.

Brookfield

Preferred solution

The technologies considered displayed graphically below, showing their contribution to meeting the 43 kg CO_2/m^2/year target savings.



Graph showing technologies considered and their respective carbon savings

The above graph shows that a number of the options explored achieve the target emissions rate of 80 kg CO_2/m^2/year, a World benchmark for a major hospital project.

The preferred solution to meet the CO_2 emission targets is a combination of on site wind power, CHP units and absorption cooling. As discussed earlier in the report, the use of biofuels and the increase of the CHP electrical output have not been considered at this stage and will be investigated further during design stage 2.

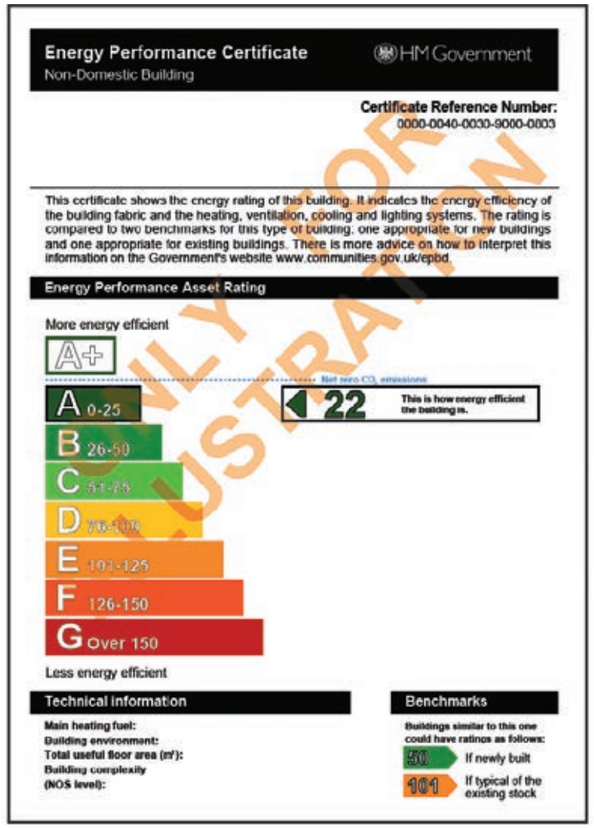
The combination of CHP units and absorption cooling will achieve the target emissions rate of 80 kg CO_2/m^2/year. By combining CHP units with absorption chillers, the CHP units would be able to operate at maximum efficiency throughout the year.

The use of CHP units and absorption cooling also allows all aspects of the building's energy strategy to be located within the energy centre.

The requirement to generate 0.5% of the building's design energy target by means of a visible renewable energy source will be achieved by twelve small vertical axis wind turbines, installed on the roof of both the energy centre and laboratory building.

EPC Rating

Following the energy saving measures and carbon reduction strategy, the IES thermal simulation software produced a provisional EPC asset rating of 22, which is comfortably within the target of 40.



The provisional Energy Performance Certificate for the New South Glasgow Hospital

Brookfield

Public Engagement

It is important that, in a building where the reduction in carbon emissions is integral to its overall design, it is possible that this can be displayed to those who will be using the building.

The CHP units will be located within the energy centre, and therefore out of sight of the building users. If they were to be prominently located elsewhere, it is unlikely that the units would be identifiable by the general public and building users.

Therefore, a method of displaying information on the quantity of carbon savings achieved by the various technologies within the building should be explored.

This could take the form of a ‘carbon counter’ display within the main entrance to the building, detailing the savings being achieved by the installed technologies.

By displaying this information, the Board can show its commitment to a low carbon future and ensure that those who use the building are aware of it.

APPENDIX A
ENERGY CONSUMPTION MODEL

ASSUMPTIONS MADE IN PREPARING THE MODEL

The Energy Consumption Model has been produced assuming the following statements.

Design Conditions
1. External conditions are set to: Winter: -6oC
Summer: 26.2oC db, 18.5oC wb
2. Internal conditions are set to: Heating: 21oC
Cooling: 18oC db, 16oC wb
General
1. Plant will be maintained to optimum operating efficiency.
2. Any change to the building shape or size will affect the energy consumption total.
Electrical Systems Energy Usage - General Power
1. Intermittently occupied departments to have their power consuming equipment switched off out of hours.
Electrical Systems Energy Usage – Lighting
1. Intermittently departments to have their lights switched off out of hours.
2. Automatic presence detectors with adjustable time delay timers for switch OFF are provided within storerooms, linen cupboards, toilets, changing rooms and offices.
4. Energy efficient lighting has been used throughout.
Electrical Systems Energy Usage - Ventilation
1. Diffusers will be maintained in a clean order and will not be blocked, which may increase the pressure thereby increasing the ventilation electrical consumption.
2. The BMS will control the operation of the AHUs as outlined in the usage profiles and set-back rates where applicable.
Electrical Systems Energy Usage - Humidification
1. Any deviation in weather conditions from average yearly conditions have not been accounted for.
Electrical Systems Energy Usage – Pneumatic Tube
1. The Pneumatic Tube System will remain blockage free to prevent the blowers being overused.

Brookfield

Electrical Systems Energy Usage - Chillers
1. The BMS will control the operation of the chillers and pumps as per the indicated usage profile.
2. Any deviation in weather conditions from the average yearly conditions such as higher than average temperatures have not been accounted for.
Electrical Systems Energy Usage - Lifts
1. The lifts will not be overloaded.
2. 50 No. lifts have been allowed for in the model.
Fossil Fuel Energy Usage - Fabric Heating
1. Doors and windows will remain closed and the fabric of the building will be sufficiently maintained.
2. The operational times of the building and type of plant will not change.
Fossil Fuel Energy Usage - Air Heating
1. Only the AHUs indicated will provide air heating at the levels shown.
2. There will not be any additional diffuser/grilles installed or existing ones adjusted or blocked.
3. Windows will be maintained to prevent excessive air infiltration.
Fossil Fuel Energy Usage - Hot Water Services
1. Improper use of the hot water system will affect the final consumption figure.
2. The domestic hot water consumption used is 135litres/bed/day, plus an additional 30% allowance for non-bedded areas.

Brookfield

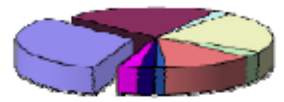
Brookfield

A) ELECTRICAL SYSTEMS ENERGY USAGE

GENERAL POWER ELECTRICAL CONSUMPTION

The total consumption associated with general power usage has been calculated by applying a load assessment figure to each departmental area. Usage factors are then applied for two time periods in a day, the first 10 hours (day) then the remaining 14 hours (night). This produced a daily maximum load value that was then converted to a weekly value. The weekly load values for each department were then summed to obtain an annual total for the general power usage.



Intermittent deptartments are highlighted in yellow and based on a 5 day working week[1]

Brookfield

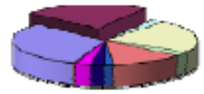
LIGHTING ELECTRICAL CONSUMPTION

The total consumption associated with lighting usage has been calculated by applying a load assessment figure to each departmental area. Usage factors are then applied for two time periods in a day, the first 10 hours (day) then the remaining 14 hours (night). This produced a daily maximum load value that was then converted to a weekly value. The weekly load values for each department were then summed to obtain an annual total for the lighting usage.



Intermittent deptartments are highlighted in yellow and based on a 5 day working week[1]

TOTAL ELECTRICAL CONSUMPTION FOR LIGHTING (kWh/Week) 113849

ANNUAL TOTAL (kWh/Year) 5920160

Notes

[1] *Intermittent departments are highlighted in yellow.*

Brookfield

MECHANICAL PLANT ELECTRICAL CONSUMPTION

SUPPLY VENTILATION

The total electrical consumption per week for each air handling unit was calculated by converting the supply air volume into an estimated power value. The hourly electrical usage was then applied to a weekly usage profile for each unit and the total weekly electrical consumption for each unit were summed to produce a yearly electrical consumption value for the supply ventilation.

TOTAL ELECTRICAL CONSUMPTION FOR SUPPLY VENTILATION (kWh/Week)	84968
ANNUAL TOTAL (kWh/Year)	4418314

Notes

[1] *Rule of thumb calculation from BSRIA Rules of Thumb (4th ed.). Fan electrical input (kW) = 1.57 x total fan pressure (kPa) x volume flow rate (m^3/s). Assuming the total fan pressure = 1400 Pa and 1.57 = (1/(fan eff.* motor eff.)) where the fan efficiency = 75% and the motor/drive efficiency = 85%.*

Brookfield

MECHANICAL PLANT ELECTRICAL CONSUMPTION

EXTRACT VENTILATION

The total electrical consumption per week for each air handling unit was calculated by converting the extract air volumes into an estimated power value. The hourly electrical usage was then applied to a weekly usage profile for each unit and the total weekly electrical consumption for each unit were summed to produce a yearly electrical consumption value for the extract ventilation.

YEARLY TOTAL (kWh/Year)	78468

[1] *The usage factor is determined from the Hourly Carrier Traffic flows of the Pneumatic Tube System from past projects*

[2] *The diversity figure allows for when the start up current of the pneumatic tube system fans will produce a higher power consumption than normal due to the on/off operation of the blowers when there is continual movement of the capsules in the system.*

Brookfield

MECHANICAL COOLING ELECTRICAL CONSUMPTION

The electrical consumption associated with the mechanical cooling equipment has been obtained by using a cooling load profile against the total cooling capacity per month which produced a monthly mechanical cooling load. This was then converted into an electrical cooling consumption (kWh) using an SEER of 4.5. The monthly totals were summed to produce an annual electrical consumption for the chillers. The electrical consumption for the primary and secondary pumps was calculated by making a monthly assessment of the usage of the pumps and applying this to the cooling profile which produced a monthly electrical energy consumption. The monthly totals were summed to obtain the annual electrical energy consumption.

Notes

[1] *Day-time operational hours are between 8am and 6pm, 7 days a week.*

[2] *Night-time hours are between 6pm and 8am, 7 days a week.*

[3] *This is the Annual Cooling Load Profile expressed as a percentage of the Total Cooling Load. Where the Annual Cooling Profile has been applied to the Secondary Cooling Pumps, a factor of 15% has been used as a minimum operating percentage.*

[4] *There are 6 No. Primary Pumps which have an electrical load of 7.5 kW per pump.*

[5] *The total electrical load for all the Secondary Pumps = 120 kW.*

Brookfield

LIFTS ELECTRICAL CONSUMPTION

The lift electrical consumption has been calculated by determining how often the lift is used, and how much power is required to operate the lift during these periods. Information regarding motor ratings, loading factors and lift traffic data from past projects was used. The cycle time and motor rating were used with day-time (8 am to 6 pm) and night-time (6 pm to 8 am) usage factors (to represent the utilisation of each lift) to produce an electrical consumption for each lift. The totals from each lift were then summed to obtain an annual total for all lifts.

LIFT No.	FULL LOAD MOTOR RATING (kW)	ADJUSTED MOTOR RATING (kW)[1]	No. STARTS PER HOUR	TIME IN MOTION PER CYCLE[2]	DAY-TIME U.F[3]	NIGHT TIME U.F[3]	CONSUMPTION (kWh)

DAILY TOTAL (kWh)	859
INCREASE BY 100% - P'BORO TO GLASGOW	1718
ANNUAL TOTAL (kWh/Year	627064

Notes

[1] *This figure assumes that the lift will rarely work to full capacity.*

[2] *The operating cycle of the lift will include stationary time when the doors open and close. The time in motion will vary depending on the speed of the lift.*

[3] *Different usage factors have been assumed for the day-time period (8am to 6pm) and night-time period (6pm to 8am) which allows for the daily usage patterns, lifts travelling more than one floor at a time, lifts to be loaded and un-loaded and for lifts not being used. The goods lifts have a lower usage factor as it is assumed that they will not be used as much as the passenger lifts and will likely take longer to load and un-load due to the items being transported.*

B) MECHANICAL FOSSIL FUELS ENERGY USAGE

FABRIC HEATING

The energy consumption of the boilers to compensate for the losses through the fabric of the building has been calculated over two heating time periods, 24hr and 12hr, which assumes that various areas within the building will only be used for 10hours per day and other areas will be used for 24hours per day. The 12hr heating areas will have different losses during the day and at night. To obtain the total thermal energy for fabric heating per year a fabric heating load assessment figure was applied across the volume of the building associated with its time period which produced the fabric heat loss (kW).
The degree-day method was then used along with correction factors to calculate the yearly thermal energy for fabric heating for both time periods, which were then summed to obtain a combined figure. Factors for the seasonal efficiency of the boiler and the distribution losses were then incorporated into the final energy consumption figure.

	TREATED AREA (m^2)	FABRIC HEATING LOAD ASSESSMENT (W/m^2)	FABRIC HEAT LOSS (kW)
24hr/Htg	113887.70	17.00	1936.09

[5] *Factor for boiler seasonal efficiency = 86%. Distribution losses in the system = additional 10%.*

Brookfield

AIR HEATING

The air ventilation heat load for all the air handling units was calculated using the supply air volume, the temperature difference, the heat reclaim factor (derived from % of supply air lost to space, % of supply air passed through heat recovery and lost to space and % of supply air passed through heat recovery returned to plant) and a conversion factor to convert into GJ. The degree-day method was then used along with correction factors for the operating hours to calculate the yearly thermal energy for air heating. Factors for the seasonal efficiency of the boiler and the distribution losses were then incorporated into the final energy consumption figure.

TOTAL THERMAL ENERGY FOR AIR HEATING (GJ/Year)	28748
TOTAL ENERGY CONSUMPTION FOR AIR HEATING (kWh/Year)	7985571
TOTAL INCLUDING BOILER SEASONAL AND DISTRIBUTION LOSSES (kWh/Year)[7]	9749825

Notes

[1] *Taken from CIBSE Guide A Glasgow region for base temperature of 18.5 °C.*

[2] *The Heat Reclaim Factor is the amount of heating required for ventilation air following recovery of heat from exhaust system. These factors have been derived from a 70% efficiency of a thermal wheel and 55% efficiency of a plate heat exchanger*

[3] *Temperature Ratio taken from CIBSE Guide B-Table 18.9 (from base temp of 15.5 °C).*

[4] *Weekly Factor taken from CIBSE Guide B-Table 18.11, assuming a heavyweight building.*

[5] *Response Factor taken from CIBSE Guide B-Table 18.12, assuming a heavyweight building.*

[6] *Daily Factor taken from CIBSE Guide B-Table 18.13, assuming a heavyweight building. This factor is not applicable to continuously occupied spaces (24 hour).*

[7] *Factor for boiler seasonal efficiency = 86%. Distribution losses in the system = additional 5%.*

Brookfield

HOT WATER SERVICES

The total yearly hot water services heat load was derived from obtaining the total hot water consumption per year. This figure was achieved by applying a consumption figure for each bed then multiplying this figure by the total number of beds within the hospital. A conversion factor was applied to the yearly consumption figure to convert this into kWh per year. Factors for the seasonal efficiency of the boiler and the distribution losses was then incorporated into the final energy consumption figure.

HWS HEAT LOAD

CONSUMPTION (LITRES/BED/DAY)[1]	NO. OF BEDS	ANNUAL CONSUMPTION (LITRES)	TOTAL (kJ/YEAR)[2]	TOTAL ENERGY CONSUMPTION (kWh/YEAR)
135	1435	70709625	14778311.63	4105087

TOTAL INCLUDING +30% FOR NON-BEDDED AREAS (kWh/Year)	5336613
TOTAL INCLUDING BOILER SEASONAL EFFICIENCY AND DISTRIBUTION LOSSES (kWh/Year)[3]	6988421

Notes

[1] *Based on CIBSE Guide G*

[2] *The total energy per year required raise the water temperature from 10°C and distribute at 60°C.*

[3] *Factor for boiler seasonal efficiency = 84%. Distribution losses in the system = additional 10%.*

APPENDIX E - STEAM DATA

HUMDIFICATION

Using the dry-bulb and wet bulb data for the average temperature (°C) over 24 hours taken from Table 3.11 of CIBSE Guide J, the Moisture Content of Dry Air (kJ/kg3) was extracted from the CIBSE Psychrometric Chart (10 to +60oC), figure 1.2 in CIBSE Guide C. Using the yearly profile for the Moisture Content, the days which were below 0.008339 kg/kg3 (the moisture content for 45% relative humidity at 21oC) are the days which require the addition of moisture. The total steam required to maintain the humidity level was calculated by multiplying the difference in moisture content with time that the moisture content is below that of 45% relative humidity at 21oC. Using the total steam required to maintain the humidity level, the humidification load was calculated by determining the steam usage for each air handling unit associated with the steam system. The total yearly thermal energy was then determined by multiplying the steam usage by the sum of the enthalpy of steam and the enthalpy of saturated steam.

Building Carbon Target

Gross Building Floor Area	136,490	m^2
Total Emissions	16,834,959	Kg CO_2 per year
Gives	123	Kg CO_2 per m^2 per year
With CHP, emissions drop to	9,568,563	Kg CO_2 per year
Which Gives	70	Kg CO_2 per m^2 per year

Brookfield

Wind, Solar Thermal, Photovoltaics and Ground Source Cooling

Wind Energy

Windprospect.com - wind turbine installers		
Quoted annual output from 2MW turbine	5,000,000	kWh per year
This is equivalent to	2,840,000	Kg CO_2 per year
	21	Kg CO_2 per m^2 per year
Quietrevolution qr5 - quoted output	4,000 - 10,000	kWh per year
For this calculations, say	8,000	kWh per year
Number of turbines	12	
Carbon Saved	54,528	Kg CO_2 per year
	0.40	Kg CO_2 per m^2 per year

Solar Hot Water

Calculated from Viessmann quotation	465	Annual heat output (kWh) per m^2 of panel
Assume	200	m^2 of panels (1 panel is approx 4.3m^2)
Gives	93,000	kWh hot water generated per year
	18,042	Kg CO_2 per year
	0.13	Kg CO_2 per m^2 per year

Brookfield

Groundwater Cooling

Total Cooling Capacity	5500	kW
Chilled Beam Capacity	550	kW
Percentage of total taken from groundwater	10%	
Energy Saved	247,317	kWh per year
Carbon Saved	104,368	Kg CO_2 per year
	0.76	Kg CO_2 per m^2 per year

PV Cells

Area	6	m^2 required per kWp
Generation	810	kWh per 1kWp of pv installed
Size of PV Array	200	m^2
Raing of Array	33	kW
Power Generated	27,000	kWh per year
Carbon Saved	15,336	Kg CO_2 per year
	0.11	Kg CO_2 per m^2 per year

Brookfield

BREEAM Scoring Schedule

BREEAM Excellent – Scoring Summary

Achieving BREEAM Excellent has meant evaluating design proposals with the design team in order to ensure that the maximum possible number of credits is scored in the different BREEAM categories. The integration of the BREEAM assessment early on in the design process resulted in a BREEAM responsibility matrix being circulated at a point where the different members of the design team could ensure that the BREEAM action and supporting evidence can be easily accommodated into their work. Individual meetings with all BREEAM responsibility holders were held so that the detail of the credits could be discussed and that the requirements for the evidence are known, to avoid extra work at a later date. This approach means that the pre-assessment presented here is as an accurate reflection of the final BREEAM score, as deemed possible at this stage in the design. Details of how the credits will be scored are given within the pre-assessment, with the following table showing the overall summary:

BREEAM Section	Score
Management	12%
Health and Wellbeing	11.67%
Energy	13.15%
Transport	6.29%
Water	2.67%
Materials	5.83%
Waste	4.69%
Land Use and Ecology	7%
Pollution	6.15%
Innovation	2%
Final Score	71.45%

The BREEAM Assessor (appointed from WSP) will start to collate evidence as soon as possible, whilst providing ongoing advice and support to the design and construction team in order to ensure that the predicted Excellent rating becomes reality.

To achieve an Excellent rating in BREEAM Healthcare, there are a number of mandatory credits as well as additional credits for the low carbon design requirements, identified by the Greater Glasgow and Clyde NHS Board. These are shown in the following tables, with commentary on how they are achieved.

Mandatory BREEAM Healthcare Credits for Excellent

BREEAM Ref.	Credit Name	Commentary	Scored?
Man1	Commissioning	Brookfield have appointed a commissioning manager for the entire development, whose responsibility will include fulfilling this credit.	✓
Man2	Considerate Contractors	Brookfield and Dunne have a strong track record with the Considerate Contractors scheme and are confident of achieving this.	✓
Man4	Building User Guide	A building user guide will be developed by Brookfield in conjunction with ZBP, Mercury and the rest of the design team.	✓
Hea4	High Frequency Lighting	ZBP are specifying this as standard throughout the building.	✓
Hea12	Microbial Contamination	This is now a standard requirement due to Health and Safety requirements for ZBP in healthcare design.	✓
Ene1	Reduction of CO_2 emissions	The predicted EPC rating is 22, which will result in 11 points being scored under this credit.	✓
Ene2	Sub-metering	ZBP have included sub-metering for all relevant areas of the building, linked directly to the BMS.	✓
Ene5	LZC technologies	The energy strategy includes a natural gas CHP supplemented by wind power, allowing maximum points to be scored.	✓
Wat1	Water Consumption	Water efficient fittings have been specified throughout in accordance with the Board's stipulations.	✓
Wat2	Water meter	A mains water meter will be fitted as well as sub-water metering, linked to the BMS	✓
Wst3	Recyclable Waste Storage	This requirement has been designed into the main hospital building with complimentary space in the facilities management area.	✓
Le4	Mitigating Ecological Impact	Gillespies has used the Ecologist's feedback to inform their landscaping strategy and will continue to work with them to maximise the ecological potential of the site.	✓

Brookfield

Additional Low Carbon Design Credits, as specified in Vol. 2/1, App. M&E.4: Sustainable Design Considerations.

BREEAM Ref.	Credit Name	Commentary	Scored?
Man12	Whole Life Cycle Costing	Doig and Smith are completing this as part of the Life Cycle Costing required within the bid submission.	✓
Hea1	Daylighting	Daylight levels have been maximised in all areas of the hospital, allowing good levels within the wards in particular. Due to the necessary design of the podium and the tower, this credit has not been able to be scored however.	
Hea7	Potential for Natural Ventilation	Operable windows have been provided for all patient areas however this has not been due to the necessary design of the podium and the tower.	
Hea10	Thermal Comfort	The thermal comfort assessment has been conducted using thermal building modelling to understand how the buildings'' internal temperatures will change through the course of a year.	✓
Ene3	Sub-metering of further areas	ZBP have included sub-metering for all relevant areas of the building, linked directly to the BMS.	✓
Ene4	External lighting	ZBP and Gillespies have worked together to ensure that energy efficient lamps are specified and also fit with the landscaping strategy.	✓
Ene8	Lifts	Schindler are well acquainted with the BREEAM requirements and are providing energy efficient lifts as required by BREEAM.	✓
Ene15	Energy Efficient Equipment	This credit has not been scored on the basis of feedback from the NHS Board.

BREEAM Healthcare 2008 Pre-Assessment Estimator

Indicative Overall BREEAM Score
71.45%

BREEAM Rating Benchmarks	
PASS	≥30
GOOD	≥45
VERY GOOD	≥55
EXCELLENT	≥70
OUTSTANDING*	≥85

Ref	BREEAM Issue Title	BREEAM Healthcare - Issue Criteria	Number of BREEAM credits available	Total predicted BREEAM credits achieved	Minimum BREEAM Standards: Pass	Good	Very Good	Excellent	Outstanding	Notes
					YES	YES	YES	YES	NO	
					Minimum required credits by BREEAM issue and rating					
Management										
Man 1	Commissioning	One credit where evidence provided demonstrates that an appropriate project team member has been appointed to monitor commissioning on behalf of the client to ensure commissioning will be carried out in line with current best practice. Two credits where, in addition to the above, evidence provided demonstrates that seasonal commissioning will be carried out during the first year of occupation, post construction (or post fit out).	2	2	1	1	1	1	2	Brookfield Commissioning Manager is lead, supported by Mercury, ZBP, Schindler, Swiss Log etc as appropriate
Man 2	Considerate Constructors	One credit where evidence provided demonstrates that there is a commitment to comply with best practice site management principles. Two credits where evidence provided demonstrates that there is a commitment to go beyond best practice site management principles.	2	2	-	-	-	1	2	Joint responsibilty between Dunne and Brookfield.
Man 3	Construction Site Impacts	One credit where evidence provided demonstrates that 2 or more of items a-g (listed below) are achieved. Two credits where evidence provided demonstrates that 4 or more of items a-g (listed below) are achieved. Three credits where evidence provided demonstrates that 6 or more of items a-g are achieved: a. Monitor, report and set targets for CO2 or energy arising from site activities b. Monitor, report and set targets for CO2 or energy arising from transport to and from site c. Monitor, report and set targets for water consumption arising from site activities d. Implement best practice policies in respect of air (dust) pollution arising from the site e. Implement best practice policies in respect of water (ground and surface) pollution occurring on the site f. Main contractor has an environmental materials policy, used for sourcing of construction materials to be utilised on site g. Main contractor operates an Environmental Management System. One additional credit where evidence provided demonstrates that at least 80% of site timber is responsibly sourced and 100% is legally sourced.	4	4	-	-	-	-	-	To be formulated by Brookfield.
Man 4	Building user guide	One credit where evidence provided demonstrates the provision of a simple guide that covers information relevant to the tenant/occupants and non-technical building manager on the operation and environmental performance of the building.	1	1	-	-	-	1	1	With input from Mercury, Schindler, Swiss log, BSL - FM
Man 6	Consultation	One credit where evidence provided demonstrates that consultation has been, or is being, undertaken and feedback given to the local community and building users. In addition, advice should also have been sought from any relevant national and local history, archaeological bodies or military history groups regarding the heritage value of the building/site/surroundings. Two credits where, in addition to the above, evidence provided demonstrates that changes to the design and/or action has been taken as a result of the above consultation process. This should include the protection of any parts of the building (or site) having historic or heritage value in accordance with independent advice from the relevant body.	2	2	-	-	-	-	-	Consultation has been undertaken by the Board already, with relevant details fed back to the Brookfield design team
Man 8	Security	One credit where evidence provided demonstrates that an Architectural Liaison Officer (ALO) or Crime Prevention Design Advisor (CPDA) from the local police force has been consulted at the design stage and their recommendations incorporated into the design of the building and its parking facilities (if relevant).	1	1	-	-	-	-	-	Nightingale Associates has undertaken this credit

Brookfield

Man 11	Ease of Maintenance	One credit where evidence provided demonstrates that specifications for the building and the building services/systems and landscaping have considered ease and efficiency of maintenance in line with best practice.	1	1	-	-	-	-	-	ZBP's responsibilty with input from Mercury and Nightingale Associates.
Man 12	Life Cycle Costing	One credit where evidence provided demonstrates that a Life Cycle Cost (LCC) analysis based on the feasibility study proposals has been undertaken on the building design at a strategic and system level. Two credits where, in addition to the above, evidence provided demonstrates that the results of the feasibility study and consideration of LCC have been implemented.	2	2	-	-	-	-	-	Mandatory in NHS Board Employers Requirements and to be undertaken by Doig and Smith.

Brookfield

Man 13	Good Corporate Citizen	One credit where evidence provided demonstrates that the Good Corporate Citizen model has been used to assess the development and that there is a commitment to continue to use the model to re-assess the development regularly.	1	1	-	-	-	-	-	Managed by Brookfield, however commitment from the NHS Board also required.
		Indicative Management (weighted) Section Score	**12.00%**							
Health & Wellbeing										
Hea 1	Daylighting	Two credits where at least 80% by floor area of occupied staff and public spaces have an average daylight factor of 2% or more. And at least 80% by floor area of occupied patient spaces (dayrooms, wards) and consulting rooms have an average daylight factor of 3% or more.	2	0	-	-	-	-	-	Mandatory in NHS Board Employers Requirements. ZBP to conduct daylighting assessment to assess compliance.
Hea 2	View Out	One credit where evidence provided demonstrates that all workstations/benches and desks and at least 80% by floor area of public areas have an adequate view out. One credit where evidence provided demonstrates that all patient-occupied spaces have an adequate view out.	2	2	-	-	-	-	-	Nightingale Associates - as illustrated in hospital drawings
Hea 3	Glare Control	One credit where evidence provided demonstrates that an occupant-controlled shading system (e.g. internal or external blinds) is fitted in relevant building areas.	1	1	-	-	-	-	-	Nightingale Associates - part of ward designs
Hea 4	High frequency lighting	One credit where evidence provided demonstrates that high frequency ballasts are installed on all fluorescent and compact fluorescent lamps.	1	1	1	1	1	1	1	ZBP
Hea 5	Internal and external lighting levels	One credit where evidence provided demonstrates that all internal and external lighting, where relevant, is specified in accordance with the appropriate maintained illuminance levels (in lux) recommended by CIBSE.	1	1	-	-	-	-	-	ZBP
Hea 6	Lighting zones & controls	One credit where evidence provided demonstrates that, in all relevant building areas, lighting is appropriately zoned and occupant controllable.	1	1	-	-	-	-	-	ZBP
Hea 7	Potential for natural ventilation	One credit where evidence provided demonstrates that fresh air is capable of being delivered to the occupied spaces of the building via a natural ventilation strategy, and there is sufficient user-control of the supply of fresh air.	1	0	-	-	-	-	-	
Hea 8	Indoor air quality	One credit where air intakes serving occupied areas avoid major sources of external pollution and recirculation of exhaust air.	1	1	-	-	-	-	-	ZBP - as demonstrated in the building services drawings
Hea 9	Volatile Organic Compounds	One credit where evidence provided demonstrates that the emissions of VOCs and other substances from key internal finishes and fittings comply with best practice levels.	1	1	-	-	-	-	-	Nightingale Associates
Hea 10	Thermal comfort	One credit where evidence provided demonstrates that thermal comfort levels in occupied spaces of the building are assessed at the design stage to evaluate appropriate servicing options, ensuring appropriate thermal comfort levels are achieved.	1	1	-	-	-	-	-	Mandatory in NHS Board Employers Requirements - ZBP

Brookfield

Hea 11	Thermal zoning	One credit where evidence provided demonstrates that local occupant control is available for temperature adjustment in each occupied space to reflect differing user demands.	1	0	-	-	-	-	-	
Hea 12	Microbial contamination	One credit where evidence provided demonstrates that the risk of waterborne and airborne legionella contamination has been minimised.	1	1	1	1	1	1	1	ZBP
Hea 13	Acoustic Performance	One credit where evidence provided demonstrates that indoor ambient noise levels and airborne and impact sound insulation levels achieve the recommended performance benchmarks outlined HTM 08-01 Part A. One credit where evidence provided demonstrates that reverberation times are compliant with the recommended performance benchmarks outlined HTM 08-01 Part A.	2	2	-	-	-	-	-	Acoustic Logic
Hea 15	Outdoor Space	One credit where evidence provided demonstrates the provision of an adequate outdoor amenity space accessible for use by the building's occupants.	1	1	-	-	-	-	-	Gillespies to provide evidence
Hea 19	Arts in health	One credit where evidence provided demonstrates that an art co-ordinator has been appointed or an art strategy and policy have been prepared for the development.	1	1	-	-	-	-	-	Gillespies and Nightingale Associates producing Arts Strategy
		Indicative Health & Wellbeing (weighted) Section Score	**11.67%**							

Brookfield

Energy

Ene 1	Reduction of CO2 Emissions	Up to fifteen credits where evidence provided demonstrates an improvement in the energy efficiency of the building's fabric and services and therefore achieves lower building operational related CO2 emissions (refer to the BREEAM manual for benchmarks)	**15**	**8**	-	-	-	6	10	**Predicted EPC ratings indicate at least 31 points is possible.**
Ene 2	Sub-metering of Substantial Energy Uses	One credit where evidence provided demonstrates the provision of direct sub-metering of energy uses within the building. Two credits where, in addition to the above, evidence provided demonstrates that sub meters are connected to a BMS or other type of automated control device.	**2**	**2**	-	-	1	1	1	**ZBP have designed a full metering strategy**
Ene 3	Sub-metering of high energy load Areas and Tenancy	One credit where evidence provided demonstrates sub-metering of energy consumption by tenancy/building function area is installed within the building.	**1**	**1**	-	-	-	-	-	**ZBP have designed a full metering strategy**
Ene 4	External Lighting	One credit where energy-efficient external lighting is specified and all light fittings are controlled for the presence of daylight.	**1**	**1**	-	-	-	-	-	**ZBP**
Ene 5	Low zero carbon technologies	One credit where evidence provided demonstrates that a feasibility study considering local (on-site and/or near site) low or zero carbon (LZC) technologies has been carried out and the results implemented. Two credits where evidence provided demonstrates that the first credit has been achieved and there is a 10% reduction in the building's CO2 emissions as a result of the installation of a feasible local LZC technology. Three credits where evidence provided demonstrates that the first credit has been achieved and there is a 15% reduction in the building's CO2 emissions as a result of the installation of a feasible local LZC technology. Or alternatively: A maximum of one credit where evidence provided demonstrates that a contract with an energy supplier is in place to provide sufficient electricity used within the assessed building/development to meet the above criteria from a 100% renewable energy source. (Note: a standard Green Tariff will not comply)	**3**	**3**	-	-	-	1	1	**An onsite natural gas CHP is an acceptable LZC technology and will provide the majority of the power and heat for the buildings.**
Ene 8	Lifts	Up to two credits are available where evidence provided demonstrates the installation of energy-efficient lift(s).	**2**	**2**	-	-	-	-	-	**Schindler**
Ene 15	Provision of Energy Efficient Equipment	One credit where evidence provided demonstrates procurement of office and domestic scale equipment on the basis of energy-efficient performance over the product life cycle.	**1**	**0**	-	-	-	-	-	**Advised as not possible by NHS Board**
Ene 16	CHP Community Energy	One credit where evidence provided demonstrates that a feasibility study has been carried out on the potential for the building to set up, contribute to or benefit from a local CHP community energy scheme.	**1**	**1**	-	-	-	-	-	**WSP Sustainability - meetings with Sustainable Glasgow Initiative and SSE completed, to be written up.**
		Indicative Energy (weighted) Section Score	**13.15%**							

Brookfield

Transport

Tra 1	Provision of public transport	Up to five credits are awarded on a sliding scale based on the assessed buildings' accessibility to the public transport network.	5	3	-	-	-	-	-	**Currently indicative score, potential to score more once full assessment complete.**
Tra 2	Proximity to amenities	One credit where evidence provided demonstrates that the building is located within 500m of accessible local amenities appropriate to the building type and its users.	1	1	-	-	-	-	-	**As stated within the NHS Board's documentation**
Tra 3	Cyclist Facilities	One credit where evidence provided demonstrates that covered, secure and well-lit cycle storage facilities are provided for all building users. Two credits where, in addition to the above, adequate changing facilities are provided for staff use.	2	2	-	-	-	-	-	**Gillespies - cycle storage; Nightingale Associates - cyclist facilities.**
Tra 4	Pedestrian and cycle safety	**Medium/Large developments** e.g. acute, teaching, specialist and mental health hospitals One credit where evidence provided demonstrates that the site layout has been designed in accordance with best practice to ensure safe and adequate cycle access. One credit where evidence provided demonstrates that the site layout has been designed in accordance with best practice to ensure safe and adequate pedestrian access.	2	2	-	-	-	-	-	**Gillespies**
Tra 5	Travel plan	One credit where evidence is provided to demonstrate that a travel plan has been developed and tailored to the specific needs of the building users.	1	1	-	-	-	-	-	**Gillespies to produce marked up site plan**
Tra 6	Maximum car parking capacity	One credit where evidence provided demonstrates that the number of parking spaces provided for the building has been limited.	1	0	-	-	-	-	-	**Advised as unlikely by NHS Board - to be fully investigated when finalised.**
Tra 7	Travel information point	One credit where evidence provided demonstrates there is a dedicated space within the development for the provision of real-time public transport information.	1	1	-	-	-	-	-	**Gillespies to incorporate into site master plan**
Tra 8	Deliveries & manoeuvring	One credit where evidence provided demonstrates that vehicle access areas have been designed to ensure adequate space for manoeuvring delivery vehicles and provide space away from manoeuvring area for storage of refuse skips and pallets.	1	1	-	-	-	-	-	**Gillespies/WSP C&S**
		Indicative Transport (weighted) Section Score	**6.29%**							

Water

Wat 1	Water Consumption	Up to three credits where evidence provided demonstrates that the specification includes taps, urinals, WCs and showers that consume less potable water in use than standard specifications for the same type of fittings.	3	1	-	1	1	1	2	**The Board has confirmed that flush volumes of 4.5litres are unacceptable, therefore only able to score credit for flow rate on taps.**
Wat 2	Water meter	One credit where evidence provided demonstrates that a water meter with a pulsed output will be installed on the mains supply to each building/unit.	1	1	-	1	1	1	1	**ZBP**
Wat 3	Major leak detection	One credit where evidence provided demonstrates that a leak detection system is specified or installed on the building's water supply.	1	1	-	-	-	-	-	**ZBP**

Brookfield

Wat 4	Sanitary supply shut off	One credit where evidence provided demonstrates that proximity detection shut-off is provided to the water supply to all toilet areas.	1	0	-	-	-	-	-	
Wat5	Water recycling	Up to two credits where evidence provided demonstrates the specification of systems that collect, store and, where necessary treat, rainwater or greywater for WC and urinal flushing purposes.	2	0	-	-	-	-	-	
Wat 6	Irrigation systems	One credit where evidence provided demonstrates that a low-water irrigation strategy/system has been installed, or where planting and landscaping is irrigated via rainwater or reclaimed water.	1	1	-	-	-	-	-	Gillespies (with liaison with ZBP if green roof irrigation is needed)
		Indicative Water (weighted) Section Score	**2.67%**							
Materials										
Mat 1	Materials Specification (major building elements)	Up to six credits are available, determined by the Green Guide to Specification ratings for the following major building/finishing elements: 1. External Walls 2. Windows 3. Roof 4. Upper Floor Slabs 5. Internal Walls 6. Floor Finishes / Coverings	6	3	-	-	-	-	-	Nightingales - estimated score, to be revised when final materials choice completed
Mat 2	Hard landscaping and boundary protection	One credit where evidence provided demonstrates that at least 80% of the combined area of external hard landscaping and boundary protection specifications achieve an A or A+ rating, as defined by the Green Guide to Specification.	1	1	-	-	-	-	-	Gillespies
Mat 3	Re-use of building façade	One credit is awarded where evidence provided demonstrates that at least 50% of the total façade (by area) is reused and at least 80% of the reused façade (by mass) comprises in-situ reused material.	1	0	-	-	-	-	-	
Mat 4	Re-use of building structure	One credit is awarded where evidence provided demonstrates that a design reuses at least 80% of an existing primary structure and for part refurbishment and part new build, the volume of the reused structure comprises at least 50% of the final structure's volume.	1	0	-	-	-	-	-	
Mat 5	Responsible sourcing of materials	Up to 3 credits are available where evidence provided demonstrates that 80% of the assessed materials in the following building elements are responsibly sourced: a. Structural Frame b. Ground floor c. Upper floors (including separating floors) d. Roof e. External walls f. Internal walls g. Foundation/substructure h. Staircase Additionally 100% of any timber must be legally sourced.	3	1	-	-	-	-	-	Brookfield Procurement - to be included in contract documents
Mat 6	Insulation	One credit where evidence provided demonstrates that thermal insulation products used in the building have a low embodied impact relative to their thermal properties, determined by the Green Guide to Specification ratings. One credit where evidence provided demonstrates that thermal insulation products used in the building have been responsibly sourced.	2	1	-	-	-	-	-	Nightingale Associates/ Brookfield Procurement
Mat 7	Designing For Robustness	One credit where protection is given to vulnerable parts of the building such as areas exposed to high pedestrian traffic, vehicular and trolley movements.	1	1	-	-	-	-	-	Nightingale Associates
		Indicative Materials (weighted) Section Score	**5.83%**							
Waste										

Brookfield

Wst 1	Construction Site Waste Management	Up to three credits are available where evidence provided demonstrates that the amount of non-hazardous construction waste (m3/100m2 or tonnes100m2) generated on site by the development is the same as or better than good or best practice levels. One credit where evidence provided demonstrates that a significant majority of non-hazardous construction waste generated by the development will be diverted from landfill and reused or recycled.	4	3	-	-	-	-	-	Brookfield
Wst 2	Recycled aggregates	One credit where evidence provided demonstrates the significant use of recycled or secondary aggregates in 'high-grade' building aggregate uses.	1	0	-	-	-	-	-	Dunne - Recycled aggregates will be used where possible but need to assess if 25% possible.
Wst 3	Recyclable waste storage	One credit where a central, dedicated space is provided for the storage of the building's recyclable waste streams.	1	1	-	-	-	1	1	Nightingale Associates - this will be part of the facilities compound
Wst 4	Compactor / Baler	One credit where evidence provided demonstrates that either an industrial waste compactor or baler is installed for compacting/baling waste materials generated on site and a. A water outlet is provided for cleaning b. The development achieves the BREEAM credit for storage of recyclable waste.	1	1	-	-	-	-	-	Brookfield - this will be part of the facilities compound
Wst 5	Composting	One credit w here evidence provided demonstrates there is a vessel on site for composting food waste, and adequate storage for such waste generated by the building's users and operation. OR Where space or access is limited, there is a dedicated space for compostable food waste to be stored prior to removal and composting at an alternative site.	1	0	-	-	-	-	-	Possibly - dependent on how food waste collected on site is disposed of.
		Indicative Waste (weighted) Section Score	**4.69%**							
Land Use & Ecology										
LE1	Re-use of land	One credit where evidence provided demonstrates that the majority of the footprint of the proposed development falls within the boundary of previously developed land.	1	0	-	-	-	-	-	Advised by NHS Board not possible
LE2	Contaminated land	One credit is awarded where evidence provided demonstrates that the land used for the new development has, prior to development, been defined as contaminated and where adequate remedial steps have been taken to decontaminate the site prior to construction.	1	0	-	-	-	-	-	
LE3	Ecological value of site AND Protection of ecological features	One credit is awarded where evidence provided demonstrates that the construction zone is defined as land of low ecological value and all existing features of ecological value will be fully protected from damage during site preparation and construction works.	1	1	-	-	-	-	-	Dunne - with input from appointed ecologist
LE4	Mitigating Ecological impact	One credit where evidence provided demonstrates that the change in the site's existing ecological value, as a result of development, is minimal. Two credits where evidence provided demonstrates that there is no negative change in the site's existing ecological value as a result of development.	2	2	-	-	1	1	1	Gillespies - with input from appointed ecologist
LE5	Enhancing Site Ecology	One credit where the design team (or client) has appointed a suitably qualified ecologist to advise and report on enhancing and protecting the ecological value of the site; and implemented the professional's recommendations for general enhancement and protection of site ecology. Two credits where, in addition to the above, there is a positive increase in the ecological value of the site of up to (but not including) 6 species. Three credits where, in addition to the above, evidence is provided to demonstrate a positive increase in the ecological value of the site of 6 species or greater.	3	2	-	-	-	-	-	Gillespies - with input from appointed ecologist. Possibiltiy for more credits to be scored.

Brookfield

LE6	Long term impact on biodiversity	One credit where the client has committed to achieving the mandatory requirements listed below and at least two of the additional requirements. Two credits where the client has committed to achieving the mandatory requirements listed below and at least four of the additional requirements.	2	2	-	-	-	-	-	Brookfield
		Indicative Land Use & Ecology (weighted) Section Score	**7.00%**							
Pollution										
Pol 1	Refrigerant GWP - Building services	One credit where evidence provided demonstrates the use of refrigerants with a global warming potential (GWP) of less than 5 or where there are no refrigerants specified for use in building services.	1	0	-	-	-	-	-	
Pol 2	Preventing refrigerant leaks	One credit where evidence provided demonstrates that refrigerant leaks can be detected or where there are no refrigerants specified for the development. One credit where evidence provided demonstrates that the provision of automatic refrigerant pump down is made to a heat exchanger (or dedicated storage tanks) with isolation valves. Or where there are no refrigerants specified for the development.	2	1	-	-	-	-	-	ZBP
Pol 3	Refrigerant GWP - Cold storage	One credit where evidence provided demonstrates the use of refrigerants within cold storage systems with a global warming potential (GWP) of less than 5.	1	0	-	-	-	-	-	
Pol 4	NOx emissions from heating source	One credit where evidence provided demonstrates that the maximum dry NOx emissions from delivered space heating energy are ≤100 mg/kWh (at 0% excess O2). Two credits where evidence provided demonstrates that the maximum dry NOx emissions from delivered space heating energy are ≤70 mg/kWh (at 0% excess O2). Three credits where evidence provided demonstrates that the maximum dry NOx emissions from delivered space heating energy are ≤40 mg/kWh (at 0% excess O2) and emissions from delivered water heating energy are 100 mg/kWh or less (at 0% excess O2).	3	1	-	-	-	-	-	Mercury
Pol 5	Flood risk	Two credits where evidence provided demonstrates that the assessed development is located in a zone defined as having a low annual probability of flooding. One credit where evidence provided demonstrates that the assessed development is located in a zone defined as having a medium or high annual probability of flooding AND the ground level of the building, car parking and access is above the design flood level for the site's location. One further credit where evidence provided demonstrates that surface water run-off attenuation measures are specified to minimise the risk of localised flooding, resulting from a loss of flood storage on site due to development.	3	3	-	-	-	-	-	WSP C&S
Pol 6	Minimising watercourse pollution	One credit here evidence provided demonstrates that effective on site treatment such as Sustainable Drainage Systems (SUDs) or oil separators have been specified in areas that are or could be a source of watercourse pollution.	1	1	-	-	-	-	-	WSP C&S
Pol 7	Reduction of Night Time Light Pollution	One credit where evidence provided demonstrates that the external lighting design is in compliance with the guidance in the Institution of Lighting Engineers (ILE) Guidance notes for the reduction of obtrusive light, 2005.	1	1	-	-	-	-	-	ZBP

A48235836

Brookfield

Pol 8	Noise Attenuation	One credit where evidence provided demonstrates that new sources of noise from the development do not give rise to the likelihood of complaints from existing noise-sensitive premises and amenity or wildlife areas that are within the locality of the site.	1	1	-	-	-	-	-	Acoustic Logic
		Indicative Pollution (weighted) Section Score	**6.15%**							

Brookfield

Innovation

Man 2	Considerate Constructors	Where post construction, a Considerate Constructors Scheme certificate can be provided demonstrating that the site achieved CCS Code of Considerate Practice with a score of at least 36. OR Where post construction, the site has complied in full with the alternative, independently assessed scheme, and the alternative scheme addresses all the mandatory and optional items in Checklist A2.	**1**	**1**	**Scored through Brookfield and Dunne, based on past performance**
Hea 1	Daylighting	At least 80% of the floor area (for the building spaces/room identified above in the standard requirements) has an average daylight factor of 3% in multi-storey buildings and 4% in single-storey buildings.	**1**		
Ene 1	Reduction of CO2 emissions	One additional innovation credit can be awarded where evidence provided demonstrates the building is designed to be a carbon neutral building as defined by the NCM (i.e. in terms of building services energy demand), as follows: a. A new building achieves a CO2 index less than 0 on the benchmark scale. b. A refurbished building achieves a CO2 index equal to or less than 0 on the benchmark scale. Two additional innovation credits can be awarded where evidence provided demonstrates the building is designed to be a True zero carbon building (in terms of building services and operational energy demand).	**2**		
Ene 5	Low or Zero Carbon Technologies	A local LZC energy technology has been installed in line with the recommendations of a compliant feasibility study and this method of supply results in a 20% reduction in the building's CO2 emissions.	**1**	**1**	**Scored through CHP solution, devised by ZBP**
Wat 2	Water Meter	Where sub meters are fitted to allow individual water-consuming plant or building areas to be monitored such as cooling towers, car washes, catering areas, etc. If the building does not have any major water consuming plant this exemplar credit is not available. Each sub meter has a pulsed output to enable connection to a Building Management System (BMS) for the monitoring of water consumption. In addition to the above, for sites with multiple departments e.g. large health centres or acute hospitals, separate pulsed sub meters are fitted on the supply to the following areas where present: a. Staff and public areas b. Clinical areas and wards c. Letting areas: On the water supply to each tenant unit d. Laundries e. Main production kitchen f. Hydrotherapy pools g. Laboratories h. CSSD/HSDU, pathology, pharmacy, mortuary and any other major process water user.	**1**		
Mat 1	Materials Specification	One exemplary BREEAM credit can be awarded as follows: a. Where assessing four or more applicable building elements, the building achieves at least two points additional to the total points required to achieve maximum credits under the standard BREEAM requirements. b. Where assessing fewer than four applicable building elements, the building achieves at least one point additional to the total points required to achieve maximum credits under the standard BREEAM requirements.	**1**		
Mat 5	Responsible Sourcing of Materials	Where, in addition to the standard BREEAM requirements, 95% of the applicable materials, comprised within the applicable building elements, have been responsibly sourced.	**1**		

Brookfield

Wst 1	Construction Site Waste Management	Where non-hazardous construction waste generated by the building's development meets or exceeds the resource efficiency benchmark required to achieve three credits (as outlined in the guidance). Where at least 90% by weight (80% by volume) of non-hazardous construction waste and 95% of demolition waste by weight (85% by volume) (if applicable) generated by the build has been diverted from landfill and either: a. Reused on site (in-situ or for new applications) b. Reused on other sites c. Salvaged/reclaimed for reuse d. Returned to the supplier via a 'take-back' scheme e. Recovered from site by an approved waste management contractor and recycled. Where all key waste groups are identified for diversion from landfill at pre-construction stage SWMP.	1		
		Indicative Innovation (weighted) Section Score	**2.00%**		

Brookfield

Helipad M&E Services Design Strategy

General

The Mechanical and Electrical Engineering requirements for the helipad will be as detailed in HBN 15-03.

Special consideration will be given to the position of adjacent intake or exhaust vents, which may be influenced by the location of the helipad.

Helipad lighting will provide reliable illumination in exposed conditions, including the strong winds caused by helicopter downwash. The lighting will meet the chromaticity and illumination levels specified in ICAO Annex 14. The luminaires will be supplied by accredited aviation suppliers.

All helipad guidance and obstacle lighting will be operated by a single switch near the helipad.

Brookfield

LIGHTING

Lighting for Night Operations

A locating beacon, approach lights, and visual alignment and approach slope indicators will be provided as necessary.

The windsock will be illuminated.

The Energy Centre Flue will carry a light.

Helipad Lighting

The helipad will be lit by:-

- Omni-directional green lights in straight lines off each side of the helipad but within 1.5m of the perimeter. The lights will not project more than 25cm above the helipad, and the light sources will not be visible from below the helipad level. There will be one light at each corner and others evenly spaced in between at intervals of not more than 3m.
- Four low-level (25cm) Xenon floodlights to illuminate the landing surface, well-shielded so as not to dazzle pilots.

Drainage

Fire-resistant guttering will be provided around the perimeter of the helipad to carry rainwater, fuel and fire-fighting media into the drainage system. Rain water will be directed into the foul water sewage system. In the event of a fire, a valve will divert aircraft fuel, fire-fighting media, and all other fluids to an oil/water separator. The capacity of the separator will be suitable for the size of the helicopter. The down-pipes will be fire-resistant and will include a system to exclude air (sufficient to extinguish burning fuel).

Water

The water for extinguishing and for making foam will be supplied from tanks immediately below the helipad level, pressurised by an inert gas to propel the water to the nozzles when activated. The delivery pipe for the system will be inside the building. Tanks will also be provided for the foam concentrate. A break tank and pumps with hose will be provided for washing the helipad surface to remove routine dirt and bird droppings in order to retain the friction characteristics of the surface.

Ventilation

Consideration will be given to:-

- Hot air from exhaust vents and flues which might disrupt the airflows around the helicopter
- Roof-level ventilation intakes; any fumes from the helicopter are likely to be dispersed, but could be mistaken for the smell of fire by hospital staff, who might then sound the alarm.

Brookfield

Maintenance and Major Plant and Equipment Replacement Strategy

General

The engineering services will be designed to allow safe and satisfactory access for routine maintenance activities, and provide means of carrying out future major plant replacement without causing significant disruption to the general operation of the hospital, in line with the requirements of the Construction, Design and Management (CDM) Regulations 2007.

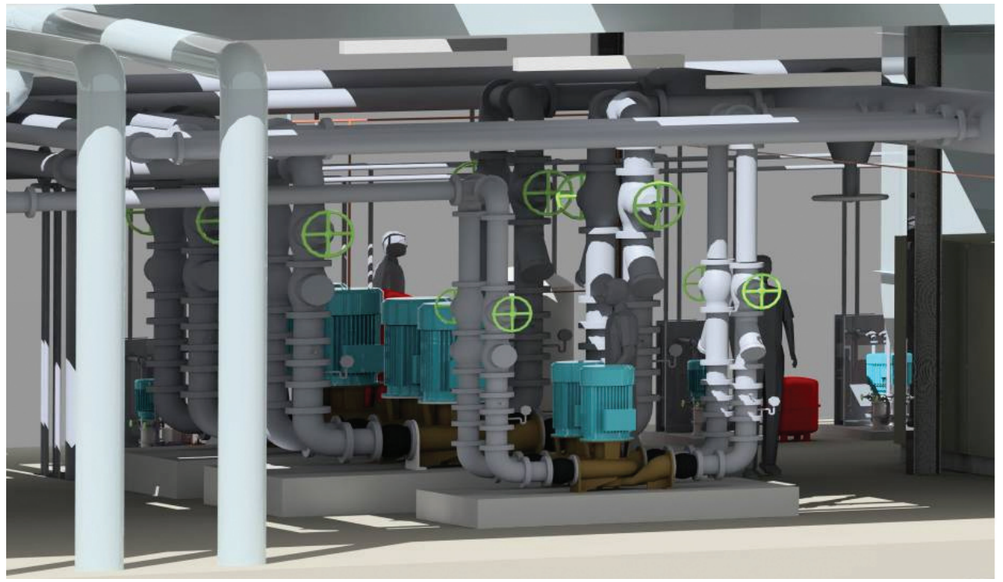
Whenever possible, engineering services plant and components which require regular inspection and maintenance, will be provided with access from floor level, without the use of steps and ladders or access towers.

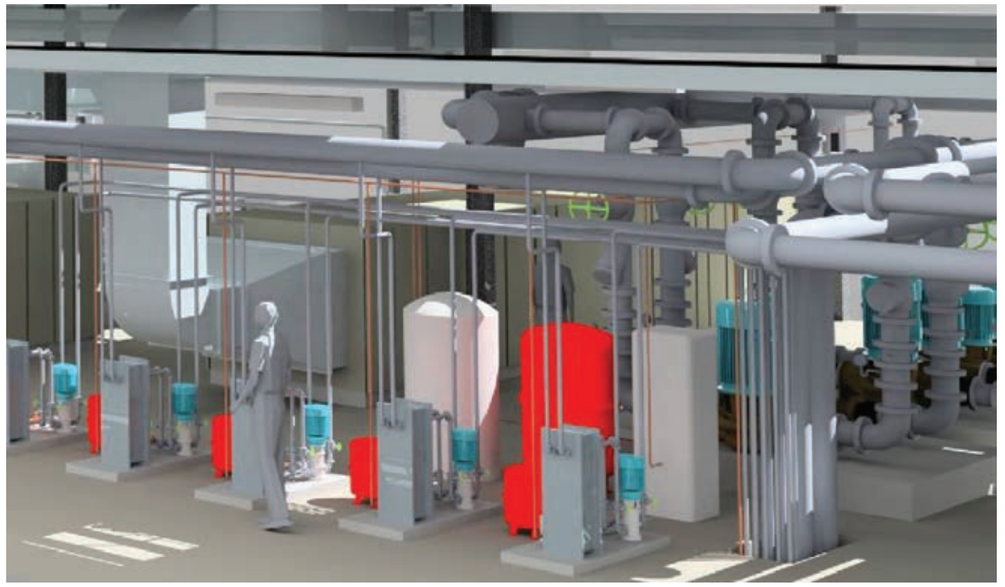
Access routes through plantrooms will be designated on the design drawings, and have a clear width suitable for personnel and equipment passage. The Goods Lifts serving plantroom levels will be maximised in their use for transporting of items such as filters, motors, AHU internal components, etc. Limitation on the use of the lifts will generally be on weight and door opening restrictions.

Space for component withdrawal will be identified. In some cases, due to the infrequent use of such spaces, these may be shared with general access provisions.

It is envisaged that for air handling units internal components will be replaced during the life of the plant, rather than complete units.

The following describes specific allowances in key areas for engineering services maintenance and replacement.





Plantrooms will be arranged to provided satisfactory access for maintenance and plant replacement

Brookfield

Maintenance

Refer to drawing numbers ZBP-XX-ML-PL-520-010, ZBP-XX-ML-SE-520-011 & 012, ZBP-XX-02-PL-520-021 & 022, ZBP-XX-03-PL-520-023 & 024, ZBP-XX-04-PL-520-025 and ZBP-XX-12-PL-520-026 & 027.

The above drawings of the plantroom layouts show that space has been afforded around and adjacent to all the major items of equipment. This space is for both general maintenance and the removal and replacement of both small and large items of equipment.

Atria

Wherever possible, luminaires in high ceiling spaces, such as the atria, will be of a type that can be accessed from floor level without the need for ladders and steps or access towers.

However, in some instances this may not be practical. In these cases, the luminaires will be maintained using cherry pickers, which are also used for building fabric maintenance. When in use, certain areas of the space may be restricted and cordoned off to avoid public access.

In all cases, low maintenance luminaires with long life light sources will be used to minimise the need for frequent access.

Ductwork Cleaning

In order to maintain hygiene in ventilation systems, it is necessary to carry out regular inspections of ductwork interior surfaces and occasionally undertake extensive cleaning.

To undertake this, access doors are provided on ductwork system at interval recommended by HVCA document TR19.

Since ductwork is located within ceiling voids and high level within plant areas, the use of mobile access platforms will be required. Wherever practical, access doors will be positioned in conveniently accessible areas, but it is likely that some disruption will occur in spaces where cleaning is necessary.

These cleaning activities will need to be coordinated between the Facilities Management and the Hospital Board to minimise disruption to hospital activities.

Major Plant and Equipment Replacement

Energy Centre

Refer to drawing numbers ZBP-XX-00-PL-525-104, ZBP-XX-01-PL-525-105, ZBP-XX-02-PL-525-106, and ZBP-XX-RF-PL-525-107.

The Energy Centre houses major generation plant for electricity, heat and cooling, and is divided over three floors and roof.

Generally small items of plant and consumables will be conveyed via the main personnel access and the good lift serving all floors. This should cover all but the major plant items of replacement.

The ground floor houses the bulk oil storage tanks and oil transfer plant. Plant removal/ replacement will be via doors direct to outside above bund level.

The first floor houses the generators, transformers and electrical equipment. Plant replacement will be via removable louvres which enable the plant to be withdrawn from the building onto a temporary platform from where it can be craned away.

The second floor houses the boilers and water services equipment. Plant replacement will also be via removable louvre panels which enable the plant to be withdrawn from the building onto a temporary platform from where it can be craned away.

It is envisaged that the major plant items, e.g. boilers and generators, will be removed/ replaced through these openings by the use of rollers and heavy lifting equipment for loading onto transport vehicles.

The transformers are readily accessible from the roadway. Electrical switchgear will be cubicalised to allow for dismantling and replacement.

The main chillers on the roof of the Energy Centre will be craned from their permanent location directly onto transport vehicles.

These activities may require closure of parts of the adjacent service road.

Brookfield

Basement Acute Hospital
All services will be accessed and removed via the FM tunnels and FM lifts to outside.

Plantroom 21 (Second Floor Acute Hospital)
Refer to drawing numbers ZBP-XX-02-PL-525-100.

This plantroom is located at second floor level and is served by one of the FM lift in the Central Core.

This plantroom houses air handling and water services plant, as well as electrical substations and switchrooms.

The only items of the electrical sub-stations that will not follow the general plant replacement principles are the transformers, each weighing in the order of 5,000 kg.

The transformer bays are located on the perimeter of the building and have demountable louvres for access for replacement and to allow the transformer to be removed and craned from plant level down to ground level.

The air handling equipment will be dismantled into sections, and along with other plant items, will be taken to the designated access point for craning down to ground level.

Small items of equipment of a suitable size and weight, e.g. pumps, coils and filters, will be taken from the plantroom via FM lifts in the Central Core.

The erection of a scaffold platform will provide a landing platform and permit safe personnel access for manoeuvring activities.

Craning activities will require partial closure of the service road adjacent to the plantrooms, and alternative traffic management arrangement will need to be put in place during these times.

Plantroom 22(Second Floor Acute Hospital)
Refer to drawing numbers ZBP-XX-02-PL-525-100.

This plantroom is located at second floor level and are served by one of the FM lift in the Central Core.

This plantroom houses air handling and water services plant.

The air handling equipment will be dismantled into sections, and along with other plant items, will be taken to the designated access point for craning down to ground level.

Small items of equipment of a suitable size and weight, e.g. pumps, coils and filters, will be taken from the plantroom via FM lifts in the Central Core.

The erection of a scaffold platform will provide a landing platform and permit safe personnel access for manoeuvring activities.

Craning activities may require partial closure of the service road adjacent to the plantrooms, and alternative traffic management arrangement may need to be put in place during these times.

Brookfield

Plantroom 31(Third Floor Acute Hospital)
Refer to drawing numbers ZBP-XX-03-PL-525-101.

This plantroom is located at third floor level and is served by one of the FM lift in the Central Core.

This plantroom houses air handling and water services plant, as well as electrical substations and switchrooms.

The only items of the electrical sub-stations that will not follow the general plant replacement principles are the transformers, each weighing in the order of 5,000 kg.

The transformer bay adjacent to the service road is located on the perimeter of the building will have demountable louvres for access for replacement and to allow the transformer to be removed and craned from plant level down to ground level.

The transformer bay adjacent to the children's roof garden is located on the perimeter of the building will have demountable louvres for access for replacement and to allow the transformer to be removed. The transformer will have to be moved on spreader plates across the roof to a designated landing point and craned down to ground level.

The air handling equipment will be dismantled into sections, and along with other plant items, will be taken to the designated 'plant landing' zone for craning down to ground level.

Small items of equipment of a suitable size and weight, e.g. pumps, coils and filters, will be taken from the plantroom via FM lifts in the Central Core.

The erection of a scaffold platform will provide a landing platform and permit safe personnel access for manoeuvring activities.

Craning activities may require partial closure of the service road adjacent to the plantrooms, and alternative traffic management arrangement may need to be put in place during these times.

Plantroom 32 & 33 (Third Floor Acute Hospital)
Refer to drawing numbers ZBP-XX-03-PL-525-101.

This plantroom is located at third floor level and is served by one of the FM lift in the Central Core.

This plantroom houses air handling and water services plant, as well as electrical substations and switchrooms.

The only items of the electrical sub-stations that will not follow the general plant replacement principles are the transformers, each weighing in the order of 5,000 kg.

The transformer bays are located on the perimeter of the building and have demountable louvres for access for replacement and to allow the transformer to be removed and positioned on designated 'plant landing' zone and craned from plant level down to ground level.

The air handling equipment will be dismantled into sections, and along with other plant items, will be taken to the designated 'plant landing' zone for craning down to ground level.

Small items of equipment of a suitable size and weight, e.g. pumps, coils and filters, will be taken from the plantroom via FM lifts in the Central Core.

Craning activities will require partial closure of the service road adjacent to the plantrooms, and alternative traffic management arrangement will need to be put in place during these times.

Brookfield

Plantroom 41 (NCH Fourth Floor)
Refer to drawing numbers ZBP-XX-04-PL-525-102.

This plantroom is located at fourth floor level and is served by one of the FM lift in the Childrens Hospital Core.

This plantroom houses air handling and water services plant, as well as electrical substations and switchrooms.

The only items of the electrical sub-stations that will not follow the general plant replacement principles are the transformers, each weighing in the order of 5,000 kg.

The transformer bay is located on the perimeter of the building will have demountable louvres for access for replacement and to allow the transformer to be removed and craned from plant level down to ground level.

The air handling equipment will be dismantled into sections, and along with other plant items, will be taken to the designated ‘plant landing’ zone for craning down to ground level.

Small items of equipment of a suitable size and weight, e.g. pumps, coils and filters, will be taken from the plantroom via FM lifts in the Central Core.

The erection of a scaffold platform will provide a landing platform and permit safe personnel access for manoeuvring activities.

Craning activities will require partial closure of the service road adjacent to the plantrooms, and alternative traffic management arrangement will need to be put in place during these times.

Plantrooms 121 & 122 (Twelfth Floor Acute Hospital)
Refer to drawing numbers ZBP-XX-12-PL-525-103.

These plantrooms are located at twelfth floor level and are served by one of the FM lift in the Central Core.

These plantrooms house air handling plant.

The air handling equipment will be dismantled into sections, will be taken to the designated ‘plant landing’ zone designated for craning down to ground level.

Small items of equipment of a suitable size and weight, e.g. coils and filters, will be taken from the plantroom via FM lifts in the Central Core.

Craning activities will require partial closure of the service road adjacent to the plantrooms, and alternative traffic management arrangement will need to be put in place during these times.

Brookfield

Building Services Commissioning, Handover And Training Strategy

1.0 BUILDING SERVICES COMMISSIONING STRATEGY.

Purpose of the Document.

The purpose of this document is to explain the Brookfield plan for MEP testing & commissioning strategy being proposed for the New South Glasgow Hospitals Project, how the individual suppliers will be managed in regards to the commissioning process, and to demonstrate how Brookfield intend to successfully deliver the commissioning of systems and the hand-over to operational readiness prior to public opening.

What the Strategy Covers.

Brookfield will approach the delivery and management of commissioning internally and through the suppliers engaged by Brookfield to test and commission the systems within the hospital, in order to prove to the stakeholders, both client & design team that the integrated design meets the requirements of the hospital.

How the Strategy will be Delivered

Delivery of the hospital services commissioning is dependent on the integration and cooperative working of the various supplier teams. The QITP strategy covers the off-site testing and pre-commissioning (where applicable), on-site pre-commissioning, commissioning and acceptance of systems and the integration tests leading to handover to operational readiness; ACHP completion.

The QA processes Brookfield and their suppliers will follow throughout the project shall outline the interface boundaries and requirements regarding 3rd party teams for validation and independent certification.

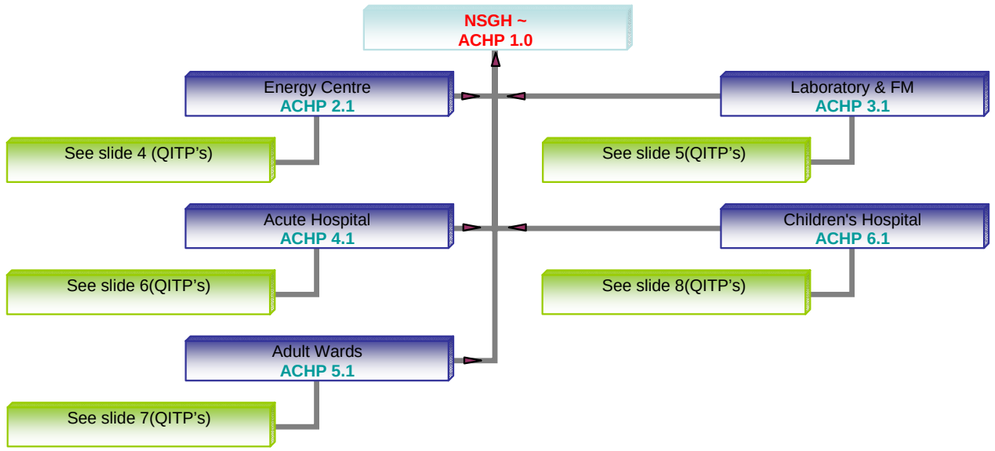

Fig 1; Asset Commissioning & Hand Over Plan

The diagram above demonstrates a high level overview of the Brookfield approach to the commissioning process using the Asset Commissioning & Handover Plan (ACHP) system:

Developing the Outline Commissioning Plan.

For this project this document will define the scope and detail of the commissioning process. This deliverable is created during the design stage by the Brookfield commissioning manager with input from the design team, subcontractors and will serves as a guideline for team members to follow. It will identify the processes and procedures that will be undertaken, including schedule of all activities, and the roles and responsibilities of each team member.

The Commissioning Plan is an evolving document that defines the project's commissioning activities, schedule, documentation requirements, and the roles and responsibilities of team members.

The final Commissioning Plan will include:

- General building information and contact information
- Project objectives.
- An overview of the commissioning process ~ FAT, SAT and IST protocols including the O&M delivery.
- Building and systems description, including a list of components and systems that will be commissioned.
- Develop the scope of commissioning QITP's and the Hand over procedure.
- List of team members, their responsibilities, and expected deliverables
- Description of communications, reporting, and management protocols
- Detailed description of power monitoring procedures ~ specifically for the periods up to PC and during the 36 month DLP.
- Recommended training activities

Brookfield

Perform Commissioning-Focused Design Review.

During the stage review Brookfield will review with our design team to further understand their reasoning and assumptions for choices made about how to accomplish the project goals. The Brookfield commissioning manager will review design documents for clarity, completeness and compliance.

The design review process has several steps and takes place throughout the pre construction phase of the project:

- Next, the lead examines the implications of system choices to ensure that the design will meet the project requirements. At this stage of the development of the project this general review would be carried out as a concerted effort with the design team.
- A coordination review to examine how systems will interact and whether there are any potential conflicts.
- When the specifications are drafted, the lead will carry out a final sweep up review for anomalies.

Some of the most important decisions for the commissioning manager to review during the design phase include:

- Sizing and selection of building systems and equipment accessibility of equipment for operations and maintenance
- Sustainability objectives such as target emission reduction.
- Details of the controls design relative to equipment being controlled & monitored.
- Ability of controls interface to facilitate trending and identification of equipment faults during functional testing.
- Identification and access of test ports, sensors, and in-situ measurement devices for use in functional testing & analysing performance

Brookfield Commissioning Team Structure

It is important to note that the commissioning process will be adapted to meet the needs of this building project. During all phases of commissioning, the Brookfield commissioning manager will be interacting with members of the design, construction, and operations teams. The Brookfield team will develop and establish a clear and pragmatic process for sharing information early in the project in order to get the full benefit from the Brookfield commissioning process.

Our suppliers will have a commissioning manager/supervisor (as appropriate) who shall be accountable for their commissioning plan/deliverables and its integration into the overall project wide commissioning plan. These commissioning managers/supervisors will be accountable for the detailed commissioning planning and activities at sub-project level, this detail will be fed back into the Integrated commissioning programme.

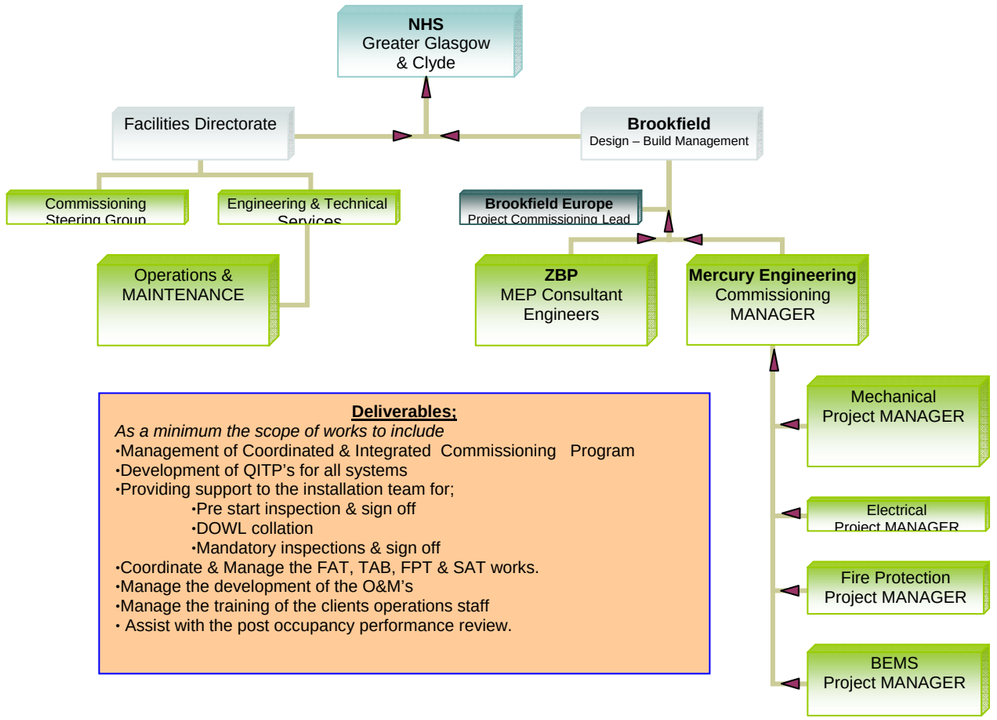

Fig 2; MEP Commissioning Team

Brookfield

Who will be involved in delivering the commissioning

In order that commissioning can succeed (and in turn that operational readiness and handover can be achieved), it is vital that handover from construction / installation to commissioning is carried out strictly in accordance with the integrated commissioning programme.

To overcome the time schedule issues between construction / installation / fit-out / commissioning, a co-ordinated time schedule will be produced by Brookfield that highlights the dependencies that the systems have upon each other and the impact that they can have.

Commissioning periods cannot be permitted to be viewed as “float” for construction activities

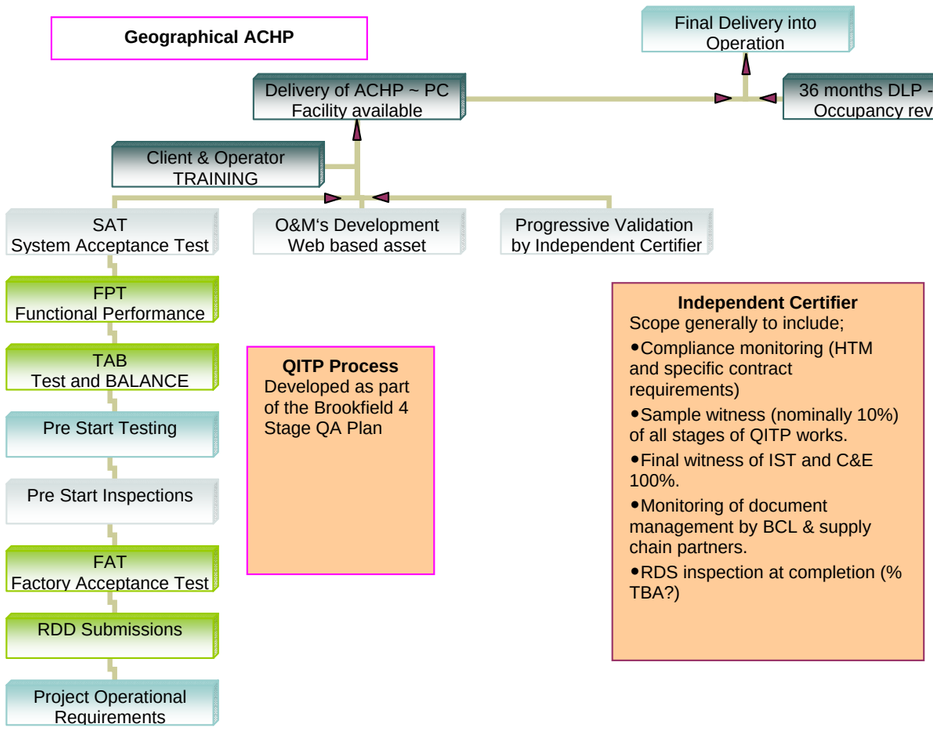

Fig 3; Assurance PROCESS diagram

Perform Functional Tests (System Acceptance Test)

The development of SAT procedures assists in practical levels of % witness validation of the system operation. In many cases it is impractical to naturally observe every possible operating regime. The Brookfield commissioning manager will agree protocols for the witnessing and documentation to be conducted by the contractors.

The commissioning manager and contractors schedule the testing and make any necessary preparations, such as checking and calibrating control points or temperature sensors.

Functional tests typically involve forcing the system into a series of operating modes, and observing the system’s response. The commissioning manager will ensure that all data is meticulously recorded and observations noted on a pre-defined data sheet, and then ensure that all systems are returned to a “normal” state.

During functional testing, the commissioning manager uses an Issues log to track any performance issues that may arise, and their resolutions.

Brookfield

Systems that we would define for specific review include:

No;	Discipline	Detail	% Sample Witness
1	HV operation	Normal and alternate demand for EDF supply and generator back up.	25%
2	LV operation	Essential power feed ACO functionality and demand.	10%
	UPS/IPS	Normal and autonomy testing for the IT hub rooms & Endoscopy / Recovery rooms.	10%
	Fire Alarm & Detection & Life Safety	Fire detection and suppression and interfaces detailed in C&E matrix	100%
	Stair Pressurisation and smoke extract ventilation	Functional testing and interfacing of SFD/FD scenario requirements. (see C&E)	100%
	Lighting	Normal control & emergency functionality	10% & 100%
	BEMS	System management & functionality tests including status monitoring & telemetry	20% - 50%
	Security / Access Control	System functionality and resilience under power failure.	10%
	Nurse Call / Alarm systems	System functionality and resilience under power failure.	10%
	IT and communication systems	System functionality and resilience under power failure.	10%
	CHW	System functionality and resilience under power failure	10%
	LTHW	System functionality with the operational sequencing of the CHP lead and Biomass boiler	10%
	PHE	Operational tests of the HWS/BCWS and the SVP/RWP systems. This should include the surge protection, PRV setting, temperature blending & the leak detection system.	10%
	Medical Gas	Integrity and functionality checks in readiness for the Clinical team Pharmacist validation and setting to work.	20% - 50%
	General Ventilation	Functional Testing and balancing of comfort cooled areas and the dirty extract systems. FD drop test demonstration to BCO	10% & 100%
	Clinical area ventilation	In particular the pre testing of the departments with close controlled operation - pressure and temperature regime areas such as the Aseptic suite and Isolation rooms& including the setting up of the fume cupboard extracts	20% - 50%
		The final set up by the Clinical team Pharmacist validation and setting to work to be agreed	

Brookfield

Integrated Systems Test

The Integrated Systems Test is the ultimate shakedown demonstration of the commissioned building performance. This test can only occur after all individual SAT's have been successfully verified and documented to function according to their respective design intent. The goal of the Integrated Systems is to finally verify the overall reliable functional interactivity of the MEP systems for the whole building during normal, emergency, and other failure scenarios.

The diagram below is indicative of the approach that Brookfield will use on the NSGH project. The QITP's are integral to the milestone process regime that will culminate in the final system functional performance tests that are required to complete the ACHP. This plan provides flexibility and ongoing assurance that the works and systems will deliver the requirements of the project.

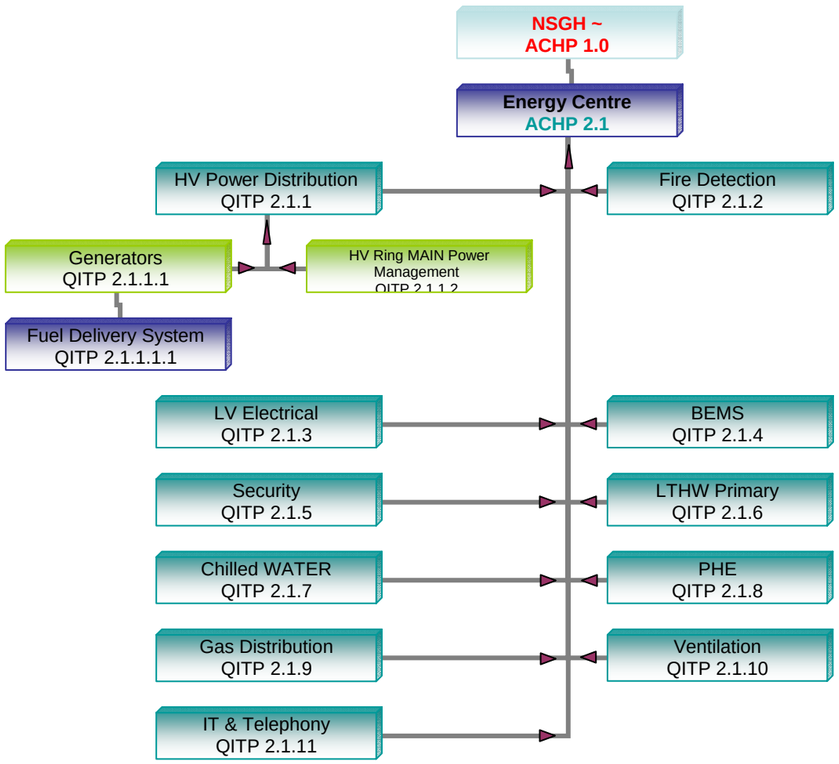

Fig 4; QITP process diagram

Documentation

As part of the final hand over procedure the documentation that would traditionally populate the O&M's will be updated into the digital web based asset management system.

This database will be in use from the project design commencement until handover to NSGH operational use.

Brookfield will during the course of the contract maintain online access to the system and will provide at the time of handover a computer complete with hard drive containing all completed information.

NSGH may wish to consider the offer provided by Zutec for extended use of the online system after expiration of Brookfield defects liability period.

Verify Training of Client Staff and Review.

Brookfield realise the importance of these activities and will ensure that this phase of the delivery is not underestimated because of its role in assuring long term benefits for the operational health of the facility. The Brookfield commissioning manager will verify that they are carried out to the operator's satisfaction.

Post Occupancy DLP period

The requirement within the outline brief to verify the systems conditions at the end of the extended defects liability period will necessitate sample readings of all systems.

At the handover the building will be taken over by the hospital Board and operation staff, although the Project will have achieved practical completion, Brookfield will continue to monitor the power consumption of the facility in normal operation for the defects liability period.

Brookfield commissioning manager will develop ongoing review and feedback with the hospital operations management staff regarding system performance. Fundamental building commissioning will have been completed, witnessed and recorded, further fine tune commissioning ,may be required post practical completion during the defects liability period.

This will include as an example; the setting of ambient lighting control post FFE completion and post occupancy seasonal testing, calibration checks of control systems.

Brookfield experience that the post construction period environmental checks on the performance of systems is beneficial to making sure that the energy efficiency objective is maintained; monitoring during operational conditions usually provides more reliable data to make adjustments and provides key information to the hospital operation & maintenance staff.

Brookfield

Brookfield will ensure that this is a coordinated monitoring regime with the operational staff to verify system performance during different seasons – as a minimum winter and summer. Upon completion the data would then be reviewed with a concerted issue log developed as appropriate.

Towards the end of the 24 months defects liability period, initially this will follow specific periods (1 month/3 month post PC) whereby Brookfield will address comments from the operators and address any adverse data from the building energy management system. The Brookfield commissioning manager will review and update the issues log and assist in updating the electronic asset management system with the revised information.

Additional Training During Handover

It is proposed that during the construction period a number of locally sourced junior engineers will be employed and trained on the project. These engineers will form a critical part of the final commissioning teams.

During the commissioning period these engineers will be involved with every aspect of the setting to work of all of the mechanical and electrical systems. This will provide a resource to the hospital at handover stage of personnel who will be fully conversant with the systems and who will have had an active part in the commissioning of this system. These engineers can eventually work directly within the FM department of the hospital.

Definitions of Testing & Commissioning

The meaning of the terms “testing” and “commissioning” used in this document are those defined in the acknowledged standards published by BSRIA, CIBSE, IEE 17th edition and requirements of NSGH, SHTM’s and HTM’s.

The activity “Handover”, which is linked to commissioning, is not specifically covered in this strategy but is recognised as a key output from the successful commissioning of systems.

The precise sequence and processes for handover are yet to be defined; this strategy will be amended to incorporate the specific details once they are made available.

Due to the significant quantity of system and items required to be witnessed by the client’s representative, the standard industry practice of 10% of each system type will be offered.

After all systems are put into use, a final inspection of the power quality will be made and should adjustments be required these will be undertaken during the defects period.

Definition of Systems.

Systems are generally defined by the typical functional groups such as Chilled Water & LTHW. Systems will be split into a component level of detail that may be used in the method statements and commissioning programmes to further identify interfaces between systems.

2.0 HANDOVER STRATEGY.

Asset Management System.

Brookfield hand over procedure will be based on the use of digital web based asset management system that will be populated from the project design stage until final handover to New South Glasgow Hospitals for operational use.

Brookfield will during the course of the contract maintain online access to the system for continual review and comment of all information to ensure that a very smooth and efficient handover process is completed.

Brookfield will provide at the time of handover a computer complete with hard drive containing all completed information.

The hospital Board may wish to consider the offer provided by Zutec for extended use of the online system after expiration of Brookfield defects liability period.

The reason why Brookfield use a digital web based technology for asset and handover management is that it provides a complete user friendly collaborative tool that is progressively used to development all data and information required for a successful handover and operation of the hospital. This system provides the client with the benefit of full participation with the joint development of the right information for hospital operation use commencing from the design phase until handover.

The result is that the information contained in the asset management system is exactly what the client requires including staff that participate with the system development are fully trained to use the system. The result of this collaborative approach means access to vital information can be found in an instance as required for operation and or crises management.

The system provides a seamless tool that enables successful handover of all necessary documentation including an instant process for operational and maintenance use.

The online asset system includes:

- Room data sheets.
- Construction period online snagging system.
- Design data and design functional descriptions.
- Technical submissions.
- Energy Performance model calculation data sheet.
- BREEAM rating schedule.
- Whole Life Cycle Cost Plan
- Operating and maintenance manuals.
- Commissioning records.
- As-built drawings.
- Plant replacement strategy.
- Training manuals (Documents that we use for handover training)
- Building Log book.
- High level control interface with energy monitoring system to provide instantaneous energy consumption data.
- Health & safety residual risk assessments. (CDM)
- Maintenance service log book.
- Call out log book.
- Observations report system.
- PPM system.
- Maintenance calendar.
- Interface with Maximo.

User features include instant access from any location enabling online review and comment of all data loaded on to the system; starting from design details through construction, commissioning, operation and maintenance, reducing the risk of data being lost, providing quick access to any item of information to all authorized parties.

The application includes direct data input of design details on equipment scheduling, asset tagging and provides a methodology for tracking sustainable assets.

The following captions outline the Asset Management System.

We have set up a sample demonstration home page for the New South Glasgow Hospital as outlined in Figure 1 below

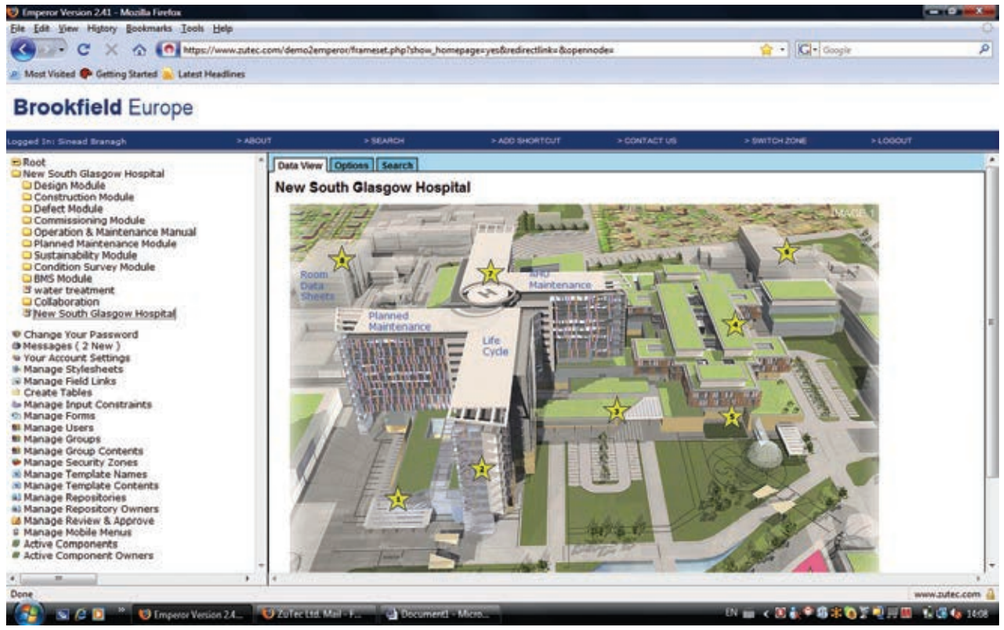

Figure 1 – Zutec Home Page

Brookfield

The asset system includes the facility to capture actual Kilowatt Hour data from equipment schedules for comparison with construction submittals / commissioning test sheets and actual meter readings taken from energy metering management control system, thus giving an accurate picture of the changes which may occur throughout the building lifecycle.

By capturing all the major components of the maintainable assets using the online database approach, we are ensuring that these assets are logged and tagged in a manner that is both effective and efficient in a modern hospital facility. Completing this exercise from design stage and using an online system saves time and massively improves the quality of information provided to the operators.

Project Process

Described below is a brief detail explaining how the process for the asset management system evolves from the design stage in to operational use.

Stage 1 – Design

During this stage, the design team creates and uploads the room data schedules, equipment schedules, technical submissions, functional design descriptions and asset tags all the major maintainable assets.

The room data sheets can then be modified during the course of the project and handed over accurately completed.

This is shown in the screen shots below;

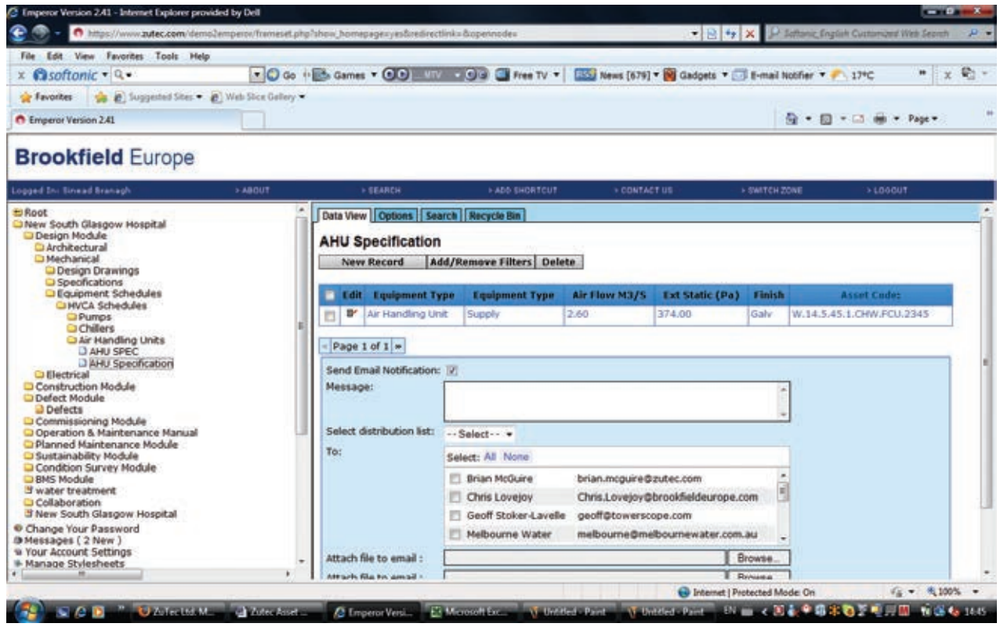

Figure 2 Design Schedule – (showing equipment schedule e.g. Mechanical Air Handling Plant)

Brookfield

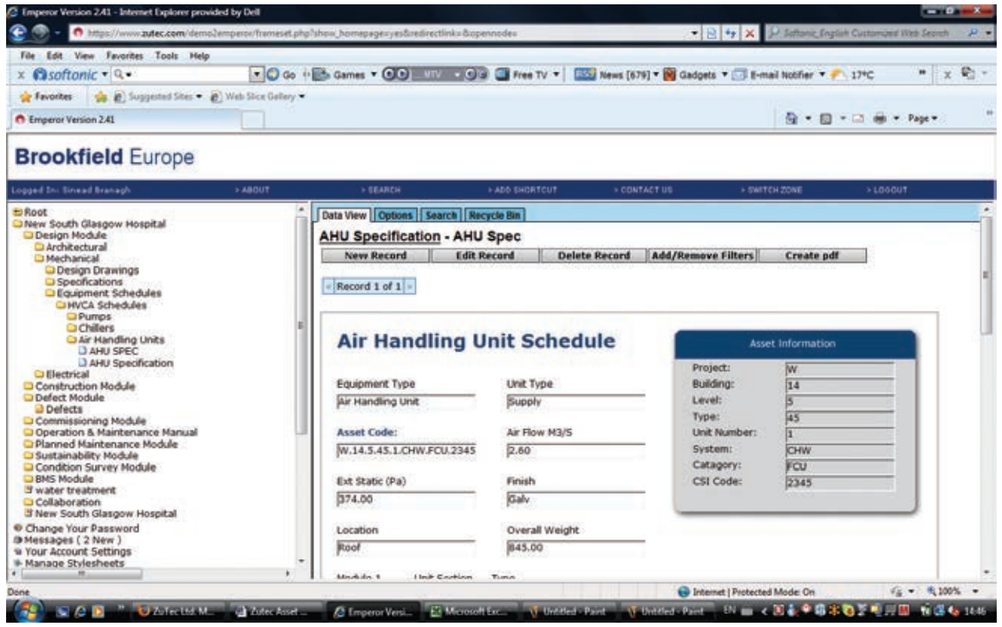

Figure 3 The Inclusion of Asset Registering as Part of Design Data Input

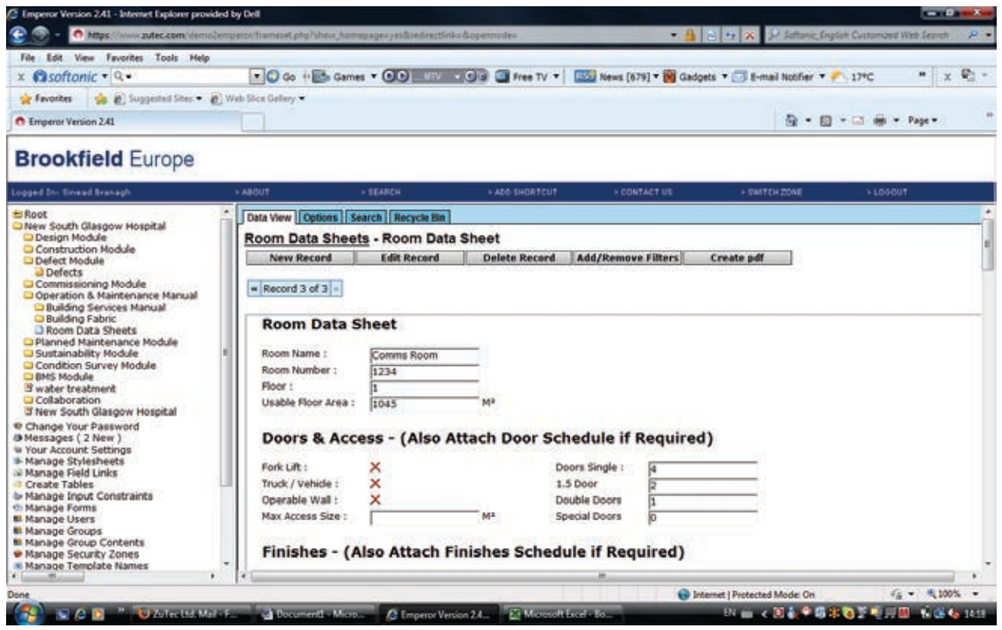

Figure 4 Room Data Sheets

Stage 2 – Construction

This stage moves from design to construction, using the already loaded Asset Tag Numbers we can ensure there is a direct link between the design equipment schedule and the construction submittal schedule – (ensuring no deviations from the BREEAM requirements).

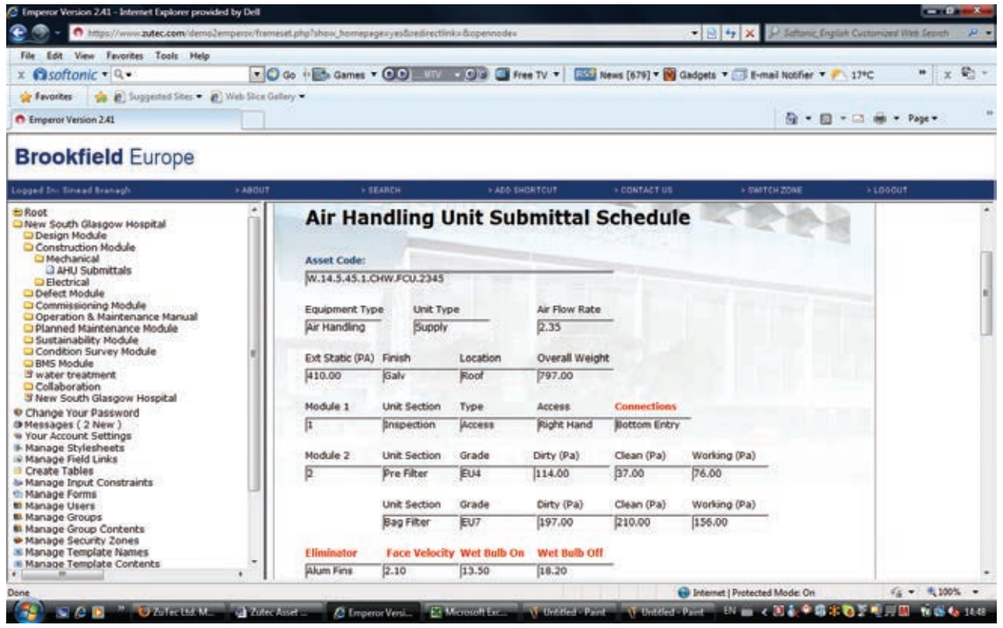

Figure 5 AHU Submittals

A48235836

Brookfield

Stage 3 – Commissioning Management

The commissioning management section of the system is based on BISRIA, CIBSE and IEE commissioning templates.

During this stage commissioning data is loaded directly into the required templates again under the direct data input model – the example below shows a duct traverse reading recording ductwork velocities. The system in this instance has an algorithm to calculate the average velocity in a given duct traverse reading. Using this method will ensure a major productivity gain for the commissioning company as this avoids double handling of information.

All specialist plant commissioning records are also recorded on the system.

In addition we will record actual kilowatt readings on each of the sustainable assets for design / construction and commissioning, again ensuring at an early stage that we stay within the BREEAM requirements on sustainable development.

The system enables drawings to loaded on to the system with commissioning tag points set that enables the user to click on an icon and open to see commissioning results recorded on any system of component such as individual grills, duct system and or plant item.

Remote checking of progress by authorised users from any location is available and up to date status can easily be established.

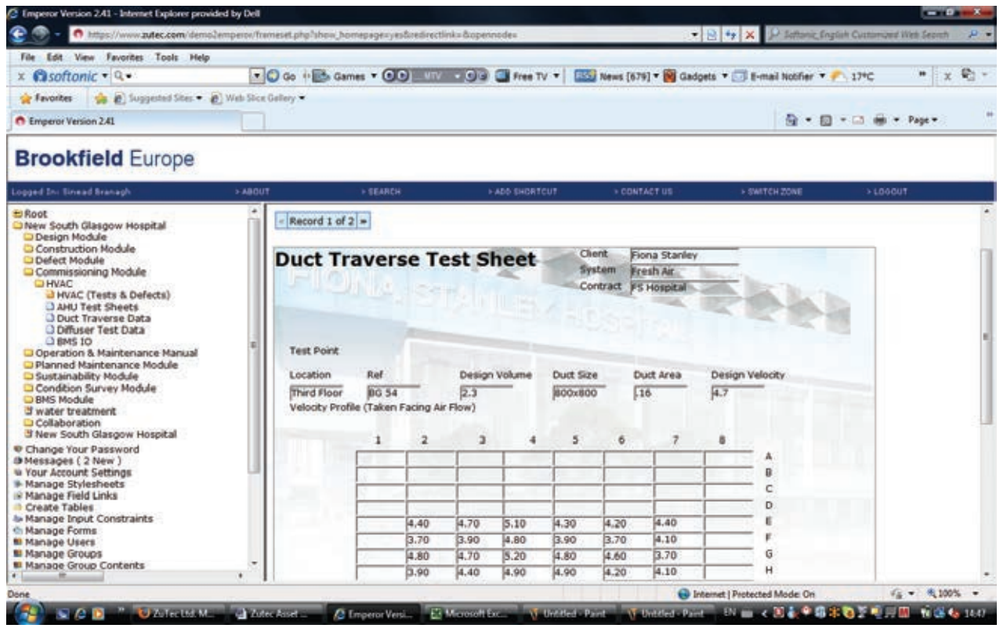

Figure 6 Commissioning Management Module

Stage 4 – Handover

In this stage we will compile the As Built Asset Register / Operation and Maintenance Manuals / As-Built Drawings / Health and Safety Files (including residual risks), client training manuals including attendance schedules and training feedback questionnaires.

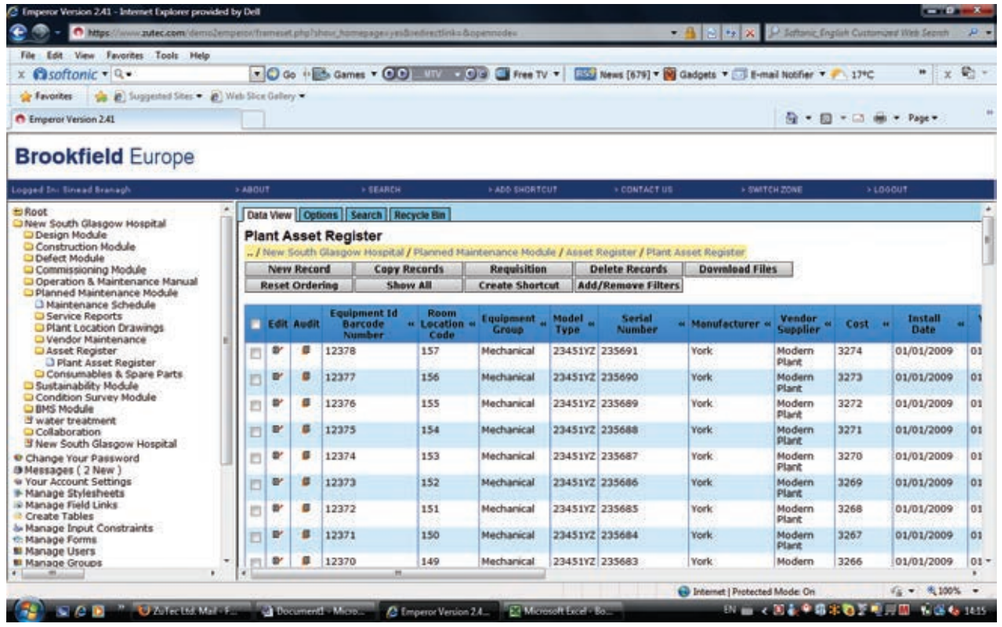

Figure 7 Asset Register

Brookfield

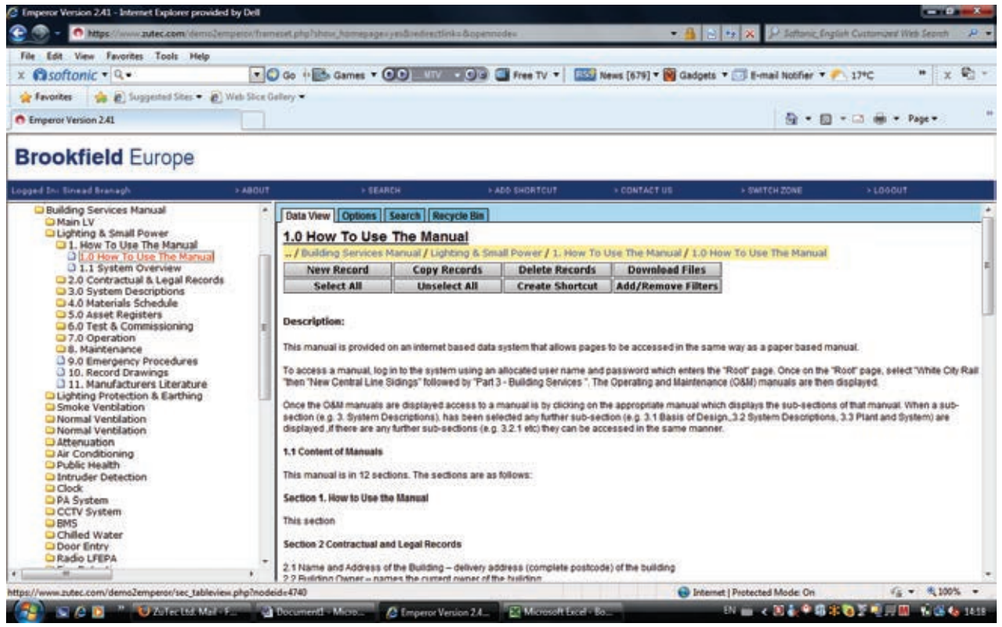

Figure 8 Operation and Maintenance Manuals

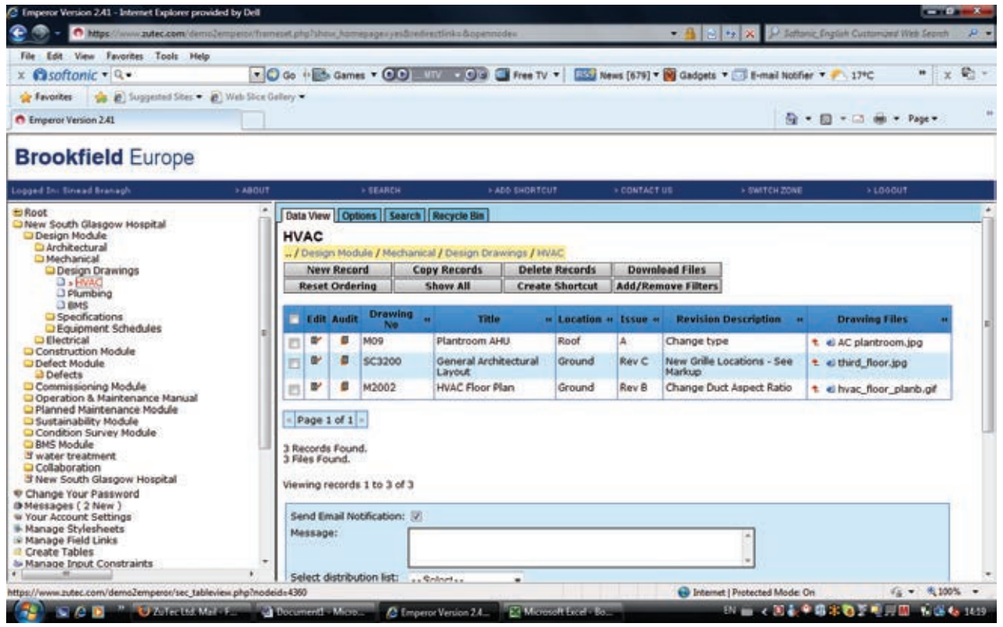

Figure 9 Drawing Register

Brookfield

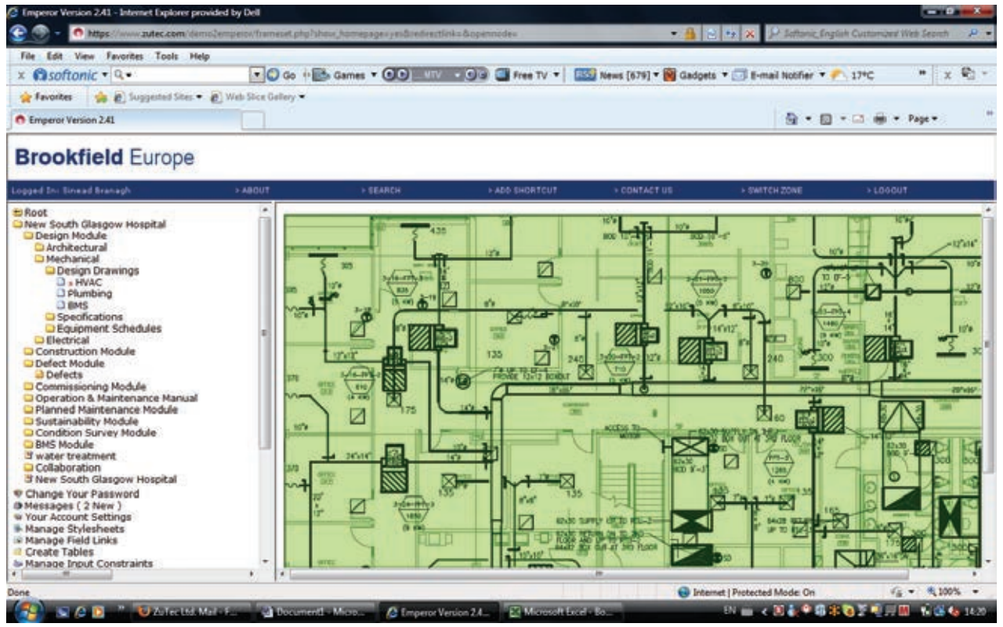

Figure 10 Drawing Detail

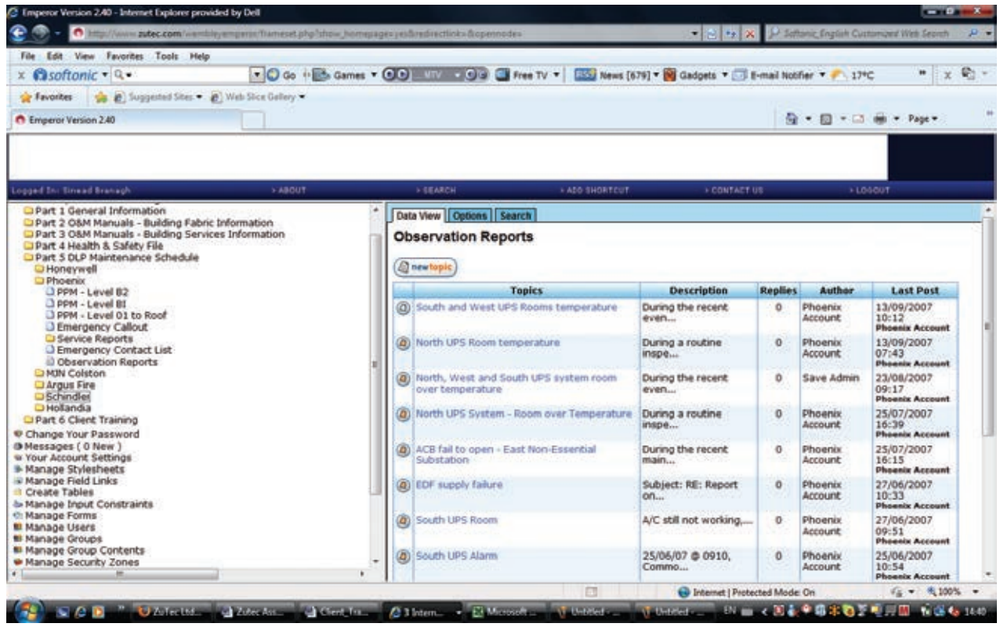

Figure 11- Observation Reports

Stage 5 – Operations

During this phase the data collected during the previous stages can be used to set up planned preventative maintenance calendar and linked to service reports (either directly or by way of drawings showing plant location.

The system includes a maintenance service log book that enables all maintenance technicians attending any equipment item or system to record materials, labour and time used. This can be picked up instantly by accounts departments.

To optimize preventative maintenance a discussion thread module is used to provide an observation report system that can be used to identify potential maintenance issues feed back directly to the maintenance management. Some of the benefit provided by this facility is to identify items that have been observed that may not need immediate attendance but only need to be dealt with at the next scheduled routine maintenance.

Brookfield

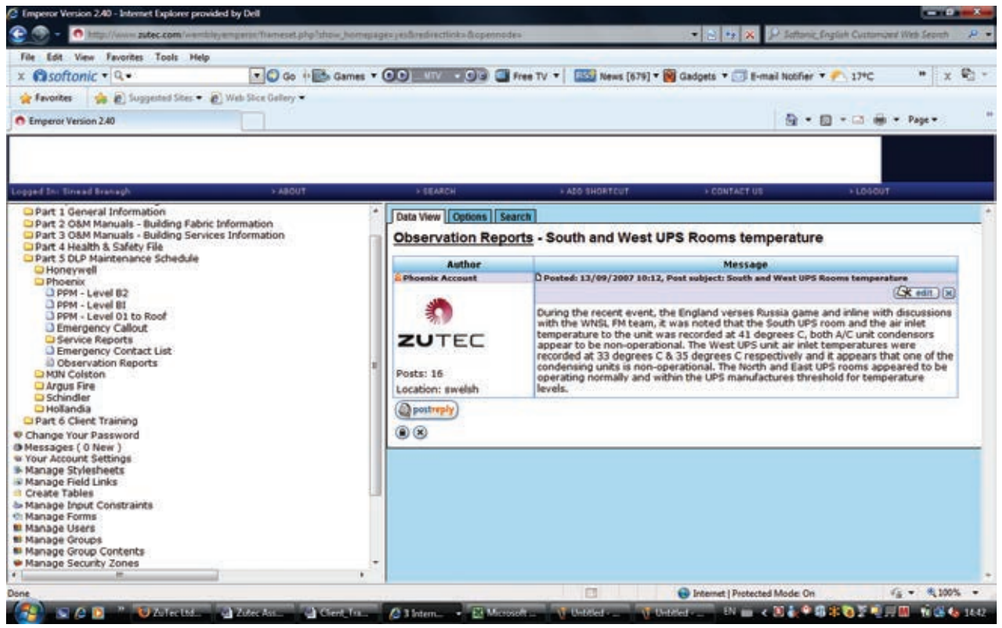

Figure 12 Observation Reports

Snagging / Defecting Tool (Please see the screen shot below).

The online snagging record tool is a natural addition to the suite of handover modules. The module allows Brookfield and the client to capture defects on a mobile camera phone, and upload the image complete with a snag description immediately into system. The system enables the inspector to superimpose the snag request by clicking on the image and send it as an email to the relevant party.

The relevant party can respond to the request with a link directly back to the module to confirm the status of the snag. The system will automatically update the defect module to reflect the status of any snag as either “Open or Closed” The application is Blackberry enabled which means that the system can be updated remotely without the need to have system access. A management report can be created listing all building trade snags and their status.

Status of defects for a typical floor or room can be accessed quickly by clicking on a tag marking the snag within a room or an area. This provides a simple user friendly methodology of clearing defects for handover and provides a precise record of all defects to be cleared during the defects liability period.

Brookfield

Brookfield

3.0 TRAINING STRATEGY.

Brookfield client training program is be based on a five stage process.

The first activity the Brookfield training facilitator will establish with the client is a detail calendar training program to ensure that all types of hospital staff required to be trained is planned in advance but spread of a reasonable period of time to enable there work commitments implemented as well as the demand for training on the facility

The five stage training process enables each staff member being trained on a specific topic to fully understand the training stage before moving on the next stage, this process is managed by a feed back questionnaire issued to all individuals attending the relevant stage who are required to identify if they are “Satisfied or Not Satisfied”

- Status “Satisfied” trainee to sign off accepting that the stage has been completed and understood.
- Status “Not Satisfied”, Brookfield training facilitator is to immediately discuss with trainee and establish the items that need to be changed or improved to meet an acceptable requirement.

Once all five stages have been completed and signed off “Satisfied”. The client will be required to provide final sign off “A” status concluding the training program for the specific package is completed.

Final sign off will confirm that the training requirements for the particular trade package presented has been completed in accordance with contract conditions and client requirements.

Information required to be provided by client.

Client to confirm:

- Quantity of personal to be trained.
- Employment role & responsibility of each individual / group required to be trained.
- User level training requirement.

Brookfield and client will jointly develop the user group training schedule so that the right level of training is provided to the relevant user level.

Five stages of training:

- Stage 1. Sub-Contractor introduction.
- Stage 2. Classroom training.
- Stage 3. Site geographic familiarization.
- Stage 4. Site hands on user training.
- Stage 5. Control systems head end user training.

Example of User Group Training Schedule

USER LEVEL	CLIENT TRAINEE / GROUP	TRAINING STAGE	PRIORITY TOPICS
Level 1.	Building manager.	Stage 1. Stage 2.	Overview of all systems. Emergency procedures. Emergency contacts.
Level 2.	Building manager.	Stage 1. Stage 2. Stage 3. Stage 5.	Overview of all systems. Emergency procedures. Emergency contacts. Security systems. Maintenance plan. Site geographic familiarisation. User level of all control systems.
Level 3.	Control systems operator.	Stage 1. Stage 2. Stage 3. Stage 5.	Overview of all systems. Emergency Procedures. Emergency Contacts. Site geographic familiarisation User level of all control systems.
Level 4.	Maintenance technicians.	Stage 1. Stage 2. Stage 3. Stage 4.	Overview of all systems. Emergency procedures. Planned preventative maintenance. Site geographic familiarization Site Hands-on User training.
Level 5.	Building manager.	Stage 3.	Emergency procedures. Site geographic familiarization.

Brookfield

Priority topics listed in the table above identify the critical elements that the training program will ensure that the relevant user level will fully understand and be able to implement.

Client representatives who will participate in the training program need to have suitable skills, abilities, traits, knowledge and a level of experience for the user level defined.

Community training.

In addition to the training of staff necessary to successfully operate the hospital systems Brookfield will as part of the community commitment train entrant level persons.

The training of entrant level person is detailed in the Brookfield Community Engagement and Benefits deliverable documentation.

The content and requirements of each stage will include:

Stage 1. Sub-Contractor Introduction.

Brookfield will arrange for each subcontractor and specialist to introduce their company and include in their presentation the following key points:

- Organisation chart of the company.
- Brief background of key personnel.
- Any special services that company can provide.
- Maintenance operations of the company and emergency contact personnel / contact details.
- Subcontractor will briefly explain what services and specific packages of work they have provided on the project.
- Subcontractor will briefly describe the role and support services provided by key suppliers & specialist's contractors used on the project.

Stage 2. Classroom Training.

Classroom training will be based on using the web based asset management system.

Training will demonstrate how to navigate through the asset management system and all necessary documentation, locate key sections and information that the client facility operators & maintenance technicians will need.

Key sections that will be studied during the training sessions will include:

- Operator user information & details.
- Emergency procedures.
- Asset register.
- CDM residual risks register.
- Commissioning records.
- Building log book and energy performance information
- Planned preventative maintenance calendar and requirements of each system, item of plant & equipment.
- Service log book.
- Call out system.
- Observation reporting.
- Specialist companies required to attend and their function.
- Review of the spares shopping list, including supply sources and lead times.

Brookfield

Stage 3. Site Geographic Familiarisation.

Site familiarization will require all attendants to learn the geographic location of each key system, plant and equipment.

As-Built drawings will be used as part of the geographic training.

The training session will include locating and identifying various key elements of the systems installed on site within each building, department etc.

Specific key items will include:

- Building locations and all main plant areas.
- Major system isolation points.
- Plant room locations.
- Specialist systems such as medical gas, renal water, etc.
- Specific system and the areas they serve.
- Electrical power & lighting distribution switchboards and mechanical motor control panels.
- Communications key equipment locations.
- Various control systems such as BMS, fire alarm, nurse call, IT/Data network, security communications systems, etc and all key equipment locations.
- Control rooms and control system head ends.
- Fire control centre.

Stage 4. Site Hands-On User Training.

Each Sub-contractor will demonstrate how to operate the (user level) on site plant, equipment and local control systems that they have installed for the purposes of maintenance or to enable any system to operate in a manual mode in the event of a failure.

Example of key equipment user level training will include:

Energy centre plant and equipment

Control room systems.

Mechanical Motor Control Panels.

LV switchboards.

Demonstrate access to plant and equipment.

Drain down & system venting points.

Medical Gas.

Pneumatic tube.

Chemical treatment dosing facilities.

Domestic CWS water treatment plant.

Change air handling unit filters.

Specialist equipment and systems.

Stage 5. Control System Head End User Training.

The objective of this training stage is to teach the operators and technicians how to use all of the IT / data, hospital electronic systems and building services control systems to a level of competence that enable the successful operation of each system to a user level.

Each user will be trained on how to change control set points, set up trend log information, fault finding etc

The training will not include teaching to program or system author / architecture level, or how to change the cause and effects data.

Brookfield

Drainage Strategy

Section
3.25

Deliverable
Drainage strategy including:-

Methodology for Addressing the requirements of the Hydraulic Assessment and Flood Risk assessment as scoped out on the Drainage Impact Assessment and Strategy Report

SUDS and Drainage Strategy statement which recognises the requirements as outlined in the Drainage Impact and Strategy Report

The below ground drainage design strategy report has been prepared to demonstrate a thorough understanding of the situation and condition of the existing site and the complexities of addressing the limitations of the existing drainage infrastructure adjacent to and on the main site. The report also demonstrates that the design issues specific to the NSGH site adopting best practice and in accordance with URS DIA report and dialogue with the relevant statutory authorities.

1 Introduction

2 Foul Drainage

3 Surface Water Drainage

4 Summary

Appendix A

Appendix B

Appendix C

Appendix D

Brookfield

Introduction

The Site

The site is located at approximate OS grid reference 252398, 665707 and is part of the overall existing Southern General Hospital. The area to be developed occupies half of the 29 hectares owned by the NHS at this facility.

scope

This document relates to reference 3.25 of the bid submission deliverable requirements and is prepared by WSP to support other design information that is also submitted in the form of drawings, schedules and specifications. It describes the design criteria and principles that have been applied to the below ground drainage design for this project.

2 FOUL DRAINAGE

2.1 Existing Foul Drainage System

The Foul drainage from the Southern General Hospital currently discharges to a number of private combined sewers which cross the site. This drainage is generally routed from south to north before finally exiting the site and connecting to the public sewer network. A copy of Scottish Water's sewer network record drawing is included as Appendix A.

The proposed development site is currently intersected 300mm diameter combined drain which collects foul water from a number of the buildings in the centre of the hospital site. It also collects some of the surface water run-off from impermeable areas within the site. This drain runs generally in a north easterly direction before connecting into the public combined sewer in Govan Road.

A portion of the private drainage runs under the existing Library building and is also under the south east corner of the proposed main building footprint. This drain will be diverted around the proposed building and into the hospital roadway as illustrated on CD-P1-00-PL-140-01.

2.2 Proposed foul drainage

It will be necessary to divert the existing 300mm diameter combined sewer which currently runs under the south east corner of the proposed building footprint. An extract from diversion drawing is included as figure 2.1, below.

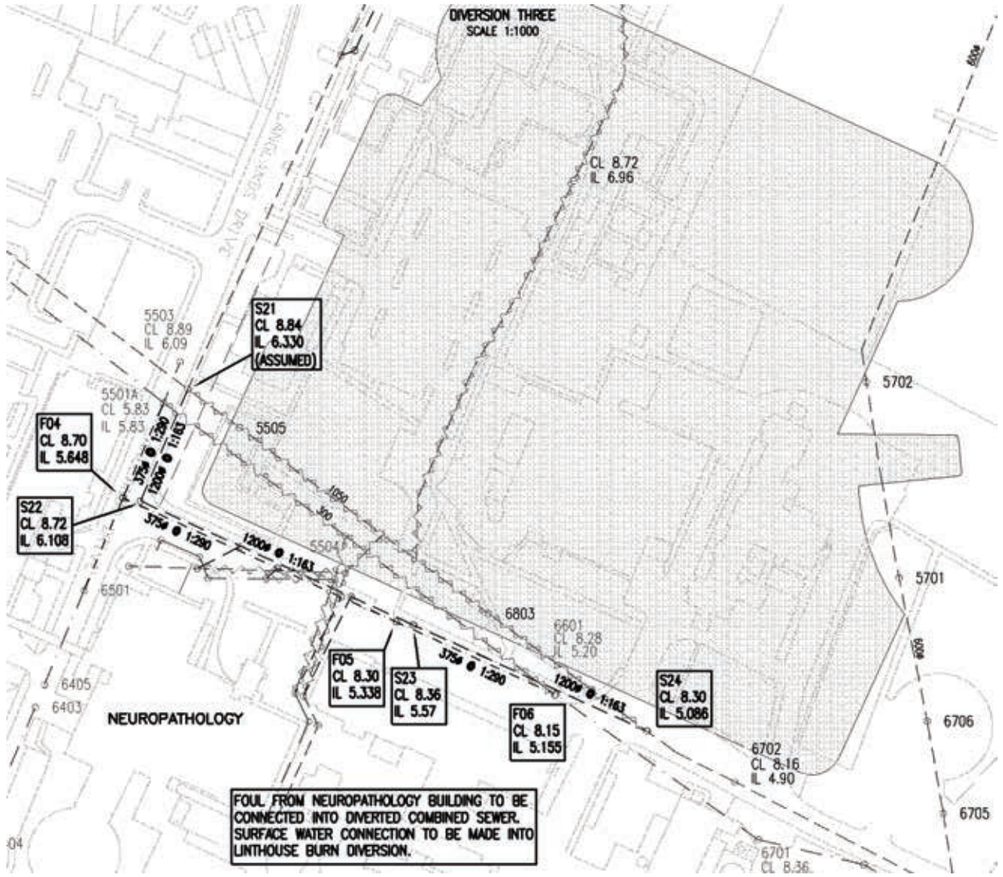

Figure 2.1: Extract from Drainage Diversion Drawing

Approximately two thirds of the foul flows from the new hospital will be connected at a number of locations to the 300mm diameter combined drain which runs under the access road immediately to the east of the building. These flows ultimately connect to the public sewer to the north of the site under Govan Road. The remainder of the foul flows taking the proposed Childrens Hospital, Laboratory and FM buildings will be directed to a new point of connection on the public combined sewer to the west of the site in Hardgate Road.

Flow rate allowances have been made for the maximum rates provided in section 4.3 of the URS Drainage Impact Assessment and Strategy Report 2009. These flow rates would be reviewed during the detailed design stage as the project progresses.

The foul water will be constructed using structured wall uPVC pipes for the majority of drain runs with the exception of those identified as carrying specialist waste. In these instances vitrified clay pipes shall be used incorporating EPDM Rubber seals at the joints.

External service areas that are covered, high pollution risk areas associated with on site processes and the helipad will drain to the foul sewer.

The foul water drainage strategy has been developed in consultation with Scottish Water. Foul drainage shall be designed in accordance with Sewers for Scotland and BS EN 752.

3.0 SURFACE WATER DRAINAGE

3.1 EXISTING SURFACE WATER DRAINAGE

The Hospital site is crossed by two culverted water courses. The principal water course (Linthouse Burn) runs from the south of the site and outfalls to an open section of ditch just to the north of Govan Road. This open section of the watercourse travels north before discharging in to the River Clyde. The River Clyde is tidal at this the point of discharge and therefore the levels in the Linthouse Burn are likely to be subject to change as a result of this influence.

The Jenny's Burn culvert enters the hospital site from the western boundary at Hardgate Road and heads in an easterly direction before connecting to the Linthouse Burn under the existing main access road near the helipad. Evidence from a recent CCTV inspection survey indicates that it is highly likely that the Jenny's Burn is capped off upstream of the hospital site and is probably redundant.

A section of Linthouse Burn is currently situated under the proposed building footprint and will be subject to diversion along a new route under the nearby access road.

The entire length of Jenny's Burn which passes under the site will need to be diverted to avoid building footprints. It is proposed that Jenny's Burn will be routed to the rear of the laboratory and waste compound buildings before heading east to a new point of connection on the Linthouse Burn. Refer to drawing number CD-WS-00-PL-140-07 included as Appendix B.

3.2 Proposed surface water Drainage

The URS DIA report indicates that approximately 3 hectares of the site currently discharges into the Linthouse Burn culvert. A copy of the URS plan showing the areas of combined separate systems is included as Appendix C. We have proposed a scheme which will discharge surface water from all roofs and hardstanding areas into this watercourse with no increase in flow rates to those that currently enter the Burn from the site. The new surface water system will also direct drainage from some areas that currently drain into the combined sewer and discharge these flows into the culvert. The removal of the connections for contributing surface water catchment areas to the on site combined sewers will result in a reduced surface water discharge to the nearby Shieldhall Sewage Treatment Works. The result of this will be a reduction in the dilution of the flows to the treatment works which Scottish Water have confirmed will be beneficial to the operation of the works.

Brookfield

3.2.1 Discharge Rates and Capacity

With the use of source control techniques such as green roofs on some buildings and permeable surfaces on new large hardstandig areas we have been able to increase the time it takes for rain water to enter Linthouse Burn. This attenuation process together with the use of open swales in a soft landscaped area has been modelled using the design software suite WIN DES. The software has helped us to design a new surface water system which carries sufficient self cleansing velocities during a 1 in 2 year design storm and which will not flood at any point during a 1 in 1000 year storm.

3.3 sustainable drainage Considerations

Careful consideration has been given to minimise the impacts the development will have on the quantity and quality of surface water run off leaving the site. SUDS methods which are proposed include the following:-

Green-roof zones above the podium levels of the main hospital building.

Permeable paving areas for the surface level car parking areas and the service yard between the laboratory building and the waste compound.

Surface water swales located in the soft landscaped area to the north of the hospital.

These features perform two main roles in relation to water quality and surface water attenuation. A plan showing the areas that contribute to the SUDS treatment train is included as Appendix D.

3.3.1 Water Quality

All loading bays, service yards and car parks will be drained into lined granular storage areas beneath their surface. This will provide a form of primary treatment. Before discharging into Linthouse Burn all surface water drainage will pass through at least one swale feature to ensure that the levels of treatment are compliant with those described in table 5.2 of the URS drainage Impact Assessment and as directed by CIRIA Report C697.

3.3.1 Amenity

The swale features have been designed to provide the necessary storm water storage but also to add amenity value to the scheme. With regards to planning condition 36 and the fact that the hospital on the flight path of Glasgow Airport, the swales will not be permanent open water features, therefore they will not increase bird activity in the area. With due regard to safety in mind, the swales will be shallow and have gradually sloping sides.

We have developed the surface water strategy in consultation with SEPA, Glasgow City Council and Scottish Water.

4.0 SUMMARY

All foul drainage will be routed to the existing private combined sewers within the site. These flows ultimately drain to the Shieldhall Sewage Treatment Works immediately to the north of the site. Further consultation with Scottish Water will be required following the completion of an area network study before full approval can be granted.

All surface water will be routed to a new point of connection with the Linthouse Burn. The rate of flow will be limited through the use of storm water storage which will be provided to ensure that there is no increase in discharge beyond the current levels to the existing watercourse and the nearby River Clyde. There will be a further drainage area assessment required for the existing watercourses prior to detailed design to examine the effects of existing flows and tidal conditions.

The surface water drainage system has been designed to ensure that there will be no flooding of the system during storm events under a 1:1000 year return period criteria.

There will be a series of SUDS features such as green-roof areas, swales and permeable paving which will address the water treatment guidelines set out by SEPA.

Brookfield

Structural Design Strategy

Section
3.26

Deliverable
Structural Design Strategy which should include:-

- Outline description demonstrating understanding of topography, geology, soil conditions, contamination, ground water, history, services
- Demonstrate outline principles or design including, general description, stability, joints, floors, vertical structure, foundations, stairs and ramps, retaining walls, earthworks, slope stability, drainage, external works etc.
- Design Standards and Sources of Reference (Codes of Practice and Standards)

The structural design strategy report has been prepared to demonstrate a thorough understanding of the situation and condition of the existing site and the complexities of addressing the limitations of constructing the new hospital facility there. The report also demonstrates that the design issues specific to complex hospital buildings are understood and have been addressed with reference to relevant design standards.

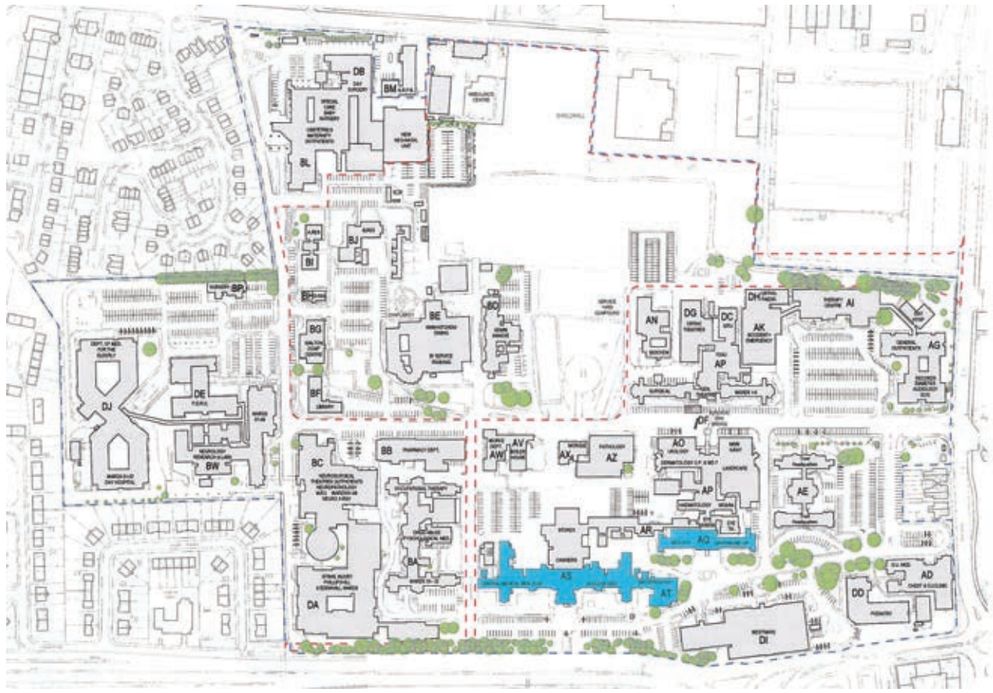

Figure 1.1: Existing Site Plan

1 Existing Information

1.1 THE SITE

1.1.1 Location
The site is located at approximate OS grid reference 253298,665707 and is part of the overall existing Southern General Hospital complex. The complex is bounded by Govan Road to the north, Hardgate Road to the west, the A739 to the east and Shieldhall Road to the south. Local landmarks in close proximity include junction 25 on the M8 motorway to the south, Scottish Water Shieldhall Waste Water Treatment Works to the west. Existing and proposed site plans are shown on figures 1.1 and 1.2 respectively, below.

A48235836

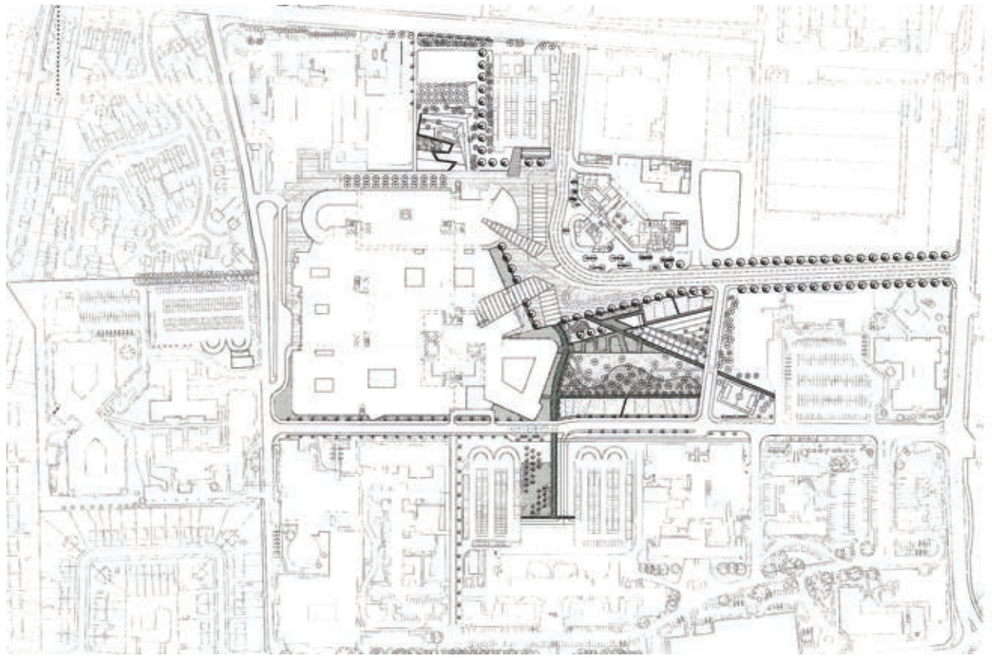

Figure 1.2: Proposed Site Plan

1.1.2 Building Footprint

The proposed building footprint area is currently occupied by existing buildings, roads, footpaths, car parks, vegetated areas etc and is underlain by existing drains, sewers, culverts, ducts and services. The buildings are to be demolished and all underground infrastructure is to be removed by the Board and a clean and clear site provided to the contractor ready for construction. This work will be carried out in phases with some parts of the overall site not being made available to the contractor until later in the programme due to being required to remain operational until after the new building has been constructed and operational.

1.1.3 Ground Conditions

Information on the site ground conditions has been derived from the preliminary Site Investigation Report information prepared by URS Corporation and provided by the Board. This report is provided at “Draft” status as results from contamination and geotechnical testing and monitoring are outstanding. The report further notes that it has been carried out to provide an indication of the conditions on site with further detailed investigation work being required to facilitate the final design and negotiations with the statutory regulators.

Therefore any assumptions with regard to contamination status and ground conditions are subject to review. Additional historical reports procured in support of various works that have been carried out at the site have also been provided and reviewed.

1.1.4 Contamination

A review of the available data from the reports notes that contamination testing in the historical reports is limited (except URS 2009) and the screening tools applied are no longer acceptable best practice. Made ground containing ash has been observed on site as a potential contaminant source beyond land use operations. The most recent reporting of URS 2009 including analytical results, gas and leachate testing are assumed to present the latest and most robust assessment of the site. This data remains outstanding, however a review of the raw analytical results by WSP suggests that the hazard at the site is low. This requires to be confimed however, following receipt of outstanding test data.

The full text of the contamination review is included in Appendix A.

1.1.5 Geotechnical

The solid geology plan for the site (Scotland Sheet 30 – Solid Edition) indicates the solid strata beneath the site to comprise the limestone coal group to the south and east of the site with the lower limestone group elsewhere. An igneous intrusion is shown to run from SE to NW across the middle of the site. A fault is recorded trending south east to north west towards the northern part of the site with the down throw to the south.

The exploratory hole records from the Norwest Holst factual report and bam Ritchies ground investigation report indicate the following sequence of strata:

Stratum	Depth to top of Stratum (mbegl)	Thickness (m)
Made Ground	0	0.4 – 3.0
Peat*	1.3 – 1.6	0 – 0.7
Alluvium	0.4 – 3.0	3.5 – 23.8
Glacial Till	4.1 – 24.8	0.3 – 19.5
Bedrock	17.4 – 26.3	-

*Only encountered within BH09 & BH17

Brookfield

Made Ground
Made ground was generally encountered across the site. The made ground encountered generally comprised a very loose to loose sand occasionally containing fragments of brick, ceramics, shale, clinker, cinders or sandstone. The surface or near surface deposits include re-worked naturals soils, imported granular materials for road and hardstanding construction, imported topsoil and vegetated areas etc.

Alluvium
The alluvial deposits at the site generally comprise sand underlain by clay then silt. The sand is typically a very loose yellow brown slightly silty sand. The underlying clay generally comprises a very soft brown slightly sandy clay. The silt, where present normally comprises an un-compact grey very sandy silt with laminations.

Glacial Till Deposits
The glacial till encountered is typically a stiff and very stiff grey slightly sandy slightly gravelly clay with occasional cobbles.

Bedrock
Bedrock encountered comprises mostly moderately weak to moderately strong mudstones and sandstones with very closely to medium spaced sub vertical and sub horizontal discontinuities. Strong Siltstone is encountered in places. An intrusion of dolerite was encountered in the middle of area 1B.

Groundwater
Groundwater monitoring records for the main site area have not been made available. Once available, this section will require to be revised. Groundwater observations made during the drilling works indicate that groundwater in some areas may be encountered at shallow depths, i.e. within 3m of ground level. Although not specifically recorded in the reports supplied, given the nature of the superficial deposits and the proximity of the river, it would not be unreasonable to expect ground water levels to be up to 1.0m below existing ground level at times. This will vary due to seasonal and tidal effects.

The full text of the geotechnical review and recommendations is included in Appendix B.

2 Design Information

2.1 ARCHITECTURAL DESIGN PROPOSALS

2.1.1 Building Design
The main accommodation comprising outpatients, accident and emergency, theatres, imaging, support services etc is housed in the ground, first and second floor levels which covers the entire building footprint while the adult wards are housed in medium rise multi-storey section which extend over approximately one third of the overall footprint. Plans showing the relationship of the various departments are shown in figure 2.1 below.

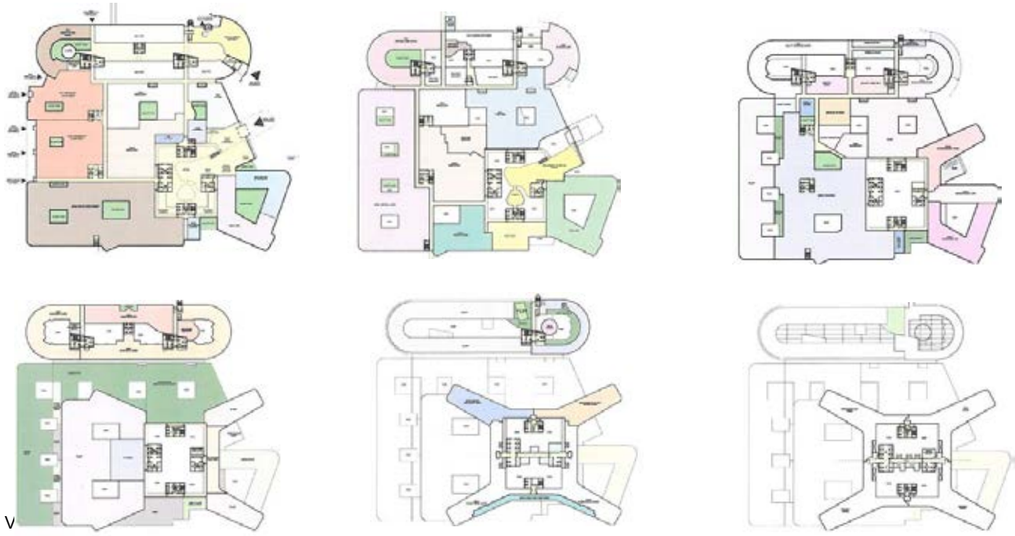

Figure 2.1: Architectural Departmental Plans

2.2 STRUCTURAL DESIGN PHILOSOPHY

2.2.1 Optioneering

The team reviewed a number of potential options for the building structure and assessed these based on compliance with the Employers Requirements (ER's), structural efficiency, buildability, flexibility, availability of materials and labour, economy, services integration, structural depth, sustainability, embodied energy, thermal mass, recyclability, fire resistance and vibration response.

In summary, the structural form for the main buildings with the highest ranking, and therefore adopted, was that consisting of cast in-situ reinforced concrete (RC) flat slab floors supported directly on columns without downstand beams or structural screeds.

This selection will be periodically reviewed and updated by the team to ensure that the principles on which it was made are still current.

Variations such as post tensioning and / or lightening dead loads using proprietary slab void formers may be included subject to the costs and potential risks in adopting these measures being satisfied. A schedule of possible variations and associated comments is included in Appendix C.

2.3 SUPERSTRUCTURE

2.3.1 Structure

The building is approximately 180x180m square on plan with most of the clinical functions being provided in the three to five storey "podium" area which is situated over most of the plan footprint. Departments and functions primarily serving the children's block are grouped to the west side of the podium while the adult wards are housed in a tower on levels five to twelve projecting above the podium. Plant is accommodated in various locations in the podium but primarily at the interstitial level five and on top of the adult ward tower roof. A helipad is incorporated on top of one wing of the ward block roof.

The building super structure is of in-situ RC flat slab construction with precast RC columns. The columns are arranged on a relatively regular grid with a maximum span of 7.5m. Internal columns are generally of square section with those situated on the building perimeter being rectangular blade columns to co-ordinate with the room arrangement and external wall construction.

Storey heights are generally 4.5m at ground, first and second floor levels, 5.4m at level four and 3.8m at the adult ward levels thereafter.

The slab thicknesses have generally been dictated by the vibration response requirements, particularly for theatres, imaging and wards and are shown on the structural drawings included in Bid Deliverable Reference 2.22. Refer also to section 3.5 of this report.

Plots from the structural analysis model are shown in figures 2.2 and 2.3, below.

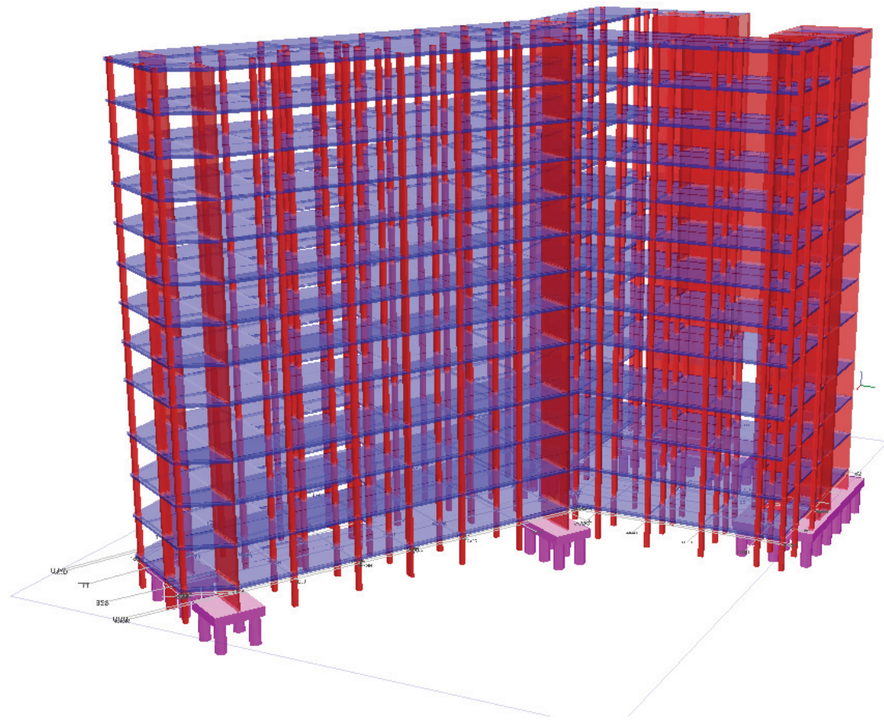

Figure 2.2: 3D View of Structural Analysis Model

Brookfield

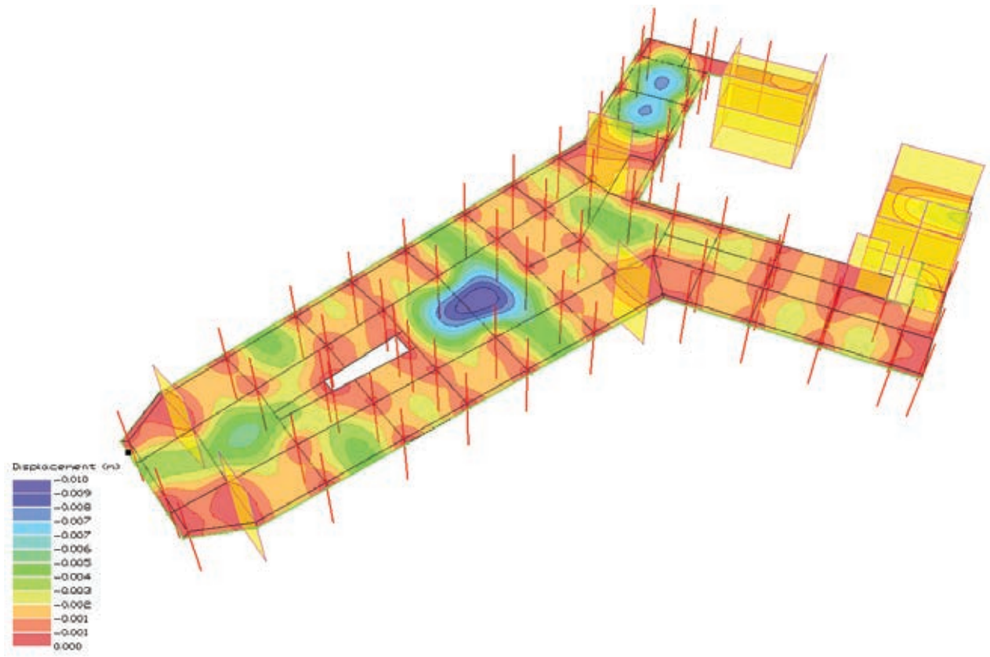

Figure 2.3: Contour Plot From Structural Analysis

2.3.2 External Walls

The external walls are understood to be of a proprietary panel glazed cladding system to the towers and a rainscreen cladding to the lower floors, all as specified by the architect. It is understood that these are designed to be fixed to, and span, between floor slabs, therefore no additional secondary support or restraint structure is required.

2.3.3 Internal Walls

Internal walls are generally non-loadbearing partitions for maximum flexibility and are to the architect's details.

2.3.4 Plant Rooms

Plant rooms serving the adult wards are situated on the tower roofs and are generally constructed of simple steel framing with sheet metal cladding roofs and walls on lightweight steel purlins and side rails.

Plant rooms serving the accommodation at the podium levels are situated between levels 2, 3 and 4. In these locations they can be housed within the concrete framed structure or in lighter weight steel framed enclosures as above, constructed on top of the main concrete superstructure.

2.3.5 Roofs

Roofs separate from the plant rooms generally comprise the upper level slab of the concrete framed structure and have a "green roof" finish to the landscape architect's details or a waterproof membrane finish as per the architect's details. Proprietary fabric ETFE roofs are proposed over the atrium spaces in the ward tower and children's block.

2.3.6 Stairs

The stairs generally will be constructed of precast concrete. These will be pre-fabricated off site and mechanically lifted into place as soon as the floor construction sequence allows to provide a safe means of access for construction operatives prior to being finished for their final use by the building occupants.

2.3.7 Atrium Upper Corridor Structure

A corridor at each level of the adult wards links the north and south stair and lift cores spanning 12m across the open atrium space below. There are also smaller rooms projecting from the sides of the corridor. This structure is a multiple storey height steel girder supported on and spanning between the concrete cores. The projecting rooms will be formed of braced lightweight framed boxes which will cantilever from the main girder structure.

2.3.8 External Link Bridges

Corridors are required to link the new main hospital building at first floor level to the existing maternity and neurosciences buildings adjacent. These corridors must span over existing roads and access areas and have been conceived as lightweight bridge structures separate from the main building. They are formed from a steel framed box structure with composite steel decking concrete slab floors.

Brookfield

2.3.9 Builderswork in Connection with Services and Equipment

The services for each department are generally fed vertically through a dedicated service riser in each block passing through each floor and then distributed laterally through the block. The risers are typically located around lift and stair cores (although some are discrete) and effectively form holes in the slab that have to be taken into account in its structural design. Holes are also required to accommodate penetrations through the slabs for drainage pipes and other services. The main grouping of services distribution laterally is above the corridors and the design load adopted allows for the concentration of loading in these locations. The flat slab design adopted allows uninterrupted routing of the services along the ceiling without obstructions such as downstand beams etc. Cast-in channels have been allowed in the slab soffits to facilitate post fixing of bracketry to suspend services and equipment where known without the requirement for drilling.

The main plant items are housed in the dedicated plant rooms generally located on the roof of each block. Exceptionally heavy items such as MRI scanners, UPS batteries and water tanks have been identified and have been checked against the design load allowance for plant areas. Other items of plant are within the design load allowance for their location.

Other specific loads for medical equipment are being continually identified as and when possible and checked against the design load allowance and the actual structure design for their respective areas.

2.3.10 Energy Centre

The items of plant providing the main heat and power for the hospital complex are housed in the energy centre building separate from the main building and adjacent to the laboratories. This building is also conceived as an open plan concrete framed structure with masonry external walls to the ground floor level and metal faced cladding on cold rolled side rails above.

2.3.11 Laboratories and FM Buildings

The laboratories, mortuary, waste transfer and facilities management functions are housed in a combined building separate from the main hospital and adjacent to the energy centre. The building links to the main hospital by an underground tunnel to allow discrete and uninterrupted transfer between the areas by porters and remotely operated trolley vehicles (robots).

This building is also shown as a concrete framed structure similar to the main building.

The design of this building has been carried out up to scheme stage by the Board adviser team and as noted previously, WSP (and other team members) do not at present have a design remit for this area. The team has however reviewed the design and identified some possible amendments that could be made to incorporate some of the areas within the main hospital and / or energy centre building. Therefore drawings are included showing the revised building structure for consideration by the Board.

2.4 BUILDING STABILITY & MOVEMENT

The stability of the building will be considered for wind loads, seismic loads and code defined notional loads.

2.4.1 Wind Loading

Lateral wind loads acting on the building are transferred from the outer walls to the floor slabs at each level. The floor slabs act as stiff diaphragms to transfer these forces to full height RC shear walls or braced bays in the opposing direction and thus to the foundations. The walls comprise a mix of stair and lift shaft core walls and other independent concrete walls located throughout the structure, co-ordinated with the architectural layouts.

2.4.2 Seismic Loading

Seismic loading is not considered appropriate for a building at this location.

2.4.3 Disproportionate Collapse

The building will be designed in accordance with the current British Standards to avoid a situation where damage to a small area of structure or failure of a single element leads to a disproportionate collapse of a major part of the structure.

This system will provide an increased redundancy in the structure and alternative paths for the redistribution of loads should a destructive event occur.

2.4.4 Movement

The building structure will move throughout its life due to thermal effects, drying shrinkage, creep, wind loading etc. This movement is accommodated by splitting the building into blocks and incorporating movement joints at the interfaces. The joints are formed in the faces of the slab junctions and allow movement laterally in one or two directions but not vertically.

Joints are typically positioned to suit the grouping of various clinical functions and also to avoid joints passing through critical areas for cleanliness such as theatres and treatment rooms.

2.5 SUBSTRUCTURE

2.5.1 Foundation Strata

The existing ground is known to consist of approximately 20m of superficial deposits comprising made ground, alluvium and glacial till overlying sandstone and mudstone rockhead with the water table noted to be very high and possibly within 1m of ground level at times.

These deposits have been assessed as being unsuitable to accommodate foundations loads of the extent and magnitude of those required for the new buildings, therefore a non-standard solution will be required. This will involve a deep foundation solution, such as piling.

2.5.2 Foundation Design

A detailed review and assessment of all available information has been undertaken by WSP in-house Geotechnical Engineers in conjunction with discussions with specialist piling contractors. A variety piling options were considered as potentially suitable with varying cost and programme benefits and associated risks.

The review concluded that fluid supported rotary bored cast insitu reinforced concrete piling socketed into rock is the most suitable least risk option and the details have been prepared on this basis. Other options may give economy and programme benefits but carry associated greater risk. There is currently insufficient site investigation and geotechnical testing data to conclusively mitigate or address these risks. The risks and benefits of utilising any other method will continue to be reviewed and the most suitable system selected when all information has been received and incorporated. A schedule of possible variations and associated comments is included in Appendix C.

Working load capacities for various diameters of pile have been established and comparison of these with calculated column loads has allowed a number of piles per column foundation to be established and these are shown on the drawings submitted. Pile cap requirements per column location have also been established and are shown on the drawings.

The pile sizes have been selected such that the minimum load requirement has a three pile pilecap group which will be stable in the temporary condition without additional ground beams being required for lateral restraint. This will allow the superstructure frame to commence construction prior to the remainder of the substructure being in place. The installation of drainage and other services under the ground floor slab can also proceed unhindered by ground beam obstructions.

The piles will require to be temporarily cased through the made ground deposits and fluid support will be used while drilling through the alluvial deposits. All piles will also be drilled through the glacial till and socketed into the upper layers of the bedrock to transfer loads without differential settlement.

2.5.3 Shear Wall Foundations

Shear wall foundations will generally be of an extended pilecap linking multiple piles in a group to transfer the lateral stability loads rockhead.

2.5.4 Basement Structure

The excavation and construction of a basement on this site and the maintenance of its watertightness is potentially a significant undertaking and expensive option given the poor soils and groundwater regime on this site. Therefore, as part of the process discussed in 2.2.1, the design team has examined the design requirements to establish if the basement can be omitted and the planned accommodation re-located elsewhere while maintaining the required operations of those departments. The team has established that some, but not all, of the accommodation can be successfully relocated resulting in a less extensive, easier to construct and more economic basement being required. The basement area is linked by a tunnel to the facilities management and energy centre complex to facilitate the distribution of services and the transport of goods into and waste out of the hospital.

The basement and tunnel structure could be constructed of insitu concrete walls, interlocking secant piles, or sheet piles.

As in section 2.5.2 of this report, there are risks, limitations and benefits associated with each option and these are discussed in Appendix C. At present the rotary bored hard/firm secant piled wall with secondary concrete lining has been assessed as the most suitable least risk option although this will be continually reviewed as more relevant information is made available.

The piled wall will be designed as cantilevering in the temporary condition and propped by the basement and the ground floor slabs in the permanent case. The firm piles will require to be drilled at least into the glacial till to prevent water within the alluvial deposits transferring under the base of the piles and into the basement excavation. The wall can also be designed to align to the column positions from above and therefore the hard piles at these locations will require to be drilled to rock to transfer the loads as per section 2.5.2. The basement floor will be effectively suspended and will span between and be supported from the piled wall and resist uplift from water in the ground.

2.5.5 Basement Waterproofing

The basement walls will be designed to resist water penetration and provide accommodation to Grade 3 standard to BS 8102 ie a dry environment. This will be achieved primarily by the interlocking secant wall with a secondary cast-insitu internal waterproof concrete floor and wall lining incorporating sufficient reinforcement to limit crack widths and hydrophilic seals where appropriate.

2.5.6 Ground Floor Slab

As noted above, the founding strata is also unsuitable for supporting a ground bearing slab without improvement and therefore a suspended slab design has been adopted. This will be similar to the upper slabs and of cast insitu RC and will be two-way spanning between the column foundation pilecaps.

Brookfield

2.6 EXTERNAL WORKS

2.6.1 Earthworks

The formation of the new building and associated infrastructure will require significant excavations, movement of materials and work in the ground. It is desirable from a cost, nuisance and sustainability perspective to minimise these works and also the export and import of materials. The proposed level for the buildings has been developed to allow as much as possible of the existing soils to remain insitu and for the new works to effectively be constructed on top. This is possible as the building foundations will be piled and the ground floor slab will be suspended.

Some suitable construction hardcore material could be gained from the demolition works and site strip subject to agreement with the Board. There will also be a significant quantity of arisings from basement, pile, pilecaps, drainage and services excavations but these will generally be of poor quality soils as noted in section 1.1.3. It may be possible to remediate these soils on site with cement or lime to enable them to be re-used as non- structural fill in landscaped areas or under suspended slabs and this will be the subject of further investigation works.

2.6.2 Drainage

New drainage will be provided to serve the new buildings and to incorporate the existing site drainage where affected by the removal of existing buildings and the positioning of the new building. The new system will incorporate separate foul and surface water networks and will be designed to ultimately connect to existing infrastructure within the hospital complex. The drainage design philosophy is the subject of a separate deliverable report reference 3.25 included in the overall submission.

2.6.3 Roads and Hardstandings

The layout of the road network and external hardstanding areas has been designed by the landscape architect with input from WSP on layout, traffic flows and junction geometry. Surface finishes are generally of traditional paving materials and details of the construction make-ups are shown on the drawings. These generally comprise granular sub-bases with bituminous macadam or small element paved concrete or stone paving upper layers.

As the near surface soils are in made ground, it is anticipated that in-situ CBR values will be low and that the roads and hardstandings will require the sub-base to be enhanced with a granular hardcore capping layer below.

3 Structural Design Criteria

3.1 DESIGN STANDARDS

3.1.1 General

British Standards will generally be adopted for the structural design. Some of the main relevant titles are noted below.

BS 5606: Guide to accuracy in building

3.1.2 Loading

BS 648: Guide to the weights of construction materials

BS 6399: Loading for Buildings.

- Part 1: Code of Practice for dead and imposed loads
- Part 2: Code of Practice for wind loads
- Part 3: Code of Practice for imposed roof loads

3.1.3 Concrete Works

BS 8500: Concrete - Method of specifying and guidance for specifier

BS 8002: Code of practice for earth retaining structures

BS 8004: Code of practice for foundations

BS 8007: Code of practice for the design of aqueous liquids

BS 8102: Code of practice for protection of structures against water from the ground

BS 8110: Structural use of concrete

- Part1: Code of practice for design and construction
- Part 2: Code of practice for special circumstances
- Part 3: Design charts for singly reinforced beams, doubly reinforced beams a rectangular columns

3.1.4 Steel / Composite Works
BS 5950: Structural use of steelwork in building

Part 1: Code of practice for design in simple and continuous construction: hot rolled sections.

Part 2: Specification for materials, fabrication and erection: hot rolled sections.

Part 3: Section 3.1: Code of practice for the design of simple and continuous composite beams.

Part 4: Code of practice for design of composite slabs with profiled steel sheeting.

3.1.5 Masonry
BS 5628: Code of Practice for use of masonry Part 1: Structural use of un-reinforced masonry.

3.1.6 Regulatory
UK Building Standards 2003.

3.1.7 Other
Current industry guidance and best practice will also be used and adopted where appropriate (eg Concrete Society, CIRIA, SCI, BCSA) as well as WSP Group Technical Centre internal published recommendations for design betterment.

3.2 UNITS
The structural calculations will be completed using the following units.

- Length: m and mm
- Mass: Kg and tonne
- Force: N and kN
- Stress: N/mm_, kN/mm_ and kN/m_
- Moment: kNm and Nmm
- Velocity: m/s and km/hr

Acceleration: m/s_ and proportion of g

3.3 DEFLECTIONS AND TOLERANCES
Deflections and tolerances will be the subject of a separate Movement and Tolerances Report that will be prepared following contract award, to describe these elements in more detail.

3.3.1 Deflection Generally
Details of deflection criteria for structural elements will be provided in the Movement and Tolerances Report.

Spandrel beam/slab edge live load deflection:

span / 360 or 12mm (beam / slab supported at each end)

span / 300 or 12mm (cantilever beam / slab)

Interior beams / slabs live load deflections:

span / 360 or 20mm (beam / slab supported at each end)

span / 180 or 20mm (cantilever beam / slab)

3.3.2 Horizontal Sway (Wind)
The movement criteria used for the design of the core walls are defined as follows:

Overall sway deflection of the building due to design wind load < H/500 where H = height of the building

Sway deflection of any one storey (to be accommodated by the perimeter cladding) < h/500 where h = storey height

The design wind load used in conjunction with these design criteria is the 1 in 50 year design wind speed.

3.3.3 Foundation Movement
Details of foundation movements will be provided in the Movement and Tolerances Specification that will be prepared following RIBA Stage D. All foundations are designed to be piled to rockhead thus limiting total and differential settlement to a minimum.

3.4 BASEMENT WATERPROOFING
Basement waterproofing will be designed to suit the following intended uses as defined by BS8102 table 1.

Mechanical plant rooms	Grade 2
Accommodation / circulation areas	Grade 3

3.5 VIBRATION LIMITS
The floor structures will be designed in accordance with the A Design Guide for Footfall Induced Vibration of Structures and Hospital Floor Vibration Study by The Concrete Centre.

The design guides recommend that the floors should be assessed on the basis of their response to an appropriate near-resonant component of a regular walking force. The criterion adopted for the design of floor beams on all occupied (non-plant) floors is as follows:

Theatre & Imaging Floors:	Response Factor R < 1
Wards Floors:	Response Factor R < 2
All other areas (non plant):	Undefined

Brookfield

3.6 EXPOSURE CONDITIONS

In accordance with BS8110-1 table 3.2, the following exposure conditions are adopted for the design of the structure:

Substructure	
Piles generally	Moderate
Retaining Walls	Moderate
Basement Walls	Moderate
Basement Floors	Abrasive
Superstructure	
Internal floors, columns and walls	Mild

3.7 DURABILITY OF THE STRUCTURE

The structure is to have a design life of 70 years. Some structural elements, such as those with concrete wearing surfaces and corrosion protection will require periodic inspection and maintenance.

Steelwork members that are inaccessible and not easily maintained will be designed for the loss of steel section over the 100 year life of the building.

The substructure perimeter retaining walls will be designed in accordance with BS 8500-1: 2002, and satisfy this standard for the most onerous structural performance level, being a structure of long service life (more than 100 years).

3.8 FIRE RESISTANCE PERIODS

The following fire resistance periods have been assumed in the design of the structure:

Superstructure generally: 2 hours

Substructure generally: 2 hours

Medium duration compartmentation and short duration sub-compartmentation between / within departments and rooms for fire protection will be provided by the partition walls and ceilings specified by the architect. Isolated higher risk areas or fire hazard rooms exist within the building and these will also be separated by walls or partitioning specified by the architect.

Fire engineering is the subject of a separate deliverable report included in the overall submission.

3.9 MATERIAL PROPERTIES

3.9.1 Substructure concrete:

Piles, pile caps, ground beams, pad foundations, strip foundations, basement slabs, retaining walls and ground bearing slabs: Grade RC40 concrete.

Blinding or mass fill concrete (if required): Grade Gen 1 concrete.

3.9.2 Superstructure concrete:

Internal and external insitu RC columns, walls beams, upper slabs, roof slabs: Grade RC40 concrete

3.9.3 Reinforcement:

Reinforcement type ‘A’: grade 500, deformed type 2 conforming to BS 4449.

Fabric reinforcement conforming to BS 4483.

3.9.4 Structural Steelwork:

Grade S275 or S355 (in accordance with BS EN 10 025).

A48235836

4 Structural Design Loads

4.1 DEAD LOADS

4.1.1 Self Weight Dead Load

The self weight dead loads are calculated form the known density and geometry of the element under consideration.

4.1.2 Superimposed Dead Loads

Additional allowance is made for the fixed finishes and services as follows:

Typical Hospital / Office Floors	
(Floor finishes, ceiling, services and fixed equipment below)	2.5 kN/m_
Plant Rooms	
(ceiling, suspended services)	2.5 kN/m_
Green Roof	
(Finishes, insulation, tapered slab, ceiling and suspended services)	3.0 kN/m_
Other Roof	
(Finishes, insulation, tapered slab, ceiling and suspended services)	0.5 kN/m_
Perimeter Wall Cladding	10 kN/m

4.2 IMPOSED LOADS

4.2.1 Design Imposed Loads

Floor loadings have generally been standardised throughout the building floor plates to allow for future flexibility and to simplify design, detailing and construction. Specific exception loads for large items of plant or medical equipment will be included over and above these loads where necessary.

The following loads have been adopted in the design in kN/m_

Clinical / Admin Areas	4.0
Partitions	1.0
Staircases & Cores	5.0
Circulation Areas	5.0
Plant areas	7.5
Tower roof (with maintenance access)	7.5
Podium roof (access for maintenance only)	1.5
Plant roof (no access)	0.8

4.2.2 Environmental Loads

Wind and snow imposed loads acting on the main building frame and the various elements of cladding will be determined from BS 6399 Part 2.

4.2.3 Notional Loads

The building is designed to resist notional lateral loads applied at each floor simultaneously equal to 1.5% of the characteristic dead weight of the structure, as stipulated in BS 8110 Part1. This is an ultimate load and is applied in multiple directions.

4.2.4 Lift Loads

All lift shaft walls and lift motor room slabs will be designed to all dead and imposed loading information loadings provided by the lift consultant.

4.2.5 Temporary Hoist and Crane Loads

The permanent structure will be designed to support the loads from the temporary cranes and hoists required by the Contractor.

4.2.6 Construction Loads

To be determined by the Contractor and any enhancement to the structure required to account for such loads to be determined by the Contractor’s temporary works engineer and included in the construction requirements.

4.2.7 Piling Plant Loads

Loads from piling plant are to be accommodated by a temporary piling mat designed by the contractor’s temporary works engineer.

Brookfield

Appendix A WSP SI Review - Contamination

New South Glasgow Hospital: Summary Land Quality Review.

The following reports have been provided for summary review in no particular chronological order. Note that salient points only have been extracted for consideration. It has not been WSP's objective to reiterate the findings of others, should further clarification be sought then reference to the original source materials is recommended:

- Aitken laboratories Ltd. Fax Message dated 5th Feb 2003;
- Ove Arup and Partners. Drawing No. 1481-2, date unknown;
- Nicholson Site Investigation, Site Investigation Report, Southern General Hospital, Dated September 1989;
- Fugro, 1985, Soils Investigation Report, Proposed Geriatric Units at Southern General Hospital, Glasgow, Reference 85/2580;
- Ove Arup and Partners 1998, Proposed Extension to Oral and Maxillofacial Unit, Southern General hospital, Glasgow Reference 53500\980129a.rep;
- URS, 2007. New Laboratory Facility at Southern General Hospital, Substructure Options Report. Reference 49339768;
- Rocksoil, 1998. Site Investigation at Southern General Hospital, Glasgow. Reference S97/1496;
- Thorburn and Partners, 1978. Southern General Hospital, Glasgow. Proposed Redevelopment, Geotechnical Study. No reference;
- Wimpey Environmental Ltd, 1994. Proposed Geriatric Unit Southern General Hospital, Glasgow. Reference SULY/7523; and
- URS, 2009. Preliminary Geo Environmental Report. New Southern General hospital. Draft. Reference 49339768/GL:RP0010.

Comments on these reports are provided below, followed by our overall conclusions and recommendations. It should be noted that WSP has not provided comment here on the geotechnical content (including mineral stability sections) of these reports. We have concentrated solely on the environmental aspects of the above reporting. Such review works are however to be delivered under separate cover by WSP.

Aitken Laboratories Ltd - Fax Message dated 5th Feb 2003.

- This document presents borehole logs denoted as BH1 and BH2 plus trial pit logs for 7 locations across an area of circa 480m2 in association with a proposed new theatre suite;
- No chemical test data is provided nor interpretation beyond factual logs;
- Maximum trial pit depth was 1.6m bgl and borehole depth was 6.0mbgl;
- Of note is made ground to a maximum observed depth of 0.75m bgl including ash, clay, gravel and bricks. The observed ash may be associated with PAH type contamination;
- Rockhead was not proven; and
- Below the observed made ground loose to medium dense sands and gravels were reported.

Ove Arup and Partners. Drawing No. 1481-2 date unknown.

- Inclusion of a site plan denoting borehole and trial pit locations in proximity to the sites Psychiatric Department;
- Two boreholes records are included neither without installation notes nor to British Standard nomenclature. These boreholes however support the observation of sands, gravels and boulder clay.

Nicholson Site Investigation, Site Investigation Report, Southern General Hospital, Dated September 1989.

- Delivered in support of the construction of a Spinal Unit at the request Beattie Watkinson Partners Consulting Engineers to the Greater Glasgow Health Board, works delivered included boreholes and laboratory testing;
- 3. No boreholes were advanced to a maximum depth of 18m bgl;
- No madeground was reported. Alluvium and glacial till dominated observations in this area of site;
- Groundwater's were observed 2-3m bgl;
- Factual reporting testing and interpretation were restricted to geotechnical issues only.

Fugro, 1985, Soils Investigation Report.

- Delivered in support of the construction of a 30 bed Geriatric Unit at the request Andrews, Kent and Stone Consulting Engineers to the Common Services Agency, works delivered consisted of four static cone penetration tests with two trial pits to inform foundation solutions;
- Chemical testing was limited to sulphate and pH;

- Madeground fill was again observed to a maximum of 1.3m including “slag waste” as a potential source of contamination. No testing of these materials were delivered compliant with an assessment of land quality;
- A near neutral pH was however observed and a total sulphate content of less that 0.5% was observed in the north of the target area while sulphate resisting cement was recommended elsewhere.

Ove Arup and Partners 1998, Proposed Extension to Oral and Maxillofacial Unit.

- Appointed as consulting civil and structural engineers for the scheme the reported intrusive works were delivered for the design of sub structures and land contamination;
- The ground investigation was performed by Wimtec Environmental 1997;
- Five boreholes were advanced by cable percussive drilling rig. All boreholes with the exception of BH5 were then advanced into rockhead by rotary drilling;
- Seven trial pits were advanced (5 by hand and 2 by excavator) to obtain soil samples for geotechnical and chemical testing;
- Selected samples of made ground (9 total) were assessed for a general suite of contaminants;
- No leachate, groundwater or gas testing was progressed;
- Groundwater levels were observed between 1.5 and 4.3m bgl;
- The use of ICRCL screening values is not considered in line with current UK best practice, however observation of the analytical results suggests limited concerns with the exception of
  - A maximum solvent extractable matter of 3162mg/kg;
  - High Copper concentrations
  - Absence of appropriate PAH and TPH testing that would be requisite in the presence of ash filled madeground limits the value of this investigation however under changes in best practice.

URS 2007, Laboratory Facility at Southern General Hospital, Substructure Options Report.

- Delivered by URS to assist in the building of a mixture of 4 and 5 storey structures with partial basements accommodating mortuary, facilities management and laboratory spaces;
- Ground conditions recorded were in summary – madeground consisting of silty gravelly sands or clayey ash fill ranging in thickness between 0.5 and 4.56m, underlain by granular alluvial deposits and then glacial till;
- Bedrock was encountered 16.8 to 27.7m bgl as generally moderately weak to moderately strong inter bedded sandstones, siltstones and mudstones;
- Groundwaters were monitored between 0.65 and 4.98m bgl;
- Artesian conditions were encountered in a single borehole;
- No borehole logs, chemical testing or gas monitoring results were reported for comment.

Rocksoil, 1998. Site Investigation at Southern General Hospital, Glasgow.

- Commissioned upon the instruction of Fleming Consultants of Glasgow to assess the engineering properties of the soils on site, fieldworks were performed in November and December 1997;
- Works were limited to 2 times 150mm boreholes (BH1 and BH2) to depths of 17.45 to 17.70m respectively;
- Testing was restricted towards geotechnical classification, strength and compressibility together with sulphate and pH;
- Chemical, gas, groundwater and leachate testing compliant with current best practice was again absent;
- Of note however was ash rich madeground in BH2.

Thorburn and Partners, 1978. Southern General Hospital, Glasgow. Proposed Redevelopment, Geotechnical Study.

- Committed by Greater Glasgow Health Board across an area of ~7.9ha this reporting pertains specifically to geotechnical observations;
- Works included the advancement of 10 boreholes and geotechnical testing;
- Madeground was noted to a maximum depth of 5.2 mbgl;
- No comments again made in regards to land contamination.

Wimpey Environmental Ltd, 1994. Proposed Geriatric Unit Southern General Hospital.

- Delivered as an “Environmental Audit” on the instructions of Wimpey Healthcare Limited” to provide information on ground conditions for foundation designs in support of a new geriatric unit build;
- 7 soils samples were retained for testing of madeground materials;
- Confirmation of the chemical test suite appears to be unavailable. However main body reporting denotes screening against ICRCL and Kelly values (no longer deemed as acceptable). Concentrations of analytes are not reported by WSP comment yet Wimpey observe that recorded levels were below thresholds assuming landscaped open areas;
- High levels of boron, copper, zinc and nickel were however noted as phytotoxic requiring the importation of clean fill.

Brookfield

URS, 2009. Preliminary Geo Environmental Report. New Southern General hospital. Draft. Reference 49339768/GL:RP0010.

- Appointed by Currie and Brown in September 2008 the aim of this reporting has been to deliver compliant Phase 1 and Phase 2 reporting for 3 areas within the footprint of the Southern General Hospital;
- Reported in “Draft” awaiting final copy;
- 3 distinct areas have been defined
  - Area 1 at 9ha (subdivided into areas 1a and 1b);
  - Area 2 at 0.9ha; and
  - Area 1B at 0.95ha.

Site Investigation and Sampling Strategy

- URS did provide a summary of exploratory hole rationale stating that exploratory holes were placed to provide general coverage across the site post Phase 1 desk study reporting.
- A total of 41 trial pits have been mechanically excavated to a maximum depth of 4.4 metres below ground level (m bgl).
- 3 No light percussion boreholes were installed with groundwater/ground gas monitoring installations to a maximum depth of 5.0 m bgl in Area 1B.
- 45 No cable percussion boreholes advanced to a maximum depth of 15-29.4 m bgl.
- 23 No rotary boreholes were advanced to a maximum depth of 23.6 to 47.75 m bgl.
- Combined groundwater and gas monitoring installations were installed within 19 boreholes with response zones predominantly observed within the alluvial deposits.
- A total of 40 soil samples (24 madeground and 16 natural) and 19 groundwater samples were retained from site.
- Retained soil samples were submitted for an analytical suite including heavy and phytotoxic metals, _. Selected samples were analysed for polyaromatic hydrocarbons (PAHs), speciated total petroleum hydrocarbons with aromatic and aliphatic splits (TPH-CWG), Metals, phenols, asbestos screen, pH and total organic carbon.
- 14 soil samples were additionally analysed for a leachate suite comprising a similar test suite to the above soil analytical suite.
- Groundwater samples were analysed for a chemical suite comprising to the above soil analytical suite.
- Groundwater level and ground gas monitoring was carried out on 5 occasions between 12th March and 10th April 2009.

Investigation Results

- Ground conditions were generally consistent with the anticipated geology, with variable depths of Made Ground (up to 4.56 m bgl) comprising a silty gravelly sands or sandy clay fill with fragments of brick, tar, cinders, clinker, burnt shale, ash, and plastic bags. The underlying natural materials were found to comprise peat in three positions; granular cohesive alluvium (0.15 -15.36m bgl); glacial till (0.3 – 14.7m bgl) and bedrock comprising mudstone, sandstone, siltstone, limestone, dolerite and some coal.
- Bedrock was encountered in 23 exploratory holes at depths between 16.8 and 34.8m bgl
- Groundwater ingress was noted during advancement of exploratory holes at depths between 16.8 and 26.7m bgl. Subsequent standing waters were noted over 5 occasions ranging 0.65 – 4.98m bgl.
- No visual or olfactory evidence of contamination was noted by URS.
- Ground gas monitoring indicated carbon dioxide ranged between <0.1 and 4.1% v/v, methane between <0.1 and 80.1% v/v, and typical flows of <0.1l/hr. Oxygen varied between 3.5 and 20.9% v/v indicating mostly well-aerated conditions. Monitoring was carried out over a range of atmospheric pressures.

Chemical Results and Assessment

- The soil analytical results have not been compared against published Contaminated Land Exposure Assessment (CLEA) Soil Guideline Values (SGVs) protective of human health;
- Phytotoxic risks have not been assessed with reference to screening values.
- Risks to drinking water supply pipes have not been assessed with reference to the Water Regulatory Advisory Scheme (WRAS) document The Selection of Materials for Water Supply Pipes to be Laid in Contaminated Land (Reference 9-04-03, October 2002)
- Groundwater and leachate results have not been compared against published UK Drinking Water Standards (DWS) nor UK Environmental Quality Standards (EQS).

Site Investigation and Sampling Strategy

- The sampling density (77 exploratory hole locations on a 10.8 ha site) is considered to be appropriate and in accordance with guidance for a exploratory investigation given in 10175:2001, with an average grid spacing of exploratory holes of at least 30m.

Chemical Results and Assessment

- URS's chemical testing strategy is considered to be appropriate based on the site history and reported ground conditions observed.
- No assessment of the analytical soils results has been made. However, and by way of preliminary assessment only then when assuming a commercial land use and WSP Generic Assessment Criteria:
  - No Speciated TPH exceedences are noted in raw analytical results;
  - No PAH exceedences are noted in soils;
  - No Asbestos has been observed in soils;
  - No metals are noted in soils above screening criteria.
- No assessment of the analytical groundwater or leachate results has been made by URS. Again by way of preliminary assessment only:
  - No Speciated TPH exceedences are noted in raw analytical results;
  - No PAH exceedences are noted in groundwaters or leachates;
  - No Asbestos has been observed in groundwaters or leachates;
  - No metals are noted in groundwaters or leachates above screening criteria (minor exceedences noted in the vicinity of TP12 for copper and nickel.
- The presence of elevated carbon dioxide would indicate that the ground gas conditions are not representative of Characteristic Situation 1 despite the low flow rates. However it is observed that the gas exceedences are observed within an area out with our own red line boundary of concern.

Overall Conclusions

- Reporting to date has principally been of a geotechnical focus;
- Where available land contamination testing to date has been limited (except URS 2009) and screening tools applied are no longer acceptable best practice;
- Madeground containing ash has been observed on site as a potential contaminant source beyond land use operations;
- WSP's independent review of aerial mapping and geologic mapping is commensurate with the geologic sequence and land use operations denoted within the historic reporting listed;
- The most recent reporting of URS 2009 including analytical results, gas and leachate testing are assumed to present the latest and most robust assessment of the site. This data remains outstanding however a review of the raw analytical results by WSPsuggests that the hazard at the site is low.
- Detailed and compliant interpretation remains outstanding from URS (2009) beyond draft reporting.

Report Review

Ove Arup and Partners. Drawing No. 1481-2 date unknown.

This drawing comprised a site plan that showed the locations of 7 boreholes and 1 trial pit in the vicinity of the Psychiatric Department to the south of area 1B. Only two borehole records have been included indicating the sequence of strata as topsoil, alluvial sands, alluvial clay, alluvial silt, boulder clay, bedrock.

Thorburn and Partners, 1978. Southern General Hospital, Glasgow. Proposed Redevelopment, Geotechnical Study. No reference

These works comprised 10 cable percussion boreholes, CPTs and geotechnical testing. The plan that goes with this report is not available, and therefore the positions of the boreholes can not be ascertained. However, the report notes the possible existence of an exploratory shaft in the vicinity of the mortuary sunk in 1868 to a depth of about 70m to locate an ironstone seam. There is no evidence to suggest that mineral extraction took place beneath the site. The method of securing the shaft could not be established.

Ground water monitoring over a 4 month period recorded ground water levels from 2.75 to 7.55 mOD. Superficial deposits comprised alluvial sands, silts and clays.

Fugro, 1985, Soils Investigation Report, Proposed Geriatric Units at Southern General Hospital, Glasgow, Reference 85/2580

4 static cone penetration tests and 2 trial pits undertaken for the construction of a 30 bed Geriatric Unit south east of area 1B near Carleith Quadrant. The investigation indicated the sequence of strata to comprise Fill, loose to medium dense sand, soft to firm clay, soft to firm silt, loose to medium dense clay, stiff to very stiff sandy silty clay. The discussion on foundations in the report suggested that conventional shallow spread foundations founded at least 0.9m would suffice for a lightly loaded structure. Raft foundations could be used to reduce differential settlements. Piled foundations would be required for anything other than lightly loaded.

Nicholson Site Investigation, Site Investigation Report, Southern General Hospital, Dated September 1989

Works comprised 3 cable percussion boreholes sunk to maximum depth of 18 mbgl for the neurological building SE of area 1B. Ground conditions comprised 0.5m of sandy topsoil underlain by silty sand, very weak alluvium and glacial till. The glacial till was encountered at depths between 11 and 12 mbgl. Groundwater was encountered in 2 out of the 3 boreholes during drilling at depths of 3 – 4 mbgl. Nicholsons advised an allowable bearing pressure of 75 kPa for shallow foundations founded on the shallow sand layers. For heavier loads. Piles were recommended.

Wimpey Environmental Ltd, 1994. Proposed Geriatric Unit Southern General Hospital, Glasgow. Reference SULY/7523

Copy of the report provided does not include a plan showing the exploratory hole locations. Report notes that the investigation covered an area to the south of Langlands drive. This is

out with the development area currently being considered. 5 cable percussion boreholes, 3 of which were extended into bedrock were undertaken at the site. Ground conditions encountered comprised up to 1.75 of made ground underlain by loose sand; very soft, soft and firm clay; very soft and soft silt; clacial till; bedrock. An allowable bearing pressure of 50 kPa was advised for shallow foundations founded on natural soils. Vibro techniques and piling were discussed as alternatives.

Rocksoil, 1998. Site Investigation at Southern General Hospital, Glasgow. Reference S97/1496

Fieldworks comprised 2 cable percussion boreholes to 17.45 and 17.7m depth in the vicinity of the mortuary and wards 33 to 36. These structures were reported as settling at the time of the fieldworks. Ground conditions encountered comprised made ground (1.94 to 2m); intertidal marine deposits (marine silts and clays); and glacial till. Groundwater was encountered at depths of 6 and 8m during the fieldworks. The report recommended that underpinning in the form of either driven or CFA piles be used to mitigate the settlements. This report did not mention the possible exploratory shaft in the vicinity of the mortuary which was reported by Thorburns in their 1978 report.

Ove Arup and Partners 1998, Proposed Extension to Oral and Maxillofacial Unit, Southern General hospital, Glasgow Reference 53500\980129a.rep

Fieldworks comprised 7 trial pits and 5 cable percussion boreholes, 4 of which were advanced into rockhead by rotary drilling. The site is located to the SE of area 1B close to Carleith Quadrant. The fieldworks encountered topsoil (0.3 to 1.4 mbgl); Alluvium (3.7 to 17.5m bgl); Glacial Till (5.7 to 14.6 mbgl). Groundwater was encountered at levels of 4.7 to 7.2 mAOD. CFA piles were recommended as a foundation solution for the structures in this area.

Aitken laboratories Ltd. Fax Message dated 5th Feb 2003

Fieldworks undertaken in northern part of area 1B and comprised 2 cable percussion boreholes and 7 trial pits. Ground conditions encountered comprised made ground and alluvium.

URS, 2007. New Laboratory Facility at Southern General Hospital, Substructure Options Report. Reference 49339768

Report is dated 2007, but refers to 2009 ground investigation. Report discusses the options considered for the substructure elements for the proposed laborities facility. Driven, CFA and bored cast in place piles considered. Large diameter bored cast in place piles recommended as providing most appropriate solution. 900mm diameter piles socketed 3m into bedrock determined by URS as having SWL of 3500kN in compression and 1700kN in tension. Report also discusses retaining wall option.

URS, 2009. Preliminary Geo Environmental Report. New Southern General hospital. Draft. Reference 49339768/GL:RP0010.

This report was undertaken specifically for the development under consideration. The report currently available is a draft issue only. This investigation covered 4 separate areas:

Area 1A Covers the area adjacent to the NW of area 1A.

Area 1B covers the new ortho theateres to the north of the helipad all the way down to Langlands Drive.

Area 2 covers wards 30 – 32, the drug abuse and psychological Medicine building and the Pharmacy department.

Area 3 covers the podiatry department and the car parking area to the north of the trust headquarters.

This BDS adopts the same nomenclature throughout.

The fieldworks comprised 44 trial pits, 3 competitor boreholes, 33 cable percussion boreholes of which 23 were continued by rotary coring into rock, 7 CPTS, in-situ geotechnical testing, gas and groundwater monitoring, geotechnical and chemical laboratory testing. Ground conditions encountered generally comprised made ground, alluvium, glacial till and bedrock. The draft report does not include any groundwater monitoring records.

General

The proposed development is to comprise the construction of a new 15 storey hospital with laboratory building and energy centre in area 1; the construction of a research and development centre in area 2; and a residential cancer care unit in area 3.

This BDS discusses the ground conditions across the development areas and advises risks and recommendations for the following:

- Foundations
- Retaining Walls
- Earthworks
- Formations
- Designers Risk Assessment

This statements is intended to inform the tender design only. They should not be used for detailed design purposes for which an interpretative report will be required. These statements can be updated to incorporate new or revised information.

Brookfield

Principal Material Types

The solid geology plan for the site (Scotland Sheet 30 – Solid Edition) indicates the solid strata beneath the site to comprise the limestone coal group to the south and east of the site with the lower limestone group elsewhere. An igneous intrusion is shown to run from SE to NW across the middle of the site. A fault is recorded trending south east to north west towards the northern part of the site with the down throw to the south.

The exploratory hole records from the Norwest Holst factual report and bam Ritchies ground investigation report indicate the following sequence of strata:

Area 1A

Stratum	Depth to top of Stratum (mbegl)	Thickness (m)
Made Ground	0	0.5 – 3.2
Alluvium	0.5 – 3.2	0.6 – 21.0
Glacial Till	0.6 – 21.4	0.3 – 19.4
Bedrock	16.8 – 25.2	-

Area 1B

Stratum	Depth to top of Stratum (mbegl)	Thickness (m)
Made Ground	0	0.4 – 3.0
Peat*	1.3 – 1.6	0 – 0.7
Alluvium	0.4 – 3.0	3.5 – 23.8
Glacial Till	4.1 – 24.8	0.3 – 19.5
Bedrock	17.4 – 26.3	-

*Only encountered within BH09 & BH17

Area 2

Stratum	Depth to top of Stratum (mbegl)	Thickness (m)
Made Ground	0	0.8 – 1.8
Alluvium	0.8 – 1.8	5.1 – 17.8
Glacial Till	6.6 – 18.3	5.6 – 18.8
Bedrock	17 – 18.8	-

Area 3

Stratum	Depth to top of Stratum (mbegl)	Thickness (m)
Made Ground	0	0.4 – 2.5
Alluvium	0.4 – 2.5	17.8 – 28.4
Glacial Till	18.7 – 28.8	0 – 6.0
Bedrock	25.5 – 34.8	-

Made Ground

Made ground was generally encountered across the site. The made ground encountered generally comprised a very loose to loose sand occasionally containing fragments of brick, ceramics, shale, clinker, cinders or sandstone.

Alluvium

The alluvial deposits at the site generally comprise sand underlain by clay then silt. The sand is typically a very loose yellow brown slightly silty sand. The underlying clay generally comprises a very soft brown slightly sandy clay. The silt, where present normally comprises an un-compact grey very sandy silt with laminations.

Glacial Till Deposits

The glacial till encountered is typically a stiff and very stiff grey slightly sandy slightly gravelly clay with occasional cobbles. Glacial till was absent to the south of the podiatry unit in area 3 (BH43).

Bedrock

Bedrock encountered comprises mostly moderately weak to moderately strong mudstones and sandstones with very closely to medium spaced sub vertical and sub horizontal discontinuities. Strong Siltstone is encountered in places. An intrusion of dolerite was encountered in the middle of area 1B.

Groundwater

Groundwater monitoring records for the main site area have not been made available. Once available, this section will require to be revised. Groundwater observations made during the drilling works indicate that groundwater in some areas may be encountered at shallow depths, i.e. within 3m of ground level.

Engineering Discussion & Recommendations

Foundations

In view of the nature and thickness of the compressible alluvial deposits traditional shallow spread footings will not be suitable as foundations for the proposed development. Suitable foundations can be provided by installing piled foundations

The construction of both bored and driven piles would be technically feasible at this site. The use of continuous flight auger (CFA) piles should not be considered due to the risk of over-flighting of parts of the alluvial deposits and the relatively low pile capacities compared to the high pile loads proposed. Overflighting is a significant risk where softer soils overlie very dense/stiff soils or rock. Overflighting causes large overbreaks and significant settlements in adjacent structures through extracting larger soil volumes than required. Reinforcement cage lengths greater than 15m are unsuitable for the CFA method.

Driven piled foundations, although technically feasible may be inappropriate due to likely noise restrictions at the site. Noise restrictions at the site need to be clarified. Silent hammers will reduce noise levels through the made ground and alluvial deposits but will be unable to drive piles through any boulder obstructions within the glacial till. Consideration should be given to the use of pre-boring at some pile locations to overcome obstructions.

Bored piles will require either temporary casing throughout their depth or the use of a polymer support fluid due to the presence of groundwater. There is the possibility that fine sands may ‘blow’ under semi-confined conditions within the alluvial sands.

The most appropriate form of piles for the proposed development are large diameter bored piles socketed into the bedrock.

A detailed pile design is outside the scope of this BDS. The design procedure for piles varies considerably, depending on the proposed type of pile. However, for illustrative purposes, the following table gives likely working pile loads for large diameter bored piles of various diameters with a 1m deep rock socket.

The bearing capacity of the bedrock is determined by the equation published by Kulhawy and Goodman and reproduced by Tomlinson (eq 7.16a) in Foundation Design and Construction 6th edition.

qub = cNc + _BNg/2 + _DNq

Rock socket skin friction = _ x Ø_x h x c

Parameters assumed:

UCS = 5000 kN/m2

_’ = 30o for RQD 0 – 70%

c’ = 0.1 UCS = 500 kN/m2

A factor of safety of 2.5 is applied to both end bearing and rock socket skin friction.

Preliminary Pile Capacities for Large Diameter Bored Piles

Typical Pile Working Loads (kN)					
Pile Diameter (m)					
0.6	0.8	1.0	1.2	1.5	1.8
1,000	1,700	2,600	3,600	5,400	7,600

It should be noted that pile group effects have not been taken into consideration in the above values.

Retaining Walls

Embedded retaining walls are required for the basement excavations. The ground investigation reports made available suggest that shallow ground water will be encountered. Lowering of the ground water out-with the excavations may result in settlements which adversely affect adjacent structures and services. In light of this, lowering of the groundwater outwith the excavation should not be considered.

Dewatering of the groundwater within the excavations also needs to ensure that hydraulic failure at the base of the excavation is avoided. This can be achieved by installing a water tight cut off wall with a penetration deep enough to prevent hydraulic failure. The penetration of the cut-off wall to prevent hydraulic failure should be designed in accordance with the method shown in the NAVFAC design manual.

Retaining walls types that will provide a water tight solution include diaphragm, sheet piles and secant pile walls. The cost of providing a diaphragm wall may prove prohibitive. A sheet pile wall will be cheaper, but noise restrictions at the site may preclude their use. Silent driving may be an option, but this will be dependant on the depth of penetration required and the materials through which the sheet piles are to be driven.

A secant pile wall may provide the most suitable solution. The installation process is relatively quiet when compared to a driven pile solution. The piles can also be used as permanent foundation piles, an advantage it has over steel sheet piles. The installation of a secant pile wall requires careful monitoring ensuring that the wall is water tight down to and beyond the dredge line. This can be done by tightening up the installation tolerances stipulated in the piling specification and/or increasing the diameter of the female (soft) piles to ensure that no gaps are formed between piles that allows the ingress of groundwater.

The provision of lateral support to the secant pile walls may reduce the cross sectional area of the piles and the embedment depth. The lateral support can be provided in the form of either tie back anchors or struts. The use of tie back anchors depends on the proximity of structures behind the excavation. In many areas of the site, this may preclude their use. The use of struts will be dictated by the sequence of operations within the excavation and access requirements.

Brookfield

Mineral Stability

The CA report obtained by URS indicates that there may be shallow unrecorded workings at the site. The investigation undertaken by URS did not identify any workings. However, it would be prudent to undertake some mineral bores at the site to bottom this out. The Thorburn report from 1978 notes the possible existence of an exploratory shaft in the vicinity of the mortuary sunk in 1868 to a depth of about 70m to locate an ironstone seam. There was no evidence to suggest that mineral extraction took place beneath the site. The method of securing the shaft was not established. The URS report advises that this shaft is some 70m south of area 1B. However, a mortuary building is shown adjacent to the urology unit to the east of the helipad. An RFI was raised to query this matter and the Board have responded that the mortuary building referred to in the Thorburn's report is not the same as the current mortuary building.

Earthworks

There is insufficient earthworks testing to assess whether the material won from the site is likely to be acceptable for re-use as a general fill. However, it is likely that most of the material will be acceptable for re-use as a landscape fill subject to acceptable chemical testing.

Formations

The information made available does not include any CBR tests within the development area. However, it is anticipated that most of the formations to the road pavements will be formed in made ground deposits. Most local authority design guidelines for roads require full capping for formations in made ground. As such the tender should allow for full capping throughout with an allowance for removal of soft spots.

Risks

- Strength of rock may be weaker than assumed. Allow contingency for weaker rock in piling costs. Rock testing to be carried out to confirm strength of rock.
- Insufficient EW testing – Unable to assess proportion of site won material that may be re-used as general fill. Assume that all material will be unsuitable for re-use as general fill, but that most will be suitable for use as landscape fill subject to acceptable chemical testing.
- Insufficient Geotech testing – Again probably sufficient info for tender design but should allow contingency should ground conditions be worse than anticipated. This will impact on embedded retaining wall design for basement excavations. Assume worst case soil parameters.
- No permeability tests – Risk that should be addressed during tender design. Permeability of the soils may dictate depth of embedded retaining walls required for prevention of piping/ hydraulic failure.
- No CBR tests – Allow full depth capping everywhere to overcome this risk.
- Mineral stability – Issue that is yet to be bottomed out which will affect the consolidation works and piling depths.
- Shallow GWT – Dewatering should be allowed for within excavations only along with water tight embedded retaining walls.
- Running sands – All excavations through such material will require closed support.
- Piling system selected – Due to Clyde Alluvium, CFA piles must not be considered for use at this site due to risk of overflighting. EN 1536 recommends that where unstable ground conditions are encountered, the contractor should demonstrate the feasibility of CFAs by means of trial piles or local experience before the commencement of the works. Due to the scale and profile of the project, local experience alone should not be relied upon as it will probably be very selective and in a different context. If the project is keen to pursue the CFA option, despite the risk of overflighting, then the piling contractor should undertake trial piles before the piling type is finalised. If the trial piles indicate overflighting, then the piling contractor will need to resort to a different piling solution.
- Driven piles may be precluded due to nuisance factor and proximity of hospital buildings. Guidance and case studies for sound levels and peak particle velocity (ppv) associated with piling activities may be found in BS8233 pt 1 tables 4, C4 and C5. Acceptable noise levels and ppv limits have yet to be defined. Once these are available, the piling contractor should be consulted as to whether his piling operations will remain below these levels whilst still being able to install a pile that will achieve the required specified working load.
- Cased bored piles should be used. Piles will probably have to be founded on or into bedrock to achieve design loads likely to be required. If mineworkings close to bedrock are encountered (treated or otherwise), piles will need to be taken beyond.

Appendix C Building Structure and Foundation Options

Element	Presented Details	Options	Advantages	Disadvantages / Risks
Structural Frame	Traditional RC Frame			
		Traditional RC Frame with Bubbledeck or similar void formers	Same capacity, lighter slab dead loads, smaller columns, smaller foundations, less formwork	Reduced dead weight limits slabs' ability to resist vibration (limit's future flexibility)
		Post tensioned floors	Potential larger spans, potential thinner slabs, earlier striking times	More complex method, specialist design and installation required
Foundations	Small diameter cast insitu rotary bored			
		Large diameter cast insitu rotary bored	Can be placed in all conditions, fewer piles required	Ground beam lateral restraint required spoil produced.
		CFA	Quicker, quieter, less vibration,	Potential flighting, obstructions, spoil produced, insufficient GI to assess risks
		Driven	Quicker, no spoil,	Noise, vibration, obstructions, alignment, insufficient GI to assess risks
Basement	Cast in place rotary bored secant wall			
		Sheet piled wall	Quicker, no spoil	Noise, vibration, obstructions
		Open cut excavation and traditional tanked insitu RC retaining walls and tunnel box	Tried and tested method, visible structure integrity	Dewatering, large excavations, ground instability, space sterilisation

Brookfield

Brookfield

Demolition Strategy

Submission Reference:

3.27 Demolition Strategy.

Submission Response.

Scope of Works.

The scope of demolition work by Brookfield at Stage 3A is Buildings AN, DG, DC, AP and the Surgical Link Bridge DF as shown on BMJ drawing PD- HLM-S(00)X-XX-005. (enclosed)

Programme

The Laboratory Facilities, Adult and Children's Hospitals and the Energy Centre will all be operational when demolition commences and the new access road off Govan Road will be in use.

Brookfield Logistic Drawing BE-DJ-LOG-104 (enclosed) shows our site arrangement at Stage 3A

Segregation

Our protection and safety measures for segregation between our demolition works and adjacent buildings will vary with the proximity to each one together with the structural heights of the buildings to be demolished.

The selection of barrier type is influenced by the duration required; if the demolition in an area is a 2 day operation after which the barrier needs to be adjusted for external landscaping works then a demountable system is more economical and convenient at the same time adequate for safety purposes.

Heras fencing also provides better sight lines for vehicles and pedestrians.

South Boundary.

The existing roadway to the south provides a substantial clearance zone between the single storey building AN and the public area. The erection of a Heras fence will suffice in this location.

West Boundary.

Buildings AN, DG and DC are all single storey and set back far enough from the new access road to allow Heras fencing to be used.

North Boundary

The close proximity of the Accident and Emergency building AK, to be retained, and buildings DC and AP to be demolished, does not allow for an effective hoarding to be erected. Our demolition contractor will provide hard barrier protection to windows and to the fabric of building AK for the short duration of demolition works to this location, removing on completion.

Building AK will provide segregation provided any doors are temporarily secured. If any doors on this elevation are fire exits then escape routes must be maintained or diverted. After demolition is complete Heras fencing will suffice.

Any connecting parts between demolition and retained structure will be made good.

Brookfield

At the East of the North Boundary a full 2.4m high solid hoarding will be erected to give increased protection at the gable end of Wards 1-6 where public car parking and existing hospital facilities involve greater numbers of vehicles and pedestrians.

East Boundary

This boundary will also have full 2.4m high solid hoarding on the outside line of the footpath and if necessary, to the front of the car park bays. Although the existing footpath will be within our site and pedestrians using the footpath on the opposite side of the road, the Long Corridor Building is 3 storeys high and at a busy location, where enhanced dust and noise containment will be required.

It is also important that the image presented to the public is one of cleanliness, tidiness and control, and the solid hoarding will allow this to be effectively communicated whilst delivering robust physical protection.

Pedestrian Routes

Main routes pedestrians will be taking will be from Car Parks 1A and 1B to the newly constructed facilities, the existing facilities to the East side of the complex and along the access road off Govan Road.

From our enclosed phasing drawing it is evident that the demolition has the minimum effect on these routes.

Traffic Routes.

By the formation of the temporary link road, traffic routes to the Laboratory Building are maintained and the

New Site Entrance Road is unaffected.

Construction Works

Construction traffic will enter and exit from the demolition site directly onto the entrance road, leading to Govan Road. All demolition materials will be carted away via this route.

Our Site Accommodation and Welfare establishment will be located next to our site entrance but will be relatively small, providing for 6.Brookfield staff and the demolition subcontractor (external works subcontractor overlaps with demolition for a short period only).

Management

The Brookfield organisation chart for Stage 3A - Team for Demolition and Externals is enclosed.

Before any demolition work commences our HS&E manager will ensure that type 3 asbestos surveys are carried out that an initial survey for Aspergillus is completed and that a service decommission certificate is issued by the Board and verified on site by ourselves.

Temporary works designs for the Link Bridge demolition / removal will be produced by our subcontractor and checked by Brookfield.

Regular monitoring for Aspergillus will be carried out during demolition works and site inspections completed by managers.

Summary

On an initial visit we were accompanied by a potential demolition subcontractor to view the works to be carried out in stage 3A. We did not foresee any unusual features or complications on the demolition.

We did however recognise that the removal of the Link Bridge will require specific and detailed method statements after having ascertained how it has been constructed, The timing of removal of the bridge over the Blue Route must be agreed with the Board and demolition of the section over the east footpath carefully planned.

Diversion Strategy

Submission Reference

Volume 3 Section 3.28.1 Culvert Diversion

Submission Response

Existing Situation

Drawing WSP-WS-00-PL-140-03 identifies 3 drainage diversion location relating to the adult and Children's hospital works

The Maternity combined sewer diversion will be carried out within the confines of the site and will have no impact on the facility with a new manhole constructed over the existing sealed pipe before final connection is made out of normal working hours.

The Linthouse burn a 1050mm surface water culvert and a 300mm foul drain currently runs across the south east corner of the proposed Adult Hospital site. In order to facilitate the construction of the new hospital both these existing services require diverting away from the site. An existing underground HV electrical service runs around the perimeter of the south east corner of the site which must be maintained. The existing blue light ambulance route runs north / south into Langlands Drive adjacent to the south east corner of the site and 24 hour access MUST be maintained at all times. This set of constraints presents a particularly challenging activity to divert these culverts.

The foul drain diversions to the hospital main entrance area also presents a challenge an will require a detailed risk assessment and method statement to agree an acceptable traffic management strategy to install the new sewer connection.

The connection has been designed such that any traffic management requirements will not affect the Govan road blue route, but the less trafficked Renfrew road that is not generally used as an ambulance route with shieldhall and Hardgate road providing access from the west

In addition to this the Jenny Burn runs from the existing ambulance station site and will be diverted as part of the stage 1 operations. These works will also be contained within the site boundary with no impact on any hospital facilities.

Proposed culvert and foul drain Diversion

The proposed diversion routes for both services are shown on Diversion Strategy drawing No CD-WS-00-PL-140-14.

In order to maintain the blue light ambulance route along the main road we propose to utilize the tract of parking bays spaces shown orange hatch on the above drawing. The width of the track of road will be maintained at least 7.0m wide providing adequate separation for two way traffic and minimal impact on hospital service delivery.

A detailed risk assessment and method statement that will be agreed with the Board regarding method and timing prior to any activity commencing. This will enable suitable notifications to be issued to hospital staff on forthcoming activities so they are aware of the traffic management controls that will be instigated including signage and barriers to highlight the temporary road re-alignments.

The proposed hoarding line on the west side of the existing road will run approximately 3.0m away from the existing kerb line taking in the existing car parking bays on this side of the road and providing the opportunity to carry out the proposed drainage diversions inside the protective hoarding line, particularly to the south east corner of the site avoiding the need for any lane closure on to this busy corner of the blue route.

Live Services Protection and diversions

All works affecting the normal operation of the hospital campus will be planned and advised well in advance and raised at the weekly site liaison meetings with the Board's project administration team.

Brookfield propose to carry out a full subscan of the site area to confirm existing service routes. From this and in discussion with the Hospital board a diversion plan and methodology will follow that will identify areas where site works interface with functional services and proposals to protect or divert.

The existing HV service to the site perimeter will be traced along all boundaries through CAT scan and trial hole methods to validate the findings of the subscan survey. Any excavation work that is to be carried out in the vicinity of any section of the HV cable will be subjected to a detailed method statement and controlled through a strict permit to work system.

Brookfield

Brookfield

Medical Gas Line Workplan.

Existing VIE Compound

The existing VIE compound will require relocation to the south and east during the construction phase of Stage 3.

To achieve the removal and relocation of this VIE compound with no disruption to the hospitals existing operations, we will in conjunction with Air products disconnect the existing pipework arrangement and move the stores approximately 35m to the south and 15m east of its current location.

To ensure that operations within the existing hospital campus does not suffer any down time or disruption we will with the approval of the hospital operational staff install J type cylinders and manifolds to temporally back feed the existing Oxygen systems during the relocation of the VIE store.

This temporary system will be linked to local Oxygen alarms that we will monitor during the relocation of the VIE compound.

In critical areas emergency back up oxygen bottles will be made available to give additional resilience in these areas should the need arise.

On completion of the relocation of the existing VIE compound all new lines will be tested and purged, the final installation will be checked and signed off by the Approved Person before the VIE compound is put back into service.

New Duplicated VIE Compounds.

It is proposed that two new VIE compounds will be form part of the installation within Phase 3 of the project, these stores will be sited within suitable locations to ensure compliance with the SHTM, Local Approved Person, suppliers requirements and will serve as operational and stand-by for the new the hospital.

Both these stores will be independent of each other and will come complete with alarms and telephone links as required within SHTM002.

The system shall be rated to accommodate the full site wide requirements and shall include interlinking the new plant with the retained estate systems via valved off interconnectors to improve overall site resilience.

Introduction

Submission Reference:

Section 3.29: ‘Statement of Compliance with Lab design information contained in ITPD (Vol. 5 of BIW)’.

Submission Response:

Brookfield recognises the work carried out to date by Board’s designers for the Laboratory scheme and understands that certain areas are still being developed.

Nightingale Associates have considerable expertise in laboratory design and have an appreciation of the work carried out to date in defining the functional associations and adjacencies required.

We confirm having received the Laboratory design information contained in the ITPD (Volume 5 of BIW), as listed in the schedule 1. The Brookfield submission has taken cognisance of all the information contained therein and confirms the following:

- All design information in Volume 5 has been priced and is contained in Volume 12 of our bid submission
- Laboratory Construction Programme No BCL-NSGH-TN01-0017 has made allowance for the Laboratory Design Brief.

Brookfield

Introduction

Submission Reference:

Section 3.29: ‘LABORATORY’.

Submission Response:

Brookfield recognises the thoroughness and completeness of the brief and scheme developed by the Board, Estates Office, Architects, service Engineers and Users. Our architects, Nightingale Associates have considerable expertise in Laboratory design and recognise the hard work the board and its team have put into defining the functional associations and adjacencies. We also understand that all buildings have to be future proofed and require inbuilt flexibility.

In proposing an alternative for the Laboratory building, Brookfield have reviewed the current design, taking Volume 2/2 Employers requirement and the above items into consideration. We have also reviewed how the laboratory building form, location, structure and function interfaces with the wider Masterplan context.

Our primary aim is to add value in terms of cost saving while delivering an exemplar Laboratory facility that meets the employer’s requirements. Our proposal therefore meets the employers requirements for planned area adjacencies and future proofing.

We have proposed minor changes to the laboratory building these are

- Repositioning of Post Mortem room to ground floor from basement.
- Rationalisation of M&E/ Plant services
- Extension of link from main laboratory building to blood science specialist accommodation building block.
- Realignment of gas storage compound at FM yard level.
- Repositioning of some hard FM facilities to a bespoke area within the energy centre.

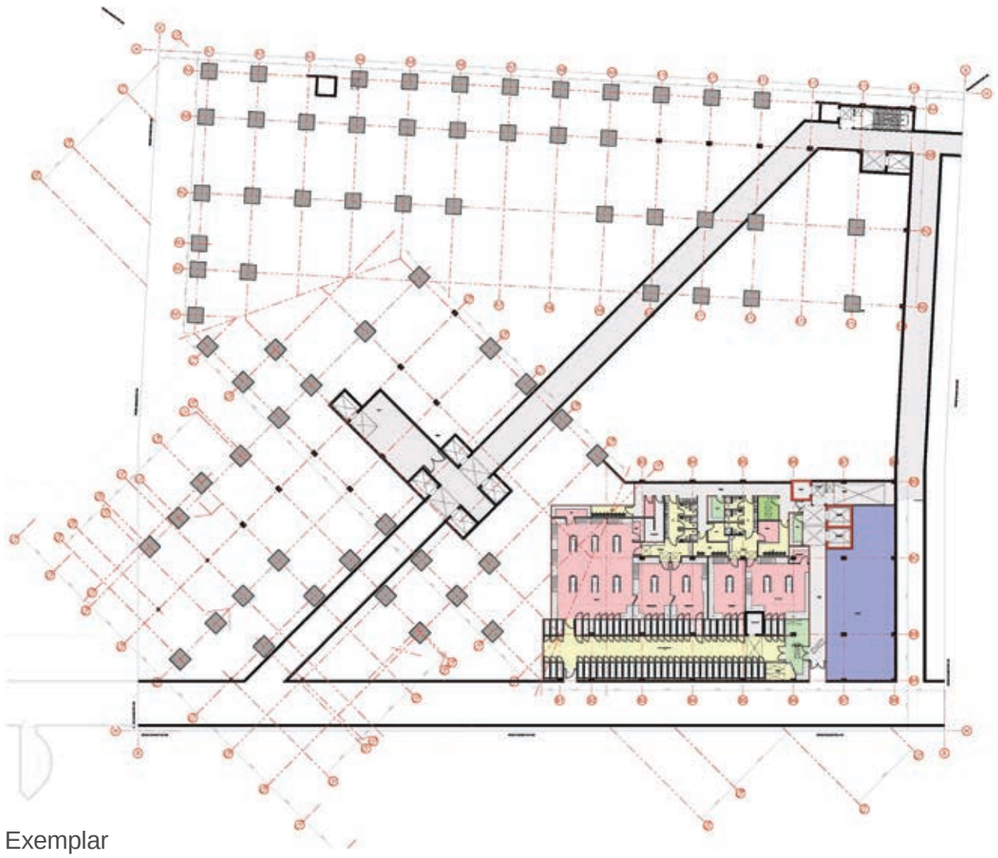
Brookfield

Repositioning Of Post Mortem Room To Ground Floor From Basement

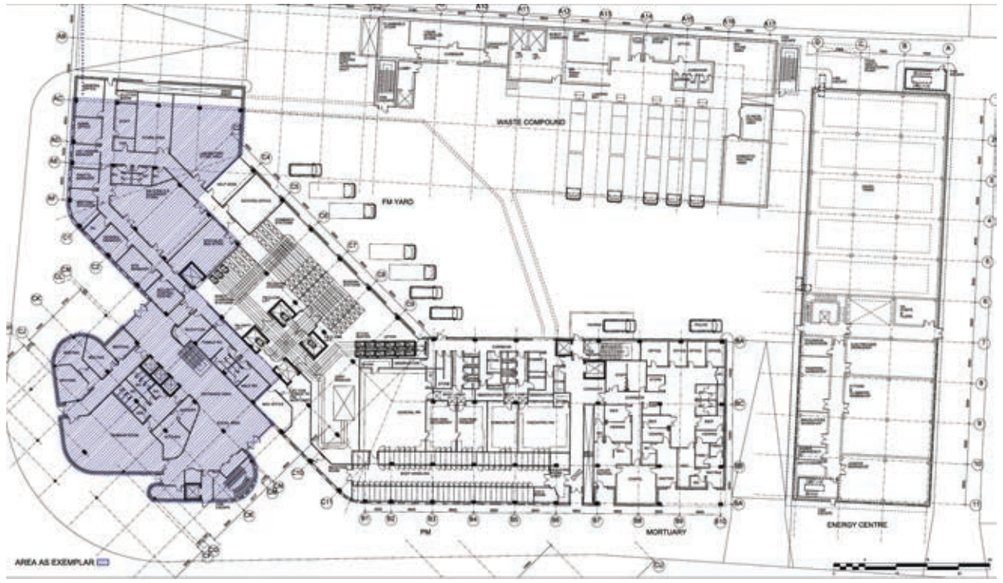
We believe we have added value to the exemplar scheme by co locating the PM/ Mortuary and Public Viewing facilities whilst allowing for natural light and ventilation where the function permits. Our scheme also has the added benefit of minimising travel distances, travel time and level changes should a body need to be moved between the body storage area and public viewing facility. Our use of the lift cores in the centre of the laboratory building also delivers resilience for body transfer from the underground tunnel should a lift be out of order or require maintenance.

Provision of double entry lift ensures no cross flow/ privacy issues when a body is in transfer.

The flows and adjacencies indicated in the exemplar design have been accommodated in our proposal.



Exemplar



Proposal

Brookfield

Rationalisation Of Mechanical And Engineer/ Services Plants

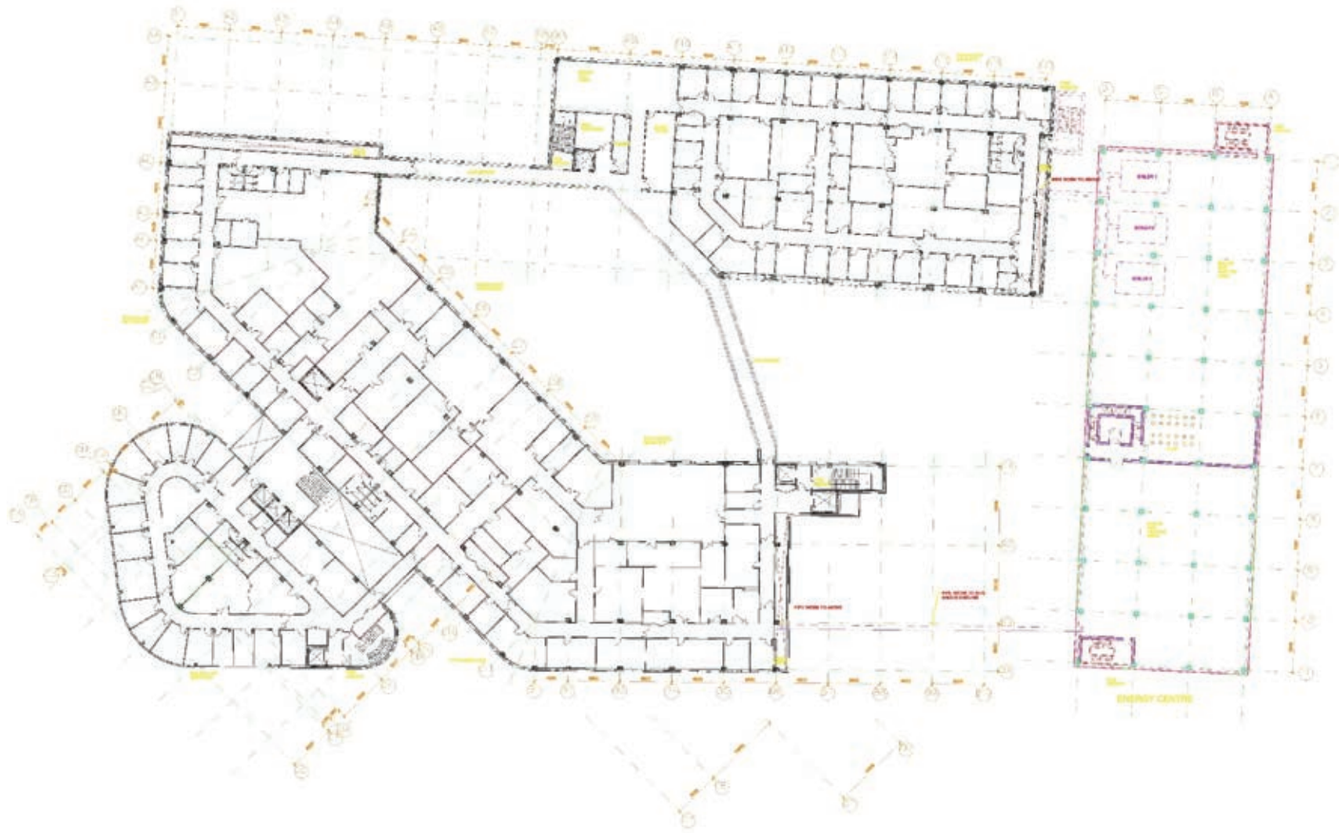
In response to RFI 144 and a review of the Stage D design proposals for the laboratories, it was evident that the buildings services design as detailed within the stage D would fall short in achieving the overall Carbon reduction requirement for the campus and the overall build budget for the Laboratories Building.

To achieve the overall carbon emission reduction target of 80KgCO_2m^2 for the hospital project which includes the laboratory building we would propose the following modifications to the current stage D design.

- Reduce the number of Boilers in the Labs from 54 located in the North/South/East and office plantrooms to a more manageable and efficient 3 boilers which will be rated to give the total connected load of heating elements within the design.

Option 1, we propose to use 3 boilers configured as 2 run and 1 standby. Each boiler will be selected to provide 66% of the connected load and this will provide a more efficient means of low load control throughout the life of the building.

There are 2 options within this proposal, firstly locate the boilers within the new energy centre and link at the front end of the project the energy centre to the Labs building. These boilers can be selected to act in the future as possible back up to the main hospital, and become a part of the final strategy for energy to the total campus.

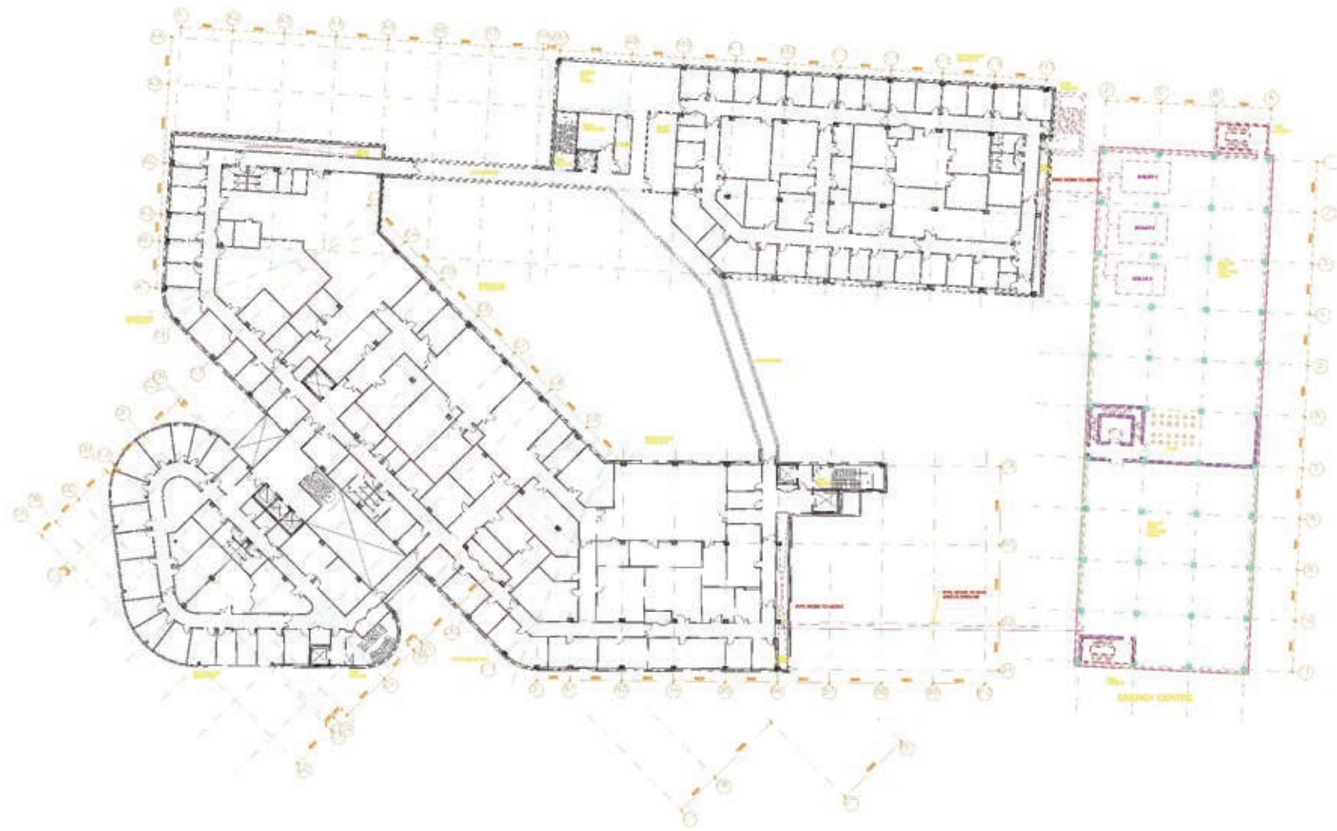


Brookfield

Option 2, locate these 3 boilers and HWS plant in a separate plantroom above the new Mortuary section. These boilers will distribute the heating water thought-out the building in a similar fashion to that already detailed in the stage D plans.

From an energy usage calculation, the use of 3 large boilers versus 54 smaller ones, will increase the overall efficiency of the required energy use within the building by increasing the COP of the boiler plant, by reducing the required electrical power connections , the number of flue and gas connections.

The cost reduction from 54 boilers to 3 boilers will add a substantial saving to the overall build cost of this building by reducing the, number of boilers, flues, pumps, BMS connections, gas connections, gas safety equipment etc.

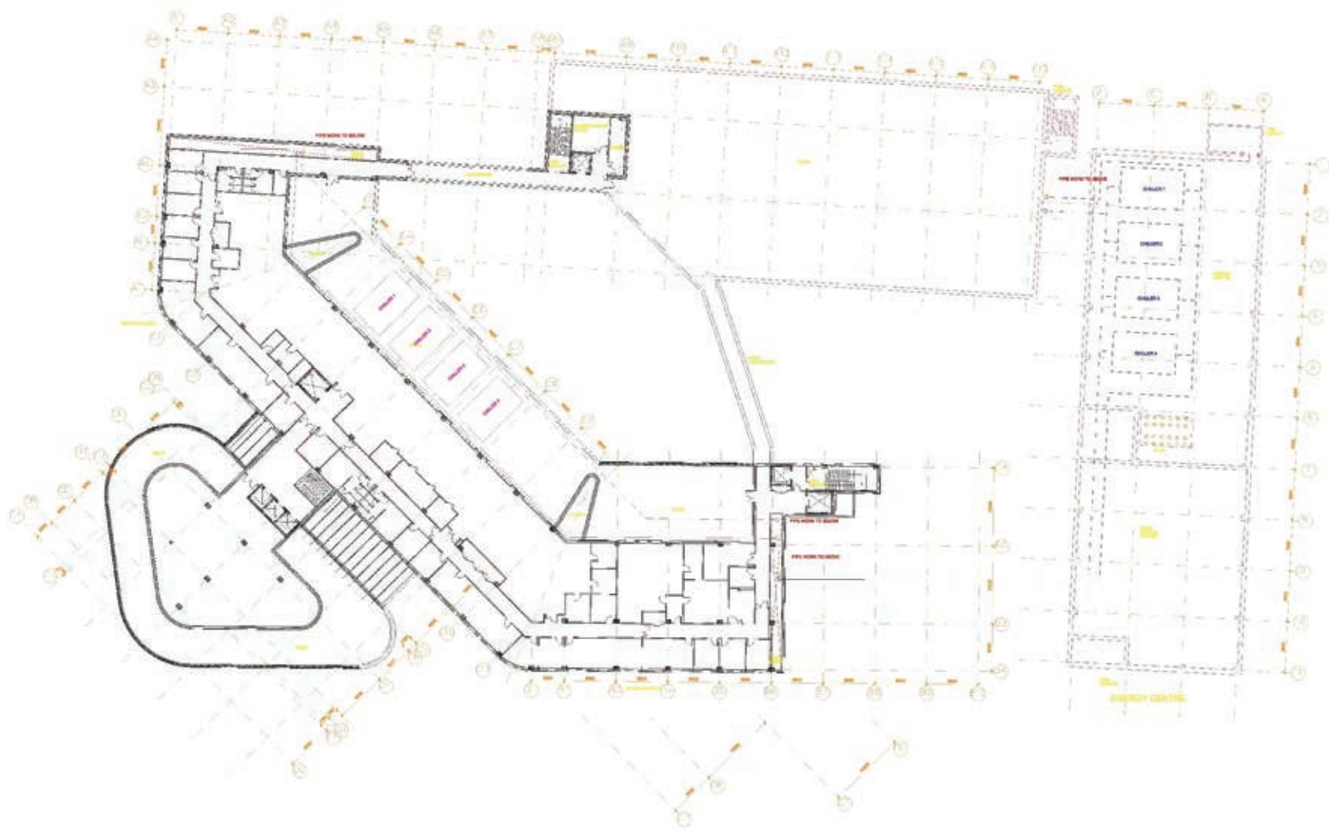


Brookfield

- Reduce the number of chillers currently selected in the stage D design.

Option 1, Again we would propose 2 options, install within the new Energy centre the required number of chillers for the connected load of the laboratories building plus one additional chiller for standby.

Connect the chilled water distribution lines from the new energy centre to the laboratories building during the construction of the Labs building and use these chillers to service the load of the labs during the build of the main hospital. The standby chiller will become the overall stand by chiller for the total complex and this will reduce the total number of large plant items within the complex.



Brookfield

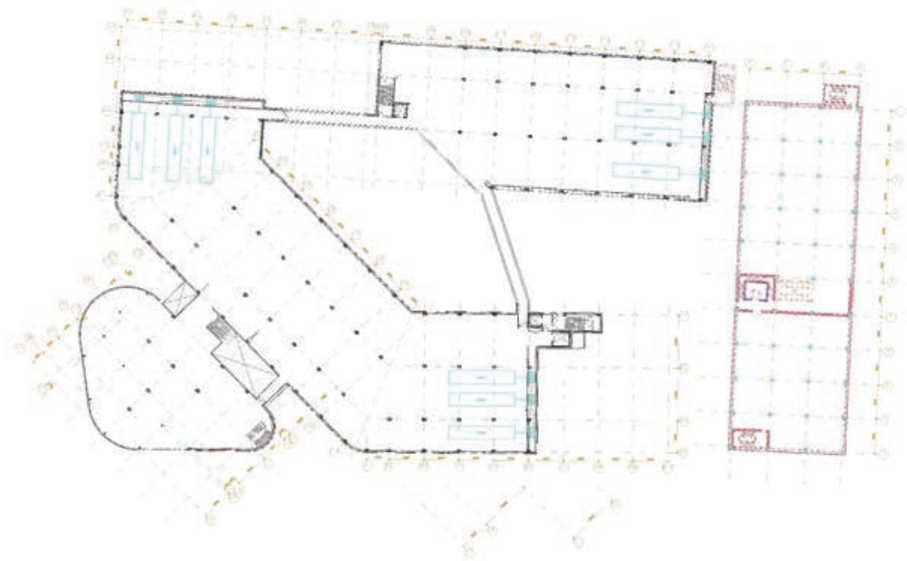
Option 2, If there is a requirement for the Labs building to maintain its own chilled water plant, we propose to locate 4 chillers centrally on the roof of the labs building and via a ring main distribute the chilled water to the 4 major plantrooms. This would remove the 4 standby chillers currently detailed in the stage D

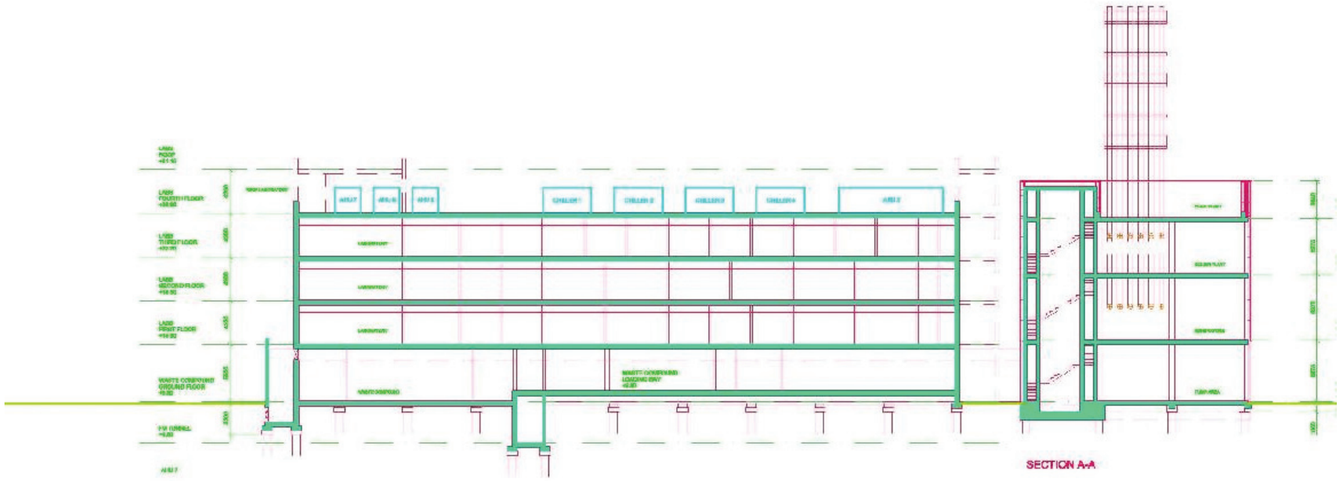
Similar to the cost savings associated with the boiler plant above, the reduction of chiller plant will initially reduce the capital expenditure of the total build of the labs in the short term, in the long term the running and operational costs will be reduce by improved efficiencies and reduced maintenance costs.

- Reduce the total number of large plant items within the complex.

To reduce the number of overall plantrooms detailed within the stage D design, we propose to reduce the number of Air Handing Units serving the Labs floors and locate 6 central units at roof level with vertical service risers at each corner of the building, these duct risers will connect to the horizontal ducts as detailed within the current stage D design.

The reduction in AHU's will initially reduce the capital expenditure of the total build but again the future reduction in energy cost and maintenance operational costs will add to the overall reduction of the carbon requirement of 80Kg for the campus.





A48235836

Brookfield

Extension of Link from Main Laboratory Building to Blood Science Specialist Accommodation Building

Our review of the exemplar scheme has identified that the access point to the FM yard for the vehicles required was a CDM risk issue. Our main concerns were

- Turning off main road on hospital campus into FM area.
- Location of gas storage facilities
- Access under laboratory building
- Maintenance issues within this narrow access zone.
- Delivery issues when/ if required to gas, storage facilities.
- Structural integrity of the building supports and layout due to FM traffic flow.

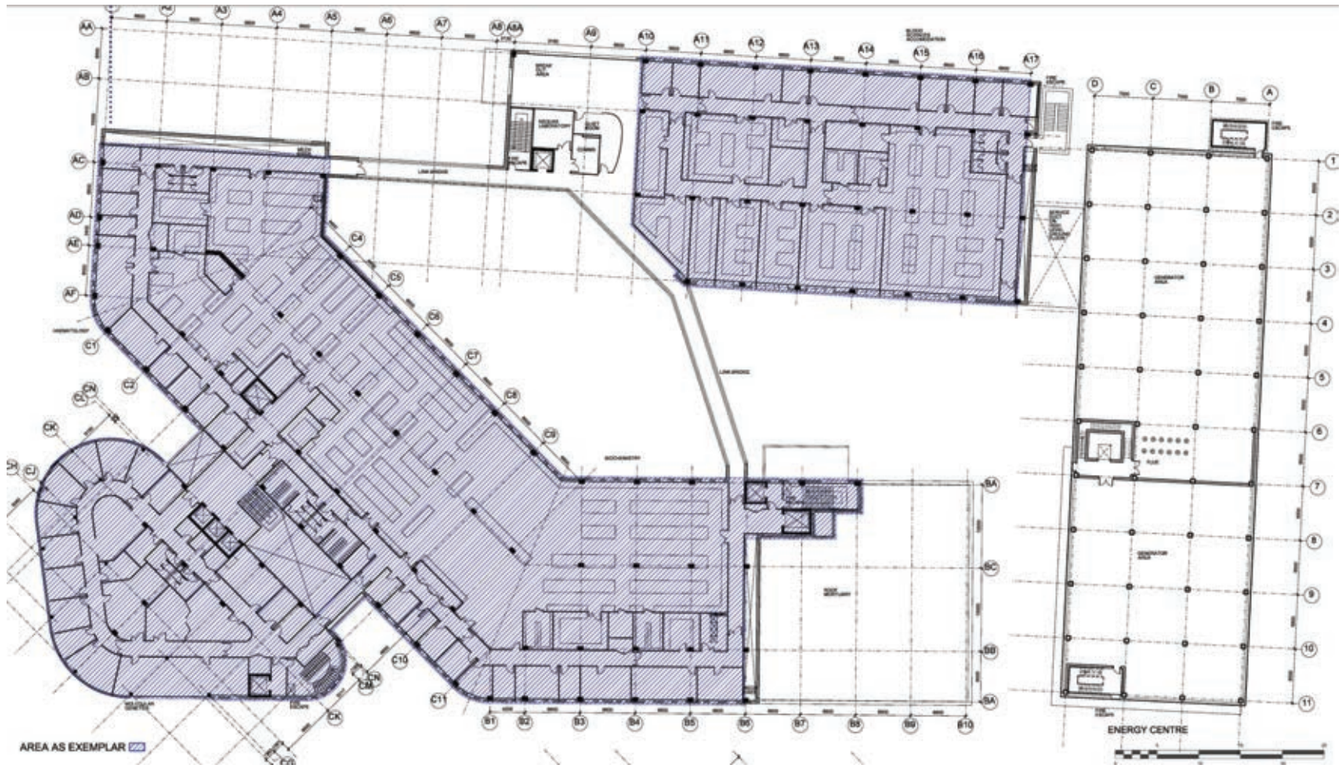
To address the above items our option

- Moves the gas storage facilities.
- Extends the link between the main laboratory building and the main blood sciences block.

Our proposal utilises the exemplar laboratory layouts and we therefore believe there is no impact on the exemplar adjacencies demonstrated in the Employers Requirements.

The proposal also provides the atrium, social facilities and seminar spaces that are required in the exemplar scheme.

Our reprovision of this space in its new location also allows for greater natural daylight, ventilation and views.

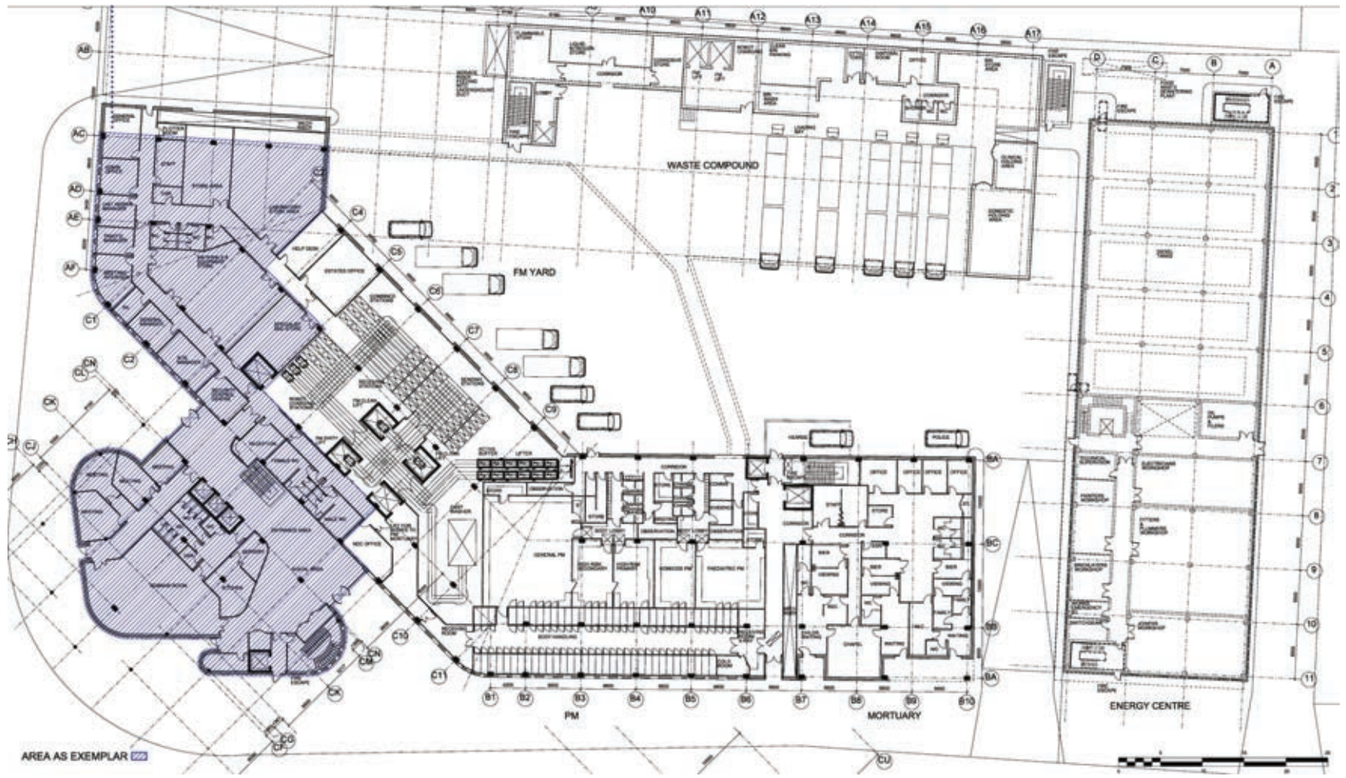


A48235836

Brookfield

Realignment of Gas Storage Compound at Fm Yard Level

Our scheme provides a like for like alternative in a location that allows for ease of access and maintenance it also ensures that the compound is moved out of the narrow entry point to the FM yard.



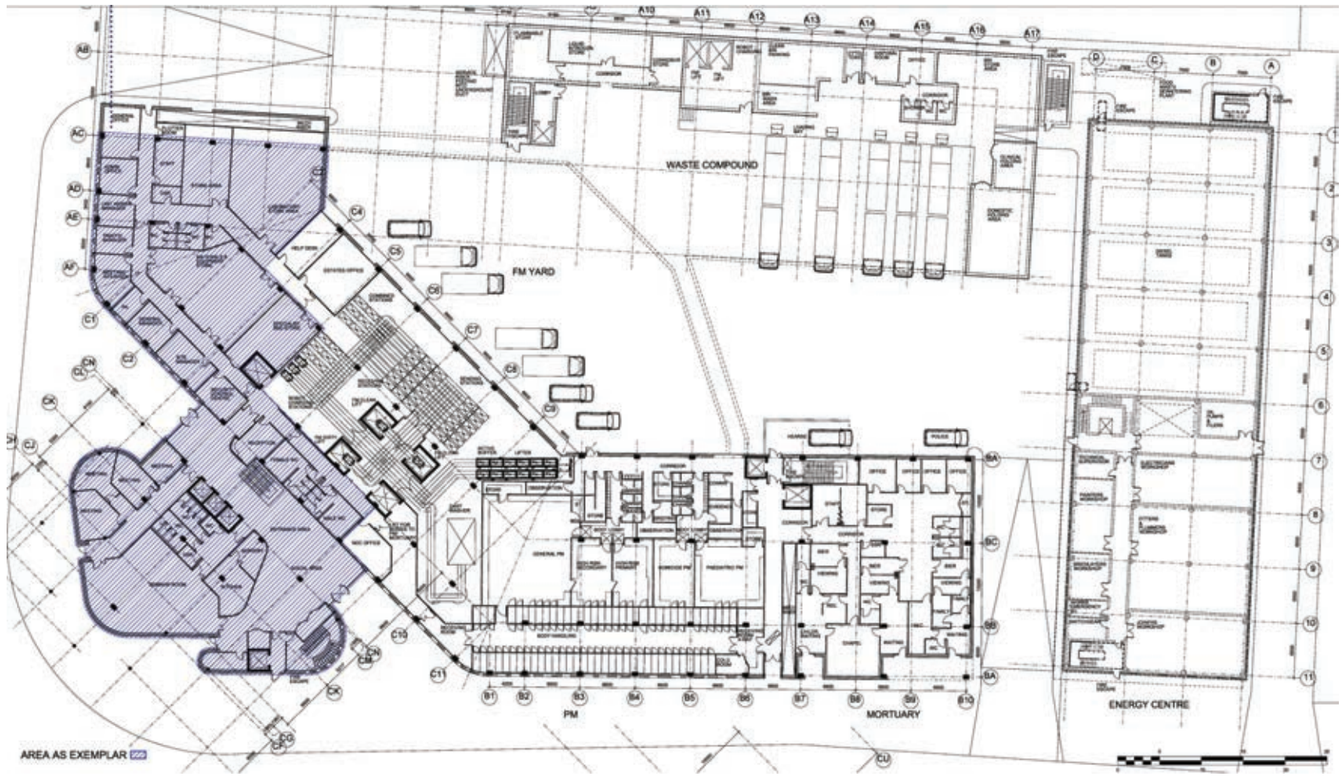
A48235836

Brookfield

Repositioning of Some Hard Fm Facilities to a Bespoke Area within the Energy Centre

As agreed with the board we have repositioned some FM facilities into the Energy Centre. Our proposal clearly defined the service zone and activity, it also minimises activity cross flow issues.

Should we be successful we will review our current proposal with the board to ensure flows, links and service delivery are optimised



Introduction

Submission Reference:

Section 3.30: 'AEDET RESPONSE'.

Submission Response:

At the PQQ stage Nightingale Associates Organogram identified Brookfield proposal for ensuring that our scheme delivered a state of the art healthcare facility.

By including a peer review group who liaise with healthcare designers and operators on a worldwide basis, we have ensured that our scheme is mindful of and adheres to exemplar facilities worldwide.

Gillespie's, our Landscape and Masterplan Consultants, also have a representative on the Architecture and Design Scotland review panel, they have contributed to the review process.

Brookfield

As the scheme has progressed we have strengthened the peer review process by adding an external consultant John Jenner.

John Jenner is a founding partner of Greenhill and Jenner Architects, an award winning healthcare practice. Johns areas of expertise are architectural, interior and urban design, and masterplanning; especially for health buildings. His focus is on community and user group consultation and participation.

John is also a CABE Enabler and Chair of the Department of Health Design Review Panel which means he is a regular member of the review panels for major healthcare schemes in the UK.

John has facilitated and reviewed Brookfield's design proposal against the AEDET criteria.

Brookfield

IMPACT: Character and innovation

Average score: 5.0

The four IMPACT sections deal with the extent to which the building creates a sense of place and contributes positively to the lives of those who use it and are its neighbours.

Section A deals with the overall feeling of the building. It asks whether the building has clarity of design intention, and whether this is appropriate to its purpose. A building that scores well under this heading is likely to lift the spirits and to be seen as an exemplar of good architecture of its kind.

ID	Description	Weighting	Score	Notes
A.01	**There are clear ideas behind the design of the building**	High (2) ▼	Strong agreement (5) ▼	Clear and distinct buildings providing: Adult and Children and young peoples services
A.02	**The building is interesting to look at and move around in**	Normal (1) ▼	Strong agreement (5) ▼	Work in progress: further development of interior desin and arts strategy required
A.03	**The building projects a caring and reassuring atmosphere**	High (2) ▼	Strong agreement (5) ▼	Variety of environments for adults,children and young people have been provided
A.04	**The building appropriately expresses the values of the NHS**	Normal (1) ▼	Strong agreement (5) ▼	Design delivered will aid staff retention and will be a destination for the community and the people of Glasgow.
A.05	**The building is likely to influence future designs**	Normal (1) ▼	Strong agreement (5) ▼	Improvement on PSC to maximise clinical efficiences

◄ Project workshop setup ►► Results summary Form and materials ►

Brookfield

IMPACT: Form and materials

Average score: 5.0

Section B deals with the nature of the building in terms of its overall form and materials. It is primarily concerned with how the building presents itself to the outside world in terms of its appearance and organisation. Although it deals with the materials from which the building is constructed it is not concerned with these in a technical sense but rather the way they will appear and feel throughout the life of the building.

ID	Description	Weighting	Score	Notes
B.01	**The building has a human scale and feels welcoming**	Normal (1) ▼	Strong agreement (5) ▼	The building has a significant scale which fits within the existing urban context, the aspect of 'human scale' will rely upon the quality of detailing
B.02	**The design takes advantage of available sunlight and provides shelter from prevailing winds**	Normal (1) ▼	Strong agreement (5) ▼	Sunlight is maximised within the constraints of the site.
B.03	**Entrances are obvious and logically positioned in relation to likely points of arrival on site**	Normal (1) ▼	Strong agreement (5) ▼	Separation between pedestrians and vehicles, make the entrances more legible and achieve better connection to the external landscape.
B.04	**The external materials and detailing appear to be of high quality**	Normal (1) ▼	Strong agreement (5) ▼	Strong commitment to high quality external materials and detailing throughout project.
B.05	**The external colours and textures seem appropriate and attractive**	Normal (1) ▼	Strong agreement (5) ▼	

◄ Character and innovation ►► Results summary Staff and patient environment ►

Brookfield

IMPACT: Staff and patient environment		Average score: 5.0		
Section C deals with how well an environment complies with best practice as indicated by the research evidence.				
ID	Description	Weighting	Score	Notes
C.01	The building respects the dignity of patients and allows for appropriate levels of privacy and dignity	Normal (1) ▼	Strong agreement (5) ▼	100% single rooms in the acute building and 83% single rooms in childrens building.
C.02	There are good views inside and out of the building	Normal (1) ▼	Strong agreement (5) ▼	All wards planned to maximise views out of the building, good connections being proposed from inside to outside landscapes spaces.
C.03	Patients and staff have good access to outdoors	Normal (1) ▼	Strong agreement (5) ▼	The scheme providesa variety of outdoor spaces,well landscaped for patients, staff and visitors.
C.04	There are high levels of both comfort and control of comfort	Normal (1) ▼	Strong agreement (5) ▼	Good levels of comfort ventilation and lighting achieved.
C.05	The building is clearly understandable	Normal (1) ▼	Strong agreement (5) ▼	Clear distinction between acute and childrens services, the atriums provides a strong reference point for orientation and wayfinding.
C.06	The interior of the building is attractive in appearance	Normal (1) ▼	Strong agreement (5) ▼	
C.07	There are good bath/toilet and other facilities for patients	Normal (1) ▼	Strong agreement (5) ▼	Wards, visitors and staff have good access to generous bathroom/toilet facilities
C.08	There are good facilities for staff, including convenient places to work and relax without being on demand	Normal (1) ▼	Strong agreement (5) ▼	Good variety of staff rest and breakout spaces provided

◄ Form and materials ►► Results summary Urban and social integration ►

Brookfield

IMPACT: Urban and social integration

Average score: 4.8

Section D deals with the way the building relates to its surroundings. It asks whether the building plays a positive role in the neighbourhood whether that is urban, suburban or rural. A building that scores well is likely to improve its neighbourhood rather than detract from it.

ID	Description	Weighting	Score	Notes
D.01	**The height, volume and skyline of the building relate well to the surrounding environment**	Normal (1) ▼	Fair agreement (4) ▼	Work in progress: design tem are investigating long distance impact of building in the city
D.02	**The building contributes positively to its locality**	Normal (1) ▼	Strong agreement (5) ▼	
D.03	**The hard and soft landscape around the building contribute positively to the locality**	Normal (1) ▼	Strong agreement (5) ▼	Proviion of gardens, public spaces and childrens park all contribute to both public and private realms within the scheme.
D.04	**The building is sensitive to neighbours and passers-by**	Normal (1) ▼	Strong agreement (5) ▼	Building positioned sensitively to adjacent residential buildings.

Brookfield

BUILD QUALITY: Performance

Average score: 5.0

The three BUILD QUALITY sections deal with the physical components of the building rather than the spaces. This is therefore what might be thought of as the more technical and engineering aspects of the building. It asks whether the building is soundly built, will be reliable and easy to operate, last well and is sustainable. It is also concerned with the actual process of construction and the extent to which any disruption caused is minimised.

Section E is concerned with the technical performance of the building during its lifetime. It asks whether the components of the building are of high quality and fit for their purpose. However we are not concerned here with how well the building functions in relation to the human use of it which belongs in another section.

ID	Description	Weighting	Score	Notes
E.01	**The building is easy to operate**	Normal (1) ▼	Strong agreement (5) ▼	FM,AGV service yard and vertical cores ensure ease of operation
E.02	**The building is easy to clean**	Normal (1) ▼	Strong agreement (5) ▼	Durable and robust finishes,hard landscaping and cleaning cradles will ensure the building is easy to clean.
E.03	**The building has appropriately durable finishes**	Normal (1) ▼	Strong agreement (5) ▼	The consortia has a commitment to providing good quality durable materials throughout that meets lifecycle requirments
E.04	**The building will weather and age well**	Normal (1) ▼	Strong agreement (5) ▼	The consortia has a commitment to selecting external materials that will weather and age well.

◄ Urban and social integration ►► Results summary Engineering ►

Brookfield

BUILD QUALITY: Engineering

Average score: 5.0

Section F is concerned with those parts of the building that are engineering systems as opposed to the main architectural features. It asks whether the engineering systems are of high quality and fit for their purpose, will be easy to operate and if they are efficient and sustainable.

ID	Description	Weighting	Score	Notes
F.01	**The engineering systems are well designed, flexible and efficient in use**	Normal (1) ▼	Strong agreement (5) ▼	Well designed,integrated and efficient.
F.02	**The engineering systems exploit any benefits from standardisation and prefabrication where relevant**	Normal (1) ▼	Strong agreement (5) ▼	Very high percentage of service prefabrication throughout the design.
F.03	**The engineering systems are energy efficient**	Normal (1) ▼	Strong agreement (5) ▼	CHP units,absorbtion cooling and highly efficient plant will achieve TER objective.
F.04	**There are emergency backup systems that are designed to minimise disruption**	Normal (1) ▼	Strong agreement (5) ▼	High level of resiliance throughout design.
F.05	**During construction disruption to essential services is minimised**	Normal (1) ▼	Strong agreement (5) ▼	

◄ Performance ►► Results summary Construction ►

A48235836

Brookfield

BUILD QUALITY: Construction

● Average score: 5.0

Section G is concerned with the technical issues of actually constructing the building and with the performance of the main components. A building that scores well is likely to be constructed as quickly and easily as possible under the circumstances of the site and to offer a robust and easily maintained solution.

ID	Description	Weighting	Score	Notes
G.01	If phased planning and construction are necessary the various stages are well organised	Normal (1) ▼	Strong agreement (5) ▼	Phasing and construction well considered throughout building programme.
G.02	Temporary construction work is minimised	Normal (1) ▼	Strong agreement (5) ▼	
G.03	The impact of the building process on continuing healthcare provision is minimised	Normal (1) ▼	Strong agreement (5) ▼	Consortia are actively supporting and investing in maintaining healthcare provision on site.
G.04	The building can be readily maintained	Normal (1) ▼	Strong agreement (5) ▼	Plant replacement strategy and CDM compliance developed to provide ease of access and maintenance.
G.05	The construction is robust	Normal (1) ▼	Strong agreement (5) ▼	
G.06	The construction allows easy access to engineering systems for maintenance, replacement and expansion	Normal (1) ▼	Strong agreement (5) ▼	
G.07	The construction exploits any benefits from standardisation and prefabrication where relevant	Normal (1) ▼	Strong agreement (5) ▼	

◄ Engineering ►► Results summary Use ►

Brookfield

FUNCTIONALITY: Use

Average score: 5.4

The three FUNCTIONALITY sections deal with all those issues to do with the primary purpose or function of the building. It deals with how well the building serves these primary purposes and the extent to which it facilitates or inhibits the activities of the people who carry out the functions inside and around the building.

Section H is concerned with the way the building enables the users to perform their duties and operate the healthcare systems and facilities housed in the building. To get a good score the building will be highly functional and efficient, enabling people to have enough space for their activities and to move around economically and easily in a way that relates well to the policies and objective of the Trust. A high scoring building is also likely to have some flexibility in use.

ID	Description	Weighting	Score	Notes
H.01	**The prime functional requirements of the brief are satisfied**	High (2) ▼	Virtually total agreement (6) ▼	Adjacencies and health planning well considered and in line with Board requirements
H.02	**The design facilitates the care model of the Trust**	High (2) ▼	Strong agreement (5) ▼	Refinement of PSC scheme with exemplars demonstrated through bid dialogue and site visit
H.03	**Overall the building is capable of handling the projected throughput**	Normal (1) ▼	Virtually total agreement (6) ▼	
H.04	**Work flows and logistics are arranged optimally**	Normal (1) ▼	Virtually total agreement (6) ▼	Clearly demonstrated through workflow diagrms,FM strategy and AGV instillations Volume 2
H.05	**The building is sufficiently adaptable to respond to change and to enable expansion**	Normal (1) ▼	Strong agreement (5) ▼	Some provision has been made for increasing clinical rooms within departments and integrated service strategy will allow for adaptation and
H.06	**Where possible spaces are standardised and flexible in use patterns**	Normal (1) ▼	Strong agreement (5) ▼	Generic room sizes,modular construction and service strategy allows for flexible use patterns
H.07	**The layout facilitates both security and supervision**	Normal (1) ▼	Strong agreement (5) ▼	Layout facilitates passive surveillance

◄ Construction ►► Results summary Access ►

Brookfield

FUNCTIONALITY: Access

Average score: 5.3

Section I focuses on the way the users of the building can come and go. It asks whether people can easily and efficiently get onto and off the site using a variety of means of transport and whether they can logically, easily and safely get into and out of the building.

ID	Description	Weighting	Score	Notes
I.01	**There is good access from available public transport including any on-site roads**	Normal (1) ▼	Strong agreement (5) ▼	
I.02	**There is adequate parking for visitors and staff cars with appropriate provision for disabled people**	Normal (1) ▼	Strong agreement (5) ▼	
I.03	**The approach and access for ambulances is appropriately provided**	Normal (1) ▼	Virtually total agreement (6) ▼	
I.04	**Goods and waste disposal vehicle circulation is good and segregated from public and staff access where appropriate**	Normal (1) ▼	Virtually total agreement (6) ▼	
I.05	**Pedestrian access routes are obvious, pleasant and suitable for wheelchair users and people with other disabilities / impaired sight**	Normal (1) ▼	Strong agreement (5) ▼	Dedicated set down and pick up for OPD/Discharge lounge.
I.06	**Outdoor spaces are provided with appropriate and safe lighting indicating paths, ramps and steps**	Normal (1) ▼	Strong agreement (5) ▼	Good variety of public and private outdoor spaces.
I.07	**The fire planning strategy allows for ready access and egress**	Normal (1) ▼	Strong agreement (5) ▼	Independent peer review carried out by Waterman.

◄ Use ►► Results summary Space ►

Brookfield

FUNCTIONALITY: Space

Average score: 5.0

Section J concentrates on the amount of space in the building in relation to its purpose. It asks if this space is well located and efficient and whether people can move around in it efficiently and with dignity.

ID	Description	Weighting	Score	Notes
J.01	**The design achieves appropriate space standards**	Normal (1) ▼	Strong agreement (5) ▼	
J.02	**The ratio of usable space to the total area is good**	Normal (1) ▼	Strong agreement (5) ▼	
J.03	**The circulation distances travelled by staff, patients and visitors are minimised by the layout**	Normal (1) ▼	Strong agreement (5) ▼	Development of the PSC
J.04	**Any necessary isolation and segregation of spaces is achieved**	Normal (1) ▼	Strong agreement (5) ▼	
J.05	**The design makes appropriate provision for gender segregation**	Normal (1) ▼	Strong agreement (5) ▼	Including flexing of wards.
J.06	**There is adequate storage space**	Normal (1) ▼	Strong agreement (5) ▼

Brookfield

The Sustainable Design Brief for the New South Glasgow Hospitals Project

"Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs."

Our Common Future, Brundtland Commission, 1987

"Our objective is to construct sustainable buildings which ensure that sustainable solutions and targets provide optimum performance using practical solutions."

Brookfield Construction Ltd

The entire design process for the New South Glasgow Hospital (NSGH) has been underpinned by Brookfield's corporate approach to sustainability, which acknowledges the principles of the Brundtland Commission and Brookfield's own role and responsibility in building new hospitals. The NHS, due to its large estate and workforce, has the potential to make a large impact in terms of reducing its environmental impact but also through educating its staff and patients by putting sustainability into practice. The design of the buildings plays a key role in this, as stated by the Sustainable Development Commission:

"Building sustainably provides healing environments and healthier workplaces that enhance public health. This helps reduce pressure on healthcare services, contributing to the long-term viability of the NHS."

Sustainability represents more than a design approach however, and this document illustrates how the sustainable design targets (for example BREEAM Excellent) have been met as well as ensuring that the social and economic impacts of the development have been addressed. Brookfield believe that the final proposal is sustainable through virtue of its comparatively low environmental impact and the social and economic benefits it would bring to the local community.

The Brookfield design and construction team has been working to put forward a design and construction proposal which fits with the Greater Glasgow and Clyde's (GG&C) NHS Board's requirements in terms of actual content and also meeting sustainability objectives. The sustainable design principles for the buildings are set out in the Board's Low Carbon Priorities and these have been addressed throughout the design and recorded in this document.

The following two extracts were fundamental reference points in developing the sustainable design approach for New South Glasgow Hospital:

GG&C NHS Board Environment and Sustainability policy:

- reduce the consumption of energy
- reduce, re-use and recycle waste
- sustainable procurement policy
- reduce the usage of transport
- reduce the use of water."

Key Principles for Healthcare Buildings, SHINE (Learning Network for Sustainable Healthcare Buildings):

1. Integrating with the local environment & promoting regeneration
2. Meeting the needs of & providing facilities for local communities
3. Providing accessible transport options for all members of the community
4. Delivering cleaner, greener and safer public spaces that are rich in biodiversity
5. Using resources (e.g. energy & water) efficiently
6. Providing flexibility and adaptability to meet changing service needs
7. Considering whole life performance, including long-term asset value
8. Providing a quality internal environment to support health and well-being for users
9. Using materials that reduce environmental and health impacts
10. Reducing pollution and waste to avoid health and other impacts."

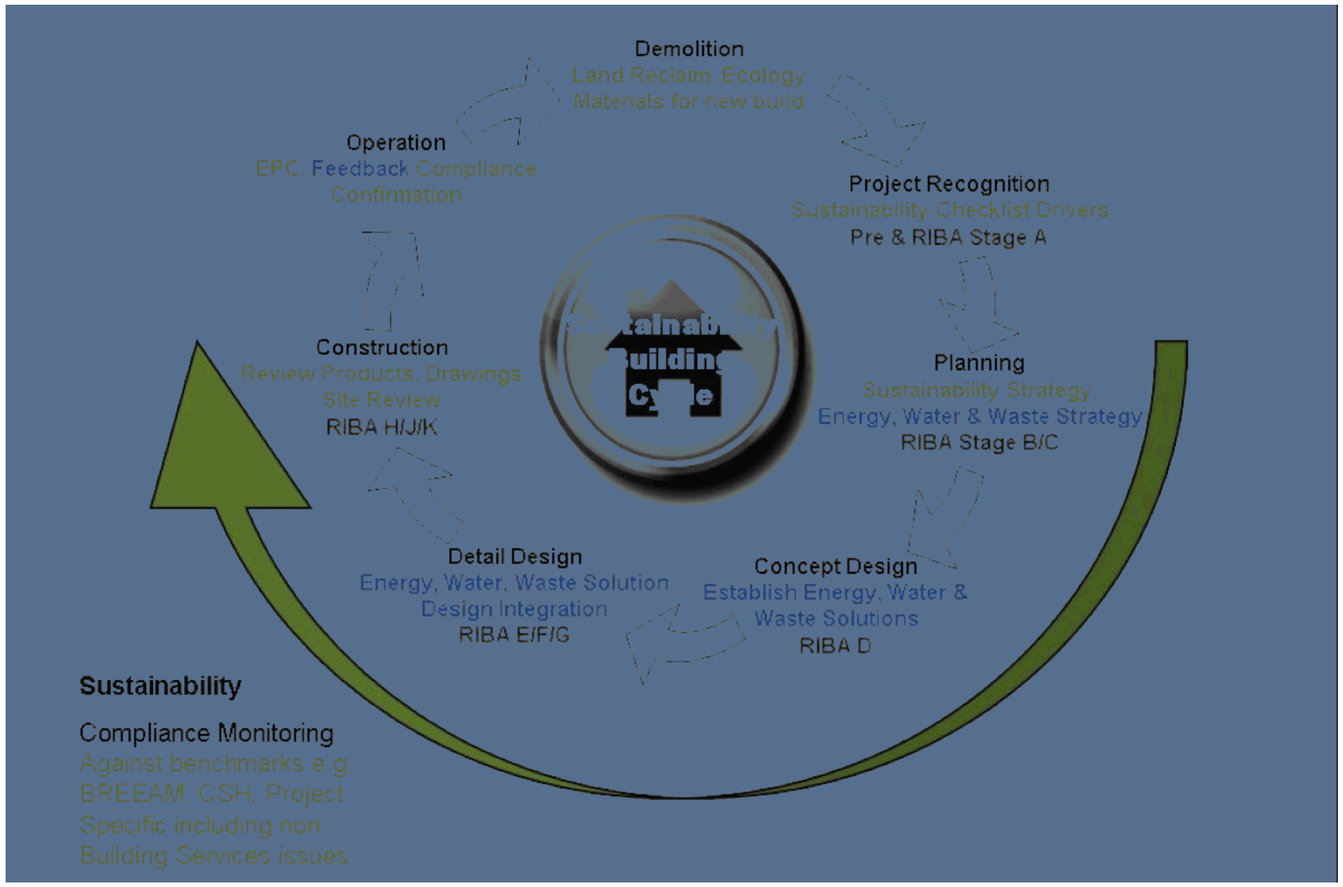
Contents



An outline of the sustainable design process followed so far and proposed for the remainder of the project.

Brookfield

1. Community Engagement

Design, Construction and Operation

An inclusive and comprehensive community engagement process underpins social sustainability. The community engagement strategy, which has been developed for the New South Glasgow Hospital, has been ongoing since the early design stages. Local residents, community groups, schools, colleges and businesses have been actively engaged wherever possible. Information has been made publicly available and distributed to stakeholders through a range of media including the NHS GG&C website. Stakeholders have been engaged in consultations on a wide range of topics including:

- Transport and Travel;
- Employment opportunities; and
- The design of the hospital.

The above process has influenced the outcome of the design, for example with the inclusion of a community garden and the levels and modes of transport provision (BREEAM Man 6 & 7).

The lengthy construction phase of New South Glasgow Hospital will offer significant employment opportunities in a variety of sectors. Brookfield and its contractors will combine meeting the 10% new entrant target set by the NHS Board by prioritising opportunities for local people and businesses. The new entrants will constitute a range of people and skills including the long-term unemployed, apprentices and students. Community engagement does not stop post-construction. The ethos of community engagement will be maintained throughout the life of the New South Glasgow Hospital. It will be a welcoming, user-friendly environment that will build upon the positive and strong community engagement that has been achieved during the design and construction stages. This will help maintain the 'sustainable community' that has been developed.

The full Community Engagement Strategy is included in this bid submission, under Volume.10.1.

2. Management

"Buildings constructed in line with environmentally conscious principles are good long-term investments, with lower operating costs and a greater ability to meet changing environmental controls and legislation." Building a Brighter Future: A Guide to Low Carbon Building Design – Carbon Trust.

Design

Sustainable Project Management is part of Brookfield's corporate Sustainable Strategy which provides clear guidelines for all their construction projects and ensures a minimum standard with regards to sustainability in their projects. During the design stage, early identification and then incorporation of the project's sustainability objectives in the design process along with the integration of the BREEAM pre-assessment into the design team meetings, established a sustainable project solution.

Decisions relating to the choice of building services and materials have been influenced by a lifecycle costing analysis, which has taken into account not only the costs of the different options, but also their environmental impact in terms of energy consumption or material source (Man 12). The results of this exercise were fed back into the design process and used to decide the final specifications for the building. To ensure that these sustainable objectives become reality, Brookfield will include a condition in all subcontracts to fulfil the predetermined targets. In addition to the lifecycle cost analysis, consideration has been taken of pending legislative changes relating to carbon emissions from large organisations in order to meet the overall goal of reducing Scotland's carbon emissions by 42% by 2020. The increasing importance of carbon emissions and the potential risk of not designing a low carbon building have been taken into account and influenced the final design, for example in relation to the choice of building service systems.

The approach to sustainable management of the design process can be summarised as follows:

- The BREEAM Assessment is integrated throughout the design process.
- Brookfield Sustainability Strategy underpins the project management structure.
- Life Cycle Costing to understand full financial and environmental cost of material and equipment choice.
- The design team has worked together with the facilities management team to choose engineering and design solutions that are practical and easy to maintain (Man 11).

Brookfield and their main civil construction contractor Dunne are confident of their performance and have a strong track record in the Considerate Constructors Scheme. This is therefore an area where an innovation credit has been targeted in the BREEAM Healthcare pre-assessment for New South Glasgow Hospital. The commissioning programme will extend to include post-occupancy monitoring to ensure that the commissioned systems perform in reality as they were designed. This will ensure that the sustainable design becomes reality (Man 1).

- Ongoing monitoring of the construction targets set by Brookfield during the design phase, relating to energy, water, pollution and waste.
- Brookfield has international ISO 14001 certification and will ensure that their operations at the NSGH construction site will meet the requisite Environmental Management System's standards.
- Sustainable management extends to the health and wellbeing of staff, for example the onsite canteen will also be offering healthy food choices in order to teach healthy food practice.

Brookfield

2. Health and Wellbeing

"The research team found rigorous studies that link the physical environment to patient and staff outcomes in four areas:

- Reduce staff stress and fatigue and increase effectiveness in delivering care
- Improve patient safety
- Reduce stress and improve outcomes
- Improve overall healthcare quality."

Ulrich, The Role of the Physical Environment in the Hospital of the 21st Century

Design

Health and Wellbeing encompasses not only the patients but staff and the local community as well. One way to ensure the health and wellbeing of users is to have a high level of stakeholder engagement. 99% of nurses believe it is important for them to be consulted about decisions relating to the design of hospitals, rising to 100% for nurses in a management position (CABE, Healthy Hospitals). Brookfield's consultation will expand upon the results of the Board's consultation to incorporate an extensive consultation process with all community stakeholders, from which Brookfield has developed a Community Engagement Strategy (Vol. 10.1).

A number of design decisions affect the health and wellbeing of building users and the following lists design considerations were made to make the hospital a pleasant place to work, recuperate and visit:

- The Ward Tower has been designed to ensure that each bedroom will be outward facing to take advantage of distant views and maximise natural daylight. The Children's Wards have a combination of inward and outward facing bedrooms, with the integration of both indoor and outdoor play spaces (BREEAM Hea 2). Building users will also be able to close blinds as required to reduce glare within the building (BREEAM Hea 3).
- All patient areas will have operable windows, allowing fresh air into the ward areas.
- Within internal areas, lighting will also be appropriately zoned, so that occupants can control it (BREEAM Hea 6).
- The main Ward Tower has been designed in conjunction with standard Health Guidance critical dimensions will reduce the risk of infection. The Children's Wards include a number of 4-Bedded Bays, which utilise Nightingales' Cruciform design, which ensures that each patient's bedhead is at the maximum possible distance from the other, thus reducing infection risks.
- The choice of internal fixtures and fittings has been made to reduce emissions of VOC[1]s as much as possible, in line with best practice recommended levels (BREEAM Hea 9).
- Noise levels, air quality and thermal comfort all significantly impact a person's health and wellbeing. In the New South Glasgow Hospital all elements impacting on air quality and thermal comfort will be specified to a high standard and noise levels will achieve the recommended performance benchmarks as outlined in HTM 08-01 Part A (BREEAM Hea 10 and 13).
- Wide corridors and access as well as clear signage will help to reduce stress and anxiety and improve a patient's experience when in the building.
- The provision of outdoor amenity space and green areas is a well recognised means to improve general wellbeing. Brookfield's proposal for the hospital has outdoor amenity space for patients and visitors to the acute and children's hospitals, a children's play area and plenty of seating provision (BREEAM Hea 15).
- An arts strategy is being prepared for New South Glasgow Hospital by Gingko Projects in conjunction with Gillespies and Nightingales, to address enhancing the healthcare environment and building relationships with the local community, patients and their families (BREEAM Hea 19).

Construction

During the construction phase of New South Glasgow Hospital there will be a number of issues affecting the health and wellbeing of the workforce, neighbouring residents and existing building users. The Glasgow South West Regeneration Agency (GSWRA) is working in partnership with Brookfield to liaise with the local community groups and agencies, thus ensuring their involvement is coordinated and effective.

- Dunne has an ongoing working relationship with the GSWRA to provide health and wellbeing open days for the local community.
- Health and safety on a construction site is paramount. All of the contractors involved for the Construction of the New South Glasgow Hospital and all employees, including new entrants, will abide by and follow the relevant Health and Safety regulations and codes and follow the Health and Safety Executive's best practices for health and safety in the construction sector.
- Personnel working on the construction of the hospital will need access to a range of amenities. During the lengthy construction phase, provision will be made on site for a permanent on site health advisor, who will undertake a series of awareness raising sessions to improve education and understanding around issues such as obesity and smoking.
- Brookfield will ensure that the onsite canteen for construction staff will promote healthy food and eating habits.

1 Volatile Organic Compounds, released from some man made materials.

Brookfield

Operation

The health and wellbeing of the local community is the ultimate goal of all operational hospitals. The New South Glasgow Hospital will be no exception and the design intends to support the delivery of a high standard of healthcare as well as providing a healthy working environment that promotes a work-life balance, a place that is safe and encourages speedy recuperation, and is a pleasant place for people to visit. The following points are the main issues that have been addressed to benefit health and wellbeing in the New South Glasgow Hospital:

- The proposed design will encourage people to walk or cycle to the hospital, improving health of the individual.
- The food retail outlets on site will promote healthy food options, using organic and locally sourced produce wherever possible to illustrate a balanced and varied diet.
- The landscaped areas are designed to allow staff, patients and visitors alike the opportunity to walk outside, take some fresh air and have some time to relax away from the inevitably busy hospital environment.

3. Energy

"To provide an energy efficient building which provides better indoor conditions for patients and staff and reduces operational energy costs." HTM – 07-02:Encod – making energy work in healthcare..

Design

The most effective way to reduce energy consumption during operation is to create a design which eliminates and reduces energy use through the choice of materials, location, lay-out and design. This approach is clearly laid out in a range of guidance, including the HTM Encode, the Carbon Trust's guide to low carbon building design and reflected in GG&C NHS Board's requirements for this project, with the low carbon tracker. All of these documents have been referenced and integrated into the approach to developing the NSGH's final design, so that a structured approach, based on the energy hierarchy, was taken. This follows a simple hierarchy of measures to firstly eliminate energy demand where possible through building design, for example maximising daylight, thus reducing the need for lighting. Secondly, where energy is used, it is done so in an efficient manner, with items such as energy efficient lighting externally which is only illuminated when it's required (BREEAM Ene4). Finally, the feasibility of renewable energy sources to meet the remaining demand is assessed in line with the hospital's location and natural assets. The choice of natural gas CHP onsite means that when a stream of biogas from the Shieldhall STP becomes available, this can be directly used in the energy centre. Another alternative low carbon source of energy to be investigated is an off-site wind turbine, providing zero carbon electricity to the hospital.

For full details of how the energy demand of the building will be met, the energy strategy (Vol. 3.20) should be reviewed. The main features of the energy strategy are as follows:

- Energy demand has been eliminated through choosing external fabrics with good insulating properties and allowing natural ventilation to be used wherever possible.
- The design includes energy efficient lighting with intelligent lighting controls and heat recovery on all air handling units, which will ensure energy is used efficiently. High efficiency chillers are specified, which will result in high performance efficiencies, particularly at part load.
- The remaining energy demand for the hospital will be met through a natural gas CHP energy centre, which will have in total 3MWe of CHP plant and adsorption cooling, able to be respond to the changing demand. This will be supplemented by 12 on-site building mounted turbines to provide a visible commitment to renewable energy.
- The 15% reduction in CO_2 emissions as required under SPP 6 has been met by using the onsite natural gas CHP and 12 small wind turbines on site (BREEAM Ene 5). This will actually exceed the 15%.
- On the basis of the above design, the predicted EPC rating will be at least 31, which results in a score of 8 points under BREEAM Ene1.
- The design energy target of 80kgCO_2/m^2/annum will also be exceeded.

Construction

During construction the most important aspect will be to minimise the impact of the construction activities on carbon emissions. Targets will be set for the construction site as a whole to reduce energy consumption (BREEAM Man 3) through careful use of powered equipment, lighting and also through a construction site travel plan.

- Building (Scotland) Regulations, set by the Scottish Building Standards organisation, will be implemented and exceeded.
- Construction site targets will be set for site energy consumption and carbon emissions (BREEAM Man 3).
- The choice of recycled content and materials reduces embodied carbon in materials (reference the Materials section).
- Pre-fabrication will be specified for large parts of the hospital which is an energy and waste efficient means of production.

Operation

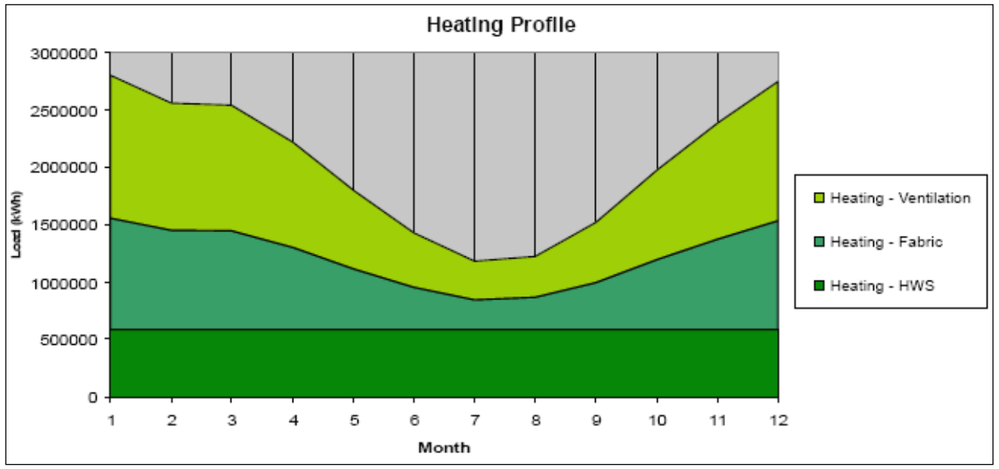
The GG&C Carbon Management plan includes a target to reduce its CO_2 by at least 25% over the period of 2006 – 2016. As the NSGH is a new hospital, replacing older building stock, it presents a real opportunity to contribute to this overall target. This will be achieved through meeting and exceeding the operational target of 55GJ/100m^3, as laid out in the Department of Health's guidance. Although hospitals are inevitably energy intensive to operate, with clear guidance as to how to operate the building to meet its designed level of performance, energy efficiency can be achieved. The proposed NSGH design includes features such as energy efficient lighting and lifts (BREEAM Ene 4 and Ene 8), HVAC systems with heat recovery and CHP units in the energy centre with an overall efficiency of 85% (approximately). Other aspects to reduce energy consumption include:

- Sub-metering of different areas of the building will facilitate monitoring of energy consumption within the hospital and, through the BMS, allow identification of areas of high energy usage and efficacy of energy saving measures (BREEAM Ene 2 and Ene 3).
- Regular audits of energy consumption and major energy using equipment to ensure operating efficiently.
- Post-occupancy audit to ensure building is meeting the expected performance standards.
- The operational energy demand is predicted to exceed the target set of 55 GJ/100m^3/yr.

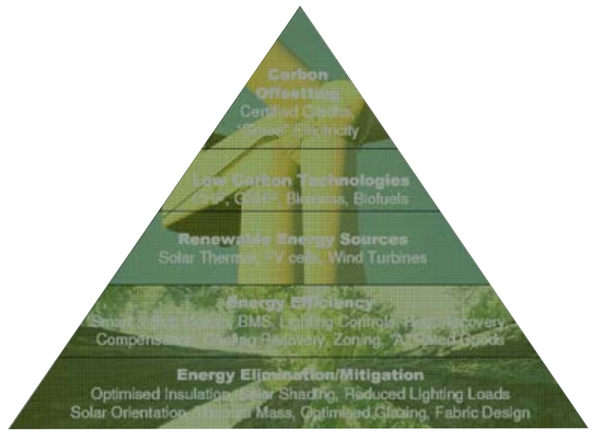
Brookfield

BREEAM Summary

Anticipated Credits:	Predicted Percentage Achieved:
Reduction in CO2 emissions	69%
Sub-metering of substantial energy Uses	
Sub-metering of high energy load areas and tenancy	
External lighting	
Low and zero carbon technologies	
Energy efficient lifts	
CHP Community Energy study	



Heating profile taken from the energy strategy (Vol.3.20), showing the demand could be met.



The Energy Hierarchy, used to structure the approach to designing NSGH.

A48235836

Brookfield

4. Transport

"Providing accessible transport options for all members of the community." SHINE

Design

The design and plan for transportation to and from the New South Glasgow Hospital will support Glasgow Council's Transport Strategy to provide a world class transport system that is safe, reliable, integrated and accessible to all citizens and visitors (Keeping Glasgow Moving: Glasgow's Local Transport Strategy, 2007-2009). In order to do this, transportation during the construction and operational phases of a building must be addressed during the design phase, if a sustainable transport plan is to be ensured. The following lists the design features of the proposed design which will reduce the reliance on private vehicles for travel:

- The new Clyde Fastlink is an integral part of the transport plan and so its route and stopping area within the hospital have been carefully incorporated to the landscape plans.
- A network of pedestrian and cyclist routes have been laid out across the site and designed in accordance with best practice such as the National Cycle Network 'Guidelines and Practical Details issue 2' (Sustrans, 1997) and LTN 2/04 'Adjacent and Shared Use Facilities for Pedestrians and Cyclists (DfT, 2005) to ensure safe and adequate pedestrian and cycle access (BREEAM Tra 4).
- Cycle storage racks for both staff and visitors have been placed close to the main entrances and staff entrances, with staff showering facilities available (BREEAM Tra 3).
- During the design phase there have been a large number of meetings, for which Brookfield has encouraged using teleconferences and webinars where possible or encouraging attendees to consider alternative options prior to opting for private vehicle use.

Construction

The potential for interruption to local services and facilities within the site during construction has been carefully analysed and will be managed to minimise the disruption to the hospital and nearby building users and residents (Southern General Hospital Travel Plan, 2007). It is envisaged that the hospital will continue to operate uninterrupted on a day-to-day basis during the construction and commissioning of the new facilities. The following actions will be undertaken to ensure impacts from transportation, whether noise, congestion or pollution, are minimised for both the local community and the staff and patients:

- A public website will give information about the construction activities in order to keep the local community informed about vehicle movements.
- Materials and construction traffic will be used as efficiently as possible for example, removal vehicles will be completely full before they leave site and delivery and removal vehicles will follow the most efficient routes.
- Contractors will be required to actively promote the transport hierarchy to all staff, encouraging walking, cycling, use of public transport and car sharing wherever possible.

Operation

The Sustainable Development Commission 'Healthy Futures #5: Sustainable Transport and Active Travel' suggests that the NHS can lead by example and encourage staff and visitors to get out of cars and onto bikes and public transport. The proposed design will facilitate a large number of travel options for the New South Glasgow Hospital to accommodate all building users, whether staff, patients or visitors. The design has referenced the 2007 Travel Plan (drawn up by JMP) to ensure a 'joined up' solution to transport. The following points illustrate the main measures that have been addressed to ensure New South Glasgow Hospital has a sustainable transport plan:

- GG&C NHS Board has a dedicated Travel Plan Coordinator to produce a comprehensive sustainable travel plan and travel options for users of the hospital, transport issues and options have been analysed as early as possible.
- The new hospital will have excellent public transport links. There is a large number of bus stops on and surrounding the site and these provide regular buses to and from the city centre and major towns. There is also a railway station less than 1000m from the new hospital site (BREEAM Tra 1).
- Real time public transportation information will be displayed in the hospital for building users to maximise the use of public transport (BREEAM Tra 7).
- The new hospital will have various amenities such as food outlets, cash machines, a post box and pharmacy either on-site or in close proximity. These amenities will all be reachable through safe pedestrian access and will help reduce the need for private vehicle use (BREEAM Tra 2).

For further information on all the above points and many other travel issues for the new hospital see: New South Glasgow Hospitals, Transport Assessment, April 2007.

5. Land Use, Ecology and Pollution

"Delivering cleaner, greener and safer public spaces that are rich in biodiversity." SHINE

Design

Land-use and Ecology

The Brookfield design team has worked to incorporate requirements of the Glasgow Local Biodiversity Action Plan (LBAP) and the best practice recommendations from CIRIA's 'Working with Wildlife' in order to maximise the benefits to the local and wider natural environment, patients, staff, visitors and the community.

Although the existing green spaces have been identified as having 'low ecological value', there are in excess of 350 trees within the site boundary with a Glasgow City Council tree preservation order. Where possible, these trees have been protected and incorporated into the landscaping plans, preserving their ecological value. It is anticipated that there will be a positive change in the ecological value of the site as a result of the development and so it was concluded that there are likely be no negative ecological impacts (BREEAM Le 4/Le 5). This has been determined on the basis of the following features, recommended by the URS (appointed ecologists):

- The incorporation of bat bricks within the structure of the new buildings or bat boxes on the buildings.
- A wide variety of native plant species across the development as recommended in 'Scotland's Biodiversity (Scottish Executive). These include native trees (e.g. sycamore, birch), shrubs and grasses (e.g. hawthorn, dog-rose, oxeye daisy), aquatic plants and meadow flowers/ grasses for green roofs (including agrimony, St.John's Wort and meadow buttercup).
- Reed beds, which provide a diverse habitat for numerous species of plants, insects, birds and other wildlife.

Pollution

Localised pollution has been reduced or eliminated from the hospital's design through the following:

- Night time trespass of light from the site will be minimised by implementing an internal lighting design strategy which ensures all non-emergency lighting will be automatically switched off in rooms which are not occupied and exterior lighting will only be operational when required for safety and comfort.
- Water run off will be minimised to prevent overwhelming of existing stormwater drains and disruption of natural hydrology. Infiltration will be promoted on the site using permeable paving (Reference the Landscape Strategy by Gillespies for further information) and vegetated roofs and stream channels will be protected to prevent erosion.
- Although the hospital's site is located within a 'low flood risk' area (SEPA), measures such as infiltration of water onsite using permeable paving and diverse green roofs will be implemented to reduce the impact of potential future flooding with allowances made for climate change (BREEAM Pol 5) (Reference the Drainage Strategy).
- Leak detection systems are included in the building services systems to detect, capture and store refrigerant leaks when they occur (BREEAM Pol 2).
- Space and water heating systems with low levels of NOx (nitrogen oxides) will be specified by the Brookfield design team (BREEAM Pol 4).

Construction

Land Use and Ecology

Brookfield and Dunne will work together to ensure that the construction site management plan will include provision for protection of any existing ecological features (e.g. any trees to be retained) during site preparation and construction (BREEAM Le 3), These features will be protected using barriers and prohibition of entry by personnel as well as ensuring that all site personnel are aware of the need for protection. Habitats which will be lost as a result of the development will be compensated for through new landscaping, garden areas and diverse planting.

Habitat protection measures, which will be implemented, include the following:

- All scrub clearance will be undertaken outside of the bird breeding season, July to March. Any clearance which takes place during the nesting season (March to September) will only take place once a survey for active nests has been conducted and confirmation is provided that nests are no longer in use.
- Night surveys will be performed during the months of June and September to assess the use of buildings by bats. Construction workers shall be briefed as to the potential for bats to be discovered. An emergency procedure will be put in place in case bats are discovered during demolition/construction.
- Mature trees will be retained where possible as these provide a habitat type which is relatively uncommon within the development site and cannot be readily replaced.

Pollution

The following measures are recommended by the USA's Leadership in Energy Efficient Design (LEED) scheme to minimise the pollution of construction sites and will be implemented on the hospital development:

- Soil erosion will be prevented during construction by implementing temporary/permanent seeding and mulching, earth dikes and sedimentation traps/fences and basins where appropriate.
- Air pollution will be minimised by periodic water spraying of external areas during dry periods to discourage the generation of atmospheric particulates and minimising site traffic levels (see Transport section for further details).

Brookfield

Operation

Land Use and Ecology

When the buildings are occupied, Brookfield Facilities Management in collaboration with the GG&C NHS Board will maintain the onsite levels of biodiversity through the appointment of a Biodiversity Champion and following the Landscape and Habitat Management plan (BREEAM Le 6). This will be produced by the appointed ecologist and will cover at least the first five years after project completion and include:

- Management of any protected features on site
- Management of new, existing and enhanced habitats
- A reference to the Glasgow Local Biodiversity Action Plan[2]

Pollution

The main sources of pollution during operation will be from the hospital's use of energy, its waste streams and the means of transportation chosen by staff and visitors. These aspects have been covered in detail under the energy, waste and transport sections. Other aspects which will reduce pollution from operation include:

- Local noise-sensitive areas including residential areas, will be protected as much as possible from noise pollution through noise mitigation measures.
- In line with UK legislation, tobacco smoke will be confined to designated outdoor areas. Outdoor areas and shelters for staff and visitors who wish to smoke will be provided.

BREEAM Summary (Ecology and Land Use)

Anticipated Credits:	Predicted Percentage Achieved:
Ecological Value of Site and Protection of Ecological Features	70%
Mitigating Ecological Impact	
Enhancing Site Ecology	
Long Term Impact on Biodiversity	

BREEAM Summary (Pollution)

Anticipated Credits:	Predicted Percentage Achieved:
Preventing Refrigerant Leaks	62%
NOx emissions from heating source	
Flood Risk	
Minimising Watercourse Pollution	
Reduction of Night Time Light Pollution	
Noise Attenuation

Brookfield

6. Materials

"Making changes to the materials, products and production processes used in the construction industry could significantly reduce their impact on the environment." Green Book Live

Design

When examining and selecting materials for use in New South Glasgow Hospital, both the environmental impacts and life cycle of materials have been assessed to ensure the most sustainable materials will be utilised. The BRE Green Guide to Specification and Green Book Live have been used to help specify and select the most sustainable materials for the construction of New South Glasgow hospital (BREEAM Mat 1), which will help to ensure that Brookfield's design is able to meet the 10% target for materials derived from recycled/reused content. From the onset of Brookfield's design, the efficient use of resources has been a priority and the design has aimed to reduce the use of materials and resources wherever possible.

- The dimensions of the proposed New South Glasgow Hospital have been designed to limit waste. Any masonry will be set-out to block dimensions to minimise cut-offs and the internal partitions will be set-out on a standard 300mm grid.
- Considerations have also been made during the design stages for the entire life cycle of the building. Materials designed for long life and low maintenance have been specified wherever possible, for example the solid masonry base for the external walls of the ground floor of the podium and the durable polymeric type paint finish (BREEAM Mat 7).
- Sandstone from the demolition of the surgical buildings is to be incorporated in the landscape design of the arrival space outside the main hospital entrance.
- ETFE roofs have been chosen over glass roofs for the atria due to their higher light transmission and improved thermal performance, helping to reduce energy demand as well as maintenance during the operation of the hospital.
- Materials with a low environmental impact have been prioritised for example, low VOC paints and vinyl floor coverings with an A rating in the Green Guide.
- The proposed materials with a recycled or reused content will include concrete, aggregates, steel, plasterboard as well as the re-use of demolition material in the landscaping.
- All timber to be used for New South Glasgow Hospital will be Forestry Stewardship Commission (FSC) certified and as many materials as possible used for most building elements will be responsibly sourced with proof of Chain of Custody (BREEAM Mat 5).

Construction

The following points illustrate a range of sustainability measures that will be undertaken during construction:

- Materials will be locally sourced wherever possible. Local sourcing of construction materials has a range of benefits including reduced carbon emissions through shorter vehicle journeys to the site and benefits for the local economy through utilising local suppliers and businesses.
- The nature of the cladding systems proposed dictates a large proportion of off-site fabrication utilising a modular system which provides greater production efficiency with less waste and energy expenditure.
- The concrete structure will incorporate a proportion of recycled material (for example, Ecocem which utilises GGBS to reduce cement content) within the concrete mix. Steel for reinforcement in the UK is 100% recycled.
- Brookfield's Sustainability Strategy outlines sustainable procurement as part of its construction project management, which will encompass choosing sustainable materials and minimising wastage allowances.

Operation

Brookfield FM operates a sustainable procurement policy for the operational phase of New South Glasgow Hospital. This will ensure the use of sustainable materials is continued throughout the life cycle of New South Glasgow Hospital.

- The internal wall build-up will be constructed to allow ease of adjustment to enable change of use in the future if required.
- The building has been designed so that when it reaches the end of its operational life, the structure can be recycled.

BREEAM Summary

Anticipated Credits:	Predicted Percentage Achieved:
Highly Rated Green Guide Materials	47%
Hard Landscaping and Boundary Protection	
Responsible sourcing of materials	
Highly Rated Green Guide Insulation	
Designing for Robustness	

7. Waste and meeting WRAP Best Practice

"Reducing pollution and waste to avoid health impacts and the depletion of natural resources." SHINE

Design

Best Practice Guidelines will be used to determine how waste will be managed on site and also to ensure that the waste hierarchy is put into practice, by minimising waste and reducing the amount which needs disposal[3] . One effective means to reduce the total amount of waste created by the project is to reduce the wastage allowances on each supply contract. This will be implemented by Brookfield ensuring that reduced levels are agreed as part of the tendering process, thus reducing the amount of materials which enter the site.

Modern Methods of Construction for some elements will also reduce the amount of waste generated. MEP Solutions will be used to supply ready made bathroom and ward components, which include multi-service modules of pipework, ductwork, medical gases and all electrical services. Pre-cast concrete beams and staircases are to be supplied from Dunne's own pre-casting site in Bathgate, reducing waste and carbon emissions through the avoidance of long journeys.

Given the fact some demolition on site will be undertaken, the demolition materials will be incorporated into the landscaping and construction. Sandstone from the demolished surgical buildings has already been allocated for parts of the landscaping elements. It is recommended, if Brookfield are not conducting the demolition, that it should follow the Institution of Civil Engineer's Demolition Protocol to maximise the amount of material available for re-use.

WRAP's Net Waste Tool

WRAP's guidance has been used to try and design out waste where possible, as detailed above, and for the remaining waste predicted to be generated on site, the Net Waste Tool will be utilised. Once the final design is complete and the materials have been specified, the Net Waste tool will be completed for the NSGH. The resulting waste targets, based on the analysis of waste segregation, recovery and recycling options, will be integrated into the Site Waste Management Plan (SWMP). Although this has not been completed as yet, it is anticipated that the tool will also assist in determining the targets for waste reduction in contractual conditions for sub-contractors and help Brookfield achieve a high level of resource efficiency across the construction site.

Details of the sustainable design for reducing waste:

- A Site Waste Management Plan will be developed before construction starts, which centres around the results from the WRAP Net Waste Tool, and will set targets and assign specific responsibilities to contractors and the Brookfield management team.
- The most significant waste streams will be identified through a pre-construction review and plans made for their segregation and most cost effective recovery solutions.
- The main hospitals and the ancillary buildings are designed to facilitate to segregation at source and accommodate the storage of different waste streams in a waste compound (Wst 3).

Construction

In Scotland, annual construction and demolition waste totals approximately 10.6 million tonnes (2005/2006). This is makes construction sites responsible for approximately 20% of all waste, with wasted materials worth millions disposed of in landfill each year. Avoidance of waste creation is the first step but waste that is generated on site will be segregated to allow ease of recovery or recycling. Brookfield has signed up to WRAP's commitment to halve waste to landfill, a target they have committed to exceeding by 30% in their Corporate Responsibility Statement. In order to achieve this, a Site Waste Management Plan is an integral part of Dunne's Site Environmental Management Plan. During construction, a dedicated waste compound will be established and to facilitate achievement of the waste targets on site; less than 12m^3 waste/100 m^2 of floor area and a landfill diversion rate of 80% (BREEAM Wst 1). Waste minimisation and management will be the direct responsibility of the construction site manager, with contract conditions to defer a mandatory requirement on all suppliers and contractors to reduce waste and packaging on site.

- Where possible, materials with a high level of recycled content will be chosen for use on site, to support the development of a recycled material supply chain. Examples at NSGH include cement replacement and recycled aggregates.
- Transportation of waste off site will be done as efficiently as possible in order to minimise the number of journeys.
- Through the use of the Net Waste Tool, recovery rates will be set for the different waste streams. These targets will be monitored as part of the overall construction site management, with financial penalties in place for contractors who do not meet these targets.
- Liaison with NISP Scotland will find as many alternative routes for waste generated on site as possible and thus reduce the amount of waste sent to landfill or reprocessing.

3 Using WRAP's Designing out Waste Guide for examples of best practice

Brookfield

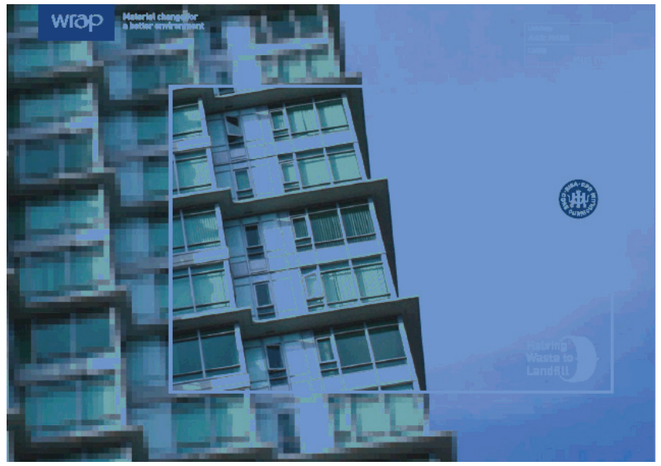
Operation

A review by the National Audit Office (2005) estimated that waste management costs the NHS around £8 million each year and that the cost of clinical waste disposal could be reduced by about £1.3 million if hospitals sorted waste properly. The way that the NSGH has been designed will ensure that for the foreseeable waste streams, this volume of waste can be minimised and properly segregated and managed. Public areas will be designed to accommodate separate waste streams and the food outlets will avoid supplying goods in packaging which cannot be recycled. Reducing the amount of waste sent to landfill is not only good for the environment as it reduces the depletion of natural resources but is also sound financial management as it avoids paying landfill tax, scheduled to keep rising. Brookfield's Waste Management Plan has been developed on the basis of WRAP guidance and Brookfield FM is committed to finding alternate waste recovery routes for the NSGH waste wherever possible.

- Once collected, sufficient space has been allocated to the waste compound so that waste on site can be stored in the necessary waste streams, compacted and baled on site where necessary (BREEAM Wst3/Wst4).
- Waste management will be the responsibility of a named individual on the Brookfield Facilities Management team.
- Retail outlets on site will be encouraged to reduce the amount waste for which they are responsible, by ensuring that they are fully aware of the waste management costs as part of their lease agreements.
- Food waste will be collected and stored separately on site so that it can be either composted and or transferred off site for use elsewhere (As stated in the Board's clarification to ITPCD Documents, Volume 2/1, Appendix M&E 7 Pneumatic and Automated Material Transfer Systems.).

BREEAM Summary

Anticipated Credits:	Predicted Percentage Achieved:
Construction Site Waste Management	63%
Recyclable Waste Storage	
Compactor/ Baler	
Composting	



Brookfield

8. Water

"Sustainable water management means minimising our impact on the healthy functioning of the water cycle, reducing carbon emissions and lowering environmental and economic costs." sustainablecities.org

Design

Although water is generally more than plentiful in Glasgow, water consumption is still an important issue to address in order to minimise the volumes consumed. Aside from the clear cost benefit from not consuming too much, the environmental costs need also to be considered. Waterwise produced figures, which show that the production of potable water requires chemicals and energy in large amounts and creates a carbon footprint for water of almost 300kgCO2/1000 m3. Therefore, the proposed NSGH design, which is designed to use low levels of water, will not only save money during the operation of the hospital but also reduce the total environmental impact of running a large acute and children's hospital.

As the Department of Health's HTM on Water Management and Water Efficiency states water minimisation is not just about sanitary fittings, as a large amount of water is also used in hospitals' energy centres, the catering areas and externally for irrigation. The landscaping has been designed so that no additional irrigation will be needed, other than during the settling in period on the green roof. Catering use of water will be reduced through improved preparation procedures and water efficient equipment. Other water saving features include:

- Low flow fixtures and fittings will be fitted in every ward, public area and staff accommodation (BREEAM Wat 1).
- Shut off valves are specified to the toilet blocks to reduce potable water consumption through leaks or faulty taps (BREEAM Wat 4).
- Proximity sensor taps will be installed in public areas, so that taps cannot be left on.
- The external landscaped areas have been designed so that no additional irrigation is needed (BREEAM Wat 6). The green roof has been designed so that it will retain approximately 60% of fallen rain, so it will only need additional manual irrigation in prolonged periods of dry weather.
- The target water consumption for NSGH has been based on the Environment Agency's Best Practice for Hospitals (May 2008), with anticipated consumption being in the order of 350-400 litres per bed /day.

Construction

Although in comparison to the operational period, less water will be used through the construction period, the same attention to water consumption will be observed by Brookfield and Dunne.

- Water consumption targets will be set for the construction site and usage will be monitored. Visible targets like these help to encourage behaviour change within staff members, so that hoses are not left running or excessive water usage for vehicle wash down is avoided.
- Any water from washing down of items on site or run off after storms will be captured and filtered to avoid contamination of local watercourses by sediment.

Operation

In addition to the outlined measures in the design to reduce the amount of water consumed through operation, water from the aquifer could be used for sanitary fittings. This is reliant on feedback from the study of the ground water levels and the aquifer and could still form part of the final design, dependent on when the results are available.

- Water meters will be installed on the mains supplies to each building so that consumption can be tracked through the BMS (BREEAM Wat 2). Sub-metering of water is provided to all major hospital zones and hot water will be separately metered for energy calculations.
- The BMS will include a water leak detection facility, which will monitor flows of water throughout the hospital buildings and make an alert when any anomalous consumption levels are identified, allowing leaks to be quickly investigated and dealt with (BREEAM Wat 3).

BREEAM Summary

Anticipated Credits:	Predicted Percentage Achieved:
Water Consumption	44%
Water Meter	
Major Leak Detection	
Sanitary Supply Shut-off	
Irrigation Systems	

Brookfield

Brookfield

Strategy for Controls and Building Management System

General

The Building Management System will comply with the relevant clauses of the NHS Model Engineering Specification and provided local and site wide control of the building services systems associated with the hospital.

Building Management System

Overview

The key strategy objectives are:

- High Level of Distributed Control
- Modular Approach
- Full Open Protocol
- A Front End Graphical User Interface that works as a Systems Integration platform

Field Side Environment

The field side environment can be broken into three main areas:

- Primary plant control (AHU's, Chillers, Boilers, CHP, pumps, fans, etc.)
- Environmental Control (Chilled Beams, radiant panels, FCU's, underfloor heating, etc)
- Supervisory function Control (Systems requiring overview, leak detection, metering, etc.)

Primary Plant Control

The control solution for this type of application will be a fully contained controller with associated electrical requirements. Also the sensing and actuation required for the process will be controlled and connected directly to this unit. With regard to Air Handling Units, the control enclosure will be integrated. Pumps, Fans, etc. will be complete with an associated control and power cabinet located adjacent to the equipment.

Environmental Control

Within the building there are key environmental controls that control occupant comfort and also occupant driven energy usage. The two key areas of environmental control will be the operation of the HVAC systems and Lighting control.

Systems Integration and Graphical User Interface

The Open System Integration framework solution will have seamless transfer of information to and from certified field devices.

This system for the hospital will be a software solution of two parts:

- The Integration of field systems
- The Graphical User Interface (GUI)

Power Management System Overview

The hospital energy management needs will be viewed in two areas:

- Supply Side
- Demand Side

The demand side will be dealt with via the Building Management System (BMS) and the supply side, consisting of on site generating capacity and also connected capacity from the national grid, be dealt with by the Power Management System (PMS).

The overall energy supply, on site capacity, is a combination of different plant:

- Boilers
- Chillers
- Absorption Chillers
- CHP Engine Sets

It has been determined that these combined items give the best energy performance over the entire demand side operating range and ensure that the highest operating efficiencies overall are achieved.

For example; with the integration of the absorption chiller into the scheme and the gas fired CHP engines, it is desirable that the engines are loaded as much as is possible to ensure highest efficiency electricity is available to the demand side, while the heat is captured effectively and utilised for chilling (Via absorption chiller) and heating. The system will factor key plant characteristics and potentially present and forecast weather, to ensure effective sequencing of plant to take advantage of ambient conditions and also performance curves of equipment.

Cooling Design Strategy

Selection of system

The choice of cooling medium has been considered and the use of Chilled Water

Location of Cooling Plant

The Exemplar scheme indentified a number of chiller plants located close to the load centres within the hospital. However, it is proposed to locate the main cooling plant at the main energy centre for the following reasons:-

- Chillers create noise and vibration which is easier to control remote from clinical use. The building can also be more economical to construct.
- Chillers are large and heavy. Locating chillers on the roof of the ward tower block would require very sizeable cranes to remove and replace them, and other large components, and would cause significant disruption adjacent to the hospital.
- Electrical power is derived from the energy centre. With the chiller being local transmission losses and major cable routes within the hospital are avoided.

The chillers will be air cooled and mounted on the energy centre roof with associated pumping equipment located on the first floor below.

The cooling plant will be divided into two in a similar way to the heating plant. The plant will be designated A and B and essentially work as independent systems to provide resilience.

Cooling Plant Sizing

The cooling load for the new hospital has been assessed using the ventilation plant volumetric flow rates calculated from the proposed scheme and are described in section 3.9. An allowance for heat recovery on ventilation plants has been assumed. In addition to this thermal modelling of sample parts of the building has been used to determine cooling requirements for terminal cooling devices

The total cooling load can be summarised in the following table:

Cooling (kW)								
Description	**Total AHU**	**Heat Recovery**	**Total AHUs**	**Chilled Beams**	**FCUs**	**Total Clg load**	**Pipe Gains 2%**	**Total HEX Duty**
Plantroom 21	610	-30	580	190	50	820	15	835
Plantroom 22	1085	-55	1030	0	20	1050	20	1070
Plantroom 31	2475	-120	2355	300	75	2730	55	2785
Plantroom 32	1620	-80	1540	750	50	2340	45	2385
Plantroom 41	515	-25	490	300	75	865	15	880

Total	5995	1540	270
Diversity	10%	25%	25%
Load diversity	-600	-385	-65
Corrected loads	5395	1155	205
Total Chiller Load (kW)	**6755**		

Therefore, the total cooling load for the new hospital will be in the order of 7,000kW, which equates to 42W/m^2. This compares favourably with similar projects as noted below;

Princess Royal University Hospital – 36 W/m^2 (Largely Naturally Ventilated)

Barnet Hospital Phases 1a/1b – 35 W/m^2 (Largely Naturally Ventilated)

Peterborough Hospital – 58 W/m^2 (High degree of Clinical Accommodation, inc atria with sealed windows, designed to 2006 Building Regulations)

Kings College Hospital – 50 W/m^2 (High degree of Clinical Accommodation, inc atria with sealed windows)

The laboratory/FM block is provided with its own cooling plant and therefore no capacity is included in the main hospital's cooling plant.

Brookfield

Cooling Plant Arrangement

The total cooling load will be met by eight chillers at 1000kW providing standby capacity (N+1).

As described earlier, for resilience, the cooling plant will be divided into two. The total load to be supported by each part will therefore be some 3500kW, which will be met by four chillers at 1000kW. Therefore, each cooling plant will approach a capacity of 60% of the total building load, which should be sufficient to allow the hospital to continue to function in the event of a catastrophic failure on one system. This standby chiller can also be used for service capacity reserve.

It is proposed, in order to reduce carbon emissions, to provide CHP plant and use the waste heat in summer for cooling utilizing an absorption type chiller. Therefore, a 1000kW cooling capacity chiller will be installed on the 'A side' chilled water system and act as lead chiller whenever there is sufficient cooling load and waste heat available.

An ADsorption type chiller may be considered as an alternative to traditional absorption technology, since the chemicals employed in the cooling cycle are more environmentally friendly.

The heat driven chiller will still need to reject the cooling effect and driving heat to atmosphere very much as a vapour compression unit. This will be achieved by using dry air coolers mounted on the roof of the energy centre alongside the other chillers. Adiabatic spray coolers will be considered to improve efficiency.

The absorption chiller and dry air coolers will be linked by a closed loop condenser water circuit, with water temperature controlled by fan operation on each dry air cooler.

Free cooling from the dry air coolers, for the use with the chilled beams, has been considered but with the current location of the coolers and the additional pipework distribution required and the associated pumping energy currently it has been discounted.

Absorption type heat driven chiller

Dry air cooler

The balance of the cooling capacity (7000kW) will be met by seven high efficiency packaged air cooled chillers, each rated at 1000kW and located on the roof of the energy centre.

These high efficiency chillers will offer the following advantages:-

- low maintenance, oil-free compressor
- highly efficient performance, particularly at part load (COP approaching 9.0 at part load).
- high integrity refrigerant pipework giving low refrigerant losses
- Low starting current

High efficiency air cooled chiller

A48235836

Chilled Water Distribution

From the energy centre chilled water will be distributed to the main hospital to serve the various major plant zones.

It is proposed to employ buried underground pipe mains to avoid the need for a major tunnel system, with the associated complications of access, ventilation and fire protection, etc running in parallel with the heating mains (described in section 3.8).

The two cooling systems (A & B) will be replicated in the chilled water distribution between the energy centre and the main hospital building, thus providing resilience in the event of a pipework problem necessitating the shutdown of one circuit. At the main hospital the two circuits will be brought together for final distribution to the main load centres.

For resilience purposes the primary chilled water generated by the cooling plant will be separated from the final secondary circuits by heat exchange stations will be formed at load centres.

Whilst the Exemplar Design utilized a constant volume pumping distribution arrangement with 3-port bypass valves at the load centres this does mean that the pumps have to run at constant speed and offer no facility to reduce pump power across the site. It has been estimated that this could consume up to 1.4GWh across all pumping systems more than is necessary equating to 4kg/m^2 of CO_2, which with such a stringent carbon and energy target needs careful consideration.

It is therefore proposed to employ variable volume pumping arrangements and 2-port valve control to maximise pumping efficiency, with the pump speed being varied automatically as the heating load changes.

Plate heat exchanger used to separate primary and secondary cooling circuits

Brookfield

IN STRICT CONFIDENCE

DIRECTORATE OF ACUTE SERVICES STRATEGY IMPLEMENTATION & PLANNING

PROJECT EXECUTIVE MEETING – 24th OCTOBER 2007

Re-Tender for Technical Advisers Role - ASR II

At the meeting of the PEG held on Wednesday 18th April a paper was tabled outlining the revised scope of the project. Following consideration of the aforementioned paper authority was granted to the Project Team to advertise and re-tender the Technical Team role for the new project at the Southern General Hospital; this course of action having been ratified by both the Board's legal advisers and auditors.

On 23 May 2007 the Board placed an advertisement within the Supplement of the Official Journal of the European Union (OJS), OJEU Ref 2007/S 97-119682, seeking the services of a technical advisory team to co-ordinate and manage the PFI/PPP procurement process for the re-development of the Southern General Hospital campus to provide a single in-patient site for South Glasgow, the project to comprise the creation of a new build Acute Hospital, Children's Hospital and Laboratory facility within the campus, linked to the more modern buildings within the site.

Following publication of the May advertisement the Board received some twenty six (26) expressions of interest. Of those twenty six expressions of interest, the Board received four tenders from the companies listed below;

Capita Symonds
Currie & Brown
Davis Langdon LLP
Mott Macdonald

Following receipt of tenders on Tuesday 3rd July and a clarification exercise, each of the four bidders were interviewed between 27th and 29th August. Following the interviews and tender evaluation process, one party is clearly lagging well behind the others and the Project Team would propose not to take them any further in the process. Of the three remaining, the Project Team has a preferred candidate, but with the continued uncertainty regarding the procurement route means that it is not possible to appoint Technical Advisers at present.

At the interviews the bidders were advised that the Board would update the teams towards the end of September. All of the teams have been back in touch on a number of occasions and to try and keep them on side until the Board can confirm the way ahead, Board Officers have met with the ASR legal advisers to discuss options, and the following course of action is proposed.

- The teams are advised of the current work to revise the OBC to consider various funding and procurement options.
- The Board cannot make an appointment until this work is complete; the legal view is that the scope of work for a PPP TA role as apposed to D&B role is substantive and not transferable.
- That the Board write to the top three bidders (Currie & Brown, Davis Langdon and Mott Macdonald) and explain the situation and ask that they hold their bids until late January 2008 until the situation becomes clearer. Advise the Capita team that they have been unsuccessful, rather than prolong the situation.

IN STRICT CONFIDENCE

In the meantime, the Davis Langdon team continue to provide advice to the Board in terms of the works associated with the completion of the OBC for the Acute and New Children's Hospitals. The cost of any works is agreed in advance and is based on their current hourly rates.

Recommendation

That the PEG note the current position and approve delegated authority to the Project Team to pursue the above course of action.

EXECUTIVE SUMMARY

CHAPTER 1 - EXECUTIVE SUMMARY

INTRODUCTION

The purpose of this Full Business Case is twofold:

1) To present the proposals for a new children's hospital and new adults' hospital (The New South Glasgow Hospital) on the site of the current Southern General Hospital.

2) To confirm the proposals set out in this document are fully in line with the phased construction contract signed between NHS Greater Glasgow and Clyde[1] and Brookfield Construction UK Limited in December 2009.

The proposals represent the largest investment in health services undertaken in Scotland and will transform the experience of healthcare for patients and staff alike with Glasgow becoming the home to one of the largest, most advanced NHS developments in the UK.

This document confirms that the strategic drivers for the project have been reviewed and revalidated and that NHS GG&C's strategy (the Acute Services Review), to modernise the health services in Glasgow remains unchanged. This strategy has been implemented over the last 8 years with phase 1, two new state of the art ambulatory care hospitals, completed in 2009.

The option of a new build children's hospital and adult hospital on the Southern General Hospital campus (as described in the Outline Business Case) continues to be the preferred option. These new hospitals will achieve the gold standard triple co-location of adult, children's and maternity services and modernise services, facilitating the closure of the Western Infirmary, the Victoria Infirmary, Mansion House, Royal Hospital for Sick Children and some existing parts of the Southern General Hospital with the transfer of inpatient services to new, state of the art facilities.

The construction of the new hospitals will give the opportunity to redesign the way in which health services are delivered and to reappraise the skills and profile of the workforce to deliver modern health services for the 21st century. The development of this new hospital complex also has the potential to breathe new life into South West Glasgow and beyond, generating jobs and commercial opportunities for the local population both during construction and once in operation.

[1] For the remainder of this document NHS Greater Glasgow and Clyde is referred to as NHS GG&C or the Board, and Brookfield Construction Limited is referred to as BCL.

The Outline Business Case Approval

The proposals for a new adult and children's hospitals, new laboratory, facilities management (FM) and new 33KV electrical sub-station were previously presented to the Scottish Government in an Outline Business Case (OBC) which was approved in May 2008.

Procurement Process

Subsequent to OBC approval in May 2008 the Board commenced a procurement process to contract to design and build the new hospitals and laboratory facility which concluded in October 2009.

The outcome of the procurement was presented to the Board in November 2009. The Board approved the signing of a contract with Brookfield Construction UK Limited which was complete on 18th December 2009. The contract made provision for:-

- Stage 1- construct the new laboratory, the FM facility and the new 33kv electrical substation

- Stage 2 - design the new adult and children's hospitals which informed the work for this Full Business Case (FBC)

Upon Scottish Government approval of the new adult and children's hospitals FBC, BCL are contracted to complete stages 3 and 3a below

- Stage 3 - construct the new adult and children's hospitals

- Stage 3a - Demolition of the surgical block and associated buildings and completion of the soft landscaping

New Laboratory Build

A Full Business Case for the laboratory and FM component was approved by the Scottish Government on 4th December 2009. Building work commenced in February 2010 and is anticipated to complete on 10th March 2012. The construction work is on schedule and within the project budget with a governance structure, risk management and change control process fully established.

This document therefore addresses the remaining components of the current contract which are a new adult and new children's hospital. *(Please note details of the FM facility are given where relevant in explaining the functioning of the new hospitals.)*

It is planned to construct the adult and children's hospitals as a single building, (*albeit with distinctive and different external and internal identities reinforced by*

separate approach and entrance areas), in order to benefit from the clinical co-locations and support services synergies offered by an integrated build.

Business Need – Case for Change

In 2002 Greater Glasgow Health Board described the case for change for adult services. This identified that the status quo was not an option, due to significant challenges in the sustainability of services and improving patient pathways creating more efficient and effective care. All of the factors identified in 2002 remain relevant today with further challenges and pressures resulting in even greater need to reduce hospital sites and duplication of services. In brief the issues are:

- The need to achieve the objectives of government policy such as the 'Healthcare Quality Strategy for NHS Scotland' and 'Better Health, Better Care' and other key national policies. These policies drive clinical excellence, continuity of care and the modernisation of services. Implementation also drives efficiency and productivity through more streamlined service models and through investment in technology, leading to a reduction in waiting times and more rapid patient access to diagnosis and treatment. Implementation of the guidance puts patient needs at the centre and promotes the provision of a clean safe environment reducing rates of hospital acquired infection. To achieve these objectives a major programme of investment in buildings, information technology and redesign of services is required for Glasgow
- Fragmented services. At the moment there is a requirement for patients to move within and around sites and different buildings in Glasgow. This leads to a loss of continuity of patient care. Furthermore, important co-locations of services are not possible therefore making it challenging to achieve streamlined patient flows.
- An increasing need to move towards larger teams to ensure that all patients can access the appropriate Specialist on a 24-hours a day and 7-days a week basis
- Pressures on the workforce in sustaining the current number of multiple staff rotas across the different Glasgow hospital sites
- Outdated buildings which are unfit for modern healthcare offering a poor patient environment with unsuitable facilities for modernising services

THE SOLUTION - THE ACUTE SERVICES REVIEW (ASR)

In response to the above pressures the Board undertook a review of the acute services (The Acute Services Review) and proposed a strategy to address the Board's business needs by modernising services across Glasgow. The key components of the strategy are to reduce the number of adult inpatient sites from the current six hospital sites to three. Two sites, Glasgow Royal Infirmary and the new Southern Glasgow Hospitals, will have Accident & Emergency (A&E) and trauma facilities. The third inpatient hospital will be Gartnavel General Hospital. These acute sites will be supported by the two Ambulatory

Care Hospitals, one on the Stobhill Hospital site and one on a site adjacent to the Victoria Infirmary.

Implementation of the ASR strategy has been taking place over the last 8 years, and around two thirds of this strategy will be in place by the beginning of next year, 2011.

The two Ambulatory Care Hospitals (noted above) opened in 2009. These Ambulatory Care Hospitals represent a significant modernisation of Glasgow's healthcare facilities; however three of Glasgow's major adult hospital sites are now operating below physical capacity with inpatient services only remaining in some buildings in Stobhill Hospital, the Western Infirmary and the Victoria Infirmary.

NHS GG&C are currently carrying out an accelerated ASR in the North and East of the city with transfer of inpatient services from Stobhill Hospital to Glasgow Royal Infirmary planned for early 2011. This will allow the subsequent closure of the old Stobhill Hospital leaving the New Ambulatory Care Hospital on the Stobhill Hospital site.

The proposals for the new South Glasgow Hospitals on the Southern General Hospital campus form the pivotal phase of the ASR Strategy and therefore the key transitional aspect of the transformation of service delivery by the Board.

On completion in 2015, the Board will be able to enact the following:

- inpatient services in the Victoria Infirmary to transfer to the new South Glasgow Hospitals
- inpatient services at the Mansion House Unit (MHU) to transfer to the New Southern Campus allowing closure of the MHU
- inpatient services housed in outdated buildings on the Southern General Hospital and Western Infirmary sites to be relocated to the new South Glasgow Hospitals
- transfer of A&E services and associated beds from the Victoria Infirmary, the Western Infirmary and the Southern General Hospital to the new South Glasgow Hospitals
- these transfers will facilitate closure of the Western & Victoria Infirmary and Mansion House sites and the older parts of the Southern General Hospital

The above means that by 2015 the plans for the 3 site inpatient configuration of adult services in Glasgow will be achieved.

Children's hospital services are currently provided by the existing Royal Hospital for Sick Children (RHSC) which is sited at Yorkhill. In 2004 the Minister for Health and Community Care announced that the Scottish Government would provide funding to enable a new children's hospital to be built on a site which would support the "triple co-location of services".

Following an option appraisal in 2005 of potential locations for the new children's hospital, the Southern General site was identified as the only location to offer both co-location with maternity and adult services and appropriate vacant land for building. This process was undertaken in collaboration with a Ministerial Advisory Group chaired by Professor Andrew Calder. The report of that Group, published in March 2006, affirmed the selection of the Southern General site as the location for the new children's hospital. Following a period of consultation this recommendation was accepted by the Minister for Health and Community Care in 2006.

In 2009, some of the maternity services provided at the Queen Mother's (Maternity) Hospital (QMH) adjacent to the Children's Hospital transferred to the Southern General Hospital campus as part of the implementation of the ASR in preparation for the transfer of services from RHSC onto the Southern Site. (The remaining maternity services transferred to the Glasgow Royal Infirmary.)

As a result maternity and neonatal services are no longer co-located, and interim arrangements are in place in anticipation of the transfer and re-establishment of the co-location at the Southern campus.

PROPOSED FUTURE ADULT AND CHILDREN'S SERVICES

New Adult Hospital

A 1,109 bedded adult new build acute hospital is planned providing state of art A&E, critical care, theatre and diagnostics services. The facility will offer acute specialist in-patient care, medical day case services and will have out-patient clinics serving the local (South-West Glasgow) population. No day surgery will be undertaken as this will be provided at the new Victoria Hospital.

New Children's Hospital

The proposed new 256 bedded children's hospital will provide a comprehensive range of inpatient and day case specialist medical and surgical paediatric services on a local, regional and national basis. The new development will also have state of the art A&E, critical care, theatres, diagnostic and outpatient services. The Board's strategy is that all Glasgow's children's services (up to the age of 16 and up to 18 years where appropriate) will be provided at the new children's hospital.

EXPECTED BENEFITS OF THE PROJECT

It is anticipated that the project will deliver a range of benefits including:

- Provision of high quality services which are timely, accessible and consistently available by providing local access to core medical and surgical services and consolidation of specialist and tertiary services on fewer sites within the city

- Provision of gold standard services through the triple co-location of adult, children's and maternity services on a single site
- Provision of more efficient services with increased productivity and clinical capacity by:
    a) the concentration of clinical teams onto fewer sites
    b) optimising departmental and functional relationships
    c) protecting elective activity from disruption by emergencies
    d) improving patient flows
    e) improving access to diagnostic services such as laboratory and imaging services

This will allow the Board to continue to meet the Government HEAT targets and increase the ability to meet future waiting time guarantees for 2015.

- Implementation of the 'Healthcare Quality Strategy for NHS Scotland' guidance by providing a clean and safe environment with reduction in Hospital Acquired Infection. 100% single rooms in adult wards will afford patients greater privacy and dignity and improve private communication between staff and patients about diagnosis and treatment
- Fit for purpose hospitals providing a pleasant healing environment
- Enhanced staff skills and knowledge with improved recruitment and retention due to a radically better working environment
- Enhanced University links through co-location of University and NHS Staff within the new hospitals on the Southern General Campus. This will enhance teaching and research and will play a significant role in attracting and retaining high quality staff in all disciplines
- Reduction in carbon emissions and achievement of BREEAM ''Excellent Status'' for the new hospitals
- Contributing to the regeneration of the South West Glasgow community and beyond offering opportunities for local businesses and jobs

The Economic Case

To ensure that the project continues to provide the Board with optimum value for money the original options considered at the Outline Business Case were reconsidered and it was confirmed that the proposal for new Adult and Children's Hospitals at the Southern General site, with the retention of some existing buildings e.g. Neurosciences and Maternity, remains the preferred option.

The OBC also considered three potential procurement routes, i.e. traditional procurement, Private Finance Initiative (PFI) and Not for Profit Distribution Model (NPD). The NPD model provides for the redistribution to the Board of any excess profit which may arise in the form of a "charitable surplus".

In conjunction with the Board's Financial Advisors the three procurement routes were retested and it was confirmed that the traditional procurement route represents substantially better value for money than both the PFI and NPD options.

Commercial Case

As an outcome of the tender competition and procurement administered by the Board, all key commercial aspects of the project are clearly defined and have been agreed between the Board and the Contractor. These include scope and coverage of the specification requirement for the hospitals (from both a clinical and technical perspective), how risk is managed, the basis for payment for the design and construction services that have been purchased, the form of contract (including therefore the rights and obligations of the parties), and the timetable for the construction of the new facilities.

Financial Case

The capital and revenue requirements of the project have been fully reviewed in order to confirm that the preferred solution continues to be affordable in both capital and revenue terms.

This review concluded that the capital costs, including provision for Value Added Tax at the increased rate of 20% from January 2011, remains affordable. In addition, by proceeding with the project, the Board will achieve net overall recurring savings in excess of £18.2m through enhanced efficiencies.

Consequently the construction of the New Adult and Children's Hospitals is deemed to be affordable in both capital and revenue terms.

Management Case

The project has followed good management processes and has robust risk management and governance structures in place. The governance structure continues to be reviewed and reconfigured in response to the changing needs of the project through each different stage. There is a strict change control mechanism in place, the success of which is demonstrated by the cost of the project remaining stable since contract award in December 2009. The project is subject to regular external audit and there is close liaison with the Scottish Government regarding direction and progress of the project.

Stage 2 Design Work Undertaken

Pre-contract, over 70 user groups were involved in the development of the schedules of accommodation, clinical output specifications, identification of key critical co-locations and, for the podium specialties, development of exemplar drawings. Following award of the contract the user groups have been working closely with the Project Team and Contractor's architectural team to develop the detailed 1:200 layouts of their departments and 1:50 typical room drawings.

Full size mock-ups of an adult bedroom and en-suite, child's bedroom and en-suite with staff touchdown and a critical care space were built to assist users in developing the individual room layouts (1:50 drawings). This has proved to be extremely helpful in progressing the design.

The new hospitals incorporate state of the art design and equipment with a range of innovative features including the use of automated guided vehicles to provide transportation of catering and supplies around the hospital, advanced Information Technology supporting a paper-lite environment, a roof top helipad, a high tech Building Management System, in-built resilience and a range of low to zero carbon technologies.

The Board are taking cognisance of the Government's sustainability agenda and have been working in association with the Carbon Trust and Sustainability Glasgow to achieve substantial reductions in carbon output and obtain "Excellent" BREEAM Assessment rating for the new hospitals.

Planning Consent

In June 2010 planning consent was granted for the Masterplan Matters Specified in Conditions (MSC) application, based on the BCL scheme.

Planning approval for the design of the Adult and Children's Hospitals was given on 19th October 2010.

Community Economic Benefits

In order to realise potential regeneration opportunities to South West Glasgow and beyond targets were set in the contract to support local recruitment and Small /Medium Enterprises (SME's) and Social Enterprises (SE).

In brief 10% of recruits are to be new entrants and BCL are working in partnership with Glasgow South West Regeneration Agency and Glasgow City Council training and supporting local businesses to tender for work on the project.

Outcome of Gateway 3

A Gateway 3 Review was undertaken by the Scottish Government Gateway Review Team between 4th-6th October 2010. The project was awarded a green level of Delivery Confidence Assessment, defined as:- "successful delivery of the project/programme to time cost and quality appears highly likely and there are no major outstanding issues at this stage that appear to threaten delivery significantly."

The Gateway report is very positive and recommends that the project should develop a case study of the procurement approach (so this could be shared with other NHS and Government organisations). There are two actions highlighted to be completed before the next gateway review and these are to add some indirect risks (e.g. political risks) to the risk register and continue to develop the benefits management plan to define targets and gather baseline data.

Timetable

A summary timetable for the project is shown below.

Event	Milestone
Stage 2 completion, Full Business Case (FBC) approval by Health Board	26 October 2010
FBC considered by Scottish Government Capital Investment group	November 2010
Stage 3 (Construction of adult and children's hospitals) programmed to commence	November 2010
Stage 1 Completion (Construction) - laboratory facilities	March 2012
Stage 3 Completion (Construction) – adult and children's hospital	January 2015
Operational Date – adult and children's hospital complete service transfers.	Summer 2015
Stage 3a completion, demolition of surgical block and completion of landscaping	Summer 2016

LAYOUT OF THE DOCUMENT

The layout of this business case is summarised below:

Full Business Case – Structure & Content	
Chapter 1:	Executive Summary
Chapter 2:	The Strategic Case This chapter provides an overview of: • the organisation, NHS GG&C • the children's hospital - the current service and business needs and provides a description of the future requirements and redesign work • the adult hospital – business needs, future service requirements, the bed modelling, and redesign work undertaken • Investment Objectives and Benefits Criteria • the strategic risks facing the project and • constraints and dependencies
Chapter 3:	The Economic Case Revisits and revalidates the previous data in relation to options, calculations and selection of the preferred option.
Chapter 4:	The Commercial Case Details the agreed scope and services, allocation of risk, key contractual arrangements, timescales for delivery, and identifies accountancy treatment.
Chapter 5:	The Financial Case Examines the capital requirement, impact on the balance sheet and income & expenditure account, and any other costs or comments on the overall affordability.
Chapter 6:	The Management Case Demonstrates the approach to procurement, project management, risk management, benefits realisation, post project evaluation and the project timetable.

CHAPTER 2

THE STRATEGIC CASE

CHAPTER 2 - THE STRATEGIC CASE

2A. STRATEGIC CONTEXT

The main objective of NHS GG&C's strategy to modernise services, the Acute Services Review (ASR), is to address the mounting pressures to change the way in which services are delivered by reducing the number of acute sites across Glasgow and investing in fit for purpose facilities.

The new South Glasgow Hospitals comprise the major part of the plans to reconfigure services by reducing the adult inpatient sites from the current six hospital sites to three from 2015. Two sites, Glasgow Royal Infirmary and the new South Glasgow Hospitals, will have A&E and trauma facilities. The third inpatient hospital for Glasgow will be Gartnavel General Hospital. These acute sites will be supported by the two new build Ambulatory Care Hospitals which opened in 2009.

The construction of the new South Glasgow Hospitals provides the opportunity to redesign the way in which health services are delivered and reappraise the skills and profile of the workforce tailoring delivery of modern health services in keeping with the 21st century. The development also has the potential to regenerate and breathe new life into Govan and the wider area.

This chapter of the Full Business Case gives an overview of the organisation, its business aims and objectives and then identifies the strategic case for the new hospitals (adult and children's hospitals separately to allow their distinct and unique aspects to be clearly described). The investment objectives and benefits are highlighted as well as strategic risks and constraints to the scheme that exist.

2B. ORGANISATIONAL OVERVIEW

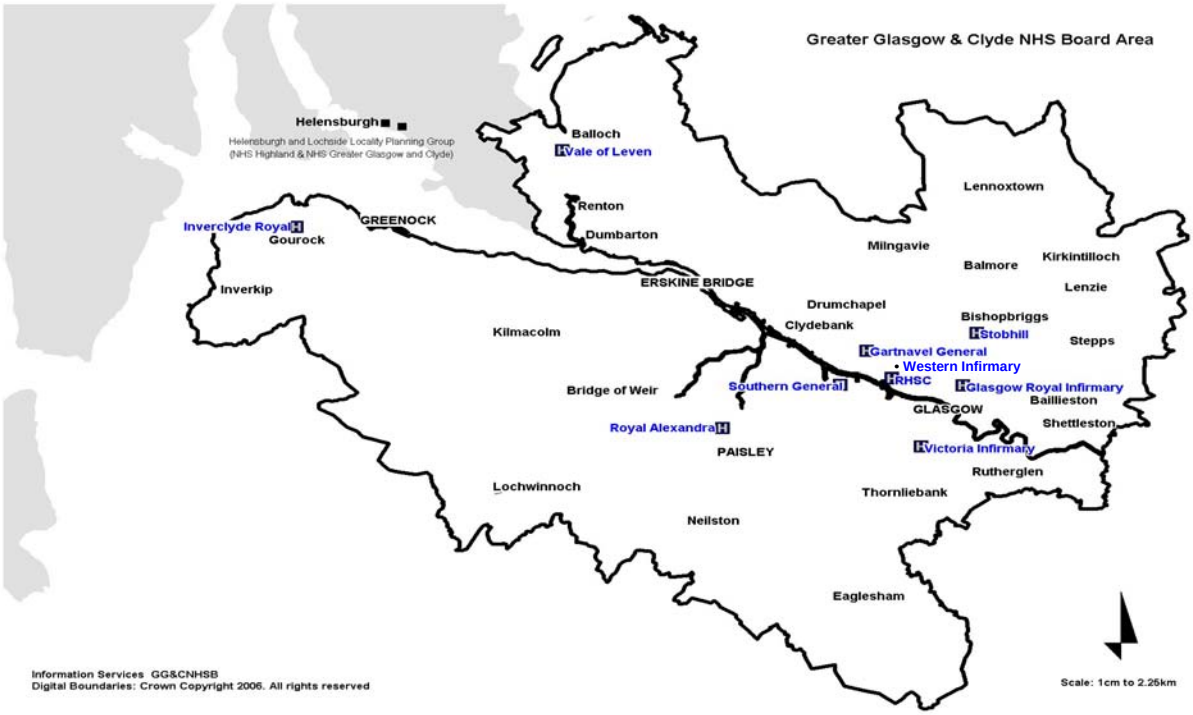
NHS GG&C, formed in April 2006, has 44,000 staff (with over 26,000 wte within the Acute Division) and serves a total population of 1.2million people, with an annual budget of £2.7 billion.

Acute services are delivered from 10 hospitals, 3 lie within the Clyde area and the remaining 7 are located within Glasgow City.

Within Glasgow, the Western Infirmary and Gartnavel General Hospitals operate in tandem delivering acute care in the west of the city. In the north and east of the city acute care is delivered from Stobhill Hospital and Glasgow Royal Infirmary. The Victoria Infirmary serves the south-east and the Southern General Hospital the south-west of the city. Services for children are provided centrally from the Royal Hospital for Sick Children, Yorkhill. Full adult Accident and Emergency (A&E) services are provided at the Western Infirmary, Glasgow Royal Infirmary, the Victoria Infirmary and the Southern General Hospital.

Stobhill Hospital has a casualty department which is covered by consultant staff from Glasgow Royal Infirmary and the Western Infirmary.

The location of these acute hospitals can be seen the in diagram below.



2B.1 Organisational Structure

NHS GG&C is comprised of an Acute Division, a Mental Health Partnership and 10 CHCPs/CHPs.

The Acute Division brings together all acute services across the City of Glasgow and Clyde under a single management structure led by the Chief Operating Officer (COO). The Division is made up of six directorates of clinical services each managed by a director and clinical management team supported by the Facilities Directorate. These are:

- Diagnostics
- Emergency Care and Medical Services (ECMS)
- Regional Services
- Rehabilitation
- Surgery and Anaesthetics
- Women's and Children's Services

2B.1.1 *Services and Activity*

The Acute Division of NHS GG&C provides a comprehensive range of services from community based care (midwives, dental services and various outreach services) in addition to the full range of general hospital services. The organisation also hosts some of the most specialised health services in the country, including: the new West of Scotland Cancer Care Centre on the Gartnavel General Hospital site, the Institute of Neurological Sciences at the Southern General Hospital campus, renal and bone marrow transplant services in addition to world-class specialist paediatrics and obstetric services.

In 2009/10 there were 269,987 inpatient, 146,972 day cases and 422,552 new outpatient attendances in Glasgow acute adult hospitals. Over 80% of this activity was attributable to residents of the NHS GG&C area.

In 2009/10 the following 0-15 year old patient activity was seen within NHS GG&C's hospitals; 19,550 inpatients, 10,370 day cases and 32,630 new outpatient attendances. Sixty four percent of this activity was attributable to NHS GG&C residents, with thirty six percent outwith the Health Board reflecting the specialist tertiary nature of Royal Hospital for Sick Children Services.

Further details of the breakdown of both adult and paediatric patient activity seen within Glasgow Acute Hospitals by Health Board of patient residence in 2009/10 is shown in Appendix A.

2.B.1.2 *Demography & Health Status*

The mid-year population estimate for NHS GG&C as of 30 June 2009 was 1,199,026. This makes NHS GG&C the largest health board in Scotland. The size and complexity of NHS GG&C pose unequalled management and service provision challenges. The social deprivation for which Glasgow is well known poses considerable further demands on health and social services. Further details of this are given in Appendix B.

2C. BUSINESS AIMS OF NHS GREATER GLASGOW AND CLYDE

NHS GG&C aims to ensure that the health needs of the local population are met, and national government targets and directives are implemented. In order to achieve safe, sustainable and equitable treatment for patients the Board's aims are:

- To achieve gold standard services through the triple co-location of Adult, Children's and maternity services onto a single site

- To provide facilities with capacity and capability to facilitate modern healthcare with flexibility to adapt to future requirements underpinned by effective use of technology

- To increase efficiency and productivity by –

    - reducing the number of acute adult hospital sites across Glasgow
    - centralising specialist services
    - investing in fit for purpose facilities with optimum co-locations and improved information technology.

These aims form the basis of the Investment Objectives and also reflect the benefits which are anticipated from the project.

2D. OTHER ORGANISATIONAL STRATEGIES

Health Information Systems and the underpinning Information Technologies will be key to successful clinical service delivery in the new hospitals.

NHS GG&C has developed a clear vision for HI&T (Health Information and Technology):

> ***"To enable a safe, high quality, equitable and efficient health system for the citizens of NHS GG&C - by transforming the way information is delivered, utilised and shared to plan, manage and provide patient care."***

This vision will be delivered through 6 core programmes, defined by the benefits they bring to patients, clinicians and other staff,

- Electronic Patient Record (EPR) – Clinical Portal / Paperlite
- Implementation of the Patient Management System (PMS)
- Acute Services Review (ASR) – including the new South Glasgow Hospitals and new laboratory facility
- Primary and Community Care – General Practice Systems
- Business Reporting
- Infrastructure Development

Whilst the drivers for these programmes are broader than the new hospitals, they will deliver in timescales that allow service change to be embedded into every day clinical practice before services move into the new buildings.

Further major change programmes will build on these core programmes and facilitate enhanced service provision across clinical specialties.

Key drivers for the core HI&T programme include:

- Requirement for information to be gathered and shared quickly and effectively to support complex modern care; the existing combination of paper and electronic systems that are not linked do not readily support this

- Availability of Information and Communication Technology (ICT) based tools; help clinicians to ensure that all patients receive appropriate, safe, secure health care and good-quality service

- Requirement to have single system working across organisational boundaries and multi-disciplinary areas

- Efficiency savings – NHS GG&C must maximise benefits from resources and investments

- Need to standardise the HI&T estate by reducing the number of applications and interfaces

The delivery of the planned programmes will therefore provide the information and tools to allow clinicians to work efficiently in a paperlite environment before they move into the new hospitals.

2D.1 Specific HI&T Requirements for New Hospitals

The NHS GG& C HI&T Strategy will deliver core programmes that will underpin the move to the new hospitals. The core programmes will identify and deliver both requirements that are specific to the new hospitals and act as a catalyst for health services across NHS GG&C. The new hospitals will also benefit from any new strategic HI&T priorities that are developed over the next 5 years.

The key areas of HI&T that are specific to the new hospitals are:

- the technical infrastructure
- equipment
- standardised systems
- transition

HI&T will also work with the service over the next 5 years to identify any further opportunities to improve patient care and deliver efficiencies through use of technology.

In terms of technical infrastructure the new hospitals will require a high speed resilient network with wireless capability available throughout to support new ways of accessing and sharing data.

The NHS GG&C current standard for new builds is I/P telephony and the network will be designed to enable this service. The network will also have the capability to support non-clinical services such as Building Management Systems and CCTV.

Description of the following sections 2E and 2F

For ease of understanding the following sections of this document describe separately the issues surrounding the children's hospital and then the adult hospital. The next section, 2E describes the children's hospital section 2F details the adult hospital.

2E. CHILDREN'S HOSPITAL (THE STRATEGIC CASE)

This section describes the following aspects of the new children's hospital scheme:

- The case for change and the future strategy for delivery of services
- A description of the current services
- A description of the future service requirements

The benefits that the scheme will deliver:

2E.1 Case For Change And Future Strategy

Children's hospital services are currently provided by the existing Royal Hospital for Sick Children (RHSC) which is sited at Yorkhill. In 2004 the Minister for Health and Community Care announced that the Scottish Government would provide funding to enable a new children's hospital to be built on a site which would support the "triple co-location of services". Following an option appraisal in 2005, of potential locations for the new children's hospital, the Southern General site was identified as the only location to offer both co-location with maternity and adult services and appropriate vacant land for building. This process was undertaken in collaboration with a Ministerial Advisory Group chaired by Professor Andrew Calder. The report of that Group, published in March 2006, affirmed the selection of the Southern General site as the location for the new children's hospital. This recommendation was accepted by the Minister for Health and Community Care in 2006 following a period of consultation.

In 2009, the maternity services provided at the Queen Mother's (Maternity) Hospital (QMH) adjacent to the Children's Hospital transferred to the Southern General Hospital campus as part of the implementation of the ASR in preparation for the subsequent transfer of services from RHSC onto the Southern Site.

As a result maternity and neonatal services are no longer co-located. The Regional Medical Genetics Service, which provides services to children, young people and adults remains on the Yorkhill site until it also transfers to the new laboratory build on the Southern General Campus.

2E.1.1 *Neonatal Transition Arrangements During Gap Period*

NHS GG&C has centralised all compromised neonates linked to Queen Mother's Hospital foetal medicine service to be born at the Southern General Maternity Hospital. To support the interface between this hospital and the RHSC Neonatal Intensive Care (NICU) a number of clinical pathways have been agreed. These include newborns with cardiac problems, complex airway anomalies, diaphragmatic hernia and abdominal wall defects, and these pathways are supported by the West of Scotland Neonatal Transport Service and the Scottish Ambulance Service.

Babies requiring surgery/complex tertiary medical care are managed in the RHSC NICU and then transferred back to their local neonatal unit across the West of Scotland Boards and indeed nationally in some instances. For Glasgow and Clyde surgical/ complex medical babies this could be the Southern General Maternity, Princess Royal Maternity and Royal Alexandria Hospital. RHSC paediatric teams continue to support foetal medicine counselling to mothers and families at the Southern General Maternity since closure of Queen Mother's Hospital.

NHS GG&C has set up a monthly transition group to review all clinical adjacencies between the Southern General Maternity neonatal and foetal medicine services, RHSC NICU and neonatal transport and Scottish Ambulance Service. This will include compliance and outcome measurement of babies and mothers using these established clinical pathways. From 1st April to 31st March each year there will be a 6 monthly and annual review of service. Individual cases can be referred by specialties for exceptional review through the monthly transition group. No cases have been referred to date by any specialty. This transition group is represented by a wide variety of senior medical staff from neonatology, neonatal surgery, ENT surgery, foetal medicine, radiology, cardiology and medical paediatric sub specialties including intensive care. It is also represented by senior nursing and the neonatal transport team.

The rationale for transferring Yorkhill services to the Southern General Hospital campus was explained at length in the Outline Business Case and agreed after consultation in 2004 and an 'options appraisal' to determine the optimal site in 2005. In essence, co-location of maternity and paediatric services provides 'gold standard' and seamless care for the foetus and the new born baby.

As described in the Outline Business Case, transfer of children's hospital services to the Southern General Hospital campus will also align some other key services to confer significant additional benefits:

- Provide enhanced and age-appropriate services for adolescents and young people, including easier 'shared care' arrangements between adult and paediatric staff

- Support collaboration between paediatric and adult specialties to support 'transition' from children's to adult services for those young people with long-term conditions for whom the transition from paediatric to adult services is often a very unsettling and clinically disruptive period

- Strengthen clinical links between paediatric and adult services. This is particularly important for specialties with only a small paediatric component (such as gynaecology) and for conditions in which training in adult practice is especially relevant (for example, some post-pubertal fractures)

- Co-location of childrens and adult neurosurgical services, will, for the first time in Glasgow, offer neurosurgical care in the context of a full complement of paediatric medical, surgical and intensive care expertise

2.E.2 Description Of The Current Services

The RHSC in Glasgow is Scotland's largest children's hospital and it provides a comprehensive range of secondary care locally and specialist services to the West of Scotland Region and the rest of Scotland.

Annual activity for 2009-2010 comprised:

- Out-patient attendances: 20,307 (New)
- Inpatient admissions 16,751
- Day Cases 9,822
- Emergency department attendances 40,000

In NHS GG&C, the RHSC essentially provides all inpatient care for children up to their 13th birthday (with the exception of most paediatric neurosurgery). The majority of young people aged 13 - 15 years receiving secondary care, however, are currently managed within adult hospital services. As discussed in the Outline Business Case, this is no longer considered appropriate and in the future, all young people aged up to the 16th birthday (and some aged 16 or 17) in Scotland will be cared for in children's hospitals with the emphasis on providing service and facilities that are appropriate for their age and maturity. This will result in an increase in overall activity in the new children's hospital of 5 – 10%. However, for some specialties (for example, orthopaedic trauma) the impact will be much greater.

In addition to the RHSC, Accident and Emergency (A&E) services for children aged 1 – 12 years continue to be provided at all the city's current A&E Departments (excluding the Western Infirmary) and the minor injuries Units at the Victoria and Stobhill Hospitals. Within the constraints of the current hospital at Yorkhill, centralisation of all emergency services for children and young people, whilst desirable, is not possible. However, all babies younger than 12 months are seen in the RHSC and there is an agreement with the Scottish Ambulance Service that, in the near future, all children younger than 13 years *'in extremis'* will be brought straight to the RHSC. It is also likely that, in the

future, the city's minor injuries units will continue to manage children, in line with the ethos of *'providing care as locally as possible'*.

The majority of paediatric outpatient activity takes place at the RHSC although there are close links with Community Health and Care Partnerships (CHCPs) and some work is carried out in Child Development Centres. A small number of children are seen in other hospitals (e.g. orthoptics, gait analysis). In considering local hospital services, it is important to remember that, as shown in the 2001 census, 25% of the children in the NHS GG&C area live in areas characterised by maximum deprivation ('Depcat 7'). This concentration of deprivation is not replicated elsewhere in the UK and impacts on both the pattern and the incidence of disease as well as aspects of service use.

The RHSC also supports the full range of specialist regional paediatric services comparable with those provided in an adult teaching hospital. These include cardiology, haemato-oncology, neurology, rheumatology, specialist surgical services, diabetes & endocrinology, burns, chronic pain and many others. Due to the specialist nature of these services and the long-term care required, patients frequently remain under the care of RHSC at least until they are 16 (or even older, if appropriate). These specialist services are accessed from across the West of Scotland and work in collaboration with, and in support of, the services provided by local paediatric units in district general hospitals. The Yorkhill campus also hosts the regional Medical Genetics Service. To maintain close links with paediatrics, this service will also relocate to the Southern General site as part of the new labs development.

In addition to these regional services, the RHSC hosts a number of specialties designated as national services and for which, in most cases, it is the sole provider in Scotland:

- Kidney transplantation
- Bone marrow transplantation
- Cardiac surgery
- Interventional cardiology
- Extra corporeal life support (for respiratory failure, this is delivered in collaboration with only three other UK centres)
- Paediatric intensive care transport (shared service with Edinburgh)
- Paediatric intensive care (from April 2007 – shared service with Edinburgh)
- Complex airways surgery
- Endoprosthetic bone replacement
- Vein of Galen aneurysm (a UK service shared with the Great Ormond Street Hospital for Children)
- In-patient child psychiatry
- Brachial plexus palsy
- Cleft lip and palate (shared service with Edinburgh / Aberdeen)

The role played by RHSC in the delivery and support of these regional and national services is reflected in the fact that more than half of the total inpatient activity is accounted for by patients beyond NHS GG&C.

2.E.3 Description Of Future Service Requirements

Relocation of the RHSC to the Southern General Hospital campus will not fundamentally change the role of the hospital to provide local, regional and national services. The future service will therefore closely mirror the current activity of all young people from Glasgow aged 13 up to 16 years, and some others aged 16 to 18 years, accessing secondary, specialist care and neurosurgical procedures. Psychiatric services for 13 - 15 years and obstetric patients will be treated elsewhere.

The increase in the upper age limit for admission equates to 2795 inpatient episodes, 545 day cases and 9992 new outpatient attendances each year (2009-10 activity). Neurosurgical activity equates to 297 admissions and 1,650 bed days annually for patients aged 0 - 15 years. The children's hospital will remain the main provider of specialist care for the West of Scotland, although there may be some scope for shared care with district general paediatric units so that at least some care can be delivered nearer home (i.e. *'as locally as possible'*). The growing Managed Clinical Networks (MCNs) are very important in supporting this. However, a number of drivers that affect the sustainability of district general paediatric services and arguments for increased specialist input into care, have tended in the past to increase inward referrals. There is no immediate evidence that this trend will not persist.

As explained in the Outline Business Case, children's neurosurgical services nationally are under review and there is still no decision on their future configuration. Clearly, this may lead to realignment of some of the services provided by the specialist children's hospital services (Glasgow, Edinburgh, Aberdeen, Dundee) with an impact on future activity in Glasgow.

The review of children's cancer services, linked to the National Delivery Plan, has now concluded. In the future, Scotland will function with two Level 4 services (of which one will be in Glasgow) supported by a MCN with no anticipated change in the requirement for beds at the new children's hospital.

In considering future service requirements, it is important to note that, for many hospital services, the RHSC in Glasgow is the sole provider either at a local or regional level (and for some cases nationally) and these are underpinned by range of specialties / disciplines It is vital therefore, to ensure that the accommodation and services provided in the new hospital are capable of maintaining activity levels commensurate with clinical demand and of coping with anticipated periods of peak activity.

2E.3.1 *Bed Model*

The proposed number of beds for the new children's hospital is 256. This number is based upon:

- Hospital activity data for patient flow into RHSC aged 0 – 15 years
- Comparison of average length of stay with comparable UK institutions
- Occupancy rates of 85% for elective work and 65% for non-elective work
- Transfer of all neurosurgical activity in patients aged up to 15 years from the Institute of Neurological Sciences
- Predictions for demographic changes

The model excludes young obstetric and adolescent psychiatric patients (who will be accommodated elsewhere) and secondary care activity in Clyde. The 256 beds comprise:

<u>207 in-patient beds</u>:

• Neonatal surgical cots in the Maternity Hospital	12
• Cardiology	14
• Haemato-oncology (including 4 Teenage Cancer Trust beds)	26
• Psychiatry	6
• Combined medical and surgical acute receiving unit	40
• Medical and surgical wards	72
• Intensive care / high dependency care	22
• 23 hour beds[1]	15

<u>49 day case / ambulatory care beds</u>:

• Observation ward	20
• Day surgery[1]	15
• Day case oncology	4
• Medical investigation unit	10

This number of beds is an increase on that submitted for the Outline Business Case, largely because of revised predictions for demographic change (see Appendix C) *'Bed complement for the New Children's Hospital. Review of planning assumptions'*). In order to provide a combined neonatal medical and surgical service serving both the maternity and children's hospitals, twelve of the 256 beds (the neonatal surgical cots) will be accommodated within the redeveloped maternity / neonatal building on the Southern General site to which the NCH will be immediately juxtaposed. These cots will be accessed by neonatal surgical patients currently cared for in RHSC.

[1] A total of 30 beds to be used flexibly for day surgery and 23-hour stay

The estimates for hospital activity also anticipate about 60,000 attendances at the A&E Department each year, depending upon the number of children and young people attending Minor Injuries Units.

2E.3.2 *Service Re-design*

The proposed overall reduction in beds and shift to day and short stay care needs to be accompanied by significant re-configuration of patient pathways and service delivery. Service re-design is already well embedded within the operational activities of the Women's and Children's Directorate. The aim is to ensure that optimal service models are implemented and tested before transfer to the new hospital.

A number of reviews are already complete, with the recommendations being implemented within the physical limitations of the current hospital:

- The *'Redesign of elective surgical and anaesthetic services'*. Surgical Short Stay Group (2008)

- A *'Rapid improvement event for theatres'* to review operating department processes and improve efficiency by adopting 'lean processes' (2009)

- *'Design of Front Door and Acute Receiving Services'*. Front Door Sub-group (2009)

Recent developments that will improve the quality of clinical care, reduce the length of stay, improve the utilization of resources and / or support more sustainable workforce models (including Hospital at Night) are:

- Day-case tonsillectomy
- Elective operating lists on Saturdays (ENT and general surgery)
- All day theatre lists and extended working (08:45 – 17:30 from 2010 compared with 09:00 – 16:30 in 2009)
- Day-case, rather than inpatient, diagnostic cardiac catheters as routine and pre-operative assessment for all patients undergoing cardiac surgery / catheterization
- Planned expansion of general pre-operative assessment services to all patients having elective surgery / anaesthesia (admission on the day of surgery to become the norm for all patients); development of an e-form for elective surgery / anaesthesia
- Integration of the Medical Assessment Unit and the A&E Department with a common workforce and shared rotas; common assessment framework for those attending the A&E Department with all patients managed according to their triage category rather than route of referral; transfer of initial management / observation of some surgical conditions to emergency care physicians (for example, minor head injuries)

- In anticipation of the model of care in the generic wards of the NCH, alignment of related medical and surgical specialties including co-location of gastro-intestinal medicine with general surgery (inpatient beds), complex airway surgery with respiratory medicine and cardiology / cardiac surgery (inpatient beds; pending) and renal medicine with urology (inpatient beds and outpatient clinics)
- Centralised height and weight facility in the Outpatient Department, releasing rooms for consultation / examination; revised clinic schedule so that the same specialty is accommodated in the same rooms throughout the day to avoid overruns impacting on other services
- Extended working day in diagnostic imaging and routine MR imaging at weekends; development of strategies to reduce the need for general anaesthesia in children (MR compatible video player as distraction) and infants (late evening scans after 'feed and sleep')
- Rationalisation of ward accommodation
- A new 'drop in' diabetes facility
- A joint base for paediatric and neonatal transport service has been established at the RHSC, with specialist ambulances interchangeable between the two services. The paediatric and adult Emergency Medicine Retrieval Services have undertaken joint missions in support of critically ill children in remote and rural locations.

Policies / practice under review to further reduce length of stay or follow up are:

- Minimum acceptable age and maximum acceptable distance to travel after day surgery
- Criteria for day case surgery / anaesthesia, including review of the management of diabetic patients
- Rationalisation of routine follow up after surgery
- Care pathway for patients with abdominal pain and the planned transfer of initial management from general paediatric surgeons to emergency department physicians

Planned future developments at the RHSC before move to the Southern General campus are:

- Establishment of a 23-hour surgical short stay ward (effectively extended day surgery)
- Pilot of extended working in the outpatient department (three sessions rather than the previous two)
- Establishing a joint medical and surgical Acute Receiving Unit across two wards on a single floor of the tower block, which would also free up space adjacent to the current A&E Department (see below)
- Expansion of the A&E Department with clear segregation of patients according to category of illness / injury (resuscitation, major, minor, 'see and treat') and provision of an observation ward

The Directorate is also collaborating with regional planners (for example, through the Regional Acute Paediatric Clinical Redesign Interface Group) and other West of Scotland Health Boards in order to identify and accommodate any anticipated changes in service that would impact on the future role and contribution of the Royal Hospital for Sick Children. Clearly, unidentified changes in provision elsewhere would impact on capacity in the new children's hospital.

2E.3.3 *Building The Capability To Deliver High Dependency Care Throughout The Hospital*

A high proportion of acute and specialist paediatric inpatient care can be defined as 'high dependency' (according to the national audit of paediatric high dependency care). In the RHSC currently, the greater part of this is provided across acute and specialist inpatient areas. In the new children's hospital, there will be clear separation of patient pathways according to illness severity and elective versus emergency care.

Most elective surgery will be managed, for example, through the combined day surgery / 23-hour unit and generally inpatients in ordinary wards elsewhere will be sicker than currently. This will mean 'high dependency care' being delivered more widely throughout the hospital. The critical care service is already committed to developing this capability before the move to the Southern General Hospital campus, building flexible and tiered high dependency care everywhere.

The current High Dependency Care Unit is integrated with the Paediatric Intensive Care Unit and is orientated towards intensive care 'step down' and post-operative care. It also supports intensive care capacity during peak periods of activity, especially during the winter. Care in other areas is supported by mobile and flexible support from the critical care service in conjunction with assessment and observation tools such as the Children's Early Warning Score system.

2E.4 The Benefits That The Scheme Will Deliver

The benefits of the scheme are categorised below under the four headings:

- Clinical effectiveness and patient safety
- Facilities that are 'fit for purpose'
- Positive impact for staff
- Maintaining and enhancing academic links

2.E.4.1 *Clinical Effectiveness And Patient Safety*

Fundamental to the rationale for locating the new children's hospital at the Southern General Hospital campus is the wish to achieve the clinical benefits of co-location with adult and, in particular, maternity services.

2E.4.1.1 Co-location of children's and maternity services and integration of medical and surgical neonatal care

Restoring the geographical links between maternity and paediatric facilities, such as existed previously at Yorkhill, will further facilitate the multi-disciplinary care of the high risk foetus and new-born baby. This care includes diagnosis, advice and intra-uterine management for the foetus with significant abnormalities, the appropriate management of labour and prompt intervention for newborns with serious abnormalities.

Co-location allows immediate access to all the relevant staff and clinical facilities whilst avoiding; transfer across the city, interventions by clinical teams working in an isolated site or inappropriate separation from the mother. This is particularly relevant to life-saving *'exit procedures'* that require immediate attendance by a multi-professional team of specialists such as paediatric surgeons, anaesthetists and neonatologists.

Co-location with other adult services, notably critical care, will additionally ensure that mothers with co-morbidity or pregnancy-related complications obtain the highest standard of appropriate clinical care in a timely manner.

Over recent years, the surgical neonatal critical care unit at Yorkhill has changed from a unit run entirely by paediatric general surgeons to one staffed jointly by them and neonatologists. Both bring their specialist skills and knowledge to this very vulnerable group of patients. In parallel, the nurse workforce has changed and now includes midwives trained in neonatal care as well as paediatric nurses.

The anticipated transfer of children's hospital services will fully integrate surgical and medical neonatal care within a purpose built facility on the Southern General campus to further strengthen these developing professional relationships to the benefit of patients and support a sustainable workforce model.

2E.4.1.2 Neurosurgery

Currently, the children's neurosurgical service in Glasgow, with the exception of neonatal surgery and some ventriculo-peritoneal shunts, is provided at the Institute of Neurological Sciences on the Southern General Hospital campus. Whilst this service is now supported by paediatric neurologists and anaesthetists, with input from paediatric intensive care staff, many important components of a comprehensive paediatric service are not immediately available on the Southern General Hospital site. This includes, for example, general paediatrics, neurology, paediatric rehabilitation medicine and oncology.

There would be significant clinical advantages to all these services being on the same site. Co-location of the children's hospital with the Institute of Neurological Sciences would also help sustain staff rotas and facilitate further professional collaboration between neurosurgical and other specialist paediatric staff.

2E.4.1.3 Young people

In the RHSC young people commonly share ward facilities with small children or babies and in adult hospitals, they share facilities with older adults/the elderly. Neither scenario is appropriate, and each fails to recognise either the vulnerabilities or the physical, emotional, social and behavioural needs of young people.

The new children's hospital provides an exciting opportunity for the first time in Glasgow to provide age-appropriate and needs-appropriate facilities and services for those aged up to the 16th birthday in line with the recommendations of the Age Appropriate Care Working Group (National Steering Group for Specialist Children's Services, 2008).

Whilst clinical staff have concluded that the safest model of care is for young people to be managed on specialist wards, rather than a multi-specialty adolescent unit, the configuration of beds, with a high proportion of single bedrooms, will ensure them privacy whilst providing opportunity to configure their personal space appropriately. As discussed in the Outline Business Case, co-location with adult services will more effectively support shared arrangements between adult and children's service with patients easily able to access the most appropriate clinical teams and facilitate smoother transition from children's to adult services for those with long term, chronic conditions.

In the proposed design for the new children's hospital, special consideration has been given to young people's social needs for example, through the facilities funded by the Teenage Cancer Trust on the haemato-oncology ward, dedicated social space on the third floor and separate waiting facilities within the same-day admission unit and outpatient department. The proposed information technology (IT) strategy, with personal entertainment consoles at each bed-space, will also help maintain important social and educational networks through the internet during episodes of inpatient care.

2E.4.1.4 Maximising resources

Hospital buildings and equipment are expensive. In order to maximise use of these resources, departments such as outpatients and theatres are already planning to extend their normal working hours with the aim of running from 08:30 – 18:00 (theatres) and 09:00 – 19:00 (outpatients).

The ergonomic design of the new children's hospital will further support efficiencies and flexibility through the internal co-location of key departments, separation of patient flows and the greater provision of single bedrooms (see below):

(a) Internal co-location of key departments

The new children's hospital project team and clinical staff have critically reviewed and realigned the adjacencies of key departments to improve safety, efficiency and the ergonomics of the patient journey. For example, in the new hospital:

- The general anaesthetic imaging facilities are integrated into the operating department. This enhances patient safety by minimising journey times for patients undergoing diagnostic imaging and surgery under one general anaesthetic, avoids the hazards of working in isolated sites and improves patient turn-over by the use of a well-staffed and centralised recovery ward
- In-patient beds for neurosurgery will be co-located with those for neurology to provide an integrated neuroscience service
- The A&E departments for adults and children are co-located to minimise the risk of ambulances and public attending the wrong site and support collaboration between clinical staff from both services in the event of a major incident

(b) Separation of emergency from planned care

Currently, many clinical areas in the RHSC manage both elective and emergency patients and a wide range of illness severity and lengths of stay. This mixing of patient types hinders the delivery of well-structured care and causes 'bottle-necks' and inefficiencies. Two of the key principles in designing the new children's hospital have been to review departmental layouts, critical adjacencies and the configuration of hospital services to separate and optimise different 'patient journeys and match staffing arrangements with clinical need. For example, in the new children's hospital:

- Most patients will be admitted on the day of surgery through a 'same day admission unit' co-located with the operating department and integrated day surgery/23-hour unit. This will effectively separate emergency from elective flows, reduce unnecessary admission to hospital and minimise journey times to theatre
- Post-operatively, most patients having elective procedures under general anaesthesia will be managed through the integrated day surgery/23-hour unit, clearly segregating them from those undergoing major procedures or with complex co-morbidity, who will be cared for in one of the generic wards
- Those wards with the greatest requirement for support from medical staff out-of-hours (haemato-oncology; acute medical and surgical receiving wards) will be co-located with the 'Hospital at Night' base on the same floor
- The design of the A&E Department will allow clear segregation of patients according to the severity of their illness / injury (in *'see and treat'*, minors, majors, resuscitation)

(c) Infection control and efficient use of beds

A significant constraint in the efficient use of beds in the RHSC currently, particularly during the winter with the seasonal rise of RSV bronchiolitis, is the need to isolate patients with infectious diseases in cubicles. The new children's hospital will provide more single bedrooms (> 80% for inpatient beds) than currently, thereby allowing greater flexibility to isolate patients and manage peaks of activity during the winter months. In addition, the new hospital has been designed in accordance with best practice for infection control to minimise hospital acquired infections and the associated risks.

2E.4.1.5 Information Technology

Information technology (IT) plays an increasingly vital role in healthcare by improving communication, supporting safer, more efficient care and providing better information for patients and families.

High quality IT can also support more equitable access to health services and maintain social and educational links for children and young people in hospital. As a tertiary centre, the RHSC has been at the forefront of developing *'telemedicine'*, particularly for remote and rural care, and already provides a telemedicine centre and links from the critical care unit. The new children's hospital offers opportunity to provide these links more widely to support, for example, shared care arrangements and pre-operative assessment of patients from other health boards and ensure that patient transfers are safe and timely. State-of-the-art patient management systems will facilitate good care, minimise risk and ensure efficient working practices.

2E.4.1.6 Centralisation of Children's A&E Department

An additional advantage of a new children's hospital will be the opportunity to centralise emergency care in Glasgow for children up to their 16th birthday and, for the first time, to provide an appropriate environment in which to meet the clinical, developmental, psychological and social needs of young people.

Centralisation will significantly increase overall activity and, although the policy has already been agreed in principle, physical constraints in the current RHSC that cannot be resolved even with significant capital investment, mean that centralisation can only be achieved with relocation. In the new children's hospital, the A&E department has been designed to cope with this additional work, manage peaks of clinical activity and take account of modern clinical practice and optimal patient pathways (including, for example, clear segregation of patients according to the severity of their illness / injury).

To reduce hospital admissions, the A&E department will be supported by a 20-bedded Observation Unit for assessment of minor head injuries, non-specific abdominal pain (both previously under the care of paediatric general surgeons), ingestion of poisons and medical patients.

2E.5 'Fit For Purpose' Facilities

The design of the new children's hospital will support optimal service delivery whilst retaining the flexibility to respond to changes in the technology and models of care in the future. The structure has been designed ergonomically *'around'* the patient pathway to reduce unnecessary journeys (both of staff and patients / families) and hospital admissions.

- Patient pathways have been clearly segregated in the A&E department according to the severity of illness or injury into the category of *'see and treat'*, minor and major injury/illness and resuscitation
- The theatre department is adjacent to both a same-day admissions unit and the integrated day/23-hour surgical unit. For most patients, this avoids admission on the day before surgery, which patients and their parents / carers dislike, and minimises journey times to improve efficiency and reduce *'bottlenecks'*
- The majority of patients having procedures under general anaesthesia will be transferred from theatre to the co-located integrated day / 23-hour surgical unit. Again this reduces journey times, which means safer transfers and fewer *'bottlenecks'*, and allows medical staff to easily review patients between cases
- Close proximity also improves communication between the staff involved in each stage of the patient's journey through admission, operating department, post-operative care and discharge

Relevant departments/services are co-located:

- The operating and general anaesthetic (GA) imaging departments are fully integrated. This enhances patient safety by minimising journey times for patients undergoing diagnostic imaging and surgery under one general anaesthetic, avoids the hazards of working in isolated sites and improves patient turnover by the use of a well-staffed and centralised recovery ward. There are a purpose-built interventional radiology facilities for complex multi-interventional procedures, including surgery
- The A&E department is co-located with diagnostic imaging and immediately beneath the critical care and operating theatres with easy access to both by a dedicated lift
- A&E departments for adults and children are co-located to minimise the risk of ambulances and public attending the wrong site and support collaboration between clinical staff from both services in the event of a major incident. The decontamination unit, which will be used only very rarely, is shared between both departments
- Co-location of interventional cardiology and neurosurgery with the critical care unit will also support improved working efficiencies
- The main block of the current children's hospital at Yorkhill was built in 1970 with amended and additional facilities added subsequently. The design therefore either reflects outdated models of care or the constraints of limited space and operational feasibility. The opportunity to develop a *'fit for purpose'* hospital built around current and anticipated patterns of

patient care and the flexibility to respond to change will offer significant advantages to staff, patients and their families:

- Integrated neonatal medical and surgical services
- Well-structured dedicated 23-hour, day and ambulatory care services
- Appropriate separation of emergency and elective activity and levels of acuity
- In-patient wards configured to support clinical synergies (for example co-location of neurology with neurosurgery and renal medicine with urology) but with the flexibility to manage peaks of activity especially during the winter
- Purpose-built discharge facilities associated with in-patient wards

The ease of movement for staff, patients and their families between related areas of the new children's hospital will have a number of benefits:

- Better, more efficient (and ultimately safer) pathways of care
- Enhanced communication between different teams and stronger professional links
- Improved sustainability of workforce models including staff rotas and the delivery of the *'Hospital at Night'* service
- Better infection control management
- More efficient use of resources

The new children's hospital will also give opportunity to centralise children's emergency care within Glasgow, with an anticipated increase from 40,000 to 60,000 attendances each year. The proposed scheme includes a purpose-built paediatric A&E department designed around best practice and ergonomic patient pathways supported by adjacent and adequately sized short-stay and assessment / observation facilities to minimise hospital admissions.

The planned arrangement of departments within the new hospital supports rapid access to diagnostic imaging and swift transfer to the critical care unit and operating department. As described above, co-location with the adult emergency department and shared emergency ambulance routes reduces confusion, supports joint working in the event of a major incident and provides the opportunity to share facilities that are only extremely rarely used, such as the decontamination unit.

Professionals providing therapy and rehabilitation services, who have traditionally worked in very separate parts of the hospital, will, for the first time, come together in a *'therapies and rehabilitation hub'*. These include physiotherapists, occupational therapists, psychologists, psychiatrists, orthotists, speech and language therapists, dieticians and nurses.

Providing a range of treatments in a single location will help reduce the burden of hospital visits for families by avoiding multiple appointments in different places on different dates and supports multi-disciplinary care through better coordinated treatment and improved communication. This is important for those children and young people with the most complex conditions. The hub

will also provide resources for patient education, such as a therapeutic kitchen. Learning about food, how to cook and how to manage their own diets is a powerful way of empowering young people to become increasingly independent in the face of ongoing illness. For those recovering from life-changing illness, the hub will be a real bridge from hospital into normal life.

Finally, there is evidence that the construction, layout and ambient environment of a hospital influences well-being, clinical outcomes and patient safety. Examples of good design include:

- Ergonomic wards that increase patient contact for nurses
- Single room accommodation with well-positioned and adequate hand-washing facilities to reduce hospital acquired infections
- Good lighting and well-designed facilities that reduce dispensing errors; facilities/pathways that limit patient transfers, improve continuity of care and minimise risk of clinical errors.
- Noise reduction, daylight and views of nature to reduce physiological and psychological stress

The ambient environment can impact positively on clinical outcomes, for example:

- Visual distraction reduces the experience of pain during procedures
- A view of nature (real or simulated) reduces analgesic requirements and length of stay after surgery
- Daylight reduces depression, improves pain control and reduces associated medication costs

Evidenced-based design principles in the new children's hospital, enhanced by other influences, such as the artwork and interior design, will have a very positive influence on everyone in it, patients, their families and the staff that care for them.

2E.5.1 *Child, Parent And Family-Friendly Facilities*

For many patients accessing regional or national services; admission to hospital will mean being a long way from home and for a long time. In some specialties, notably haemato-oncology, patients can remain in hospital for many months, with major disruption to family life, finances and social and educational links. The current arrangement of beds in the RHSC, with limited cubicle space, significantly compromises private family life. There is also no access for patients and families to modern means of communication, such as the internet, and restrictions on the use of mobile 'phones. In the new children's hospital:

- Patients' personal space will be more generous than it is currently, improving privacy and reducing stress. In inpatient general wards, more than 80% of beds will be in single rooms, thus providing more private family space, better sleep, reduced stress and minimising acquired infections

- Each bed space will have an entertainment console. In addition to entertainment, the console will be a source of distraction during treatments, give access to the internet to help maintain links with friends and family in the outside world and support continuing education during inpatient admission

The different psychological, developmental and clinical needs of babies, children and young people, their dependence on parents and carers and the complex dynamics of the wider family mean that hospital facilities need to be carefully designed with the whole family in mind. In contrast to the situation in adult hospitals, parents / carers not only provide emotional support and comfort to patients, but are joint partners with healthcare professionals in their care. Meeting the needs of parents / carers, especially their physical and psychological needs, is fundamental to improving the well-being of sick children.

Providing appropriate facilities for parents/carers and the wider family is a key principle in the design of new hospital, for example:

- The hospital will provide well-designed and dedicated facilities for parents/carers located particularly in areas of stress (for example, critical care) or the longer-stay wards including dignified and comfortable waiting areas, shower and wash facilities and convenient spaces near to the ward in which to relax, socialise and meet other parents
- Except for critical care, every inpatient bed space will have an adjacent bed for a parent
- There will be purpose-built facilities for a family resource centre and bereavement services

Play has developmental and therapeutic benefits for all children and young adolescents. It is fun, helps to keep them healthy, helps develop an awareness of risk and danger and is important for building social, emotional and life skills. All children and young adolescents have a right to play (UNCRC 1989) but for those with mobility, visual or auditory impairments or learning difficulties, special measures are required to provide access to play spaces. Due of their importance, access to play and socialisation spaces, for all patients and siblings, has been given a high priority:

- The master-plan for the new hospitals includes a children's play park, a roof garden and access to outdoor balcony space from the haemato-oncology and inpatient psychiatric wards

- Access to indoor recreation appropriate for all ages and needs is a theme that runs through the entire design of the new children's hospital

- Providing facilities and services appropriate to all age groups and abilities is challenging, and to date, the needs of adolescents and young people in hospital have been neglected. In the current RHSC, there are only limited facilities designed specifically for them (it is not uncommon, for example, to find a 15 year old adolescent nursed alongside babies and small

children). This situation will be even more challenging with the increase in the routine upper age for admission to the 16th birthday, with some patients aged 16 – 18 also accessing care. The plans for the new children's hospital incorporate both dedicated facilities and flexible accommodation that can be configured to meet their needs:

- The interior design and art strategy in generic spaces will be planned to appeal to all ages, from toddlers to adults
- The single bedroom accommodation provides privacy and the flexibility to personalise space
- Dedicated socialisation space has been provided for young people adjacent to the generic wards and separate waiting facilities are included in the designs for the outpatient department and operating department
- The entertainment console, described above, will allow young people access to social networking sites and e-mail as well as links for continuing education

In addition to NHS funding, the RHSC has relationships with a number of key partners. The project team is working very closely, for example, with the Yorkhill Children's Foundation, on proposals to further enhance the new children's hospital environment to ensure that these are flexibly age- and needs appropriate and improve facilities for patients and their families. The current RHSC benefits greatly from the additional parent/family accommodation provided adjacent to the hospital through the generosity of the charities Ronald McDonald House and CLIC / Sargent. These facilities have been designed specifically to meet the needs of the parents and families of those children who have to stay for long periods in hospital. The decisions to re-provide these facilities alongside the new children's hospital have been agreed with the charities involved and there is a clear intention to work closely with these respective charities to facilitate the continuation of the current, and much valued, arrangements.

2E.6 Positive Impact For Staff

Many of the potential advantages of the NCH discussed above are also of major benefit to staff. These include ergonomic physical design that will reduce stress, increased access to natural light that will improve general well-being, close proximity to other services that will support multi-disciplinary working and enhance professional relationships and development.

Evidence-based design, including architecture, interior finishes and the art strategy, will impact on the attitudes and behaviours of everyone using the hospital. The design team's close attention to detail in some of the more stressful areas (such as interview rooms and waiting spaces) will help defuse difficult emotional situations, making the new children's hospital a much more pleasant and rewarding place in which to work.

Co-location with adult and maternity services, an innovative building based on best practice and an understanding of the impact of environment on well-being and outcome, facilities appropriate for all age groups (including young people) and needs and access to first rate education and research facilities will further develop the reputation of the children's hospital as a world class institution.

2E.7 Research and Education

Yorkhill is a major academic institution, comprising Scotland's biggest children's hospital (the Royal Hospital for Sick Children), the medical genetics services for the West of Scotland (Duncan Guthrie Institute), the Scottish Centre for Autism, the Scottish Muscle Centre and, until 2009, one of Glasgow's principal maternity centres (the Queen Mother's Hospital).

Yorkhill is also the home of many internationally acclaimed research groups, and a major site for the teaching and training of doctors, nurses and other health professionals who care for children. Through the Children's Services Research Group, Yorkhill acts as a focal point for academic activity in community children's services. Glasgow is unique in Europe in having such a strong constellation of clinical, scientific and educational facilities dedicated to the care and study of mothers' and children's health and Yorkhill has contributed significantly to its national and international reputation, demonstrated by:

- the commitment of the Medical Research Council, Wellcome Trust, Scottish Office, Cancer Research Fund, European Commission, and many other external funders to support the large number of research projects underway
- the relevance and high quality of scientific research and publications by Yorkhill staff
- the excellence of teaching and training of doctors, nurses and students of all professions allied to medicine
- the affection and support shown by the public who respond willingly to appeals for new equipment and services
- Yorkhill has close links with the University of Glasgow and with the nursing and AHP departments of the University of the West of Scotland and Glasgow Caledonian University

2E.7.1 *Research*

A number of specific achievements over the years have had a major impact on the care and health of mothers and children. These include:

- the invention of ultrasound scanning to detect fetal abnormalities in the womb
- the development of extra-corporeal membrane oxygenation for critically sick babies
- new ways of correcting heart defects in babies without surgery
- molecular markers for the rapid detection of birth defects in the womb

- pioneering of minimal access fetal surgery to correct abnormalities in the womb
- understanding how brain development is influenced by diet in early life
- the development of non-invasive, safe methods to measure metabolism and body composition in children
- the use of viral vectors for gene transfer to treat childhood cancers

The pursuit of research, the provision of education, the delivery of medical care, and the promotion of child health are interdependent missions of Yorkhill. Research is inseparable from medical practice, and innovation and development are only possible through cooperative partnership between scientists and clinicians. The importance of supporting paediatric research has been increasingly highlighted by the Chief Scientist Office through initiative such as the Academic Health Sciences Collaboration and the Scottish Medicines for Children Network.

At Yorkhill, research occurs within the hospital and University departments, through partnership between NHS and academic staff. More than 60% of the hospitals' consultant staff are engaged in research and teaching, with around 30 senior university academic staff (professors and lecturers) collaborating with NHS research groups and over 100 postgraduate students undertaking PhD, MD and MSc projects.

Although research within children's nursing is still in development, there is a commitment for Paediatric Clinical Nurse Specialists and Paediatric Advanced Nurse Practitioners to be actively involved to further develop the nursing care of children, young people and their families.

Research grants held by Yorkhill staff exceed £6m. Publications total over 300 peer-reviewed papers per year. Yorkhill's position as a leading academic centre for child health is strengthened by its successful collaboration with others in Glasgow, Scotland, Europe and internationally, including with Dundee University (Wellcome Fetal Surgery Group, Paediatrics and Nutrition), Glasgow Caledonian (Faculty of Health Sciences - Nursing, Vision Sciences and Nutrition), Scottish Universities Research & Reactor Centre (stable isotope research), University of Newcastle-upon-Tyne (Fetal Medicine), University of Edinburgh (Nutrition & Surgery), University of Cambridge (MRC) and the Universities of New York and Cincinnati (Fetal Medicine & Genetics).

Many NHS staff are honorary professors, readers, senior lecturers, lecturers, research fellows and clinical teachers in the University of Glasgow, Strathclyde and Glasgow-Caledonian Universities, and play a vital role in teaching and training of medical and nursing staff, and those of professions allied to medicine.

A major strength is the multidisciplinary nature of its research teams, forming a critical mass of working partnerships of clinical and non-clinical scientists and staff supported by a well-organised NHS Research and Development department with dedicated staff for paediatric research.

The recently established Clinical Research Facility (CRF) at Yorkhill, developed with the support of the Children's Foundation and NHS GG&C Research and Development department, will further support and promote and high quality research in children. Co-location of adult, children and maternity services on the Southern General Hospital campus offers the opportunity for this children's CRF to be incorporated into a much larger generic facility with the benefits of efficient use of resources and close liaison between professionals and disciplines.

2E.7.2 *Teaching And Training*

Yorkhill is a major centre for higher and continuing education in medicine, nursing and allied health professions.

- Main provider of children's nursing experience for undergraduates from Glasgow Caledonian University and, as a centre of excellence, nursing students from other countries within the United Kingdom and the European Union frequently request practice placement experience
- Houses the only paediatric focussed research and practice development unit (RPDU) within NHS Scotland
- More than 250 medical students from Glasgow University undertake clinical attachments each year
- Students/trainees include over 190 occupational and physiotherapists, radiographers, dieticians, clinical psychologists, and child psychologists

Higher professional training and continuing education include courses for UK and overseas graduates as well as for local doctors, nurses and other professionals allied to medicine. Yorkhill offers four fulltime MSc courses (in human nutrition, medical genetics, paediatric sciences and clinical paediatrics), which attract more than 50 students each year, and an increasing number of children's nurses studying towards masters level qualification with a few children's nurses undertaking doctoral studies.

Significant investment has also been made in the nursing clinical educator role to support the development of the registered paediatric nurse and clinical nursing practice. The clinical nurse educators and RPDU work in close collaboration with the nursing schools in the University of the West of Scotland and Glasgow Caledonian University to develop clinically relevant undergraduate and post graduate education

2E.7.3 *Benefits Of The Southern General Hospital Campus Location*

A new children's hospital on the Southern General Hospital campus will re-establish the physical links between children's and maternal services and, for the first time in Glasgow, offers the opportunity for co-location with researchers and teachers from adult disciplines. Not only will this foster professional collaboration, it also offers the opportunities for efficient use of educational and research resources through economies of scale**.**

2F. ADULT HOSPITAL (THE STRATEGIC CASE)

This section describes the following aspects of the Acute adult hospital development: -

- The business needs (case for change)
- Overview of the Acute Services Review (ASR) Strategy
- Description of current service at the Southern General Hospital
- Proposed future adult services on the Southern General Hospital campus

2F.1 The Business Needs (Case For Change For Acute Services Within Glasgow)

NHS GG&C recognises the need to ensure that patients who require access to hospital care can be seen, fully investigated and treated as quickly as possible within appropriate facilities.

For patients presenting as an emergency there should be access to specialised care of the highest quality, with access to state of the art investigations and treatment facilities on a 24 hour/7days a week basis. For elective care, patients should be seen, investigated and leave the hospital with a diagnosis and treatment plan wherever possible on the first visit. Underpinning this should be effective information and computer systems which allow General Practitioners, Specialists and patients access to all relevant information needed to deliver high quality and effective joined up care.

In 2002 Greater Glasgow Health Board described the case for change, which identified that the status quo was not an option, as there were significant challenges to the sustainability of the configuration of services across Glasgow and to the ability to improve patient pathways and create more efficient and effective care pathways. All of the factors identified in 2002 remain relevant today with additional challenges and pressures resulting in even greater need to reduce hospital sites and duplication of services. These issues include:

- The need to achieve the objectives of the guidance in the 'Healthcare Quality Strategy for NHS Scotland' and 'Better Health, Better Care' and other key national policies. These policies drive clinical excellence, continuity of care, reductions in waiting times, fast track access to rapid diagnosis and treatment; provision of services designed around the needs of the patient; modernisation of healthcare through better use of technology, effective communication and collaboration with patients over their care and provision of a clean safe environment. To achieve these objectives a major programme of investment in buildings, information technology and redesign of services is required
- Fragmented services. There is a requirement for patients to move within and around sites and different buildings in Glasgow with an inevitable loss of continuity of patient care. Important co-locations of services are often not possible to achieve and difficulties arise in transferring information amongst services

- Increasing sub-specialisation in medicine and surgery and an increasing need to move towards larger teams to ensure all patients can access an appropriate specialist on a 24 hours a day and 7 days a week basis
- Pressures on staff in sustaining appropriate staffing levels, for example 'Reshaping the Workforce' (formally Modernising Medical Careers) and the European Working Time Directive impact upon the availability of medical staff and therefore on the sustainability of multiple (often duplicated) rotas
- Outdated buildings unsuitable and unfit for modern healthcare offering a poor patient environment with unsuitable facilities for modernising services. Many of the Victorian facilities do not meet statutory requirements around, for example, bed spacing leading to a poor healing environment and inadequate patient privacy. Poor departmental co-locations restrict capacity and create bottlenecks and delays in treatment. These older buildings are also difficult to heat and costly to maintain

In summary, the status quo is not an option, as it will result in the following:

- Potential failure to provide a clinical service in accordance with nationally recognised standards
- Failure to provide good clinical services with enhanced outcomes through sub-specialisation and redesign
- Failure to sustain services. For example, many of the existing clinical teams are too small to sustain rotas across multiple sites without significant cost, for example the use of external staff agencies with a corresponding knock on affect to quality and expenditure
- An increased incidence of elective cancellations to cope with the rising emergency workload. The consequence of this trend will be a reduced ability to deliver elective activity with a shift towards an 'emergency only' service
- Failure to attract and compete for staff, especially in areas of acute shortages
- Failure to provide a modern service with sub-specialisation and up to date technology

2F.2 The Acute Service Review (ASR) [to address business needs]

The Acute Services Review (ASR) identified a programme of change to address NHS GG&C's business needs and this has been implemented over the last 8 years following approval of the proposals by the then, Minister for Health and Community Care in 2002.

The ASR programme sees the reduction in the number of adult inpatient sites from the current six hospital sites to three. Two sites, Glasgow Royal Infirmary and the new South Glasgow hospitals, will have A&E and trauma facilities. The third inpatient hospital for Glasgow will be Gartnavel General Hospital. These acute sites will be supported by the two new build Ambulatory Care Hospitals.

The components of the Acute Services Review (ASR) Strategy are:

- Two Ambulatory Care Units, one on the Stobhill Hospital site and one on a site adjacent to the Victoria Infirmary. These were completed and opened in 2009.
- A reduction in Maternity services from three sites to two, those being the Princess Royal Maternity Hospital on the Glasgow Royal Infirmary site and the redeveloped maternity facility on the new Southern General Hospital campus. This was completed at the end of 2009.
- In North Glasgow, acute in-patient services will be provided from the Glasgow Royal Infirmary and Gartnavel General Hospital sites
- In South Glasgow, acute in-patient services will be provided from a major new development on the Southern General Hospital site (the new South Glasgow Hospitals).
- A new build laboratory on the Southern General Hospital campus to support the new adult and children's hospitals.
- Full A&E services will be provided from two sites, located at Glasgow Royal Infirmary and the new South Glasgow hospitals
- Trauma and orthopaedic in-patient services will be provided from the two full A&E sites. Orthopaedic out-patient and day-case services will be provided from all five adult sites (Gartnavel General Hospital, Stobhill Hospital, Glasgow Royal Infirmary, the new Victoria Hospital and the new South Glasgow hospitals)
- Minor injury units will be provided from all five adult sites

The Ambulatory Care Hospitals represent a significant modernisation of Glasgow's healthcare facilities. However three of Glasgow's major adult hospital sites are now operating below capacity with only inpatient services remaining in some buildings at Stobhill Hospital and the Victoria Infirmary.

NHS GG&C is currently carrying out an accelerated ASR with the redesign of services for the north and east of the city to transfer inpatient services from Stobhill Hospital to Glasgow Royal Infirmary in 2011; the recent rationalisation of urology services to 2 sites and the centralisation of vascular surgery and renal services to the Western Infirmary by the end of 2010 - in preparation for achieving a single site model within the New South Glasgow Hospitals.

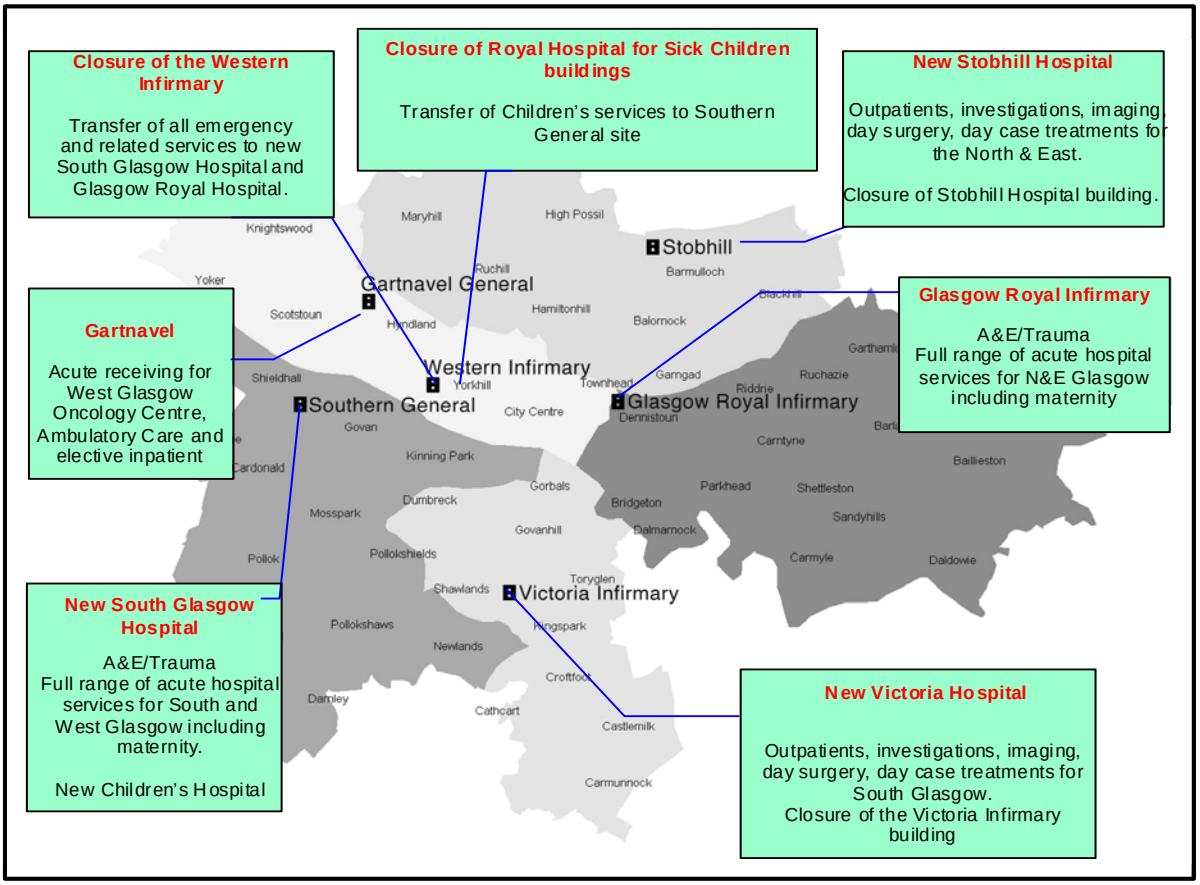
The proposals for the new South Glasgow Hospitals on the Southern General Hospital campus form the second phase of this Acute Strategy and are pivotal in achieving the transformation of services provided by NHS GG&C into a modern, fit for purpose 21st century healthcare system.

On completion in 2015, NHS GG&C will be able to enact the following:

- inpatient services in the Victoria Infirmary to transfer to the new South Glasgow Hospitals
- inpatient services at the Mansion House Unit (MHU) to transfer to the new South Glasgow Hospitals allowing closure of the MHU
- inpatient services housed in outdated buildings on the Southern General Hospital and Western Infirmary sites to be relocated to the new South Glasgow Hospitals .
- transfer of A&E services and associated beds from the Victoria Infirmary, the Western Infirmary and the Southern General Hospital to the new South Glasgow Hospitals

Following these transfers closure can take place of the Western & Victoria Infirmary sites and of older parts of the Southern General Hospital. This means that by 2015 the plans for the 3 site inpatient configuration of adult services in Glasgow will be achieved.

The planned future configuration of acute hospital services in Greater Glasgow is illustrated below.



2F.3 Description Of Current Services On The Southern General Hospital Site

The Southern General Hospital is a large teaching hospital with an acute operational bed complement of 900 beds. The hospital is situated in the South-West of Glasgow and provides a comprehensive range of acute and elective clinical services.

District General Hospital Services are provided for the South-West of Glasgow, with some services provided for the whole city. Services include Accident and Emergency, Dermatology, ENT, General Medicine (including sub-specialities), Assessment, Rehabilitation and Day Services, Gynaecology, Neonatal Paediatrics, Obstetrics, Ophthalmology, Orthopaedic Surgery, Urology, Physically Disabled Rehabilitation as well as in-patient Continuing Care. The Urology and Dermatology Departments provide the single in-patient location for South Glasgow and Glasgow respectively.

The Maxillofacial Surgery Service for NHS GG&C was centralised at the Southern General Hospital in the autumn of 2002 providing trauma and elective surgery and specialist provision for head and neck cancer. South and West Glasgow's In-patient Gynaecology Service was centralised at the Southern General Hospital in early 2004. The Assessment and Rehabilitation Service for the physically disabled is provided for the whole city from the Southern General Hospital campus. There is also a wide range of diagnostic and therapeutic services including audiology, clinical psychology, dietetics, occupational therapy, ECG, physiotherapy, radiology (including MRI and CT provision for the general hospital service) and speech therapy.

The Institute of Neurological Sciences is based at the Southern General Hospital and provides neurosurgical, neurological, clinical neurophysiology, neuroradiological and neuropathology facilities for the West of Scotland.

The Queen Elizabeth National Spinal Unit for Scotland provides a spinal injuries service to the whole of Scotland. This is housed in a purpose-built facility attached to the Institute of Neurological Sciences.

The Langlands building houses care of the elderly, young chronic sick and dermatology services. The WESTMARC (West of Scotland Mobility and Rehabilitation Centre) unit is a purpose built facility and houses the clinical services for prosthetics and orthotics including the artificial limb and appliance centre.

2F.3.1 *Buildings*

The Southern General site extends over 28.9 hectares and is located in Govan, South West of the city centre. The Southern General Hospital campus has evolved over 130 years. The site and the buildings within it are owned by NHS GG&C on behalf of the Scottish Ministers and incorporates the area of land earmarked for the development of the new adult and children's hospitals and laboratory build.

The facilities which make up the Southern General Hospital campus consist of a mix of buildings of varying ages, architectural style and quality spread across the site. The buildings date from 1872. In 1902-05 a facility accommodating a further 700 beds was built as the hospital continued to expand its services. A new maternity unit was opened in 1970 and the Institute of Neurological Sciences was completed in 1972. There have been a number of more recent additions to the campus over the last decade including the Langlands (PFI Project), and the WESTMARC buildings which house rehabilitation services.

As with all hospital sites of this vintage, piecemeal development throughout the lifespan of the site has resulted in the fragmentation of clinical facilities across the campus, resulting in a number of very poor clinical adjacencies and departmental relationships. Theatres are spread throughout a number of locations on site with each theatre suite dedicated to an individual specialty.

The A&E department is located next to the main rehabilitation facility with very poor adjacencies to other acute services on site. At present given the sprawling layout of the site there are two imaging departments - one co-located with the neurosciences/spinal complex and the other at the north of the site to service the main general medical and surgical inpatient facilities. The latter imaging facility, the main outpatient department and many of the in-patient wards are located some distance away from A&E.

2F.4 The New South Glasgow Hospital – Scope And Services

2F.4.1 *Proposed Future Demand - Bed Modelling*

Plans for the adult hospital include 1109 beds with an A&E Department with the capacity for 116,000 attendances per annum. The hospital will function as an acute site with an outpatient department and a medical day area serving the local population of South-West Glasgow. All surgical day case activity now takes place at the new Victoria Hospital. There will be no day surgery activity at the New South Glasgow Hospital.

The following section describes the bed modelling work which has informed the size and scope of the new hospital.

2F.4.1.1 Benchmarking with peer hospitals

NHS GG&C continues to progress a programme of benchmarking of acute services. Civil Eyes (an independent clinical activity analysis service), has been engaged to collaborate with NHS GG&C to build on the benchmarking exercises that the Board has undertaken for a number of years in order to review and determine the bed model for the acute adult services across Glasgow. The objectives of the programme are to:

- Provide an objective assessment as to the current performance of the acute adult hospitals across Glasgow relative to peers

- Identify the potential for improving efficiency in terms of use of beds and patient throughput
- Provide a projection of future demand in 2015
- Provide an indication as to the potential bed requirements

The planned bed model also takes cognisance of better clinical adjacencies, more efficient patient pathways, projected demographics and national policy adjustments.

Within the core specialties covered by the adult bed model there are currently inpatient beds across the 6 acute sites, against which the future bed provision is considered. The bed model for acute services was updated during 2009/10 using the 2008/9 activity, and performance information to identify the currently proposed bed model in support of this FBC.

In considering the Adult Bed Model 2008/9; data was used to consider the efficiencies to be delivered through improved performance of Glasgow's hospitals compared to a range of peer hospitals across the UK.

By incrementally applying the impact of,

a) operating at best peer performance rates across each specialty
b) achieving occupancy rates of 85% for elective work and 82% for non-elective activity
c) growth in medicine and the impact of demographic changes
d) performance targets on current and future activity such as waiting times

The number of beds required for the core specialties for implementation of the Acute Services Review (ASR) suggests a Pan Glasgow Bed Model of 2782. This number excludes beds associated with the following services; clinical haematology, oncology, homeopathy, spinal injuries and physical disabilities.

Modelling work has been undertaken to consider current patient activity flows and the extant strategy position, including the model for the single site specialties, in relation to the number of beds required in light of the future plan of 3 inpatient sites for the city (at Glasgow Royal Infirmary, Gartnavel General Hospital and at the new South Glasgow Hospitals site).

In addition, consideration has been given to potential developments to specialist services in Glasgow and changes to patient flows from Clyde in understanding the in-patient bed capacity required across the Glasgow acute hospitals.

At the time of undertaking the latest bed modelling exercise for the ASR it was recognised that there might be future changes to bed numbers as the result of changes to regional services provision such as neurosciences, oral-

maxillofacial services and renal services. With the exception of renal services, which has already been factored into the new South Glasgow adult hospital bed requirement other potential changes to requirements in relation to beds do not affect the new South Glasgow adult hospital current proposals and will be accommodated within existing services.

To ensure the focus on efficiency continues, the work in relation to the bed model will continue as an iterative process. Bed modelling with key performance indicators feeding into the ongoing service redesign will underpin the new service models that will be provided across Glasgow and in particular in the new South Glasgow hospitals.

2F.4.1.2 New South Glasgow Hospitals

The in-patient bed numbers used for planning purposes for the New South Hospital are as follows:

Table 1 – Planned New South Glasgow Hospital Bed Numbers

Specialty	Inpatient Beds
Acute Assessment Unit	118
Critical Care & Stroke	105
Medical Specialties & Care of Elderly	605
Surgical Specialties & Rehabilitation	281
Total Inpatient Beds	1,109

The total number of in-patient beds planned for the New South Glasgow Hospital is 1109. In addition, a medical day case unit (22 day beds) is proposed for the New South Hospital.

2F.4.1.3 Retained beds

There will be approximately 600 beds retained on the Southern Campus associated with care of the elderly, maternity, gynaecology, neurology & neurosurgery, and spinal services.

2F.5 Proposed Future New Adult Hospital Services (New South Glasgow Hospital)

Within the new hospital; emergency and elective work will be segregated as far as possible with inpatient and day attendances within one section of the hospital and A&E, critical care and the Acute Assessment Unit (the Emergency Complex), within another zone.

The adult wards will have 100% single rooms each with ensuite toilet/shower facilities. This will increase patient privacy and dignity and reduce risk around hospital acquired infection.

There will be separation of patient and staff routes through the building from visitor and Facilities Management (FM) flows. The schedules of accommodation reflect the opportunity for both (adult and children's) new hospitals to share facilities such as a pharmacy dispensing facility, aseptic suite, estates maintenance, waste compound, supplies delivery and distribution, kitchen, staff dining and other FM services.

A helipad is planned within the development with a rapid access route into the resuscitation area within A&E.

2F.5.1 *Service Profile*

The profile of specialties/services that will be provided at the new South Glasgow Hospital is set out in Table 2 below. All specialties will be providing inpatient care; some, but not necessarily all, will also provide outpatient clinics and medical day-care services on-site.

2F.5.2 *In-Patients*

The New South Glasgow hospital will be an acute in-patient site. The proposed in-patient services are shown in Table 2 below:

Table 2: Proposed Service Profile – Inpatient Services - New Adult Hospital (New South Glasgow Hospital)

Surgical Specialties	Medical Specialties	Other Specialties/Services
General Surgery	General Medicine	A & E
Urology	Cardiology	Acute Receiving
Vascular Surgery	Dermatology	Minor Injuries Unit
Trauma & Orthopaedics	Diabetes & Endocrinology	Critical Care
ENT	Gastroenterology	Rehabilitation Services
Renal Transplant Surgery	Haemato-Oncology	Complex Elderly, Care
		Radiology
		Endoscopy
	Medicine for the Elderly	Rehabilitation, Orthopaedic Rehabilitation & Surgery Rehabilitation)
	Nephrology	
	Respiratory Medicine	
	Rheumatology	
	Stroke Medicine & Rehabilitation	

2F.5.3 *Outpatients*

The New South Glasgow hospitals adult outpatients department will provide services for patients resident within the south west of Glasgow.

The anticipated profile of outpatient clinics is shown in Table 3 below:

Table 3: New South Glasgow Hospital - Proposed Outpatient Services

Surgical Specialties	Medical Specialties	Other Specialties/Services
ENT	Cardiology	Acute Assessment Unit outpatient service
General Surgery	Dermatology	Rehabilitation
Ophthalmology	Diabetes and Endocrinology	Radiology
Orthopaedics	General Medicine	
Urology	Medicine for the Elderly and Stroke Services	
Vascular Surgery	Haematology	
	Respiratory Medicine	
	Rheumatology	
	Gastroeneterology	

There will be a primary care out of hours service providing emergency GP access (which will utilise the children's outpatient area).

There will also be a 22 'bedded' Medical Day Unit providing day care relating to rheumatology, respiratory, diabetes and endocrinology and gastroenterology.

2F.5.4 *Principal Themes of the New Model of Care*

The key themes underpinning the new model of care are described below:

- Patient-focused services
- Systematic and managed services providing streamlined assessment of patients to facilitate early diagnosis and treatment avoiding bottlenecks and queuing
- Use of formally agreed pathways, guidelines and protocols
- Early involvement of Senior ''decision makers'' in the patient pathway
- Shared objectives of care by different teams, professionals and parts of the organisation
- Separation of emergency and elective pathways of care
- Single portal of entry for emergency admissions, through the Emergency Department and the Acute Assessment Unit
- Central emergency and elective operating theatres department.
- Rapid access to diagnostic services
- Patients requiring rehabilitation will move through a care pathway defined by their needs not by their age or disability. Early access to rehabilitation will be a feature of medical and surgical pathways
- Discharge planning will commence at the earliest opportunity including pre-assessment.

- Maximum use made of extended evening and weekend working to provide diagnostic services
- Modern career framework with both a multi-skilled and a specialist workforce
- Separation of staff and patient, public and facilities management routes

These key themes will be central to the design and operation of the new South Glasgow Hospital and will be at the core of the required service modernisation and new ways of working.

2F.5.5 *Elective Services*

The majority of elective services at the new South Glasgow Hospital will be undertaken on an inpatient basis. The development of elective services will be supported by the separation of elective and emergency care streams with the protection of capacity in relation to key facilities such as inpatient beds, operating theatres and post-operative recovery.

Elective admissions will be assessed pre-admission. The majority of elective patients will be asked to attend on the day of surgery and be admitted straight to theatre via a Day of Surgery Admission Unit which will work in close liaison with the pre-assessment clinic.

There will be no elective day surgery at the new hospital; therefore no day surgery facilities will be required.

A Medical Day Unit with 22 day care beds will provide day case investigation and treatment. This will be available to all medical specialties and provide care for patients resident in South-West Glasgow.

Outpatient facilities will be provide services for the local South-West Glasgow population.

The majority of day-case endoscopies and therapeutic endoscopy, will be provided at the Victoria Ambulatory Care Hospital and Gartnavel Hospital, with the exception of ERCPs, which will be carried out at the new South Glasgow Hospital.

2F.5.6 *Emergency Care*

Emergency Care Services will be provided in an Emergency Complex, which comprises the Emergency Department, the Acute Assessment Unit and Critical Care.

As part of the Emergency Complex there will be an ‘Acute Assessment Unit’, consisting of 118 beds organised into the following components:

- An Immediate Assessment Area
- An Acute Admissions Area
- A Clinical Decisions Unit
- An emergency outpatient area

These units will all be co-located, alongside the Emergency Department (ED), and will be the focal point of emergency service provision for the majority of patients (some patients may be admitted directly to specialist wards including stroke maxillo-facial surgery, gynaecology and ENT).

It is essential for patients with a high risk of being a source of infection to others to be managed "separately" to avoid the risk of infecting other patients. This will include; Influenza, Norovirus, Gastroenteritis, SARS, MRSA etc. This will require isolation facilities. The Infection Control Team have been fully involved in the planning of hospital to address and reduce the risk of spread infection through the design of the facilities. For example departments, especially those at the 'front door' emergency receiving will be capable of sectioning off areas to allow infected patients to be co-horted into one area and the single bed rooms and choice of easily cleaned floor and wall finishes will reduce the spread of infection.

2F.5.7 *Diagnostics*

It is anticipated that the majority of routine diagnostic tests for patients from South and West Glasgow will be undertaken at the Victoria Ambulatory Care Hospital and Gartnavel Hospital respectively. Investigations carried out at the new South Glasgow Hospital will therefore be of a specialist nature, with the exception of support provided for out-patient attendances.

Rapid Access imaging is particularly important for ED, Critical Care and theatres. Redesign of the diagnostic and imaging services, the physical layout of imaging in the new hospital and linkage with the new labs build will help to achieve this. The following describes this in more detail.

Strategic Reviews of Imaging and Laboratory Medicine Services resulted in a range of service redesign initiatives. NHS GG&C are putting in place high-volume, no-wait services which support rapid diagnosis and treatment for all patients. The separation of emergency and elective flows will support the work towards the new targets. The modernisation strategies have resulted in automation of haematology and biochemistry laboratory services. Major redesign of the workforce for Diagnostic services will include a transition to full shift working, moving away from the traditional on-call arrangements currently in place. To support the delivery of the bed model for Glasgow, Imaging Services will be provided in A&E and Acute Receiving 24/7. This redesign strategy will achieve radical increases in capacity allowing NHS to achieve a high volume no-wait service. Much of this work has been undertaken through the Diagnostics Collaborative, providing a good foundation on which to take forward further redesign.

The effective functioning of the Emergency Complex is underpinned by the support provided by Radiology and laboratory services. The redesign described above allows for extended day working and rapid patient access to diagnostics. This affords the opportunity to further develop ambulatory care within the fields of acute medicine and surgery (and admission avoidance) and to be associated with significant reductions in lengths of stay.

The design of the New Adult Hospital arranges imaging over 2 floors. On the ground floor the diagnostic facilities can easily be accessed by both outpatients and patients attending the emergency complex while the diagnostic services located on the first floor are adjacent to Critical Care, Stroke and Theatres but can also be easily accessed by the in-patient wards in the tower block.

Haematology, biochemistry, microbiology, pathology, genetics and mortuary services will be provided in the new laboratory building at the Southern site. This will be linked to the New South Hospital via an underground passage and pneumatic tube system which will facilitate rapid transport, and rapid turnaround of test results.

2F.5.8 *Critical Care*

The Critical Care Unit will be located on the first floor and will have rapid access to ED and theatres. It is composed of 4 discrete co-located areas as follows:

- Intensive Care Unit (ICU)
- Medical High Dependency Unit
- Surgical High Dependency Unit
- Coronary Care Unit (CCU)

The proposed design allows flexibility of bed use between the units, for example the High Dependency Unit (HDU) beds which can be used flexibility for either surgical or medical patients, and in cases of pandemic can be upgraded to an ICU bed. There will also be flexibility between the HDU area and co-located CCU.

In addition to the above there is a renal HDU which will be located within the renal unit with close access to both the critical care zone and the theatres department.

2F.5.9 *Theatres*

The theatre department will consist of 20 theatres with appropriate designation and separation of elective and emergency theatres. These theatres will have state of the art facilities, 10 theatres will have ultraclean facilities. The theatres will be supported by a dedicated recovery room.

2F.5.10 *Therapy Services*

Therapy areas will be located alongside the Care of Elderly beds, surgery beds and General Medicine beds in order to enhance service integration.

The design of the hospitals has been developed in liaison with a wide range of staff user groups and the Community Engagement Team has undertaken a comprehensive programme of consultation with patients and carers, groups such as 'Better Access To Health', and local community organisations. Further detail is available in Section 6.

2F.6 Service Re-Design

The new hospitals will facilitate service redesign which in turn will maximise the full potential of the new hospitals allowing new ways of working to be developed ensuring services are patient focussed and quality driven.

Key national guidance and good practice will be incorporated in the models of care, including:

- Patient centred care
- Investing in the latest Information Technology (IT)
- Extending the roles of nurses, Allied Health Professionals and other non-medical personnel
- Extending the availability of senior (trained) medical staff within elective and emergency care so patients see the most appropriate clinician in the most appropriate setting in a timely fashion
- Fully utilising the most modern healthcare equipment and technology in patient care
- Delivery of services associated with low rates of healthcare acquired infection
- Provision of facilities which promote high levels of staff morale and job satisfaction

The New Victoria and Stobhill Ambulatory Care Hospitals (ACH's) have set the scene for the new post ASR reconfiguration of services. The separation of planned and emergency care and the anticipated increase in day surgery rates will require major redesign in relation to how care is delivered. Some of the redesign work required at the new hospitals is already in place at the ACH's and in other hospital sites and is supported by the development of new roles. Examples of this include Emergency Nurse Practitioners who support new service models, such as the Minor Injury Units in the new Ambulatory Care Hospitals and Acute Care Medicine Consultants who in the future can provide leadership around the working of the new Emergency Medicine Complex.

The service redesign strategy work that was carried out by the Ambulatory Care Hospitals Team was closely linked to the planned changes in regional planning. This process will be continued in the redesign work for the new hospitals build. The redesign process will also be closely linked to the development and implementation of the Health Information and Technology (HIT) strategy and its phased rollout across the acute division.

The Accelerated ASR will mean that services such as renal, and vascular will be centralised in the West and therefore have an established single site service model before transfer in to the New South Glasgow Hospital.

The methodology and templates that have been put into place within the ASR work to date will also be applied to the New South Glasgow Hospital ensuring consistency in care models and a streamlined, joined up flow of service provision within Glasgow.

The sections below highlight the mechanisms for taking forward redesign in relation to scheduled care, unscheduled care and diagnostics.

2F.6.1 *Elective Care*

In implementing 'Better Health Better Care' Boards are tasked with achieving a shift in the balance of care and ensuring improvements are made in productivity and capacity, whilst sustaining improvements in waiting times and reducing the need for hospital admissions.

Key areas around the redesign of services required for elective care relate to improved day surgery rates and the development of integrated care pathways, which promote pre-assessment, pre-admission planning and improved discharge and follow-up procedures

Integral to delivering these improvements will be:

- improved referral and diagnostic pathways;
- treating day surgery (rather than inpatient surgery) as the norm;
- actively managing admissions to hospital;
- actively managing discharge and length of stay;
- actively managing follow up.

Clearly the acute services will be subject to a range of government targets and the HEAT targets are already embedded into the plans for the new hospitals, however the new service models and systems facilitated by the New South Glasgow Hospital will allow the targets to be fully sustained and provide the flexibility to meet future targets.

Managing change across the whole patient management pathway is key to achieving success in this area. Patient care pathways are being mapped and developed often requiring existing staff to work differently. Changes in working patterns however need to be underpinned by access to appropriate training through a competency based approach. This approach allows working roles to be adapted and expanded and helps avoid restrictions around the way services are delivered within previously traditional ways of working.

The new South Glasgow Hospitals Build supports these developments within elective care. Examples of this include:

- Development of an Admission on Day of Surgery (AODOS) area. AODOS requires robust pre-admission assessment but results in better admissions planning and shorter lengths of stay
- More care is being delivered now, and will be delivered in the future, through multi-disciplinary teams (MDTs). MDTs require access to good information (good IT) and good communication across all team members. Areas for MDTs to meet are of importance. Meeting areas suitable for this purpose have been developed across all in-patient areas in the new hospital
- Telemedicine is becoming of ever increasing importance. Space for this and IT support will be provided within the new hospitals build. Telemedicine has an increasing role to play in both elective and emergency care. Examples of this might include dermatology reviews to remote/rural areas and assessments that can be provided by the emergency retrieval team
- In many healthcare set-ups elective care can be threatened by peaks in emergency activity. This risk can be minimised by effective separation of these two functions. This thinking is integral to the design for the new South Glasgow Hospitals where emergency and elective work is clearly separated. Examples of this separation include having a dedicated radiology area to support the Emergency Complex with a separate area on the floor providing services for in-patients (and some out-patient work) as well as taking care to provide physical separation between “emergency” and “elective” areas
- A Medical Day Unit will be developed. This area will link with outpatients and with emergency care to provide high quality investigation/treatment facilities. This area will also provide a function in supporting early hospital discharge where some ongoing treatments might still be required

2F.6.2 *Emergency Services*

There are plans for the redesign of acute receiving within Glasgow hospitals, some of which is already in place. This has modernised and transformed the front-end of the acute hospitals allowing improved triage for patients, the introduction of streaming, separating patient flows and minor injuries to be assessed and treated by Emergency Nurse Practitioners separate to the main A&E/Acute Receiving areas within Glasgow's hospitals.

The current old, often Victorian, real estate of the Victoria Infirmary, the Southern General Hospital and the Western Infirmary have limited opportunity for redesign. A new build hospital will allow significant opportunity for redesign one of the key areas being the new adult hospital Emergency Complex which will embrace the changes described above but also promote:

- Streaming of GP referred medical patients into a dedicated Immediate Assessment Area (within the Acute Admissions Area) bypassing the Emergency Department
- Development of a design that allows very close proximity of the Emergency Department, the Acute Admissions Unit (AAU), emergency imaging (Radiology) , critical care facilities and theatres.

- Development of a Medical High Dependency Unit
- Design of facilities that allow complex use – such as interventional theatres and dedicated interventional labs within radiology
- Development of a dedicated acute stroke unit

Optimal operation of these facilities will require changes to current working practice. These changes include primary assessment of "999" presentations being completed within the Emergency Department, the further development of the role of the consultant acute care physician to staff the Immediate Assessment Area and provide clinical leadership within Medical High Dependency. These changes have the support of key members of medical staff involved in the redesign process.

The bringing together of three acute hospitals onto one site allows significant opportunities for economies of scale especially around the clinical and non-clinical workforce. Out of hours rotas can be significantly redesigned allowing opportunity to reduce the number of people who need to be on call and develop extended day working for more senior medical staff.

The large number of emergency admissions that will be seen daily (110-150/day) makes it practical to develop on call teams by speciality rather than have emergency cover provided solely by generalists. This has a number of advantages including: quicker patient access to the relevant "specialist", quicker "front door" decision making, better use of diagnostics and a likely shorter patient length of stay.

Although extended day working will be developed across a number of key areas; out of hours service provision will remain a challenge. The design of the New Adult and Children's Hospitals with their proximity (and physical linkage) to the maternity departments and Institute for Neurological Sciences allows the extension of the current Hospital at Night service to be developed into a Hospital Out-of Hours Service. A focus for this service has been planned within AAU.

2F.6.3 *Whole Service Issues*

There are a number of important services/developments as part of the new South Glasgow Hospitals build which have clear benefits across the whole hospital. These include:

Development of high quality, state of the art IM&T. The aim is for this hospital to be paper light/less as far a possible. This aim will be supported by the effective use of IT with easy access for staff to appropriate clinical information both through networked IT links and a whole hospital wireless facility. Facilities for telemedicine are of importance (as described above) and will be supported by the IT strategy. Other areas critically dependent on IM & T include bed management with bed availability information required in real time.

The separation of elective and emergency work has been alluded to above however in addition to this there is clear separation of staff and public routes as

far as possible. This is important from both a general security perspective and also from a staff safety perspective (especially out of hours).

2G. INVESTMENT OBJECTIVES

The Investment Objectives stem from the Board's business aims. Core Investment Objectives are: the need to modernise patient care, speed up the patient journey, reduce the number of inpatient sites, invest in fit for purpose facilities and information technology, reduce hospital acquired Infection rates, make more effective use of clinical time to ensure patients are seen by the specialist team much earlier in their care pathway and the achievement of gold standard services through the triple co-location of Adult, Children's and Maternity Services onto a single site.

The fundamental aim of this project is to provide modern, state of the art facilities that will deliver redesigned patient pathways which streamline patient care, deliver improved efficiency and productivity and more effective service models. This will ensure that the Health Board are providing the best level of patient care to the highest standard, as good as any to be found throughout Europe.

The Investment Objectives reflect the benefits which are anticipated from the project, and these are given in more detail below along with a description of how they will be measured.

2H. BENEFITS CRITERIA AND REALISATION

The benefits expected from this project fall into the following 9 categories:

1. Clinical Quality
2. Sustainability of Services – (consolidation of services)
3. Physical Environment (quality environment)
4. Performance Improvement
5. Staffing and Workforce
6. Environmental considerations
7. University
8. Accessibility to hospital
9. Economic and Community

These are unchanged from the Outline Business Case with the exception of the additional benefit category of Economic and Community.

The following table outlines the benefits along with how and when success will be measured. Further detailed description of each benefit, and the process for reviewing and monitoring is given in Appendix D.

Table 4: Anticipated Project Benefits and Benefits Realisation – Adult and Children's New Hospitals

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
1	Clinical Quality	The 'gold service' triple location of adult, paediatric and maternity services.	Development of integrated services. These include integration of neonatal and maternal ICU, integration of adult medicine and maternity services and development of streamlined transitional care.	Adult, paediatric and maternity services located on a single site. Reduction in number of inter-hospital transfers for adult, maternity & paediatric patients and babies. Improved transitional care for young people as measured by patient satisfaction survey.	Yes. 12 months post transfer of services.	Project Director Medical Director, Director of Nursing
2	Clinical Quality	24/7 patient access to specialist services.	Implementation of the Acute Assessment model means that patients will be seen by senior medical staff at an earlier stage than currently, and, as a result will have quicker diagnosis and implementation of treatment plans.	Senior decision makers available at the beginning of the patient journey. Implementation of viable sub-specialty rotas. Sustained delivery of Government targets, e.g. 4-hour trolley waits; 18 –	Yes. 6 months post transfer to new hospitals.	Medical Director, Director of Nursing

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			Enhanced critical care with state of the art facilities including Development of a Medical High Dependency Unit. Improved access to electronic patient information supports diagnosis and commencement of treatments & continuity of care.	week waiting time target. A&E. Shorter lengths of stay & reduction in unnecessary admissions. Access to electronic records at point of care.		
3	Clinical Quality	Achievement of the guidance in 'Healthcare Quality strategy for NHS Scotland ' for providing :a clean and safe environment, clinical excellence and continuity of care with clear communication and effective collaboration between staff and patients about their condition and treatment.	Single room provision will reduce patient transfers due to gender, infection etc. Provision of single room with en-suite shower & toilet facilities aids infection prevention and control as there is greater flexibility in isolating patients. Patients who are	Reduction in HAI rate attaining the Scottish Government Health Departments HAI targets for 2015 onwards. Fewer patient moves once admitted Reduced boarding of patients. Compliant with CEL27 (2010) and SHFN 30	Yes. 12 months post transfer to new build adult and childrens hospitals.	Medical Director Nursing Director

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			subsequently diagnosed as having an infection will already be in a single room and therefore risk to other patients reduced.	Patient satisfaction survey, monitoring communication and collaboration in diagnosis and treatment.		
		Provision of a modern environment	Provision of single rooms will facilitate private conversations between clinicians and patients supporting shared decision making regarding treatment.	Improve compliance with hand hygiene. Address CEL 05 (2005), improved audit scores and reduced HAI rate. Achievement of the SGHD HAI targets for 2015 onwards.		
			Improved hand hygiene through easily accessible wash hand basins.	Adherence to CEL 53 (2008) NHS Scotland Dress Code.		
			Hand hygiene training facilitated through provision of training and seminar rooms within the new hospitals. In addition to monthly	Compliant with SHFN Note 30 V3 Infection Control in the Built Environment.		

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			teaching sessions and the online Training Tracker, sessions of supported learning are being run for the Cleanliness Champions programme. Careful selection of materials/finishes which are easy to clean and maintain. Segregation of clean and dirty routes through the hospitals.			
4	Sustainability of Services (consolidation of services)	Continued sustainability of clinical services and compliance with Workforce Directives. Development of new service models through service redesign.	Centralisation of clinical staff, services and resources onto a single site.	Reduction in the number of medical rotas following reduction of sites. Sustained achievement of European Working Time Directive and 'Reshaping the Workforce' (formally Modernising Medical Careers).	Yes. Immediate effect post transfer of services to new hospitals.	Medical Director, Director of Nursing Directors for Surgery & Anaesthetics, Diagnostics and Emergency Care

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
				Reduction in the number of sites requiring overnight staffing e.g. emergency theatres, emergency imaging and Emergency Departments.		
5	Sustainability of Services (consolidation of services)	Enhanced quality and sustainability of children's neurosurgical services.	Delivery through state of the art/fit for purpose design with physical links between children's hospital and neurosciences.	Physical links to facilitate an integrated paediatric neurosurgical service.	Yes. Immediate effect post transfer of services to new hospitals.	Director of Women and Childrens services and Regional Services Director
6	Physical Environment (Compliance, Adjacencies and Links)	Modern 21st century fit for purpose facilities. More patient and staff amenities for example, cafeteria, shops, changing facilities. Good levels of natural light and ventilation Aesthetic environment Improved maintenance Improved wayfinding	Through delivery of the Employer's Requirements with interlinked equipment strategy and healing arts strategy. Compliance with NHS guidance and statutory regulation. Improved Health and Safety regimes. Improved logistics support.	Optimum co-location of departments as specified in Employers Requirements resulting in improved communication. Achievement of physical links between adult and children's, neurology and maternity services. Evidence of 100% single rooms. Patient satisfaction survey	Yes. Measure 6 months post transfer.	Project Director (Delivery of ER's) Medical Director, Director of Nursing

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			Easily cleaned and maintained finishes.	Achievement of physical link between new hospitals and new labs build via tunnel and pneumatic tube hence faster turnaround of lab results. Reduced number of reported accidents. Evidence of energy efficiencies and reduced maintenance costs.		
7	Physical Environment (Operational Benefits)	Operational benefits through efficient working practices and design e.g. Efficient delivery of goods and removal of waste through distribution by AGV and Pneumatic systems. Increased security with controlled access to	Through delivery of ERs and subsequent implementation and appropriate use of systems and controls. Separation of FM routes from patient/staff and visitor routes, i.e. dedicated AGV lifts and routes.	Staff efficiencies through distribution by AGV and Pneumatic systems. Specimen response times improved. High levels of control of access and egress to relevant areas. Full BMS system with monitoring, recording and management ability of building systems. Improved scores from	Yes. 6 months post transfer.	Project Director (Delivery of ER's) Director of Facilities (Implementation)

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
		wards and departments, extensive CCTV and ability to lockdown areas.		national monitoring system re cleaning specifications. Reduction in reported security incidents.		
8	Performance Improvement	Increased efficiency and throughput to sustain current HEAT Targets, and increased ability to meet future waiting time guarantees for 2015 (and beyond).	By consolidation onto 1 site, achieving better co-locations, new more efficient models of care such as the Acute Assessment Unit and Day of Admission area in theatres leading to more streamlined patient flows.	Achieving Gov waiting time targets. Increased throughput of beds. Reduced length of stay for emergency admissions (by improved clinical adjacencies, diagnostic resources availability and efficient and appropriate utilisation of diagnostics). Reductions in re-admission rates (through the Acute Assessment model using early ambulatory care supported by appropriate specialist input). Reduced new to return outpatient appointments. Evidence of more senior	Yes. 6 months post transfer.	All Acute Directors

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
				clinicians involved in the front end emergency care ensuring appropriate referrals to diagnostics and good use of resources.		
9	Performance Improvement	Increased efficiency in support services such as Facilities (materials) Management and pharmacy, communications and maintenance supporting a higher throughput of patient care. High speed material and specimen transport 24/7to the new lab building facilitating a faster turnaround of test results in conjunction with the new IT system allowing automatic down load of lab results.	Through use of installation of Automated Guided Vehicles and automated pharmacy dispensary. Through installation of pneumatic tube system.	Increased delivery of goods to scheduled times –'just in time' scheduling. Pharmacy - increase in number of discharges before noon (i.e. reduced delay through getting discharge prescriptions), efficient and effective delivery of services, improved tracking of specimens.	Yes. 6 months post transfer.	Director of Facilities Head of Pharmacy
10	Staffing and workforce	Improved quality of recruitment and retention.	New state-of-the-art facilities and equipment, together with co-location of university attracting	Increase in the number of applications for posts and a reduction in leavers to other NHS boards.	Yes. 12 months post commissioning.	Director of Human Resources

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			potential employees and improving ability to retain staff.			
11	Staffing and workforce	Improved staff access and work towards a greener environment.	Dedicated transport hub designed in conjunction with local public transport providers. Reduction in the need for inter-site travel by staff due to consolidation of services.	Measuring change in staff's method of travel to work through staff survey. Reduce number of miles claimed.	Yes. 6 months post commissioning.	Director of Human Resources
12	Staffing and workforce	Reduction in staff absence and increase in staff morale.	New fit for purpose facilities and good working environment. Good access to natural daylight.	Improved absence levels in 12 months post move compared to 12 months prior to move. Staff questionnaire.	12 months	Director of Human Resources
13	Environmental Considerations (Carbon Reduction)	New hospitals to contribute to reduction in CO2 emissions in line with Board's Carbon Reduction and Management Plans in compliance with Climate Change Act (Scotland).	Through consultation with stakeholders including Carbon Trust during design stage to set targets prior to procurement. Employer's requirement's to	Achieve operational 80kg/CO_2/per sq meter per annum target or lower.	Yes. Immediate and ongoing with follow on benefit delivered when retained estate connected to new Energy Centre.	Project Director (delivery of ER's) Director of Facilities

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			prioritise low carbon and ensure that future reductions in retained estate CO_2 emissions can be realised from investment in advanced Energy Centre. Achievable with use of modern technologies such as CHP & Heat Recovery. Also through Green Travel Plan, cycle routes in the campus, promotion of car share, access for public transport.			
14	Environmental Considerations	New Hospitals will deliver sustainable high quality User product and User environment.	Appoint BREEAM advisor to advise on Design Development and Track Status.	Targeting of BREEAM "Excellent Status"	Yes. Immediate and ongoing, design assessment to be approved by BRE at design completion and certification to be applied for and measured on	Project Director

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
					completion of project.	
15	University	Consolidation of 3 sites onto 1 will enhance opportunities for teaching, and research and play a significant role in attracting and retaining high quality staff in all disciplines.	Through implementation of engagement plans with the teaching organisations.	Teacher and student satisfaction surveys. Increased high quality research output as measured by publications and award of research funding.	Yes. 12 months post transfer of services.	Chief Operating Officer
16	Accessibility to Hospital Campus	Easy transport links to support patient and visitors attending the hospital, improved cycling and walking routes + provision of appropriate car parking.	Through construction of physical roadways, paths and access routes followed by implementation of the Board's Travel Plan.	Travel survey monitoring mode of travel to hospital and ease of travel experienced.	Yes. 6 months after completion and then every 2 years.	Project Director (Infrastructure) Director of Facilities (Implementation)
17	Economic and Community Benefits	Recruitment protocol to support route to employment	Through establishment of a recruitment protocol with the Contractor and Regeneration Agency.	Identifiable protocol enabled for use individuals employed on the construction project recruited through the recruitment protocol.	Yes. Annually to the end of the construction period.	Community Engagement Manager
18	Economic and Community Benefits	Regeneration of the South West Glasgow Community.	By developing, assessing and supporting SMEs and Social Enterprises in	Number of local businesses and Social Enterprises securing contracts in the	Yes. Annually to the end of the construction period.	Community Engagement Manager

No	Criterion	Benefit	Action to achieve	Measurement of success	Realistic/ Timescale	Responsibility
			conjunction with the Contractor.	construction of the building.		
19	Economic and Community Benefits	Learning pathway in South West Glasgow for individuals to pursue a career in healthcare.	Through local and pan-Glasgow awareness and support to potential employees and individuals with a healthcare interest.	Level of NHS Greater Glasgow & Clyde employees who work on the NSGH site resident in South West Glasgow.	2020	Director of HR Community Engagement Manager

2I. STRATEGIC RISKS

In developing all aspects of planning the new facilities the Project Team and advisors have pro-actively managed potential risks by identifying them early and taking early action to ensure maximum reduction and mitigation of risk. Therefore, this approach has been enacted at all key stages of the project such as:

Pre-procurement:	Tender and process development
During procurement:	Competitive dialogue, evaluation and due diligence
Post procurement:	Construction and design stages.

Headline examples of this essential activity to mitigate and manage strategic risks includes:

- Acknowledgement of the wider economic background – in order to assess viable market uptake and bidder interest in the scheme a thorough market sounding exercise was under taken to support and test the proposed procurement route and approach to the competitive dialogue process;

- Consultation with key organisations – extensive consultation took place with the Scottish Government Health Directorates, Partnerships UK and A+DS in order that the procurement and market engagement proposals were thoroughly transparent and agreed prior to implementation;

- Community engagement – thorough and wide ranging consultation and interaction with local neighbours, communities and businesses has resulted in the project being accepted. The potential benefits to the local economy and landscape have been clearly identified and the impacts discussed locally with information pertaining to the project readily available and provided to interested parties;

- Consent and approvals – as an extension of the community engagement the Health Board has actively engaged with Glasgow City Council, Strathclyde Partnership for Transport (SPT), the Fastlink Team and other organisations throughout the planning process. This has been a two-way process that has demonstrated joint working and allowed issues, concerns and relevant considerations to be raised, discussed and resolved as the project has moved through the regulatory system. This included, for example, undertaking various environmental impact studies and associated activity in order to thoroughly assess and consider the impacts of the scheme;

- Service planning – the hospitals have been scoped to ensure the sustainable delivery of present and future healthcare targets and clinical aims. Clear output requirements have been established through extensive consultation with clinical users and benchmarking with other large hospital new builds for example in Birmingham, Forth Valley Health

Board, Peterborough, and Oslo. Finally the Board commissioned consultants to provide bed modelling analysis.

- Control of change - There is a robust change management control mechanism in place. Requests for change need to be supported by the respective Director, and a case presented to the Acute Services Strategy Board Executive Sub Group for consideration and approval. Due to the extensive user consultation undertaken prior to tender there have been very few requests for change from users during the development of the 1:200 and 1:50 design.

- Programme and resources – effective project management and leadership is displayed by the Board which supports a robust delivery team that is well resourced and supported to work in partnership with the contractor and with other agencies and parties engaged in delivery of the project.

- Financial Planning – Financial planning and financial risk management have been at the heart of the project and controlled through each of the project's stages. Making allowance for known and unforeseen risks has been integral in planning as can be seen from the contract risk registers.

2J. CONSTRAINTS & DEPENDENCIES

Constraints that affect the project are the physical site for the construction works, due to this being located within the boundary of the existing Southern General Hospital, and the financial envelope as there are dependencies with regard to the provision of capital and revenue funding for the project.

2J.1 The Physical Site

The Southern General campus is bordered and accessed from the north by Govan Road and on its west side off Hardgate Road.

The eastern boundary is formed by the Clyde Tunnel approach and Moss Road. The southern boundary is bordered by residential property. Road access is not currently available along either of these edges.

The north-western corner of campus site between Govan Road and Hardgate Road is bordered by existing industrial land and Sheildhall Water Treatment Works. At present Hardgate Road does not extend beyond the Treatment Works and therefore does not link with Govan Road.

The existing hospital buildings are spread out over a large area of the campus and in a number of cases require elevated bridge links across the spine road. Surface car parking is distributed sporadically adjacent to the numerous entrances arising from the existing fragmented site layout.

A number of bus services pass close to, or through, the site.

Emergency blue light traffic use the same spine road network to access A+E, Maternity and Neuro/Spinal Injuries.

The site area within the campus, which is 15.5 acres or 6.3 hectares, will be passed to the contractor in a phased sequence (firstly for the construction of the laboratories, secondly to allow demolitions to proceed and thirdly to allow the main hospitals build to commence) while the existing SGH services continue to operate.

The potential for interruption to day-to-day services and facilities within the site during construction has been carefully analysed, and will be managed by a series of enabling works. The construction site will be isolated from the remainder of the hospital with materials and construction traffic accessing the site from a discrete entrance off Hardgate Road and a link road to Govan Road that presently exists within the site. Details of the various enabling and de-risking activities and planning for the site are included in the project risk section in Chapter 4B.

The hospital will continue to operate uninterrupted during construction and commissioning of the new facilities. Control of all activities is managed in conjunction with the Southern General Hospital FM Department through a series of regular formal meetings.

2J.2 The Financial Envelope

Specific detail around the funding and affordability of the project is included in both Chapter 3 (The Economic Case) and Chapter 5 (The Financial Case). In headline terms however, the proposals within this Business Case are that the Scottish Government will provide the capital funding for the project and the Board will be responsible for providing the revenue funding for the project.

CHAPTER 3

THE ECONOMIC CASE

CHAPTER 3 – THE ECONOMIC CASE

3A. CRITICAL SUCCESS FACTORS

As stated the purpose of this Full Business Case is to reaffirm the case laid out in the Outline Business Case, in other words that the Board's Strategic direction remains the same and that the preferred option is still valid and supports the Board's overall service change strategy and subsequent capital programme.

Key CSFs	Broad Description
Strategic fit and business needs	The preferred option remains the key phase in the overall Board's strategy for service change, the Acute Services Review. This is further detailed in chapter 2. The benefits and efficiencies arising from the implementation of the project are integral to the sustainability of Glasgow's acute health service.
Potential VFM	The project continues to demonstrate Value for Money; this is further detailed in Chapter's 3 and 5.
Potential achievability	Extensive pre-planning has taken place to establish the Board's clinical and technical requirements and a construction partner capable of delivering the scheme is appointed. Specific logistics pre-planning and engagement is taking place to minimise any impact on the delivery of clinical services on the exiting site. The design and construction plans are developing as are outline plans for commissioning and transfer of services.
Supply-side capacity and capability	The new hospitals will create capacity to enable the sustained delivery of current government targets e.g. HEAT targets and create flexibility in meeting new future targets.
Potential affordability	The project continues to demonstrate an affordable solution in both capital and revenue terms, this is detailed in Chapter 5. The capital and revenue remain within the funding envelope identified in the OBC.

3B. ECONOMIC CASE – VALUE FOR MONEY

3B.1 Introduction

This section covers the economic appraisal of the value for money implications of the project. The appraisal has been conducted with reference to the relevant guidance from HM Treasury, Scottish Futures Trust and the Scottish Capital Investment Manual published by the Scottish Government in August 2009. The economic case is structured as follows:

- A summary of the position at OBC stage is presented
- Developments that have occurred since completion of the OBC are described and their impact on the preferred way forward assessed;
- Details of the costs to be included in the appraisal are provided;
- Results of the appraisal are presented.

The following paragraphs consider each point in turn.

3B.1 Summary of Economic Case at Outline Business Case

The OBC considered three options for implementing the project

1. Greenfield Option – A new build whole site solution for all facilities currently provided at the Southern General site, together with new Adult Acute and Children's Hospitals, plus related facilities. Land for a Greenfield site would be required under this option.

2. "Option 1" – This option represents an entire new build solution on the current Southern General site for the Adult Acute and Children's Hospitals, plus new build Laboratories, and other related services.

3. "Option 1A" – A new build provision on the Southern General site for the Adult Acute and Children's Hospitals, plus the refurbishment of some existing facilities on the Southern General site to provide Laboratories and other related services. This option allows for the retention of Neurosciences, Maternity, the Spinal Unit and the Langlands buildings currently on site.

   For options 1 and 1(A) two scenarios were also considered. These were:
   - Base case, which modelled a scenario with 57% single room provision for the Adult Hospital; and
   - Alternative case with 100% single room provision within the Adult Hospital.

In addition the Board considered three potential procurement routes:

1. Traditional Procurement – also referred to as the Conventionally Procured Asset Model ("CPAM");

2. Private Finance Initiative ("PFI");

3. Not for Profit Distribution Model ("NPD"). This model provides for the redistribution to the Board of any excess profit which may arise, in the form of "charitable surplus".

   The risk adjusted net present values from this exercise are set out in the following table:

Table 5 - OBC Position: Summary of risk adjusted net present values by option

OBC Position: Summary of risk adjusted net present values by option							
	Greenfield CPAM £'000	**Option 1 CPAM £'000**	**Option 1A CPAM £'000**	**Option 1A PFI £'000**	**Option 1A NPD £'000**	**Option 1A PFI Bond £'000**	**Option 1A NPD Bond £'000**
Base Case	2,031,093	1,099,535	1,012,725	1,020,915	1,009,694	997,749	984141
100% Single Rooms	2,068,056	1,129,425	1,042,615	1,051,924	1,040,160	1,028,700	1,014,531
Ranking (excluding bond)			*2*	*3*	*1*		

For both the "base case" and "100% single rooms" scenarios, Option 1A represented the preferred option, when compared to the Greenfield site and Option 1, in terms of risk adjusted net present value. On this basis, a full value for money appraisal was carried out on Option 1A, examining the relative costs of each alternative procurement route.

When assessed in risk adjusted net present value terms the three procurement routes produced very similar results, the variation between the options being only 1.1%. In terms of ranking, excluding Bond, the NPD model ranked first, followed by CPAM then PFI. At the time of the OBC, it was noted that a Bond had not been used to finance any NPD project which had closed in Scotland.

The Board reviewed the options, particularly in light of the results of the affordability assessment, and the OBC proposed the adoption of a Traditional procurement route for Option 1A with 100% single room provision. This position was ratified by the Scottish Government in its approval of the OBC.

3B.3 Main Business Options

In the period following the approval of the OBC there have been a number of developments in both a policy context and market positions that have an impact on the economic case. These developments include:

- For the Greenfield site option a suitable site had not been available to the Board at the time the OBC was prepared. During the intervening period an appropriate site has still not become available;

- The Board has commenced the investment of over £100m in major capital works on the Southern General site including the recently completed extension of the Maternity Hospital (£28m) together with construction of a major new Laboratory and combined Facilities Management complex at a total cost of £90m. Both of these developments form part of the programme of building works associated with the Acute Services Review;

- The Scottish Government, through the work of the Scottish Futures Trust, has developed the Non Profit Distributing Model as its preferred form of Public Private Partnership. The model has been successfully used on education projects and also in the health market for NHS Tayside's Mental Health Developments Project. It is currently being applied in the transport sector for the procurement of the Borders railway project;

- In common with the wider economy the global financial crisis had a significant impact on the infrastructure market. The availability of credit has severely contracted and the price of credit has increased substantially. This has resulted in a significant reduction in both the number of lenders in the market and the number of transactions reaching completion. Furthermore there has been no use of bond funding of PFI transactions, in part due to the exit from the market of monoline insurance providers.

Each of these factors has influenced the Board's preferred way of taking the project forward.

3B.4 Preferred Way Forward

In considering the way forward the Board re-examined the Greenfield option. The conclusion was reached that due to the lack of a suitable site this option was not viable. Accordingly this option was not taken forward.

With respect to Option 1, the new build option, the significant demolition of existing buildings and the development of new facilities on the current site precludes further analysis of the new build option.

Consequently, Option 1A, with 100% single room provision for the Adult Hospital per CEL 27 (2010), remains the preferred option against which the various procurement routes should be retested.

The traditional, PFI and NPD procurement routes all remain potential options for delivery. However, as the use of bond funding is no longer deliverable, this funding option was not taken forward.

On this basis the options for assessment in the economic case within this FBC are:

1. Option 1A – Traditional Procurement;

2. Option 1A – PFI Procurement (Bank funding);

3. Option 1A – NPD Procurement (Bank Funding);

The three options have been appraised using the same methodology as in the OBC, with the risk adjusted net present cost of the CPAM compared to that of the PFI and NPD options.

3B.5 Assessment of Procurement Routes

This section provides details of the main inputs and assumptions used in the economic case. It covers the capital, lifecycle and facilities management costs, plus details on adjustments in respect of tax and risk quantification.

3B.5.1*Capital costs*

The capital costs are summarised in the following table

Table 6 – Capital Costs

	£'000
Base Costs	585,394
Equipment	51,700
VAT	114,856
Total Capital Costs	**751,950**

The capital costs represent the cost to the Board for construction of the new Adult Acute and Children's Hospitals, plus the provision of equipment. The Board's approach to equipment remains unchanged from the OBC position, with equipment being the subject of a separate procurement exercise. Accordingly for the purposes of the economic case equipment costs are excluded from the analysis.

3B.5.2*Movements from OBC*

The table above demonstrates that the total capital cost amounts to £751.950m. At the OBC stage the figure of capital costs was £841.700m. The difference between the amounts is a result of the removal of laboratories costs, as demonstrated below:

	£'000
Total Capital Costs including Optimism Bias at FBC	751,950
Laboratory project Costs	89,750
Capital costs at OBC Stage	**841,700**

The procurement of the new multi-disciplinary laboratory and facilities management building was considered in a separate Full Business Case approved in December 2009. As this project was the subject to a separate appraisal and approval process the costs have been excluded from this economic case in order to avoid double counting.

3B.5.3 *Lifecycle and facilities management costs*

The appraisal includes costs in relation to the provision of lifecycle and facilities management for the new facilities. The following table summarises the lifecycle and hard facilities management costs, discounted to present values, which will be incurred over a 30 year operating period.

Table 7 – Lifecycle and facilities management costs

	£'000
Lifecycle costs	157,684
Facilities management costs	153,878

3B.5.4 *Tax Adjustment*

It is necessary to take account of the relative impact of taxation applicable to each procurement route in carrying out VFM assessments. This has been provided for as required by existing Green Book Guidance at 6%.

3B.5.5 *Short list of procurement routes*

As described above the PFI and NPD procurement routes are based on a senior bank debt funding solution. Funding terms have been estimated by Finance Advisors on the basis of current market conditions. A LIBOR rate of 4.1% has been used, representing the market rate in June 2010 when it is envisaged that financial close would have occurred under these procurement routes. A fully indexed unitary charge has been applied.

3B.5.6 *Discount rates*

In order to demonstrate transparency and to allow comparability the discount rate assumptions remain unchanged from the OBC.

The net present value calculations have been performed to a base date of 1 May 2010.The Treasury discount rate of 3.5% real (6.0875% nominal) has been used for all cash flows except for any charitable surpluses (NPD model only) Charitable surpluses are discounted at 6.0% real (8.65% nominal) reflecting the fact that the surplus cash flows are at risk.

3B.5.7 *Risk Adjustment*

As different procurement methods bring different risks which require to be managed, it is necessary to identify and quantify relative risk impact in carrying out VFM assessments.

Incorporated into the value for money analysis are risk adjustments based on the outcomes of risk workshops carried out by the Board. These take account of the relative impact which a wide range of different risks might be expected to have on every cost element within each of the alternative procurement routes. For the CPAM procurement model, the risk adjustment for the base case scenario equates to 8.3% of the value of the CPAM, of this 5.4% could be transferred under the NPD or PFI procurement models with 2.9% retained under all procurements.

Further details on the Board's approach to risk management are set out within Chapter 4 of this FBC.

3B.6 *Results of appraisal*

The results of the appraisal, in terms of the net present cost on a risk adjusted basis, are set out in the following table:

Table 8 - FBC Position: Risk Adjusted Net Present Values by Option

	Option 1A CPAM £'000	Option 1A PFI £'000	Option 1A NPD £'000
NPV of CPAM / Unitary Charge Payments	695,928	893,946	895,882
Risk adjustment	57,840	20,440	20,477
	753,768	**914,386**	**916,359**
Tax adjustment	41,756	-	-
Charitable distributions	-	-	(15,358)
Risk Adjusted NPV	**795,524**	**914,386**	**901,001**
Ranking	*1*	*3*	*2*

The results demonstrate that the traditional procurement represents better value for money than the PFI and NPD options by £118,862,000 and £105,477,000 respectively. This supports the Board decision to procure the facilities through the traditional procurement route.

3C. BENEFITS APPRAISAL

The Project Team reviewed and re-affirmed the benefits appraisal undertaken at Outline Business Case Stage. In other words the weightings and scores of the options remain as per Outline Business Case with the scores in a very tight band, those options involving an increased percentage in new build producing slightly higher scoring. For details of scoring please see Appendix E.

3D. WORKFORCE

3D.1 Introduction

The new South hospitals project will have a significant impact on the overall workforce of the Acute Services Division. As the anticipated economies of scale are realised from consolidating the acute sites we have the opportunity to review existing practices and redesign the way patient services are currently delivered. With over 26,000 WTE staff within the Acute Services Division of NHS Greater Glasgow and Clyde (NHSGG&C), accounting for three quarters of the Board's workforce, this project will, ultimately, impact either directly or indirectly on all employees.

NHSGGC recognises that in order to deliver new models of care within the new hospital significant workforce development and engagement will be required. Over the last few years, NHSGGC has been responding to workforce modernisation and technological advances, in particular with the new Beatson Oncology Centre, the 2 new Ambulatory Care Hospitals and the new Laboratory on the South Campus and will continue with this approach in the wider Board area. The new hospital buildings will provide further opportunities to develop and modernise the way in which the workforce deliver services in response to the developing models of clinical care.

3D.1.1 *Workforce Engagement*

In developing new roles and redesigning service provision, NHSGGC has put in place arrangements for regular strategic engagement with staff representatives. In addition to regular updates through the Acute Partnership Forum, there are formal and regular engagement with employees and their representatives at Directorate level and at Division level through an overarching Acute Workforce Engagement Group.

This model of engagement provides staff and their representatives with meaningful opportunities to participate in the change programme from inception to implementation.

3D.2 Current Workforce Profile

3D.2.1 *Whole Time Equivalents*

During the summer of 2010, the Acute Services Division of NHS Greater Glasgow & Clyde employed 26003.9 WTE members of staff (see Table 9).

Table 9 - Current Workforce

Administrative Services	4046.4
Allied Health Profession	1754.6
Senior Management	169.1
Healthcare Sciences	1783.4
Medical and Dental	2599.0
Medical and Dental Support	307.5
Nursing and Midwifery	10812.2
Other Therapeutic	657.8
Personal and Social Care	52.9
Support Services	3820.8
Total	26003.9

3D.2.2 *Workforce Demographics*

The workforce within the Division is predominantly female (76.3%) with 34.7% of those between the ages of 41 and 55. A more detailed breakdown of the Division's workforce demographics is contained in Tables 20-22 at the end of this section.

Based on a default retirement age of 65 for both men and women, approximately 1,409 WTE staff will retire over the next five years. See Table 10 below.

Table 10 - Retirement Projections

	WTE
2011/12	298.3
2012/13	179.8
2013/14	311.3
2014/15	293.5
2015/16	326.2
Total	1409.1

3D.3 Workforce Redesign

The process of workforce design is already underway within our Directorates and Partnerships. By evaluating the ways in which our workforce skills and practices can be modified we can ensure we are developing the best practice pathways and at the same time ensuring best practice is applied consistently across the Division and wider Board.

In the Rehabilitation and Assessment Directorate there were two pilot schemes funded by the Scottish Government Health Directorate. The first considered the practicability of establishing more skilled support workers to assist Allied Health Professionals, thereby shifting our skill mix by increasing the number of Band 4 posts in order to free registered Nursing and AHP time to perform tasks more appropriate to their skills and experience. The second pilot explored the development of an advanced practitioner role to assist with assessment of patients within medical receiving, thus freeing the time of medical staff.

Within the Diagnostics Directorate work has commenced to consider the competencies required in laboratories and the educational pathways required providing greater flexibility in accessing careers in laboratory medicine. This work is being undertaken in partnership with our local higher education establishments.

A significant piece of the redesigned workforce will be in the greater use of trained workers on levels three and four of the NHS Careers Framework which should allow a shift in skill mix of 10% from Band 5 to Bands 3/4. These posts will operate in a support worker role across a range of disciplines. To this end, we are working in partnership with a number of further and higher education establishments to develop a curriculum to facilitate recruitment to these new roles. The first students from the new courses are expected to qualify in 2012. The curriculum has been developed in conjunction with the colleges using nationally agreed core competencies to ensure the qualifications are both nationally and officially recognised.

The creation of this new pathway into a career in the NHS will assist the Board in not only enhancing the skills of some of our existing staff but also in promoting opportunities in the local communities of which our hospitals are often the main employer in the area. This is particularly important as it is predicted that over the next five years (see Table 23), within the Board's area the proportion of the population at working age will decrease whilst the number of over 65 will increase. Through our partnership arrangements with local regeneration agencies and local education services we aim to make the NHS an employer of choice for pupils and students of all disciplines which will help deliver the aims of *a Force for Improvement.*

A considerable amount of work has been on-going over the previous three years in shaping the medical workforce for the new hospitals in 2014/15 taking account of Modernising Medical Careers and the announced Scottish Government intention to move towards a trained medical workforce. This work coincided with CEL 28 (2009) which asked Health Boards to review the shape of their medical workforce for 2014 and to use a number of key assumptions which were taken into account in our medical workforce modelling.

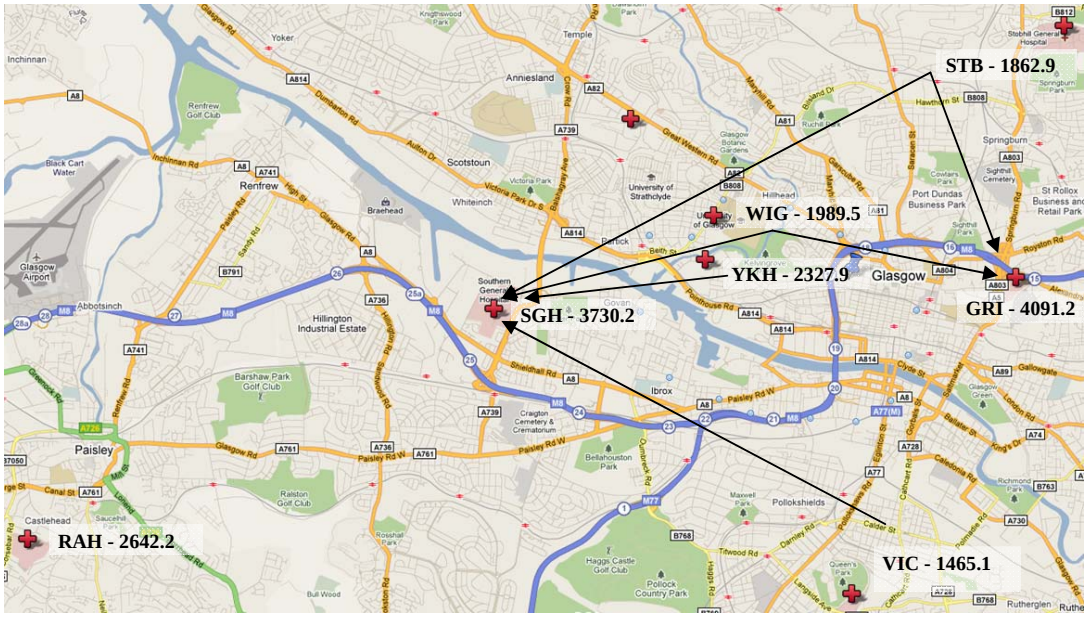
Some significant rota remodelling was undertaken for senior and trainee medical staff creating new rotas which help determine the numbers of new staff required, i.e. Acute Care Physicians in Medicine and in Emergency Medicine to determine the numbers of specialty doctors and consultants needed. These rotas have been designed on a real life basis, with the assumption (also in anaesthesia) that consultant staff will be expected to undertake shift work on a 24/7 basis shared amongst substantial numbers of consultants.

3D.4 Site Consolidation

As part of the consolidation of the acute sites approximately 6250 staff will be affected by moving site. The majority are on four existing hospital sites; Yorkhill Hospital, the Western Infirmary, Stobhill Hospital and the Victoria Infirmary. A proportion of staff on the Western Infirmary and Stobhill Hospital sites will move to the existing Glasgow Royal Infirmary as part of the wider Acute Services Strategy.

The complexity and scope of the relocation of such significant numbers of staff from the four major sites in the north, north-west and south-east of the city to north-east and south-west localities is well understood and it is recognised that good communications will be key to the successful delivery of workforce re-location. Extensive and in-depth consultation at all levels will take place with staff and staff representatives, together with regular meetings and newsletters. Consultation has already commenced with those affected by the relocation of laboratory services within the city to the new laboratory building on the Southern General Hospital site, which is due to open in 2012.

The map below shows the locations of the Glasgow city hospitals affected by the relocation of services to the new South Glasgow Hospital site.



3D.5 Workforce Change

As previously indicated, the development of the new South Hospital provides an opportunity to redesign the way current services are delivered and for a thorough review of potential new roles to support service delivery issues. The Organisational Development and Learning and Education Teams of Human Resources are working with Directorates to provide appropriate levels of change management and leadership development support to underpin the change programme. The detailed work, thus far, on the implications for the workforce due to the new hospitals has been underpinned by working completely in partnership with our trade union and professional association colleagues from the outset. The use of standard workforce planning and workforce tools together with comprehensive staff involvement has been instrumental in ensuring patient care is at the forefront of the proposed workforce change.

3D.5.1 *Allied Health Professions*

The Allied Health Professions (AHP) workforce within adult is split into a number of professions, as shown in Table 11 below.

Table 11 – Allied Health Professions WTE as at Summer 2010

	WTE (all grades excl admin)
Dietetics	89.6
Speech and Language Therapy	66.41
Physiotherapy	394
Occupational Therapy	201.6
Podiatry	22.96
Orthotics	10.48
Prosthetics	21.5
TOTAL	806.55

An AHP redesign group has been working in Acute and across the Board's Community Health Partnerships over recent months and this will result in the transfer of the physiotherapy musculoskeletal outpatient service of 59.69 WTE to a Community Health Partnership, the podiatry service will also transfer to a Community Health Partnership. 87.81 AHP and support workers working in supported discharge and community disability services are also transferring to community management later this year. This will reduce AHP staffing in the Acute Division by 170.46 WTE during 2010 -11 resulting in a total workforce of 636.09 WTE.

The AHP workforce will experience significant changes over the coming years which include the introduction of 7 day working, alteration of skill mix and new service models

AHPs traditionally have provided services within fixed hours on a Monday – Friday basis. Physiotherapy services have additionally provided a respiratory on call service to ensure 24hour cover on a 7 day basis. To assist reducing the time that patients spend in hospital some AHPs will be moving towards working longer days and at weekends.

It is anticipated that this will result in a reduction in the requirement for on-call services with a rationalisation from 5 separate on call services to 2 overnight services commencing at 9pm rather than from 5pm as at present. Initial work has indicated that the majority of calls are prior to 9pm.

Workforce redesign is ongoing to alter the existing skill mix. This redesign will increase the use of support workers at levels 2, 3 and 4. The rationalisation of sites will also offer the opportunity to reduce management overheads. It is anticipated that there will be a reduction of 20 Band 6 WTE which will be replaced with support worker posts with a resultant saving

AHP services are currently managed across sites by profession, where appropriate a move to AHP team leads will be introduced rather than Profession specific Team Leads. This will result in a minimum reduction of three Band 7 WTE with the potential of further reductions over the next five years

Acute medicine is concerned with the immediate and early specialist management of adult patients. It is fundamental that specialist AHP management also occurs at this early stage. strong multi-professional working is pivotal to providing an integrated and coherent standard of service with rapid assessments and discharge planning.

Occupational Therapists and Physiotherapists play a central role in the preliminary assessments required for prevention of admission, early intervention and timely discharge and have a positive effect on efficiency and patient flow. It is proposed to introduce Band 7 AHP clinical decision makers from within existing resources to provide a service to the new Emergency Receiving Centres.

The overall reduction of 404 beds will not reduce the numbers of AHP staff required as inpatients will require speedier interventions by AHPs to ensure rapid discharge from hospital and surgical patients being treated as daycases will continue to require AHP input at pre-assessment and on treatment.

Within radiography, the implementation of a 4 tier structure continues. The Board has positively embraced the 4 tier structure, demonstrated by the recruitment and training of 8 assistant practitioners and 2 consultant sonographers. Overall the Board anticipate no significant changes to the diagnostic imaging workforce.

The overall changes within AHP staffing are shown in Table 12 (below).

Table 12 – Changes within AHP Staffing by 2015/16

AfC Band	Change (WTE)
Band 7	- 3
Band 6	-20
Band 4	+20
Band 3	- 8
Band 2	+ 8
Total	-3

3D.5.2 *Nursing & Midwifery*

The Nursing and Midwifery workforce will see some significant changes to workforce numbers due to the overall reduction in beds and the efficiency gains of working in the new hospitals, whilst retaining the current average nurse to bed ratio of 1.19. This will see a reduction of some 480 WTE nursing posts over the next five years.

The changes in bed numbers will see a reduction of 278 beds during 2011/12 with a further reduction of 126 being phased out over the following four years. The overall reduction of 404 beds includes an increase of 54 beds in General Medicine. The overall savings accruable are shown below at Table 13.

Table 13 – Nursing changes due to bed reductions

	Bed Reduction	WTE Change
By 2011/12	-278	-330.8
By 2015/16	-404	-480.8

At the same time, nursing is undertaking workforce redesign to alter the existing skill mix. This redesign will increase the number of support workers at levels 3 and 4 of the NHS Career Framework to allow the professionally qualified workforce to focus their time to direct patient care. Overall the number of level 3 and level 4 support workers is anticipated to increase by approximately 440 WTE across the Acute Services Division over the next five years. The national workload tools are being used to assist in predicting our future workforce numbers, with the Nursing and Midwifery Workload Tool being used to test the professional judgement used to predict the nursing numbers for the new South Glasgow Hospitals. The review of skill mix is being delivered in partnership with key staff side organisations through a structured Programme Board and Implementation Group.

Whilst the overall affect of the change in skill mix on nurse staffing numbers will be neutral, the associated savings of these changes are set out below at Table 14.

Table 14 - Nursing Workforce Skill mix change by 2015/16

NHS Careers Framework	Current WTE	New WTE
Level 3	876.4	1183.9
Level 4	39.4	171.1
Level 5	4393.0	3953.7
Total:	5308.8	5308.8

In addition to these savings there will be an additional 6.25 WTE of efficiencies from reduced nurse management overheads due to the reduction in beds.

3D.5.3 *Medical Workforce*

The Medical workforce will experience three significant changes over the next five years. First, the number of core trainees is expected to decrease by 44 WTE, secondly the number of specialty trainees is expected to reduce by 82 WTE and lastly the number of consultant doctors is expected to increase by 16 WTE. This will assist NHSGGC in working towards an increasingly consultant-led service.

The following describes some of the specific changes under scope.

Anaesthesia

Anaesthesia is an on-call, on-site specialty, it is expected that rationalisation of the number of sites will produce a dramatic reduction in the number of staff required to be on-call. Virtually all elective work is now performed by consultants, and while a reduction in junior staff may reduce the capacity to flexibly cover annual leave, the capacity released by the reduction in acute sites, particularly consultants committed to day time on-call will assist in covering this. A detailed analysis of existing rotas revealed that only about 60% of a core trainee's and around 66% of ST3+ trainees work is for service. On-call arrangements for consultants will include on-site working till 10 o'clock in the evening in both our major receiving sites, and within intensive care there will be two consultants present until 10 pm and thereafter there will be a consultant presence on the floor on-site overnight.

General Surgery

General Surgery also benefits from substantial reduction in the on-site, on-call commitment by trainee staff. It is not proposed to increase the numbers of consultant staff, as in most sub-specialties the elective workload is such that the critical balance between the number of cases and retained practical skills has been reached already.

Acute Medicine

Within Acute Medicine, in both GRI and the new Southern General there will be a substantial redesign of the receiving arrangements for medicine. The current medical receiving model proposed for the new SGH (with some variation at GRI) is based on receiving driven by specialty teams supported by a general physician and an acute care physician. Bringing our acute units together will give us critical mass in two acute sites to give us the capacity to provide senior staff for these receiving teams. This model will see an increase of 14 acute care physicians (seven on each site).

In addition, on-call work already allocated in job plans will be redirected to the new model. The increase in consultant numbers of 14 posts will all be Acute Care Physicians. There will be two rotas of Acute Care Physicians, one on each site receiving and they will play a significant role in handling seriously ill medical receiving cases and running the medical HDU. This represents a substantial investment and will enable us to reduce the role of trainee medical staff in these areas. There is also an increase in specialty doctor numbers, but this is mainly to allow replacement in certain specialties of the elective component performed by ST trainees.

Emergency Medicine

Emergency Medicine will be re-aligned from four sites to two, and take cognisance of the previous decision to close the casualty at Stobhill Hospital and realign to Glasgow Royal Infirmary. It is also proposed to have a 24/7 presence of consultant staff in both of the remaining A&E departments, these departments will be amongst the busiest units in the UK and this 24/7 consultant model is already present in A&E departments in London where similar numbers of patients are seen.

The overall changes within medical staffing are shown below at Table 15.

Table 15 – Changes within Medical Staffing by 2015/16

Grade	Change (WTE)
Consultant	+16 *
Specialty Registrars	-82
Core Trainees	-44
Specialty Doctors	+38
Totals	-72

* Includes a reduction of 5 Consultant posts within Anaesthetics

3D.5.4 *Senior Management / Admin Support Staff*

As the Board continues to improve productivity and adopt new technologies to support administrative functions, the relocation of a significant volume of the Acute Division's activity on a single site and the associated rationalisation of services, together with the adoption of a paper-lite strategy, will allow deliver further economies of scale within both senior management and admin/clerical support staff.

Further information is set out below at Table 16.

Table 16 – Senior Management and Administration Staff Changes by 2015/16

Staff	Reduction (WTE)
Senior Management	7.0
Admin Support	30.75

3D.5.5 *Facilities – Support Services*

A rationalisation of hotel services is underway and will result in significant changes, particularly within catering which will see a reduction in production units across the Board to two sites. The closure of major parts of the Board's existing estate with the associated relocation of patient activity will further allow rationalisation within the portering and estates/maintenance functions. The move to 100% single rooms within the new hospital will, however, see an increase in domestic staff on the site.

The overall effect on Facilities staffing will see a reduction of some 170 WTE however work is continuing to identify further possible efficiencies.

3D.6 Consolidated Changes

The overall effect on current staffing due to changes to the current bed model, skill mix changes and associated rationalisation of services for each of the staff groups is shown below at tables 17 and 18.

Table 17 – Overall Effect of Skill Mix change on the workforce implemented by 2015/16

NHS Career Framework Level	AHPs (WTE)	Nursing (WTE)
Level 2	8	0
Level 3	-8	307.5
Level 4	20	131.8
Level 5	0	-439.3
Level 6	-20	0

Table 18 –Summary of Changes to Workforce by Job Family

Workforce	Current	By 2015/16	Difference
Administrative Services	4046.6	4016.4	-30.2
Allied Health Profession	1754.6	1751.6	-3.0
Senior Management	169.1	162.1	-7.0

Support Services	3820.8	3648.8	-172.0
Job Family To be Assigned	194.3	194.3	0.0
Total	26003.9	25232.2	-771.8

3D.7 Linkage With Community Care Services

Within NHS Greater Glasgow and Clyde, the Acute Services Division together with CHCPs/CHPs and Mental Health Services are working together to look at different ways in which the balance of care can be shifted with more people receiving care within their own home supported through GP and community nursing input.

There are a number of areas of work focussing on how we can better improve care through Acute Services and community colleagues working more closely. The Collaboratives for Planned Care, Unscheduled Care and for Diagnostics established a programme of joint working where Acute and CHCP/CHP colleagues have been working together to improve the interface between primary and secondary care, streamline the patient journey and deliver the access targets. The Board will continue to build on this approach as progress is made in the programme to deliver the 18 week referral to treatment standard. With the new Long Term Condition Programme both Acute and CHCP/CHPs are working together to consider new ways of delivering patient care and further development of existing schemes, which look to maintain patients at home, through anticipatory care models that seek to avoid admission and readmission as well as to support getting patients home earlier.

The planning process for the opening of the new Stobhill and Victoria Hospitals in 2009 saw a number of clinical specialty planning groups established involving representatives from the Acute Division and from CHCPs/ CHPs. The role of planning groups will be built upon and they will consider new patient pathways between primary and secondary care allowing a shift in care. This redesign work was integral to the implementation of the Acute Services Review both in preparation for the recently opened Ambulatory Care Hospitals at the Victoria and Stobhill sites but also sets the framework for the redesign of inpatient healthcare in Glasgow's acute sector in particular for the New South Glasgow Hospitals.

The shape of the workforce will need to support this transition. Work is already underway to redesign the workforce in Children's Services to develop integrated children's teams bringing health and social care professionals together. Specialist paediatric staff, many of whom are already managed within CHCP/CHPs, will be further augmented from the acute sector as services develop further. The Board are at an advanced stage in looking at the role of Health Visitors in this model.

The Long Term Conditions Programme will require a community based workforce which has the skills to maintain patients at home. This will require existing community nursing staff to acquire more specialist skills or for more specialist staff to be more readily accessible. The Board will continue to develop this based on the range of competencies necessary in line with the NHS Careers Framework.

Table 19 – Gender Breakdown by Age Range (At Summer 2010)

Age Range	F	M	Total	F	M	Total
<21	101.8	38.6	140.4	0.4%	0.1%	0.5%
21 - 25	1,433.5	319.3	1,752.8	5.5%	1.2%	6.7%
26 - 30	2,459.1	618.0	3,077.1	9.5%	2.4%	11.8%

CHAPTER 4

THE COMMERCIAL CASE

CHAPTER 4 – THE COMMERCIAL CASE

4A. AGREED SCOPE & SERVICES

The following section describes:

> the requirements for the new adult and children's hospitals
> concept and vision of the overall design
> the agreed output specifications
> design development
> timetable for the project

Project Requirements

The Project includes the provision of 1,109 adult and 256 children's beds. Key elements of the project include:

a) Development of an integrated adult acute and children's hospital proving the full range of acute health services;

b) Provision of a rooftop helipad; and

c) The supply and installation of Group 1 equipment, location and/or fitting of Group 2 equipment supplied by the Board and provision of structural, space and services requirements to support Group 3 and 4 equipment.

The project requires advanced IT networks. Hardwired and wireless infrastructure are included throughout the hospitals providing the backbone for developing systems. This will support the implementation of a paper-lite environment, the efficient input and re-call of patient records and other telemedicine initiatives and practices.

4A.1 Accommodation Overview

4A.1.1 *New Adult Hospital*

This will provide A&E services and acute specialist in-patient care as well as medical day services and out-patient clinics serving the local population.

Key components of the facility include:

a) In Patient Accommodation - Surgical beds (general surgery, orthopaedics, urology, vascular, ENT and renal); Medical beds; Acute Assessment Unit – 118 beds, ICU/HDU/CCU – 79 beds, Acute Stroke – 26 Beds and Care of the Elderly beds;

b) Out Patient Accommodation - Full range of general outpatient clinics including, among others, diabetic unit, respiratory, orthopaedics and urology;

c) Day Services - 22 medical day bed area; 30 station dialysis unit;

d) Treatment & Diagnostic Services - Emergency Department, 20 operating theatres, imaging, and endoscopy;

e) Clinical Support Services - Pharmacy dispensary, medical physics, medical illustration. Laboratory services linked to the hospital by underground route and pneumatic tube system, aseptic unit within the children's hospital. Capability of the pneumatic system to extend across the abutment with maternity and the link to neurosciences to provide for expansion of the system to these areas has been planned; and;

f) Non Clinical Support Services - Main entrance, medical records, administration, sanctuary, staff changing, switchboard, estates, facilities, security, catering, portering, domestic, management and energy centre.

Main Entrance - Adult Hospital

4.A.1.2 *New Children's Hospital*

This will provide A&E services and a comprehensive range of inpatient and day case specialist medical and surgical paediatric services on a local, regional and national basis. The new development will also have outpatient facilities. The care strategy is that all of Glasgow's Children's Services (up to the age of 16 and up to 18 years where appropriate) will be provided at the New Children's Hospital. Of the 256 beds planned, around 20% of the beds will be for day patients and the balance for in-patient requirements.

Key components of the facility include:

a) Outpatient Accommodation - Full range of Children's outpatient clinics including audiology, general paediatrics, orthopaedics, ENT etc

b) Day Services - Circa 10 medical day beds; 4 dialysis stations and circa 15 day surgery beds

c) Treatment & Diagnostic - Emergency Department, Imaging, 9 theatres, rehabilitation

d) Clinical Support Services - Aseptic unit, pharmacy, medical physics, medical illustration (laboratory services linked to hospital by underground route and pneumatic tube system and

e) Non Clinical Support Services - Facilities, ancillary services, administration, spiritual services, medical records, staff change, main entrance,

Main Entrance - Children's Hospital

4.A.1.3 *Other Relevant Accommodation*

- **Facilities Management Building and Energy Centre**

This is located to the north-west of the site and provides accommodation for all the power and heat generation requirements for the new hospitals and capacity to also support the retained estate. The facilities management accommodation is integrated into the laboratories facility, with access provided to the new hospitals by an underground tunnel link. The Energy Centre is a stand alone structure adjacent to the laboratories build and constructed as an aspect of the new hospitals programme.

- **Retained Estate**

The Southern General Hospital site will retain approximately 600 beds within the Institute of Neurological Sciences, Maternity and Neo-natal, Spinal Injuries and Langlands buildings. The Langlands facility provides older people's services and services for the young physically disabled. This retained accommodation does not form part of the scope of the Project, although energy generation to support the retained estate is included in the scope of the Project.

- **Laboratory Facilities**

The new laboratory facilities were a feature of the overall procurement process, although approvals in relation to that aspect of the facilities were considered under a separate FBC (approved in December 2009). The laboratory facility is currently on site (forming Stage 1 of the implementation phase) and therefore not a feature of the development considered by this FBC.

For information, it can be noted that the new laboratory facilities will be one of two major Laboratory sites in Glasgow. The services planned to be delivered from the new laboratories at the New South Glasgow Hospitals include Biochemistry, Microbiology, Haematology, Medical Genetics, Mortuary and Post Mortem. The mortuary and post mortem facilities include the re-provision of the Glasgow City mortuary which also provides forensic services for the City of Glasgow.

- **Car Parking**

Car Parking is a key feature of the overall development and sustainability of the Southern General campus. Additional car parking is being procured separately by the Board (Carparks 1A and 1B to the east of the site, Carpark 2 to the west of the site and Carpark 3 to the south of the site) and therefore do not form part of the FBC.

4A.2 Agreed Output Specifications

The accommodation requirements noted above are included in the Employers Requirements (ERs) documentation. The ERs are the output based specification documentation agreed between the Board and the contractor that identify the specific requirements and standards to be achieved in the construction of the new facilities.

The ERs include specific outputs to be met for all aspects of the construction and design, including reference to and application of NHS (e.g. Scottish Health Technical Memorandum) and other standards, commissioning and handover requirements, sustainability targets, treatment of arts, community engagement and benefits, plus other technical requirements, together forming a comprehensive set of requirements to be met by the contractor.

The ERs comprise the under noted sections (plus associated appendices):

Employer's Requirement Contents
Section 1 – Development Context
Section 2 – Responsibilities of the Parties
Section 3 – The Site
Section 4 – General Design Requirements
Section 5 – General Construction Requirements
Section 6 – Construction Phase Requirements
Section 7 – Architectural Requirements
Section 8 – Building Services Requirements
Section 9 – Civil and Structural Engineering Requirements
Section 10 – Sustainability
Section 11 – Community Engagement

As is noted below and further described and discussed at Section 6A, the ERs were developed following extensive consultation with User Groups in order to develop and agree the required clinical output specifications.

The clinical output specifications, as well as forming an essential element of the ERs in themselves, therefore informed development of the wider brief, the establishment of a Board exemplar design and schedule of accommodation and associated ADB room data sheets and room layouts. This overall package of output requirements and statements forms the 'backbone' of the project brief and therefore the output requirements, establishing particular 'must have' aspects of the Project including, for example, a physical link to the existing Institute of Neurosciences building and an abutment to the existing maternity facility to the west.

4A.3 Design Development

The requirement to develop the design post-contract and pre-FBC (Stage 2 of the contract) is an integral element of the procurement strategy and a managed process involving the Board and the contractor that is tracked and reported to the Project Management Group. A collaborative approach involves interaction with Users in specific workstreams/areas of design development, including, for example the review and sign-off of the departmental plans.

Additionally, the established technical workgroups have been reviewing the wider design development, with inputs from the Project Team (including, for example, the infection control representative), Board technical advisers and other specialists where necessary. This activity is in order to ensure that the level of detail provided is commensurate with the stage of the process and the that requirements of the Board are being demonstrated and developed as well as allowing cost checks and procurement plans to be progressed by the contractor. As with any design process, the evolving design is 'moving' as it is influenced by internal and external factors and requirements – including, for example, planning and roads department inputs, fire strategy consultations and the like.

The requirement for information submissions during the pre-FBC (Stage 2) design development, and tracking of due dates and status is controlled and captured through the "Appendix K" tracker. The tracker is a 'live' document that is discussed between all parties, controlled and updated by the contractor in order that progress in design development can be monitored.

The design process will continue to develop into the next stage (Stage 3) of the process (post-FBC), with both further development of design and construction activity taking place. At FBC the extensive interaction with the User groups and technical review and activity has resulted in 1:500 and 1:200 floor plans for all levels and all departments signed off by the Board, with the 1:50 review process well developed such that each individual room type has been reviewed and agreed as representative of the Boards requirements in terms of size, equipment content and generic layout. Additionally, an extensive programme of workshops and reviews of technical data is in place and being progressed – this considering and addressing, for example, mechanical and electrical systems, access controls, acoustics, fire strategy,

finishes, equipment, wayfinding, arts and other technical and related project data.

This level of sign-off has been facilitated by the engagement with over 70 separate User groups, each consulted on rounds of 1:200 and 1:50 reviews to provide the current position. The process was managed by the Board Project Team who co-ordinated and supported the User input and interface with the designers and contractor. A sample tracker for the 1:200 'Design User Group Meetings' (DUGM), is attached at Appendix F for information.

4A.3.1 *Other Relevant Aspects of Scope, Content and Context*

The following identify additional relevant and important aspects of scope, content and context of the Project:

- **Sustainability**

The Board have consulted and worked in association with both the Carbon Trust and Sustainability Glasgow in scoping the project, during the bidding stage and evaluation of bid returns as well as into the design development phase. The requirement is to target an "Excellent" rating under the BREEAM Healthcare Assessment in order to achieve a high quality user environment and amenity for patients, visitor's and staff as well as reduced carbon outputs and reduced energy costs.

The design development includes input and support from the Carbon Trust in order that the sustainability agenda is maintained through the process and all partners are challenged to continue to actively contribute and support the aims of the project in this regard. The under noted low to zero carbon technologies are included in the project scope:

a) 3 no. 1MW Combined Heat and Power Plant: will reduce carbon and energy costs by using a modular approach to track loads and target operating efficiencies

b) Thermal Wheel Ventilation Equipment: to ensure high performance of heat recovery in the ventilation systems

c) The installation of 12 no. Vertical Axis wind Turbines prominently on the energy centre roof

d) An "Absorption Chiller" unit to facilitate waste heat from the CHP to be used to provide cooling during the high summer demand periods

e) High efficiency (normal) chiller units with magnetic bearings within the compressors;

f) High efficiency motors in equipment to reduce consumption

g) High standards of air tightness and insulation materials to reduce the building demand for energy

h) Modern efficient metering, monitoring and control systems to allow the performance of equipment and building facilities to be monitored and controlled

i) Electric Vehicle Charging points provided in the Facilities yard

j) Low energy lighting systems to reduce consumption; and

k) Variable Volume Circulation systems incorporated in heating and cooling pumps which allow the pumps to slow down during low demand periods reducing consumption

4A.3.2 *FM Requirements*

The new hospitals will include a range of leading edge equipment and operational systems in order that clinical services are supported by high quality, efficient and technologically advanced facilities management services. In this regard the following are included:

- **Automated Guided Vehicles (AGVs)** – these will be utilised to provide on-time transportation of catering, linen/laundry, sterile supplies and general supplies around the facilities by the use of technologically advanced, fully programmable laser-guided vehicles. Goods will be transported from the dedicated FM Centre through the underground link to the hospitals and on to departments and wards via dedicated FM lifts. Efficiency gains in portering models will be achieved through the extensive use of AGVs, with a consequential reduction in injuries to staff associated with movement of materials. Additionally, the system will allow the exchange of waste bins on a 'full for empty' basis and therefore eliminate double handling of waste by FM personnel.

- **Pneumatic Tube System (PTS)** – the placing of ninety-two strategic 'send and receive' stations throughout the facilities will provide extensive coverage to all wards and departments allowing high speed and efficient movement of supplies (including specimens and medication) around the buildings via a fully sealed and secure distribution network. This will ensure a direct link between Emergency Department and Pathology facilitating a 'high priority' service to support the ED function on a 24/7 basis.

- **Automated Pharmacy** – Outpatient dispensing will be provided from an automated dispenser in the new hospitals supporting the efficient distribution of medication.

- **Dedicated FM Service Centre** – a dedicated and strategically placed FM Service Centre will function as the operational hub for the FM services and logistics: serving both the new facilities and the existing estate. Critically, separate vehicle access is incorporated in order to minimise impact on

hospital operations, with all deliveries being received at the FM Centre for checking, storage and distribution via the tunnel network to the hospitals.

- **Bedhead Services** – all bedheads will include highest level of patient services including data points, appropriate voice and data comms in accordance with current SGHD guidance.

- **Information Technology (IT)** - technologically advanced IT networks providing hardwired and wireless infrastructure are included throughout the hospitals providing the backbone for developing systems. This will support the implementation of a paper-lite environment, the efficient input and re-call of patient records and other telemedicine initiatives and practices.

- **Building Management System** – a comprehensive and extensive building management system is incorporated that allows control and reporting of all major building functions and systems. This will allow an extensive volume of building performance and fault situations to be monitored and managed, including adjustment of controls and systems where necessary.

- **In-Built Resilience** – a key design feature is the introduction of specific resilient systems to minimise the occurrence or impact of failures on service delivery. This includes compartmentalised plant rooms, bunded plant areas with drainage, contingent access routes to theatres and other key areas, dedicated AHUs per theatre and specific access detailing for maintenance to avoid disruption. Additionally, routes for the removal of expired and delivery of new specialist equipment (e.g. MRI) have been established. This includes specific loading to floors and access along corridors to minimise interruption and provide safe routes for transportation. Power supplies are provided on a [100%] back-up basis, with heating able to be run stand alone for 200 hours should supplies be affected, with resilience in water supply created by supply split between two mains (one to the west and one to the north of the site) in addition to on site storage.

- **Energy Efficiencies** – as noted previously, a range of low to zero carbon technologies are incorporated in the design – including high efficiency CHP plant, thermal wheels, efficient metering and monitoring systems, low energy lighting and the provision of electric vehicle charging points.

- **Security Systems** – extensive coverage and controls to ensure a safe environment for patients, staff and visitors are incorporated. A mixture of active and passive systems will be provided, including extensive CCTV coverage to internal and external areas, dedicated controls to departments and staff areas and specific ‘hospital at night’ provisions.

- **Specialist systems** – a range of specialist systems and accommodation are included in order to support the clinical services and capability in the hospitals, including RO water and a dedicated decontamination suite.

- **Rooftop Helipad** – the hospital is served by a roof-top helipad, located on the south-west limb of the tower and providing a key direct vertical link to the Emergency Department (Resuscitation) or Theatres. This significant support element will allow both Scottish Ambulance Service and Air/Sea aircraft to service the hospitals on a local and national basis.

- **Medicinema and Retail** – the facilities are supported by integral education and entertainment facilities, including spiritual centres and a cinema located in the children's hospital as well as retail outlets adjacent to the main entrances.

4A.3.3 *Improving Health & Health Inequalities*

In order to continue the promotion of health improvement as well as reducing health inequalities appropriate aspects have been incorporated into the ERs and service planning activity (flowing from consultations and activity arising from the *Design Action Plan* as well as the *Health Promoting ASR Action Plan*) as follows:

- Development of a Patient Information Centre (PiC) within the central Atrium of both the Adult's and Children's hospitals. The PiC's are based on the successful developments in the New Ambulatory Care Hospitals within Glasgow and will provide the following:

  > A 'shop front' for the voluntary sector, encouraging patients to utilise the range of specialist support and counselling services in cases of disease diagnosis and bereavement

  > a programme of onsite health promotion services for both staff and patients to address health behaviours in relation to smoking, physical activity, alcohol and weight management; and

  > a personalised information service, providing advocacy and patient information tailored to the needs of individuals and families and extending the 'information prescription' service currently being piloted with clinicians and library services

  > The integration of the existing family support centre at Yorkhill with the PiC programme to maximise support for the current service and secure continuation of good practice into the new children's hospital

  > Within the defined retail space, retailers will be required to comply with Board policies to ensure support for health living through initiatives such as a Healthy Living Award, Fruit and Vegetable retail, healthy vending options etc. A current pilot with community enterprise initiatives at the GRI hospital site will inform the potential to support a similar initiative; and

- the inclusion of an external environment that provides significant areas of accessible green space which can be used by patients, visitors and staff including well lit and clearly marked walk ways across the campus, bike parking facilities, therapeutic gardens and play areas and a range of seating and defined outdoor relaxation spaces.

Additionally, accessibility has been promoted across the campus with a number of engagement and consultation exercises having informed current proposals including: work to identify options for the designation of disabled parking spaces; consideration of patient journeys across the campus and within buildings has informed both the location of services and wayfinding strategies; drop-off points are closely located to key departments/buildings and on-site transport options to help less able patients move across the campus are being considered

In order to monitor and ensure incorporation of relevant and appropriate physical measures a number of Equality Impact Assessments have been identified and will be undertaken at different stages of the development.

Further, as an aspect of the procurement process, social economy policies have been developed to promote local regeneration and afford community benefit through employment and procurement. These are further described in Section 6A (Procurement Strategy).

4A.3.4 *Integration of Healing Arts Strategy*

The Board recognises that good design in healthcare buildings makes a measurable difference to the experience of patients, visitors and staff. A wide cross section of individuals and groups have and are engaged in influencing the design development with regard to environment and ambience, with a specific Workgroup established by the Board to actively agree and manage the Arts Strategy and advise the design process on opportunities for art.

The ER plan for the development and delivery of an arts strategy is illustrated below, with the Stage 2 (Design Development) phase presently seeing the development of the strategy between the Board and contractor for implementation in the Stage 3 construction phase.

STAGE	TASKS	RESOURCES
Stage 0: Competitive Dialogue	Develop Art Strategy as part of bid proposals. The strategy developed by your team will form part of the evaluation process.	Identify bidder resources that will be provided during Stage 2 design and anticipated costs over the time period for stage, along with assumptions on frequency of meetings etc. The proposals should therefore ring fence money and time for Stage 2.
Stage 2: Design Development	The successful bid team will develop their strategy along with Board managers and other associated groups as noted earlier. As a key member of the Board's Arts Development Group you will meet monthly to develop plans and incorporate a full arts strategy into the detailed designs for the new builds. Prepare detailed costs and budgets for these works for Board consideration. Working to the Arts Development Group will be the artists and designers who will meet weekly through design development forum to discuss concepts, plans, detailed and help prepare detailed costs.	The successful bid team will be required to take forward the strategy subject to Board involvement and work with teams to develop a workable proposal that is both achievable, realistic and affordable in the run up to FBC and approval to proceed with construction of the adult and children's hospitals. Note: costs for the arts strategy may be included within the contractor's price, or funded by external Board source, or from a combination of these.
Stage 3: Construction of Adult and Children's Hospitals	Incorporate the agreed art strategy design into the new builds.	Manage the construction and full integration of the approved strategy on site by the successful bid team. Attend periodic meetings (quarterly) to review progress.
Stage 4: Commissioning	Fully commission any loose art works requiring service connections.	This would occur during post handover Board equipping stage, detail and input from bidders would be developed during Stage 2.

The Stage 2 (design and development phase) updated Arts Strategy includes input from desk based research and a number of Design Workshops, Clinician led 'Walk and Talks', review of other new build hospitals, consultation with Spiritual Care and Better Access to Health groups, a review of existing archive and engagement with the Glasgow arts and cultural sector.

This initial consultation process identified a universal ambition to ensure the Arts Strategy added value to the patient journey and was integrated into the hospitals in a way which energises the hospital environment and makes the most difference to patients, families, carers and staff. In addition the Arts strategy draws on the existing evidence base for therapeutic design focusing on; reducing recovery time, de-institutionalisation and orientation and way finding.

The analysis driving the strategy includes;

- New South Glasgow Hospitals landscape is well developed and provides key opportunities
- The Atrium in both Hospitals expresses ambitions and provides opportunities to link to wider way-finding language
- There are Sanctuaries, but there are many other spaces used for bereavement, families, relatives, etc that could be enhanced
- The Beacon provides an opportunity to link to the catchment area directly
- The Podium is a large area and will benefit from landmarking
- Bringing the detail of the landscape into the building will add points of interest
- The strength of patient and staff impact on the environment at Yorkhill emphasises the need for participatory strategies
- With a modest art budget the strategy is to focus on places where significant impact can be made, building on existing design infrastructure

The strategy therefore incorporates 4 central themes:

- To create a sense of place
- To meet stress with dignity
- To support treatment through distraction
- To promote participation and personalisation

The strategy comprises a comprehensive programme of art and design with 3 stages:

- Integrated projects delivered during construction
- Stand alone artworks delivered during the commissioning phase
- A post construction arts programme

Further detail of the 3 stages is given in Chapter 6.

4A.4 Timelines for Delivery for the Project

The project timelines from publication of the OJEU notice in early 2009 to operational handover in 2015 are detailed below. Further specific detail around the contract work stages and timelines are included in Section 6, as are details with regard to Post Project Evaluation (PPE) Proposals and Commissioning Plans.

Table 23 – Overall Project Timetable

Event	Milestone
Publication of OJEU (incl MoI and PQQ)	06 February 2009
Issue of Invitation to Participate in Competitive Dialogue (ITPD) to bidders	May 2009
Stage 1 Final Tender Return	11 September 2009
Evaluation of Bids and Contract Award	18 December 2009
FBC For New Children's and Adult Hospital and approval by Health Board	November 2010
Stage 3 (Construction of Adult and Children's Hospitals) programmed to commence	November 2010
Completion (Construction) – Adult Hospital and Children's Hospitals	January 2015
Operational Date – Adult and Children's Hospitals	Summer 2015
Stage 3a completion, demolition of surgical block and completion of landscaping	Summer 2016
Post Project Evaluation	Summer 2017

4B. AGREED RISK ALLOCATION

Risk Management has been, and remains, a primary focus in the management of the Project.

From the outset of the procurement process the Board have completed a Risk Register and this has been continually maintained throughout the life of the Project to date, and will continue to be managed until completion of the project.

As part of the contract agreement with BCL the Board and the Contractor each have an agreed risk allocation. As noted in Chapter 6A (Procurement Strategy) risk transfer was a key discussions topic during Competitive Dialogue (as an agenda item in the Commercial Group as well as inherent in the Design and, specifically the Logistics, workstreams).

The following describes the risk management undertaken pre procurement, the risk allocation in the contract and risk management in the stages 1 and 2.

4B.1 Managing Risk Pre-Procurement

Active identification and management of risks in the procurement planning stage led to adopting risk strategies to mitigate potential adverse impacts on the project. These included developing and implementing a market engagement/sounding exercise to determine the capability of the players in the market to deliver the project. This activity was carried out in order to improve the chances of strong market engagement, avoid delays and 'challenges' to process where possible and to ensure appropriate review and approvals of project planning were adhered to and incorporated into the process. Activities in this regarded included:

- consultation with potential private sector partners (contractors) to establish appetite to bid for the project
- workshops to option test procurement routes with adviser/consultancy firms
- detailed workshops with three main contractors to further test approach to procurement
- validation of chosen procurement route/approach through tiered approvals and subject to external scrutiny and comment (audit and Gateway)
- establishment of key workgroups and design-development sessions to support the drafting of the Employer's Requirements
- clear direction, leadership and management of the timetable and requirements to take the project to market, combined with a close collaborative working between the core NHS team and the advisers in the project team
- determination of robust output requirements (captured in the ERs) as a result of User stakeholder consultation as well as engagement with Facilities Management and other specialist (technical) groups and individuals
- visits to other UK hospital sites to review relevant technical and clinical aspects of operational hospitals to inform the ER requirement
- continued engagement and communication with the public locally (neighbours) as well as updates to the wider population and staff with regard to progress and details of the proposals
- continued engagement and communication with the Scottish Government Health Directorates with regard to process, progress and programme
- strict adherence to internal governance and reporting lines within NHS GG&C
- continued engagement with external partners and stakeholders (including, for example, Glasgow City Council, A+DS, and local businesses)
- review and refinement process to ensure coverage and completeness of documentation prior to tender issue
- clear bid programme and engagement plan for competitive dialogue as well as expectation (requirement) for bid returns
- setting of distinct competitive dialogue workstreams, populated by appropriate Board and adviser personnel to engage with the bidders

4B.2 Risk Allocation in the Contract Agreement

As part of the NEC3 contract conditions a risk allocation matrix was agreed. The mechanism to agree maximum and target price relies on the agreed risk sharing between the Board and the Contractor and this was agreed during the Competitive Dialogue Process.

The under noted matrix identifies some of the key risk allocation between the Board and the Contractor:-

Risk	Board	Contractor
Secure Detailed Planning Consent – design information and submission by required programme dates		X
Planning Authority do not comply with Statutory timescales for review and approval of Planning Submissions	X	
Building scale, layout and form to meet NHS Schedule of accommodation and Clinical Adjacencies		X
Design Development / Co-ordination / Programme		X
Detailed Design		X
Ground conditions below existing buildings vary significantly from that interpreted from Site Investigations	X	
Ground conditions across site vary significantly from that interpreted from Site Investigations	X	
Ground conditions across site generally in accordance with Site Investigation information		X
Schedule of Accommodation – Rooms & Net Area requirements	X	
Group 1 & 2 Equipment arising from User Group 1:50 room layout development identifies additional equipment out with standard ADB Data Sheets	X	
Inflation – below 2.5% p.a.		X
Inflation – above 2.5% p.a.	X	
Failure to achieve Key Approval Dates – FBC Approval	X	
Unknown existing services discovered within site boundary	X	
Drawing approval process – Reviewable Design Data – not	X	

undertaken to agreed timescales		
Scottish Ambulance Service land acquisition not achieved to programme	X	
Construction Programme		X
Sub-contractor procurement		X
Construction design information		X
Construction interfaces		X

Since appointment of the Contractor the risk management process of ongoing reviews / mitigation meetings is undertaken at regular intervals through the commercial group meetings (please see Section 6B for Governance Arrangements).

In addition to formal reviews of the Contract Risk Register, as part of the Contract Management processes, a weekly Early Warning Notice[2] review meeting is held. This meeting is the Risk Reduction Meeting to review progress and close out of any Early Warning notices issued by either the Board or the Contractor in accordance with the Contract, recognising that in a project of this scale the arrangement of individual meetings for each Early Warning Notice would be inefficient.

The current Risk Registers are included in Appendix G.

4B.3 Risk Management – Project Measures in Stage 1 & 2

As is noted in the earlier sections of this chapter, risk management is inherent in the structure of the project governance as well as in the NEC form of contract that is being utilised.

This manifests itself in a governance structure which has direct and frequent reporting lines both within the core project structure as well as to the groups established by the Board to monitor and oversee the programme (e.g. the Acute Services Strategy Board Executive Sub-Group).

The contract utilises the raising of Early Warnings by either party and these are reviewed weekly by a combined Board/contractor team in order that potential impacts are understood and acted upon.

[2] Early Warning Notice is a defined term in NEC3 contract conditions and is the first identification of potential risk or change to the project.

This active risk management of the project supports partnership working as well as providing clarity with regard to status and impacts of potential risks to the project. The project risk registers, which are owned by the Project Director, are updated and reviewed jointly by the Board and contractor at frequent intervals in order that the impact of events and passage of time on the project is reflected in the detailed registers of individual classifications of risk.

Continuing to think ahead regarding adverse impacts on the project, the project team have endeavoured to reduce future project risks (post FBC) by planning associate works in advance such as:

- **Demolitions/site clearance** – this enablement work is being procured in readiness for providing a clear site to the contractor as well as to allow key diversion works to be carried out and maintain programme. The lead time for demolitions included the decanting of staff and equipment to allow services isolations to take place and provide access for intrusive surveys (in the buildings as well as in associated service ducts) and the carrying out of further site investigations to support the ongoing design development of the hospitals. These key tasks could not take place while the buildings (non-clinical support accommodation) were occupied and in use. The accommodation in question includes the main hospital kitchen which has been relocated to another area of the campus in a modular arrangement until the new hospital is operational. The (temporary) kitchen relocation, which is an aspect of a Board-wide catering review and service implementation, has been discussed and co-ordinated with the relevant managers of the existing hospital campus in order that the service is kept live and operational and the moves dovetail with the timelines and requirements of the project in a collaborative and safe manner.

- **Detailed site investigations** (SI) – as is noted above, detailed SI works have been carried out in the areas decanted for demolitions. This has allowed access to gain information to support and verify the initial SI exercise and inform the design development process as well as the treatment of ground conditions risk under the contract.

- **Culvert diversion consents** – the relevant agreements and pre-planning matters are being arranged for the necessary diversion of the culvert to the south of the site. The demolition of non-retained estate in that locale will support the construction of a temporary roadway to ensure that the culvert works can be carried out whilst maintaining blue-light access through the hospital campus and day to day vehicular traffic (public transport, private transport and hospital traffic) movement around the site.

- **Off-site parking agreement** – the contractor has an agreement in place to utilise an adjacent commercially owned site for the purposes of car parking into the Stage 3 construction phase. This pre-planning will allow the construction site to grow in a managed and capacity led manner and supports the overall logistics management of the site and access for the workforce.

- **Helipad relocation** – as the Stage 3 works necessitate the handover to the contractor of the area where the helipad is presently located, the Board have been in consultation with several partners and associated organisations with regard to the relocation of the helipad. The Board has successfully reached agreement with its partner organisations and an off-site (near site) relocation of the helipad has been agreed.

- **Relocation of Scottish Ambulance Service Facilities** – the existing SAS facility is located in an area to the west edge of the site that is part of the project masterplan. The Board have been working with SAS to reach agreement for the relocation of their facilities and ownership of the (SAS) land reverting to the NHS. Agreement is in place and alternative accommodation is being provided for the SAS services to allow on-time handover of the land to avoid impact on the construction process and programme of the contractor.

- **Agreement to Purchase Scottish Water Land** – in order to facilitate construction of the new hospitals and create the associated infrastructure the logistics dialogue identified the requirement for the Board to acquire a portion of land from its Scottish Water neighbour. The necessary negotiations have been carried out and agreement reached with Scottish Water in respect of the land. The legal work was progressed (with the agreement execution dependant upon FBC approval) in order to avoid delay and provide clarity of this essential requirement and timeline to the Board and contractor.

- **Staged Building Warrant Application** – the contractor has proposed and agreed with Glasgow City Council that the Building Warrant will be submitted in stages including sub-structure, super-structure and fit out. This allows forward planning and activity in specific segments of design and detail to be captured and submitted into the necessary regulatory process promptly which will allow warrants to be secured in cognisance of the stage of design and construction and mitigate work at risk by the contractor. An addition benefit is the associated clarity around cashflow of application related fees.

- **Early Stage Application (Fire Strategy)** – the relevant fire strategy information was submitted (by agreement) at an early stage in the overall process in order to engage GCC Building Control and other essential parties in key discussions and communications. This was carried out in order to de-risk this specialised aspect of design development and progress by engaging with the relevant parties.

- **Sub-Structure Warrant Application** – the building warrant application for the Energy Centre and Hospitals sub-structure is to be submitted immediately post-approval of FBC to mitigate design risk and support on-programme commencement of works on site. Stage 2 design related activity has therefore been carried out to develop this aspect of design and related warrant information and paperwork to the requisite level of detail. This management of information, requirement and detail is a pre-planned activity to seek to maintain programme whilst gaining the necessary approvals through liaison and joint-working with GCC.

4B.4 Risk Management – Strategic Risks

The approach to and treatment of strategic risks is identified and discussed at Section 2i of the FBC, above.

4C. AGREED CHARGING MECHANISMS

The Contract Payment Mechanism is generally in accordance with the NEC3 Conditions of Contract Option C Target Price.

In recognition that the Contractor has formally committed to contract for the Design & Build of the Hospitals at a relatively early stage in the design life cycle, the Contract has been varied to introduce the principal of shared risk within a Target and Maximum Price threshold.

Essentially, if outturn costs are less than the Target the Board and Contractor share in any savings at pre agreed ratios. Where outturn costs are above Target then there is a share of the overrun costs at pre agreed ratios and should outturn costs exceed the Maximum Price then any liability for the Board to make further payments stop, and the Contractor absorbs 100% of the overrun.

4C.1 Target & Maximum Price

Based on the Employers Requirements (Works Information) and the agreed risk allocation, the Contractor has provided a Target and Maximum Price for the Design and Build of the New Hospitals and associated landscaping works.

The Contract Price is structured into three discrete areas that require approval Gateways prior to any expenditure within each Stage being incurred:

- Design Stage – commenced Jan 2010
- Hospitals Construction – approval to commence to be given following FBC Approval
- Demolition and Landscaping Completion – approval to commence to be given on handover of Hospitals

Any changes to the agreed Target and Maximum Price arising from changes to the Works Information or the Board Accepted Risks will be administered in accordance with the Conditions of Contract.

The pricing / payment mechanisms are on basis of risk and reward structure. By accepting risk transfer, the contractor is participating in a pain / gain share contract structure. He is incentivised to manage costs within his Target through good supply chain procurement, value engineering, and general efficiencies etc and share in any savings below the Target with the NHS. A further incentive to control costs is that should costs exceed the Target he will only recover a percentage of his costs through a pain share mechanism with the NHS. This sharing mechanism applies only up to the agreed Maximum

Price. The Maximum Price is the maximum liability of the Board and all costs incurred above the Maximum Price are borne by the Contractor.

Detail regarding the agreed pain / gain share split has been removed due to commercial sensitivity.

4C.2 Payments

Payment Assessments are based on standard Conditions of Contract Cashflow derived from an Activity Schedule, with a Contract Amendment confirming Board liability only to pay each month the lesser of actual cost incurred or the Cash flow forecast.

Retention is held on Design Stage Payments at 10% of amount due, and progressively released as one of five under noted Design Milestones are achieved:-

- Achieve 85% User Group sign off to 1:200 Drawings for Adult Hospital
- Achieve 85% User Group sign off to 1:200 Drawings for Children's Hospital
- Achieve 95% sign off to Standard Room Type ADB sheets and 1:50 Drawings
- Conclusion of Planning Submission - Final Reserved Matters Approvals
- Achieve Formal Planning Consent from Glasgow City Council

Due to the value of the project, a standard retention approach was not favoured by any of the bidding contractors. In order to address concerns and avoid any premium being added to bids the under noted approach has been included in the contract:-

- No retention held during construction years 1 to 3
- Retention fund built up during Year 4 payments to arrive at fund on handover equivalent to 2½ % of overall Hospitals Construction Value
- Retention held for 24 months and released on completion of defects period

Standard 5% retention is held on final stage of works - Demolition and Landscaping Completion – with half retention released on handover, 24 months defects period and final retention release on completion of defects period.

4C.3 Damages for Late Completion

Delay Damages are included as follows:-

Hospitals Construction: £250,000 - provided that In the first 4 weeks after the *completion date* delay damages will be levied at 25% of £250,000 per week; in weeks 5 - 8 inclusive after the *completion date* delay damages will be

levied at 50% of £250,000 per week; in weeks 9 - 12 inclusive after the *completion date* delay damages will be levied at 75% of £250,000 per week; and from week 13 after the *completion date* delay damages will be levied at 100% of £250,000 per week

Demolition and Landscaping Completion: £20,000 per week

4D. AGREED KEY CONTRACT ARRANGEMENTS

The Contract Conditions are generally in accordance with NEC3 Conditions of Contract Option C Target Price.

Amendments were made to accommodate bidders' requirements (only insofar as did not amend NHS protection under contract) and the discussions agreed during Competitive Dialogue.

4D.1 Key Amendments to Standard Form

The under noted is a summary of key amendments to the Contract and X Clauses included:-

- Appendix to Contract introduction Overriding Principle of Partnership / Collaborative working
- Amendment to incorporate Target & Maximum Price mechanism
- Amendment to Stage works and have approvals before commencement of each Stage, ability to terminate contract at end of each stage without penalty, and transfer of ownership of design to NHS on termination
- 24 months defect period, and timescales for priority based defect correction
- Incorporation of Board Retained Risk Register, and confirmation all other risks to deliver Works Information are transferred to Contractor
- Damages for Late Completions as noted in Section 4C above
- Performance Bond for 5% on works value
- Collateral Warranty requirements from Designers and Sub-contractors
- Programme based deliverables for Design Stage retention payments
- Payment Assessment periods amended to 4 week overall - 2 weeks for review of actual costs incurred in month, and 2 weeks for NHS to process payments

4E. AGREED IMPLEMENTATION TIMESCALES

The overall timetable from publication of OJEU is noted in Table 24. The more specific implementation timescales, in relation to the staged activity schedules recognised under the contract, are as under noted. The Stage 1 activity (Design & Construction of the New Laboratory Building) FBC was approved in Q4 2009 and as such that activity is not a feature of this FBC, the inclusion in the table below is for information and context purposes only with regard to identification of overall timescales and concurrent activity.

Stage	Activity	Start	Finish
Stage 1	Design & Construction of the New Laboratory Building	Q1 2010	Q1 2012
Stage 2	Design Development of New Hospitals	Q4 2009	Q4 2010
Stage 3	Finalise Design + Construct New Hospitals	Q4 2010	Q1 2015
Stage 3A	Demolition of Surgical Block and completion of Landscaping	Q3 2015	Q3 2016

4E.1 The Construction Stage Programme

The contract (NEC3 Option C, Target and Maximum price with Activity Schedule) provides for the inclusion of a detailed construction stage programme which identifies the key dates for deliverables. In this instance, the overall project is to be delivered in four stages:

- ***Stage 1: New Laboratories and Mortuary***

Previously approved under a separate Business Case in December 2009, the construction of the facility, which includes not only the mortuary facilities but also the Facilities Management Centre for the new hospitals, began in March 2010 and is currently on programme to be completed and handed over to the Board in March 2012.

- ***Stage 2: Detailed Design of the Adult Acute and Children's Hospital***

Commenced in January 2010, following execution of the contract in December 2009, the detailed designs for both hospitals have advanced as programmed, to the point where 1:500 scale adjacency layouts, 1:200 departmental layouts and the vast majority of 1:50 room layouts have been agreed and signed off with user groups.

Concurrent with this clinical design, the architectural design has been further developed, with external agencies including Glasgow City Council and Architecture & Design Scotland being consulted with at length. Full Planning Consent for the Masterplan was granted in June 2010 and a subsequent application for approval of Matters Specified in Conditions (MSC) relating to the architecture of the two hospitals and the associated Energy Centre was due for consideration at Glasgow City Council Planning Committee on 19th October 2010. However, due to there being only one formal objection from the local neighbourhood the project can now be dealt with under delegated powers by officers without reference to their planning committee. The collaborative work carried out by the Board, and the design team provides a high level of confidence that approval will be granted.

Further MSC applications will be submitted in the coming months to satisfy the conditions contained within the original outline consent, but these are not pre-start requirements and are therefore do not impact upon programme at this stage. Furthermore the detailed matters affected by these conditions do not represent any un-assessed risk to the Board.

An initial application for Building Warrant has been submitted to Glasgow City Council in order to allow consideration of key elements including the Fire Strategy and this has been successful in resolving a potentially complex issue at an early stage, thus allowing design development to conclude without impact upon programme. These negotiations also provide greater cost certainty in the design.

- ***Stage 3: Construction***

Enabling works, including demolition, to deliver a clean site for development are currently underway and are planned to complete by the end of October 2010 and the purchase of two additional land parcels from Scottish Water and Scottish Ambulance Service are subject only to the approval of the Full Business Case.

A November approval will permit instruction to be issued to BCL in line with the current programme and will ensure that the impacts upon the Laboratories Development will be minimised as the structure of the Energy Centre, for the full facility, will be completed in advance of service delivery from the new Laboratories.

Site works including expansion of the existing Contractors/Board Accommodation and diversion of water courses will commence in January 2011, with the works to the Hospitals commencing in March 2011.

The construction and technical commissioning of the Hospitals will complete in January 2015 with service transfer commencing late Spring 2015 and concluding in Summer 2015.

- ***Stage 3a: Demolition and Completion of Landscaping***

The demolition of existing Surgical Block and completion of external landscaping cannot commence until after decommissioning of the affected buildings and require service delivery to be transferred to the new facility before they can commence. These works will be completed without significant impact upon the operation of the new facility and will complete in the summer of 2016.

A feature of the contract is the treatment and management of the programme, whereby the programme is submitted by the contractor on a monthly basis for acceptance by the Project Manager. There are only set, specific reasons for the programme to be rejected by the Project Manager and the 'live' nature of the programme supports awareness of all aspects of the process and activities as well as management of issues (Early Warnings/Risk Reduction) as they occur during the contract. This scrutiny, awareness and real time management of the programme is beneficial in reporting status internally and to stakeholders as well as in providing clarity to concurrent activity (such as planning and implementation of transition of services to the new facilities) to the workgroups engaged in those activities.

A copy of the master programme as at September 2010 is attached at Appendix H for information.

4E.2 Commissioning Plan

The construction process dove-tails with commissioning and handover requirements and activities.

An outline operational commissioning plan for the transfer of services from Yorkhill Hospital, Western Infirmary, Victoria Infirmary and part of the Southern General to the New South Glasgow Hospitals is given in Appendix I.

This document describes the new structure to take forward the commissioning plan which is based upon the good work undertaken in commissioning the two new ACHs. The paper also gives a 'first pass' at the operational commissioning plan which will be further developed through the new structure.

CHAPTER 5

THE FINANCIAL CASE

CHAPTER 5 – THE FINANCIAL CASE

5A. INTRODUCTION

This chapter explains the methodology used to calculate the capital and revenue consequences of the New South Glasgow Adult and Children's Hospitals.

It utilises the output from a number of key elements of the project, including workforce planning, capacity planning and design to establish the capital and revenue implications and confirm the preferred solution is affordable in both capital and revenue terms.

All relevant current guidance has been followed in constructing the financial appraisal, principally the Scottish Government Capital Investment Manual – Business Case Guide (2010).

The Outline Business Case approved in May 2008, presented a proposal for new Adult and Children's Hospitals and a new Laboratory and Facilities Management complex with a combined capital cost of £841.7m. A Full Business Case for the Laboratory and FM complex was approved by the Scottish Government on 4th December 2009. The capital value of this aspect of the overall project amounted to £89.750m and building work commenced at the beginning of 2010 and is on target to be completed by March 2012.

The purpose of this FBC is therefore to address the remaining elements of the development, namely the New Adult and Children's Hospitals with a capital value of £751.950m.

For completeness and to improve users' understanding of the full financial position of the development, the tables within this section include details of the Laboratory and FM aspects for information only.

The table below states the key assumptions used in the Financial Case:

Table 24 - Key Assumptions used in the Financial Case

Key Assumption	
Price Base for Revenue	2010/11 – no inflationary uplifts applied
Contract Type	NEC3 Option C Target contract with activity schedule
Main Construction Contract Costs	Brookfield Construction Ltd. Maximum Price
Optimism Bias	All Risks are now quantified and included within the Risk Registers.
VAT Rate	17.5% to 3rd Jan 2011 and 20% from 4th Jan 2011
Depreciation Rate for New Build	60 years
Depreciation Rate for Equipment	10 - 15 years
Interest on Capital	Nil

5B. CAPITAL REQUIREMENTS

A summary of the capital costs of the development are shown in the table below:

Table 25 – Summary of Capital Costs

Capital Cost	Adult & Children's £'000	Laboratory & FM FBC £'000	TOTAL £'000
Total Capital Costs	**751,950**	**89,750**	**841,700**

* Detail of costs removed due to commercial sensitivity

Key drivers that underpin the capital costs for the Adult & Children's Hospitals are:

- The capital costs reflect the construction programme with a Stage 3 commencement date of November 2010;
- In accordance with NHS Scotland Sustainability Objectives, costs include the requirement to target a BREEAM "Excellent" rating;
- Construction costs include group 1 equipment and fitting of group 2 equipment;
- An Allowance for quantified risk is also included within the capital costs;
- All capital costs are inclusive of VAT at 17.5% up to 3rd January 2011 and 20% thereafter.

5B.1 Risk

Full details of the identification and mitigation of risk within the project are contained within Chapter 4 – The Commercial Case. This describes the robust procedures in place to both identify and manage potential risks, including regular and formal reviews of the Risk Registers and Early Warnings, and notes that risk management is inherent in the structure of the project governance as well as in the NEC form of contract that is being utilised.

This approach, together with the advanced stage of design undertaken to date, has enabled, through detailed modelling of risk probability, a fully costed risk provision which is included in the capital expenditure requirements.

5B.2 Capital Spend Profiles

The capital expenditure profiles of the project are forecast as follows:

Table 26 – Capital Expenditure Profiles

Financial Year	Adult & Children's £'000	Laboratory & FM FBC £'000	TOTAL £'000
2008/09	2,652	-	2,652
2009/10	7,717	3,455	11,172
2010/11	16,556	44,669	61,225
2011/12	120,374	41,626	162,000
2012/13	270,213	-	270,213
2013/14	234,607	-	234,607
2014/15	94,204	-	94,204
2015/16	3,824	-	3,824
2016/17	1,803	-	1,803
Total capital spend	**751,950**	**89,750**	**841,700**

5B.3 Capital Funding

The Scottish Government has confirmed that, subject to approval, it has assigned overall capital funding for this project, as highlighted below:

- New South Glasgow Hospitals Project (This FBC) £751.950m
- New South Glasgow Hospitals Laboratory Project (Approved) £ 89.750m

£841.700m

5C. IMPACT ON BALANCE SHEET

The project will be funded via Public Capital through a specific capital allocation to be received from Scottish Government Health Department (SGHD). This will form part of NHSGG&C's overall Capital Resource Limit (CRL). The expenditure will be capitalised in the Board's Balance Sheet and will be recorded as a fixed asset on NHSGG&C's Fixed Asset Register in accordance with International Financial Reporting Standards (IFRS) and the requirements of the NHS Capital Accounting Manual.

5C.1 Impairment

Construction of the new Hospitals is scheduled to be completed in the first Quarter 2015. As current valuation guidance is only available up to the second quarter of 2011, it is not presently feasible to accurately assess the final valuation of the completed building.

However, on completion, the new build will be subject to initial valuation by the District Valuer. In the likely event that the assessed value of the asset is less than the capital spend, an impairment value will be calculated. This impairment value will be communicated to the Scottish Government Health Directorate and a request for funding made. This business case makes the assumption that funding will be granted by the Scottish Government for the full

amount of the impairment. The asset will subsequently be capitalised at the assessed value and depreciated over the useful life of the asset.

The level of any potential impairment will be kept under continual review as construction progresses towards completion and appropriate updates on the potential level of any impairment will be provided to SGHD as required.

5C.2 Disposals

The Outline Business Case noted that the Board would target generating £135m, over a 10 year period, from the disposal of sites declared surplus. This was based on a series of projections carried out by the Board's Property Advisors, based on the potential disposal of a wide range of sites within the Board's portfolio.

Subsequent to Outline Business Case, and per recent guidance CEL 32 (2010), it is now assumed that any capital receipts which accrue will go directly to SGHD.

5D. REVENUE COSTS AND SAVINGS

5D.1 Methodology & Approach

The revenue cost and savings analyses focus on the additional costs and savings that will accrue under the proposed project and revisits the work previously undertaken at OBC stage.

Key Revenue Assumptions:

- All costs and savings are based on full year impact at 2010/11 price base – no inflationary uplifts have been applied;
- The useful economic life of the new builds is assumed to be 60 years. The useful economic life of equipment is assumed to be between 10 & 15 years;
- 3.5% interest has been excluded for capital charges.

5D.2 Summary of Revenue Costs

The table below summarises the gross revenue impact for the Preferred Option:

Table 27 – Gross Revenue Impact for the Preferred Option

Gross Revenue Costs	**Adult & Children's £'000**	**Laboratory &FM FBC £'000**	**TOTAL £'000**
Building & Non Works Cost Depreciation	11,490	1,496	12,986
Equipment depreciation	5,737	-	5,737
Life Cycle Costs	4,600	-	4,600
Total Gross Revenue Costs	**21,827**	**1,496**	**23,323**

5D.3 Summary Revenue Savings

The table below presents a summary of service and site savings associated with the total project:

Table 28 - Summary Revenue Savings

	£'000
Service Savings	30,689
Site Savings (Depreciation & Maintenance)	12,985
Total Recurring Revenue Savings	**43,674**

5D.4 Overall Revenue Impact

As can be seen from the table below, the project presents a recurring net saving of £18.2m and confirms the overall affordability of the project.

This net saving also recognises depreciation of £2.1m arising from capital costs connected to enabling work required at the Southern General site. The capital costs of this work are already included in the Board's capital plan and do not form part of the capital requirements noted in this full business case.

Table 29 - Overall Affordability of the Project

	£'000
Gross Revenue Costs (per above)	(23,323)
Total Revenue savings (per above)	43,674
Gross Savings before Depreciation on Enabling Costs	**20,351**
Less Depreciation charge associated with Enabling Costs	(2,100)
Recurring Net Cost Savings after Depreciation on Enabling Costs	**18,251**

5D.5 Description of Service Savings

The New South Glasgow Hospitals will have a significant impact on the workforce. This results from economies of scale generated from site consolidations and enhanced efficiencies arising from the redesign of Patient Service delivery models.

This is described in further detail under the Workforce section of the Full Business Case, however, the savings can be summarised as follows:

1. Site Consolidations - This is anticipated to deliver savings in the following areas:

- Medical - due to improved efficiencies in rotas and on-call arrangements;
- Facilities including Rates, Heat, Light & Power and Hotel services;
- Depreciation and Maintenance;
- Site Management and Administration.

2. Redesign of Patient Service Delivery Models – This is anticipated to deliver savings in the following areas:

- Nursing
- Nursing Skill Mix
- Allied Health Professionals Skill Mix

5E. TRANSITIONAL/NON RECURRING COSTS

A high level assessment of Transitional /Non recurring costs has been undertaken and will be continually developed and refined in the years leading up to the handover of the buildings. It is anticipated that such costs will be funded through the non recurrent use of service savings capable of early release.

5F. NET EFFECT ON PRICES

As the project is forecast to produce recurring revenue savings, there will have no adverse impact upon the Board's prices.

5G. IMPACT ON INCOME AND EXPENDITURE ACCOUNT

The revenue assumptions noted within this FBC will be incorporated within NHS Greater Glasgow & Clyde's future revenue plans.

5H. OVERALL AFFORDABILITY

Both the Target and Maximum Prices for the construction of the Adult and Children's Hospitals are within the capital affordability limits for the project. Other areas of capital expenditure, including equipment, other non-works costs and fees are also within the capital provisions available. Extensive risk reviews have also enabled a risk provision to be established which is supported by robust risk registers which remain under continual review. The capital costs, including provision for Value Added Tax at the increased rate from January 2011, all remain with the capital funding levels noted within this FBC.

By proceeding with the project the Board will achieve net overall recurring savings of £18.2m through enhanced efficiencies and the project is therefore self-funding.

Achievement of this level of savings is not dependent upon increased future revenue funding which is deemed to be a prudent assumption in the current economic climate. Indeed, proceeding with the project and enabling these savings to be achieved will directly support the Board in its efforts to address any future negative funding growth and the financial impact this may have.

Consequently the construction of the New Adult and Children's Hospitals is deemed to be affordable in both capital and revenue terms.

CHAPTER 6

THE MANAGEMENT CASE

CHAPTER 6 – THE MANAGEMENT CASE

6A. PROCUREMENT STRATEGY

6A.1 Process To Contract Signature

The Procurement exercise for the New South Glasgow Hospital project concluded with the appointment of BCL to design and construct the works within the following contractual stages:

- Stage 1 – Design & Construction of the New Laboratory Building
- Stage 2 – Design Development of New Hospitals
- Stage 3 – Finalise Design and construction of New Hospitals
- Stage 3A – Demolition of Surgical Block and completion of Hard Landscaping

The contract has approval Gateways prior to the Contractor commencing any Stage. Stage 1 & 2 were given approval to start at NHS GG&C Main Board meeting 3rd November 2009 which endorsed the Project Team recommendation to appoint BCL. In the event of subsequent Stages not progressing the Contract protects the Board from any damages etc and ensures ownership of design completed at end of Stage 2 transfers to the Board.

6A.1.1 *Governance / Approval Of Procurement Strategy*

At all Stages in the process NHS GG&C Procurement & Finance Group (as in existence during Pre Contract Stages) were fully engaged in the development and implementation of the Procurement Strategy. In addition to Senior NHS Staff, key non NHS GG&C members of this Group were representatives from Partnerships UK and Scottish Government.

Other external Peer Review Groups endorsing the Procurement Strategy were:-

- Gateway Review Team
- PWC Board Auditors
- Atkins Consulting – third Party review engaged by Project Team

6A.1.2 *Market Engagement*

Due to the scale and complexity of the Project a major consultation exercise was undertaken to engage with the Contracting market to test thoughts on the procurement process to arrive at a solution that would both engage the market to bid by limiting cost to bid, and protect the Boards commercial position.

Initial market engagement commenced early 2008 with a number of major contractors contacted to establish their appetite to bid for the project. This initial exercise resulted in a small number of contractors actually indicating they would be interested in bidding for the Project.

Shortly after this initial market engagement, a workshop was arranged with NHS Staff, and 4 Construction Consultancy companies, with whom the Board had previous experience, to test thoughts and ideas over potential ways to procure the project. This workshop presented a range of options to be further tested with the Contractors who expressed an interest in bidding for the Contract.

After appointment of the Board's Technical Advisors, Currie & Brown, detailed workshops were organised with 3 Main Contractors to test further thoughts and opportunities for procurement of the Project. Key outcomes from these workshops were:-

- Contractors concern over use of Competitive Dialogue and potential for protracted bidding period
- Protracted bid period leading to abortive bid costs for unsuccessful contractors
- Cross contamination of bids during competitive dialogue
- Fair competition and evaluation process – quality / price ratio selection
- Form of 2 stage design & build was acceptable
- No issues with use of Incentivised NEC3 Target Price type contracts

Based on market engagement and consideration of Board requirements in terms of Guaranteed Maximum Price type framework, the Procurement Strategy outlined as follows was recommended and implemented:-

- Prequalification of Contractors based on key criteria including:
  - Financial Standing
  - Technical Capability
  - Experience of Hospitals in excess of £200M
  - Personnel
- Shorlisting minimum of 3 contractors
- Single stage bid – quick selection of Preferred Bidder
- Single overall contract Price for delivery of the total project requirements. Approval Gateways included to provide control mechanism
- Competitive Dialogue structured to maximise benefit of dialogue within short period
- Robust procurement programme – set deadlines and achieve them
- Pricing Structure set to provide incentivised delivery framework – Target & Maximum Price
- Contractor Selection based on Most Economically Advantageous Tender – best ratio of quality & price
- Affordability threshold test – deselecting if bid exceeded threshold

6A.1.3 *Development Of The Tender Documentation*

Between September 2008 and April 2009, the Project Team and Technical Advisers worked with users, legal and financial advisers and others, preparing the clinical, technical and other information required to take the Project to market. This information formed the tender documentation which informed bidders of the NHS Board's requirements.

The tender documentation constituted 3 volumes as follows:-

Volume 1 Project Scope and Commercial Document

This provided an overview and outlined the scope and commercial parameters of the Project. It set out the background to the Project, outlined the detailed procurement process and timetable, identified the competitive dialogue process and incorporated the draft construction contract.

Volume 2 Employer's Requirements

This set out the technical and clinical requirements of the Board. These included Clinical Output Specifications for all departments, master plan and exemplar design information, output specifications regarding the construction works, building and engineering services to be provided plus Activity database (ADB) Room Data Sheets and Equipment Lists (by Group).

Volume 3 Bid Return and Evaluation

This detailed the range of deliverables required from bidders and the evaluation strategy and scoring approach to be applied by the Board.

6A.1.4 *Exemplar*

Key aspects of the Employer's Requirements (ER) were an Exemplar of the Hospitals to Royal Institute of British Architects (RIBA) Stage C, Schedule of Accommodation and Clinical Output Specifications. The Exemplar was developed with input from User representatives from over 70 User Groups from Specialties/Departments which will be housed within the New Adult and Children's hospitals.

The Exemplar involved development of 1:500 block plans for the Adult and Children's Hospitals, a number of 1:200 detailed design plans and 1:50 room information. The following describes this in more detail.

The 1:500 block plans demonstrate:

(i) the clinical adjacencies required for the key specialties;
(ii) flows of visitors, patients, staff and Facilities Management through the building;
(iii) the clinical links required between the new hospitals and the Neurosciences Institute and Maternity Buildings.

User Groups worked with the Board's Project Team and Technical Advisers to develop detailed 1:200 departmental layouts for 8 major clinical Department/areas, these being: A&E, Theatres, Critical Care, Imaging, Wards, Acute Assessment Unit in the Adult Hospital and Imaging and Emergency Department for the Children's Hospital. The detailed design plans illustrate how the department might be laid out and the flows for patients, staff and Facilities Management (FM) within it.

1:50 room information was developed using the ADB activity database which is a standard database for all UK hospitals showing general arrangements of standard rooms and suggested positions and location of equipment.

6A.1.5 *Tender Process*

In compliance with European Procurement Directive the Project was advertised utilising the OJEU process on 6th February 2009 and invited Expressions of Interest/Prequalification Questionnaire Completion from suitably qualified/competent Contractors. The PQQ required responses from Contractors to the following key criteria:

> Financial Standing
> Technical Capability
> Experience of Hospitals in excess of £200M
> Personnel

Completed documents were received from five Contractors and following a detailed evaluation process only three Contactors were deemed to have satisfied fully the required criteria to be selected to be invited to tender for the project. A full debrief was provided to the contractors not selected.

On 1st May 2009 the tender documents were issued to the three selected Contactors. The documents clearly set out the bidding timeframe and Competitive Dialogue structure.

Dialogue meetings were held to cover the following topics:

- **Design** – as bids were invited based on Exemplar Design and Output based specification, design dialogue sessions were required to allow bidders to test their design solution against the Employers Requirements, refine bid solution and allow the Board to clarify any areas of the brief

- **Logistics** – due to scale of development and impact on existing hospital site and surrounding neighbourhood, a Logistics group was formed to allow bidders to discuss solutions around construction methodology, temporary access arrangements, temporary car parking, temporary offices etc

- **Commercial** – this Group had three key remits, namely to continually test the affordability threshold with bidders to ensure affordable bids were received, fine tune any contract terms drafting and agree pre bid submission, and to test some key contract conditions with the bidders. Key contract items

discussed were Inflation risk, general risk management, who was best placed to hold risks, damages for late completion, retention and payment process; and

- **Laboratories** – as this element of the Project involved detailed design work continuing direct with the Board and novation of the Design Team post contract, this Dialogue presented design updates to the Bidders to provide an overview of design development and identify any construction / logistics issues

Four corresponding Groups were formed to represent the key areas with members from a range of stakeholders and advisers including Board Representatives, Medical, Nursing, FM and infection control representatives and Technical, Legal & Financial Advisers.

The bidders were represented from their own internal teams and their associated partners.

As part of the dialogue process the bidders formulated the agenda items based on their need to clarify any aspects regarding the tender documentation/project. The agenda items were discussed and subsequently action/query lists were drawn up and responded to within agreed timescales. A Request for Information (RfI) process was also operated whereby bidders sent questions for clarification to the Board.

Through the process described above bidders were given clear and detailed direction on the Board's requirements.

The Competitive Dialogue Period closed 14th August 2009 with the Invitation to Submit Final Bids issued which provided clarity on any changes to the Employers Requirements and the basis of bids to be submitted.

After dialogue and before submitting their tenders offers, bidders were asked to present their proposals to date as a final pre-submission exercise to determine that, through competitive dialogue, they were in line with the Employer's Requirements.

Contractor's bids were submitted on programme on 11th September 2009 and before a detailed evaluation process commenced bidders were requested to present their bids to the evaluation team to enable the evaluation team to gain a full and clear understanding of their bid content.

The evaluation process was rigorous and measured the bids received against the set criteria stated in the Invitation To Participate In Dialogue (ITPD). The ITPD clearly set out the Evaluation Methodology and provided scoring information on the items being evaluated, method of scoring and items individual and group weighting. The following describes this in more detail.

To ensure that the Evaluation Team complied fully with the process as outlined, training workshops for the evaluators were held in advance of the tender return date.

An Evaluation Centre was established at Gartnavel Royal Hospital, providing a secure base from which to manage and undertake the process. All members of the Design and Logistics groups co-located to this Centre for the full 5 week duration, thus ensuring interaction between individuals and Groups was possible at all times

A detailed evaluation programme was produced for the Team in advance, setting out the key actions and dates for the Groups, areas covered by the evaluation, were:

- Design
- Logistic
- Commercial

The evaluation of the Design and Logistics sub-groups were then reviewed, for consistency of approach, scoring and reasoning, by Senior Managers in the first instance and then finally by the Commercial Group who were tasked with making a recommendation to the Board.

The tender prices submitted were assessed for errors, inconsistencies, exclusions and caveats, then equalised to adjust for bid allowances and missing items. The out turn adjusted bid prices reflecting the estimated target were then calculated

The Most Economically Advantageous Tender (MEAT) scores , calculated as a ratio of quality and price were then generated using the full quality score and the adjusted bid prices, with a higher score representing better Value for Money.

The conclusions of the Evaluation Group were presented to the Project Executive Board on 22nd October 2009, which included the attendance and involvement of the Chair, Vice Chair and Non Executive Member of the NHS Board. Consequently on 26th October 2009 the Project Executive Board considered the comments from the meeting on 22nd October and formally endorsed the outcome.

Recommendations for appointment of the Preferred Bidder were presented to the NHS GG&C Board on 3rd November 2009. The Health Board endorsed the recommendations of the Project Team.

A comprehensive debrief was offered to, and accepted by, the two unsuccessful bidders. The de-brief comprised of a written feedback report, a presentation on Evaluation Team findings and a Question & Answer Session.

The formal Contract to award BCL to Design & Build the New South Glasgow Hospitals & Laboratory Project was signed on 18th December 2009.

6A.2 The Planning Process

6A.2.1 *Outline Planning Permission*

In April 2007 the Board lodged an outline planning application with Glasgow City Council which was accompanied by an Environmental Statement (ES). The planning application and ES were the subject of consultation with an extensive range of statutory and non statutory bodies, agencies and the general public. The application was reported to the Council's Development and Regeneration (Development Applications) Sub Committee in January 2008, with a recommendation for approval. The Sub Committee voted to grant outline planning permission subject to 43 planning conditions and the signing of a Section 75 Agreement. The outline planning consent for the New South Glasgow Hospitals project was issued by Glasgow City Council on 30th July 2009.

The consent stated that subsequent planning approvals would be dealt with as 'Reserved Matters'. This two-stage approach meant that there would be a requirement for reserved matters applications to be scrutinised by the planning authority to determine whether further environmental information and assessment is required to allow the detailed consideration and determination of reserved matters.

With the implementation of the Development Management component of the Planning Etc. (Scotland) Act 2006 on the 3rd August 2009, the submission of 'reserved matters' applications was replaced by the submission of 'Matters Specified in Conditions' applications.

6A.2.2 *Approval of Masterplan*

In April 2010, a Matters Specified in Conditions (MCS) application (Ref: 10/00945/DC) was submitted to Glasgow City Council to audit the changes between the indicative campus masterplan and the finalised masterplan, and assess the extent to which the finalised masterplan accords with the ES, as required by Condition No.1 of the Outline Planning Permission. The application outlined the following information.

- Setting the scene
    - Strategic Context
    - 2007 Campus Development Plan
    - 2009 Campus Masterplan
- 2010 Masterplan
    - Site Context
    - Design Vision
    - Masterplan Layout
    - Landscape Framework
    - Elements of the Masterplan

- 2010 Masterplan Strategies

    - Transportation
    - Site Circulation
    - Landscape
    - Drainage
    - Arts and Healthy Environment
    - Sustainability

The MSC application was approved by Glasgow City Council on 24 June 2010, subject to six conditions addressing issues including waste management, surface water, residential amenity, and wind turbines.

A further MSC Application was submitted to Glasgow City Council on 14th July 2010, covering the architecture of the buildings and the external areas. Planning approval was given on the 19th October 2010.

Architecture and Design Scotland (A+DS) have been a key partner and provided support and input review and commentary to the evolving design from the exemplar through to the submitted planning documents.

6A.2.3 *Building Warrant Status*

- The Building Warrant application will be submitted in stages including sub-structure, super-structure and fit out;
- Early stage application submitted to engage GCC Building Control in discussions regarding the Fire Strategy (close to conclusion);
- Negotiated fee levels agreed by the contractor with GCC;
- Energy Centre and Hospitals sub-structure application to be submitted on approval of FBC to allow early commencement of works on-site; and
- Further staged applications to be submitted to meet project programme and cash flow requirements.

6A.3 Architectural Design Statement & Design Development

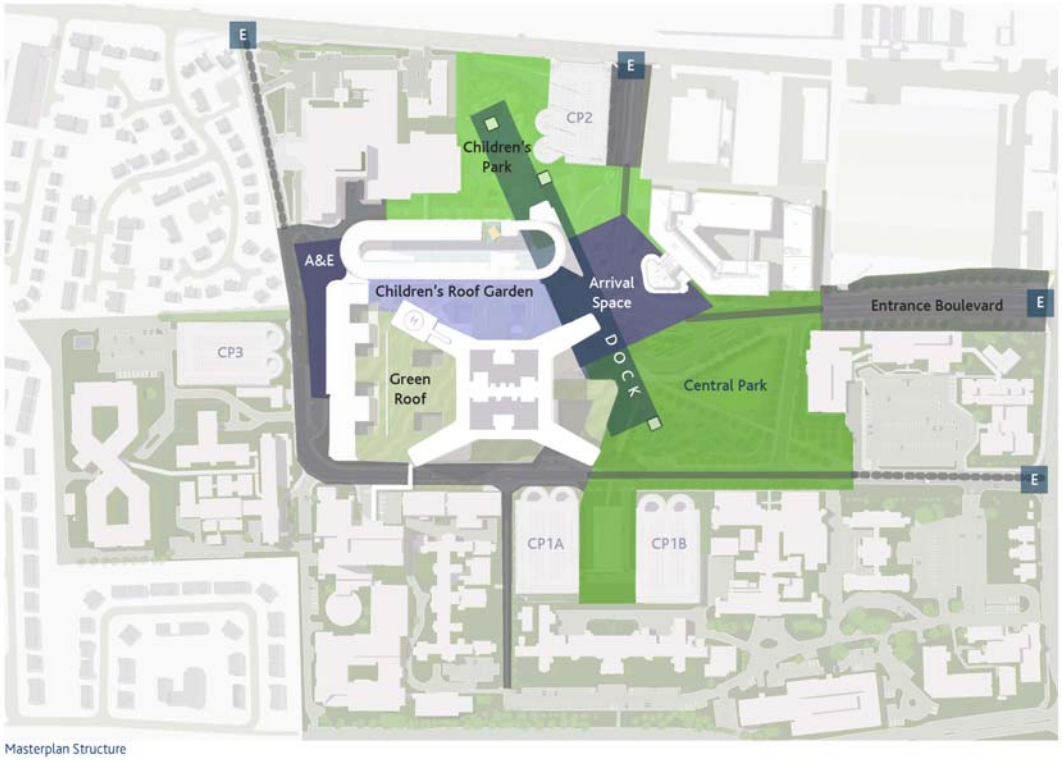
The Architectural Design Statement which accompanied the 'Matters specified in Conditions' application follows the principles set out in the Scottish Government's *Planning Advice Note No. 68 Design Statement* published in August 2003. It sets out to explain the scheme in terms of the brief, analysis of context, design development (following consultations) and the final proposals. The Design Statement, part 1 and 2, is attached at Appendices J and K for information, and highlights are summarised below.

The following describes the concept and vision of the overall design:

6A.3.1 *Design Vision*

The vision is based upon the creation of a landmark healthcare campus environment with emphasis upon a green character as an influential setting for state of the art hospital facilities.

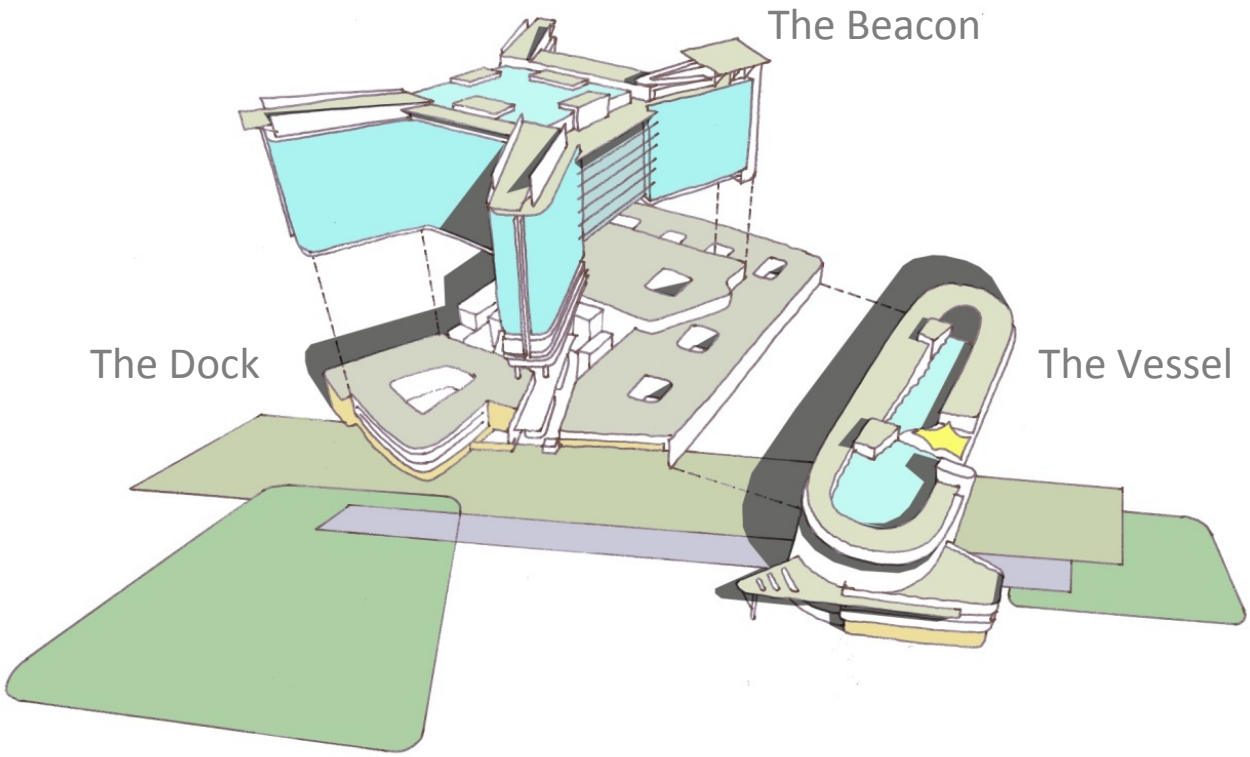
The setting of the new buildings within a designed sequence of public spaces is intended to de-institutionalise the hospital environment as far as possible and to create an engaging environment with a variety of designed external spaces. The masterplan design includes an arrival space which functions as a transport hub, an enhanced central park, a further Children's park dedicated to the new Children's hospital and a new entrance boulevard.



Masterplan Structure

6A.3.2 *Design Concept*

The project is large and complex and a simplified conceptual approach to exploring the forms and their relationships can assist in explaining the design. A ship-building concept applies to the form and character of the new buildings, which have been defined as a Dock (the broad podium), a Landmark Beacon (the ward tower located on the podium) and a vessel anchored alongside the dock (the Children's hospital). This captures the coming together of the primary components of the new hospital buildings and links to maternity and neurosciences are referred to as anchor points for the new hospital buildings to connect appropriately with the existing site.



6A.3.3 *Masterplan Structure*

The layout of the new campus heart has been structured in response to the functional requirements of the hospital site. The hospitals have three main public entrances. The new entrance boulevard from Govan/Renfrew Road is aligned with the main entrance to the acute hospital. The layout has been arranged to aid way-finding through the placement of key destinations in visible locations.

A public transport hub is located in front of the hospital entrances to provide a high quality experience for bus users. The extent of the arrival space also encapsulates the entrance to the new laboratories building.

A blue light route for ambulances provides a second main route through the campus and this gives direct access to accident and emergency to the south of the building. This route is also used by buses within the campus and for access to the two eastern car parks which frame the listed tower clock and surgical block.

An illustrative plan of the Masterplan is shown below.

Illustrative Plan-Landscape Masterplan

NEW SOUTH GLASGOW HOSPITALS DESIGN STATEMENT Page 21

A48235836

6A.3.4 *Adult Inpatient Block – 'The Beacon'*

The inpatient block consists of 8 floors with four 28 bed wards provided per floor (typically). In order to allow a degree of flexibility of use, and in particular to allow notional departmental boundaries to adjust to meet varying service demands, the plan form of this block is arranged to ensure a continuous 'ribbon' of bedroom accommodation around the perimeter. [This approach ensures the optimum response to this requirement and, coupled with the 'internalisation' of fire escape and vertical circulation cores, allows every inpatient bedroom an uninterrupted view with zero overlooking other bedrooms]. This innovative approach to ward planning also provides the opportunity for each ward to be arranged around a central, covered day-lit atrium. The adult atrium provides a naturally lit, temperate space for provision of day-light to 'internal' spaces and at its base, for orientation, waiting and amenity. The connection of the two proposed 'FM' circulation cores by bridge links at levels 4 to 11 within the adult ward tower provides an opportunity for drama through the expression of support services as coloured pods linked to the bridge. Although conceived as a continuous ribbon of bedroom accommodation the plan form opens up at the end of each wing through the introduction of a shared 'social space'. This space allows a direct visual link to the outside, exploits elevated panoramic views and provides an appropriate termination to the internal ward corridor axis. The beacon is conceived as essentially glazed with alternate pairs of floors grouped and separated with a horizontal recessed channel. This device mitigates the effects of scale and introduces a strong horizontal emphasis.

6A.3.5 *Adult Podium – 'The Dock'*

Having located all adult inpatient facilities in the beacon the remaining (OPD, diagnostic, day, emergency, interventional) adult facilities are all contained in the podium (dock).

The dock consists of three storeys of clinical accommodation (with plant on a fourth floor where necessary). Courtyards and light-wells are inserted into strategic locations to mitigate any 'deep-plan' effects and to ensure adequate access to day light and view.

The dock is treated as a simple architectural element. Horizontal emphasis, through the use of recessed channels aligning with the building floor levels, with full-height vertical panels/windows set within the bands, provides an appropriate back-drop for the more expressive 'Beacon' and 'Vessel'.

6A.3.6 *Children's Hospital – 'The Vessel'*

The children's hospital, whilst sharing some of the podium is a hospital in its own right. In response to a requirement to invest the children's hospital with an identity all of its own, the building is conceived as a more transitory form, 'moored' alongside the 'dock' (adult podium). It is in the 'vessel' (the children's hospital) that maritime references are most evident. The 'apsed'

North and South treatments are also intended to provide a clear sense of identity and a link to maritime forms. The building is arranged as a simple linear block on the West side of the site, to connect to the existing Neo-Natal facilities. There is a 15m wide atrium separating the East and West sides, providing a large, internal, day-lit, temperate space. The atrium provides a large, covered amenity/waiting space as well as an intuitive internal way-finding device providing easy access to key vertical circulation cores.

Externally, an emphasis is placed upon the North and North Western facades (facing the arrival space and children's park). The main entrance and adjoining facilities at levels 1 and 2 have been developed to ensure response to the diagonal geometry and link between parks, as well as appropriate level of transparency and openness at the entrance.

A 'DNA' theme is employed in the compositional treatment of the vessels' facades, ensuring a consistent campus approach to the suite of buildings. In order to express the identity of the children's hospital, and to encourage a degree of 'playfullness', vertical coloured fins are applied radially around the entrance façade and along the West façade, where oblique views when moving North and South along the façade can be exploited. As a further gesture to integration with the children's park the consult/examination suites on the Western façade have been expressed as coloured 'play-boxes'.

View of children's hospital from the children's park

6A.3.7 *Development of the Arts Strategy*

The key strategic elements incorporated in the ERs have been developed and incorporate core, and enhanced elements that reflect consideration of building scale and funding aspects. A number of criteria such as improved care, function of space, level of impact, sustainability, inclusion and value for money were considered in prioritisation of the final programme and the relevant enabling works have been identified within the build programme. In collaboration with the core landscaping, architectural design and interior design programmes the Arts Strategy will specifically undertake the following programme of work:

Table 30 – Art Strategy Programme of Works

1. Building Design and Healing Environment	
The Beacon Project - therapeutic environment of socialisation spaces in Adult ward block The Beacon Project - Ward identity location and orientation marking in Adult ward block	Core - Adult
Dignified Spaces - Therapy rooms, imaging departments and long stay wards e.g. Distraction therapy	Fundraising - NCH
Dignified Spaces – Interior upgrading of quiet and respite spaces including installation of arts (Bereavement rooms/ Family rooms / Discharge Lounge / Waiting Rooms)	Core - NCH / Adult
2. Interior design and landscaping	
Atrium Colours and finishes - staff participation in colour palette development	Core – Adult
Stencils and Graphics - Way-finding in Wards and Podium	Core & enhanced - Children
Dignified Spaces -100 flowers for multiple location installations (themed works in waiting areas, staff areas and quiet rooms)	Core & enhanced - Adult
Orchard and therapeutic gardens/ landscape	Fundraised Adult / Children
Landscaped Courtyards	Core & enhanced - Adult
3. Integrated art, specimen art	
Podium Landmarking – Feature wall wayfinding at key junctures in podium	Core - Adult / Children

4. Architectural elements	
Focal points and human spaces - External shelters within Adult landscape and Children's play park, internal atrium Play Pods in NCH	Core - Adult / Children
Roof garden shelter structure NCH	Core- Children
5. The provision of programmable spaces	
Flexible exhibition space, framing devices and corridor artwork	Core - Adult / Children
Personalised spaces - Flexible white walls	Fundraised - Adult / Children
Atrium public performance space for ongoing commissioning e.g. Music	Core - Adult / Children
Artist Residencies: performing and visual arts	Fundraised - Adult / Children

6A.4 Design Development

To inform the development of service models and departmental designs members of the User Groups and project team undertook benchmarking visits to a number of UK hospitals, to gain ideas and identify service models/design which work well or, just as importantly, don't work well and to learn from other NHS hospital staff experiences.

The hospitals visited were chosen for their innovative models, single room provision and comparable size of departments. Of particular interest were Acute Assessment models for management of emergency activity, the layout of Theatres and models of Day of Admission, issues of other comparably large Critical Care and the optimum organisation and design layout of wards. The models of nursing within a single room environment was of interest along with differing ward bedroom arrangements comparing inboard, outboard and interlocking ensuites and different arrangements of support facilities.

The focus of benchmarking in relation to the new children's hospital was the design of the Emergency and Outpatient Departments, innovations in distraction therapy and the type and location of parental overnight beds.

The work described above helped confirm the service models and 1:200 design as users were able to see the options proposals tried and tested at other sites. It was also invaluable in highlighting pitfalls to be avoided.

It should be noted that use of the information gleaned from the benchmarking (hospital visits) exercise was not just used in the design development for the new hospitals but has also been put into practice as part of the Accelerated ASR. For example AAU models have recently been put into place in the West

of the city and are planned to be in place at the Glasgow Royal Infirmary at the start of 2011. In addition an Admission on day of service unit has recently commenced in the north of the city, this will allow these service models to be implemented, tested and further refined: with the out turn experience transferred to the New South Glasgow Hospitals.

The Clinical Briefs, Schedules of Accommodation and exemplar drawings described above formed a key element of the Employers' Requirements.

Following contract award in December 2009 the User Groups have worked closely with the Project Team and contactor architectural team to further develop and refine individual department layouts (1:200) and, having signed these off, the layouts of the individual rooms (1:50 drawings).

Full size mock-ups were built to assist users in developing the individual bedroom layouts (1:50 drawings) for the ward bedrooms and critical care. These consisted of an adult bedroom and en-suite, child's bedroom and en-suite with staff touchdown and a critical care space. The mock up rooms simulated in spatial terms the location of furniture, sanitary fitments, location of wall mounted equipment and bed head services. This has assisted clinical users in 'bringing architectural drawings to life', ensuring that the bedroom & en-suite design is fit for purpose, safe for patients and creates a healing environment. The mock-ups were also used to confirm high levels of visibility of patients from the corridor and staff touch down.

The mock-ups have also been visited by ward Senior Charge Nurses to assist them in understanding how the new wards will function in preparation for the move from multi-bed rooms to single bedrooms.

As previously mentioned the design of the ward and model of nursing are very much interdependent, the following (as well as the Change Management narrative at Chapter 6C) describes both in more detail and explains what action in being taken to prepare the nursing workforce for the move to the new environment.

6A.4.1 *Development of the Ward Design (Adult)*

A number of UK sites were visited in support of design development, including the Bevan Ward at the Hillingdon Hospital NHS Trust which is a pilot site for different layouts of 100% single rooms. The main elements of an effective design were identified as the maximisation of patient visibility, good access to natural light and minimising travel distances

Other key concepts taken from site visits were:

- the layout & design of the ward is crucial – especially in terms of the impact on nurse staffing and patients
- good design can facilitate the shift from multi-bed to 100% single accommodation within current staffing levels

- central positioning of support services such as clean & dirty utilities, disposal hold, linen bay and equipment /storage areas can reduce nurse walking times therefore increase time spent at the bedside
- provision of single rooms can facilitate staff to deal sensitively and privately with patient issues allowing private conversations and discussion of diagnosis and care
- single rooms give greater flexibility in isolating patients. This decreases patients ward transfers and boarding resulting in less staff time spent trying to find a single room for patients
- access to natural daylight and use of colour is very important to provide a healing environment
- observation panels into bedrooms increase patient visibility
- the use of touchdown spaces (mini nurse stations) support a devolved nursing model which allows the nursing staff to be closer to, and more in contact with, the patient; and
- including clinicians, nurses, allied health professionals, patients and families in the ongoing design process will maximise opportunities to improve staff workflow and patient safety and to create patient-centred environments

The following describes firstly the typical layout of a current ward within the existing estate and then the new ward design generated as a result of the benchmarking visits and subsequent work between the users, project team and architects.

6A.4.2 *Current typical Ward layout*

Across the Board area the majority of the hospital estate was built within in late 19th & early 20th century. The current design of ward areas consists of a variety of multi-bedded wards, ranging from nightingale wards to four bedded rooms.

Wards are commonly designed with a centralised nursing station with heavily used areas (clean & dirty utilities) at the end of or outside the ward area. Increased workload caused by travel back and forth to the nursing station and utility areas is inherent in current nursing care models which is not time efficient and inhibits care delivery.

Bottlenecks caused by full occupancy in gender specific multi-bed rooms can lead to challenges in managing beds and the result in knock-on impacts of delays in patient flows from emergency wards, Intensive care unit and post surgery recovery rooms.

6A.4.3 *New Ward Design*

The adult hospital is planned with each of the 8 floors of the ward stack comprising 112 bedrooms, all of which will be single bedrooms, each with en-suite shower and toilet facilities. Each floor is subdivided into four wards comprising 28 bedrooms.

The layout of each ward is a longitudinal triangular shape which provides the optimal design solution to support patient safety & reduce risk, enable social interaction between staff and patients and facilitate good observation. To enable effective operational management and minimise walking distances for staff regularly used rooms e.g. clean & dirty utilities, linen & equipment bays are centrally located. This will reduce walking times for nurses and maximise the amount of time spent with patients at the bedside.

The provision of hot desk facilities, interview rooms, staff change and seminar & medicines management rooms close to ward areas are also key to the smooth operation of the new service model. All bedrooms are placed on the perimeter affording all patients access to natural daylight and extended views. The design affords maximum flexibility allowing specialties to 'flex' across into another ward during peak activity. The wards will have staff touch down bases spread through the ward and near patient access to patient records.

6A.4.4 *Bedroom Design*

All single rooms can provide flexibility to manage differing levels of acuity even within a single speciality ward. Technologically the rooms are state of the art. All equipment required for the needs of patients including medical gases, access to computer technology and patient call systems are easily accessible on the bed-head services. It is anticipated that patient data entry will be done at the bedside.

A key design principle is good visibility from the corridor into the bedrooms. The design achieves good lines of sight into all rooms, achieved by incorporating large observation panels to give direct line of sight into the bedroom. Privacy issues will be addressed by the incorporation of interstitial blinds into the observation panel.

A key aesthetic and safety feature is that each patient will have his or her own en-suite toilet & shower room. The layout as designed, utilising interstitial en-suites provides good outward views for patients and high levels of daylight into rooms.

Although toilet & shower rooms are not the sole source of nosocomial infections, they are certainly important contributors. The design has an added benefit of an uncomplicated route from bed to en-suite in every room, giving patients direct access to toilet facilities.

6A.4.5 *Touch-Down Bases*

In addition to a centrally located nurse's station, multiple touch-down bases are a key design feature. These mini communication bases will allow nurses to complete handovers, communicate within the ward & other departments and enter data onto the computerised Patient Management Systems.

Decentralised Nurse Bases will reduce walking distances for nursing staff and will support good lines of sight into single rooms. The National Patient Safety Agency supports this view and suggests that walking time per shift can be reduced from 6km to 2.9km per shift, therefore increasing the time spent at the bedside.

There will be a devolved 'Team Nursing' model, whereby rather than working from one nurse station, nursing teams will be assigned to clusters of bedrooms supported by touchdown spaces to enable a safe and efficient model of care delivery.

6A.4.6 *Children's Ward*

There are wards on 5 floors of the new children's hospital and the design for each level is different reflecting the needs of that ward however, room bedroom sizes are the same and reflect the same principles as the adult wards, that is good vision, flexibility, and en suite WC and shower rooms.

There are not 100% single rooms in the children's hospital. This was agreed following consultation on the appropriate mix of single/multi-bed wards for children. The outcome of the consultation with children, young people and their carers was that there was a strongly expressed preference from both patients and their carers for the retention of a mixture of single and small bed-bays (2-4). This mixture was seen to offer flexibility in addressing a number of factors including the level of illness, the need for isolation, the need for company to aid recovery, and the preference of teenagers, in particular, for either privacy or companionship. The proposed build has 83% single rooms.

The current RHSC has a mixture of single and multi occupancy bedded areas and is therefore similar to the proposed design. There are not therefore the same challenges as the adult hospital around workforce training.

6A.4.7 *Information Management & Technology (IM&T)*

The provision of IM&T appropriate to the single room solution is a critical enabler to the nursing care model. To improve operational efficiency all single rooms are enabled for near patient data entry, with voice and data communications on the bed head services.

The new hospitals will include use of intelligent staff call systems, with the potential to link to the staff call, cardiac arrest, pager / telephone alert system. When the staff call is initiated, 'follow me' lights on digital panels sited at the staff base and at key points in corridor areas will indicate which patient is calling and allow the appropriate staff member(s) to respond. The Board has begun rollout of national patient management system (PMS) which will reduce duplication of effort and support communication systems for nursing staff.

In summary key ward design features such as near patient data entry, touchdown spaces and local support services will minimise staff movement by reducing supply trips, will significantly increase time spent providing direct care to patients and optimise nursing performance and efficiency.

Single bedroom accommodation will enhance patient flow whereas multiple bedded rooms paradoxically limit flow. The movement of patients will be reduced as bed management will be more efficient and productive, for example once a patient is admitted to a single room there is no need to transfer due to infection control, gender specific issues or end of life care

It is recognised that the move from multi-bed accommodation to 100% single rooms will be a significant change in practice for nursing staff, and this topic is discussed in more detail in Section 6C (Change Management). Substantial work has been undertaken to initiate cultural change by actively involving key clinical users in developing the ward design. As described the Generic ward user group has had, and continues to have, active ongoing involvement through the detailed design process during 1:200 and 1:50 stages for FBC. In addition the project team have held workshops, meetings and road shows to enable active input from wider professional groups.

6A.5 User And Stakeholder Consultation

As identified in Chapter 4, the procurement process was under pinned by the establishment of a clear brief of requirements from the NHS expressed in written and drawn format in the ERs.

Wide ranging and extensive consultation with Users, staff, patients, carers, other partners/stakeholders and the community was carried out (and continues through the design development process) in order that the specific requirements of the varied parties are considered and included where relevant.

Consultation activity in the following areas is identified and summarised below:

- Stakeholder User Groups;
- Technical & Facilities; and
- Community.

6A.5.1 *Stakeholder User Groups*

Stakeholder User Groups were formed in early 2007 for each of the departments within the Adult & Children's Hospitals, there are over 70 such groups and they will remain active throughout the design and construction of the project.

Membership includes Medical, Nursing, Allied Health Professions, Facilities Management, Diagnostic and Pharmacy staff. In addition the user groups are supported by input from medical physics and IT and, where required,

radiological protection officers. It should be noted that infection control have been fully involved in the design with a senior infection control nurse being a full time member of the Project Team and therefore part of the team liaising with the bidders, undertaking bid evaluation and working with the User Groups to develop the schedules and design.

Between 2007 and 2009, in preparation for the tender period, the User Groups were instrumental in identifying critical co-locations and developing the Schedules of Accommodation and Clinical Briefs. Since then, the Users have been involved in developing the 1:200 and 1:50 layouts.

6.A.5.2 *Technical & Facilities*

Specific workshops and consultations were arranged during the development of the ERs to ensure that the numerous specialist technical aspects of the requirements were discussed and agreed with the relevant individual(s) and groups in the Board (and out with where necessary).

This included mechanical & electrical workshop sessions with Senior Board Facilities Managers in order that the proposed output specifications were reviewed, adjusted where necessary, and agreed topic by topic as well as to support the setting of specific requirements for protection against critical failures (e.g. plant room floods and resilience to failures) which were embedded in the ERs. Similar such consultations included:

- infection control review of technical documents and outputs in relation to surface finishes and other aspects of the requirements;
- HFS in relation to draft SHTM standards and the updating of standards;
- Radiation protection officers in respect of gauss lines, building fabric and associated measures;
- the Board's procurement team in respect of equipment strategy and ADB codifying of the requirements;
- renal in relation to RO water and other specialised aspects of the department;
- fire and acoustic engineers to support the drafting of the specific requirements in relation to these specialised areas; and
- sustainability advisors in relation to the various energy and sustainability facets of the scheme.

6A.5.3 *Community Engagement and Benefits*

6A.5.3.1 Community economic benefits

As described in the Outline Business Case NHS GG&C commissioned a socio- economic analysis of the planned investment in South West Glasgow. The analysis concluded that the NSGH project is a catalyst for broader economic and social regeneration, contributing positively to the physical development of the local area and contributing significantly to the South West economy and that of the wider locality (see Table 32).

Table 31: NSGH Economic Impacts Summary (£m)

	Estimated future direct impact of services locating to NSGH (using scenario 2) (£m)	Estimated combined future impact, with multiplier effects (£m)	Estimated combined future impact of the site based on employment level of 8,400, with multiplier effects (£m)
South West Glasgow	£30	£30 – 40	£40-£50
Glasgow City	£90	£110 - £140	£140 -£175
Glasgow City Region	£170	£240 - £290	£300 - £370

Source: SQW Socio-Economic Impact Analysis

However, the analysis was also clear the potential impact of the new South Glasgow Hospitals Campus will only be realised through effective collaboration between partner organisations, building on existing partnership structures in South West Glasgow and Glasgow City. The approach undertaken by the NHS GG&C has sought to embed the activities described below within existing partnership structures.

6A.5.3.2 Economic impacts from the construction programme

In taking forward the recommendations from the socio-economic analysis NHS GG&C incorporated Community Benefit considerations in the procurement process for the New South Glasgow Hospitals project.

In doing so, the board aims to work in partnership with the successful bidder to ensure as far as possible, that investment supports local businesses, sustains local employment and creates new training and employment opportunities. The community benefit provisions within the procurement process focussed on:

- Targeted Recruitment and Training
- SME supplier development
- Social Enterprises development

In furthering the community benefit programme, BCL have entered into a partnership agreement with Glasgow South West Regeneration Agency, Glasgow City Council and Community Enterprise in Scotland. Through established partnership structures BCL will work with NHS GG&C to:

- Achieve target of 10% of total labour required to deliver the project (including those works delivered by specialists, or sub-contractors) to be delivered by New Entrants
- Devise a Local Labour Action Plan and establish requirements with Sub-Contractor/s to recruit and source supplies locally where these exist
- Establish an operational team to deliver services including: vacancy promotion, skills assessment and matching, general and vocational training and business development
- Establish a “Recruitment & Training Centre” in close proximity to the New South Glasgow Hospitals Project

- Adopt a recruitment protocol to support mainstream recruitment from communities in South West Glasgow
- Engage Small Medium Enterprises (SME's)/ Social Enterprises to assess and develop their capacity to participate in the project
- Establish a project portal, www.nsghproject.com for individuals and businesses to register for employment and procurement opportunities

To support the implementation of the community benefit programme, a Community Benefit Delivery Group has been established with partners and sub-contractors. This group is responsible for co-ordinating partners' activities, overseeing the implementation of the community benefit programme and ensuring the project is achieving the targets set out in BCLs bid submission.

6A.5.3.3 NHS careers

As described in the workforce section, NHS GG&C recognises that in order to deliver new models of care within the new provided hospitals significant workforce development will be required.

A partnership group including representation from NHS GG&C, South West Community Health Partnership, Community Planning Glasgow, Glasgow South West Regeneration Agency, Glasgow City Council Education Services and Cardonald College has been established.

The partnership aims to raise aspirations within South West Glasgow to pursue a career in healthcare and focuses on supporting individuals achieve the skills and competencies to access the workforce at NHS Carers Framework levels 1-4 (Scottish Curriculum and Qualifications Framework Levels 5-9).

Through the partnership, the board has already undertaken a number of early actions in South West Glasgow, these include:

- Presentations and briefings to Skills Development Scotland staff working with school age children and adult returners
- Programme of careers sessions undertaken by NHS recruitment in secondary schools in South West Glasgow
- Engaging secondary schools in South West Glasgow to increase number of pupils indicating a preference for NHS work experience placements
- In partnership with Job Centre Plus, Skills Development Scotland and NHS Recruitment deliver monthly NHS careers sessions in Govan and Shawlands Job Centres
- In partnership with Cardonald College establish HNC/D Applied Science to be delivered in 2011
- Increase participation on the HNC/D programme through piloting Skills for Work: Laboratory Skills qualification in South West Glasgow.
- In partnership with workforce development establish HNC/D Health to be delivered through Cardonald College in 2011

- Increase participation on the HNC/D programme through piloting Skills for Work: Health qualification in South West Glasgow

As the final configuration of services on the NSGH is implemented, NHS GG&C will work in partnership with employability services in South West Glasgow and Glasgow City to maximise opportunities for communities and co-ordinate activities with partners to implement a long term strategy.

6A.5.3.4 Housing sector

Through established partnership structures, NHS GG&C continues to work closely with Glasgow City Council, GHA and local housing providers in South West Glasgow. The focus of this engagement has been to inform future housing investment and improve access to affordable housing for NHS staff in South West Glasgow. This includes planning for the East Govan/Ibrox transformational area and Central Govan.

To support this programme, Govan and Elderpark Housing Associations and Crudens Homes in partnership with the NHS Credit Union and Glasgow Credit Union launched Unique Property Solutions. The project aims to provide financial support through the NHS Credit Union to support NHS staff access affordable housing in South West Glasgow.

In doing so, the board aims to retain the economic impacts in South West Glasgow through increasing the proportion of staff employed in the NSGH resident in South West Glasgow.

6A.5.3.5 Life sciences

Life science has become a key sector in Glasgow due to the benefits it derives from being part of a comprehensive national life sciences strategy, backed by industry, academia, the National Health Service and the government.

The redevelopment of the NSGH will bring significant benefits in terms of infrastructure and the co-location of clinical and academic staff.

Subject to FBC approval, NHS GG&C will engage Scottish Enterprise and the University sectors to establish a site commercialisation strategy based on the future configuration of university services to be delivered on site. This will be supported through existing planning structures to establish a land use strategy conducive to supporting investment in life science related industries.

6A.5.3.6 Conclusion

The approach undertaken by the NHS GG&C has sought to embed the activities described above within existing partnership structures. Subject to Full Business Case, NHS GG&C will continue to engage with partners and embed activities within established partnership structures.

For further information regarding the community benefits please see Appendix L.

6A.6 Community Engagement In The New South Glasgow Hospitals Project

As described in the Outline Business Case, NHS GG&C established dedicated engagement structures to support the continued engagement of stakeholders and communities throughout the design, build and commissioning phases of the project. These include:

- A Community Engagement Advisory Group (CEAG) to support engagement around the new South Glasgow hospital
- The Better Access To Health (BATH) disability advisory group to support engagement on physical access issues around the New South Glasgow Hospitals
- A Community Engagement Advisory Panel to support engagement of families, children and young people in the planning processes for the new children's hospital
- A Youth Panel to engage young people in the design of the new children's hospital
- A Family Panel to engage families in the design of the new children's hospital

Through these engagement structures, the board aims to ensure that:

- Patients, carers and community interests have been appropriately engaged in the design of the new South Glasgow Hospitals
- Patients, carers and community interests' views have informed the design of the new South Glasgow Hospitals
- Patients, carers and community interests have developed the necessary skills and knowledge to engage in the design process
- Neighbourhood stakeholders and geographic communities have participated in engagement and partnership processes, thus ensuring awareness of progress with the planning of the new South Glasgow hospitals
- The engagement of patients and carers met Scottish Government Health Department guidance on participation and involvement

As described in the Outline Business Case, the board undertook extensive engagement through these established structures to inform the Outline Business Case and Employers requirements, with an emphasis on the themes outlined below:

- Access & Wayfinding
- External landscapes
- Wards and Single Rooms
- Accident & Emergency

- Family & Carer facilities
- Children's Play Areas
- Out patient areas
- Main entrance
- Bereavement Pathway
- Renal Facilities

6A.6.1 *Detailed Planning*

Building on the work described in the Outline Business Case, NHS GG&C has supported a process to engage stakeholders in the 1:200 and 1:50 detailed planning for the new hospitals. This has included:

- A presentation from design team on 1:500 designs and treatment of identified themes and incorporation in 1:200 designs
- Group work and 1:1 interviews with over 100 Renal patients on the 1:50 design of the dialysis unit and renal inpatient accommodation
- Patient/carer/family engagement and commentary on the detailed design of mock up rooms and engagement on 1:50 design
- BATH Group engagement with the design team to consider the key access and way-finding themes identified during their work on the New Victoria and New Stobhill Hospitals
- Engagement with the NHS GG&C Spiritual Care Committee to assist in the development of the bereavement pathway and to finalise the 1:200 and 1:50 drawings for the design of spiritual care facilities in the new hospitals
- Youth and Family Panel participation in the planning meetings for 1:50 designs for family, adolescent, spiritual care and public areas
- Youth and Family Panel participation in the detailed planning of design installations for distraction, well-being and personalisation in treatment areas, bed rooms and public facilities

The above activity was supported by fact finding visits and training events to develop participants' technical understanding of the design process and capacity to engage in the process.

6A.6.2 *Engaging Communities in South West Glasgow*

Engaging communities around the hospital campus has focussed on raising awareness of NHS GG&C proposals within the South West Glasgow area and engaging partners in developing joint working opportunities. This will remain the focus as the project moves forward.

Working with the New South Glasgow Hospitals Project Team and partners, community engagement has participated in outreach activities and local events to brief community stakeholders on proposals for the new South Glasgow Hospitals. Briefings on the New South Glasgow Hospitals Project have regularly been provided for Area Committees, Community Reference Groups and Community Councils.

Community Engagement also works in partnership with the South West Public Partnership Forum to disseminate information and engage with their membership on the new adult and children's hospital.

In addition to the above, NHS GG&C continues to undertake outreach activity in local venues and utilise local newspapers, community based publications and events to raise awareness of the project.

In relation to the construction programme, BCL, supported by NHS GG&C have established a Good Neighbour Agreement, this includes a commitment to provide regular briefings to neighbours and notification of future activities, via a newsletter and website.

The programmes outlined above have established the foundations future engagement activity. Subject to Full Business Case, future community engagement will continue to reflect the ongoing commitment of NHS GG&C to keep patient and community stakeholders informed and involved in the delivery of the NSGH Project.

6B. PROJECT MANAGEMENT

6B.1 Previous Arrangements

The Outline Business Case identified the governance arrangements (including therefore those for project management of the process) relevant at that point in time. Post appointment of preferred bidder, the Governance Arrangements were reviewed and refreshed in order to meet the changing requirements and dynamics of the next stage of the project.

The new governance arrangements oversee the Acute Services Review (ASR) acceleration programme as well as the next phase of the Project. The arrangements are described below:

The key changes proposed included:

- Creation of a bi-monthly Acute Services Strategy Board with the amalgamation of the ASR Programme board and New South Glasgow Hospitals and Laboratory Executive Board;

- Creation of a weekly Acute Services Strategy Board Executive Sub-group (to be responsive to NEC3 Contract arrangements)

- Creation of a number of client/contractor groups to manage and control stages 1 and 2 of the project

- The Acute Services Redesign Group to undertake the necessary system modernisation, to work in achieving service and clinical transformation, also to obtain buy-in from the service directors who will be responsible for the new hospitals' operation.

The proposed arrangements were approved, in turn, by the New South Glasgow Hospitals and Laboratory Project Executive Group, the ASR Programme Board and the Performance Review Group (as well as subject to audit by PricewaterhouseCoopers UK) – the diagram below illustrates the arrangements which now form the framework for the project management of the project. Further information regarding the membership and remits of the various groups and sub-groups is attached at Appendix M.

Preformance Review Group
Acute Services Strategy Board
Acute Services Strategy Board Executive Sub Group
ASR Redesign Group
Joint Project Steering Group
Project Team
Project Management Group
Commercial Group
Construction Interface Group
Technical Design Group
Art Group
Joint Commissioning Group
Medical Planning Groups
IT Group
Equipment Selection Group
Communication and Marketing Group
NCH Project Group
Adult / Children's Users Groups
Laboratory Medicine Project Group
Site Co-ordinating Group

6B.2 Project Management

At a project level, the Project Director oversees and has responsibility for the progress and delivery of the Project on a day to day basis. He is supported by the Deputy Project Director, Project Team and Adviser teams as well as the interaction and partnership working between the Board and BCL which is inherent in the NEC contract and facilitated by the combined nature of the workgroups (i.e. resourced by a mixture of Board, Adviser and BCL personnel with the correct skills and experience) that have been established. The requisite daily activity and communication between the parties is encouraged and supported by the co-habitation on site of the Board (including Adviser personnel) and BCL delivery teams.

As is noted in the organogram above, a specific and particular structure of workgroups and hierarchy has been established in order to manage the day to day operations of the project and ensure communications, control and effective use of resources are engaged in progressing the delivery of the Project. As the Stage 2 activity has progressed, the Medical Planning Group and Technical Design Group have come-together and meet jointly to ensure the necessary coverage and interface between the concurrent technical design and medical planning matters. This group meets monthly as a forum to report on progress and management of the issues arising in the design development process.

As is identified in the table below (Table 33 – Governance Workgroups and Remits), each workgroup is comprised of individuals from the Board, BCL and the Adviser team and has an established Remit, Membership, Frequency (day and time) of meeting, and clear reporting line as well as a clearly identified lead (Chair).

With the exception of the 'IT Group' and 'Design and Healthy Environment Strategy Group' (which are sub-sets of the 'Technical Design Group') all workgroups report to the Project Management Group (PMG). The PMG meets fortnightly to review and address matters arising on the project. This includes issues which have been reported/referred to the PMG from a workgroup as well as any other relevant issues affecting the Project no matter their origin (e.g. internal to the Project or from external factors/parties). In the circumstance where matters arise that require to be addressed out with the PMG setting (due to timing/urgency) these are addressed at either the weekly Early Warning (Risk Reduction) Meeting or the fortnightly Commercial Group meeting or, if necessary, by arrangement of a dedicated meeting/discussion. The ability to arrange meetings/discussions at short notice is benefited from the co-habitation on site of the Board, Adviser and BCL teams.

The PMG reports to the Project Steering Group (PSG) on a monthly basis, the PSG being a principles forum to facilitate escalation of matters between the Board and its partner, BCL. Critically, the BCL membership includes dedicated director attendance from out with the immediate BCL project resource thereby providing a corporate presence and visibility to the process and Project. The intention is to review the structure in October 2010 and

make necessary changes to continue to adapt the arrangements to suit the needs of the project.

The Project Director (supported by members of the Project Team or Advisers as necessary on a case by case basis) attends the fortnightly Acute Services Strategy Board Executive Sub Group (ASSB-ESG) meeting. The ASSB-ESG has senior Board representation, including the Chief Executive, Chief Operating Officer, Acute Director of Finance and Head of Capital Finance, and exists to ensure a continuity of communication and reporting between the delivery team and the Board with regard to programme, process and matters arising. The ASSB-ESG has delegated authority to make decisions on project issues to maintain programme as well as to commit funding through management of issues referred by the Commercial Group. In this regard the group has delegated authority in line with the Boards Standing Financial Instructions (SFIs) which provides an agreed delegated limit for the Project Manager, Project Director, Acute Services Strategy Board Executive Sub Group, and Performance Review Group. In turn the ASSB-ESG reports to the Acute Services Strategy Board (ASSB) on a bi-monthly frequency.

In addition to the project management framework noted above, the core Project Team has a weekly meeting at the end of every week which provides discussion of cross workgroup items, allows any matters of concern to be raised and provides a diarised session for the team to receive any essential briefings, information updates or instructions from the Project Director.

The PEP (Project Execution Plan) and the RACI (Responsible Accountable Consulted and Informed) for the Project are appended at Appendix N and O.

Table 32 – Governance Workgroups and Remits

NEW SOUTH GLASGOW HOSPITALS PROJECT CONSTRUCTION MANAGEMENT

Group	Project Steering Group	Project Management Group	Commercial Group	Construction Interface Group	Technical Design Group	Design and Healthy Environment Strategy Group *(Sub-group of Technical Design Group)*	Joint Commissioning Group	Medical Planning Groups	IT Group	Equipment Selection Group
Remit (refer to Group remits paper)	- On a monthly basis identify key Strategic Drivers for the coming quarter. - Carry out a monthly review of Project Strategic Drivers providing direction to the Project management Group as required. - Carry out a monthly review of project issues (reported from sub groups via the PMG) that have not been cleared at sub group level. - Provide direction to the sub groups on the resolution of issues. - Monitor and identify any shortfalls in Project resources. - Monitor critical path of Project Programme	- Manage change control - Monitor short term design, procurement and construction programmes - Monitor project administration ie diary, document control, meetings -Oversee work of sub groups - Monitor sign off progress of sub groups - Monitor Community Benefit progress - Unblock sub group issues - Report key issues to Steering Group	- Manage Changes to Brief - Manage Payment Process - Manage valuations and costs - Manage Risk Register - Manage Early Warning/Compensation Event process - Report key issues to Project Management Group	- Identify short term works on site particularly any that may impact upon the hospital activities - Identify short term Hospital activities that may impact upon the construction works - Communicate construction activities to relevant 3rd parties - Monitor impact of works on surrounding area - Report key issues to the Project Management Group	- Ensure that planning Applications are submitted on time - Ensure that Planning Conditions are discharged on time - Ensure that Building Warrant application is submitted on time and all queries closed out - Monitor design compliance with the ER's and CP's. - Monitor design sign off - Monitor progress of key design strategies – fire, access control, acoustics etc - Manage any derogations from ER's and CP's - Manage any clarifications required against ER's and CP's - Monitor design programme - Manage Mock up and samples programme and signoff - Report any key issues to the Project Management Grp	- Review how art can best be incorporated into the scheme - Agree Project Art Strategy - Advise the design process of opportunities for art - Advise the design process and spatial and technical requirements for art - Report any key issues to the Technical Design Group	- Monitor the production of a Project Commissioning Plan - Monitor the production of a Project Commissioning Programme including operational commissioning - Review the design for "commissionability" - Manage specialist validations required ie pharmacy, CSSD, mortuary - Ensure equipment installation programme co-ordinated with main commissioning programme - Report any key issues to the Project Management Group	- Monitor the Medical Planning Programme and clear any blockages - Monitor resource levels required to meet programme - Monitor the medical planning sign off process and identify any critical delays - Ensure that other sub groups ie IT and Equipment feed into the medical planning process - Manage mock ups for functionality sign off - Monitor production of Room Data Sheets - Report changes to the Project Management Group	- Produce Project IT Strategy in sufficient time to inform the main design - Ensure that IT spatial requirements are co-ordinated with the main design - Ensure that IT technical requirements are incorporated into the design - Ensure that Equipment IT requirements are identified sufficiently early to inform the main design - Report any issues to the Technical Design group	- Monitor the inclusion of Equipment spatial and technical information on the Loaded Plans and Room Data Sheets - Ensure that Equipment spatial and technical information is provided to meet the design programme - Ensure that Equipment selection and procurement is carried out in time to meet the design and construction programme - Manage the approval of Equipment Selection - Manage change control in relation to Equipment provisions - Ensure that Equipment installation and commissioning is integrated into the Joint Commissioning Group - Report key issues to the Project Management Grp

These groups will merge at some point

I:\SSHONING\Child Health\Files\New South Glasgow Project\NSGP - Files\Project Management\NSGH Construction Management - Current.doc

6B.3 Commercial Project Management

Reporting to the PMG, the Commercial Group meets fortnightly to discuss and consider the various commercial matters arising. The requirement to manage and agree commercial aspects of the project is a natural aspect of the design and construction process, provided for in the NEC form of contract governing the Project.

The group consider standing agenda items, such as the Assessment (payment application on a monthly cycle), Early Warning matters, potential Compensation Events and Risk. Issues of a commercial nature that are raised ad hoc by either party (whether through one of the workgroups or otherwise) are addressed where necessary at the meeting.

In order to support ongoing management and assessment of commercial issues, a weekly review of Early Warnings is also carried out (the Risk Reduction Meeting) with relevant individuals attending to supplement the Commercial Group attendees where necessary due to particular aspects within the coverage of EWs or impacting as a result of EWs. Early Warnings are the correct contractual process under NEC for the raising of matters (by either party) that may impact the project, with the weekly session arranged to ensure active and live management of matters raised under this aspect of the project governance.

As noted on organogram above, there presently exists a Construction Interface Group which provides a critical function in the identification of impacts on the existing (Southern General) hospital site, wider neighbourhood and access etc. This group meets weekly, as well as attending the immediate neighbourhood and the existing hospital site where necessary to plan, discuss or oversee activity or proposed activity (e.g. adjustment to parking arrangements on the Hardgate Road campus entrance, demolitions of existing buildings on the hospital campus).

6B.4 Data Management

Complementing the overall contract management of the project and commercial matters is the Sypro web tool, which is kept up to date by the Board and records all of the ongoing contract paperwork and forms between the parties. The use of a live-time process and toolkit allows review and analysis of the status of EWs and other key project management sources at any time during the process.

General data management of the Project is controlled by the use of a web-based system, Aconex, which hosts all drawn and technical information generated as part of the design development. This is managed by BCL with Board and BCL individuals accessing and utilising the system (following training) to issue and respond to design and other project matters such as information requests and the like.

In respect of management arrangements post-implementation, individuals from the Facilities team (Estates) at the Board will be integrated into the construction phase (Stage 3) of the project to work alongside the Supervisor team. This will provide for key individuals to be involved in the construction process, testing and handover (including commissioning) aspects of the Project and therefore have an operational understanding of the components and equipment as well as interfacing with manufacturers and being involved in training and awareness sessions. The Project Team currently includes Facilities representation and this will continue through Stage 3 and into the operational phase, allowing a continuity of understanding and awareness to develop, manage and implement the operational environment from a support services perspective.

6B.5 Communications

A Communications and Marketing sub-group has been formed to strategically plan for the handling of proactive communications milestones, staff communications, marketing, media and joint working with the PR/marketing departments of the contractor and others as appropriate.

The communications and marketing plan will aim to:

- Raise awareness of the plans for the new hospital and the wider redevelopment of the Southern General Campus
- Build and maintain enthusiasm for the project amongst the local community
- Ensure staff, patients, the general public and other key stakeholders are kept updated as plans progress – including key milestones and decisions
- Highlight benefits for patients, staff and the local community – including new or improved facilities and services, economic impact and contribution to the wider regeneration of the Govan area

The main methods which are, and will be, used to keep stakeholders involved include:

6B.5.1 *Internal Communications*

NHS Team Brief - the monthly message from the Chief Executive which is used as the basis for face-to-face communication throughout the organisation

NHS GG&C Core Brief – a real-time electronic bulletin, which is used to brief staff across the organisation on key developments, decisions and achievements

NHS GG&C SN (online and print) - the monthly NHS GG&C staff magazine, which is circulated to 44,000 staff across the organisation and available online via the intranet. This has already carried several features on plans for the new hospitals

NHS GG&C Staffnet – Attracting 71,000 visitors a day, the intranet has dedicated pages on the new hospitals to keep staff informed of progress

Staff Briefings – in recognition that there is no substitute for face-to-face briefings, all the above is underpinned and supported by a regular programme of staff briefings and open drop-in sessions to update staff on progress and activity

6B.5.2 *External Communications*

The NHS GG&C Website receives around 60,000 hits a month. Within one click, visitors are taken to key information about the Southern General Campus with links to the latest news and information on the two new hospitals. The web is undergoing a redesign to deliver a stronger emphasis on patient and public information. Over the coming months the hospital pages will be enhanced with video footage and flythrough and other available visuals to help promote the development.

Health News – the quarterly NHS GG&C newspaper is distributed with three titles, the Herald, Sunday Herald and Evening Times, and is widely distributed across Greater Glasgow and Clyde. It is also sent to the 5000-strong Involving People database which includes politicians, community representatives and other individuals with an interest in health. It has already carried a series of articles on the hospital modernisation programme and will be used to provide regular updates on the redevelopment of the Southern General Campus as plans progress.

Media relations – the Communications Directorate will work with project leads and others to identify promotional opportunities to maximise media coverage on the redevelopment of the Southern General Campus. There has already been widespread media coverage of the announcement of the successful bidder for the contract and of the sod cutting for the laboratory development. This proactive work will inform the development of an action plan of activities to promote the new hospitals on an ongoing basis. Communications will also explore opportunities to develop campaigns and joint initiatives with key media partners.

Stakeholder Briefings – regular one-to-one briefings with key stakeholders such as local MSPs, business leaders and university colleagues will also be arranged to ensure they are kept updated on the development of the Campus.

6C. CHANGE MANAGEMENT

6C.1 Defining the Organisational Development Strategy

NHS GG&C has a major capital programme and service change programme in place to continue to implement the Acute Strategy Review (ASR) agreed in 2002. The key areas of focus over the next 3 years are:

- Continued planning for the New Glasgow South Hospitals, the new Children's Hospital and the Laboratory Strategy
- Redesign of services for the North East of the city to transfer inpatient services from Stobhill to Glasgow Royal Infirmary
- Centralisation of Vascular and Renal Services to the West and the rationalisation of Urology Services to 2 sites
- Continued integration of Clyde services
- Continuing to support a single system culture
- Integration and flow of patient information through the implementation of the Electronic Patient Record and the Patient Management System

The Organisational Development function will support these priorities by developing capability and capacity within the organisation to redesign services and manage change/support individuals and teams through significant change while also promoting and developing a culture of continuous improvement, in line with the Quality Strategy for NHS Scotland, through a strategic approach to LEAN.

The Head of Organisational Development (OD) is responsible for ensuring the development and implementation of divisional and directorate level OD Plans on an annual basis to support both short term and longer term change management processes arising from service modernisation and ongoing continuous improvement, aligned with board priorities and targets. OD Advisors provide local support to individuals and teams within each of the directorate management teams to develop capability and capacity for leading and managing change on an ongoing basis.

There is considerable experience of managing large scale change within the organisation and we are keen to ensure that lessons learned from previous change, e.g. the recent opening of 2 Ambulatory Care Hospitals/hospital closures and transfer of services to new sites, are incorporated into the overall planning process for the new south build. In addition we will work closely with other health boards through formal and informal networks to ensure continual sharing of experience and learning from other large scale change initiatives across NHS Scotland.

The overall strategic approach and planned programme of OD support is discussed and approved via the ASR Group, of which the Head of OD is a member and which reports to the Acute Services Strategy Board.

OD plans will be based on an Organisational Effectiveness Model capturing four workstreams: People and Other Resources; Structure and Infrastructure; Business/Service Processes; Values and Culture. Each of the areas impacted by change will be mapped to define the current position and undertake a gap analysis that will enable OD interventions to be identified and delivered in partnership with other support functions including H&IT, HR, Learning and Education. This will ensure that staff are well informed of proposed changes to service delivery and have the opportunity to provide input and feedback as the change is being planned and incrementally implemented over the next few years.

6C.2 The Change Management Framework - Summary of Core OD Themes

The ASR Group has agreed that the following areas will form the focus of any planned organisational development activity to support the change management agenda:

a) Supporting the engagement/communication strategy

There are significant workforce issues arising from the development of new service models and workforce planning which will be achieved through proposed centralisation, modernisation and redesign of services and the planned re-alignment of services at the Vale of Leven and the Royal Alexandria Hospital and between Stobhill/GRI and West Glasgow Hospitals.

In addition the implementation of the Electronic Patient Record and the Patient Management System (PMS) are significant change programmes which also require the adoption of new ways of working as well as changes to existing roles and practice.

The Head of OD participates as a member of the HR Workforce Engagement Group to identify how OD can best support communication and engagement processes aligned to the transitional arrangements. Senior OD Advisors are required to participate in local workforce engagement groups and continue to work closely with directorates to agree appropriate OD support at local level. All working groups and senior committees have staff side representation to ensure full consultation on any proposed changes that impact on staff.

b) Managing change

The acceleration of the ASR is a major change programme for the Acute Services Division and we will work closely with identified managers to ensure that they build on existing skills to lead change effectively through the use of a range of tools/techniques and OD interventions as well as providing advice and support on typical reactions and resistance to change and strategies for addressing these.

There is a variety of leadership development opportunities currently in place ranging from modular programmes, breakfast seminars, action learning sets in addition to coaching and mentoring arrangements. We will continue to provide leadership development opportunities based on annual needs analysis to ensure managers and clinical leaders at all levels possess the necessary skills to lead and manage change within their area of responsibility. This includes promotion and raised awareness of national and local organisational change policies and the Change Management Toolkit recently developed by NHS GG&C. Focused work is planned in the autumn of 2010 to consider the overall organisational culture, aims and aspirations and ensure appropriate leadership styles and behaviours are in place to support this.

Through discussions with Directors we will define specific teams requiring OD facilitation to further support them throughout the change process. Typically this type of approach will be used to flush out issues using tools/techniques such as SWOT Analysis/Current vs Future Landscape, Commitment Planning and the Change Curve to help understand resistance and reactions to the change process and to provide an awareness of the human behaviours associated with change.

c) New teams/integrated teams

It is clear that all of the changes will result in the integration of existing teams and in some cases the establishment of new teams. The OD function has considerable experience in supporting teams through transformational change and it has been agreed that work will be undertaken early in the change process to identify concerns/issues and address typical reactions and resistance to change. This may include:

- Exploring the practical issues arising from integration and the merging of 2/3 teams into 1 by establishing different ways of working, challenging traditional thinking and seeking agreement and commitment to newly defined ways of working to support effective integrated models of delivery
- Identifying values and addressing cultural and identity issues within this large and complex organisation e.g. attitudes and behaviours and unpicking the unwritten rules which define " how we do things around here"
- Clarifying new roles/responsibilities and standard operating procedures or integrated processes required in the new model
- Expressing and addressing fears/anxieties/hopes and aspirations and assumptions/misconceptions arising from planned change interventions
- Considering how best to ensure that staff moving from previous site(s) are not just expected to "be made to fit "into an existing site
- Ground rules/action plans to support all of the above and gain commitment to integrated team working

d) Redesign/LEAN

NHS GG&C is in the early stages of implementing a strategic approach to continuous improvement based on LEAN methodology. Initial work is focussed on defining priority areas for improvement activity across the board and the Head of OD will work closely with the Executive Sponsor, the Joint Operational Leads and Directors to identify priority improvement initiatives aligned to the ASR and implementation of PMS which will be undertaken during 2010/11, and on annual basis thereafter, to support the longer term strategy and ensure that services are appropriately designed prior to the transfer of services and the opening of new hospitals. An example of this is the recent Rapid Improvement Event within Renal Services which will inform both the short term centralisation of renal services on the Western Infirmary

General site as well as the longer term planned transfer of this service to the new south hospital.

We will continue to develop the capability and capacity across a range of managers and clinicians through the provision of a variety of training interventions. Building on existing redesign activity and the central provision of a core curriculum of redesign training we will place stronger emphasis on a whole system approach to redesigning patient pathways and administrative processes to shift the balance of care.

Desired outcomes for all improvement activity will be clearly defined at the outset and monitored through defined management structures and the Board's performance management arrangements to ensure sustainable change is achieved and provide evidence of benefits realisation and return on investment.

e) Longer term implications

While much of the initial focus has been on changes planned in the short term with specific emphasis on the transfer of inpatient services from Stobhill Hospital and centralisation of services to the West there have also been detailed discussions with directors/senior clinicians and the Head of OD to begin to consider longer term issues arising from the new South Glasgow build including Laboratory Services and the New Children's Hospital.

Planned OD interventions are in the process of being defined as pilot areas of work to consider operational issues and the full implications of the proposed service model and involve key stakeholders at the onset to ensure that individuals and teams have an opportunity to engage in the detailed plans required to support the full business case.

These areas of planned work will examine the cultural and workforce implications arising from the change, identify training and development requirements, agree areas for redesign to develop new processes and clarify changes to working practice and how this impacts on individual and team roles and responsibilities.

Examples of planned OD interventions include an initial session scheduled for November 2010 to consider the operational issues arising from the proposed Acute Assessment Unit which will capture key lessons learned from the opening of the Ambulatory Care Hospitals and reflect on ongoing progress with the planned transfer of services from Stobhill Hospital, in addition to a large focus group event scheduled for October 2010 focused on the implementation of the Laboratory Strategy.

Outcomes from these events will be reported via the ASR Group to inform future recommendations and ongoing implementation of the Organisational Development Strategy. This will ensure that all activities are targeted towards the delivery of the necessary service changes required to facilitate the

projected bed model and provide valuable learning early on in the planning process.

6C.3 Change Management Plans:

6C.3.1 *A Planned Approach to Organisational Change*

The overall emergent picture is one of continuous change and redesign impacting on individuals and teams at all levels. Experience has shown that often the people issues associated with change are addressed once the change is implemented or after the change has been introduced. It is therefore intended to have a more planned approach to change management in place. This will be an incremental process of change management and plans will evolve over the next 3 years (which will inform and be informed by local OD plans produced and reviewed annually) to support mangers and clinicians address resistance to change and challenge attitudes and behaviours to ensure effective implementation of the defined changes whilst redesigning key services prior to the opening of the new south hospitals.

A wide range of management groups and working groups are already in place and have informed the proposals set out in the full business case. A detailed programme of planned OD priorities is currently being defined to support the imminent transfer of inpatient services from Stobhill Hospital to GRI and the centralisation of identified services to the West early in 2011. During July and August a series of meetings were scheduled with the Head of Organisational Development, directors and key stakeholders to scope out the requirements to facilitate these transitional arrangements and consider potential targeted areas of OD work to support the New South build and the planned implementation of the Patient Management System.

We are in the process of discussing this in more detail with the relevant directors as executive sponsors of the change process and with relevant clinicians and managers to identifying wards/departments affected by change and plan a series of multi-disciplinary focus groups and/or events to be scheduled between September 2010 – January 2011 and then longer term, which the internal OD team will facilitate.

All planned interventions will focus on existing and planned clinical pathways to inform future model(s) of service delivery and consider the workforce implications arising from any proposed change. The multi-disciplinary approach will be designed to engage clinicians, staff side representatives and staff throughout the process to inform the final model and ensure effective communications of the intended change(s). Key support services (e.g. Medical Records, Facilities and Diagnostics) will also be represented in any planned interventions to ensure consideration is given to wider service implications.

The range of OD interventions designed to support this will include facilitated team sessions, one to one coaching and leadership development through an overarching OD Framework to ensure a consistent whole system approach to the change process.

Processes are in place to ensure close working with the HR and Learning and Education functions both informally and formally via HR Workforce Engagement Groups to ensure both transactional and transitional change management arrangements are fully considered throughout the process.

Measurable outcomes will be defined in the overall OD Strategy for all planned OD interventions to track progress and monitor the effectiveness of OD support in the implementation of the ASR. Clearly defined objectives and outcomes will be defined for all planned OD interventions and will be evaluated throughout the process with regular reports via the ASR Group to ensure delivery of the overall change plans and that corrective action and/or additional OD support is identified where necessary thus ensuring that the overall aims and objectives are achieved within agreed timescales. Benefits realisation arising from the change will include efficiency savings, increased productivity and improvements to the quality of patient care.

6C.3.2 *Change Management Planning – Current Activity and Initiatives*

As noted above, planning and readiness for service activity is under way in a range areas and activities. Two specific and essential areas of preparation in respect of the project are in nursing and facilities management, where the following activity is under way and planned.

6C.4 Nursing Readiness For Service Change

Professional nursing is about delivering a service that embraces the human values of caring and compassion alongside the necessary technical and decision making skills. The report *Modernising Nursing Careers: Setting the Direction (2006)* defines four priority action areas:

- Developing a competent and flexible nursing workforce.
- Updating career pathways and career choices.
- Preparing nurses to lead in a changing healthcare system.
- Modernising the image of nursing careers

The nursing workforce for the new hospitals is predicated on the agreed Board wide bed model. The generic ward establishments have been calculated using nationally validated tools in conjunction with the national Nursing & Midwifery Workload and Workforce Planning Programme.

Consensus amongst Nurse Directors within Scotland is that single room accommodation in itself should not increase the number of nurses required to care for patients and high quality nursing care should be achieved by appropriate staffing levels. Over the build period the Board will work towards

achieving the appropriate nursing workforce profile to support the operational management of single rooms.

With reconfiguration onto one site there will be economies of scale leading to increased efficiencies and better use of senior nurse resources.

Clinical leadership is vital to the delivery of safe and effective care within the new hospital. The Senior Charge Nurse (SCN) role is a key focus of Modernising Nursing Careers in order that the leadership of care quality is at the front line of patient care. The SCN has a pivotal role in ensuring safe and effective clinical practice, managing and developing their clinical teams and enhancing the patient experience. Each ward will have a SCN, the ward leader, who will play a key role in maintaining standards of high quality care and supporting continuous improvement. The SCN will be supported by a team of Registered and Unregistered nursing staff.

There will be a greater focus on the contribution & productivity of Clinical Nurse Specialists (Band 7/6). There will be a realignment of resources within the Band 5 Generalist Registered Nurse Co-hort, Assistant Practitioner and Housekeeper roles are currently being developed & piloted within NHS GG&C supported by an Education and Development Framework that describes the key capabilities, knowledge and skills required for the role. This has been designed to enable a flexible approach to learning and development and has been aligned to the NHS Knowledge and Skills Framework.

Assistant Practitioners work at level 4 of the NHS career framework developed by Skills for Health and will carry out some tasks traditionally undertaken by a Registered Nurse releasing those staff to deal with more complex cases.

6C.4.1 *Quality and Productivity*

Nursing quality & productivity is vital to the delivery of safe and effective care within the new hospital. The Board has ensured that the leadership of care quality is at the front line of patient care by the implementation of *Leading Better Care* to develop the pivotal role of the SCN in ensuring safe and effective clinical practice.

6C.4.2 *Leading Better Care*

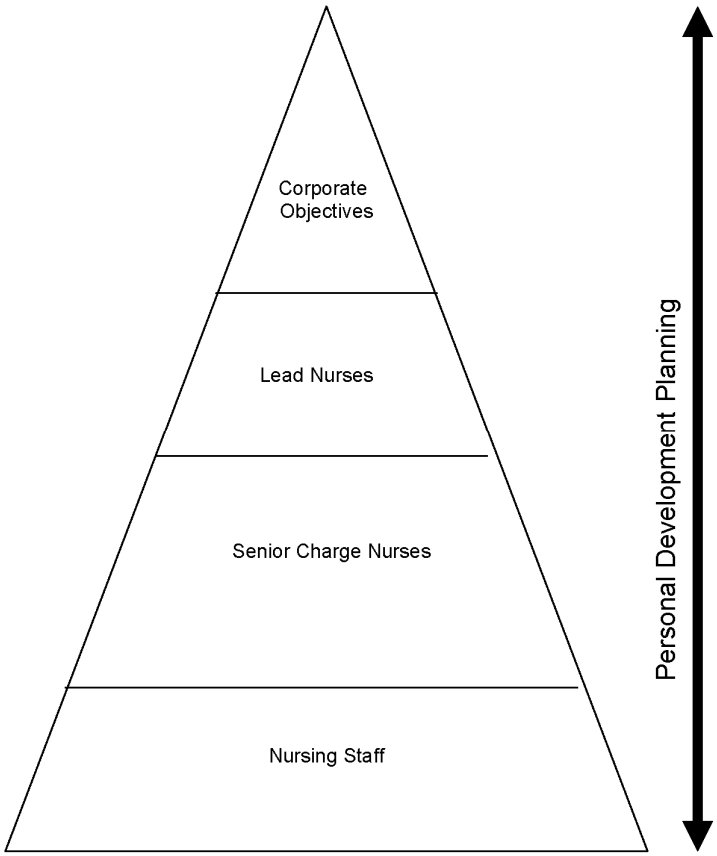
The Board has a strong focus on ensuring SCNs have the skill and tools to allow them to prioritise improving the patient experience. The aim of *Leading Better Care* is to create a modern clinical leadership role to enable frontline Band 7 Senior Charge Nurses (SCN) to maximise their contribution to delivering safe and effective care by developing their leadership capacity and capability. A national role framework has been developed which reflects four areas of SCN responsibility;

- to ensure safe and effective clinical practice
- to enhance patient experience

- to manage and develop the performance of the team
- to contribute to the delivery of the organisation's objectives

Through *Leading Better Care* Senior Charge Nurses are being empowering to be clinical leaders and guardians of safety and quality in their area. *Leading Better Care* establishes a national role framework (developed in partnership with NHS Education for Scotland) for SCNs working in hospital settings across the Board area. This has been rolled out across the Board as a key priority of the Nursing & Midwifery Strategy with key milestones and timetable co-ordinated by the assistant Director of Nursing. Further, the associated development, testing and roll-out of *Clinical Quality Indicators* (CQI) for *Falls Prevention*, *Pressure Area Prevention* and *Nutrition* provides real support to the SCN in improving care quality and provide direct read across to associated national workstreams. Close links have also been made between Leading Better Care and the roll-out across the Board of *Releasing Time to Care (Productive Ward)*. Together these initiatives are driving and sustaining real changes in care quality.

The Board has successfully delivered 8, with the 9th and last cohorts of Leading Better Care being delivered in October 2010. All SCN's will be working within the revised role by 2010. During the build cycle one cohort per year of Leading Better Care will be delivered to ensure any new SCNs in post have the key clinical leadership knowledge and skills for the role and it is expected that after attending this programme SCNs will develop and be supported in their leadership role. SCN's will facilitate ongoing Personal Development Planning with staff members through the KSF Framework to achieve organisation goals and the change process throughout the commissioning period. The cascade of objectives in the personal development planning context is illustrated below.



Leading Better Care reflects the need for SCNs staff to be clearly identifiable and visible to the public therefore the Board have adopted the national navy blue uniform for Senior Charge Nurses as described in CEL 36 (2009) and CEL 46 (2009).

Clinical leadership is a key driver for improving the quality of care that the patient receives. In conjunction with this, NHS GG&C are supporting senior nursing staff through the 'Prepare To Lead' programme. This programme creates a co-hort of leaders equipped to view issues strategically when delivering high quality healthcare. This means that nursing staff will be appropriately prepared to deal with changes in the nursing model.

6C.4.3 *The Releasing Time to Care Programme*

Research carried out by the NHS Institute found that ward nurses in acute settings say that they do not spend enough time on direct patient care, and that patient care suffers as a result. In 2007, the NHS Institute for Innovation and Improvement launched a programme that aimed to combat this. The 'Releasing Time to Care: Productive Ward' programme is being implemented across NHS GG&C alongside Leading Better Care.

Continuous quality improvement through the application of LEAN methodology, *Releasing Time to Care & Clinical Quality Indicators* will be consolidated to support the single room approach during the build & commissioning period to improve patient journeys, increase efficiency and contribute to more effective ward processes and procedures.

The Releasing Time to Care programme provides a structured framework for the use of continuous improvement methodologies with the ultimate aim of 'releasing time to care' in ward areas. This Programme has the potential to support SCNs to use a variety of quality improvement tools in their areas with the aim of having more capacity within the current resource envelope. The Releasing Time to Care Programme aims to combine factors to produce an environment that will:

- Increase the proportion of time staff spend on direct patient care
- Enhance the patient experience
- Reduce costs and all forms of waste
- Improve safety
- Increase staff well being

The Releasing Time to Care programme is split into parts, three foundation modules and eight process modules. To date, the Board have rolled out 2 cohorts of the programme and have concentrated on the three core modules:

- Knowing how we are doing (recording, displaying and using key measures)
- The well organised ward – (workplace organisation)
- Patient status at a glance – (improving the patient status display board)

Whilst the Productive Ward is a 'bottom up' methodology, its success depends on clear and visible links to the organisation's strategy. The objectives of the programme reflect clearly Board's mission and values and an improvement culture aimed at achieving a high quality experience for every patient.

6C.4.3 *Clinical Quality Indicators*

Four initial clinical quality indicators have been developed which are supported by a national electronic quality improvement programme. The background to Clinical Quality Indicators (CQI) is *Planning Ward Nursing - Legacy or Design?* (Audit Scotland 2002). This report emphasised that despite high numbers of nursing and midwifery staff in the NHS workforce, there was limited information available to compare nursing numbers, costs and impact on quality.

This is linked into the Scottish patient Safety Programme & Leading Better Care. These indicators are:

- pressure ulcer prevention,
- falls prevention,
- food fluid and nutrition,
- and monitoring and observation.

The SCN is responsible for ensuring measurement takes place but this can be delegated to anyone in the team as they deem appropriate. This provides SCNs nurses, when they are completing their CQIs compliance, with real-time reports and data to support where they are doing well, and highlight areas that require further work and are an important tool for senior charge nurses to establish a continuous quality improvement culture in their areas.

6C.4.4 *Clinical Nurse Specialists*

In the Board area 75% of the working week is spent on clinical activity however the aim is to increase this to 80%. In order to achieve this target, the Board is undertaking a CNS Workload Project to develop a principled approach to CNS's job planning. CNS's will be closer aligned to specific clinical areas and the aim is to allow one ward based clinical shift per week. In addition these nurses can provide a visible role model, support and advise ward staff whilst maintaining their own clinical credibility and competence.

6C.4.5 *NHSScotland Healthcare Quality Strategy*

The Quality Strategy has been incorporated into the Board's Nursing & Midwifery Work Plan 2010/11 and will be embedding into Directorate work streams.

6C.4.6 *Education*

Pre- and post – registration nursing and midwifery education is at the centre of nursing care delivery for patients, their families, relatives and carers. This entails the development and delivery of nursing care packages to ensure high standards of care are maintained and developed within a continuous quality cycling approach. Significant investment has been made in the clinical educator and practice development role to support the development of the registered practitioner and support staff to continue to deliver high quality patient care.

There are close links with the Schools / Departments of Health, Nursing and Midwifery within the University of Glasgow, University of the West of Scotland and Glasgow Caledonian University to support the clinical practice experience of undergraduate and pre-registered nurses, midwives and Allied Health Professionals. The clinical areas and environment enable undergraduate students to develop the skills required to care for patients under the supervision of a registered practitioner. There are many areas with international recognition for clinical practice within NHS GG&C, consequently practice placement experience is frequently requested from nursing students from other countries within the United Kingdom and the European Union.

6C.4.7 *Research*

There is a growing cadre of nurses developing research skills who are employed within the within the Clinical Research Facility and some specialist clinical areas, e.g. Oncology. However, in general nurses and midwives involved in clinical research tend to undertake this as a component in their academic studies, with an increasing number of nurses / midwives undertaking academic study at post graduate level. Although research activity within nursing and midwifery continues to develop there is a commitment for Clinical Nurse Specialists and Advanced Nurse Practitioners to be actively involved in nursing research to further develop the nursing care of patients and their families, relatives and carers.

6C.5 Facilities Management

The Facilities Management strategy for the New South Glasgow Hospitals and Lab Building has been developed to ensure that operational processes are enhanced in order to provide a patient focussed service delivery and that this service evolves through investment, innovation and acquired experience. The Board wish to provide a sustainable service through appropriately designed and well maintained facilities and also to be flexible and responsive to accommodate future change. FM user groups were established with representation from Catering, Portering, Domestic, Procurement and Decontamination Services to agree the design and layout of the FM accommodation in the 1:200 and 1:50 design process and FM were also represented on the Clinical Planning User Groups.

Highlighted below are some of the key developments which will allow FM to provide effective and efficient services to the patients and staff in the new hospitals

6C.5.1 *Automated Guided Vehicles*

The FM strategy for the Lab and New Hospitals has been developed through the design process and the key strand of this strategy has been the detailed design and the functionality of the system of Automated Guided Vehicles (AGVs). The installation of automated material handling systems is rapidly becoming a worldwide standard within large new build health care facilities. The installation of such systems can produce higher standards of service performance as well as leading to substantial whole life revenue cost savings, predominantly staff savings. The system also reduces the risks associated with the moving and handling of goods and services undertaken by FM staff.

Through dialogue with members of the Project Team, FM Staff and the BCL design team the Board have developed a programme of AGV movements which will transport the majority of goods around the hospitals; these goods will be transported in dedicated segregated clean and dirty FM lifts and in non patient/public areas.

This dialogue was undertaken through one to one meetings with heads of services, workshops and simulations as well as a visit to St Trondheim's Hospital in Norway where the system was seen in operation in a large acute hospital setting and information was gleaned from staff about their experiences.

Through design development the 'carts' used to transfers goods will be compatible with the AGVs and will allow the transport of trolleys used for, catering, linen/laundry, sterile supplies, and general supplies. There will also be the ability to exchange waste bins on a full for empty basis and remove the double handling of waste by FM staff.

6C.5.2 *Pneumatic Tube System*

Pneumatic tube systems are currently used in some areas within acute hospital sites across NHS GG&C but the installation of 92 send and receive stations in all wards and department within the new hospital will provide a comprehensive system for high speed delivery of specimens to dedicated labs in the new laboratory building. The system also includes a direct link between the emergency Department and Pathology to provide a high priority service. This system will improve the efficiency and speed of the specimen delivery service and free up portering time for patient movement duties. The location of the stations has been agreed through the user group meetings and the use of the system has been developed in consultation with the Laboratory Medicine Planning Team.

6C.5.3 *Service Yard/Waste Compound*

A key lesson learned from previous healthcare projects has been the location of the FM service yard to ensure that the transitioning of goods into and out of the hospital is undertaken quickly easily. This was the key factor in the decision to locate the service yard within the footprint of the new Laboratory Medicine Building with an underground tunnel to link to the new hospitals. This location allows the high volume of goods and service deliveries to be made separately from the main hospital and that roads and entrance are kept for 'clinical' traffic. The service yard provides a dedicated area for goods to be received, checked and then efficiently despatched to their destination with the majority of these transported by the automated guided vehicles. The service yard also accommodates the waste compound which is capable of sustaining a wide range of waste products which are generated from the new buildings and also the waste from the whole of the Southern General campus. Waste from wards and departments will be stored temporarily in waste disposal holds in wheeled carts which will be taken to the AGV hold area and then transferred into dedicated 'dirty' lifts and taken directly to the waste compound. As a full waste cart is removed a clean, empty cart replaces it. The service yard/waste compound will operate 24/7 to ensure that goods and services are available to wards and departments as required.

6C.5.4 *FM Readiness*

As indicated above the new hospitals will include systems which will allow FM to deliver more effective and efficient service delivery and in order for the FM team to be prepared a detailed commissioning plan will be developed. The first step of this will be to ensure that the appropriate staff are identified and supplied with the correct level of training to ensure the systems are maintained and operated to the optimum efficiency. This programme of training will be planned well in advance and will involve NHS FM staff working closely with the BCL team as the buildings are commissioned in readiness for handover. In order to prepare the appropriate staff identification of the tasks and duties that require to be undertaken and a review of the skills needed will be developed and the appropriate job descriptions compiled. The training programme will include: sub-contractor introductions, classroom and hands on training, geographical familiarisation and control system user training.

The handover of the building from BCL to the Board's Director of FM will include an asset register, operation and maintenance manuals, as-built drawings, health & safety files and training manuals which will be used to set up a preventative maintenance schedule for ongoing operations.

6D. CONTRACT MANAGEMENT ARRANGEMENTS AND PLANS

This Section considers the arrangements in place to mange contract change, both during the construction phase and into the operational phase. This outlook therefore considers known/expected change as well future, as yet unknown, contractual change.

6D.1 Construction Phase Change

The Stage 3 and 3A construction activities are governed by the NEC contract, as identified and discussed in Section 4.4 of this document. As is normal practice in construction related agreements, the contract makes provision for change – detailing the procedures to be followed and how any associated risks, costs and impacts are to be addressed and treated between the parties to the contract.

Notwithstanding the provision for change in the contract, the process around change requires to be managed and governed by the Board. To that end the governance and project management framework identified in Section 6.2, above, are integral.

It is possible that a Change is required or requested during the construction phase, with the origin of the proposed adjustment being service led (i.e. clinical) or technical. No matter the origins of such a proposed Change, the business justification requires to be determined and clear and approvals are necessary in line with the established delegated authority provisions.

- Project Manager approval of expenditure up to £10,000;
- Project Director approval of expenditure up to £100,000;
- Acute Services Strategy Board and Executive Sub-Group approval of expenditure up to £1.5m; and
- Performance Review Group approval of expenditure over £1.5m.

Notwithstanding the approval levels and guidance, it is important to note the regular contact between senior personnel in the Board project team, adviser team and the contractor through the meeting and communications structures, including specific provision of time dedicated to the review, discussion and agreement of potential change on a weekly basis. This is carried out in a partnering arrangement and environment, with individuals aligned as to the aims and objectives of the project as well as well sighted on the remit and vision to be delivered.

6D.2 Potential Future Change

The lifetime of the facilities will see change, driven by differing requirements, aims and outcomes. These may be internal to the Board (service led) or external due to regulatory, legislative or other factors, for example.

Service led change during the operational phase of the hospitals will manifest itself in the ASR Redesign Group (or equivalent established forum) and from a governance perspective will require to pass into the approvals structure for consideration based upon business justification proposals.

The role of the Chief Operating Officer is therefore critical in the look forward consideration of Change and management of change, with business cases (business justification) for proposed change of any origin requiring to be

assessed, considered and approved (or rejected) by the COO (supported by directors as necessary).

The ongoing remit of the Board, with regular meetings including directors and organisational development teams, as well as linkage and responses to national initiatives and requirements are all important and relevant in the approach to and consideration of potential future change. That is, the Board being a cohesive and collaborative entity supports the identification, consideration, management and decision making around future change a defined activity which should assist in the management of uncertainty and continuity of appropriate service delivery.

6E. BENEFITS REALISATION

A description of the anticipated benefits of the project and how they will be measured is given in chapter 2H and appendix D.

6F. CONTINGENCY PLANS

As is illustrated and described in Chapter 6B, the Project is well resourced and managed with an appropriate set of workgroups and reporting lines such that progress and matters arising are visible and addressed by the appropriate individuals and groups (which may be a combined Board/contractor/adviser group).

Given the structure as well as the frequency and detail of reporting, there is therefore an in-built risk management of progress in the project and awareness of key dates and deliverables throughout the various individuals and teams.

From a construction (including commissioning and handover) perspective the achievement of key dates and ultimately having the hospitals complete and ready for occupation is a managed activity that is reported accurately and frequently – which will allow identification and reporting to be escalated and contingent steps implemented should the service delivery dates be threatened.

As the clinical services will (with the exception of some aspects of new service) be being delivered on other sites (including the existing Southern General) prior to the new hospitals being opened, the ultimate contingent position should the new facilities not be completed on time would involve continuity of clinical service through continued delivery at the current sites and re-appraisal of the timing and implementation of the Board's transfer programme and plans. This would have communication and logistics (as well as cost) impacts, but does provide an overall contingent position.

In order to minimise loss of service/business interruption once the hospitals are operational, the Board requested inherent aspects of resilience to critical failures and mitigation of operational interruptions to be a key feature of the

planning and design of the hospitals. The requirements within the ERs include, for example, plant rooms being sectionalised with waterproof floor slabs and services on raised grids.

Additionally, the treatment of defects in the contract provide for a 24-month defects period with a prioritisation of timescales for correction of defects dependant upon the nature of the defect in question. This approach again provides a contingent position to minimise loss of service and impact on service once the hospitals are operational.

6G. POST PROJECT EVALUATION

This Section considers both Scottish Government Gateway reviews as well as Post Project Evaluation (PPE) as considered by the *Scottish Capital Investment Manual* (SCIM).

6.G.1 Scottish Government: Gateway Reviews

A Gateway 3 Review was undertaken by the Scottish Government Gateway Review Team between 4th-6th October 2010. The project was awarded a green level of Delivery Confidence Assessment, defined as successful delivery of the project/programme to time cost and quality appears highly likely and there are no major outstanding issues at this stage that appear to threaten delivery significantly.

The Gateway report is very positive and recommends that the project should develop a case study of the procurement approach (so this could be shared with other NHS and Government organisations). There are two actions highlighted to be completed before the next gateway review and these are to add some indirect risks (e.g. political risks) to the risk register and continue to develop the benefits management plan to define targets and gather baseline data.

6.G.2 Post Project Evaluation (PPE)

The Project Evaluation requirements are a very important feature in the lifecycle of the hospitals and in accordance with SCIM allowances have been made within both the project plan and budget to undertake evaluations throughout the construction phase, and 12 months after commissioning. There will also be a requirement to undertake follow up evaluation at 5 year intervals and this is recognised by the Project Team.

The construction phase evaluation will be continuous and will involve the Project Team preparing monitoring reports at regular intervals covering:

- Management procedures
- Design Solutions
- Contractor's Performance
- Expenditure forecasts

Upon completion, an initial review of delivery and functional suitability will be undertaken prior to occupation by a multi disciplinary group representing a wide range of stakeholders in the project.

Key issues that will be addressed in this review will include:

- Was the project completed on time?
- Was it completed within the agreed budget?
- What were the reasons for any delay?
- What action would management recommend to prevent future problems?
- Functional suitability of the building?

The Post Project Evaluation will commence once the buildings are fully occupied and the services have been allowed to bed-in. It is anticipated that this will be approximately 12 months after practical completion and handover of the facility, and will be undertaken by the same group which will assess the performance of the facility against the objectives as agreed.

The project evaluation will be aligned with timelines for the Laboratory facilities, such that the reviews are taking a holistic view of the hospitals, laboratories (including FM areas) and energy centre on a look forward basis. This is seen as a suitable and relevant approach in order that benefits are considered collectively and issues to be recorded and managed are identified with consideration of the wider facilities and impacts.

CONCLUSION

This FBC revisits and revalidates the proposals for a new adult and a new children's hospital on the Southern General Campus. These proposals are fully in line with the phased construction contract signed between NHS GG&C and BCL in December 2009. The new adult and children's hospitals form the pivotal phase of the ASR Strategy and therefore the key transitional aspect of the transformation of service delivery by the Board.

Summary of Incident and Findings of the NHS Greater Glasgow and Clyde: Queen Elizabeth University Hospital/Royal Hospital for Children water contamination incident and recommendations for NHSScotland

Date: 20/12/18

Status: Final v2

Contents

Executive summary

NHS Greater Glasgow and Clyde (NHSGGC) are currently investigating and managing a contaminated water system across the Queen Elizabeth University Hospital (QEUH) and Royal Hospital for Children (RHC) with probable linked cases of bloodstream infections associated with wards 2A/2B RHC.

Wards 2A/2B RHC is a haemato-oncology unit, also known as Schiehallion, and houses the National Bone Marrow Transplant Unit. In 2016 a patient within ward 2A RHC was identified as having a blood stream infection (BSI) as a result of *Cupriavidus pauculus*. NHSGGC investigations included water samples from outlets within the aseptic suite of the pharmacy department where the parenteral nutrition received by the child was prepared. *Cupriavidus pauculus* was isolated from water samples taken from a tap on a wash hand basin within this area. The wash hand basin was subsequently removed as a result. A further single case of *Cupriavidus pauculus* was identified in September 2017 however no environmental or water sampling was undertaken at this time.

Between the period of 29th January and 26th September 2018, 23 cases of blood stream infections (11 different organisms) with organisms potentially linked to water contamination were identified. As a result further testing of the water supply was undertaken across both hospital sites early in the investigation. This testing identified widespread contamination of the water system. Control measures implemented included sanitisation of the water supply to ward 2A, installation of the use of point of use filters in wash hand basins and showers in ward 2A/B and other areas where patients were considered high risk. Drain decontamination was undertaken and on 26th September 2018 wards 2A/B were closed and patients decanted to ward 6A QEUH and 4B QEUH. There have been no new linked cases identified since the decant of the patients.

NHSGGC requested support from Health Protection Scotland (HPS) with this incident on 16th March 2018 and Scottish Government invoked the national support framework on 20th March 2018 which requires HPS to lead an investigation and provide board support. This report is a summary of the findings from this ongoing investigation for the period of 29th January 2018 – 26th September 2018. Further technical work is being undertaken for NHSGGC by Health Facilities Scotland (HFS).

Background

Health Protection Scotland

HPS plan and deliver effective and specialist national services which co-ordinate, strengthen and support activities aimed at protecting the people of Scotland from infectious and environmental hazards.

They do this by providing advice, support and information to health professionals, national and local government, the general public and a number of other bodies that play a part in protecting health.

HPS is a division of NHS National Services Scotland which works at the very heart of the health service across Scotland, delivering services critical to frontline patient care and supporting the efficient and effective operation of NHS Scotland. The specialist group involved in supporting NHSGGC in this investigation is the antimicrobial resistance and healthcare associated infection (ARHAI) group. The lead from HPS in this investigation and author of this report is a Consultant Nurse in Infection Prevention and Control with a specialist qualification in water and ventilation and is also the national HAI built environment and decontamination lead. HPS have been supporting NHSGGC with this incident since 16th March 2018. This report has been produced with full support from colleagues across NSS.

National Support Framework

The National Support Framework[1] is a structure that sets out the roles and responsibilities of organisations in the event that a healthcare infection outbreak/incident, is deemed to require additional expert support. The National Support Framework may be invoked by the Scottish Government HAI/AMR Policy Unit or by the NHS Board to optimise patient safety during or following any healthcare incident/outbreak(s)/data exceedance or Healthcare Environment Inspectorate (HEI) visit/report. Scottish Government invoked the national support framework[1] on 20th March 2018

NHS Greater Glasgow and Clyde

NHSGGC is the largest health board in Scotland serving a population of approximately 1.2 million people and employ circa 38,000 staff. The main hospital sites covered by this NHS Board are:

- Inverclyde hospitals campus
- Royal Alexandra campus
- Gartnavel campus
- West Glasgow ambulatory care Campus
- Glasgow Royal Campus
- New Victoria Hospital
- Stobhill campus
- Vale of Leven
- Queen Elizabeth University Hospitals Campus

Queen Elizabeth University Hospital (QEUH)/Royal Hospital for Children (RHC)

NHS Greater Glasgow and Clyde's (NHSGGC) Queen Elizabeth University hospital (QEUH) is a 1109 bedded hospital with 100% ensuite single side room. Construction commenced on the £842 million hospital in 2011 which was handed over to the Board on 26th January 2015 with patient migration commencing from 24th April 2015 until 7th June 2015. The adjoining Royal Hospital for Children (RHC) is a 256 bedded childrens hospital which was handed over to the Board on 26th January 2015 with migration of patients occurring between 10th and 14th June 2015. The QEUH and RHC were both fully occupied from 15th June 2015. There are a number of additional healthcare facilities in the surrounding grounds including the maternity unit, neurosurgical unit, elderly care unit and the national spinal injuries unit. The QEUH/RHC is Scotland's largest hospital and replaced a number of existing hospitals from the NHSGGC area including:

- Southern General Hospital
- Victoria Infirmary
- Mansionhouse Unit
- Western Infirmary
- Royal Hospital for Sick Children (Yorkhill)

Introduction

NHS Greater Glasgow and Clyde (NHSGGC) are currently investigating and managing a contaminated water system across the Queen Elizabeth University Hospital (QEUH) and Royal Hospital for Children (RHC) with 23 probable linked cases of bloodstream infections associated with wards 2A /2B RHC. NHSGGC requested support from HPS with this incident on 16th March 2018 and Scottish Government invoked the national support framework[1] on 20th March 2018 which requires HPS to lead an investigation and provide NHS board support. It is recognised that this investigation and remedial action is still underway and may be ongoing for a considerable period, therefore this report is a summary of the findings from this investigation and includes cases and findings for the period 29th January – 26th September 2018.

An initial report was produced by HPS and submitted to Scottish Government (SG) and NHSGGC on 31st May 2018. Due to the ongoing and complex nature of this incident and investigation a further report was requested. This report is a summary overview of this investigation however due to the large volume of data and complexities associated with this incident further technical work is being undertaken by HFS. HPS worked with the support of HFS as the technical engineering experts to support this investigation and report production. In addition the HAI Policy Unit Scottish Government (HAIPU) has requested a separate detailed review of wards 2A/B to be undertaken. This is currently underway and will form a separate report for HAIPU and NHSGGC.

Summary of clinical cases associated with this incident

Case definition

The case definition in place since January 2018 is:

"*any child linked to wards 2A/B RHC with a blood stream infection (BSI) caused by a gram negative bacillus that had been identified from organisms identified within the water system"*

Ward 2A RHC is a haemato-oncology unit, also known as Schiehallion, and houses the National Bone Marrow Transplant Unit and teenage cancer trust. Ward 2B is the day care component of ward 2A. In total there have been 23 cases identified during the period 29th January and 26th September 2018.

2016-2017

In February 2016 a patient within ward 2A RHC was identified as having a bloodstream infection (BSI) as a result of *Cupriavidus pauculus*. NHSGGC investigations included water samples from outlets within the aseptic suite of the pharmacy department where the parenteral nutrition was made that the child had received. *Cupriavidus pauculus* was isolated from water samples taken from a tap on a wash hand basin within this area. Typing by Colindale reference laboratory confirmed the isolate from the washhand basin and the patient were the same. The wash hand basin was subsequently removed as a result. A further single case of *Cupriavidus pauculus* was identified in September 2017. NHSGGC reported that a second hand hygiene sink was found to be positive but following assessment was unable to be removed. Silver hydrogen peroxide treatment was undertaken and repeat testing resulted in zero total viable counts from this outlet.

2018

On 29th January 2018 *Cupriavidus pauculus* was again identified from a bloodstream infection (BSI) in a patient in ward 2A. Following identification of this case a series of investigations were undertaken including water sampling from outlets within the ward area. On 21st February *Pseudomonas fluorescens* was identified from a BSI and between 11th and 16th March 2018, 3 cases of *Stenotrophomonas maltophilia* were identified from patients in ward 2A. On 7th April a further case of *Stenotrophomonas maltophilia* was identified. *Cupriavidas*, *pseudomonas* and *stenotrophomonas* (amongst other gram negative bacillus and fungi) were identified from water samples obtained within wards 2A/B and therefore all cases considered to be linked to the water system. No further cases were reported until April, when between April and June, a further 10 cases were reported: 5 *Enterobacter cloacae*, 3 mixed gram negative bacilli, 2 S*tenotrophomonas maltophilia*. This cluster of mixed organisms, which were present from drain samples prompted the investigation in to the drains within ward 2A/B. Following drain sanitisation and environmental decontamination using hydrogen peroxide vapour, no further cases were reported until 2nd August and between the period 2nd August and 20th September 6 further cases were identified: 1 *Chryseomonas indologenes/Stenotrophomonas maltophilia*, 1 *Serratia marsescens*, 1 *Klebsiella oxytoca*, 2 S*tenotrophomonas maltophilia,* 1 *Enterobacter cloacae.* This latest cluster resulted in immediate further drain decontamination and a temporary decant facility for wards 2A/B being identified, with the patients transferred to wards 6A and 4B on 26th September to allow for investigative and remedial works to be undertaken in wards 2A/B.

In total there have been 23 patient cases identified. A number of patients have multiple organisms so the organism total is greater than the case number.

The organisms linked to cases include:

- *Cupriavidus pauculus* (1)
- *Pseudomonas fluorescens (1)*
- *Pseudomonas aeruginosa* (3)
- *Stenotrophomonas maltophilia* (12)
- *Acinetobacter ursingii* (2)
- *Enterobacter cloacae* (7)
- *Klebsiella oxytoca* (1)
- *Serratia marcescens* (1)
- *Pseudomonas putida* (1)
- *Pantoea sp* (1)
- *Klebsiella pneumonia* (1)
- *Chryseomonas indologenes*(1)

In addition to the organisms detailed above there is evidence of fungal growth in the water system however there have been no associated clinical cases reported.

A timeline of cases is detailed in Appendix 1. This incident has resulted in a number of children requiring additional intervention and some delays in chemotherapy treatment, however, there has been no associated mortality. There have been no associated cases since the temporary closure of wards 2A/B and the decant of the patients to ward 6A QEUH on 26th September 2018.

The clinical component of this incident is considered as occurring within two phases:

- Phase one relates to the water contamination and the clinical cases associated at that time relating to the water system. Following installation of point of use filters, the water system was acknowledged as being of suitable quality for use by patients and staff. Whilst work was ongoing to investigate and manage the water contamination incident the clinical component of this phase was considered over with a debrief held on 15th May 2018

- Phase two relates to the environmental contamination and subsequent associated clinical cases occurring as a result of the contaminated drains and the impact caused by the fitting of point of use filters. Phase two is currently ongoing and will remain open until wards 2A/B have re-opened

Summary of initial findings

Following identification of the potentially contaminated water system in wards 2A/B and the resultant possible linked cases in March 2018, NHSGGC considered the decant of these 2 wards to allow for a full investigation of the source of water contamination in wards 2A/B and consider remedial action. At that time ward 4B QEUH was being prepared for the transfer of adult BMT patients from the Beatson oncology unit. Water sampling was undertaken in this ward prior to decant as a precautionary measure. Results identified the presence of *Cupriavidus pauculus* (and other gram negative bacilli) in water outlets within this ward and was the initial suggestion that there may be widespread contamination of the water system that serves both QEUH and RHC. Further testing across the site provided confirmation of this, with positive samples being identified in a number of areas across both sites at both outlet level and within the water system in the basement level (risers). Within the same timeframe staff within wards 2A/B also reported they had witnessed “black effluent” around the rim of the drain in some wash hand basins. Following visual inspection and laboratory testing, this was considered to be biofilm and sampling identified significant contamination of the drains with microorganisms and fungi. Drain contamination is not unexpected however the level of biofilm evident was not in keeping with a water system of less than four years old.

In an attempt to establish the extent of the water system contamination and any causative factor NHSGGC, supported by HFS and HPS initiated a detailed investigation into the contaminated water system within QEUH/RHC. Support was also requested from a number of external companies experienced in water incident management: These included Leegionella, Public Health England (PHE), water solutions group and Makin & Makin. The detailed investigations led by NHSGGC and supported by HFS/HPS included reviewing commission, installation and maintenance records provided by the contractor. This proved to be challenging due to the archiving of data and there were very few members of the initial project team available who are technically qualified to retrieve data and provide verbal clarification. The detailed findings from these records are included within the technical review.

Results from ongoing water testing were reviewed on a weekly basis and highlighted there was evidence of regressional seeding of contamination which supported NHSGGCs view that a whole system remedial approach was required.

Commissioning and design of the hospital water system

As part of the normal water system commissioning water samples were obtained. Initial preliminary findings have identified that prior to handover from the contractor there were a number of water samples taken that produced results with high level of total viable counts (TVCs). TVCs are indicators that there are hygiene issues within the water system and are quantified as a generic indicator for microbial contamination. Specific microorganisms which can be tested for include: Coliforms, *Escherichia coli (*including O157), *Pseudomonas aeruginosa, Salmonella spp*, *Campylobacter spp* and Environmental Mycobacteria. Testing for these is not conducted as standard within current guidance and typically occurs in response to a suspected or confirmed outbreak, or due to identification of a series of sequential cases.

In response to the high levels of TVCs found as part of the pre handover commissioning sanitisation of the water supply was undertaken by the contractor, with some impact and a reduction in TVCs in most areas, however there are a number of reports which indicate that

there may still have been a number of areas with higher than normally acceptable levels of TVCs.

Design and installation of taps and clinical wash hand basins

The design and construct of wash hand basins, showers and taps in these hospitals were agreed with NHSGGC in line with the Scottish Health Technical Memorandum (SHTM) in place at the point the hospitals were designed (commencing 2009), this included the installation of taps with flow regulators. HFS and HPS were involved in this decision making process as were NHSGGC Infection Control team. The SHTM (SHTM 04-01)[2] was revised in 2015 and no longer supports the use of flow regulators in clinical wash hand basins.

Biofilm formation in flow regulators has been identified in a previously published outbreak.[3] The manufacturers of the taps/flow regulators in place across the QEUH/RHC recommend regular removal of the flow regulators for cleaning/decontamination however do not offer more specific guidance on frequency of decontamination of the flow regulators. The flow regulators in use have a number of components and potentially create ideal conditions for the development of biofilm.

NHSGGC provided an external company (Intertek) with some flow regulators to carry out microbiological testing. This confirmed that flow regulators have the ability to harbour a significant number of micro-organisms with the presence of biofilm being detected on all flow regulators tested and 50% showing high levels of contamination. It is also worthy of note that biofilm was present on some flow regulators which was not immediately obvious on visual inspection.

The taps in place across all clinical wash hand basins in both hospitals are also reported to be non compatible with silver hydrogen peroxide, a product which was used during commission stage to sanitise the water system in view of the high TVC results. It is unclear whether this has caused any degradation of the taps. A tap was deconstructed by NHSGGC and examined for the presence of biofilm, in addition to microbiological sampling. Several components of the tap exhibited microbiological contamination.

The presence of high levels of gram negative bacteria and fungus in the water system may indicate that temperature control required has not always been achieved. Temperature control is included as part of the wider technical review being undertaken for NHSGGC by HFS.

Other aspects discussed in the detailed technical review include:

- Flushing
- Contract/project team
- Roles/responsibilities
- Design and construction
- Guidance and specifications
- Specification of water system
- Flexible hoses
- System description

- Pipe work
- Post handover and maintenance

There are a number of local and national recommendations within this review for both NHSGGC and Nationally. The key NHSGGC and National recommendations from the technical review are included within the recommendation section of this report.

Infection Control at design commissioning and handover

HAI-SCRIBE

Healthcare Associated Infection System for Controlling Risk in the Built Environment (HAI-SCRIBE) [4], reference has been designed as an effective tool for the identification and assessment of potential hazards in the built environment and the management of these risks. HAI-SCRIBE (2007) was in place during the construction and handover of both buildings.

Implementation of HAI-SCRIBE should be the responsibility of a multidisciplinary team of specialists with appropriate skills.

Compliance with HAI-SCRIBE requires an accurate record of the process of hazard assessment and risk management which is essential ‘due diligence’ information.

Evidence has been reviewed in relation to the infection control sign-off of results and the system at commissioning/handover. Whilst there is evidence of involvement with initial results and sanitisation there is no evidence of ongoing input or sign off from the Infection Prevention and Control Team (IPCT). It is noted that there is lack of clarity in current national guidance relating to roles and responsibilities of the IPCT in the commissioning, design and handover of new or refurbished builds. Water was first placed on the Infection prevention and control (IPCT) risk register in 2018. The IPC risk register is reviewed on an annual basis with risks considered and prioritised using a risk scoring system. Water safety was added to the risk register in 2018 in response to the emerging evidence of potential issues associated with this incident. Prior to 2018 water safety did not feature in the IPC risk priorities when scored.

NHSGGC employed a robust approach to the design stage of the hospital project by means of a dedicated Infection Prevention and Control Nurse (IPCN) seconded as part of the project team to support the IPCT aspect of the design stage, commissioning and handover stage.

Whilst there was dedicated resource allocated to the project team, there is no documented evidence of NHSGGC Infection Prevention and Control Team involvement in the commissioning or handover process of the project. However NHSGGC has provided a statement from the Lead Infection Control doctor at the time to confirm that they were involved in reviewing some aspects of the initial water testing methodology and the results for QEUH and RHC during commissioning and handover. The Lead ICD has confirmed being involved in:

- Quality assurance of the water testing methodology used by the commissioning engineers.
- Liaising with Facilities Colleagues in reviewing the water testing results supplied by the commissioning engineers.

- Recommending further actions (dosing), for a small number of outlets with TVCs above the acceptable limits.

In addition to a nurse consultant being seconded as a dedicated resource to the project team with involvement in design, commissioning and handover, the project team were supported by the IPCT. This support included regular review of the new builds hospital project at the infection control committee and senior IPC meetings. NHSGGC reported that both the infection control manager and associate director of nursing (infection control) liaised regularly with the project associate nurse director and ensured the numerous commissioning groups established were supported by a member of the IPCT. In addition all wards were reviewed by a member of the IPCT prior to occupation by patients.

Current management of situation/Control measures

In addition to holding regular incident management IMT meetings (IMT) NHSGGC established a multi disciplinary water technical group which is a sub group of the incident management team. This group is supported by HFS, HPS, with monthly representation from water solutions group and Makin & Makin.

A number of control measures have been instigated during this incident and in particular in wards 2A/B. These included parent and staff education sessions, daily visits to the ward from members of the infection prevention and control team (IPCT), increased domestic hours, environmental monitoring by means of audit, including Standard infection control precautions (SICPs) audits.

Limiting access to water

In the initial investigation the use of water within wards 2A/B was limited with portable wash hand basins being supplied for hand washing. Patients were requested not to use wash hand basins or showers and wipes were provide as an alternative. Drinking water was provided by means of bottled water. Access to water was re-established once point of use filters were in place in showers and wash hand basins/sinks. BMT patients continue to receive sterile water.

Point of Use filters.

Following the identification that the water contamination was widespread across both RHC and QEUH an additional control measure of point of use (POU) filters for high risk areas was implemented to ensure a safe water supply at the point of use. In addition if a high risk patient was being nursed in an area deemed to be of low risk, a point of use filter was fitted to water outlets in their room. POU filters require to be changed every 30 days and are a costly approach, however in the interim until the water contamination can be addressed, is considered the only feasible approach to ensure safe delivery of water. A number of studies found that installation of point of use filters reduced either infection rates in associated healthcare settings[5;6] or pathogen counts within tested water samples.[7]

Once the POU filters were in place the restrictions on access to water within wards 2A/B was removed and patients were able to access washhand basins and showers. It was noted that following the fitting of the POU filters there was a greater splash evident from the wash hand basins as the point of entry of the water from the outlet was closer the basin. This splash was noted more from clinical wash hand basins than ensuite wash hand basins and trough sinks.

Drain Sanitisation

Following the identification of the second phase of cases associated with this incident and the hypothesis that the cases may be related to drain contamination, the drains were inspected by the IPCT. Once the drains were identified as being visibly contaminated with what was thought to be biofilm, a programme of drain sanitisation was undertaken across high risk areas commencing with wards 2A/B.

Environmental decontamination

Prior to and following completion of the first drain decontamination process in wards 2A/B, a terminal clean of all areas using hydrogen peroxide vapour was carried out.

Water treatment

It is well recognised that drinking water distribution systems contain a diverse range of microorganisms.[8-10] The presence of microorganisms is affected by various factors including; the disinfection processes employed, the location and age of the system as well as pipe material.[11]

There were a number of options explored for longer term water treatment by NHSGGC. These options included:

Chlorine dioxide

A number of studies were identified which utilised chlorine dioxide systems within hospital settings, and use of these was found to reduce bacterial numbers.[10,12,13] Various advantages and limitations associated with use of chlorine dioxide are known, with the most relevant summarised below.[14,15]

Advantages**:** Known to be effective against a wide range of bacteria, viruses and some protozoa including Giardia.

Limitations: Production of disinfection by-products (DBP's). Although potential production of DBP's always needs to be considered, the efficacy of water disinfection should not be compromised in trying to eliminate these.[16]

UV light

A number of drinking-water treatment technologies are available which employ UV light radiation to inactivate microorganisms.[15] As with chlorine dioxide, various advantages and limitations associated with use UV are known, with the most relevant summarised below.[14-16]

Advantages: Bacteria, fungi and protozoa (considered to be more effective at killing Cryptosporidium than chlorine dioxide) are readily inactivated at low UV doses, with higher doses required for virus inactivation. In addition, UV disinfection does not result in the formation of DBP's like chlorine dioxide.

Limitations: UV disinfection does not leave any residual compound in treated water and therefore does not offer protection against possible microbial re-growth in distribution pipe-work.

Thermal disinfection

Very limited information was identified in the published literature in relation to advantages and limitations of thermal disinfection. One study found that heat shock treatment at 80˚C reduced Gram negative bacteria in a hospital water system but did not lead to complete eradication.[17] Copper silver ionisation was also considered however this was discounted due to pH levels.

Preferred solution

The NHSGGC preferred method of choice for water treatment was continual dosing chlorine dioxide. This was supported by HFS and HPS. Shock dosing of the system was considered and it was agreed that due to safety issues and the potential impact on both hospitals ability to function during the process, this was not the most appropriate approach. It was also recognised that in the absence of initial shock dosing it may take up to two years for the process to be effective from tank to tap level. The procurement process is well underway and installation expected to commence November 2018.

Temporary closure of wards 2A/B

A recommendation was made by the IMT to pursue the temporary decant of wards 2A/B to allow investigative and remedial work to be undertaken. A number of options were explored resulting in the transfer of patients from wards 2A/B to ward 6A of the QEUH. Adult patients within ward 6A QEUH were transferred to Gartnavel General. Three rooms within the adult BMT (4B) were identified and allocated to the paediatric BMT unit. The patients were transferred on 26th September 2018. It is anticipated that the decant facility will remain in place until mid/late December.

Remedial work/Investigations wards 2A/B

The planned investigations/remedial works planned during the decant period include:

- Drain Survey
- Ventilation review
- Replacement of clinical wash hand basins
- Replacement of taps (with no flow regulator)
- Review of any little used water outlets with a view to remove
- Replacement of sections of pipework where biofilm noted
- Review of toilet cisterns and adaptation to reduce potential toilet plume effect.

Hypothesis

There are a number of workable hypotheses being explored; it is currently considered the most likely cause of the widespread contamination is a combination of hypothesis B and C

A: Ingress contamination

A small low level number of micro-organisms may have been present in the water supply at the point of entry. Lack of temperature or chemical control may have enabled biofilm formation. Due to the increasing biofilm throughout the system this may have allowed any subsequent micro-organisms present at point of entry an opportunity to flourish and cause widespread

contamination of the system.

B: Regressional contamination

This may have occurred due to contamination occurring at the taps/outlets or flow straighteners and contamination has regressed backwards throughout the system causing widespread contamination. The widespread positive results and array of bacteria point to contaminated outlets at installation or contamination of high risk components in the tap from ingress as opposed to the patient contact route.

C: Contamination at installation/commissioning

Contamination may have occurred due to presence of contaminated pipework or outlets. Prior to handover the system required to be sanitised due to high TVC counts. It is unclear if a robust flushing regime was in place from installation to handover and from handover to occupancy to prevent contamination.

Secondary Hypothesis

It is recognised that in many situations control measures or actions taken in an attempt to minimise the risk of HAI there can be unintended consequences. In this scenario the secondary hypothesis is linked to the unintended consequence of the point of use filter use:

POU filters.

In an attempt to provide water of a safe microbiological quality NHSGGC applied point of use filters to all clinical and patient wash hand basins in high risk areas and areas where high risk patients were being treated. These filters meant the exit point of the water from the taps was closer to the washhand basin and as a result caused more splash which may also lead to disruption of any drain biofilm as well as potential environmental contamination. (Pictures 1, 2). At the time of fitting the filters, the issue of biofilm within the drains and the associated risk or the resultant splashing that was being caused had not been identified and therefore the subsequent increased risk of environmental contamination and potential exposure of the children was not recognised.

Picture 1

Picture 2

Additional potential considerations to minimise impact

Ensuite single side rooms/hand hygiene practice

Since 2008 it is recommended that all new build hospitals have 100% en suite single side rooms.[18] As a result this has substantially increased the number of wash hand basins and therefore the frequency with which a wash hand basin is used and the water volume in each basin reduced when compared to multi occupancy wards with a single wash hand basin. Since the introduction and widespread use of alcohol gel, the need for hand washing as a first approach has greatly decreased, as alcohol gel may be used on hands that are not visibly soiled. This requires further exploration and consideration and review of flushing regimes and number of wash hand basins required.

Disposal to drain

A number of drain samples were sent to Intertek for analysis. A report has highlighted that in addition to the general presence of biofilm, there was biofilm noted around the aluminium spigots. There was also some occlusion reported as a result of adhesive and pooling noted between the back of the sink and the pipework. All aluminium spigots in wash hand basins in wards 2A/B were replaced with PVC spigots. In addition a number of foreign objects were identified within the drains. It was also reported that there was evidence of a yellow fluid present suggestive of urine being disposed to the drain. The biofilm has a mustard yellow colour and an odour of ammonia was detected. There was a small amount of yellow liquid in the base of the bowl trap which when removed and looked at in isolation also had an ammonia smell. Parents, families and clinicians are advised that hand wash basins are for hand washing only and additional activities such as fluids being disposed of to drain via a handwash basin should not occur. Staff are aware that this is not acceptable practice however the positioning of a wash hand basin in every ensuite single side room may encourage patients or visitors to expel fluids such as contents of a drink bottle. Items such as coffee, sweet drinks encourage the growth of

bio film and microorganisms within a drain. The large open horizontal drain may also encourage the accidental disposal of foreign items.

Summary

There have been no new reported cases since the decant of patients to ward 6A on 26th September 2018. The IMT will continue to meet regularly until the patients have been transferred back to wards 2A/B. The water subgroup will continue to meet until early/mid 2019 and will be supported by HFS/HPS. It has been evident to HPS that since the identification of this widespread incident and clinical impact on wards 2A/B, patient safety has been paramount with NHSGGC clinicians, facilities, IPCT and management team. A significant financial investment has been made to minimise ongoing risks including widespread use of point of use filters in addition to remedial work planned. A number of lessons can be taken from this incident for NHSGGC and NHSScotland as a whole in relation to water safety and commission, handover and maintenance of buildings. The national work and learning for NHSScotland will be driven via the HAI built environment steering group which is widely represented and chaired by the associate director of facilities (NHSGGC) and deputy chair is the lead ICD (NHSGGC).

Recommendations

A number of local and national recommendations have been made based on the investigation to date. This includes recommendations for NHSGGC which have been identified from a detailed HFS technical review. NHSGGC/HPS/HFS will produce an action plan based on the recommendations as follows:

1. NHSGGC

- To produce a detailed action plan addressing ALL points identified within the HFS technical review and should cover as a minimum:
  - Decontamination
  - The management of the water systems
  - All required rectification work
  - Management of recording systems
  - Routine and reactive maintenance schedules

2. All NHS Boards

- All NHS boards should ensure facilities teams are adequately resourced to ensure maintenance of all aspects of the water system are maintained in accordance with policies and guidance.
- All maintenance undertaken should be recorded and maintenance records should be reviewed regularly to ensure all aspects of the water system are maintained in accordance with policies and guidance

3. HPS/HFS

HPS (supported by HFS) to undertake an urgent national water review of all healthcare premises built since 2013 to provide assurance that a similar incident has not and is not likely to occur elsewhere.

HPS (supported by HFS) to establish a national expert group to:

- Review NHSScotland current approach to water safety including as a minimum:
  - Review NHSScotland current approach to water testing in healthcare settings.
  - Review NHSScotland current surveillance and reporting of potentially linked water related HAI cases.
  - Based on findings develop risk based guidance on water testing protocols, results interpretation roles and responsibilities and remedial steps to be considered.
- Give consideration to the development of a best practice built environment manual which will be evidence based and cover as a minimum current and emerging evidence

and the technical requirements from a clinical, patient safety and HAI perspective that will be adopted by all NHS boards. This will include as a minimum:

- Review existing national and international guidance relating to water safety.
- Develop robust requirements/guidance for all aspects of water safety.
- Develop robust handover requirements in relation to water systems.
- Review of the role of the IPCT into the built environment, and produce clear guidance on roles and responsibilities.
- Establish a risk based approach to water testing and any remedial action required, including roles and responsibilities that NHS boards will adopt.
- Review the requirement for 100% ensuite single side rooms the number of clinical wash hand basins per patient/bed.
- Review the use of flow regulators across NHS Scotland and identify and associated risks and recommend any remedial actions required.

- HPS/HFS will continue to provide support to NHSGGC relating to the current water incident and provide input into the weekly meetings until mid 2019 (and reviewed thereafter).
- Further develop the existing Scottish expertise in the built environment programme (mainly water and ventilation) at national level.

HFS (supported by HPS) to:

- Review all relevant water technical guidance to ensure all aspects are covered within the guidance including as a minimum:
  - Thermal disinfection in sections of water distribution systems
  - Handover checklists
  - Contract management procedures
  - Design guides to eliminate thermal pickup in cold water systems
  - Update advantages and disadvantages of chemical disinfection techniques
  - The organisms Boards should test for and action to take on defined levels
  - Drain cleaning regimes
  - Biofilm growth in drainage systems

.

Appendix : 1 Timeline of cases

The epi-curve demonstrates that only one case of *Cupriavidus pauculus* was reported from 26th January 2018, with the other associated cases being *Stenotrophomonas maltophilia* and/or *Pseudomonas aeruginosa* positive between 21st February 2018 and 5th April 2018.

Glossary

Alcohol gel	A gel, foam or liquid containing one or more types of alcohol that is rubbed into the hands to inactivate microorganisms and/or temporarily suppress their growth.
Aseptic Suite	An ultra clean environment within a department, (for example pharmacy) where sterile solutions are prepared such as chemotherapy under strict measures.
Bacteria	Microscopic organisms (germs).
Bib taps	A tap or stop cock which has a nozzle bent downwards.
Biofilm	Collective of one or more types of microorganisms, including bacteria, fungi and protists, that stick together and can become embedded on a surface.
Blood stream infection	The presence of bacteria in the bloodstream.
Chemotherapy	A cancer treatment where medication is used to kill cancer cells.
Chlorine dioxide	A chemical compound used for a variety of antimicrobial uses, including the disinfection of drinking water.
Clinical wash hand basins	A sink designated for hand washing in clinical areas
Cluster	A group of similar things located around the same location
Copper silver ionisation	A disinfection process where positively charged copper and silver ions are added into the water system. It is primarily used to control control Legionella, the bacteria responsible for Legionnaires' disease.
Decant	Temporarily transferring people to another location.
Decontamination	Removing, or killing pathogens on an item or surface to make it safe for handling, re-use or disposal, by cleaning, disinfection and/or sterilisation.
Drain	A fixture that provides an exit-point for waste water or water that is to be re-circulated.
Ensuite single side room	A room with space for one patient and containing a bed; locker/wardrobe, clinical wash-hand basin, en-suite shower, WC and wash-hand basin.
Flexible hoses	A flexible hollow tube designed to carry fluids from one location to another and are used to connect taps to the water supply
Flow regulators	Point of use regulators designed to provide constant and maximum flow rates at taps and showers etc. irrespective of changes in demand or water pressure

Flushing	The process of cleaning or “scouring” the interior of water distribution mains (pipes) by sending a rapid flow of water through the mains.
Gram negative bacilli	Gram-negative bacteria are bacteria that do not retain the crystal violet stain used in the gram-staining method of bacterial differentiation; examples include E.coli, and Pseudomonas aeruginosa.
Hydrogen Peroxide Vapour	Vaporized hydrogen peroxide is an airborne disinfectant and infection control measure that can be used for room decontamination after patient use.
Ingress	The act of entering.
Microbiological sampling	Sampling for harmful bacteria, parasites, fungi and viruses including those in water, environment and equipment.
Micro-organism	Any living thing (organism) that is too small to be seen by the naked eye. Bacteria, viruses and some parasites are microorganisms.
Organism:	Any living thing that can grow and reproduce, such as a plant, animal, fungus or bacterium.
Parenteral nutrition:	The giving of special liquid feeding products to a person using an intravenous catheter and bypassing the normal digestion process of the stomach and bowel.
Pathogen:	Any disease-producing infectious agent
Point of use filters:	A device that incorporates an integral filter with a maximal pore size of 0.2 µm applied at the outlet, which removes bacteria from the water flow therefore protecting the end user from exposure to harmful waterborne pathogens.
Portable wash hand basins	A sink that is not connected to the mains water supply but connects to a water tank which is filled locally.
Regressional seeding	Where micro-organisms from contaminated water outlets/biofilm regress ‘back’ through the water system and seed other areas (pipes/tanks/outlets). The microorganisms embed themselves and multiply contaminating other areas of the system.
Sanitisation	Use of antimicrobial agent on objects, surfaces or living tissue to reduce the number of disease-causing organisms to non-threatening levels.
Shock dosing	The use of large quantities of chemicals to the water supply to break down organic waste and get rid of bacteria and contamination.
Silver hydrogen peroxide	A solution of stabilised silver in hydrogen peroxide that is used for surface and water decontamination.

Sterile water	Water free of all microorganisms – bacteria, viruses, fungi.
Terminal clean	Cleaning/decontamination of the environment following transfer/discharge of a patient, or when they are no longer considered infectious, to ensure the environment is safe for the next patient or for the same patient on return.
Thermal disinfection	The use of water and heat for the disinfection process for example washer-disinfectors.
Toilet plume effect	The dispersal of microscopic particles as a result of flushing a toilet.
Total viable counts	A quantitative estimate of the concentration of microorganisms such as bacteria, yeast or mould spores in a sample.
Trough sinks	A long, narrow basin designed for communal handwashing with water delivered at hand-washing temperature via mixer taps in conjunction with a thermostatic mixing valve. Usually used for surgical scrubbing.
UV light	A disinfection method that uses short-wavelength ultraviolet (UV-C) light to kill or inactivate microorganisms.
Water outlets	Any hole or opening where water is released for example taps, showerheads.
Water sampling	The analysing of the water supply for harmful bacteria, parasites, and viruses.
Water system	A system of engineered hydrolic and hydraulic components to supply water.
Spigots	A short cylindrical pipe which connects the Clinical Wash Hand basin to the main pipework.
Occlusion	Obstruction or blockage

NHS Greater Glasgow and Clyde

New South Glasgow Hospitals (NSGH) Project

INVITATION TO PARTICIPATE IN COMPETITIVE DIALOGUE

VOLUME 2/1

EMPLOYER'S REQUIREMENTS (Hospitals)

Contents

Section 6.0 Construction Phase Requirements

6.1 Site Welfare and Board Accommodation
6.2 Site Preparation Works
6.3 Workmanship, Construction Accuracy and Tolerances
6.4 Live Hospital Site (incl other works on site)
6.5 Standardisation and Prefabrication
6.6 Room Mock-Ups
6.7 Witnessing and Testing
6.8 Commissioning and Handover

Section 7.0 Architectural Requirements (incl equipment)

7.1 Masterplan
7.2 Exemplar Design
7.3 Ceiling Heights & Voids
7.4 Corridor Widths
7.5 Doors
7.6 Windows
7.7 Building Envelope
7.8 Acoustics
7.9 Finishes
7.10 Interior Design
7.11 Architectural Hardware
7.12 Staircases, Ramps, Balustrades, Walkways, Escalators & Lifts
7.13 Landscape Design
7.14 Soft Landscaping Requirements
7.15 Wayfinding & Signposting
7.16 Protection
7.17 Integration of Healing Arts Strategy
7.18 Secure by Design

Section 8.0 Building Services Requirements

8.1 General Services
8.2 Mechanical Systems
8.3 Electrical Systems

Section 9.0 Civil and Structural Engineering Requirements

9.1 General Requirement
9.2 Minimum Design and Construction Standards
9.3 Loading & Structural Flexibility
9.4 Foundations & Substructure
9.5 Basements & Tunnels
9.6 Movement Joints
9.7 Superstructure
9.8 Fire & Corrosion Protection
9.9 Durability & Maintainability
9.10 Other Performance Requirements
9.11 Underground Drainage
9.12 Roads, Footpaths, Cycle Paths and Car Parking
9.13 Other External Works
9.14 Hard Landscaping Requirements

Appendix X **Critical Failures**

Section 1.0 Development Context

1.1 Introduction

The provision of new facilities at the Southern General Hospital site in Glasgow represents the second phase of the Acute Services Strategy of the Board.

As illustrated in Appendix A, the Hospital Campus extends to some 28.6 hectares and is located within the Govan area, lying to the south-west of Glasgow City Centre adjacent to the residential neighbourhood of Drumoyne and the industrial areas of Shieldhall and King George V Dock. The site is located 500 metres south of the River Clyde. The sites northern boundary is defined by Renfrew Road/Govan Road with the eastern boundary defined by Moss Road/A739 (Clyde Tunnel approach road). Langlands Drive and residential developments delineate the southern boundary and Hardgate Road runs north-westwards to identify the western boundary of the Hospital Campus.

The Site extends to some 8.6 hectares and is located in the west-central area of the Hospital Campus (see Appendix A). The Site is bounded by operational healthcare buildings to three sides, with boundaries to neighbouring industrial areas to the north/north-west. The existing buildings within the Site (excluding the Surgical Block) are to be demolished by the Board in advance of the scheme, as described in Section 2.3 below.

The scheme includes the provision of 1,109 adult and 240 children's beds. The bed numbers are illustrated in *Table 1 – Proposed Bed Numbers – Adult and Children's Hospitals.* Key elements of the project include:

a. Development of an integrated adult acute and children's hospital proving the full range of acute health services;

b. Development of a new Laboratory facility including Mortuary and Post-Mortem Services, Biochemistry, Microbiology, Haematology and Medical Genetics;

c. Provision of a rooftop helipad; and

d. The supply and installation of Group 1 equipment, location and/or fitting of Group 2 equipment supplied by the Board and provision of structural, space and services requirements to support Group 3 and 4 equipment.

It should be noted that Information Management and Technology (IM&T) is outwith the project, the Board is procuring software and end-use hardware as part of a separate IM&T project. The Contractor shall, however, provide the required space within the building and the requisite hard infrastructure and containment, in accordance with Section 8.0 and Appendix M, to support the Board IM&T requirements

Adult Hospital		**Children's Hospital**	
Specialty	**Beds**	**Specialty**	**Beds**
General Medicine (incl MHDU + AAU)	405	Inpatient (incl critical care areas) (*12 beds in maternity facility)	193*
CCU	20	Short-stay (observation ward)	20
Stroke	26	Day Care/Day Surgery	27
Haematology	14	**Total Inpatient Beds**	**240**
Dermatology	18		
Nephrology	80		
Geriatric Medicine	93		
Surgery & Vascular (incl AAU)	164		
Urology	39		
Orthopaedics/rehab	139		
ENT	31		
ITU	20		
SHDU	23		
Clyde/Contingency	37		
Total Inpatient Beds	**1,109**		

Table 1 – Proposed Bed Numbers – Adult and Children's Hospitals

1.2 **Accommodation Overview**

1.2.1 **New Adult Hospital**

This will provide A&E services and acute specialist in-patient care as well as medical day services and out-patient clinics serving the local population.

Key components of the facility will include:

a. In Patient Accommodation
Surgical beds (general surgery, orthopaedics, urology, vascular, ENT and renal); Medical beds; Acute Assessment Unit – 118 beds, ICU/HDU/CCU – 79 beds, Acute Stroke – 26 Beds and Care of the Elderly 93 beds;

b. Out Patient Accommodation
Full range of general outpatient clinics including, among others, diabetic unit, respiratory, orthopaedics and urology;

c. Day Services
22 medical day bed area; 30 station dialysis unit;

d. Treatment & Diagnostic Services
Emergency Department, 20 operating theatres, imaging, and endoscopy;

e. Clinical Support Services
Pharmacy dispensary, medical physics, medical illustration. Laboratory services linked to the hospital by underground route and pneumatic tube system, aseptic unit within the children's hospital. The pneumatic system to extend across the abutment with maternity and the link to neurosciences to provide for expansion of the system to these areas; and

f. Non Clinical Support Services
Main entrance, medical records, administration, chaplaincy, social work, staff changing, switchboard, estates, facilities, security, catering, portering, domestic, management and energy centre.

1.2.2 **New Children's Hospital**

This will provide A&E services and a comprehensive range of inpatient and day case specialist medical and surgical paediatric services on a local, regional and national basis. The new development will also have outpatient facilities. The care strategy is that all of Glasgow's Children's Services (up to the age of 16 and up to 18 years where appropriate) will be provided at the New Children's Hospital. Of the 240 beds planned, around 20% of the beds will be for day patients and the balance for in-patient requirements.

Key components of the facility will include:

a. Outpatient Accommodation
Full range of Children's outpatient clinics including audiology, general paediatrics, orthopaedics, ENT etc;

b. Day Services
Circa 10 medical day beds; 4 dialysis stations and circa 25 day surgery beds;

c. Treatment & Diagnostic
Accident and Emergency, minor injuries, Imaging, 9 theatres, rehabilitation;

d. Clinical Support Services
Aseptic unit, pharmacy, medical physics, medical illustration (laboratory services linked to hospital by underground route and pneumatic tube system – tube system to be extended across abutment with maternity/neo-natal to provide for potential expansion of the system); and

e. Non Clinical Support Services
Facilities, ancillary services, administration, spiritual services, medical records, staff change, staff dining.

1.2.3 **Laboratory Facilities**

The new facilities will be one of two major Laboratory sites in Glasgow (the other at Gartnavel General). The services planned to be delivered from the new Laboratory build at the New South Glasgow Hospitals include Biochemistry, Microbiology, Haematology, Medical Genetics, Mortuary and Post Mortem. The mortuary and post mortem facilities include the re-provision of the Glasgow City mortuary which also provides forensic services for the City of Glasgow. The Employer's Requirements in relation to the laboratory facilities form Volume 2/2 of the ITPD and laboratories (buildability and interfaces) shall form a workstream of competitive dialogue between the Board and bidders.

1.2.4 **Facilities Management Building and Energy Centre**

These key support accommodation areas shall be developed in line with the operational needs of the Board and the energy strategy adopted for the project. The Facilities Management accommodation is located in the Laboratory building and the requirements in this regard are included in Volume 2/2 of this ITPD.

1.2.5 **Retained Services**

The Southern General Hospital site will retain approximately 630 beds within the institute of neurological sciences, Maternity, Spinal Injuries and Langlands buildings. The Langlands facility provides older people's services, dermatology and services for the young physically disabled.

1.3 **Elements of Procurement**

1.3.1 As detailed in Volume 1 of the ITPD, the procurement is following a competitive dialogue route. The areas for inclusion in the competitive dialogue have been established, with the following topics identified:

a. Design;

b. Logistics;

c. Laboratories (incl FM accommodation); and

d. Commercial.

Volume 1 of the ITPD provides further detail on the scope, extent and requirements of the competitive dialogue, including identification of the issues and aspects of each topic that shall be considered.

1.3.2 As detailed in Volume 1 of the ITPD, the Works are comprised of several Stages, namely:

a. Stage 1 – Laboratory Design & Construction;

b. Stage 2 – Hospitals Detail Design to FBC;

c. Stage 3 – Construction of Hospitals; and

d. Stage 3A – Landscaping Completion (including demolition).

Section 2.0 Responsibilities of the Parties

2.1 Introduction

The Board wish to procure Works which shall enable it to carry out its clinical functions, to combat health acquired infection and to maintain physical assets and clinical and non-clinical functionality with ease; and it shall be the responsibility of the Contractor to deliver a design and construction solution that optimises these requirements. The Board wish to provide its clinical functions in a high quality care environment which is accessible to the community, welcoming, safe and aesthetically pleasing. Innovative design and construction proposals, which as a minimum meet the requirements of the Works Information, Site Information and Employer's Requirements are sought from the Contractor.

2.2 Responsibilities of the Contractor

The Contractor shall be responsible for the following:

2.2.1 Providing Works that are fit for purpose;

2.2.2 Meeting all of the requirements of the Board stated in the Works Information, Site Information and Employer's Requirements as a minimum requirement;

2.2.3 The tasks, risks and aspects of the project identified as owned by the Contractor in the Risk Register;

2.2.4 Assisting the Board with the management of the risks identified as owned by the Board in the Risk Register;

2.2.5 Working with the Board and it's advisers in fulfilling all of the requirements and good practice inherent in the NEC3 contract;

2.2.6 Compliance with the requirements of the Construction (Design & Management) Regulations;

2.2.7 Providing a design that meets the relationships identified in the Adjacency Matrix;

2.2.8 Diverting the culverts that cross the Site and the other remaining services;

2.2.9 Obtaining all Consents required for the construction of the Works, including but not limited to the under noted. With regard to the under noted the Contractor shall provide to the Board copies of the following documents within 10 working days of all purification and discharge notices from date of issue by the appropriate authority:

2.2.9.1 Planning Approvals;

2.2.9.2 Building Warrant (incl Stage applications if applicable);

2.2.9.3 Building Warrant – Certificates for full occupancy;

2.2.9.4 Pre-construction Information and Construction Phase Health &Safety Plan;

2.2.9.5 Health and Safety File;

2.2.9.6 Utilities Suppliers Consents;

2.2.9.7 Other Local Authority Consents, including Building Control, Roads Construction Consent, Fire Strategy etc;

2.2.9.8 Certification for PMG installation;

2.2.9.9 Relevant Civil Aviation Authority and Strathclyde Fire and Rescue documentation in relation to the provision by the Contractor of a rooftop helipad;

2.2.10 Procuring that the Works are at all times performed:

a. In compliance with all Law and Consents;

b. In a manner that is not likely to be injurious to health or to cause damage to property;

c. Without injury, nuisance, interruption to, or other detriment of the existing clinical and support services current on the site;

d. In a manner consistent with the Quality Plans;

e. Except to the extent expressly stated to the contrary in the Works Information, Site Information or Employer's Requirements in compliance with all NHS Mandatory Documentation, NHS Guidance Documentation and Additional Guidance contained in Section 5.1;

f. In a manner consistent with the Board discharging its statutory duties and other functions undertaken by it as the same may be notified to the Contractor from time to time;

g. In accordance with all British and European Standards; and

h. In accordance with Good Industry Practice.

2.3 **Responsibilities of the Board**

The Board is responsible for the following:

2.3.1 The provision of the area of the Site agreed between the Board and the Contractor clear of buildings and known utilities unless otherwise illustrated. This to include the grubbing out and removal of foundations and underbuildings. Remaining utilities to be addressed by the Contractor are identified on the drawing illustrating same in Appendix M; and

2.3.2 The provision of access (agreed by the Board in writing in advance) to areas of the Hospital Campus to allow the Contractor to make utility connections, corridor/building linkages and other relevant activities identified to carry out the Works.

Section 3.0 The Site

3.1 The Site

The Site is located at 1345 Govan Road within the Hospital Campus. The boundary of the Site is identified in Appendix A.

Site Investigation (SI) work has been undertaken by the Board. The relevant SI information and associated interpretative reporting is located in Appendix N.

3.2 Travel Plan

The draft Travel Plan developed by the Board is located in Appendix W.

3.3 Planning

Outline planning permission has been secured by the Board (a copy of the communication issued by GCC in relation to the permission is attached at Appendix D.1). The outline permission has forty-three conditions attached and was conditional to the Section 75 Agreement being concluded in respect of transportation issues.

The Section 75 Heads of Terms (HoTs) are agreed between the Board and the Council, the HoTs for a proposed Fastlink service will be concluded by the Board as an aspect of the masterplanning prior to the conclusion of the competitive dialogue process.

The status of planning matters are identified in Appendix D.2, with details of the Masterplanning carried out by the Board in Section 7.0 of the ERs. As noted in Section 2.2, above, the Contractor is responsible for gaining and discharging Detailed Planning Approval.

3.4 Live Hospital Site

The Hospital Campus is a live hospital site, and as such will place restrictions on the Contractor in the construction of the Works. Essential 'blue light' and other access routes will require to be unobstructed by the Contractor 24hours per day, every day.

The 'blue light' and other access routes/site constraints are identified in Appendix A.

3.5 Other Projects On-Site

In addition to the ongoing access and operational requirements of the Board to deliver medical and related services, there shall be other construction projects and programmes ongoing on the Hospital Campus at varying times when the Contractor will be constructing the Works. This may include (but not be limited to) works to create a new-neo natal facility, multi-storey car parks and university facilities as well as a variety of site enabling, ongoing maintenance, utilities and demolitions works.

3.6 Site Logistics

Site Logistics shall form a Dialogue Issue during the Bid Period, this will include discussions in respect of both the live hospital site and other projects on-site, with relevant responsibilities, interface protocols, communications plans and emergency/contingent planning to be discussed and agreed with the Board.

Section 4.0 General Design Requirements

The following section provides an overview of the Board's key objectives for the Works. The Contractor's proposals should clearly demonstrate cognisance of these objectives in relation to the design and the construction process. In particular, the operational, functional and equipment issues contained in the Employer's Requirements must, as a minimum standard, be met by the design and construction solutions of the Contractor. Further to this, the Contractor shall ensure the design delivers a solution which indicates acknowledgement and understanding of the types of patients that are planned for the facility.

The Contractor must take cognisance of the following documentation in his design solutions and shall require to demonstrate in his bid return strategies to embrace the ethos of the documentation in the development of the design:

a. Scottish Government's Policy and Design Quality for NHSScotland;

b. The NHS Greater Glasgow and Clyde Design Action Plan;

c. Achieving Excellence in Design Toolkit (AEDET Evolution);

d. Scottish Planning Policy SPP6; and

e. Planning Advice Note 84.

Further, the Contractor shall design the Works to address the following issues:

4.1 Uses

4.1.1 Functional Requirements

The design of the Works shall:

a. Function efficiently, effectively and economically;

b. Optimise the Board's operating costs;

c. Demonstrate that the design fully reflects the special needs for each patient group in terms of access, functional relationships and planning. Patient groups are described and their particular requirements are defined in the Clinical Output Specifications in Appendix B and the mandatory and relevant guidance listed in Section 5.1. The facility as a whole should be fully accessible to the widest variety of patient groups, ambulatory, assisted and non ambulatory patients of all ages providing access to specialist services led by medical staff, allied health professionals and nursing staff;

d. Interface easily with other service providers in particular the wider services provided by the Board; and

e. The design shall be able to do this in terms of environment, scale, comfort, privacy, reassurance, style and security.

4.1.2 Human Dignity

To achieve appropriate levels of privacy, the Contractor shall provide Works which allow adequate space around patients. This may include space for relatives to sit with patients, adequate space between chairs, and seating in rest bays along corridors to provide rest places along the route of the patient / visitor journey. The privacy afforded to patients, staff and visitors shall not be compromised by inappropriate or inadequate sound reduction measures in the design or in the build standard.

Sill heights for windows shall enable outward visibility, in particular for children, patients in wheelchairs and in beds. Special consideration shall be given to the needs of the elderly and those with poor sight. Some doors and internal glazed screens shall require vision panels or other glazing systems, which may be obscured or controlled for privacy. The ability to use vision panels to view objects / small children on the other side is desirable.

4.1.3 Functional Relationships

The design shall offer all users of the Works the highest level of efficiency in their operations by way of relationships and adjacencies between functional units. Layouts shall reflect the workflow and logistics inherent in the Clinical Output Specifications in Appendix B; the parameters identified in the Adjacency Matrix; and the requirements of the housekeeping and domestic staff, catering, staff welfare and related management needs.

4.1.4 Work Flows & Logistics

Workflows within and between departments shall be direct and the routes for patients and staff as short as possible. Internal traffic cross-flows which could be inefficient or conducive to the transmission of micro-organisms either through airborne or other means shall be avoided.

The movement of people and the distribution of supplies and waste shall be carefully considered and the circulation routes shall be clear and appropriately sized, with the use of automated material transfer systems where relevant.

4.1.5 Adaptability & Expansion

The design shall consider the needs for departments to be adapted or expanded. This will require a range of approaches to be taken including the allocation of soft space adjacent to clinical spaces. The design shall demonstrate that potential change or expansion has been considered by the provision of adequate space either at the external perimeter and / or between functions and departments.

The structural grid, construction technique, structure, service penetration and engineering services strategy shall demonstrate that the design proposals for expansion, adaptation and flexibility are co-ordinated.

The provision of engineering, telecommunications infrastructure and building services shall be appropriate for the provision of anticipated changes in medical equipment.

4.2 **Spaces**

4.2.1 Space Standards

The Contractor shall provide designs which are efficient, economical and flexible for immediate and future use, and which can be managed efficiently to cope with seasonal and strategic variations in activity.

Appropriate space provision shall be given to circulation, waiting and sub-waiting space for the movement of patients, pedestrians and the storage and transportation of goods.

Space shall be considered to allow informal discussion, therapy and interaction within open and reception areas in the clinical environment, such as consultation and main waiting and reception areas. Consideration shall also be given to making use of open space areas within clinical areas and main circulation routes for 'break-away' space such as corridor recesses and courtyards.

The Contractor shall recognise that patients' and staff's perception of the spaces created may assist with their feeling of belonging and of not being intimidated, and may help with their orientation, mobility, confidence, privacy and their ability to socialise.

4.2.2 Floor Layouts

The design of departmental and unit layouts shall reflect the demand for space defined by occupancy and usage as described in the Clinical Output Specifications and reflected in the Exemplar Design/SoA. Where areas and shape of rooms results in undesirable spaces, the Contractor shall discuss with the Board alternative solutions, which may or may not result in shared space providing a more appropriate environment as well as optimising the available use of space. These may include locker rooms, sitting areas, seminar rooms etc.

4.2.3 Character & Innovation

4.2.4 Excellence for Patients

The design of buildings, external and internal appearance as well as the design of the external works, and landscape can have a positive or a negative effect upon patient care, staff experience at the work place and the way NHS healthcare buildings are perceived. The Contractor shall develop design solutions which by the use of materials, lighting, shape, scale, mass and form of the building elements make a positive contribution to engendering well-being of patients and staff.

4.2.5 Healthcare Excellence

Healthcare buildings should fit within their community and be compatible in design and the use of materials with their neighbourhood and have a strong NHS identity. The Contractor shall develop building design solutions that:

Reinforce the dependability and reassurance that the NHS means to the local community;

Respect their local environment but at the same time make a positive contribution to the urban context that they are in;

Clearly expresses their function in external and internal appearance;

Allows patient diagnostic and treatment areas that can be differentiated in design concept and detail from inpatient areas; and

Reflect that design considerations such as the distribution, size and proportion of windows and the use of materials can reflect the clinical function.

These elements shall be expressed in the scale and mass of the buildings, as well as the disposition of functions.

4.2.6 Architectural Vision

The Contractor shall develop building design solutions, which create an ordered composition of building elements in a stimulating form that successfully combines good standards of space, height, form, scale and use of materials and colours / images with associated functional requirements and its surroundings.

4.2.7 Stimulating Design

The Contractor shall develop building design solutions which create a high quality, good working environment, both externally and internally, which shall provide a reassuring, enjoyable, convenient and safe environment for all patients, their families, visitors and staff. This objective shall not be in conflict with the desire to produce a stimulating design. The Contractor shall meet this objective and shall develop a design which will not date and be capable of coping with future changes in a way that does not destroy the original design vision / concept. Further, the design shall incorporate best practice in terms of aspects of design that positively impact on health and recovery.

4.2.8 Design Innovation

Innovation in design can range from whole concepts of healthcare facilities' planning, distribution of functions etc to detail design of components, materials, spaces, use of technology etc. The Contractor shall develop designs at the concept level which shall translate the NHS modernisation agenda, and new forms of service delivery into new and innovative building solutions.

4.2.9 Recognisable Quality

The Board expects high quality design to match the best national standards of healthcare provision it intends to implement.

Materials shall be substantial and of high quality. They shall be carefully detailed and constructed such that the quality is appreciated throughout the life of the Works. They shall retain their appearance within a compatible maintenance regime. For example, detailing of external materials shall not cause unsightly staining.

The lifecycle plan and design detailing shall allow for replacement of elements in a way that does not impair design quality or service provision. A schedule of required life expectancies of building elements can be found in Section 5.3.

4.3 Citizen Satisfaction

4.3.1 Design Concept

The visual forms shall enhance the sense of place. They shall make best advantage of the environmental qualities of the Works and the wider Site.

The design concept shall be clear, and will not be compromised by the subsequent detailed design development. The design concept shall be complete and well balanced, with all parts relating to the whole.

4.3.2 Scale & Proportion

Appropriate scale and proportions shall reflect the human scale, adjoining urban surroundings and any existing buildings / structures retained on the Site. Plant rooms, lift and stair towers shall express form and function, but they shall not be perceived as dominating and oppressive.

4.3.3 Composition

The composition of the buildings shall be complete, cohesive and well balanced in massing. The visual form shall enhance the Site and sense of place. This can be done in a number of ways including by linkages to surroundings in plan form, expressions in the design of local character and including natural features of the Site in the composition.

The overall form of the buildings shall be designed to demonstrate the special needs of the function of each unit. The design shall clearly express in the form of the buildings the individuality and special nature of parts of the Works, yet the parts should harmonise with the Works and the overall site. The Contractor should give particular consideration to the architectural composition and expression of the following key aspects of the facility;

a. The form of the Adult Acute and Children's Hospital while mutually compatible should have an identifiably distinct character expressed both externally and internally as befits the nature of the patient groups; and

b. The Contractor will be require to ensure that the new Works are consistent with the overall masterplan strategy and with the existing facilities on the site, as such particular consideration should be given to the adjoining neonatal unit (which requires to be co-joined by an abutment) and the provision of a link to the institute of neurological sciences.

4.3.4 Aesthetics

The overall visual form of the buildings shall combine good standards of space, height, form and scale. The form of the buildings shall appeal to the aesthetic senses of patients, visitors and staff as follows:

The lines of the design shall clearly define forms and surfaces of the buildings;

The skyline shall reflect the mass of the buildings but not be out of scale and dominating;

The sky line shall not be monotonous;

The solid forms shall be in scale and have harmonious shapes; and

The interplay of light and shade shall add to the definition of the building form and the balance between solid and glazed elements should be carefully considered.

4.3.5 Colour & Texture

Colour decoration and motifs shall be used to facilitate identity of the Works; and its designated areas / zones and in addition improve wayfinding. It can also be used to create an immediate and distinct 'image' of the Works to visitors, which is interesting and stimulating.

The use of colour shall be co-ordinated and adapted with the lighting to the activities of each area, toned down in certain areas e.g., quiet areas, seminar rooms; but bright and stimulating in others, such as waiting and corridor areas.

The Board shall be entitled to choose the colour scheme in consultation with the Contractor and the Contractor shall liaise with the Board and nominated User groups and other representatives (e.g. BATH – Better Access To Health) in this regard.
An interior designer shall be included in the Contractor's design team to secure a clear co-ordination of the interior materials within the Works, matching the furniture, furnishings and equipment being procured by the Board. The colour scheme should be selected with due regard to integration with the Art Strategy as identified in Section 7.17.

4.4 Internal Environment

4.4.1 Quality Environment

The design of the Works shall create a high quality, good working environment, both externally and internally which will provide a reassuring, enjoyable, convenient and safe environment for all patients, their families, visitors and staff.

4.4.2 Light & Colour

The design shall provide quiet, comfortable areas with pleasing outlook easily accessible from clinical areas where patients and their families / visitors can "escape" from the clinical environment. Such areas may facilitate informal discussions with health professionals in the future, and be equipped for play / recreation. Where possible natural sunlight is to be brought into areas. The Contractor shall liaise with the Board and nominated User groups and other representatives (e.g. BATH – Better Access To Health) with regard to light and colour aspects.

4.4.3 Views

The Works shall provide quiet, comfortable areas with pleasing outlooks and easy access from clinical areas.

4.4.4 Internal Wayfinding

Design solutions shall incorporate an integrated, comprehensive wayfinding strategy that enables patients, visitors and staff to self-navigate with ease and lack of stress throughout the buildings.

The wayfinding strategy shall be designed to meet the needs of patients and visitors but routes shall be clearly defined to ensure that parts of the buildings that are restricted to staff are not used as short cuts by patients and visitors. The use of enclosed internal courtyards as an integral part of a route shall be considered. The Contractor shall liaise with the Board and nominated User groups and other representatives (e.g. BATH – Better Access To Health) with regard to the use and detailing of internal wayfinding.

Internal signage shall be easily understood and consistent throughout the journey from the entrance to the department reception and on to rooms. It shall not create clutter and the use of pictograms and graphic art should be considered.

Proposals shall be developed which acknowledge the multi-sensory process used in wayfinding and which address the need of people with impairment in touch, smell, sight or sound. The proposals should be developed with due regard to the requirements of the NHS Identikit guidance.

4.4.5 Internal Spaces

All internal spaces shall be well planned and appropriate within clinical areas.

Some spaces shall be designed to encourage social interaction for patients, visitors and staff.

Public spaces shall be used to integrate the various parts of the buildings, and shall be designed to avoid being a space joined by long, narrow corridors.

4.5 Urban & Social Integration

4.5.1 The Contractor should recognise that the design of the new hospital offers the opportunity for a responsive design which addresses the requirement for the sharing of Works with the wider community for the mutual benefit of both the functioning hospital campus and the local community at large.

Embodied in this approach will be the Travel Plan which addresses issues of local and regional access to the new Works in terms of

a. Car parking provision;

b. Public Transport Nodes;

c. Distance to Local Amenities;

d. Pedestrian routes and links;

e. Facilities for cyclists; and

f. Segregation of emergency servicing and visitor access routes.

The Contractor's objective should be to create an easily accessible healthcare facility which incorporates a Green Transport Strategy, segregates traffic flows and prioritises pedestrian routes. The strategy will require to be jointly developed by the Contractor in conjunction with the Board and Glasgow City Planning Authority taking cognisance of the Board's site-wide masterplan requirements.

Given the nature of the patient group, the children's hospital shall be extensively accessed by family groups and parents at varying time of night and day. Accessibility and amenity in design should take cognisance of this consideration.

The Contractor should consider opportunities in the building for third party development of support facilities such as retail outlets, cafes, health clubs, sports injury clinics, gymnasiums etc.

4.5.2 Sense of Place

The Works shall be designed to compliment and enhance the quality of the design in the locality in which it is sited. It shall create a welcoming, inclusive and vibrant environment, and shall enable easy access by the communities and groups who will use it. It shall be seen as a leading edge community resource reflecting the objectives of a modern NHS in the regeneration of healthcare facilities.

The Works shall be organised to establish a continuity of building frontage and a clear definition of public and private spaces. The viewing of service areas or more “industrial” looking parts of the Works from public entrances or from adjoining public spaces shall be avoided.

4.5.3 Good Neighbour

The Contractor shall ensure they are considered as a ‘good neighbour’ throughout design and construction periods. It shall add value to the neighbourhood, not detract nor be a nuisance. The Contractor shall register with and fully comply with the requirements of the Considerate Constructors Scheme. All sites registered with the Scheme are monitored by an experienced industry professional to assess their performance against the eight point Code of Considerate Practice which includes the categories Considerate, Environment, Cleanliness, Good Neighbour, Respectful, Safe, Responsible and Accountable.

The three main areas that the Scheme’s Code covers are:

a. The Environment: Registered sites should do all they can to reduce any negative effect they have on the environment. They should work in an environmentally conscious, sustainable manner;

b. The Workforce: Registered sites should provide clean, appropriate facilities for those who work on them. Works should be comparable to any other working environment;

c. The General Public: Registered sites should do all they can to reduce any negative impact they may have on the area in which they are working. Sites should aim to leave a positive impression on those they affect.

The Contractor shall provide Works which contribute to improving civic design, sensitive to its relationship with its surroundings, public transport and overall visual impact.

4.5.4 Neighbourhood & Community

The building height, volume and skyline shall relate well to the surrounding environment.

The design shall reflect the importance of the project in the context of community healthcare in the heart of an urban conurbation. Attention shall be paid to detail in the elevations, to ensure that blandness and lack of relief is avoided.

The form of development shall follow any changing topography across the Site, neighbouring properties, existing streetscape and landscape. The design of the Works shall be sensitive to and maximise existing Site features. It is envisaged that the buildings should compliment other new building developments in the area.

4.5.5 Site Fit

New buildings, parking areas, other infrastructure and services shall be located with regard to the existing landscape and topography. Amenity space shall be planned around the buildings at appropriate places.

The Contractor shall ensure that the design of the Works shall take account of the ecological and landscape features of the Site and maximise the retention of trees. There shall be a clear programme for future environmental improvements e.g., an arboricultural strategy for tree management and replanting, dedicated access to external grounds by patients, visitors, local communities and staff.

The design of the Works shall identify areas of the Site as possible expansion zones.

Suitable provision shall be made for refuse storage including provision of appropriate refuse bins and recycling facilities. Full details to be submitted to, and approved by the planning authority prior to the commencement of works

4.5.6 Hard & Soft Landscaping

The landscaping scheme shall be of a high quality. It shall assist in knitting the Works into its surroundings, and provide an interlinked network of attractive public spaces for amenity and circulation for use by patients, staff and visitors. The soft landscape design and choice of species shall be sympathetic to the character of the existing parkland landscape.

External hard and soft landscaping (including courtyards) shall be designed for therapeutic use and provide patient access. The landscape scheme shall facilitate security of pedestrians and avoid ‘No-Go’ areas. The design shall contribute to improving the environment of the local community.

Both hard and soft landscaping design require to specifically accommodate the needs of children and family groups, particularly in the areas adjacent to/around the children’s hospital.

Courtyards adjacent to the amenity area require to be accessible to patients, visitors and staff, with the Contractor to co-ordinate fire escape solutions to support this function.

A comprehensive and integrated landscape strategy taking into account the existing landscape features shall be developed. A clear strategy shall be developed for appropriate formal and informal treatment of public and private areas.

For further detailed landscaping scheme requirements refer to Sections 7.13 and 7.14.

4.6 **AEDET and ASPECT**

Healthcare building design frequently involves complex concepts which are difficult to measure and evaluate. In order to assist both the Board and the Contractor, the Board expects the Contractor to utilise the Achieving Excellence Design Evaluation Toolkit, more commonly known as AEDET Evolution and the associated supplementary tool ASPECT which are recognised as the exemplars of Design Quality Indicator (DQI) tools.

AEDET and ASPECT are to be used to assist in achieving the appropriate level of project design management and will be specifically directed towards achieving excellence in design rather than ensuring compliance with legislation, regulation and guidance. The toolkit poses a series of clear, non-technical statements, encompassing the three key areas of Impact, Build Quality and Functionality as a tool for evaluating the quality of design in healthcare buildings which have been evolved from sources including the Commission for Architecture and the Built Environment (CABE) and the Construction Industry Council (CIC) to establish an industry-wide framework for assessing design.

AEDET shall be used at various stages during the design – as the level of detail of the information available increases it should be possible to respond to more of the statements in the tool. As a minimum AEDET assessments will take place on the return bids as well as in preparation for FBC.

To complement AEDET Evolution, the Department of Health (England) Estates and Facilities Directorate has developed the ASPECT toolkit. ASPECT stands for A Staff and Patient Environment Calibration Tool and is based on a database of over 600 pieces of research. That research deals with the way the healthcare environment can impact on the levels of satisfaction shown by staff and patients and on the health outcomes of patients and the performance of staff. This research and the ASPECT toolkit itself are set out under 8 headings. When used to support AEDET Evolution ASPECT enables the user to score the Staff and Patient Environment Heading of AEDET Evolution in a more detailed, accurate way.

Section 5.0 General Design & Construction Requirements

5.1 Minimum Design & Construction Standards

5.1.1 NHS Publications

General

5.1.1.1 The Board has considered the documentary advice and guidance provided by Health Facilities Scotland and the Facilities Directorate of the Department of Health in relation to Health Building Notes ("HBN"), Health Technical Memoranda ("HTM"), Fire Practice Notes ("FPN") and other National Health Service published material.

5.1.1.2 The Contractor in carrying out of the Works shall comply with the requirements of the documents listed in *Table 2 – NHS Mandatory Documentation* in Section 5.1.2. Specific statements of compliance form an aspect and element of the bid return and evaluation process and requirements, with the requirement for bidders to clarify their approach during the bid period as an aspect of the dialogue process.

5.1.1.3 The Contractor in carrying out the Works shall have regard to and take into consideration the requirements of the documents listed *Table 3 - NHS Guidance Documentation* in Section 5.1.3. Specific statements of compliance form an aspect and element of the bid return and evaluation process and requirements, with the requirement for bidders to clarify their approach during the bid period as an aspect of the dialogue process.

5.1.1.4 Documents listed in *Tables 2 and 3* (together part of "NHS Publications") are deemed to include all volumes, supplements and any other associated requirements, unless specific volumes, parts or the like are specifically noted or noted as excluded.

5.1.1.5 Any reference to HTM/HBN is deemed to include SHTM/SHPN. The requirements of SHTM/SHPN shall take precedence over HTM/HBN unless expressly required otherwise by the Board and noted in *Table 2 or 3.* Presently *Tables 2 and 3* include reference to HTMs in relation to services systems. It is the intention of the Board that the new SHTMs in these areas, due for release by HFS late April/early May 2009, will be adopted and require to be complied with, as shall other SHTMs issued during the procurement process (subject to 5.1.9 below) – this to be clarified by the Board during the bid period. Current draft documentation is marked in *Tables 2 and 3* in blue shading.

5.1.1.6 In the event of any conflict (including differing requirements or interpretations) between the requirements of the documents listed in *Table 2 or Table 3* and the requirements of building control officers, such conflict should be highlighted to the Board for agreement and resolution. The Contractor shall notify the Board in writing of any such conflict as soon as he becomes aware of same;

5.1.1.7 In the event of any conflict between the requirements of the documents listed in *Table 2 or Table 3* or any other drawn or written information issued by the Board and the Schedule of Accommodation (SoA) information issued by the Board in this ITPD, the SoA identifies the minimum area requirements of the Board (in relation to room sizes).

5.1.1.8 In the event of any conflict between the requirements of the documents listed in *Table 2 or Table 3* and any written or drawn information issued to the Contractor by the Board in this ITPD, the information issued by the Board shall take precedence.

5.1.1.9 All references in these Employer's Requirements to NHS Facilities Scotland Requirements, building and engineering standards, Building Regulations, legislation,

Statutory Requirements, Codes of Practice, Department of Health publications, NHS Publications and other published guidance shall be deemed to mean those in place at the date of signing the construction contract. Any date reference in *Table 2 or Table 3*, therefore, may be replaced/read as that in place at the date of signing the construction contract.

5.1.1.10 Except as noted in 5.1.7 or 5.1.8 above, the Contractor shall provide Works which comply at all times with the requirements of *Table 2, Table 3* and the Additional Guidance identified at Section 5.1.4.

5.1.2 **NHS Mandatory Documentation**

In relation to the architectural design, structural design, and services design of the new buildings comprised in the Works, the documents listed in the following *Table 2* below set out that guidance which the Board considers to be mandatory.

5.1.4 **Additional Guidance**

5.1.4.1 Further to the requirement noted in Section 2.2, that the Contractor shall comply with all Law and Consents, and the requirements in relation to NHS Mandatory Documentation and NHS Guidance Documentation above, the Contractor shall also comply with the standards and documents listed below.

a) Health and Safety Legislation, including Construction (Design and Management) Regulations 2007;

b) The Technical Standards complying with the Building Standards (Scotland) Regulations 1990 as amended by all subsequent Amendment Regulations;

c) Disability Discrimination Act 1995;

d) Current British Standards, European Standards, and Codes of Practice, as appropriate;

e) Strathclyde Fire Brigade and the Glasgow City Council's Fire Officer requirements;

f) The Board's Approved Codes of Practice, Procedure and Policy documents as listed in Appendix G;

g) Control of Substances Hazardous to Health;

h) Health Department Letters (or Management Executive Letters) as appropriate published by SEHD;

i) NHS QIS (Quality Improvement Scotland) 2003;

j) NHS Model Engineering Specifications;

k) The Building (Scotland) Act 2003;

l) The Building (Scotland) Regulations 2004;

m) Requirements of the utilities companies;

n) Building Research Establishment Digest Recommendations;

o) Local Bye-Law and Regulations;

p) Scottish Centre for Infection and Environmental Health guidance / recommendations;

q) All other bodies and authorities having jurisdiction;

r) Secure by Design;

s) The Ionising Radiations Regulations 1999 (IRR99);

mm) Treatments of Adults & Children with Renal Failure – Standards & Audit Measures, 3rd Edition, Renal Association (August, 2002);

In addition the renal COS notes that water treatment should reach a minimum of the following standards:

nn) The higher European Pharmacolela (EP) XV1 standard :'Water for diluting concentrated haemodialysis solutions';

oo) ISO 13959: 'Water for haemodialysis and related therapies' or
AAMI (Association for the Advancement of Medical Instrumentation) standards; and

pp) European Renal Association Best Practice Guidance – 4th Edition 2007. NB New guidelines are due in 2009 and should be considered at that time.

5.1.4.2 The Contractor shall provide to the Board at Completion a certificate confirming that the Works comply with the requirements of NHS Scotland Firecode.

5.1.4.3 The Contractor shall provide all fixed and portable fire fighting equipment to comply with statutory requirements and the requirements and recommendations of NHS Scotland Firecode.

5.1.4.4 The Contractor shall ensure that the Works comply with the relevant requirements of Building Better Healthcare Volume 3 (published by NHS Estates); except insofar as there are NHS Scotland publications, which shall take precedence over the respective elements of Building Better Healthcare.

5.2 **Hierarchy of Standards**

5.2.1 Where there is any conflict between two or more documents, the more onerous standard shall be complied with by the Contractor, at no additional cost to the Board.

5.2.2 NHS Scotland standards shall take precedence over equivalent NHS England & Wales standards unless the NHS England & Wales standard is specifically identified in *Table 2 or Table 3*.

5.2.3 In certain instances, NHS Publications include a number of options or alternative solutions. Where the Board has defined their preference in *Table 2, Table 3* or in these Employer's Requirements the Contractor shall adopt these preferences as a mandatory requirement. As is noted in 5.1.1.2 and 5.1.1.3, the Contractor shall identify their interpretation and choice (of any options within documents) in NHS Publications during the bid period (to which the Board will review and respond) with compliance statements required in their bid return.

5.2.4 While the Board has placed a clear obligation on the Contractor in relation to NHS Publications, it also wishes to acknowledge that in certain cases the subject matter, guidance and advice included therein has been further developed and improved since the date of publication. While applying the foregoing as a base position, the Board does not wish to limit the use of current best practice or innovation in relation to the adoption of design standards. Consequently, the Board therefore wishes the Contractor to actively engage the Board in an on-going dialogue during the design process in order for the Board to review and agree to any proposed alternatives.

5.2.5 The Board considers NHS Publications reflect minimum standards and any alternatives proposed by the Contractor shall provide an equivalent or enhanced level of service and quality.

5.2.6 Further to the statements above in relation to NHS Publications, it should be noted that the Schedules of Accommodation (SoA) in Appendix C take precedence with regard to room sizes. The room sizes therein must be provided by the Contractor as a minimum requirement.

5.2.7 Further to the statements above in relation to NHS Publications, the following hierarchy of other design related documents shall apply (in order of precedence):

a. 1:50 drawings;

b. Room Data Sheets; and

c. Equipment Lists.

5.3 Life Expectancies & Lifecycle Requirements

5.3.1 The buildings, including building services components, shall be designed with materials, components and techniques that are readily available, reliable, sustainable and easily maintainable in use. The Board supports buildings constructed of proven technology components, with high life expectancy, leading to minimum cost in use.

5.3.2 Good Industry Practice for a design life at Completion for the elements listed below shall as a minimum be as indicated in the table below:

Table 1 – Component Life Expectancies

Building Element	Expectancy
Structure, including substructure	70 years
Floor structure	70 years
Roof structure	70 years
Drainage and below ground civil engineering infrastructure	70 years
External walls	45 years
External openings, windows, doors and curtain walling	25 years
Roof finishes	40 years
External Wall finishes	25 years
External hard surfaces (inc roads/carparking/footpaths etc)	Not less than 20 years to first maintenance
Internal partitions including openings	30 years
Internal doors	15 years
Internal finishes	15 years
Internal fixtures and fittings	15 years
Ironmongery	15 years
Engineering plant Volume B	CIBSE Guide
Engineering services distribution systems Volume B	CIBSE Guide

5.3.3 The Contractor shall demonstrate that the theoretical design life proposed for any element will be achieved.

5.3.4 Materials and components forming part of the Works, which require maintenance and replacement within the life of the Works, shall be selected, located and fixed in such a way as to minimise future inconvenience, disruptions and to avoid temporary closure of the Works.

5.3.5 Lifecycle Costs

5.3.5.1 It is a requirement of the Bid that a detailed Life Cycle Cost Plan (LCCP) be provided for the new facilities – it is envisaged that 3no.separate LCC Plans will be required for the project;

a. Acute Adult Hospital;

b. Childrens Hospital; and

c. Laboratory Block.

NB – it is assumed that External Works and FM/Energy Centre etc buildings will be separately identified and incorporated into the Acute Adult Hospital LCCP.

5.3.5.2 It is a requirement that the LCCP's be produced in accordance with the methodology as detailed in the following documentation;

a. BS ISO 15686 – 5 2008; Building & Construction Assets – Service Life Planning – Part 5 – Life Cycle Costing; and

b. Standardized Method of Life Cycle Costing for Construction Procurement

5.3.5.3 LCCP submissions to follow the formats as detailed in the above documentation, utilising the following base criteria:

Table 2 – Life Cycle Cost Plan component elements

REF	ELEMENT	DESCRIPTION	REQUIREMENT
1.0	Design Life	n.a.	60 years
2.0	LCCP Duration	Period to be considered within LCCP (NB – excluding Construction Period)	30 and 60 years
3.0	Discount Rate	NVP rate	3.5%
4.0	Base Date	Base Date for Costs	Acute & Childrens Hospitals – 1Q2015 Laboratory Block – 1Q2012
5.0	Client On Costs	Bidders to **exclude** Client On Costs to LCCP values	n.a.
6.0	LCCP inclusions	Schedule of LCC Information and Assumptions	
6.1	LCCP Summary Sheet	Elements for inclusion in Life Cycle Cost Plan	All as detailed in Standardized Method Appendix F.3&4, with the following **exclusions:** 1.3 – Client Definable Costs 2.7 – Client Definable Costs 3.1.2 – Internal Cleaning 3.1.3 – Specialist Cleaning 3.3. – Administrative Costs 3.4 – Overhead Costs 3.5 – Taxes 3.6 – Client Definable Costs. 4.17 Occupancy Costs 5.3 – Reinstatement & Dilapidations 5.4 – Client Definable Costs

6.2	LCCP Data Sheets		Data sheets to itemise: • Component Description • Work Description • Quantity • Unit • Component Cost Rate (£) • % Allowance of Cost Rate for Replacement • % Allowance for Replacement • Replacement Factor • Life Expectancy of Component • Number of Replacements • Cost per Replacement (£) • Total Cost of Replacement (£)
			All above elements to be provided in BCIS Elemental format
6.3	FM Data Sheets (Hard FM only)	Bidders to allow for the following FM Services: • Minor replacements, repairs & maintenance costs • Unscheduled repairs, replacement & maintenance costs • Grounds Maintenance	Data sheets to itemise: • Management Costs • Staff/Contracted Costs • Materials • Equipment Bidders to **exclude** Client On Costs to FM Services values

5.3.3.4 Although the Contractor will not be involved in the provision of FM Services, the proposed Design will impinge on the Boards operation of the facilities, and to this end the evaluation of the Bidders overall submission will take into account proposals to minimise the potential operating costs;

5.3.3.5 Bidders should therefore indicate where measures in relation to the following criteria have been utilised

a. 'Spend to Save' specification enhancement;

b. Design detailing;

c. Controls;

d. Standardisation; and

e. Modular construction.

5.3.3.6 All Innovation & Sustainability initiatives proposed by the Bidder, should be supported by a full Lifecycle Cost Plan as detailed above, and include;

a. Items as detailed in Section 6.1/2 – of the above LCC table;

b. Projected Energy & Carbon savings;

c. Payback period; and

d. Items as detailed in Section 6.1/3 – FM Data Sheets of the above LCC table.

5.3.3.7 The Bidders attention is drawn to the BREAAM LCC requirements, which need to be encompassed as part of the overall LCCP submission – all as detailed in Appendix U.

5.3.3.8 In connection with the above, and for bid comparison purposes, Energy consumption/savings calculations should utilise the following base cost and associated allowances;

a. Electrical consumption – 10p / KwH;

b. Gas consumption – 3.5p / KwH;

c. Oil consumption – 41p / litre;

d. Water consumption – £2.20 / m3;

e. Waste material disposal (bagged) – £60/ton;

f. Carbon production/reduction data to be provided to support above proposals; and

g. Payback periods to be provided.

5.4 Integration of Design

The Contractor is responsible for the integration of the various aspects and elements of the design of the Works.

5.4.1 Architectural / Structural Interface

5.4.1.1 Structural floors shall be designed to have penetrable zones co-ordinated with the modular framework for partitions and services.

5.4.1.2 Structural timber floors shall not be permitted.

5.4.1.3 Columns shall be located in-so-far, as is reasonably practical to coincide with corridor walls in order to minimise intrusion into rooms or corridors. The relationship of column ducts and walls shall permit clear internal room surfaces and not obstruct equipment or fittings.

5.4.1.4 As far as practical, the walls to vertical service shafts shall be non-load bearing and therefore maximising opportunity for future services installation, alteration and maintenance.

5.4.1.5 The elevation design shall facilitate distribution of services at the building perimeter.

5.4.2 **Integration with Engineering Services**

5.4.2.1 Internal walls, partition systems, ceiling voids and service risers shall be capable of integrating services, e.g. wiring, plumbing, medical gases and service terminals as required without detriment to the performance of any building services and other Works performance criteria such as fire resistance or acoustic properties. Services shall be co-ordinated and a satisfactory means of maintenance access shall be provided.

5.4.2.2 So far as is reasonably practicable, vertical service shafts shall not be surrounded by load bearing structural walls, to facilitate services installation and future alterations.

5.4.2.3 The Contractor shall be responsible for bunding and waterproof slab construction above theatres and in plant rooms to provide resilience and avoid flooding whilst ensuring functionality of engineering services.

5.4.3 **Manual Handling**

5.4.3.1 The Contractor, in the design of the Works, shall give due consideration to the obligations contained in the Manual Handling Regulations 1992 and ensure the appropriate allocation of space and structural capacity for the inclusion of mechanical devices, i.e. fixed and mobile hoists, robotic equipment and all FM, staff and patient lifts.

5.5 Sustainability

5.5.1 The Board has a significant asset base and, as a responsible healthcare provider and employer, it is committed to sustainability and carbon reduction in line with relevant and appropriate guidance and directives in this area. The Board has targeted an 'Excellent' BREEAM rating for the Project.

5.5.2 The specific sustainability considerations with regard to the Project and the requirements of the Contractor in this respect are detailed in Section 10.0 and Appendix M.

5.6 Control of Infection

5.6.1 Prevention and control of infection shall remain a primary consideration of the Contractor in the design and construction of the Works. The whole hospital design shall place a high priority on infection prevention and control in relation to the movement of goods and in particular the segregation as far as is reasonably practicable of clean linen, food trolleys and the removal of waste, soiled linen and empty food trolleys. The Contractor will be required to demonstrate to the satisfaction of the Board's Infection Control Team that the design and construction of the Works fully reflects and incorporates the following key infection control challenges;

a) Segregation of clean and dirty – laundry, food, healthcare waste;

b) Ventilation system – including the use of natural ventilation in relation to the affect by neighbourhood sources of environmental pollution;

c) Selection of Fixtures/fittings/flooring that are easy to clean and maintain;

d) Appropriate Isolation facilities;

e) Incorporation of appropriate workflows;

f) Handwash hygiene;

g) Wastewater and sewage/body fluid disposal;

h) Heating and lighting;

i) Water systems;

j) Food preparation.

5.6.2 The Contractor shall provide that all aspects of the Works allow the control and management of an outbreak and spread of infectious diseases in accordance with the following;

a. Infection Control in the Built Environment: Design and Planning (SHFN 30);

b. NHS Scotland HAI Scribe (Healthcare Associated Infection System for Controlling Risk In the Built Environment);

c. Scottish Infection Manual – 'Managing the Risk of HAI in NHS Scotland';

d. Guidance provided by Clinical Standards Board NHS QIS;

e. Textiles and Furniture (SHTM 87);

f. Ventilation in Healthcare Premises (SHTM 2025); and

g. The location of maintenance access to services and requirements of SHTM2023.

5.7 Design for Disability

5.7.1 The design shall comply with the requirements of the Disability Discrimination Act 1995, and take full consideration of HFN14 "Disability access", HFN20 "Access audits for primary healthcare facilities" and BS 8300:2001 “Design of buildings and their approaches to meet the needs of disabled people – code of practice”. Further guidance is provided in the NHS publication "Doubly Disabled: Equality for disabled people in the new NHS - Access to services”.

5.7.2 The Contractor shall ensure that the design and functionality of the Works meets the requirements of the Disability Discrimination Act 1995 as relevant and set standards of best practice to enable full access and use of the services and facilities available.

5.7.3 Entrances to the Works shall be clearly identified to promote ease of wayfinding and distinctive ‘landmarks’ shall be incorporated into the design particularly for the main entrances.

5.7.4 The Works’ environment, both externally and internally, shall be designed to be accessible to everyone. The journey onto the Site, from pedestrian / vehicle routes, through the main receptions, into the Works and to the desired locations shall follow a safe, logical and clear system.

5.7.5 Attention shall be paid in the design to all aspects of the physical environment relating to the accessibility of the Works as follows:

a. Access to buildings, such as level or ramped entry;

b. Emergency evacuation arrangements, in particular for the visually impaired, the disabled and the frail, such as fire refuges or alternative escape routes for people with mobility impairments;

c. The accessibility of external paths and landscaping;

d. Circulation within buildings, including their interior layout;

e. Effective lighting and signage and colour or tone contrast on doors to aid orientation;

f. Desks, laboratory benches, work surfaces and reception desks at varying or flexible heights;

g. Appropriate seating;

h. Accessible toilets; and

i. Convenient and reserved parking spaces for those who need them.

5.7.6 The Contractor shall ensure, as far as practically possible, that the Works design draws upon and endeavours to further develop improve and exceed current best practice and standards achieved in other similar projects, and incorporates full accessibility for the prospective patient groups, staff and public. This shall include aspects of both physical environment and visual and audio aids to enable full use of the Works for all groups. This philosophy of design shall be extended across all parts of the Works including access to the landscaped and external areas as well as the essential patient treatment and residential areas.

5.7.7 The Contractor shall ensure the design complies with the general accessibility ethos detailed above, whilst also addressing the detailed requirements listed elsewhere. It should be noted

that the requirements detailed are not exhaustive, and it is also recognised that specific clinical needs will determine the nature and design of Works in some areas.

In particular it is highlighted that the Works will be used by a high proportion of wheelchair users. The Contractor shall ensure that any fire evacuation procedures take full account of this.

In meeting the overarching obligations with respect to accessibility, The Contractor shall comply with the following non-exhaustive list of standards:

a. BS8300:2001 “Design of buildings and their approaches to meet the needs of disabled people – Code of practice”;

b. HFN 14 “Disability Access” and HFN20 “Access audits for primary healthcare Facilities”;

c. HFN 20 “Access audits for primary healthcare Facilities” ;and

d. HFN 21 “Car parking”.

5.7.8 BS8300:2001 is widely referred to by consultants advising on general building design in relation to the Disability Discrimination Act (1995). The Contractor shall therefore refer to this document and give full regard to its standards. It will, however be necessary to match the standards of BS8300 with others laid down in NHS guidance notes etc.

5.7.9 The Contractor shall also comply with further guidance contained in the NHS publication “Doubly Disabled: Equality for disabled people in the new NHS - Access to services”.

5.7.10 The obligations with respect to accessibility, as described in this Part 8 Section 3, are intended to reinforce the principles established within BS8300. Some, however, stand as requirements that deliberately exceed the minimum stated within BS8300. For the avoidance of doubt, specific accessibility requirements listed in this Part 8 Section 3 shall take precedence over the standards laid down in BS8300.

5.8 Equipment Requirements

5.8.1 The Equipment List is contained in Appendix F. This identifies equipment by Group (for pricing in bid returns), with location of equipment ascertained via the ADB Room Data Sheets (for all rooms) and exemplar 1:50s for those drawn at this stage. Group 1 Equipment shall be supplied and fitted by the Contractor, with Group 2 Equipment provided "free issue" to the Contractor by the Board and fitted by the Contractor. The Board are responsible for the supply and installation of Group 3 and Group 4 Equipment.

5.8.2 Notwithstanding the party who provides/supplies equipment, the Contractor shall identify and provide all necessary fixings and supports (to walls, ceilings and floors) connections and infrastructure (including supply, extraction and removal of waste) for all items of equipment listed in Appendix F.

5.8.3 The Contractor shall provide a suitable environment for each item of equipment as set out in the Room Data Sheets, this shall include accounting for temperature and ventilation requirements.

5.8.4 For the avoidance of doubt, this requirement specifically includes MEIGaN compliance and specialist service requirements by the Contractor, including for example 3-phase electrical supply, surge protection, standby power supply, ups, special water supply requirements and separation of contaminated waste.

5.8.5 For the avoidance of doubt, this requirement specifically includes the installation of renal water equipment and supplies by the Contractor to the meet the requirements of the Board.

5.8.6 Irrespective of the party responsible for the supply, installation, maintenance and replacement of each item of equipment, the Contractor shall provide Works that satisfy the following criteria:

a) allow Equipment and associated systems to be installed, commissioned, operated, maintained and replaced in accordance with:

i) Good Industry Practice;

ii) Manufacturer's instructions; and

iii) The Board's, statutory health and safety requirements.

b) Allow Equipment and associated systems to operate efficiently, effectively and in accordance with its intended function for the whole of its design life when operated in accordance with the manufacturer's requirements;

c) Take due account of the impact on the environmental conditions within the Works;

d) Take due account of the potential impact of future equipment changes through either refresh or replacement. In particular, allowance for equipment of different sizes, weights, service requirements or environmental impacts;

e) Allow the Board to provide their Clinical and Non-Clinical Services with a minimum of disruption during installation, commissioning, operation, maintenance and replacement; and

f) Provide safe and unencumbered access for maintenance and replacement of equipment during the buildings life, to include pulley hoists, barrier walkways and

landings and reinforced routes and areas as necessary to assist the safe removal and replacement.

5.8.7 The construction, structure, plant and services shall be designed to meet the specific requirements for Special Equipment and associated services. The design of the Works shall meet these requirements with regards to mechanical and electrical servicing, wall and floor loads, structural movement and deflections, the need for special (including protected) floors, wall supports, ceiling grids and other such measures to allow for the installation, maintenance and replacement of Special Equipment and associated services. Specific Special Equipment is identified in Appendix F.2. The particular interface arrangements between the Contractor and the Board with regard to the provision and fit-out of Special Equipment shall be finalised during the Competitive Dialogue process.

5.8.8 The Contractor shall not change the Group designation of any Equipment. The Equipment List issued at Appendix F.1 shall be priced and submitted in the bid return with no additions, omissions or changes unless requested in writing by the Board as an aspect of the bid period.

5.8.9 The procurement, delivery and installation of Group 2 Equipment shall be as follows:

a) The Contractor shall procure and deliver, or arrange for the delivery to Site, all Group 2 Equipment to a secure central holding area (suitable for the equipment to be stored) to be provided by the Contractor. The holding area requires to be accessible by vans, 7t trucks and articulated vehicles – with vehicle movements in the operation of dropping off or picking up from the holding area to be managed by the Contractor;

b) The off loading or up loading of any Group 2 Equipment will be attended by the Contactor who shall acknowledge receipt of every delivery and sign the relevant delivery receipts to that effect. The Contractor shall manage and carry out the conveying of all Group 2 Equipment into the holding area;

c) The Contractor shall manage the movement and delivery of all Group 2 Equipment from the holding area to the point of installation in time for installation the same day;

d) The Contractor shall prepare and maintain a log of all Group 2 Equipment delivered to Site in an electronic and paper format, providing monthly updates to the Board of the status of delivered, stored and installed Group 2 Equipment; and

e) Should the Contractor arrange for a secure central holding area off or adjacent to the Site the Contractor remains responsible for the Group 2 Equipment that has been delivered and the movement of same to the Site for installation.

5.9 Materials

5.9.1 The Contractor shall ensure that all materials incorporated into the Works shall comply with the requirements of the Construction Products Regulations 1991, and all aspects of the Employer's Requirements.

5.9.2 The Contractor shall ensure that all products and materials to be incorporated into the Works shall be new unless otherwise agreed by the Board.

5.9.3 Where materials and components are not specifically identified as complying with the Construction Products Regulations 1991, The Contractor shall ensure that they comply with the relevant British Standards and Codes of Practice.

5.9.4 The Contractor shall ensure that the whole quantity of each product and material required to complete the Works is of a consistent type, quality and overall appearance and is fit for its intended purpose. The Contractor shall ensure all products and materials are handled, stored, prepared and used or fixed strictly in accordance with the manufacturers' written instructions or recommendations and not be damaged when incorporated into the Works.

5.9.5 The Contractor shall not construct the Works utilising substances which are hazardous to health, including but not limited to substances referred to as being hazardous to health and safety in "The Control of Substances Hazardous to Health Regulations 2002".

5.9.6 The Contractor shall not specify or include products or materials that do not comply with relevant British or European Standards, Codes of Practice or which are generally known within the European Union at the time of specification to be deleterious to health and safety or to the durability of buildings and / or other structures and / or finishes and / or equipment, plant and machinery in the particular circumstances in which they are used. Such materials include but are not limited to:

a) High alumina cement in structural elements;

b) Marine aggregates or their derivatives where the chloride iron content by mass of cement exceeds the requirements of Table 4 of BS 5328: Part 1;

c) Aggregates where the drying shrinkage characteristics, when tested in accordance with BS 812: Part 120, exceed a value of 0.05%;

d) Aggregates for use in reinforced concrete which do not comply with BS 882 or with the provisions of BS 8110;

e) Water used in construction or manufacture which is not clean, fresh or free from chemical or organic impurities or does not otherwise comply with BS 3148;

f) Concrete where the total mass of the reactive alkali in the concrete mix exceeds the recommendations set out in the Concrete Society Technical Report No 30;

g) Woodwool slabs in permanent formwork to concrete or in structural elements;

h) Calcium chloride in admixtures for use in reinforced concrete or reinforced masonry construction;

i) Calcium silicate bricks incorporated within any load-bearing part of the structures, or other areas of the construction which are deemed to be load-bearing in any way;

j) Asbestos or asbestos-containing products;

k) Lead, or any material containing lead, which may be ingested, inhaled or absorbed, except where copper alloy fittings containing lead are specifically required in drinking water pipework by any statutory requirement or in architectural design features (e.g. weather flashings, radiation protection);

l) Urea formaldehyde foam, or materials which may release formaldehyde in quantities which may be hazardous with reference to the limits set from time to time by the HSE, at the time of incorporation in to the Works comprising the project;

m) Softwood used externally, except for non structural landscaping or in areas agreed with the Board (e.g. pressure treated pine decking);

n) Slipbricks;

o) Polyisocyanurate foam;

p) Polyurethane foam;

q) Extruded polystyrene other than low ozone depletion materials;

r) Other substances, which at the time of their incorporation into the project, have been designated by the Building Research Establishment and published in their Digest, as deleterious to health and safety or deleterious to the building fabric, including both substructure and superstructure, in the particular circumstances in which these substances are used;

s) Products associated with the destruction or depletion of tropical rain forest or threatened animal species;

t) Products or manufacturing processes which cause the emission of pollutants, armful radiation or ozone depleting chemicals, as identified in the Montreal Protocol;

u) Use of noxious substances including DoE “Red List” and EC “List 1” substances;

v) Materials which are generally composed of mineral fibres, either man-made or naturally occurring, which have a diameter of 3 microns or less and a length of 200 microns or less, or which contain any fibres not sealed or otherwise stabilised to ensure that fibre migration is prevented;

w) Lightweight or air-entrained concrete bricks;

x) Iberian roof slates; and

y) Fibrous boards, including MDF board, in any external construction work.

5.9.7 The Contractor shall obtain confirmation that all timbers are “Certified Wood”.

5.9.8 The Contractor shall certify at Completion that none of the materials, products or constructions listed has been used in the construction of the Works, or incorporated in them, other than where specific written consent from the Board has been obtained. The Contractor shall also notify the Board of any other material which may become designated as prohibited at any time after incorporation into the project, during the Defects Period.

5.9.9 The Contractor shall provide samples and prepare mock-ups of external cladding systems or building components as requested by and for the approval of the Board as follows;

a) Sample panel of curtain walling/external wall construction, nom 4m x 4m to include a sample window and any associated bris soleil or sun shading detail. To remain as reference sample until envelope complete;

b) All external finishes;

c) External and internal doorsets;

d) External and Internal windows and curtain walling, including all standard ironmongery;

e) Ironmongery;

f) Typical bed head arrangement for Adult and Children's Wards (could be part of mock up);

g) Nurses Station design and materials – mock up;

h) Floor, wall and ceiling finishes – samples and colour schemes indicating interior design strategy intent;

i) Light fitments;

j) Power, voice and data switches outlets etc;

k) Sanitaryware, taps outlets and IPS proposals, (part of a mock up);

l) All signage and Wayfinding proposals;

m) Lifts and other key M&E installations;

n) Wall protection and handrail systems;

o) Public art; and

p) Hard and soft landscape proposals and external works.

5.10 Energy Strategy

5.10.1 In accordance with best practice, the Contractor shall consider key design features including, but not limited to:

a) Use of passive ventilation where appropriate whilst minimizing mechanical cooling;

b) Use of heat recovery for exhaust air;

c) Use of redesigning processes and products to close the technical loop using recovered and bio-based materials;

d) Use of natural daylight into areas which require continuous illumination such as central/circulation areas;
e) Use of natural daylight through maximum use of lighting dimmer controls; and

f) Implementation of renewable energy sources – solar, wind, landfill gas, biomass and low impact hydroelectric, geothermal, low carbon heating systems and heat pumps.

5.10.2 The Contractor shall demonstrate that their proposals will effectively reduce water consumption below the average consumption data contained in SHTM 2027 for the type of accommodation being developed by the Board. The Contractor's proposals shall include estimated consumption for the Works in Litres/Bed/Day and measures that they propose allowing the Board to minimise consumption.

5.10.3 In the consideration of design for energy generation and use Bidders are requested to be aware of and consider possibilities around alignment with the "Sustainable Glasgow" initiative. The Bidders are to demonstrate such consideration and report on their findings. The contact point for Sustainable Glasgow is:

Richard Bellingham
Senior Research Fellow
Energy Policy
Fraser of Allander Institute
University of Strathclyde
richard.bellingham@strath.ac.uk

5.10.4 The Contractor shall submit a Mandatory Variant bid providing for a Maximum Temperature provision (26degC).

5.10.5 The specific energy requirements of the Board are detailed in Section 8.0 and Appendix M.

5.11 Fire Strategy

5.11.1 Fire safety in the proposed facility shall be controlled by Building Regulation, Health Technical Memoranda Firecode, and Fire Practice Notes, subject to approval by the Board's Fire Safety Advisor.

5.11.2 The Contractor must comply with the requirements of these publications, as a minimum standard, although it is recognised that alternative solutions based on a fire engineering approach may be more appropriate to the Contractor's design. Should the Contractor pursue an alternative approach it shall be their responsibility for meeting the minimum standards set out in the publications, fully satisfying the regulatory authorities of the appropriateness of its proposals and obtaining the necessary approvals.

5.11.3 The Contractor is required to prepare a Fire Safety Strategy document, including Fire Strategy drawings to demonstrate compliance with the relevant regulations. This document shall cover all aspects of fire safety, fire fighting and building management, including compartmentation and the ventilation implications of the Building.

5.11.4 The Contractor shall be required to ensure that all premises to be occupied by the Board have been appraised prior to occupation by competent persons appointed by the Board for compliance with Firecode and all Legislation are being met and shall provide the Board with an Annual Certificate of Firecode Compliance. For the avoidance of doubt the Contractor shall provide all fixed and portable fire fighting equipment to comply with statutory requirements and those of NHS Scotland Firecode. For the avoidance of doubt the Contractor requires to accommodate all fire fighting equipment which will be located within secure lockable containers housed in the wall construction, and operated by the same key throughout the development.

5.11.5 The Contractor shall provide a fully operational fire alarm system to meet the needs of the Works.

5.11.6 The specific requirements of the Board with regard to Fire Strategy are detailed in Appendix R.

5.12 Flexibility and Adaptability

5.12.1 The Contractor shall in the design of the Works consider opportunities which present themselves for the future expansion of Clinical and Non-Clinical Services.

5.12.2 The Contractor shall ensure, as far as is practical, that the Works structure and envelope, services, partitioning, ceiling, and flooring systems are consistent with a co-ordinated methodology which facilitates future flexibility for re-planning and change in the layout of departments, rooms, services outlets and equipment. In particular, it shall be possible to install or relocate fittings, fixtures, equipment and service outlets with minimum disruption to the use of the Works.

5.12.3 The design for the Works shall take full account of, but not be limited to:

a) Changes in technology, both clinical and non-clinical (e.g. systems of care and volume of work);

b) Building structures shall be designed by the Contractor to facilitate ease of alteration to the internal layout of the building, or to its plant, services or equipment, during the lifetime of the buildings. This shall be achieved by;

i. Selecting structural forms in which future builderworks holes for building services distribution, both vertically and horizontally (including ductwork), or equipment, may be cut simply and economically, minimising the installation of secondary framing;

ii. Providing knock out panels to permit the formation of holes not exceeding 150x150mm through suspended floors, adjacent to 50% of the internal columns on all floors. These knock out panels shall be positioned close to columns distributed across all areas of each floor;

iii. Designing the floors for imposed loadings that will permit the reallocation of space within the Works, so that each area of floor is structurally capable of supporting the imposed loads of offices, wards, corridors, general storage areas or waiting areas, together with their appropriate partition walls, finishes, ceilings, services and medical Equipment;

iv. Providing removable access panels within the structure, where these are required for the installation or removal of plant, services or equipment;

v. Internal room walls to be constructed such that they can be readily removed or altered i.e. the structure is not reliant on the walls for structural stability;

vi. Designing the structure of the buildings so that any future extensions can be constructed and brought into service with minimum disruption to the operation of the Works; and

vii. Designing plant space and riser space so that a future 25% services capacity expansion can be accommodated.

5.12.4 The structure and foundations of the buildings shall be designed by the Contractor to permit the construction in the future of further accommodation by extending the buildings horizontally or constructing further new buildings adjacent to them.

5.13 Facilities Management

5.13.1 The SoA and exemplar design have taken cognisance of the operational requirements and space/location requirements of the Board. The Contractor requires to comply with as well as design the Works to support and comply with the Board Policies (contained in Appendix P).

5.13.2 The specific requirements with regard to automatic material handling equipment (robotics), and the development of the Board's requirements and design in that regard, will be addressed during the competitive dialogue process. Details with regard to automatic material handling equipment is contained in Appendix M.

5.13.3 The Board shall have personnel integrated into the project development and the Works operations in relation to familiarisation and FM operations. The Contractor shall at all times liaise and support the integration and requirements of the Board in this respect at no additional cost.

5.13.4 The Contractor is required to provide space for maintainable, replaceable building services and plant.

5.13.5 The Contractor shall ensure that plant and equipment is suitably identified in line with the NHSScotland asset management system or equal and approved system/technologies.

5.14 Design Development

5.14.1 The bid period has specific bid return requirements (detailed in Volume 3 of the ITPD) with regard to written and drawn design information. Once the Contractor is appointed, the period to Full Business Case (FBC) approval comprises design development of the Contractor's Proposals in relation to the Hospitals, concurrent with the design and construction of the Laboratories. The design development to FBC will be fully programmed and demonstrable in a priced Activity Schedule forming an aspect of the bid returns from bidders.

5.14.2 The procedure for the review of design development will be agreed with the Contractor prior to the return of bids and the commencement of the design development.

5.14.3 The Contractor shall, as a minimum requirement, provide the information detailed in Appendix K (Design Development) as an output of Stage 2 (Hospitals Detailed Design to FBC). The satisfactory production of completed Appendix K information to the Board is one of the pre-conditions to the approval to proceed to Stage 3. More information relating to Stages 2, 3 and 3A are contained in Volume 1 of the ITPD.

5.15 Extended Defects Period

5.15.1 Due to a number of factors, including double-running/transition from other hospital sites, the Board are desirous of a defects period that provides management and physical benefits to the Project. In this regard a period in excess of the 'traditional' one year defects will be sought, with particular associated requirements in relation to:

a) Training and handover to Board personnel;

b) Correction times/periods for defects;

c) Seasonal commissioning;

d) Management activities; and

e) Performance requirements.

5.15.2 Volume 1 of the ITPD details further particular Extended Defects Period (EDP) requirements of the Board and identifies that this will form an aspect of Competitive Dialogue with bidders under the Commercial workstream.

5.16 Critical Failures

5.16.1 The Board require that the Works have inherent aspects of resilience to critical failures and mitigate operational interruptions.

5.16.2 In this regard, the Board have identified particular considerations and requirements that the Contractor shall adopt and develop as an aspect of bid return and design development. In addition to the resilience requirements of NHS Publications and the design requirements stated elsewhere in the Employer's Requirements, specific areas that the Board have prepared as exemplary are identified in Appendix X (Critical Failures).

5.16.3 The Contractor is required to comply with the provisions of Appendix X in their design, as well as provide for a developed strategy in relation to mitigation of critical failures in their bid return.

Section 6.0 Construction Phase Requirements

6.1 Site Logistics, Welfare and Board Accommodation

6.1.1 The Contractor is responsible for the provision of all temporary site accommodation/welfare and associated requirements, including the provision of car parking for site operatives during the design and construction stages. All such accommodation requires to be metered to provide readings of all utilities usage separately at any time.

6.1.2 No Contractor staff or personnel (including any sub-contractors, suppliers, supply chain members or other personnel providing any goods or services to the Contractor) are allowed to park on the Hospital Campus (except where attending as a patient or visiting/assisting a patient) during the Works.

6.1.3 The Board require the Contractor to provide dedicated site accommodation for the exclusive use of the Board and its representatives. This requires to be in the immediate environs of the Contractor accommodation on/adjacent to the Site to support joint working and meetings, but must facilitate segregation such that the Board area has a dedicated access for their use.

6.1.4 The Board require dedicated fully serviced accommodation including:

a) an open plan area with workstations, sockets and IT + telecoms connections for 10 persons;

b) an open plan area with workstations, sockets and IT + telecoms connections for 20 persons;

c) cellular offices with workstations, sockets and IT + telecoms connections for 5 persons;

d) a meeting room to accommodate 15 persons, serviced with sockets and IT + telecoms connections;

e) a suitably serviced room to accommodate a 1GB router;

f) secure wireless connectivity;

g) male, female and disabled toilet facilities;

h) a kitchen area with seating for 10 persons; and

i) adjacent dedicated parking for 30 cars.

6.1.5 The Contractor accommodation adjacent but separate from the Board accommodation will provide shared meeting rooms for 30, 20 and 10 persons separately as a minimum requirement.

6.1.6 The provision of site welfare and accommodation will form an aspect of Competitive Dialogue with the Board under the Logistics workstream. This workstream will also consider other logistics issues such as deliveries to site, site traffic and storage provision. The specific logistics, requirements, constraints and parameters of these aspects of the Project will be discussed and considered in detail to allow the generation of relevant information and potential solutions by bidders for the Board to consider and discuss. This will include proposals for the location of welfare, storage and parking solutions as well as layouts for site accommodation and welfare.

6.1.7 Further, specific requirements of the Planners to be met by the Contractor are identified in the Outline Planning document in Appendix D.1.

6.1.8 The Contractor shall be responsible for the cost provision and maintenance of all site signs and hoardings during the construction phase of the works. The requirements of NHS Scotland signage guidelines will require to be met by the Contractor, for the avoidance of doubt the key requirements are as follows;

a) Principal signage required at 3 no.key locations around the site as NHS Scotland signage guidelines;

b) Principal signage size will be no less that 6 x 4 metres;

c) NHS Greater Glasgow and Clyde identity prominently displayed (no less that 350mm in height) on hoardings enclosing entirety of site;

d) Graphics should be made from vinyl or other suitably durable material; and

e) All hoardings must be 2400mm high solid panels (metal or timber) with viewing panels painted white and maintained in good condition, free from graffiti and posters at all times.

6.1.9 All signage to include space for signage boards provided by the Board project manager for display and use – particular numbers and sizing of boards in this regard to be clarified to bidders by the Board.

6.2 Site Preparation Works

6.2.1 The Contractor shall be responsible for identifying and undertaking all preparation works necessary in order to make the Site suitable for the development of the Works. These works shall be undertaken prior to commencement of, or integrated with, the Stage 1 and Stage 3 activities.

6.2.2 For the avoidance of doubt, this obligation covers but is not necessarily limited to:

a) The identification of all protected trees to be removed from the Site by virtue of their condition and / or position in relation to the proposed Works. The Contractor shall be responsible for seeking the approval of Glasgow City Council for any such removal proposals, and the proposed mitigation / replacement strategy, in accordance with the conditions of Glasgow City Council's requirements and the associated Local Plan;

b) The identification and implementation of protective measures required to remaining trees, including their root systems, in accordance with BS 5837:2005, "Guide for trees in relation to construction";

c) In accordance with the Wildlife & Countryside Act 1981, any tree felling and shrub clearance shall be carried out outside the bird breeding season (March to August). Contractors shall take due cognisance of this requirement in any work programming. Where this is not possible a qualified ecologist shall be appointed to examine all potential breeding sites before any clearance takes place. If occupied nests are found, clearance and felling works shall cease until the nest is no longer in use. The contractor shall formally confirm to the Planning Authority in writing if clearance is in order following the ecologist's inspection;

d) Japanese Knotweed (JK) - Areas of the site have been the subject of contamination by Japanese Knotweed. The Board have embarked on a programme of eradication, details of which will be made available to the Contractor. The Contractor shall be

required to dig up any JK plant material and transport to a separately identified bunded area on the site (to be formed by the Contractor) where the JK shall be treated by the Board. The Contractor shall provide wheel washing provision for the vehicles utilised in the transportation and removal of JK (including Board vehicles involved in ultimate removal from the site);

e) The identification, decommissioning, removal and / or protection / relocation of live (and used), live (and redundant) or redundant (and disconnected) buried services crossing the Site;

f) The identification and removal of old foundations, drainage runs, basement structures and other below ground obstructions present following demolition of previous structures occupying the Site that are not removed by the Board (e.g. some steam duct lines);

g) Upon the finding of any medical waste or other contaminants on the site the Contractor shall advise the Board of such discovery for discussion and agreement of the necessary removal and/or protection steps to be taken; and

h) Diversion of the culverts.

6.2.3 Where relevant, the Contractor shall carry out all site preparation works (if necessary) in accordance with BS 6187:2000 “Code of Practice for Demolition” and the following:

a) Issue a method statement identifying the scope and methodology for undertaking the enabling works (if any), for approval by the Board in accordance with (TBC);

b) Break up and remove offsite all foundations, temporary accommodation, and other below ground and surface obstructions in accordance with, but not limited to, BS5528 “Demolition in open spaces”;

c) Decommission and / or break up and remove all redundant underground structures, chambers and redundant surface water and foul water drains, telecommunications, electric cables, gas mains, water mains and ducts within the Site. For the avoidance of doubt, this obligations includes for making safe all redundant works left in-situ, and sealing of voids, where left, against vermin;

d) Protect remaining services against damage or disruption; and

e) Minimise vibration and noise produced by the demolition works, and agree appropriate limits for such with the Board and neighbours.

6.3 Workmanship, Construction Accuracy & Tolerances

6.3.1 The Contractor shall ensure that general workmanship conforms to current revisions of BS 8000: – “Workmanship on Building Sites”, which covers typical building construction activities. Where specialist design proposals require construction activities outside the scope of this document, The Contractor shall propose specific quality procedures relating to these activities based on Good Industry Practice current at the time, as a minimum.

6.3.2 The buildings and the external works shall be designed and set out by The Contractor in accordance with BS 5606:1990 “Guide to Accuracy in Building”.

6.3.3 In some situations the tolerances identified in BS 5606 may not be appropriate for the particular elements or combination of elements in the Works. Where special levels of accuracy are required in relation to The Contractor’s proposals these shall be stated by The Contractor. The Contractor shall consider the recommended procedure set out in Figure 8, Section 4, Appendix B, of BS 5606.

6.3.4 The Contractor shall identify critical dimensions and setting out points on all its drawn information.

6.3.5 The Schedule of Accommodation contained in Appendix C of the Employers Requirements details the number and net floor area (as defined in paragraph 2 below) of the all relevant rooms or spaces in the Works, and the Gross Floor Area (as defined in paragraph 2 below) of the departments within The Works.

6.3.6 The actual floor area (as constructed) of a room or space may vary by up to 2% less or greater than the net floor area of the relevant room or space recorded on the Schedule of Accommodation (which actual floor area shall be measured on the same basis as that referred to in the definition of net floor area in paragraph 2 below) always provided that the proportion of the room remains generally unchanged. However the Contractor should note that the Single Bedrooms (as constructed) are required as a minimum to comply with the Schedule of Accommodation space requirements.

6.3.7 The net floor areas of rooms and spaces/departments and the other areas shown in the Schedule of Accommodation shall only be amended insofar as an Approved Project Managers Change Instruction varies such areas.

6.3.8 The Contractor will remain entirely responsible for procuring that the net floor areas of rooms and spaces/departments as shown in the Schedule of Accommodation applicable to the Works are capable of being achieved within the total gross floor area of the Works specified in such Schedule of Accommodation. The overall as built net floor area of the Works shall be not less than the total net floor area shown in the Schedule of Accommodation by more than1%.

6.3.9 The net floor areas of the individual rooms and spaces listed in this Schedules of Accommodation shall be calculated using a manually operated electronic measurement computer programme from a Computer Aided Design (CAD) system.

6.3.10 The number and identification of rooms listed on a department by department basis in the Schedule of Accommodation are as noted and identified on the 1:200 Departmental Layout plans identified in Appendix I.

6.3.11 For the duration of the Works the Contractor shall;

a) maintain computerised electronic versions of the Schedule of Accommodation and shall regularly update the areas shown in the Schedule of Accommodation from time to time in order to, inter alia, properly record the net floor areas and gross floor areas stated in all items of Design Development;

b) Afford the Board's Representative and Project Manager an opportunity to access and view such computerised Schedule of Accommodation at any time during normal working hours; and

c) As soon as reasonably practicable following finalisation of the 1:50 scale Room Layout Drawings, shall prepare and issue to the Board (in hard copy and electronic format) the final Schedule of Accommodation for the Works.

6.3.12 In connection with the above the following definitions apply;

a) Net floor area

In relation to a room the area bounded by the internal face of the walls or partitions enclosing the room. Or in relation to the space the area bounded by the internal face of

the walls or partitions and boundary(s) to any adjoining space(s). This area shall be measured elctronically from the approved plans that relate to the room or space. The net floor area is measured with deductions for:

i) column encasures

ii) pipe boxing

iii) service zones

b) for the avoidance of doubt the actual floor area may not be the net floor area of the room or space. The net floor area shall include the area of furniture, fittings and equipment within the room or space;

c) The net floor area for the department will be the sum of the individual net floor areas for the relevant rooms;

d) Gross floor area

Gross Departmental Area means the area bounded by the internal face of the external walls, centre line of partitions or boundary to adjoining departmental and/or communication space(s) that enclose that department. This area shall be measured electronically from the 1:200 scale Department Layout Plan that relates to the department. The Gross floor area shall include all elements of construction, spaces or rooms and circulation, but exclude:

i. service ducts

ii. lift shafts or other communication spaces contained within the boundary of the department.

e) Other areas means all other areas not included in a department, the balance of all service ducts, lift shafts, communication spaces (not included in department areas), corridors, plant rooms and the like measured electronically on the same basis as a Department from the 1:200 scale Department Layouts. The department areas are identified in Appendix I;

f) In relation to the Works, the Gross floor area is the sum of items d) and e) above; and

g) The departmental areas are identified in Appendix C.

6.3.13 Control of Noise & Dust

6.3.13.1 The attention of The Contractor is drawn to the provisions of Section 60 of the Control of Pollution Act 1974, with reference to the control of noise and dust in relation to any construction works. Where such works are adjacent to occupied property, The Contractor shall ascertain from the relevant authorities what requirements or restrictions, if any, shall apply, particularly in relation to Aspergillus. The restrictions may relate to the type of plant to be used, siting of plant, methods of working to be adopted, the hours of work permissible and may, in addition, impose a maximum noise level that must not be exceeded.

6.3.13.2 The Contractor shall make applications as early as possible to the utility company for the relevant connections in order to avoid the use of site generators.

6.3.14 The Contractor shall fit compressors, percussion tools and vehicles with effective silencers of a type recommended by the manufactures of the compressors, tools or vehicles but in any event to the requirements of BS 5228: Part 1: 1997 in accordance with Good Industry Practice.

6.3.15 Any equipment of a semi-permanent nature used by the Contractor, which produces noise on a regular basis, shall be positioned to cause the minimum disturbance to adjacent areas in agreement with the relevant authorities. The Contractor shall take all reasonable measures throughout the course of the Works to prevent the egress of water, dust, debris or any microbiological contamination out of the Site and into adjacent buildings. In particular, the Contractor shall establish any specific requirements for the control of dust identified.

6.3.16 The Contractor must comply with the specific planning requirements with regard to the control of noise and dust.

6.3.17 Continuity of Existing Services

6.3.18 The Contractor shall plan and execute the Works to ensure the Works activities do not affect the operational continuity of the Hospital Campus and the immediate neighbours to the Site.

6.3.19 The Contractor shall ensure that all reasonable safeguards are incorporated to ensure continuity of utility supplies to the Hospital Campus and adjacent users of the Site in-so-far as they may be affected by the Works. For the avoidance of doubt, utility supplies include, but are not limited to, gas, medical gases and air, electricity, water, sewerage and communications services.

6.4 Live Hospital Site

6.4.1 The Hospital Campus is a live hospital site, and as such will place restrictions on the Contractor in the construction of the Works.

6.4.2 As is noted in Section 6.1, above, logistics of the Site will form a workstream under the Competitive Dialogue to take place between the Board and the Contractor and this will extend to the consideration, discussion and agreement in regard to particular constraints, routes, timings and the like that will and will not be possible in the carrying out of the Works due to the 'live' nature of the environment.

6.4.3 Specific site constraints and access type requirements of the Hospital Campus and the Site have been considered in advance by the Board. These are contained in Appendix A and identify, amongst other issues, 'blue light' routes, FM delivery points and roadways that require to be unobstructed by the Contractor 24hours per day, every day.

6.4.4 The use of tower cranes on site by the Contractor may be restricted by the Board, Planners and the CAA. The Contractor is required to establish any relevant constraints and shall be responsible for implementation of craneage as permitted. This will include no oversailing of areas out with the Site and shall require the Contractor to demonstrate his management proposals in this regard, including modelling of swing-arcs and the like. Specific CAA requirement for aircraft warning lights are to be installed by the Contractor with regard to temporary and permanent structures. This will extend to, but may not be limited to, tower cranes, the flue to the new energy centre, other flues and chimneys to the Works;

6.4.5 In addition to the physical logistics and constraints in respect of the live hospital environment, the Contractor shall require to observe and comply fully with specific Board Policies for the duration of the Works when on the Hospital Campus or Site. The relevant Board Policies are listed in Appendix P.

6.4.6 The Contractor will require to carry out dilapidation surveys prior to the commencement of the Works, during the Works and at the completion of the Works – the extent, format and location of such to be agreed with the Board. Hard and electronic copies of all dilapidation surveys to be provided to the Board by the Contractor.

6.4.7 An aspect of the surveys to be carried out by the Contractor prior to the commencement of the Works is a full photographic survey of the boundary of the site, adjacent buildings, main roadways and approach roadways. Hard and electronic copies of all photo surveys to be provided to the Board by the Contractor.

6.5 Standardisation and Prefabrication (incl modular and off-site)

6.5.1 In order to take advantage of the repetitive nature of construction, maximise productivity and efficiency and minimise construction periods and waste, consideration shall be given to off-site prefabrication. It shall specifically be applied to repetitive elements e.g., sanitary assemblies, bathrooms or complex equipment such as plant assemblies.

6.5.2 The Contractor shall where reasonably practicable use standardised and / or pre-fabricated components and elements of construction which improve product quality, guarantee consistency of performance, optimise maintenance, and provide for reasonable flexibility for future changes, ease of replacement and value for money.

6.5.3 The use of standardised / prefabricated elements and building components to achieve good quality control, ease and speed of installation and flexibility for future use are welcomed. Their use shall not constrict the Board achieving clinical functionality and offer value for money. Items which may be considered include, bathroom pods, bedroom pods and other repetitive elements.

6.6 Room Mock-ups

6.6.1 The Contractor shall construct exemplar room mock-ups during the design development stage of the Works (Stage 2) for the hospitals. This will allow the Board's Representative to witness the quality standards of workmanship according to Good Industry Practice. Exemplar typical room mock-ups will be constructed for the rooms listed below in order to demonstrate important or unusual design elements of rooms i.e. integral bespoke furniture.

6.6.2 The Contractor shall provide mock-ups of the following rooms for use in the design development and approval process:

a) Single bedroom (standard) with en-suite (adult hospital);

b) Single bedroom with pull down bed for parents (children's hospital);

c) Single bed space (Critical Care) including all services and screening; and

d) Any modular accommodation proposed by the Contractor.

6.6.3 During the construction phase of the Works (Stage 3), the Contractor shall prepare a number of exemplar rooms as part of the Quality Control process, this is in addition to or a development of the mock ups noted above. The Contractor shall provide exemplar rooms of the following rooms:

a) Generic treatment room;

b) Single bedroom (standard) with en-suite;

c) Standard Outpatient Consulting Room;

d) Theatre suite;

e) Renal dialysis station and example of renal media panel;

f) Staff base; and

g) Reception point/counter.

6.6.4 These will establish minimum quality standards for the main areas and shall include main building services elements including lighting, heating, staff call, fire alarms, patient entertainment systems and all power and data accessories. This shall, where appropriate, include 3D computer illustrations.

6.6.5 The exemplar rooms to be prepared in the construction phase of the Works (Stage 3) shall portray doors, windows and the principal fitments and furniture. They shall allow definition of floors and walls, reflect the ceiling arrangements and identify the engineering services terminals. These shall be provided in a timely manner, to ensure they add value to the design development and approval process. The Contractor shall agree the content of and construct the exemplar mock-up rooms to a timetable to be agreed with the Board.

6.7 Witnessing and Testing

6.7.1 Witnessing and testing duties will be carried out by the Supervisor, all as detailed in relevant Clauses of the current NEC3 Engineering and Construction Contract, namely;

TITLE	DESCRIPTION	CLAUSE REFERENCE(S)	SUPERVISOR and CONTRACTOR DUTIES
Section 1	General	10.1; 11.2(6); 13.1; 13.3; 13.6; 14.1; 14.2; 14.4	10.1 – to act as stated in the contract and in a spirit of mutual trust and co-operation. 13.1 – to communicate in a form which can be read, copied and recorded. 13.3 – to reply to a communication within the period for reply 13.6 – to issue certificates to the Project Manager and Contractor 14.1 – Contractors duty to provide the works and be responsible for design. 14.2 – to notify the Contractor before delegating any actions or cancelling any delegation. 14.4 – replacement of Supervisor.
Section 2	Contractors Main Responsibilities	27.2; 27.3	Contractor's duties in relation to site access/action on legitimate instructions
Section 3	Time	n.a.	
Section 4	Testing and Defects	40.3; 40.5; 41.1; 42.1; 42.2; 43.1; 43.3	40.3 – to notify the Contractor of his tests and inspections before they start and afterwards of the results. 40,5 – to do tests and inspections without causing unnecessary delay to work or payment. 41.1 – to notify the Contractor of the results of the test or inspection on Plant and Materials required by the Works Information to be tested or inspected before delivery. 42.1 – instruct the Contractor to search for a Defect and to give reasons for searches which are instructed. 42.2 – to notify the Contractor of defects found before the Defects Date. 43.1 Contractor duty to correct Defects whether notified by Supervisor or not.

			43.3 – to issue the Defects Certificate at the later of the Defects Date and the last Defect Correction Period.
TITLE	**DESCRIPTION**	**CLAUSE REFERENCE(S)**	**SUPERVISOR and CONTRACTOR DUTIES**
Section 5	Payments	50.1	Project Manager duty in relation to assessing amounts due.
Section 6	Compensation Events	60.1(6)(8)(10)(11); 61.1	Actions/inactions of Supervisor in connection with Compensation Events.
Section 7	Title	70.1; 71.1	70.1 – Supervisor signing for marked Plant and Materials outside Works Area. 71.1 – Contractor action to allow Supervisor signing for marked Plant and Materials outside Works Area.
	Dispute Resolution	W1.3(5); W2.3(4)	Actions/inactions of Supervisor in connection with dispute Resolution Procedure.

6.7.2 It is envisaged that the Supervisor role will be carried out by a number of delegated parties – parties will be delegated by named Supervisor all as Clause 14.2, and are likely to comprise the following;

a) Civil & Structural Engineering;

b) Mechanical & Electrical Services;

c) Board Personnel (FM Services); and

d) Civil/M&E/Fabric Clerks of Works

6.7.3 In relation to the above duties as detailed under Section 4 – Testing and Defects, the Supervisor will carry out the following functions;

a) Design Compliance Check

i) Review the Design Data and detailed design information for general compliance with the terms of the Contract;

b) Procedure Review

i) review the quality assurance procedures proposed by the Contractor before work begins on the Laboratory and Hospital sites and review the operation of the procedures at regular intervals during The Works;

ii) regularly check to see whether the procedures employed by the Contractor are generally in accordance with the terms of the Contract; and

iii) review the proposed procedures and programmes for testing, commissioning and hand-over of The Works.

c) Construction Review

To the extent necessary to carry out the services referred to in Section 4 of the NEC3 Contract:-

i) enter the Laboratory and Hospital sites to monitor The Works to view the general state and progress of the Works to review overall workmanship, samples of goods and materials used or about to be used in The Works and to ascertain generally that the terms of the Contract have been and are being complied with by the Contractor;

ii) the frequency and timing of the Supervisor's visits are dependent on the progress of construction on the Laboratory and Hospital sites;

iii) regularly check to see whether the Contractor's work is being undertaken in accordance with Method Statements, Works Information and in a workmanlike manner;

iv) witness the testing, review and consider the suitability of all M & E and Building Management Systems, test results and certificates and other procedures within the Contractor's commissioning activities (all test results and certificates and other relevant commissioning and snagging paperwork to be collated by Independent Commissioning Engineer and provided to the Supervisor). In the event that a test carried out by the Contractor does not satisfy the terms of the Contract, check to see whether suitable remedial actions have been implemented and satisfactory results have been obtained on any re-tests;

v) generally inspect rectification works which have previously prevented the Supervisor from issuing a Defects Certificate; and

vi) undertake a visual inspection as appropriate of The Works before hand-over, to see whether the appearance is generally acceptable and in accordance with the terms of the Contract.

d) Reports

i) Report on the status of The Works following each site visit (and at any other time as appropriate) identifying any work that is non-compliant with the Contract; and

ii) Produce a weekly report following each site visit to ensure that the Employer is kept fully and properly informed on all aspects of the Works.

e) Familiarisation with Other Project Documents

i) The Supervisor shall familiarise itself with the Design Data and the Project Documents to the extent necessary to carry out the Supervisor role as provided for in accordance with the terms of the Contract;

f) Familiarisation with Quality Manuals

i) The Supervisor shall familiarise itself with and understand the Quality Manuals for the design and construction of the Project as set out in the Contract;

g) Monitoring and Inspection Procedure

i) The Supervisor and the Contractor shall agree an ongoing monitoring and inspection procedure, with reference to the Contract's key construction and

commissioning activities and the completed Works, and shall operate the same so as to ensure the efficient monitoring of construction and the efficient operation of activities;

h) Certification

i) The Contractor shall give the Supervisor (and Project Manager) sufficient notice in accordance with the Contract, of the date (the Completion Date") when it anticipates that Completion in respect of any Project Phase will be achieved;

ii) The Supervisor shall issue the relevant Defects Completion Certificate(s) in accordance with Clause 43.3 of the Contract; and

iii) As soon as practicable following the issue by the Project Manager of the Completion Certificate in respect of the final Project Phase to be completed in accordance with the Construction Programme, the Supervisor shall (provided that the Contractor has complied with its obligations to remedy any works listed in the Defects List) issue a final Defects Certificate.;

i) Snagging Items

i) The Contractor shall produce a Snagging Protocol detailing the process and individual party inputs, to cover the Phases of the Works. It is expected that this Protocol will be developed in conjunction with all interested parties e.g.:

- Board Representatives/Users/FM Team
- Supervisor
- Independent Commissioning Engineer
- The Contractor

and be provided at least six months prior to Phase Completion Date(s);

ii) The Contractor will provide for a computer/software based integrated snagging management system to be utilised during the snagging process, Provision to include all necessary peripheral equipment (PDA/Pens) and include for necessary training for Board Users and their advisors;

iii) The system will be managed and maintained by the Contractor, with appropriate access granted to project personnel; and

iv) Under the NEC3 Contract, there will be a "zero defects" approach to the project, and the Snagging Protocol will reflect this approach;

j) Notification of Completion of Defects

i) The Supervisor shall when requested by The Contractor attend any meetings convened about any part of the Works for the purpose of inspecting whether the Defects items applicable thereto have been remedied and/ or rectified; and

ii) The Supervisor shall issue a Defects Certificate, with copies of such notification also being issued, once all the works and other activities required in order to remedy and/or rectify Defects have been completed to the standards required by the Contract;

k) Miscellaneous

The Supervisor shall:

i) monitor the progress of the Contractor's design production;

ii) observe and monitor mock-ups, fabrication, construction and installation works on the Sites so as to satisfy itself that the Works comply with the Contract;

iii) audit the Contractor's Quality Assurance and the Contract control systems and procedures;

iv) issue Defect/Non-compliance notices and oversee the resolution of non-compliant matters;

v) review the commissioning of components of the Works in accordance with Contract/Works Information (as appropriate). The Supervisor will audit and monitor the commissioning work and report on the commissioning and testing of the Works;

vi) inspect and sign for marked up Plant & Materials outside of Works Area in accordance with Clauses 41.1/70.1/71.1; and

vii) hold regular meetings to discuss compliance and progress matters with the Employer and his Technical Advisors and the Contractor and attend meetings between the Employer and the Contractor as appropriate.

6.7.4 In order to assist the Supervisor in the performance of the above duties, the Contractor shall, as a minimum provide the following information;

a) the Accepted Programme;

b) copies of the Contractor's working programmes showing when the Contractor intends to carry out key activities whether off or on Site;

c) copies of all relevant documentation in connection with Plant & Materials outside of Works Area;

d) copies of such working drawings, schedules and specifications prepared for tender issue to the Contractor's sub-contractors as may reasonably be required by the Supervisor;

e) access to designs, drawings and documents register, technical and audit reports, consents, certificates and specifications to a level necessary to allow the Supervisor to assess compliance;

f) copies of correspondence relating to Building Control matters;

g) access to all quality control and quality assurance records, including procedures and method statements for the Project;

h) copies of all non-compliance reports generated by the Contractor and evidence of the clearance of the same;

i) copies of commissioning reports;

j) access to draft and final building/O&M manuals at the same time as the same are required to be provided to The Contractor under the Contract and otherwise as may reasonably be required by the Supervisor;

k) a copy of the health and safety plan and health and safety file and access to safety reports;

l) The Contractor's progress reports;

m) Any available completion check-lists prepared by the Contractor;

n) Change orders/requests prepared by the Contractor relating to the Works;

o) Copies of any reference or notice of intention to refer a dispute to the dispute resolution procedure in relation to the Works; and

p) The Defects List.

6.8 Commissioning and Handover

6.8.1 It is envisaged that the Contractor will appoint an Independent Commissioning Engineer to manage/programme/collate all M&E Testing and Commissioning processes, all as detailed in Appendix M, M&E3 Section 5 of the Employers Requirements

6.8.2 The Contractor will be required to provide the following in relation to the Commissioning and Handover process.

a) Final Commissioning Programme

i) A Final Commissioning Programme shall be prepared for each Phase to replace the Outline Commissioning Programme. The Final Commissioning Programme relating to the relevant Phase shall be prepared in consultation with the Board, in accordance with the requirement of the Completion Process;

b) Pre-Completion Commissioning

i) The Contractor's Pre-Completion Commissioning shall comprise the activities described as such in Table A Commissioning – Outline Commissioning Programme;

ii) The Contractor shall give written notice to the Project Manager/Supervisor and the Board's Representative of the commencement of The Contractor's Pre-Completion Commissioning in respect of each Phase when The Contractor (acting reasonably) considers that it shall commence The Contractor's Pre-Completion Commissioning in respect of the relevant Phase;

iii) The Contractor shall, at the times set out in the Final Commissioning Programme (and in relation to Manufacturer's Training, Induction Training and Building Familiarisation, when the Board Employees are made available for training by the Board pursuant to the Manufacturer's Training Programme, Staff Familiarisation Training Programme, Induction Programme and/or Staff Training Programme, as appropriate) undertake and complete The Contractor's Pre-Completion Commissioning in respect of the relevant Phase;

iv) The Board's Commissioning shall comprise the activities identified as such in Table A Commissioning – Outline Commissioning Programme;

v) The Contractor shall give written notice to the Board's Representative of the date upon which the Board shall be entitled to commence the Board's Commissioning in respect of each Phase, such notice to be given at least 1 month prior to the date when The Contractor (acting reasonably) considers that the Board should commence the Board's Commissioning in accordance with the Final Commissioning Programme; and

vi) The Board shall undertake and complete the Board's Commissioning for the relevant Phase, within the time period permitted within the Final Commissioning Programme, the Manufacturer's Training Programme, Staff Familiarisation Training Programme, the Induction Programme and/or Staff Training Programme (as appropriate) and shall comply with the Contractor's Site Rules and shall not cause any damage to the Works and/or Facilities or delay to the Works, in the carrying out of such activities;

c) Completion

i) The Contractor shall, no later than two months prior to the date that it anticipates (acting reasonably) a Phase will achieve the Completion Date, notify the Supervisor and the Board's Representative of such anticipated completion;

e) Post Completion Commissioning

i) The Contractor's Post Completion Commissioning shall comprise the activities identified as such in Table A Commissioning – Outline Commissioning Programme;

ii) The Contractor shall undertake and complete the Contractor's Post Completion Commissioning for the relevant Phase as follows:

- in relation to staff training, when Board Employees are made available to The Contractor for training in accordance with the Training Release Schedule, Induction Programme, Staff Familiarisation Programme and/or Staff Training Programme (as appropriate);

- in relation to clinical cleans, in accordance with the Final Commissioning Programme;

- The Board's Post Completion Commissioning shall comprise the activities identified as such in Table A Commissioning – Outline Commissioning Programme; and

- The Board shall undertake and complete the Board's Post-Completion Commissioning for the relevant Phase in accordance with the Final Commissioning Programme, Training Release Schedule, Induction Programme, Staff Familiarisation Programme and/or Staff Training Programme (as appropriate) and shall not cause damage to the Facilities in the carrying out of such activities.

e) Equipment and Training

i) The Contractor shall not clean, or move to enable general cleaning, items of equipment so identified by the Board unless in agreement with the Board's Representative. This shall include but not be limited to:

- physiological monitoring equipment;

- patient medical equipment when in use (e.g. respirators, air tanks, infusion pumps);

- department based computers, visual display units and radiographic equipment or machine consoles including anything bearing radiation or hazard Warning signs; and

- equipment that is plugged in for re-charging; and

ii) The Board shall ensure that any equipment of the Board that is transferred from an existing site is cleaned and disinfected prior to being transferred to the Facility.

OUTLINE COMMISSIONING PROGRAMME

Table A: Commissioning

Area comprised within a Phase	**Pre Completion Commissioning**		**Post Completion Commissioning**	
	The Contractor's Pre-Completion Commissioning	**Board Commissioning**	**The Contractor's Post Completion Commissioning**	**Board Post Completion Commissioning**
Rooms/areas which only contain the Contractor's equipment and movable equipment to be installed/commissioned by the Contractor in accordance with Appendix F (*Equipment*)	The Contractor to install Board Specialist Equipment as required in accordance with Appendix F2 (*Equipment*) The Contractor to commission and test equipment as required in accordance with Appendix F (*Equipment*) The Contractor to carry out Handover clean The Contractor to carry out Staff Familiarisation Training when Board Employees are made available to The Contractor by the Board for training, in accordance with the Staff Familiarisation Training Programme, Manufacturer's Training Programme,	Board to make available Board Employees for training in accordance with the Staff Familiarisation Training Programme, Manufacturer's Training Programme, Induction Programme and/or Staff Training Programme. The Board shall witness such testing as required by Approved Persons e.g.: • medical gas testing including provision of gas for such testing purposes • Clinical Cleaning in accordance with The Board's obligations as set out in the Completion Criteria of The Supervisor Contract.	The Contractor to train Board Employees made available for training pursuant to the Training Release Schedule, Induction Programme, Staff Familiarisation Training Programme and/or Staff Training Programme The Contractor to carry out Clinical Clean in accordance with the Commissioning Programme Clinical Clean of Board Equipment	Board to install, commission and test equipment as required pursuant to Appendix F (*Equipment*) and the Commissioning Programme Board to make available Board Employees for training in accordance with the Training Release Schedule, Induction Programme, Staff Familiarisation Training Programme and/or Staff Training Programme Board decant of patients to be carried out in accordance with the Commissioning Programme

Area comprised within a Phase	Pre Completion Commissioning		Post Completion Commissioning	
	The Contractor's Pre-Completion Commissioning	**Board Commissioning**	**The Contractor's Post Completion Commissioning**	**Board Post Completion Commissioning**
	Induction Programme and/or Staff Training Programme			
Rooms/areas which contain items of fixed equipment which are installed/commissioned by the Contractor and items of fixed equipment which are installed/commissioned by the Board in accordance with Appendix F (Equipment)	The Contractor fixed equipment installed, connected, commissioned and tested in accordance with Appendix F (Equipment) and the Commissioning Programme The Contractor to carry out Handover clean Completion of Works after Board Equipment installation The Contractor to insure Equipment in accordance with Appendix F (Equipment) The Contractor to carry out Staff Familiarisation Training when Transferring Board Employees are made	Board Specialist Equipment and fixed equipment installed, connected, commissioned and tested in accordance with Appendix F (Equipment) and the Commissioning Programme Board fixed equipment protected/mothballed until after the Phase Completion Date for the relevant Phase Board to protect and maintain the Board Equipment placed, and / or installed. Board to make available Board Employees for training in accordance with the Staff Familiarisation Training Programme, Manufacturer's Training Programme, Induction Programme and/or Staff	The Contractor to train Board Employees made available for training pursuant to the Training Release Schedule, Induction Programme, Staff Familiarisation Training Programme and/or Staff Training Programme The Contractor to carry out Clinical Clean in accordance with the Commissioning Programme Clinical Clean of Board equipment	Board to install, commission and test equipment as required pursuant to Appendix F (Equipment) and the Commissioning Programme Board to make available Board Employees for training in accordance with the Training Release Schedule, Induction Programme, Staff Familiarisation Training Programme and/or Staff Training Programme Board decant of patients to be carried out in accordance with the Commissioning Programme

Area comprised within a Phase	Pre Completion Commissioning		Post Completion Commissioning	
	The Contractor's Pre-Completion Commissioning	**Board Commissioning**	**The Contractor's Post Completion Commissioning**	**Board Post Completion Commissioning**
	available to The Contractor by the Board for training, in accordance with the Staff Familiarisation Training Programme, Manufacturer's Training Programme, Induction Programme and/or Staff Training Programme	Training Programme. The Board shall witness such testing as required by Approved Persons e.g.: • Medical gas testing including provision of gas for such testing purposes • Clinical Cleaning in accordance with The Board's obligations as set out in the Completion Criteria of The Supervisor Contract.		
ICT Board are responsible for installing hardware (server, PCs printers etc) and the Contractor responsible for infrastructure (containment, cabling, computer rooms etc)	The Contractor infrastructure installed, commissioned and tested in accordance with Employers Requirements (*ICT*)	Board hardware installed, commissioned and tested (Network, servers, critical clinical workstations) in accordance with Employers Requirements (*ICT*) and the Commissioning Programme	The Contractor to train Board Employees made available for training pursuant to the Training Release Schedule, Induction Programme, Staff Familiarisation Training Programme and/or Staff Training Programme The Contractor to carry out Clinical Clean in accordance with the Commissioning Programme	Board hardware installed, commissioned and tested in accordance with Employers Requirements (*ICT*) and in accordance with the Commissioning Programme Board to make available Board Employees for training in accordance with the Training Release Schedule, Induction Programme, Staff Familiarisation Training Programme and/or Staff Training Programme

OUTLINE COMMISSIONING PROGRAMME

Completion Process

A. Final Commissioning Programme

A.1 The Final Commissioning Programme shall be in accordance with the Outline Commissioning Programme and shall impose no greater or more onerous obligation on the Board or the Contractor than those set out in the Outline Commissioning Programme, unless otherwise agreed. The Final Commissioning Programme shall be developed by the Contractor in conjunction with and having consulted:

1.1.1 the Contractor;
1.1.2 the Board;
1.1.3 the Supervisor; and
1.1.4 the Board's FM Team.

A.2 The draft Final Commissioning Programme shall contain, amongst other things, full details of the following (including timing and sequence of events) for each Phase:

1.1.5 Contractor's Pre Completion Commissioning;
1.1.6 Board's Commissioning;
1.1.7 Contractor's Post Completion Commissioning;
1.1.8 the Board's Post Completion Commissioning; and
1.1.9 the Supervisor's Completion Criteria applicable to the relevant Phase.

A.3 The Contractor shall provide the Board with a draft of the Final Commissioning Programme relating to each Phase not less than 12 months prior to the anticipated Phase Completion Date.

A.4 If the Board has any comments on the draft Final Commissioning Programme, it shall issue comments on the draft Final Commissioning Programme to The Contractor on receipt of the draft Final Commissioning Programme by the Board from The Contractor, pursuant to paragraph 1.3 of this section (Outline Commissioning Programme).

A.5 If the Board raises comments on the draft Final Commissioning Programme in accordance with paragraph 1.4 of this section (Outline Commissioning Programme), the parties shall meet in good faith to discuss the terms of the Final Commissioning Programme), in order to agree the terms of the Final Commissioning Programme.

A.6 If the parties cannot agree the content of the Final Commissioning Programme, the matter shall be referred for determination in accordance with the Dispute Resolution Procedure.

A.7 Where any amendments to the scope and/or timing of the Board's Commissioning and/or the Board's Post Completion Commissioning are agreed or determined pursuant to paragraph 1.5 and/or 1.6 of this section (Outline Commissioning Programme) such change shall be treated as a Compensation Event.

OUTLINE COMMISSIONING PROGRAMME

Staff Familiarisation Training

B. Manufacturers' Training

B.1 The Contractor shall provide Technical Manufacturer's Training to such numbers of Board Employees as is agreed between the parties as being appropriate to allow for a cascade training regime, in accordance with the Manufacturer's Training Programme, which shall be submitted for agreement with the Board 4 months prior to a Phase Completion Date. The training shall be carried out prior to each Phase Completion Date, in accordance with the durations per system required pursuant to Table 1 (Outline Commissioning Programme), and in accordance with the Manufacturer's Training Programme. The Contractor shall only be responsible for those Board Employees directly trained by it. Systems requiring such manufacturer's training and thus more direct staff exposure to the manufacturer, are listed (but are not limited to those set out in) in Table 1 (Outline Commissioning Programme). The Board shall make available the relevant staff for training in accordance with the Manufacturer's Training Programme.

C. Building Familiarisation Training

C.1 Building Familiarisation Training shall be provided to each Board Employee by The Contractor to provide staff with general building and Site Familiarisation, general Site orientation and Building Health and Safety Induction. This shall be organised in small groups for half a day so that the impact on the existing sites is minimised, and subject to paragraph 2.2 below, shall comprise part of The Contractor's Post Completion Commissioning "Building Familiarisation"). The Building Familiarisation shall be programmed on a training plan, prepared by The Contractor and agreed with the Board not less than 40 Business Days of the anticipated Phase Actual Completion Date.

C.2 Board Employees at each Phase Completion Date shall receive this training leading up to their transfer, in a time period agreed with the Board and shall comprise part of the Contractor's Pre Completion Commissioning.

C.3 The Board shall make available the relevant staff for training in accordance with the Staff Familiarisation Training Programme.

D. Department Induction

D.1 Board Employees shall receive a department induction prior to the Relevant Service Transfer Date. This training (comprising two half days) shall be provided by the Contractor at the existing sites. Should the Board require this to be undertaken off site the costs associated with this shall be borne by the Board. This training shall cover department operational procedures and risk assessments.

D.2 The Induction Training shall be programmed and set out in a Training Plan with the Board Employees receiving the training in the period leading up to the Relevant Service Transfer Date. The Training Plan shall take into account the Board's responsibility for delivering the Services at the existing sites and shall therefore be designed to limit the impact on operational delivery and shall be prepared by The Contractor and agreed by the Board not less than 12 months prior to the anticipated Phase Completion Date.

D.3 The Board shall make available the relevant staff for training in accordance with the Induction Programme.

6.8.3 Handover Procedures

6.8.3.1 The Contractor's Commissioning Programmes to include for sign off of relevant Testing and Commissioning elements by other parties, e.g.:

a) Board Approved Parties

i) Fire Officer;

ii) Control of Infection Officer;

iii) Radiation Protection Officer; and

iv) Medical Gases Officer;

b) Supervisor; and

c) Independent Commissioning Engineer

6.8.3.2 It will be the Contractors responsibility to programme the above sign off requirements to ensure relevant Completion Date achieved.

6.8.3.3 In connection with the above, the Supervisor will expect the Contractor to provide the following documentation in connection with Handover/Completion;

6.8.4 General

6.8.4.1 General Requirements

The Contractor shall provide such labour, materials, stores, test equipment, tools, instruments, apparatus and assistance as are reasonably required for the purpose of the inspection by the Supervisor and shall be responsible for the provision of such electricity, fuel, water and other consumables and materials as may be reasonably required for the same. Invitations shall be furnished to the Board, its Project Manager and the Supervisor to witness such works inspections, testing and commissioning activities as the Board deems necessary. Adequate notice of testing shall be given.

6.8.4.2 The Contractor shall ensure that major items of plant shall be tested at the works for both performance and safety prior to dispatch. Major items of plant shall include, but not be limited to, the following: boiler plant, generators, chillers/refrigeration machinery, large pumps, HV/MV switchgear, large pressure vessels etc. The Contractor shall arrange to witness all factory testing and shall furnish the Board, its Project Manager and the Supervisor with the opportunity to witness all factory testing, and sign off marked items of Plant and Materials. The Board, its Technical Advisors and the Supervisor shall be given at least fourteen days notice of such testing.

6.8.5 Works inspection, testing and acceptance activities

6.8.5.1 Completion Criteria

6.8.5.2 The Contractor shall demonstrate that the following criteria have been achieved:

6.8.5.3 The building is structurally complete, all external fabric is complete and internally all the finishes are complete in accordance with the ADB Room Data Sheets;

6.8.5.4 All incoming Utilities including all associated back up systems is tested, commissioned and operational;

6.8.5.5 The Mechanical and Electrical plant and systems operate satisfactorily in accordance with the specified design criteria, and the ADB Room Data Sheet;

6.8.5.6 The Building Management System is complete, tested, commissioned and operational;

6.8.5.7 All furniture and equipment shown on the Loaded Room Layout drawings (as supplemented by Appendix F (Equipment) have been installed (and commissioned if appropriate);

6.8.5.8 The Board has been supplied with keys, access codes, swipe cards and other access devices for access to and within the Works;

6.8.5.9 Safe access and egress to and within the relevant Laboratory and Hospital sites has been established;

6.8.5.10 The relevant Laboratory and Hospital sites shall be free from all surplus materials, plant and equipment that could materially affect the completion of the Tests on Completion and shall comply with the standards and requirements of Section 3;

6.8.5.11 All internal and external drainage systems are installed and are operational;

6.8.5.12 External works as appropriate have been completed and are available for use by the Board;

6.8.5.13 All hard-landscaped external works, including roads, car parks, pavements and boundary walls/fences are complete and available for use by the Board;

6.8.5.14 Lift and Escalator systems are complete, commissioned and operational;

6.8.5.15 All building directional departmental, general information and room numbering signage as indicated within Employers Requirements/the Contractor Proposals and/or Reviewable Design Data and necessary to all the operational Services to commence has been provided and installed. This includes both internal and external signage;

6.8.5.16 The Fire Management Strategy has been finalised, The Contractor to complete and submit fire safety risk assessment in accordance with the Fire (Scotland) Act 2005;

6.8.5.17 The Fire Detection, Alarm and Suppression Systems are complete, tested commissioned and operational

6.8.5.18 All External Lighting is installed, tested, commissioned and operational;

6.8.5.19 All IT and Communication Systems are complete, tested, commissioned and operational;

6.8.5.20 All Security and Surveillance Systems, Access Controls and Call Alarms are complete, tested, commissioned, operational and available for use by the Board;

6.8.5.21 Acoustic Testing has been completed to prove compliance with the Employers Requirements and the Contractor Proposals;

6.8.5.22 The medical gas and vacuum system is complete, tested, commissioned and witnessed by NHS Greater Glasgow and Clyde's Chief Pharmacist and Medical Gases Approved Person;

6.8.5.23 A proving and training period for the Board has been offered by the Contractor, and subject to the Board making themselves available within agreed timescales, this training has been completed;

6.8.5.24 A proving and training period for the Service Provider has been completed;

6.8.5.25 The Contractor has provided all documentation to the Supervisor in accordance with the Supervisor's Contract and Section 4; and

6.8.5.26 A draft hard copy and electronic format of the relevant As Built Specification Documents, Operational & Maintenance Manuals and Health & Safety Files for the Facilities (containing, as a minimum, all the testing and commissioning information so far as it is reasonably practicable) have been issued by the Building Contractor.

6.8.6 Clinically clean

6.8.6.1 On completion of the Works, The Contractor shall provide the Facilities as "clinically clean" in accordance with NHS Scotland National Cleaning Services Specification and to the satisfaction of the NHS Greater Glasgow and Clyde's Control of Infection Officer.

6.8.7 Testing and commissioning documentation

6.8.7.1 All documentation associated with the Tests on Completion shall be collected and collated by the Contractor/Independent Commissioning Engineer and shall be presented as a bound, indexed document to the Board. The following list is indicative of the test documentation expected to be provided:

Test Documentation
Building Warrant Completion Certificates
Evidence that all Conditions attached to the detailed Planning Consent have been discharged to the satisfaction of the Local Authority.
Roads Construction Consents
Design Warrants
Flushing Cleaning and Chlorination test certificates
Boiler Plant Manufacturers Factory Test and Commissioning Sheets in accordance with CIBSE Commissioning Code B, including all steam systems
Ductwork Systems pressure test and volume flow rate Certificates
Laundry Equipment Commissioning Certificate
Kitchen Equipment Commissioning Certificate
Electrical Installation Completion and Inspection Certificates in accordance with BS 7671 and

Test Documentation
NICEIC requirements
Robotics Equipment Commissioning Certificate
Lighting and Power Certificate of Test
Fire and Intruder Alarms Commissioning Certificates, including intruder detection and alarm, access control system(s)
General Electrical Earth Loop and Insulation Resistance Test Sheets
Testing of all hot water service thermostatic mixing valves (TMV's) in accordance with BS6700 and tests to comply with HSE Document L8 and HGN 'Safe Hot Water and Surface Temperatures
Emergency Lighting Completion and Test Certificates
Certificate of Compliance/Testing of Radiation protection
Security Systems Commissioning Certificates
Certificate of Soundness Testing of Gas Installation
Gas Pipework Pressure Test and Purge Certificates
Medical Gas Pipework Pressure Test and Purge/Commissioning Certificates
Fire Suppression System Certificates (in accordance with BS6266 and tests to comply with CIBSE Guidance E)
Fire Alarm Sound Record Sheets
Lighting Calculation Sheets and Lux Level Test Results (Internal & External)
Machine (Generator/UPS/CHP etc) Specialist Commissioning and Factory Test Sheets
Acoustic Test sheets (in accordance with BS 5821)
Lift Commissioning in accordance with BS EN 81 and Factory Test Sheets
Lightning Protection Risk Analysis and Test/Commissioning Sheets
Boiler Plant Manufacturers Factory Test and Commissioning Sheets in accordance with CIBSE Commissioning Code B
Works pressure test certificates for all pressure vessels
Mechanical Pipework Systems Pressure Tests
A/C Equipment Performance Tests
Condensate Clearance Tests for A/C Equipment
BMS/EMS Tests/Commissioning Records in accordance with CIBSE Commissioning Code C
Air Distribution Systems in accordance with CIBSE Commissioning Code A
Water Systems (heating & domestic water) in accordance with CIBSE Commissioning Code W
Legionellae Testing (to include an organic check on the incoming mains) within tolerances given in HSE ACOP test sheets
Domestic water systems bacteriological quality test sheets
Rainwater harvesting systems test and completion and bacteriological quality test sheets
Plant (Calorific, Treatment etc.) Specialist Commissioning and Factory Test Sheets
Nurse Call Test Certificate
Disabled Toilet Alarm Test Certificate
Fire Alarm Test Certificate
CCTV and Access Control Test Certificate
TV Aerial Certificate
Patient Entertainment System Certificate
Telephone Cabling Test Certificate
ICT Cabling Test Certificate
Induction Loop Test Certificate
Pipeline Pressure and flowrate Test Certificates including drainage and all steam systems
Steam boiler/generator test factory test and commissioning certificates in accordance with

Test Documentation
CIBSE Commissioning Code B
Ground Source Heating installation pressure and Test Certificates
Chiller factory test and commissioning certificates in accordance with CIBSE Commissioning Code R
Chemical clean and inhibitor dosing certification to heating/chilled water systems
Ductwork physical and bactericidal cleaning certification

Section 7.0 Architectural Requirements

7.1 Masterplan

7.1.1 The Masterplan for the New South Glasgow Hospitals has been developed in consultation with various stakeholders, including User Groups, Architecture + Design Scotland, the Carbon Trust, Strathclyde Passenger Transport, Civil Aviation Authority (CAA) and Glasgow City Council Planning Department. The aims of the Masterplan are to achieve a clarity of spaces and routes within the existing Southern General Hospital Site.

7.1.2 The proposed Masterplan design seeks to improve the entrances to the site, traffic flows around the site and enable all visitors to the new hospitals to orientate themselves quickly with the campus. A new main boulevard entrance will be created from Govan Road, which will border the new Laboratory, FM & Mortuary and Energy Centre Site. However, the traffic flows have been separated and all service access to this area will be off Hardgate Road. Public Access and drop off via private car become immediately clear on the approach to the building and the traffic flows allow drop off adjacent to the relevant entrances and then onwards to the respective car parking zones. A new transport 'hub' located centrally on the site provides direct and sheltered access to the new hospital entrance. This hub will allow 'Fastlink', taxi and private car drop off within immediate walking distance to the entrances. Public Bus routes will remain on the existing road network with additional bus stops being provided at key entrances.

7.1.3 Blue Light traffic routes into and within the site are clearly identified and provide the quickest access points from whichever direction the ambulance approach.

7.1.4 Upgrading and Replacement of car parking provision has located 4 new major car parks strategically around the site:

a) Adult Hospital x 2nr;

b) Children's Hospital; and

c) A&E Entrance

7.1.5 Pedestrians and cycle routes through the site and the interaction with the building have been developed to provide clear designated routes to the new main hospital and surround buildings, while the punctuation of the site with pockets of landscaped spaces supplement the main park area situated immediately in front of the new main hospital entrance. The 'green space' within the campus is designed to provide a functional retreat for patients, visitors and staff.

7.1.6 As the final design develops within the parameters of the Masterplan, there is a requirement to update the Development Control Plan for the entire Southern General Site to identify future uses, expansion and redevelopment.

7.1.7 The Masterplan presents the Board's vision of the New South Glasgow Hospitals on the Southern General Hospital Site and requires to be followed and implemented by the Contractor.

7.2 Exemplar Design

7.2.1 The exemplar design has been developed in consultation with the Board and User Groups. The exemplar design is intended to reflect these discussions and provide an advanced level of briefing that will enable the Contractor's response at the end of the bid period to be more advanced in terms of understanding of the Board's and User's functional, clinical and quality requirements. As well as reflecting the requirements of the Clinical Brief the design exemplar is also intended to represent a design quality benchmark against which the Contractor's proposals will be measured. The exemplar demonstrates the aspirations of the Board in terms of the graphical and technical representations of the Contractors.

7.2.2 Whilst the exemplar design has not been developed with the intention of constricting the Contractor's proposals to a particular solution nor has it been developed in order to stifle innovation or creativity, it should be noted that the functional relationships indicated in the exemplar does represent the culmination of a process of detailed consultation with the Board and Users to determine their requirements and as such it is not expected that the Contractor will require to revisit the functional relationships or design principles as set out in the following exemplar information;

a) 1:500 departmental relationship drawings for all levels of each building indicating functional relationships, entrances and main circulation routes (Appendix H);

b) 1:200 departmental drawings for 7 no. key departments in the Adult's Hospital and 4no. key departments in the Children's Hospital indicating room adjacencies, circulation layouts, corridor widths, entrances and links to other departments/facilities. (Appendix I);

c) 1:50 Room Layout Drawings indicating clinical functionality, room size and shape and compliance with ergonomic data. (Appendix J); and

d) ADB Room Data Sheets (Appendix E).

7.2.3 Described in more detail below are the key features of the exemplar design which will require particular consideration by the Contractor;

a) Adult and Children's Hospital Identity;

b) Podium;

c) Ward Tower;

d) Main Entrance; and

e) Atrium including retail space;

Adult and Children's Hospital Identity

7.2.4 The exemplar proposes a single overall building footprint subdivided into the Adult and Children's facilities, creating two distinct but adjoining hospitals. This is in acknowledgement of the benefit to be exploited through the co-location of the Adult and Children's Hospitals, a great deal of consideration has been given to identifying these in the brief and in the design of the two hospitals.

7.2.5 It is important to stress that the Children's Hospital will operate as a hospital in its own right with its own clinical staff and management, with some shared facilities. It is therefore a requirement of the brief for the Children's Hospital not only that there should be an appropriate degree of clinical and patient separation between the two hospitals but also that the distinct identity of the Children's hospital shall be maintained both externally and within the patient and public areas. This requirement is expressly reflected in the exemplar design which indicates two separate entrances for the Adult's and Children's Hospital.

Building Typologies

Podium

7.2.6 A significant proportion of the overall building footprint is dedicated to integrated acute facilities which will be housed in the 3 storey podium. The podium will house such departments as Operating Theatres, Radiology, Critical Care and Outpatients Departments. The key drivers behind the location of departments are the necessities of co-location for functionality along with appropriate public/private zoning of the facilities. For example Outpatients and Accident Emergency Departments are located on the ground floor towards the external boundary of the footprint to ensure an appropriate level of public accessibility is achieved while the core of the footprint is reserved for private treatment and diagnostic areas such as Radiology.

7.2.7 Departments located in the podium;

a) NSGH Main Entrance and Discharge Lounge;

b) NSGH Emergency Department;

c) NSGH Rehabilitation;

d) NSGH Radiology;

e) NSGH Acute Assessment;

f) NSGH Critical Care;

g) NCH Main Entrance;

h) NCH Emergency Department;

i) NCH Rehabilitation;

j) NCH Radiology;

k) NCH OPD;

l) NCH Cardiology;

m) NCH Inpatient Wards;

n) NCH DCFP;

o) Operating Theatres;

p) Endoscopy;

q) Aseptic Suite;

r) Renal Dialysis;

s) Nuclear Medicine;

t) Medical Physics;

u) Dining Area;

v) Retail and Café; and

w) Pharmacy.

Ward Tower

7.2.8 Located above part of the footprint of the podium will be the 13 storey 4-wing ward tower providing single bedroom ward accommodation across a range of departments including Renal, Vascular, Haemato-Oncolgy etc. In total the facility includes the provision of 1,109 adult and 240 children's beds. While not all bed spaces noted will be accommodated in the ward towers, the ward tower typology was developed as being the most appropriate and achievable method by which these bed numbers could be accommodated. The towers are positioned and orientated to provide best use of views across the site, provide appropriate levels of natural light and to achieve patient privacy by preventing overlooking from other ward accommodation.

7.2.9 Tower Wards include;

a) Generic wards;

b) Haemo-oncology wards;

c) Vascular wards;

d) Renal wards;

e) Dermatology; and

f) Stroke;

Main Entrance

7.2.10 There are 6 staff/patient/visitor entrances on the ground floor;

a) NSGH Main Entrance;

b) NCH Main Entrance;

c) NSGH 24 Hour/Staff Entrance;

d) NCH 24 Hour/Staff Entrance;

e) NSGH Acute Assessment Entrance; and

f) NSGH / NCH Emergency Department Entrance

7.2.11 At each of the above entrances a robust glazed canopy will require to be incorporated in order to provide shelter from the elements for staff, visitors and patients and to assist in the prevention of wet contamination of flooring within the building. Entrance canopies will require to be sized appropriately to accommodate ambulances as necessary. A methodology for the maintenance and cleaning of the canopies will also be required.

7.2.12 The ambulance entrance of the Emergency Department (ED) will be expected to have the ability to be converted into an external decontamination facility. This would include the requirement to incorporate roller screens as part of the ambulance canopy and multiple water mixer points to allow shower attachments. The area will also require the ability to isolate drained water under decontamination procedures.

7.2.13 The main entrances to the Adult's and Children's Hospitals will be expected to have a light, spacious and welcoming atmosphere and the main entrance shall be immediately apparent to all users. The main entrances for the Adult's and Children's Hospitals should reflect in form, scale, space and use of materials the aspirations and design quality promoted by the Board resulting in a meaningful expression of the Board's intent for the facility; that is to deliver first class healthcare to the local population and provide a focal point for community activities and education welfare. The entrances should demonstrate the required benchmark of architectural design quality while at the same time incorporating practical considerations, for example the provision of appropriate shelter and adequate accessibility of entrances.

7.2.14 The façade of the main entrances should be fully glazed for the full height and width of the entrance area including automatic sliding entrance doors to allow views in and out of the main entrance and reception. It is important that large glazed areas such as this should be clearly identified as such for safety purposes and must be safety glass. Solar shading devices should be incorporated as necessary to achieve the Board's stated Sustainability and Energy Targets. The size and numbers of automatic entrance doors should be sufficient for the expected number of users to pass comfortably and safely through them. A glazed canopy should be incorporated in order to provide shelter across the full width of the entrance at a height that provides appropriate shelter while also coordinating as required with the façade design. The structure and glass forming the canopy shall be robust and shall incorporate all appropriate standards of security, and where reasonably practicable, limit the potential for exposure to crime and vandalism.

7.2.15 Entrance lobbies should be provided as Section 7.5.2 including the requirement for a minimum of 6 metres of barrier matting to prevent the ingress of dirt and wet contamination to flooring. Any lobby enclosure provided requires to be fully glazed to allow users to proceed safely and confidently.

7.2.16 Once inside the building the reception areas and information points are key to orientation. The tone of a building is set by the entrance and reception to the building, therefore the Contractor's design should achieve a balance of openness with patient confidentiality and staff safety, resulting in reception areas skillfully combining a friendly welcome with low-key oversight of public areas. The expected quality of the main entrance spaces should be akin to a large hotel foyer, this expectation should be reflected in the choice of quality robust materials for flooring, walls, ceilings, balustrades etc. The quality of the space should also be enhanced by interesting shapes and forms, lighting techniques and the incorporation of art.

7.2.17 The reception area and main entrance generally will be busy places, both in terms of footfall and hours worked. Materials, finishes and furnishing therefore need to be robust, as well as attractive. The Contractor's design should cater for well selected, fit for purpose furnishings which will complement a clear approach to design. One such component of the main entrance design is the flooring, it is vitally important that the floor finish in the main entrance area should combine robustness and attractiveness with slip resistance. A material such as natural stone/ceramic tiles which have a high micro-surface roughness should be used.

7.2.18 One of the most important features of the reception area is the reception desk which should be close to the entrance and should be an open well lit counter/desk with a feature or identifying sign at high level. The reception counter requires to reflect and enhance the quality of the surroundings in terms of form, quality of materials and lighting.

7.2.19 In order to provide staff, patients and visitors with access to information especially at the key points of entry to the Building it is the Board's intention that Contractor's should incorporate electronic information points utilising touch-screen technology in addition to the manned reception points and stations and the PA system. These information points should present information (in a variety of languages) on the hospital for orientation and wayfinding purposes along with information in relation to the public transport hub which should be adjacent to the main entrance giving real time information on bus/fastlink timetables. The Contractor will be required to provide a clear strategy for the provision of these information points.

7.2.20 The main entrance requires to incorporate well planned waiting rooms which can help to relax patients, thereby reducing fear and increasing confidence. Upholstered seating set out in the style of a hotel foyer with spacious waiting should be the goal, these areas allow patients, carers and visitors to relax, chat, wander or simply enjoy the space and any views afforded. This is especially valuable where the patient may be accompanied by friends or relations.

A Changing Places facility which combines a toilet, shower and changing room for use by people with complex and multiple disabilities will require to be located at the Adult and Children's entrances. The space should be provided in accordance with the requirements of BS8300:2009 item 27 and should incorporate an adjustable changing table and fixed track hoist system.

7.2.21 A requirement throughout the hospital especially within entrance areas shall be to incorporate appropriate standards of security, and where reasonably practicable, limit the potential for exposure to crime and vandalism. Guidance is provided in HFN05 -"Design against crime-a strategic approach to hospital planning".

7.2.22 Atrium including retail space

a) The exemplar indicates a linear atrium linking the main entrances of the Adult's and Children's Hospitals. This concourse performs a number of different functions;

b) Provide a link between Adult and Children's Hospitals;

c) Provide clear horizontal and vertical links to all areas of the hospital facilities with the incorporation of stairs, lifts and escalators as necessary;

d) Provide a clear route for patients, staff and visitors to frequently attended departments such as the outpatient's department;

e) Provide access to pharmacy;

f) Provide access to retail facilities such as the cafeteria to allow users to purchase drinks, food and to consume them in a pleasant and relaxing environment;

g) Continue the quality of the main entrance spaces which will be reflected in the choice of quality robust materials for flooring, walls, ceilings, balustrades etc; and

h) Provide opportunities to incorporate art, lighting techniques and tv/video display screens to enhance the quality of the space and provide a welcome distraction.

7.2.23 The multi-level linear atrium space will be formed between the outpatient department and the remainder of the departments contained in the podium such as day surgery and radiology. The atrium will contain link bridges, escalators, lifts and stairs providing all vertical and horizontal communication links across the void space providing the necessary connections between departments. The lifts should be fully glazed to all sides providing views over the atrium space for the purposes of orientation. A high level of finish will be expected for all stairs and balustrades, any handrail, barrier or guarding to stairs or corridor links should be glazed to allow views for children and those in wheelchairs. The roof to the atrium should be fully glazed to provide a light, bright welcoming environment. Solar shading devices should be incorporated as necessary to achieve the Board's stated Sustainability and Energy Targets. The atrium will also provide fully glazed areas of façade to courtyards where available, to allow users views out to external landscaped courtyard spaces. The expected quality of the atrium concourse space should be akin to a high quality shopping mall and continue the quality of the main entrance. This should be reflected in the choice of quality robust materials for flooring, walls, ceilings, balustrades etc. The quality of the space should also be enhanced by interesting shapes and forms, lighting techniques and the incorporation of art.

7.2.24 The form of the atrium shall clearly express the individuality and special nature of parts of the Works including the retail facilities, yet the parts should harmonise with the facilities as a whole. The Contractor should give particular consideration to the architectural composition and expression of the form within the atrium which should reflect an identifiably distinct character for the Adult Acute and Children's Hospital as befits the nature of the patient groups.

7.2.25 The atrium also provides opportunities for retail facilities including pharmacy and cafeteria facilities, these areas should be clearly expressed.

Helipad

7.2.26 The Contractor will require to provide a rooftop Helipad and the associated services, access requirements and safety facilities in full compliance with the following guidance;

a) HBN 15-03 – Hospital Helipads;

b) British Helicopter Advisory Board – Helicopter Site Keepers Guidance Document; and

c) Structural Design Criteria - ICAO Heliport Manual

7.2.27 The Helipad will also require to be provided in line with all requirements of Glasgow City Council Planning Department including the following requirement;

a) A detailed noise and environmental assessment regarding the relocation of the heliport landing area shall be submitted to the Planning Authority for its written approval prior to its siting and operation. The Contractor requires to consult the Director of Land and Environmental Services, Public Health Unit concerning the methodology and approach to any assessment.

7.2.28 It is understood that this type of Helipad does not require to be licensed by the CAA (Civil Aviation Authority), however due to the congested nature of the surrounding area the Helipad operator will require a Rule 5 permission from the CAA and therefore the Contractor must consult the Operator and Board to ensure compliance.

7.2.29 The Helipad Operator(s) and Board will require to be consulted on the type of helicopters that will be expected (including size and weights). However as general guidance for the size of Helipad required a rectangle with sides at least 25 m long (or a circle at least 35.4 m in diameter) will be a minimum requirement to accommodate all helicopter types likely to make use of the facility.

7.3 Ceilings Heights & Voids

7.3.1 The floor to ceiling heights, or to services level where there are no ceilings, shall be designed to accommodate the nature and use of the accommodation, but as a minimum shall be at least 2700mm irrespective of location. The ADB room data sheets define ceiling heights on a room by room basis.

7.3.2 All circulation and communication spaces shall have a minimum ceiling height of 2700mm;

Room Type	Department	Minimum Ceiling Height
All Corridors	Wards	2700mm
Lift Lobbies	All Departments	2700mm

7.3.3 Certain special types of room should be 3000mm or above in height to suit their medical or equipment needs;

Room Type	Department	Minimum Ceiling Height
All Operating Theatres	All Departments	3000mm Where Laminar Flow curtains are present – 2100mm required to u/side of curtain from ffl.
Radiology and scanning Rooms (CT and MRI)	Radiology	3000mm
Endoscopy Rooms	Endoscopy	3000mm
Therapy Room	Rehabilitation	4500mm

7.3.4 Additionally there are a number of departments where all ceiling heights should be as a minimum 3000mm – including all main communication and interdepartmental circulation routes;

Department	Minimum Ceiling Height
Operating Theatres	3000mm
Critical Care	3000mm
Imaging	3000mm
Rehabilitation	3000mm

7.3.5 The following criteria require to be incorporated in the Contractor's Proposals:-

a) Areas such as circulation spaces, patient corridors, waiting areas, reception areas, entrance areas and atria should be given particular consideration in terms of ceiling form, material and with particular regard to maximising the height of ceilings to offer a light, spacious and welcoming character. For the avoidance of doubt a suspended ceiling tiled solution throughout will not be acceptable in these areas. Where higher ceilings are present a maintenance strategy will require to be clearly demonstrated;

b) An appropriate and safe void allowance above all ceilings shall be provided, including appropriate and safe points of access for maintenance of services. The void allowed shall be adequate for the full co-ordination and installation of engineering, cabling (including IT)

and other services. Co-ordination with the electrical, mechanical and communication services shall be an inherent part of the ceiling and building design. A full and appropriate strategy for the coordination of services requires to be clearly demonstrated to the Board through the use of 3D Modelling techniques;

c) It is imperative that the Contractor shall demonstrate their solution to the above requirement to the satisfaction of the Board by providing a clear and identifiable strategy for the installation of these services , providing satisfactorily accurate sizing and positioning for ducts , cable trays etc, including access points in plan and section to confirm compliance with this key Board requirement. As part of this requirement a clearly identifiable zoning strategy will require to be demonstrated by the Contractor regarding the location of access points to ceilings or roof voids;

d) The Contractor shall also ensure that the ceiling voids are designed to accommodate the specific requirements of the fire strategy for the Facilities -and in particular, the provision of cavity fire-barriers within compartments;

e) Services access through all Category 1 ceilings will not be acceptable (ceiling categories will be as defined in the ADB Room Data Sheets). For these areas the ceiling services should be capable of being accessed from an adjoining activity space. For the avoidance of doubt services should not be accessed from below (i.e. through the ceiling) in these areas. The following list of areas is indicative only and not exhaustive;

i) Aseptic suite;

ii) Decontamination unit;

iii) Operating theatres;

iv) Anaesthetic rooms;

v) Plaster room;

vi) Post operative recovery; and

vii) Preparation;

f) Ceiling or roof voids must not be accessible to patients or visitors. Access will be by Maintenance personnel only;

g) Modular ceilings are not acceptable in the operating theatre but may be required in associated areas for maintenance purposes. The ceiling in the operating theatre should also be able to withstand regular washing and have a completely sealed finish to maintain microbiological standards in compliance with SHTM, SHPN, HBN guidance;

h) If an acoustically absorbent ceiling is considered in any location it is essential that this does not present an infection hazard in compliance with SHTM, SHPN, HBN guidance;

i) Designated access points shall be fitted with a self-contained Ramsey-style ladder or similar where appropriate to facilitate access for maintenance purposes – this should be clearly demonstrated in the Contractor's approach to access and maintenance;

j) Demountable suspended ceilings shall be readily demountable without suffering undue damage and shall be capable of being easily cleaned;

k) Ceilings will be constructed in a proprietary suspended plaster board system in areas demanding specific hygiene criteria as defined in the ADB Room Data Sheets;

l) Ceiling mounted booms required for patient support and monitoring systems in theatres, treatment or x-ray rooms shall be co-ordinated with the ceiling layouts. E.g. Background fixings within ceiling void. Access to check and maintain fixings to all structurally mounted equipment requires to be provided by the Contractor in a clearly demonstrated strategy;

m) In line with the requirements of HAI Scribe coving will be required at the junction of wall and ceilings within all theatre suites and endoscopy rooms;

n) A minimum of 2100mm clearance is required under any suspended fixtures e.g. Signage;

o) The protrusion of light fittings, radiant panels or any other fittings will not be accepted in clinical areas;

p) Consideration may be given to making use of the ceilings to provide additional natural light by way of roof-lights. However, careful consideration should be given to the implications of incorporating these, e.g. rain noise, and to how they will be cleaned;

q) Emergency egress from roof void areas into patient areas is not acceptable (this includes any garden areas internal to the facility);

r) Suitable service maintenance walkways, incorporating handrails, shall be provided within roof voids with access hatches where walkways pass through fire barriers. Services require to be entirely clear of this walkway;

s) Floor to ceiling heights must be carefully considered in relation to the overall height restriction placed on the building by the granted Outline Planning Consent; Additionally floor levels are required to tie in with adjacent building levels where clearly required e.g. Neonatal;

t) Where Laminar flow canopies are present, a height of 2100mm will be required from finished floor level to the underside of canopy curtain for headroom; and

u) Washable ceilings are required in all clinical areas.

7.4 **Corridor Widths**

7.4.1 The table below identifies the Board's minimum requirements for corridor widths on a departmental basis with which the Contractor must comply;

Corridor Type	Department	Minimum Corridor Width (clear between handrails)
Hospital Street	Communication	Requirements for Means of Escape will dictate width – however minimum of 3000mm required
General Traffic – Staff Only	All Departments	1500mm
General Traffic – Patient Areas	All Departments	1800mm – two independent wheelchair users to pass
Patient Bed/Trolley Traffic	Wards	2150mm – straight movement with passing places width 3330
Patient Bed/Trolley Traffic	Theatres/Endoscopy	2960mm – two beds to pass regularly
FM Tunnel	Links buildings	8000mm - to be developed with robotics design and requirement.

7.4.2 Corridor widths shall be as required by the nature and use of the accommodation. Minimum widths shall apply along the whole length of the corridor. Main interdepartmental corridors in areas that patients may travel in beds shall be of sufficient width to allow two beds, with any attached equipment, to pass. Departmental corridors shall have passing places and all corridor widths shall be subject to specific agreement with the Board.

7.4.3 The following criteria require to be incorporated in Contractor's proposals:-

a) the utilisation of corridor widths and profiles is an integral element of the Clinical Brief and requires to be addressed in design solutions. This may be achieved through the use of informal seating areas and the like, whilst avoiding areas where patients may be obscured from staff view where possible;

b) corridors in patient areas shall not be less than 1800mm (clear between handrails or other protrusions), with corner protection to be provided and handrails to both sides, where appropriate as defined in Section 7.16 - Protection;

c) wherever possible reduce lengths of circulation routes and provide open areas and stopping/resting points along the length of travel;

d) avoid isolated columns in open plan areas or on circulation routes where practicable; and

e) avoid dead ends to circulation routes, particularly in patient areas;

7.5 **Doors**

7.5.1 Door widths shall be identified in the relevant ADB Room Data Sheet and Schedule of minimum door widths below (in the eventuality of a conflict between the RDS and Schedule below the wider provision will apply).

Room Type	Department	Minimum Coordinating width of Door
Ensuites	All Departments	1980 mm
Recovery	Operating Theatre	1900mm
Corridors	All Departments	1900mm in corridors greater than 1800mm wide i.e. Corridors with patient access
Operating Theatre	Operating Theatre	1900mm
Endoscopy Room	Endoscopy	1900mm
Assisted Bathrooms	All Departments	1500mm
Patient Bedrooms	All Departments	1500mm
Treatment Rooms	All Departments	1500mm
DSR	All Departments	1500mm
Disposal Hold	All Departments	1500mm
Equipment Store	All Departments	1500mm
MRI Room	Imaging	1450mm (refer to HBN 06)
Interview/Sitting Rooms	All Departments	1000mm
Consult/Exam Rooms	All Departments	1100mm
Clean/Dirty Utility	All Departments	1000mm
Offices	All Departments	1000mm
Seminar Rooms	All Departments	1000mm
General Stores	All Departments	1000mm
Staff Rest Rooms	All Departments	1000mm
Staff WC	All Departments	1000mm
Patient WC	All Departments	1100mm

7.5.2 For the avoidance of doubt, the minimum coordinating width indicated above is as defined in SHTM.

7.5.3 Notwithstanding the above, the Contractor shall be responsible for establishing, through detailed consultation with the Board, additional specific requirements for door widths in all areas of the Works. Consideration shall be given to providing sufficient door width in areas where the Board's operations rely on the use of larger items of Equipment such as waste containers and regeneration trolleys.

7.5.4 Door widths and door configuration shall be provided to allow for the delivery and removal of Equipment to each area. The Contractor shall require to demonstrate replacement planning for

major items of kit including navigation routes through corridor and other doors (e.g. replacement Imaging equipment). In this respect the Contractor shall ensure that the relevant corridor and door opening widths can accommodate the replacement of plant and materials along designated routes (identified by the Contractor). This to allow the passage of new/replacement Equipment and Specialist equipment without the need for the removal of any doors, door operating gear/equipment or handrails/protection.

7.5.5 The following criteria require to be incorporated in the Contractor's proposals:-

a) doors from the single bedrooms to en-suites in all ward accommodation should comply with the requirements of both HBN 04-01 Adult Inpatient facilities and HBN 00-02 Sanitary Spaces. The double door to the shower room should consist of a sliding/folding door and a hinged door. The sliding/folding door provides staff and unassisted patient access. Both doors need to be fully open for assisted use of the facilities. The sliding/folding door should be designed to release from the overhead track in order to provide mobile hoist access to the room and transfer to one side of the toilet. The hinged door should be able to open unhindered. To maximise the free space in the bedroom, consideration should be given to making this a folding door;

b) doors will require to accommodate overhead tracks (including supporting structures as necessary) for patient hoists in all bedrooms, with patient hoists to be installed in six bedrooms per ward generally and all bedrooms in elderly wards as well as in one room per OPD cluster in the Children's hospital;

c) all main entrance doors shall be automatically operated with break-out facility in the event of fire and have an effective draught lobby;

d) internal door leaves to all areas shall be of solid core construction, reinforced with damage protection plates; They must be resistant to all damage which would be reasonably expected for the building use. In line with BS8300 requirements the Board would expect that as a minimum all doors where there will reasonably expected to be wheelchair access – 400mm high kickplates will be provided. Refer to Section 7.16 - Protection for further details;

e) doors to some rooms shall be of a security rated construction, particularly areas where medical drugs are likely to be stored as indicated in ADB Room Data Sheets;

f) all door frames must be of solid or metal construction, and must be securely fixed in to the adjoining construction;

g) all doors to bedded areas shall be minimum width of one-and-a-half size openings to allow access for hospital beds, with double width doors required in ward area corridors. In addition to the requirements of the Disability Discrimination Act, careful consideration needs to be given as to the clear opening size of doors due to the need to transport patients and items through. Patients may be supervised, with an individual on either side of them (some patients may be evacuated in their bed to a place of safety, therefore pinch-points at rooms and corridors need to be avoided);

h) doors shall incorporate vision panels as per the ADB Room Data Sheets, to permit staff observation; of these, some will require integral blinds to obscure the vision panel for privacy reasons, this will also be indicated in ADB Room Data Sheets. Integral blinds to the vision panel are to be operable only from the inside of the room where a member of staff will

be constantly present, where a member of staff will not be constantly present (bedrooms for example) the integral blind should be operable form both inside and outside the room. Integral blinds in door vision panels require to be vistamatic type (horizontal blinds are not acceptable);

i) doors should have low-level viewing panels to ensure that a baby, toddler or young children or those in wheelchairs can see and be seen from either side of the door. Where a door has a single viewing panel, the minimum zone of visibility should be between 500 mm and 1500 mm from the floor. If a door requires an intermediate horizontal section for strength or to accommodate door furniture, the door should have two viewing panels, one accommodating a zone of visibility between 500 mm and 800 mm from the floor and the other accommodating a zone of visibility between 1150 mm and 1500 mm from the floor. Doors requiring vision panels are indicated in the ADB Room Data Sheets;

j) all doors to patient bedrooms, en-suites and bathrooms shall be fitted with a break-out (anti-barricade) facility which may be achieved by a combination of outward opening doors and ironmongery solutions. The Contractor will be expected to comply with anti-ligature/anti-barricade requirements in the Children's DCFP;

k) fire doors fitted with door closers are heavy and awkward to open and hamper easy circulation. All fire doors on circulation routes, and those not needing to be closed for security reasons, should be fitted with electromagnetic stays or swing-free door closers, which will close in the event of a fire alarm and be linked to the BMS to close at night. Door holds and door closers utilised in any location must not de-rate the fire rating of the door set to below that require for the location;

l) all bedroom doors which shall have free swing door closers (as HBN 00-04);

m) swipe card access and video plus audio door access will be required at the entrances to all departments, at links between departments to provide the necessary segregation, at all ward entrances, access points to staff only areas and access to FM/back of house areas;

n) all interview and consulting room doors to have a suitable level of acoustic performance to achieve the dB rating required by the ADB Room Data Sheets. Also refer to Section 7.8 – Acoustics. No air transfer grilles shall be permitted in these particular rooms and must comply with all requirements of the ADB Room Data Sheets;

o) the requirements for Radiofrequency shielding to doors within Radiology department shall be based on the requirements of the MRI scanner supplied and the siting of the device within the room and wider environment. Door leafs will typically incorporate copper or aluminium sheet materials and special details such as compressible brass finger strips at the head, sill and door jambs to maintain the continuity of the Rf cage electrical conductive construction. For the avoidance of doubt however it is required that the Contractor must seek advice from and agreement with the Board and the Board's Radiation Protection Adviser in this matter;

p) door closers to shielded doors require to be agreed with the Board and the Board's Radiation Protection Adviser;

q) all Radiology, Imaging and Nuclear Medicine x-ray rooms require lead lined doors as do all Theatres, dental (Children's hospital) and areas of A&E. The requirements for radiation protection shall be based on the designation and nature of the area, size of the room,

location of the door in relation to equipment and other risk factors. For the avoidance of doubt it is required that the Contractor must seek advice from and agreement with the Board and the Board's Radiation Protection Adviser in this matter;

r) doors must be fire resistant in line with fire regulations but, where connected to the fire and security alarm systems, must fail closed. Any alarm system linked to doors must not be compromised by even a short term power loss or surge;

s) doors to Theatres and Recovery areas require to open automatically upon activation of a push pad (not switch). Push pads to be sited to the left and right of both approaches to the door (i.e. 4 pads per door set). It should be possible to stand automatic doors in the opening position;

t) signs on or adjacent to all doors should be at a height of 800–1500 mm and tactile so that they can be easily read by touch;

u) external doors to non-public access areas should be metal-faced, solid timber core construction, other than louvred doors to plant areas, where ventilation is required;

v) any locked fire exit doors must have the capability of release on the activation of the fire alarm, or a local release facility of a type not likely to tempt patients to misuse it in line with Building Control requirements;

w) in the Children's Hospital doors to rooms that should not be entered by young children must be fitted with high-level latches. Where rooms require privacy, the doors should be fitted with 'free-to-escape' emergency release. In this case thumb-turn locks are not appropriate as young children can easily tamper with them, which could then cause panic in an emergency;

x) all external main entrances require to fitted with automatic sliding doors which protect both ends of a draught lobby. The entrance, doors and draft lobby must be designed to ensure that all normal hospital traffic can safely enter the building without compromising the inner environment (temperature and cleanliness, etc) or security of the building, throughout all weather conditions all in full compliance with HBN 00-04. For the avoidance of doubt all main entrances should allow for bed access/egress with a minimum clear width of 1740mm and doors should open automatically in the event of fire or power failure in line with the requirements of the Technical Standards requirements;

y) all fixings to ironmongery, fixtures and fittings in the Children's Hospital must be either securely concealed or be of a tamper-proof form (e.g. non-return screws);

z) the Contractor shall provide ironmongery which shall compliment the overall quality of the interior design concept. The Contractor shall ensure ironmongery is of robust construction suitable for its specific purpose and usage characteristics and in accordance with the Room Data Sheets. For ease of use by elderly or disabled persons the Contractor shall ensure handles are colour contrasted with the door background colour and of easy grip design. For ironmongery requirements refer to Section 7.11.1 Ironmongery;

aa) in 'back of house' areas such as catering, mortuary and all FM areas doors should be wide enough for trolleys and equipment to pass through easily and will need additional protection at heights related to equipment likely to cause damage. Any external doors to catering areas will require to be pest and insect-proof. All doors in food handling areas should have vision panels. Some doors may require security devices to allow access for designated staff only. For economy of space, chilled food stores and cold rooms may be fitted with sliding doors; flush thresholds are required to facilitate the passage of trolleys. Automatic cold air curtains should be fitted to maintain the temperature when the door of chilled food stores and cold rooms is open;

bb) Consideration should be given to providing doors within the children's hospital of different shaped vision panels, ironmongery and colours to provide a less clinical feel; and

cc) all doors within circulation and communication routes require to provide as large as practicable an effective clear opening width to allow the free movement of all forms of traffic. For the avoidance of doubt, the effective clear opening width for a swing door is the available width measured at 90degrees to the plan of the doorway clear of all obstructions (such as protruding ironmongery) when the door is opened through 90degrees or more. In all main circulation and communication routes (corridors over 1800mm) doors should comprise door leafs which are floor to ceiling heights with no overpanels. At these locations any door nib should be of a transparent nature in order to provide for maximum visibility to the corridor beyond.

7.5.6 Additionally, the Contractor requires to comply with the following:-

a) ensure that door edges do not present a hazard to visually impaired people when in hold open position. Contrasting texture flooring should be considered to guide people into the line of doors, as an integral part of the way-finding strategy;

b) light pressure delay check door closers should be provided to self-closing doors;

c) colour contrasted easy grip lever furniture and ironmongery;

d) any fully glazed doors or associated screens to have additional visual identification, for example applied manifestations;

e) level access to all doors, including escape doors;

f) generally, intermediate doors across main circulation routes should be held open on electro-magnetic devices linked to the fire and security alarm systems and designed to fail closed in an emergency or power failure.

7.5.7 Door Security

7.5.7.1 Door security requirements shall be identified in the relevant ADB Room Data Sheet, however the following criteria will require to be met by the Contractor;

a) access doors to patient areas will require to be alarmed and linked to a suitable alarm system capable of being monitored by the duty room or ward manager. This is vital within the Children's Hospital where all entrance/exit doors will require door control systems to prevent unwarranted access/accidental egress. They must be controlled externally with close proximity cards and internally by a press-to-release switch at a high-level. They will also be operated from a communications base, coupled with an audio-speech facility between the entry door and the communications base for identification purposes. Door control systems must be capable of manual or automatic release on initiation of the fire alarm system;

b) security measures are also needed to control unauthorised access to all departments through the use of swipe card and video entry systems. It is recommended that access through the main entrance to all areas be controlled by use of an entry-phone or intercom system with CCTV, linked to the reception/clerical office and communications base. Programmable close proximity card or similar systems must be fitted to changing room doors and used broadly across all departments. Ideally the programmable system should grant different patterns of access to suit the needs and privileges of authorised staff and visitors. The security measures chosen should not inhibit emergency escape from the above areas or access by the staff at any time;

c) all doors must be master-keyed / carded, with allowance for a suitable quantity of sub-master suites to facilitate the security zoning arrangements within the building such that each department, ward and service area can be locked down separately and with a master key. All doors throughout the building to have the same lock to allow a single key to be used by all staff. Spare cylinder and key sets to be maintained by the Contractor to allow ease of replacement. Secure and 'staff only' areas are to be controlled by proximity card readers linked to electrical locking devices in the doors. The proximity cards are to be contained within the staff I.D. badges. Contractor to provide facility to enable alterations to cards. Twelve thousand cards and lanyards are required to be provided by the Contractor;

d) there will be a decontamination entrance leading from the ambulance bay into A&E, which can act as a decontamination "airlock" with internal drainage and integral showering facilities with a "dirty" end onto the ambulance entrance and a "clean" end into the department. This area should have piped oxygen and suction to be able to manage the rare situation of a contaminated patient requiring resuscitative measures. This area requires to have audio/intercom communication with the adjacent hospital area to allow communication between staff;

e) the A&E will have secure entry and exit points which can be locked if required. Electric swing doors will be configured to open automatically if approached by a patient trolley. All other access will be by proximity card access by staff members; and

f) the A&E will have facilities for the management of high security patients, access to the treatment area for patient transfers of this type to have a discrete external door, security rated and access controlled as agreed with the Board and Strathclyde Police.

7.5.8 Draft Lobbies

7.5.8.1 All main entrances will require a draft lobby, the enclosure to the lobby requires to be fully glazed to enable users to proceed safely and confidently.

7.5.8.2 The lobby area should have absorbent and dirt-retaining flooring, over a sufficiently large area, to minimise damp and dirt being taken into the hospital to further minimise the risk of slip accidents. Mats must be able to be uplifted and removed from matwells for cleaning. For details of these requirements refer to floor finishes section – Section 7.9.2. Further, draft lobbies require to have air curtains and consider further energy efficient design features.

7.5.8.3 The size and shape of the lobby should also:

a) allow the smooth flow of users into and out of the building;

b) allow for the fact that users may congregate there;

c) ensure that by the time the second doors are reached, the first are closed;

d) provide a “modifying” environment between the outside and inside of the hospital; and

e) if other facilities are provided within the draught lobby, such as seats and payphones, they should not obstruct the passage of users.

7.6 **Windows**

7.6.1 Bedroom windows shall be sized and positioned so that patients can view through the window from their bed while sitting up, from a seated position and when standing. In the Children’s Hospital windows must have a low-level sill, a maximum of 600 mm high, to enable small children to see outside from their bed or cot. Blinds, controlled from within the room, are required for all internal glazed screens and windows to ensure privacy and also give protection from glare and solar gain.

7.6.2 The Contractor shall ensure that appropriate solar glazing and/or solar shading is incorporated on windows on typically East, West and South facing elevations. The Board will expect the Contractor to implement solar glazing/shading strategies as part of the overall solar heat gain and ventilation strategies. Further to this the Contractor will require to clearly demonstrate compliance with the environmental/energy targets as defined in Appendix M.

7.6.3 Natural light shall be provided in public spaces and in occupied private and staff spaces within the Facilities as far as is practical. Natural and artificial light sources should be designed to avoid or minimise glare.

7.6.4 Where possible all windows shall be designed by the Contractor to be cleaned externally and internally from the inside, unless otherwise agreed by the Board. The Contractor shall ensure no portions of windows, either fixed or opening should come below the level of worktops or desks except in in-patient areas where bedrooms and day dining rooms cills may be lowered to facilitate better external views. Locking devices to enable the windows to be released for cleaning purposes shall be by key or other device such that they cannot be released by unauthorised persons.

7.6.5 The following criteria require to be incorporated in the Contractor's Proposals:-

a) windows must combine security with good natural light and ventilation;

b) window frames to be of a robust and secure construction;

c) provision of external window cleaning system to ward tower, podium and all other windows;

d) all windows (in a naturally ventilated building solution) to have robustly controlled, limited openings to a maximum of 100mm clear opening (as per ADB Room Data Sheets and SHPN 03) with a robust, secure method of restricting the extent of opening;

e) all windows (in a naturally ventilated building solution) should be capable of opening in order to meet the desire to naturally ventilate the building as far as is practicable. This is required to address seasonal changes, where external temperatures may dictate that it is not desirable to open windows to achieve ventilation. The opening operation of all windows also needs to balance the desire to open windows against compromise of the security of the building envelope. The Contractor must submit full details of the proposed trickle vent with their bid, consideration should also be given to the effects of opening windows at height in the tower;

f) there may also be reduced air flow within the building as, for security reasons, some windows may not open extensively. With this in mind, it is essential that the ventilation and temperature control systems are of a high standard. The use of passive methods is encouraged;

g) as part of any passive, natural ventilation scheme dependant on the opening of windows, The Contractor shall demonstrate through thermal simulation (IES, TAS or equivalent) the optimum window opening arrangement has been selected to optimise thermal comfort with due consideration to any restrictions on openings;

h) the Contractor shall consider use of integral blinds to windows as part of the overall external shading strategy for the building along with meeting the specific requirements of the room as indicated in the ADB Room Data Sheets. The use of Integral blinds is considered to be advantageous in the area of Infection Control offering a practical solution to a range of cleaning issues. The Contractor must demonstrate maintenance and replacement methodologies for any proposed integral blinds (to windows or screens) and include robust gear and switching/movement controls;

i) in the critical care department windows in the single bedroom should be sealed. This is essential to maintain mechanical cooling and positive/negative airflow;

j) in the critical care department integral window blinds must be installed that can provide 'black-out' which is essential for ultrasound examinations and other imaging procedures;

k) proposals for the external solar shading of the building should be considered in the context of the overall design and, only if necessary, should consideration be given to solar glazing to south elevations. No reliance on the fitting of internal blinds can be used when evaluating reduction in solar gains;

l) where any windows require external security shutters, these shall be electrically operated and fully concealed;

m) window ironmongery in the shall be anti-ligature in the Children's DCFP;

n) windows that open onto courtyards where children play may constitute a hazard. Raised planting, for example, beneath them can prevent children sustaining injuries while running. In areas where children and young adults will be present Centre-pivot windows are to be avoided. Windows should preferably be of the sash-type with restrictors;

o) In areas where children and young adults will be present child-resistant locks should be fitted to all windows;

p) cords on window blinds or curtains should be kept short and out of reach of young children;

q) in order to promote good observation and communication between staff and patients in single bedroom ward areas large internal glazed screens between bedrooms and corridors should be incorporated. This will enable staff to observe patients and equally importantly, patients to see staff. However, patients should have the means to obscure windows where required through the use of integral blinds to provide privacy when required;

r) it should be possible for cleaners to gain easy access to the inside and outside of windows. A cleaning and access strategy for all windows and curtain walling requires to be provided by the Contractor, with all necessary equipment and access included in the Contractor's Proposals;

s) selection of the type of glass is crucial for the effective control of security, and for thermal and solar glare control and should be selected in conjunction with the overall consideration of environmental modelling of the Works. Colour rendering – for diagnosis of patients should also be considered in the choice of glass type for windows and screens. The robustness of all glazing must be appropriate to the functionality, relative to safety and resistance to damage;

t) the Contractor shall ensure that all handles or control gear shall be placed at levels which enables them to be operated by staff without the use of loose poles, and which do not conflict with the location of the adjoining construction elements, including blinds and curtains. Where windows are placed over worktops or desks, or where the operation as described above is not achievable, mechanical or electrical means of opening shall be provided by the Contractor with controls located in a suitable position within the room concerned;

u) the Contractor will be expected to use toughened glass in all locations (windows, doors, balconies, balustrades etc) except areas which are vulnerable to vandals or intruders at ground floor locations. As toughened glass is inherently strong and when damaged breaks into small pieces this is deemed to be less dangerous in terms of falling shards of glass or risk to vulnerable patients at risk of self harm. Laminated glass at ground floor level only will provide greater security. Laminated glass when broken will remain in place with numerous cracks, but the fragments are held together and do not separate therefore no hole left in the window for an intruder to get in through for example; and

v) One way screens/viewing panels should be incorporated as identified in the ADB Room Data Sheets.

7.7 **Building Envelope**

Facade

7.7.1 The Board would confirm that a variety of building envelope solutions will be considered in response to the following diverse challenges;

a) Energy usage;

b) Environmental considerations i.e. Odour from the nearby sewage works;

c) Ventilation and overheating;

d) Infection Control;

e) Acoustics;

f) Natural Light;

g) Cleaning and maintenance; and

h) Solar Control strategy

7.7.2 The envelope solutions which will be considered as acceptable to the Board include:

a) a partially sealed air conditioned building working in tandem with natural ventilation;

b) mechanically ventilated building working in tandem with natural ventilation;

c) double skin facade solution.; and

d) a sealed building where a maximum temperature solution is provided.

7.7.3 The envelope solution(s) proposed by the Contractor will require to be fully developed and modelled clearly indicating compliance with the Board's stated Sustainability and Energy Targets. It is not envisaged that a fully air conditioned solution alone will be capable of meeting the stated targets, however if this option is proposed, as above, a the Contractor will require to provide to the satisfaction of the Board a fully developed and modelled solution clearly indicating compliance with the Board's stated Sustainability and Energy Targets.

7.7.4 The Contractor shall also ensure that the external envelope shall incorporate provisions for its cleaning and maintenance. The Contractor shall ensure that the external hard and soft landscaping around the buildings shall allow access for the appropriate cleaning system, whether by ladders, mobile platforms or cleaning cradles attached to the building structure. Appropriate provisions shall be incorporated by the Contractor to allow the safe use of ladders. The external skin of the building shall be designed by the Contractor to accommodate the point load access of ladders and operatives, where the cleaning and maintenance system uses this method.

7.7.5 The following criteria require to be incorporated in the Contractor's proposals:-

a) external finishes shall be durable and easily cleaned, with finishes which may be vulnerable to abuse / vandalism (including graffiti) to be avoided;

b) anti-climbing measures shall be carefully considered, specifically in relation to any external wall-fixed rainwater goods and solar shading;

c) protection / avoidance from vehicular impact at drop-off, delivery points and the like is required; and

d) external detailing to avoid;

i) nesting or perching sites for birds and other wildlife;

ii) Unsightly weather staining of facades; and

e) Method of cleaning and maintaining façade

7.7.6 The Contractor shall design the building envelope to prevent rainwater entry into the building structure and the internal accommodation. Where water penetrates cladding elements, as part of the functional design and construction techniques, the Contractor shall ensure it is controlled and drained externally.

7.7.7 The Contractor shall ensure that all building elements and retaining structures shall incorporate appropriate means to resist the passage of dampness, both into the building structure and fabric, and into the accommodation, including the resistance to any hydrostatic pressure. The Contractor shall ensure that all such construction shall be in accordance with the requirements of the Building (Scotland) Regulations 2004, BS 8102 and Code of Practice CP 102 for Protection of Structures against Water from the Ground.

7.7.8 The Contractor shall ensure that the buildings are constructed and the design is detailed to limit air infiltration to minimum levels to reduce energy consumption and improve internal environmental conditions.

7.7.9 Performance demonstration tests for all roof and wall elements shall be carried out by the Contractor in accordance with the following:

a) BS 5368, Part 2: 1986 (EN86) Resistance to Water Penetration;

b) BS 5368, Part 3: 1986 (EN77) Wind resistance; and

c) BS 5368, Part 4: 1986 (EN86) Test Report Format.

Roof

7.7.10 The roof construction shall be fully weatherproofed, designed for minimum maintenance and suitably braced and held down to resist the influence of gusting winds appropriate to their locations. All penetrations through the roof membrane or cladding shall be suitably sealed to prevent the ingress of water. The roof shall be laid to falls appropriate to the adopted membrane or cladding and shall include sufficient provision of guttering and down pipes to adequately discharge rainwater to the underground drainage regime.

7.7.11 As part of the Board's sustainability requirements a strategy for rainwater harvesting should be considered by the Contractor. Where rainwater harvesting is incorporated, full risk analysis shall be carried out and tabled for consideration, all actions shall be taken to mitigate risks to infection control requirements. Rainwater harvesting is likely to be restricted to use in areas of the FM, Energy and Laboratory buildings.

7.7.12 The Contractor shall also ensure that all roofs shall incorporate provisions for cleaning and maintenance. Appropriate provisions shall be incorporated by the Contractor to allow the safe use of ladders, guardrails, walkways, access solutions and fall protection solutions in line with all Health and Safety Guidelines to prevent fall from height. This is a fundamental aspect of the roof design and a clear strategy detailing access provision will require to be demonstrated by the Contractor as part of the overall roof design.

7.8 Acoustics

7.8.1 The Contractor shall endeavour to minimise and mask ambient noise sufficiently to preserve patient privacy, confidentiality and maintain a calming atmosphere in public and patient areas.

7.8.2 Audiology booths require to be provided to the necessary acoustic and other standards.

7.8.3 The specific requirements of the Board with regard to Acoustics are contained in Appendix S.

7.9 Finishes

General Finishes

7.9.1 All wall finishes and backgrounds shall be selected and installed in accordance with SHTMs and appropriate British and European Harmonised Standard Specifications, Codes of Practice and ADB Room Data Sheets.

7.9.2 Areas of the Facilities that are subject to potential damage from trolleys, vehicles, beds or other similar traffic shall have adequate protection to comply with as a minimum SHTM 69 and in line with the specific requirements of Section 7.16.

7.9.3 The detail design and finished quality standards of certain specific finishes will be subject to the construction of mock-ups during the design and construction stages. These will form the benchmark for quality control of Site operations.

7.9.4 The use of colour patterning, motifs and texture should be considered by the Contractor in appropriate areas throughout the buildings as an integral part of the wayfinding strategy.

7.9.5 The following criteria require to be incorporated in the Contractor's proposals for all areas:-

a) internal finishes shall be durable and easily cleaned;

b) internal wall surfaces shall be resistant to damage appropriate to the location. Certain areas will necessitate severe duty partitions in accordance with BS 5234 Part 2:1992 (or equivalent), with wall protection. Severe duty partitions will be required in major circulation and heavy industrial areas such as FM;

c) wall finishes must be in accordance with the relevant SHTMs, HTMs HBNs, Design Guides, the Scottish Building Standards, and ADB Room Data Sheets and should also be appropriate to the activity space that they serve, in terms of: imperviousness; hygiene; joints; smoothness; moisture resistance; resistance to cracking; and resistance to abrasion;

d) internal partitions finishes shall also be as required by the nature and use of the accommodation and shall incorporate radiation protection requirements, sound reduction, fire resistance, humidity, biological attack and duty as identified by relevant HBN, SHTMs and appropriate British and European Harmonised Standard Specifications, Codes of Practice and ADB Room Data Sheets and as identified elsewhere in this document;

e) all wall finishes in clinical areas in the Children's Hospital must be durable and able to withstand wet cleaning and the accidental impact of trolleys and heavy mobile equipment. Especially vulnerable points must have additional protection. Smooth paint surfaces are the easiest for cleaning, for example eggshell or vinyl silk emulsion;

f) all wall finishes in clinical areas in the Adult's Hospital should be durable and able to withstand wet cleaning and the accidental impact of trolleys and mobile equipment. Especially vulnerable points should have additional protection. Smooth paint surfaces are the easiest for cleaning – eggshell or vinyl silk emulsion. A matte finish is not acceptable;

g) as the use of ceramic wall tiles is not acceptable in terms of Infection Control, impervious wall cladding is required in shower areas and as splash backs in kitchens, toilets, cleaner rooms etc;

h) The infection control team must be consulted and involved with material specification and detailing;

i) columns should be located, insofar as is reasonably practical, to coincide with corridor walls in order to minimise intrusion into rooms or corridors. Columns or ducts must not protrude into corridors so that they reduce the required minimum width; and

j) external walls and internal partitions shall be provided with movement control joints, appropriate to their material, method of construction and anticipated movement. Where movement joints are required these are to be identified on the layout drawings, these will not be acceptable within rooms or in clinical areas.

7.9.6 Additional specific finishes requirements that must be met by the Contractor's Proposals are identified below;

a) all Radiology, Imaging and Nuclear Medicine x-ray rooms require lead lined partitions and doors as do all Theatres, dental (Children's hospital) and areas of A&E. The requirements for radiation protection shall be based on the designation and nature of the area, size of the room, location of the door in relation to equipment and other risk factors. For the avoidance of doubt it is required that the Contractor must seek advice from and agreement with the Board and the Board's Radiation Protection Adviser in this matter;

b) the requirements for radiofrequency shielding to walls and doors in the Radiology department shall be based on the requirements of the MRI scanner supplied and the siting of the device within the room and wider environment. Walls and door leafs will typically incorporate copper or aluminium sheet materials and special details. For the avoidance of doubt however it is required that the Contractor must seek advice from and agreement with the Board and the Board's Radiation Protection Adviser in this matter, however full floor to ceiling protection should be included in all patient treatment areas (as well as full protection to all doors leading to or from treatment areas) in Radiology, Imaging and Nuclear Medicine x-ray rooms as well as all Theatres, dental (Children's hospital) and areas of A&E;

c) all Theatres throughout the facility should have no reflective surfaces or bright door handles as laser surgery may be undertaken;

d) where interventional procedures are considered, or will be undertaken in any room within the Radiology Department, the room finishes should conform to operating theatre standards. Ceilings should be continuous and impermeable. The provision of specialist paint finishes for ceilings and walls is expected and will be identified on ADB Room Data Sheets;

e) in all cases in the Radiology Department, overlapped sealed joints should be used over architraves and skirtings. Floors should be finished with non-electrostatic vinyl sheeting in order to avoid electrostatic discharges that may affect the function of the MRI and associated equipment;

f) wall and ceiling finishes in operating theatres should be impervious, durable and able to withstand wet cleaning and the accidental impact of trolleys and heavy mobile equipment. Especially vulnerable points should have additional protection. Protection measures should be considered at the initial design stage to prevent the need for regular maintenance which

would require the unit to be closed for long periods. The provision of specialist paint finishes for ceilings and walls is expected;

g) in the mortuary the floor of the body handling and post mortem area must be very hardwearing, non-slip, and impervious to water and disinfectant. The floor should be self-draining towards gullies to allow for drainage after cleansing. Walls should be capable of withstanding regular washing or hosing down, and should meet the raised junction with the floor at a waterproof joint. Ceilings should be capable of withstanding frequent washing down; and

h) IPS solutions shall be required in all toilet areas and areas where wet/sink provision is required (e.g. utility rooms). The use of flexible hose connections is prohibited.

Flooring

7.9.7 The Contractor shall ensure all level and inclined flooring shall meet the following minimum slip resistance requirements:

a) "Rz surface micro-roughness of 20 µm*;* and

b) "Slip resistance pendulum value of 36 (when either dry or contaminated)

7.9.8 The choice of flooring for areas, which may foreseeably become wet or contaminated, needs careful consideration. An anti-slip floor may be an effective control in some areas, such as kitchens, bathrooms, WCs and shower rooms. The choice of flooring will be influenced by the likelihood of the floor becoming contaminated and other factors such as the use of, and levels of, pedestrian traffic in the area. Effective cleaning will be important in maintaining the performance of anti-slip floors, however, it is important to establish with suppliers and cleaning staff that anti-slip flooring can be cleaned to appropriate hygiene standards. In certain areas such as operating theatres, where hygiene is paramount, this is especially important.

7.9.9 The flooring is just one, albeit important element, in the slip potential model and in areas where contamination occurs only occasionally, it may be more appropriate to control the risk through enhanced cleaning and management regimes. Therefore the Contractor requires to comply with the following;

a) the Contractor will require to demonstrate that a Risk assessment has been carried out in accordance with SHTM guidance. This assessment will require to be conducted in conjunction with the Board since as noted above, cleaning and management issues are factors in the assessment;

b) the Contractor shall, in order to complete a thorough risk assessment, procure test results in the "installed" condition which are independently verified by the Health and Safety Laboratory, Buxton, Derbyshire or approved equivalent. The method of testing shall be performed using a pendulum-coefficient of friction instrument with "Four-S" rubber, in accordance with approved HSE test methodology. For the avoidance of doubt, the obligation to follow the pendulum-coefficient of friction methodology is a specific obligation and is derived from the HSE, which only recognises this type of test;

c) the Contractor shall also ensure adoption of similarly robust test methodology for other areas including stair treads and nosings;

d) the Contractor shall ensure that all entrances to the Facilities incorporate appropriate floor matting designed to remove contaminants including water, dirt and leaves from footwear, trolley wheels etc. Barrier matting is most effectively deployed in conjunction with other controls including effective or enclosed canopies and heating, in particular underfloor heating and ventilation or a water evaporation system such as a hot air curtain; and

e) the Contractor shall be identify a strategy proposal at each entrance for agreement by the Board. The matting must extend a minimum distance of 6 metres along the route of travel within the building in line with NHS Scotland Safety Action Notice SAN (SC)05/08. For the avoidance of doubt the Contractor shall comply with all of the recommendations provided in SHS Safety Action Notice SAN (SC)05/08;

7.9.10 The following criteria requires to be incorporated in the Contractor's proposals:-

a) floor finishes must be in accordance with the relevant SHTMs, HTMs, HBNs, Design Guides, and the Scottish Building Standards, and should be appropriate to the activity space they serve in terms of imperviousness; hygiene; joints; smoothness; anti-static; slip resistance; absorption of liquids; radius of ignition. Areas with special requirements such as Operating Theatres and ancillary accommodation require particular consideration;

b) care must be taken in the selection of the appropriate soft floor coverings, for the avoidance of doubt carpeting or soft flooring will not be acceptable in any clinical areas;

c) in all areas the floor material should be coved to form the skirting (minimum of 100mm) to avoid angles and corners where microbial colonisation can occur. All coving must have a proprietary cap strip to the upstand. This detail will allow easy cleaning of the floor finish. In areas where frequent wet cleaning methods are employed, the flooring material should be unaffected by germicidal cleaning solutions, the skirting material used should be integral with, and have properties similar to, the floor finish;

d) vinyl, linoleum or rubber are examples of slip-resistant flooring and should have welded joints. The flooring should be at least 2.5mm thick;

e) all joints between sheet floor finishes and between cove skirtings are to be hot seam welded with care taken particularly at doorways (all welded joints and set in coves, no open joints or sit on cove);

f) loose laid barrier matting is not permitted;

g) visually contrasting texture flooring surfaces should be utilised, wherever appropriate, as an integral part of the way-finding strategy;

h) zero profiles are required at external access points, including access routes to any garden/courtyard areas;

i) smooth vinyl/linoleum coverings shall not be permitted in areas susceptible to wetting and where it is not reasonably practicable to keep them dry such as all WC's , En-suites, Clean/Dirty Utility Rooms, Cleaners Rooms, Assisted Bathrooms , kitchens etc;

j) early cognisance should be taken in the positioning of construction joints in flooring bases to avoid seams in floor finishes in the centre of rooms or circulation areas, joints in these areas will not be acceptable;

k) continuous flooring to be provided as far as is reasonably practicable, with no patching and utilising welded joints and set-in coves;

l) where movement joints are required these are to be identified on the layout drawings and will not be acceptable within rooms or in clinical areas. Movement joints must by flush with the surrounding floor finish;

m) the continuity and integrity of surfaces is important in all areas and particularly in wet and more clinically sensitive locations. Surfaces should be easily cleaned and finished to avoid potential dirt trapping points;

n) in wet areas such as shower rooms with level access floors it is important to avoid tripping hazards such as floor gulley surrounds and lippings to contain water;

o) floor gulleys, gratings and associated finishes should be integrated within the overall floor build up in accordance with relevant manufacturer's recommendations and to achieve tight and continuous sealing to minimise potential for dirt traps;

p) vinyl, linoleum or rubber flooring is tolerant of small movements in the structural floor. The floor screed therefore should be perfectly smooth, crack-free and stable. Adhesives should be powerful enough to resist the formation of "waves" in the floor finish that can result when heavy equipment is moved;

q) sufficient time should be allowed for the adhesive to set prior to use. Thresholds at doorways between adjacent rooms require particular attention because they are points of stress in the floor finish;

r) in theatres with laminar flow ventilation, the floor area enclosed by the hood should be marked with lines or a contrasting coloured area of flooring;

s) in the mortuary area it is important that the floor covering is chosen can be effectively cleaned, maintained and, where necessary, repaired. Vinyl anti-slip floor is often difficult to keep clean (due to grit type surface) and its iron-based particles produce stains, particularly visible on light-coloured flooring. A slip resistant resin flooring will require to be provided;

t) sprung flooring is required in gym and other relevant areas; and

u) waterproof finishes are required in bunding to theatre plant rooms, energy centre plant rooms and other plant areas where resilience is required to prevent water damage to areas below.

7.10 Interior Design

7.10.1 The interior environment is fundamentally important in achieving a non-institutional and therapeutic environment. The Contractor should focus on creating the highest quality spatial environments, which respond to the Boards ethos and operational needs. The interior design should be developed in conjunction with the master plan and architectural solution, producing a fully coordinated and complimentary scheme.

7.10.2 The aim should be to create progressive environments which respond sympathetically to their setting, whilst creating the opportunity to develop contemporary methods of working practices, including the development of large scale dynamic public spaces. The design should respond to client and user needs, whilst emphasising quality of materials, light and space.

7.10.3 The Contractor should seek to exploit the sensory elements of design to provide both information and stimulus. It is a physiological fact that the majority of information that we receive is visual. For sighted people, promoting the sensory aspects of design adds depth and meaning to the environment whereas for visually impaired people whose ability to access significant amounts of information is substantially limited, this design approach is fundamental to understanding the environment and operating independently within it. Because most visually impaired people have some sight, the use of colour to create contrast between critical surfaces and key design features is perhaps the most powerful way of accurately describing the immediate environment.

7.10.4 The use of tactile information should also be clearly developed in the Contractors approach, to all lift signage and door signage. Audible information, including the range of sounds created by contact with different surfaces can be extremely useful and the senses of both sound and touch affect the aesthetic experience of the environment.

7.10.5 The Contractor should demonstrate colour differentiation in surfaces. Visually impaired people are generally less confident at differentiating colours that fully sighted people, but if the colour difference is above a certain threshold value their confidence improves significantly.

7.10.6 The Contractor should indicate an understanding of the principle that the nature of the light source can significantly affect the way we perceive colour contrasts that are applied to the critical surfaces of an interior. Ceilings, walls, doors and floors are all critical surfaces that should be sufficiently differentiated from each other. Navigation through a building is much easier if these large areas re differentiated sufficiently by colour or material.

7.10.7 The Works shall contain a mixture of public, semi-public, and restricted areas which should be designed and articulated to create a hierarchy of spaces, clearly identified and linked.

7.10.8 In addition to the general and special considerations consistent with good Healthcare design, designers and planners will need to recognise:

a) the need to combine the individual specialist requirements for the care of patients with an environment that is a good for staff and welcoming to visitors;

b) The Board's requirement for the Works to meet high standards of quality, efficiency, and cleanliness;

c) the requirements of the staff for an attractive and pleasant environment to work in; and

d) The Board's requirements to ensure designs recognise environmental and ecological issues;

e) For reasons of infection control soft furnishings must be covered in an impervious material within all clinical and associated areas;

f) The interior design represents a challenging opportunity to provide an interior environment appropriate for a friendly and important public building of this type; and

g) To develop this to an agreed solution it is anticipated that extensive consultation will take place with user groups to ensure that the final outcome is projected to be responsive to the specific requirements of each element of the building;

7.10.9 It is important that the interior environment should be welcoming, comfortable, and enjoyable for patients, thereby limiting the institutional atmosphere typical of many healthcare Facilities. Users should be provided with external views and views to landscaped courtyards, corridors with break out spaces providing glimpses out of the building should also be incorporated to give users orientation.

7.10.10 The scale and diversity of patient facilities to be provided means that it will be extremely important to create individual identities to key areas within the overall building design. This will not only help patients identify and orientate themselves within the facility but will also help foster a sense of ownership among staff and a community spirit within individual elements of the building. A distinct identity should be immediately apparent in the Children's Hospital which will require through the use of colour, shape and motifs to provide interest and distraction for patients, parents and visitors alike. This will require to be reflected in all aspects of the design including flooring, wall finish, doors and ceilings. The importance of play for children, and the unique role of the hospital play specialist are described in 'Friendly healthcare environments for children and young people' (NHS Estates, 2003, pp 37–38).

7.10.11 Play specialists should be included when designing the New Children's Hospital as spaces for play are an essential requirement in all patient areas and present a unique opportunity for designers to provide creative and stimulating environments for young patients. This and the use of varied colours, murals, cartoons, varied flooring and the like are of extreme importance in the design of the children's areas and will be an important aspect for bid return and consideration.

7.10.12 The use of colour will help to differentiate the separate functions which share a common structure, and the use of symbols, graphic devices, furnishings, fabrics and accessories when thoughtfully co-ordinated will provide comfortable, yet clearly identifiable, internal environments for patients and staff alike. Any approach to this area of design must be developed carefully within the exacting requirements of procurement and to ensure an easily maintained solution.

7.10.13 It is possible that the Board shall invite external patient support groups and family groups to assist in interior design solutions and activities. The Contractor shall require being aware of such, and engaging with such groups during design development and construction. Such groups shall have an ongoing role within the Works and shall be desirous of incorporating exhibitions and artwork/contributions in the Works. The Contractor shall require supporting such an interface and allowing works to be displayed on wall finishes and the like. The Contractor's Proposals shall reflect such interfacing and engagement.

7.10.14 The Contractor shall develop an interior design strategy to cover all areas of the Works. The interior design proposals shall promote the ideals of the Identikit guidelines.

7.10.15 Proposals shall be presented by the Contractor in room-by-room schedules with samples of finishes, colours, lighting fittings, materials as appropriate, and signage, supplemented by colour sketches or coloured computer images for agreement with the Board, in time to allow for consultation with the users, and for incorporating feedback into the final scheme.

7.10.16 It is expected that the Contractor will provide Interior 3D perspectives and an Interior Colour Strategy Report detailing the following – this is not an exhaustive list;

a) Internal Views of Atriums, entrances and key high profile public areas;

b) Views of Hospital street/Mall including retail area;

c) View of receptions and waiting areas;

d) Ward areas and bedrooms; and

e) Theatres.

7.10.17 The above information should indicate the following information;

a) Architectural vision – space, height, form, composition, scale, character and use of materials;

b) Finish type, colour;

c) Overall colour strategy;

d) Incorporation of Art; and

e) Wayfinding Strategy including images

7.10.18 Where the Contractor includes internal planting displays, associated irrigation and atmospheric controls shall be provided. The Contractor shall ensure that the building design and services allows for an appropriate level of light to ensure the growth and survival or any interior planting within their design.

7.11 Architectural Hardware

Ironmongery.

7.11.1 The following criteria require to be incorporated in Contractor's proposals:-

a) the locking system shall be fully suited across the Works and shall interface with swipe card / other entry systems where provided. Particular requirements with respect to electronic door access / security requirements are contained in Section 8.3.14;

b) ironmongery, fixtures and fittings in the Children's DCPF shall be anti-ligature and anti-barricade;

c) all fixings to ironmongery, fixtures and fittings (in patient areas) must be either securely concealed or be of a tamper-proof form (e.g. non-return screws);

d) where indicated in the ADB Room Data Sheets mirrors to be shatterproof glass, with concealed fixings;

e) all joints between flush fitting components and adjoining surfaces to be as tight as practicable; and

f) all fire fighting equipment to be located within secure lockable containers housed in the wall construction, and operated by the same key throughout the development (all fire fighting equipment to be supplied by the Contractor);

g) in the interest of children's safety door handles to the kitchens should be located at a high level to prevent unauthorised access;

h) the Contractor shall provide ironmongery which shall compliment the overall quality of the interior design concept;

i) the Contractor shall ensure ironmongery is of robust construction suitable for its specific purpose and usage characteristics and in accordance with the ADB Room Data Sheets. For ease of use by elderly or disabled persons the Contractor shall ensure handles are colour contrasted with the door background colour and of easy grip design; and

j) samples of all the ironmongery products shall be prepared in accordance with section 5.9. Details of lock suiting will be submitted by the Contractor to the Board to allow adequate time for discussion and amendment if necessary before the fittings are required for installation in the buildings.

Blinds & Curtains

7.11.2 The following criteria will require to be incorporated in the Contractor's proposals;-

a) the Contractor shall provide all fixings for blinds and curtains including integral blinds;

b) all blinds, curtains and associated fixings shall be Class 0 rated;

c) the Contractor shall ensure that materials for blinds and curtains (including any cubicle curtains) shall also comply with the requirements of the Board's Control of Infection Officer for cleaning, washing and maintenance, and comply with SHFN 30 and SHTM 87, and specific Safety Action Notes. For reasons of infection control curtains must be able to withstand washing processes at disinfection temperatures;

d) the Contractor shall provide integral blinds to windows, curtain walling and internal screens;

e) The locations and fixings for both blinds and curtain tracks and cubicle curtains shall be co-ordinated by the Contractor with the window and internal window sill design from the outset of the building design development and the fixings shall be designed by the Contractor to take the proposed maximum loadings possible for the tracks concerned and shall be non-weight bearing from an anti-ligature perspective in the Children's DCFP. For the avoidance of doubt all curtains, blinds, accessories including fixings are to be provided by the Contractor;

f) Curtain tracks shall be designed by the Contractor to overlap the window openings so that they do not allow light to pass into the room when drawn. Controls for blinds and curtains shall be co-ordinated by the Contractor with the window design and its opening gear, including any operating handles, levers or stays that may be required and shall be located conveniently for staff or patients to operate as appropriate;

g) The Contractor shall fix bed and cubicle curtain tracks at the height recommended in the relevant guidance and The Contractor shall ensure bed curtain tracks are co-ordinated with other service outlets and the window positions, where applicable. An adequate ventilation gap must be provided by the Contractor at the curtain head; and

h) All Single bedrooms should have glass partitions for observation purposes, complete with integral venetian blinds for privacy.

7.12 Staircases, Ramps, Balustrades, Walkways, Escalators & Lifts

Staircases and Ramps

7.12.1 Where staircases, ramps, balustrades, walkways and lifts are provided in addition to those required to satisfy means of escape criteria, these shall be designed to relate to the anticipated capacity of use and clearly designated for public, staff or service circulation.

7.12.2 For the avoidance of doubt, the Contractor requires to ensure that for all stairs the requirements of HBN 00-04 and Technical Standards are achieved. This includes the following key criteria;

a) the maximum number of risers between landings for a flight of internal stairs should be 12-14;

b) risers and goings uniform, riser height should be 150-170mm, going minimum of 280mm, 300mm preferred;

c) for steps not adjacent to a wall, a barrier, with a minimum height of 100mm above the level of the treads should be provided for safety reasons. This requirement should be developed in conjunction with the design of the stair / balustrade to viewed as a cohesive whole;

d) open areas on the underside of stairs should be avoided to eliminate the possibility of anyone walking into the overhang created;

e) to indicate that there are descending steps ahead, a hazard-warning zone should be provided on each landing. The zone should use a floor finish that contrasts visually with the general floor finish, but has the same slip resistance. The warning zone should be at least 400 mm from the nosing and a minimum of 800 mm deep and 1200 mm wide;

f) capable of achieving mattress evacuation; and

g) where ramps are provided in addition to those required to satisfy means of escape criteria these shall be suitable for independent and / or assisted wheelchair users, trolleys and ambulant disabled people. Ramps, however will not be considered appropriate for any significant changes in level.

7.12.3 The atrium will contain link bridges, escalators, lifts and stairs providing all vertical and horizontal communication links across the void space providing the necessary connections between departments. A high level of finish will be expected for all stairs and balustrades, any handrail, barrier or guarding to stairs or corridor links should be glazed to allow views for children and those in wheelchairs.

Lifts and Escalators

7.12.4 For the avoidance of doubt, the Contractor requires to ensure that for all lifts the requirements of HBN 00-04 and HTM 2024 are achieved. This includes the following key criteria;

7.12.5 The number, type, size and speed of lifts should be determined from a traffic analysis specific to the proposed facility, and should allow adequate flexibility of the lift solution to accommodate future changes. However as a guide the following dimensional requirements will be achieved;

Lift Type	Minimum Sizes
All lifts	1100mm (wide) x 1400mm (deep)
Small General Traffic	1600mm (wide) x 1400mm (deep)
Large General Traffic	2000mm (wide) x 1400mm (deep)
Patient Trolley/Stretcher Movement	1400mm (wide) x 2400mm (deep)
Bed Movement Lifts	1800mm (wide) x 2700mm (deep)

7.12.6 Handrails should be provided on both side and rear walls of lift cars to be used for general traffic, this includes where stretcher/trolley lifts are to be used for general traffic. The minimum dimensions noted in the table above will require to be provided clear of handrails.

7.12.7 In order to segregate traffic, for operational and infection control reasons, it is not anticipated that lifts for bed movement will be used for general traffic.

7.12.8 Dedicated vertical lift facilities will be required as part of the installation of the overall Automated Material Transfer System as outlined in Appendix M. A clear strategy for the incorporation of these systems will require to be provided by the Contractor in consultation with the Board. The use of public and personnel lifts by automated systems is not acceptable.

7.12.9 Lift doors for general traffic should provide a clear opening width of 1100mm and height of 2000mm. Lift doors for movement of patient trolleys/stretchers and beds should provide a minimum clear opening width of 1370mm and a height of 2100mm.

7.12.10 Additionally the following criteria should be met:

a) the lifts within the atrium should be fully glazed to all sides providing views over the atrium space for the purposes of orientation;

b) a protected lobby should be provided where a lift does not open off a hospital street;

c) wall-wash lighting, uplighting or perimeter lighting should be utilised in the lift car rather than direct downlighting to avoid dazzling patients being transported on beds, trolleys or stretchers;

d) a visually contrasting floor surface measuring at least 1500 x 1500mm should be provided outside the lift door area;

e) lifts, where provided, are to be suitable for disabled wheelchair persons and visually impaired, with tactile controls and audible warnings; and

f) the use of escalators within the atrium space to access the upper level of Outpatients department is considered as desirable. All aspects of the Escalator design should be designed to the requirements of BS EN 115-1:2008.

7.13 **Landscape Design**

General Design Approach & Aspiration

7.13.1 In accordance with the principles of 'Designing Places – A Policy Statement for Scotland' (Scottish Executive 2001) the site layout and landscape design shall create external spaces that are distinctive, safe and pleasant, easy to get to and move around, welcoming, adaptable and resource efficient.

Existing Site

7.13.2 The existing hospital campus generally presents a poor quality environment for visitors, patients and staff.

7.13.3 It is dominated by large expanses of blacktop roadway and vehicles, disparate and scattered buildings, open yards, service bays and large flat areas of featureless and exposed open space. The site does include a number of mature trees which are subject to a Tree Preservation Order (TPO). The majority of these are to the eastern side of the campus, visible from the approach to the Clyde Tunnel, away from the principal area of the proposed new hospital development. The few mature trees remaining on the proposed site of the new hospital will need to be removed to facilitate the required building footprint and infrastructure.

Landscape Masterplan

7.13.4 The masterplan prepared for the development of the Southern General Hospital seeks to address many of the negative landscape issues currently affecting the campus and to provide the framework for the development of a high quality, coherent, well organised and welcoming external environment to enhance the experience of staff and patients alike. This includes the provision of a major new access from Govan Road together with a significant rationalisation of internal roads and paths to provide clear and direct approaches to the proposed new hospital and improved links throughout the campus with its hinterland. The proposed layout attempts to integrate private vehicular access, public transport and the new Fastlink route with pedestrian and cycle circulation to provide a vibrant but coherent new public realm within the heart of the Campus. In particular, the masterplan sets out the framework for the creation of high quality public realm and street frontages to the entrances associated with the proposed hospital within a strong landscape framework of formal avenue and informal tree planting. This is essential to create both a high quality setting and to provide the human scale necessary to offset any negative influence from the visual dominance of the size and physical mass of the building envisaged.

7.13.5 In particular the masterplan creates a large, central open space within the heart of the campus to be developed as a park for the use of patients, visitors and staff alike. This is intended as a multi functional space providing for social interaction and relaxation as well as opportunities for informal exercise with marked walking routes and a trim trail. The Contractor is to also to include works of art and sculptures in this area.

Hard Landscape - General

7.13.6 Areas of landscape and public realm shall demonstrate a high quality of detailed design, utilising high hard quality sustainable and durable materials to achieve design life noted in Section 5.3 The choice of materials shall reflect both the quality and importance of the proposed new building as well as the aspirations in the masterplan to create, a people friendly external environment. The contractor's attention is drawn to the need to ensure long term sustainability and the requirement to achieve the BREEAM Healthcare "excellent" rating. In this regard due reference shall be paid to the BRE "Green Guide to Specification" to maximise the use of materials and specifications achieving an A rating or better as far as is practicable with regard to other technical and specification requirements in terms of adoption and compliance with standards and legislation noted elsewhere.

7.13.7 The masterplan envisages a hierarchy of spaces and circulation and consequently surface treatments and materials shall vary accordingly.

7.13.8 The minimum standard for a pedestrian footpath within the site shall be asphalt with pre-cast concrete flat-top pin kerb edges to GCC Roads Department adoptable standards as identified in Section 9.0. At the top end of the hierarchy in the spaces associated with the frontage of the building and the main entrances, high quality modular or unit paving shall be used that shall feature clean, crisp detailing and edging together with striking and vibrant paving patterns and designs commensurate with the very best of 21st Century urban design.

7.13.9 The contractor will be expected to demonstrate a clear gradation of hierarchy within their design and choice of materials, between these two in terms of intermediate public spaces and major footpath routes around the site and within the new public park.

7.13.10 Design of all hard landscape in terms of accessibility, surfaces and gradients shall conform to or exceed BS8300 as well as to maximise long-term sustainability and BREEAM Healthcare scores.

7.13.11 Hard landscape materials, specification and laying shall conform to the following minimum standards, where relevant.

a) BS 7533 (all relevant sections pertaining to the materials chosen);

b) BS EN 1342 (Setts of Natural Stone – Requirements and Test Methods);

c) BS EN 1341 (Natural Stone – Requirements and Test Methods); and

d) BS EN 1339 (Concrete flags – Requirements and Test Methods).

7.13.12 Maintenance of hard landscape areas shall be in accordance with BS 7370 – 2. The contractor shall develop and submit a fully detailed maintenance schedule for all areas of hard landscape and associated street furniture and play equipment.

7.13.13 New access roads and vehicular circulation routes shall be designed and constructed in accordance with current highway design standards and to Glasgow City Council Roads Department, adoptable standards to the extent identified in Section 9.0. This to include all road markings to all roads, cyclepaths and car parks (incl car parking bays/spaces and drop-off points, ambulance areas and the like) and all road signage. Raised kerbs to bus drop-off/stops to be included.

7.13.14 The detailed design of vehicular roads shall incorporate appropriate traffic calming and speed control measures to reduce vehicle speeds and contribute to a pedestrian friendly environment. Consideration requires to be given to the transport of patients (particularly spinal patients) in the design of traffic calming methods. Along the hospital frontage at drop-off points and where large numbers of patients and visitors will be expected to congregate and enter the building, a change in surface material for the carriageway shall be utilised that provides the appropriate visual signals for both pedestrians and vehicle users alike and is commensurate with the high quality paving design and external environment required for the building frontages.

7.13.15 Pedestrian crossing points shall be provided at frequent intervals as indicated on the masterplan. These shall be formed at footpath rather than at road level in order to both achieve BREEAM points as well as to provide a traffic calming measure.

7.13.16 Roundabouts and important junctions shall be landscaped distinctively to provide a clear visual orientation point within the site and to reduce the apparent expanse of road and hard standing in these areas. Where possible public art or sculpture shall be incorporated in the roundabout designs to reinforce their distinctiveness.

Cycle Access

7.13.17 The design shall include improvements and modifications to the existing cycle access points, as well as creating new cycle access at appropriate locations to the site as indicated on the masterplan. New or modified cycle access shall be off-road and shared with pedestrian traffic as far as possible. In this regard, cycle paths shall be a minimum of 3 metres wide in order to comply with current guidance from Sustrans and to gain BREEAM Healthcare points. Where cycle lanes are provided either as separate routes or on roadways, the minimum dimensions and layout shall be in accordance with the above noted guidance and to the minimum required in BREEAM Healthcare.

Cycle Shelters

7.13.18 Cycle shelters shall be provided in the numbers required to achieve BREEAM Healthcare points. Cycle shelters shall provide secure and sheltered space for the parking of bicycles and shall be in a secure and visible location. Cycle storage areas shall be located adjacent to or as near as possible to building entrances to ensure direct safe and easy access/egress. Cycle shelter areas and their approach paths shall be lit to adoptable street lighting standards and shall be capable of being overseen by CCTV both day and night. Consideration of cycle stacking systems should be pursued by bidders and proposed to the Board.

Courtyards

7.13.19 The design of the new hospital building envisages the creation of a number of external courtyards for use by staff, visitors and patients. The courtyards shall be designed to provide a variety of purposes including opportunities for meeting and social interaction as well as quiet reflection and privacy. Where appropriate, courtyards and external spaces within the building shall have a practical and or therapeutic purpose, for example the incorporation of steps and ramps to assist with physiotherapy, as well as simply providing a view of plants, green space and natural light within the interior of the building.

7.13.20 In order to comply with BS8300 and the principle of free access, the finished paving level at building entrances shall be the same as the adjacent internal floor level. The building design in this location shall utilise a raised, DPC detail in order to ensure finished levels within the courtyards are visually unobtrusive. A solution which creates a series of humps or rises and falls between doorways opening out into courtyard areas will not be acceptable.

7.13.21 The internal layout design of the courtyard shall allow for any requirements for maintenance access to the building edges.

7.13.22 The courtyard paving shall be formed from high quality modular and unit paving with detailing commensurate with scale of courtyard in question. Path widths and circulation spaces shall be in accordance with minimum standards set out in BS8300 and BREEAM Healthcare, whichever is the greater. Courtyards shall include high quality planting design that incorporates the opportunity to introduce a variety of domestic/garden scale plant material including a mixture of evergreen, deciduous and herbaceous material together with bulb planting. The extent and type of plant material shall reflect the nature and function of the courtyard in question. Courtyards shall include a variety of seating opportunities to ensure that there is provision for both quiet and private contemplation and social interaction for group discussion. All courtyards shall be provided with litter bins and low level external lighting. Seating shall be in a variety of forms but as a minimum at least half the seating provided shall include backrests and arm supports. The design of the courtyards shall not restrict seating opportunities to purpose made bench or seat provision only and seating opportunities and areas of social interaction shall be incorporated into the overall courtyard design, utilising a variety of means including low walls and edgings at seat height.

7.13.23 The courtyard design shall include wherever possible the provision of tree planting in order to provide some height and to offset the potentially oppressive effect of the courtyards being surrounded by tall walls on four sides. The courtyard designs shall also incorporate some undulations and changes in level and provide visual relief from the prospect of a flat plain. In detail, courtyard designs will be expected to provide both open and intimate enclosed spaces within their overall layout.

7.13.24 The detailed design and specification of the courtyards shall provide a variety of visually distinct spaces in order that they can contribute to the wayfinding strategy and orientation round the building for patients, visitors and staff.

7.13.25 Notwithstanding the above requirements, courtyard design shall provide low maintenance external space.

Children's Play Areas and Play Equipment

7.13.26 The masterplan envisages the creation of a children's play area adjacent to the main entrance to the Children's Hospital. The purpose of this provision is both to provide a relaxed and welcoming child friendly entrance whilst at the same time actively making safe provision for children's play, whether children are outpatients or visitors to the hospital.

7.13.27 All children's play equipment shall conform to the relevant parts of BS EN 1176 and be expected to provide a design life with regular maintenance of 25 years. The contractor shall offer a range of equipment that provides the best manufacturer's warranty available and for which the supply of spare parts in guaranteed for the anticipated design life of the equipment.

7.13.28 All play equipment shall be installed with an appropriate safety impact absorbing surface suitable for the equipment in question. All safety surfacing shall be of a 'wet pour' or other continuous type surfacing system rather than tiles or loose-fill materials such as bark or sand. The final choice shall be influenced by the materials' longevity and lifecycle costs.

7.13.29 Play areas shall include a mix of equipment suitable for a broad range of ages and abilities appropriate to the context of the Children's Hospital (from toddlers through to young teenagers) and include a degree of open or free space. Seating opportunities for casual supervision by parents and carers shall be maximised and include a sufficient quantity of litter bins. Seating may be varied but must include at least 50% with back support. Provision of equipment for young children and toddlers shall include coloured boundary fencing with non-slam self closing gates.

7.13.30 The provision of an area of the play zone to be under the neo-natal link, thereby providing for an outdoor visit or play space usable in wet or inclement weather, is to be developed by the Contractor and included in the design.

Street Furniture - General

7.13.31 Street furniture shall be robust, practical and fit for purpose whilst at the same time being of a contemporary high quality design. The specification of different materials shall pay regard to both cost and long term sustainability. Any timber utilised shall be from a sustainable source and be FSC Certified Timber, where it is not of the type that is inheritantly long lasting in external or wet conditions shall be preserved, treated with a minimum 15 year lifetime guarantee or better. Street furniture items shall form a key component of the external landscape design, especially in the public realm, at entrance areas surrounding the building and within the parkland. The contractor shall provide a well considered and coherent design that presents a suite of complimentary elements that are integrated into the overall public realm and landscape design. All mild steel components and fittings shall be galvanised to and polyester powder coated or otherwise factory painted and supplied with a minimum warranty of 15 years or better prior to any retouching or painting being required.

7.13.32 All street/external furniture requires to be securely fixed to the ground.

7.13.33 Bus stops and shelters require to be installed as necessary to comply with the relevant Planning and Travel Plan requirements;

7.13.34 Covered architectural pedestrian walkways are to be provided between the Fastlink drop off area and the adjacent entrance to the new hospital as illustrated on the masterplan drawings;

Litter Bins

7.13.35 All litter bins shall be of the type which includes a front facing door or hatch that allows the internal bin or receptacle to be removed and emptied easily

Seating

7.13.36 It is anticipated that a wide variety of seating and seating opportunities shall be incorporated into the final design. The majority of this will be purpose made seating or seat items however the contractor is also expected to incorporate into the design opportunities for seating within the landscape in the form of low walls, steps and grass mounds.

7.13.37 Where formal seating is provided at least 50% of this shall include backrests and armrests. Seating shall be designed and located as a key element of the overall landscape design. Seating and benches placed seemingly at random will not be acceptable. The contractor shall ensure that adequate seating and rest points are provided at regular intervals along pathways and walking routes.

7.13.38 All seating must be securely fixed to the ground.

7.14 Soft Landscaping Requirements

General Design Approach

7.14.1 In accordance with the principles of 'Designing Places – A Policy Statement for Scotland' (Scottish Executive 2001) the planting and soft landscape design shall contribute towards the creation of external spaces that are distinctive, safe and pleasant, easy to get to and move around, welcoming, adaptable and resource efficient.

7.14.2 The landscape of the existing campus is largely flat, featureless and unwelcoming. In accordance with the masterplan the new planting design shall include substantial tree planting to:

a) provide immediate and long term landscape structure and impact within the campus grounds;

b) create a distinctive and appropriate landscape setting for the new hospital complex;

c) mitigate against the visual impact of the buildings, roads, car parking and hardstanding across the site and provide human scale; and

d) mark progression along key routes and lend identity to the different spaces that will be created.

It is required that semi mature and larger nursery stock trees are utilised along principal avenues, paths and thoroughfares to achieve this requirement.

7.14.3 The detail planting design and specification shall provide an appropriate mixture of seasonal variety, height and colour for all year round interest. It shall provide both immediate impact and medium to long term growth and be capable of delivering a high quality landscape that will develop and mature over the medium to long term. The detail design layout and choice of plant material shall be appropriate to the immediate context, such as public realm, pathways and circulation zones, private/quiet space, spaces for adults, children, visitors and patients, whilst paying due regard to environmental and climate factors. The planting design shall help to provide shelter and shade as well as assisting users to orientate and locate themselves. The planting and landscape design should be developed to reinforce wayfinding strategies through the creation of readily identifiable and distinguishable spaces.

Retention & Protection of Existing Trees

7.14.4 As far as possible, the campus layout shall maximise the retention of existing mature trees on site and incorporate them into the overall layout and landscape design. In accordance with planning conditions and best practice, all trees to be retained in the medium to long term shall be protected in accordance with BS 5837:2005, the exact method to be agreed with the Planning Authority.

Felling of Existing Trees & Vegetation Clearance

7.14.5 In accordance with the Wildlife & Countryside Act 1981, any tree felling and shrub clearance shall be carried out outside the bird breeding season (March to August). Contractors shall take due cognisance of this requirement in any work programming. Where this is not possible a qualified ecologist shall be appointed to examine all potential breeding sites before any clearance takes

place. If occupied nests are found, clearance and felling works shall cease until the nest is no longer in use. The contractor shall formally confirm to the Planning Authority in writing if clearance is in order following the ecologist's inspection. A qualified Ecologist shall be as defined in BREEAM Healthcare.

7.14.6 Where any tree work is undertaken this shall conform to BS 3998 "Recommendations of Tree Works and current HSE/AFAG safety leaflets

CAA Restrictions

7.14.7 The site lies approximately 3 km from Glasgow Airport, well within it's 13km 'safeguard circle' and therefore detailed consultation with the CAA will be required to develop proposals that minimise any increased risk of birdstrike. The landscape and planting design shall form an integral part of the 'Bird Hazard Management Plan' which is required for submission to the Planning Authority. The Contractor shall comply with the CAA publications CAP 772 – 'Birdstrike Risk Management for Aerodromes' and Advice Note 3 – 'Potential Bird Hazards from Amenity Landscaping and Building Design'. It is likely that adherence to this guidance will impact on the specification of plant material and contractors are therefore required to consult early with the CAA to establish their requirements. Approval by the CAA of the detailed landscape proposals will be required to clear the Planning Conditions relating to the detailed landscape design.

Landscape Design and SUDs integration

7.14.8 Landscape design associated with SUDS shall comply with CAA Advice Note No.6 – 'Potential Bird Hazards from SUDS'. Any surface water features associated with a SUDS design for the site shall be fully integrated with the landscape design, as opposed to simply 'landscaped'.

7.14.9 The SUDS solution of the Contractor shall actively consider underground storage tanks which shall consider the use of the water for grey purposes on the site where possible.

Biodiversity

7.14.10 The detailed landscape and planting design shall be developed in accordance with the 'Biodiversity Action Plan' submitted to the Planning Authority as part of the Masterplan.

7.14.11 It is a Planning Requirement that the new landscape framework for the campus will link areas of established green networks within and beyond the site, SUDS proposals and movement networks (roads, footpaths and cycle paths) to habitat retention and creation, minimising the impact of the development on wildlife and vegetation. Contractors will require to reconcile the requirements of the Planning Authority with the restrictions that may be required by the CAA as noted above, together with maintenance regimes on site in the detailed landscape and planting design. Contractors will be required to undertake a detailed habitat assessment using a qualified ecologist to establish the baseline situation at the start of the contract to inform the detailed landscape design development.

BREEAM

7.14.12 The Contractor shall maximise BREEAM Healthcare points available through the landscape and external works as a key element of their designs. In conjunction with 'Biodiversity' above, a qualified ecologist will be required to undertake a habitat survey to establish the baseline situation at the start of the contract to inform the detailed landscape design development with a view to achieving maximum points available and contribute towards the required "excellent" rating.

Topsoil

7.14.13 Should topsoil stripped from the site be retained on site, this requires to be in a dedicated storage area, appropriately stored, protected from contamination, maintained and re-used within the final landscape works as required. The Contractor will be required to undertake a comprehensive soil analysis (BS 3882 Annex E) to determine whether there is any contamination present that would limit or otherwise restrict the use of site stripped topsoil within the final landscape works.

7.14.14 If it is determined that the material be taken off site, either on a temporary or permanent basis, this shall be agreed in writing with the Planning Authority in accordance with condition 9.

7.14.15 The soil analysis shall also determine nutrient deficiencies and the requirements for fertilizer and soil additives required to ensure the successful growth and establishment of the planting specified for the areas to which it is finally spread.

7.14.16 Imported topsoil shall be to BS3882 "multipurpose" grade or as required to suit the final choice of plant material. The use of peat shall not be permitted. All compost shall comply with PAS 100.

Topsoil Storage

7.14.17 Where imported or existing topsoil is to be stored in a single location for no more than 6 months (maximum) the height of storage mounds shall not exceed 2M. Where a period of more than 6 months is required the height of the mounds shall not exceed 1M high. Where existing topsoil is stripped and stored the soil shall be turned every 6-12 months.

7.14.18 All topsoil stored for longer than 6 months shall be re-tested to determine the degree of nutrients, fertilizer and ameliorants required immediately prior to re-spreading in its final location.

7.14.19 Topsoil depths for planting:

a) Shrub planted areas: 400mm minimum depth; and

b) Grass areas: 150 mm minimum depth;

i) General handling and contamination prevention; and

ii) Subsoil/ground preparation for landscape areas.

Plant Material

7.14.20 The specification criteria for plant material in general shall conform to either the National Plant Specification or BS 3936 and other related British Standards. The specification criteria for Semi Mature and Root-Balled Trees shall be to BS 4043.The handling, transportation, storage and establishment of plant material shall be in accordance with the Horticultural Trades Association publication 'Handling and Establishment of Landscape Plants'. Contractors will be responsible for developing a robust and technically competent specification for all the soft landscape and planting works in accordance with the best industry standards and practice.

7.14.21 The choice of plant species and provenance of plant material shall be appropriate to achieve the purpose required by the design and for the location, scale and situation in question. There is no general limitation on the type and range of plant material envisaged with the following exceptions:

a) Thorny or spiny plant material shall be avoided, especially within the body of the site within the ornamental species mixes. This type of material traps litter and debris which is then extremely difficult to clear and consequently encourages the nesting of vermin. Possible exceptions might include the use of Hawthorn or other native hedgerow plants along the site boundaries in association with structure or woodland planting, depending upon the final design layout.

b) Poisonous plants/skin irritants on contact with foliage/stems further definition required.

7.14.22 Planting densities and size at planting shall be appropriate to ensure a careful balance between immediate and short term impact and long term growth.

7.14.23 Tree planting pit/trench size and design shall be appropriate to ensure the long term establishment and future growth of all new trees. This shall include where required the use of drainage, irrigation tubes and root protection barriers adjacent to services. All semi mature trees shall be underground guyed using an approved proprietary product such as the Platipus system (or equivalent). All tree staking shall be double short stakes with cross bar.

7.14.24 All semi mature tree planting shall be provided with a 5 year establishment guarantee from the supplier(s) The defects period and contractors' liability for replacement planting shall extend to the full period of the guarantee, subject to standard industry limitations. The defect period for tree planting in general shall extend to a minimum of two growing seasons following agreed completion of the contract.

7.14.25 Extended establishment guarantees from suppliers shall be required in relation to semi-mature tree planting.

7.14.26 Any seeded areas are to be protected by secure temporary fencing (secure to the ground and securing the seeded areas from access) until such time as the seed takes.

7.14.27 Any grass adjacent to the children's play areas and entrance to the Children's Hospital to be turfed.

Maintenance

7.14.28 The contractor shall develop and submit a fully detailed management plan and maintenance schedule of the completed landscape design for approval. Maintenance shall generally conform to the relevant sections of BS 7370 and be designed to ensure the long term establishment and development of the new landscape and planting design.

7.15 Wayfinding & Signposting

External wayfinding strategy

7.15.1 The movement of people through a hospital site is one of the key factors to the successful scheme. Wayfinding considers the different aspects regarding this and creates a system which responds to the requirements of each separate situation. The Contractor should create a unique identity for the hospital by providing an integrated solution between signage, architecture, interior design, landscape and art. The solution should provide a clear strategy for patients, visitors and staff whilst also assisting people with restricted mobility, impaired vision and language difficulties.

7.15.2 The Contractor should in their wayfinding proposals consider the prominence of architectural and interior landmarks on the site as well as colour coding, imagery, sign types and fonts etc. to create a visually stimulating family of signs as well as providing a system which conforms to current legislation. The Planting and landscape design shall assist with wayfinding and route marking around the site and provide identity to the different spaces within and around the site.

7.15.3 The solution should eliminate doubt and uncertainty in a potentially anxious environment by providing information at the right points as well as architecturally designed areas of interest and comfort. The accessibility of the site will be enhanced by a successful wayfinding system.

7.15.4 It is the Board's intention that Contractor's should incorporate electronic information points utilising touch-screen technology in addition to the manned reception points and stations internal to the building and the PA system. These information points should be located externally at appropriate locations and should present information (in a variety of languages) on the hospital for orientation and wayfinding purposes along with information in relation to the public transport hub which should be adjacent to the main entrance giving real time information on bus/fastlink timetables. The Contractor will be required to provide a clear strategy for the provision of these information points.

7.15.5 The above should be integrated into a clearly defined arts programme, which from the beginning of the project develops a strategy considering the site as a whole.

7.15.6 The following criteria require to be incorporated in the Contractor's external signage proposals;

a) all signage (internal and external) to be provided by the Contractor;

b) the signs will be exposed to the elements and therefore will require to be robust, accident proof, vandal resistant and weather proof;

c) the signs will be mounted generally on grey ppc steel posts fixed to concrete bases, the signs are to be a matt aluminium finish;

d) all light units to signs should be externally located to be easily accessed and maintained;

e) overstuck lettering is not acceptable; and

f) traffic signage to be compliant with Transport Scotland guidance;

As a minimum the Board would expect the following external signage to be incorporated, signage to be a Hospital Campus (i.e. whole existing and new hospital) wide integrated solution:

Location	Function/Type	Identity Requirements
All vehicular, pedestrian, cycle entrances to the site	Facility Identification	All external signage requires to be as NHS Identikit Guidelines and as such feature the following ; • NHS Greater Glasgow & Clyde Identity incorporated. • Generally white background with NHS Scotland dark blue text in Stone Sans type face. • Colour on external signage to be NHS Scotland Dark Blue or Light Blue only. • If required to identify for example entry only for ambulances – this can be reversed to light/dark blue background with white text. • Signage size , height and text size should be appropriate to location and function • The limited incorporation of the caring device is acceptable. • Directional signage should indicate arrows and text ranged according to the direction. • All external signage will require to be clearly illuminated. • Matt Finish to all external signs. • Built up brushed stainless steel lettering or equivalent standard finish to signage will be expected to be incorporated at key areas of public prominence – entrances, receptions, atria, main circulation.
Vehicular routes through site	Building Identification	
Vehicular routes through site	Car Park Location – directional / Availability of Spaces	
Car Park entrances	Identification of Car Park entrances	
Car Park	Identification of disabled designated spaces	
Pedestrian and vehicular routes through site	Building Location - directional	
Building Entrances	Identification of Building entrances	
Building Entrances	Identification of Building	
Building Entrances	Building Directory – indicating key departments	
Vehicular routes through site	Identification of ambulance only / service only routes/entrances and helipad	
All locations	Statutory Signage	As guidance requirements

Internal wayfinding strategy

7.15.7 Design solutions shall present an integrated and comprehensive wayfinding solution that enables patients, visitors and staff to self-navigate the Facilities with ease. The wayfinding solution must comply with the DDA, meeting the needs of people with physical and/or sensory disabilities/impairments, and those with literacy difficulties. It shall add value to the internal environment and could be a component of the comprehensive arts programme.

7.15.8 Way-finding is a critical part of the building functionality, and must guide patients and visitors to their desired destination in the most efficient manner possible. It should be borne in mind that people using health buildings may be easily disorientated due to illness and / or upset; they may be in unfamiliar surroundings; they may have difficulties with sight, hearing, mobility or learning; they may not have English as their first language; or they may need information presented at a lower level because they are in a wheelchair.

7.15.9 An audit of the signage within the Facilities shall be completed with the Board prior to Completion to ensure that the signage is complete, and that no ad hoc signs are required to complete the wayfinding scheme.

7.15.10 The following criteria require to be incorporated in the Contractor's proposals:-

a) all lift and door signage should incorporate the use of braille;

b) all signage and signage fixings must be robust and vandal resistant;

c) colour contrasted or tactile variation flooring clues should be provided to main reception area to guide visually impaired people to reception desk point at 90 degrees from circulation route. Clear orientation markers/signals are required at changes in direction at all entrance routes and main entrance;

d) There is an expectation that the signage will require to incorporate additional colour and/or images in line with the overall wayfinding strategy. The Contractor will require to provide a clear demonstration of this approach, which may for example assign colour on a departmental or level by level basis or to identify and differentiate the Children's Hospital. However any colour strategy developed for signage should be within the standard colour ranges identified (including tints) within NHS Identikit Guidelines. Any adoption of images on signage as part of this strategy will require to be developed in conjunction with the Board; and

e) In order to provide staff, patients and visitors with access to information especially at the key points of entry to the Works it is required that the Contractor shall incorporate electronic information points utilising touch-screen technology in addition to the manned reception points and stations and the PA system. These information points should present information (in a variety of languages) on the hospital for orientation and wayfinding purposes along with information in relation to the public transport hub which should be adjacent to the main entrance giving real time information on bus/fastlink timetables. The Contractor will be required to provide clear proposals for the provision of these information points.

7.15.11 The Contractor is required to comply with the relevant NHS Publications in relation to signage and must include the following provision;

Location	Function/Type	Identity Requirements
Main Entrances	Facility Identification	All internal signage requires to be developed from NHS Identikit Guidelines and as such feature the following ; • NHS Greater Glasgow & Clyde Identity incorporated. • Generally white background with NHS Scotland black text in Stone Sans type face. Other background colours can be considered – within NHS Identikit colour ranges identified. • Signage size, height and text size should be appropriate to location and function. • Directional signage should indicate arrows and text ranged according to the direction. • Matt Finish to all internal signs • Monolith, ceiling fixed or wall mounted signage types are acceptable for internal signage. • Illumination should be incorporated for signage within areas of public prominence – for example main entrances, atria, key receptions etc.
Main Entrances	Building Identification	
Main Entrances	Reception Identification	
Main Entrances	Building Directory – Identifying department locations on a floor by floor basis – featuring building plan.	
Main Entrances	Department Locations - Directional	
Main Entrances	Identification of key facilities – Toilets , Stairs, Lifts etc	
External to Stairwells	Level Directory	
Inside stairwell	Stair Identification	
Lift Car	Level Directory	
Corridors	Departmental Locations - Directional	
Corridors	Identification of Exits - Directional	
Departmental Entrances	Identification of Departmental entrances	
Departmental Entrances	Departmental Directory	
Departmental Entrances	Reception Identification	
Departmental Corridors	Key Locations - Directional	
Departmental Corridors	Room Identifiers (Every Room)	Room signs to feature the following; • Signs should be adjacent to doors at a height of 800–1500 mm and tactile (Braille) so that they can be easily read by touch. • Room name • Room number • Occupant name (should be removeable)
All locations	Statutory Signage	As guidance requirements

7.16 Protection

7.16.1 The Contractor shall be required to demonstrate that their proposal provides the most effective height / location and orientation of protection that shall prevent direct impact with the building fabric.

7.16.2 The Contractor is required to comply with the relevant NHS Publications in relation to protection and must include the following provision;

Location	Protection	Handrail
All main communication routes/main corridors between departments	Heavy Duty ; Mid-height handrail and either durable material on lower part of walls, or lower height crash rail, and with splayed skirtings in main corridors. Corner protection also required.	Handrails required. Handrails should return into recessed doorways and openings, but otherwise be continuous to aid navigation.
Hospital Street / Building Entrances	Severe duty; Mid-height handrail or crash rail, lower height crash rails and splayed skirtings. Corner protection also required.	Handrails required. Handrails should return into recessed doorways and openings, but otherwise be continuous to aid navigation.
Departmental Corridors; All wards	Heavy Duty ; Mid-height handrail and either durable material on lower part of walls, or lower height crash rail, and with splayed skirtings in main corridors. Corner protection also required. Bed locators where required.	Handrails required. Handrails should return into recessed doorways and openings, but otherwise be continuous to aid navigation.
Operating Theatres	Rails may be omitted in favour of overall durable, washable finishes. In practice the greater care shown by the theatre users appears to compensate for the lower level of protection.	None required.
Workshops, storerooms etc	May be constructed of materials which are not necessarily given a decorative finish, or applied protection. These materials include brickwork, blockwork and concrete.	None required.

7.16.3 The Contractor will also be expected to provide, as a minimum the following provision;

a) where handrails and wall protectors are provided a minimum vertical clearance of 50 mm must be maintained between the handrail and wall protector and a minimum horizontal clearance behind the handrail of 75mm;

b) where the wall protector protrudes in front of the handrail, the clear width of the corridor will be to the wall protector; and

c) handrails should be easily visible, that is, contrast visually with the surface to which they are fixed, smooth and free of any abrasive elements, neither too cold nor too hot to the touch.

7.16.4 The Contractor shall undertake a detailed review of those pieces of mobile equipment both Clinical and Non-Clinical, that is expected to be used by the Board and The Contractor within the Works. This review shall include a process of risk assessment and shall be organised to determine the type and extent of protection that is required to the building fabric. This review shall be made available to the Board as requested.

7.16.5 The Contractor shall endeavour to minimise the extent of impact damage incurred by ensuring corridors are and free awkward comers / obstructions. The Contractor shall ensure that doors and lifts are of sufficient width to accommodate all forms of hospital traffic and shall, where necessary, be designed to be normally held in the open position or to automatically open where appropriate.

7.16.6 In line with health building guidance, continuous hand-rails should be fitted to both sides of all patient accessible routes and corridors. Certain proprietary handrails have also been developed as wall protection crash rails. A combination of these hand rails or some of the following forms of protection would be deemed appropriate in patient and non patient routes and corridors:

a) crash rails;

b) defensive coves; and

c) corner treatment and reinforcement.

7.16.7 Exposed services such as ducts, radiators and pipework can be badly damaged when struck by trolleys etc. The Contractor shall incorporate measures to avoid damage to these elements.

7.17 Integration of Healing Arts Strategy

7.17.1.1 Introduction

Art and Architecture is a key strand of the Board's Arts and Health Strategy. The Board recognises that good design in healthcare buildings makes a measurable difference to the experience of patients, visitors and staff.

7.17.2 As part of it's Design Action Plan, the Board are committed to the development and integration of Art and Therapeutic Design within the new developments at Southern General Hospital and this will include;

a. New Adult Acute Hospital;

b. New Children's Hospital;

c. New Laboratory Block (part of novated design); and

d. External space and general landscaped areas within the site boundary.

7.17.3 The Art strategy will be developed in the context of;

a. current Board arts strategy work already being undertaken in Glasgow as part of ASR I and the new Maternity Unit at Southern General Hospital;

b. the range of cultural, regeneration, funding partnerships already established within Greater Glasgow and Clyde; and

c. the need to ensure a local arts perspective is developed that reflects international level of quality.

7.17.4 Competitive Dialogue Stage (May - September 2009)

Bidders are asked to clearly demonstrate within their written and drawn responses how they will develop and deliver an Arts and Therapeutic Design Strategy that reflects:

a. Integrated art, specimen art, interior design and landscaping (e.g. stained glass, bespoke art, special lighting, floor designs, therapeutic colour choices, special procurement of non clinical looking furnishings, landmark way finding, gardens and sensory planting);

b. Art enabling works (e.g. electrical infrastructure, lighting, wall niches and strengthened walls and ceilings to host future art works);

c. The provision of programmable spaces (e.g. future exhibitions, performance or sculpture); and

d. Architectural elements (e.g. entrance canopy, art doors, curved walls, specially designed stairways and car parks);

7.17.5 Bidders are asked to prepare a detailed proposal of how they will provide resources and capacity to support the Board's aspirations to develop and deliver this strategy in conjunction with a wide range of stakeholders including patients, managers, clinicians and fundraisers ensuring that the Art strategy and design proposals are fit for purpose and in line with contract management/ build timelines.

7.17.6 Broad Plan for Developing and Delivering an Arts Strategy

The Arts strategy should be developed with a tiered approach based on priority areas for art and therapeutic design to be implemented on a discretionary basis reflecting levels of finance available. The table below gives an indicative format, but bidders should bring forward proposals which they feel will develop the most rewarding strategy.

Bidders are strongly recommended to have dedicated resource for the inputs below in terms of architecture, arts and technical requirements.

STAGE	TASKS	RESOURCES
Stage 0 Competitive Dialogue	Develop Art Strategy as part of bid proposals. The strategy developed by your team will form part of the evaluation process.	Identify bidder resources that will be provided during Stage 2 design and anticipated costs over the time period for stage, along with assumptions on frequency of meetings etc. The proposals should therefore ring fence money and time for Stage 2.
Stage 2 Design Development	The successful bid team will develop their strategy along with Board managers and other associated groups as noted earlier. • As a key member of the Board's Arts Development Group you will meet monthly to develop, plans and incorporate a full arts strategy into the detailed designs for the new builds. Prepare detailed costs and budgets for these works for Board consideration. • Working to the Arts Development Group will be the artists and designers who will meet weekly through design development forum to discuss concepts, plans, detailed and help prepare detailed costs.	The successful bid team will be required to take forward the strategy subject to Board involvement and work with teams to develop a workable proposal that is both achievable, realistic and affordable in the run up to FBC and approval to proceed with construction of the adult and children's hospitals. Note: costs for the arts strategy may be included within the contractors price, or funded by external Board source, or from a combination of these.
Stage 3 Construction of Adult and Childrens Hospitals	Incorporate the agreed art strategy design into the new builds	Manage the construction and full integration of the approved strategy on site by the successful bid team. Attend periodic meetings (quarterly) to review progress.
Stage 4 Commissioning	Fully commission any loose art works requiring service connections.	This would occur during post handover Board equip[ping stage, detail and input from bidders would be developed during Stage 2.

7.18 Secure by Design

7.18.1 It is important that security is effective but not visible and we would seek to avoid through good design the need for overt signs of security systems such as perimeter fencing and extensive CCTV provision.

7.18.2 The principals of 'Secure by Design' promote good practice, and encourage the adoption of design principles that reduce crime prevention as opposed to adopting 'active' preventative measures, The Contractor shall provide a report detailing compliance as far as is practicable with Secure By Design certification requirements. The Contractor should liaise with the local police in refining a strategic approach to the security of the facilities and the overriding safety of staff, patients and visitors.

7.18.3 While connections to the community are encouraged, not to the detriment of security Frequently, 'single point of access' is a strategy that is widely encouraged.

7.18.4 The following are extracts from the 'Secured by Design Principals' Document (2004):

a) Access design and escape routes;

To satisfy the requirements of individual developments, and in the interests of good urban planning, new development must provide adequate access to meet functional and recreational needs, including for example paths and inter-connecting open spaces, and access for emergency services. However multiple footpaths and points of access can make crime easier to commit by providing a choice of alternative escape routes from the scene of a crime. Careful attention to the disposition and design of access, and in some cases limiting the means of access to developments and to buildings, can assist in reducing opportunities for a crime, be it illegal entry, vandalism, crimes against the person or vehicle theft. Uncontrolled rear access ways to buildings and footpaths that are unduly secluded provide opportunities for crime with a low risk of detection and are to be strongly discouraged. It may on occasion be necessary to restrict access to a development to one main point, and it is always advisable to carefully consider the desirability and design of secondary access routes;

b) Footpaths and cycleways;

Public footpaths and cycle ways form a vital part of the communications network in both urban and rural settings. They also provide an important local or strategic recreational amenity. Their provision is strongly encouraged by current government planning guidance, but awareness is need of the potential problems that poorly located or poorly design footpaths can have. They can, for instance provide opportunities for unobserved access to the rear of buildings, means of escape for offenders and opportunities for crimes against people. Furthermore, poorly designed or sited footpaths may cause users to feel ill at ease and give rise to fear of crime, particularly after dark. This is likely to lead to reduced levels of use, which reduces the benefit to the community and will in turn exacerbate the problem. Well designed, well used and well maintained footpaths on the other hand provide fewer opportunities for crime and are likely to feel safer;

c) Relevant Secured by Design Key points:

i) Superfluous and unduly secluded access points and routes should be avoided;

ii) Access points to the rear of buildings should be controlled, for example by means of lockable gates;

iii) In terms of security, the design of the footpath of equal importance to the design of the building. The standard combined cycleway/footway should be 3m wide as a minimum and footways 2m wide as a minimum. Any shrub planting should start at the back of the verges;

iv) The position of the planting and choice of species should be such that hiding places are not created;

v) Good visibility should be maintained from either end, and along the route of footpaths and cycleways. Sharp changes in direction should be avoided;

vi) Footpaths and cycleways should not generally be routed to the rear of the buildings, but if this is unavoidable a substantial buffer should be planted between a secure boundary fence and the footpath margins, with planting designed so as to discourage intruders;

vii) Footpaths and cycleways shall be lit in built-up areas to adoptable street lighting standards except where the route is passing through woodland or and ecologically sensitive area, in which case an alternative lit route should be made available, such as a footway alongside a road; and

viii) Alternative routes to important destinations may be beneficial, although a balance has to be struck between advantages of greater choice and perceived security against the disadvantage of providing additional means of escape or of encouraging inappropriate movement of people.

Section 8.0 Building Services Requirements

8.1.1. Introduction

8.1.1.1. The Contractor shall in carrying out the Works comply with the following non-exhaustive list of Mechanical & Electrical requirements.

8.1.1.2. The Contractor shall provide an engineering system that utilises the latest technology to create a high quality working environment that will provide an efficient hospital for all patients, their families, visitors and staff. The Contractor shall ensure the services network is efficient, effective, flexible and unobtrusive to the clinical functions. The Contractor shall ensure that the system is easy to maintain and shall maximise the opportunities for flexible adaptation and extension of The Works.

8.1.1.3. The heating and cooling mediums shall be selected to ensure the most efficient systems are utilised taking into account integration of low carbon technologies and the site wide interconnectivity requirements.

8.1.1.4. Mechanical, Electrical, Public Health and Specialist services shall be designed to be an integral and co-ordinated part of the overall scheme. Services shall be clearly identified at regular intervals and at all locations where maintenance access is required.

8.1.1.5. Plant access shall be prioritised in all aspects of the building services design to minimise the requirement for the use of portable access equipment.

8.1.1.6. Permanent access equipment shall be provided by the Contractor to allow routine maintenance of all equipment within all plant rooms and associated areas where items of plant are located.

8.1.1.7. A systematic plant replacement strategy shall be provided by the Contractor, this shall detail the works required for the replacement of all major plant items and their major components.

8.1.1.8. All access equipment including lifting beams, access platforms, equipment cradles, slings, block and tackles and access ladders to allow all plant to be replaced in accordance with the strategy shall be provided by the Contractor with each item of equipment cross referenced to the plant items within the replacement strategy.

8.1.1.9. The location of engineering and utility services shall be co-ordinated with the structure and not constrain or conflict with clinical functionality.

8.1.1.10. Access to all services shall facilitate ease of maintenance which should be safe and able to be effectively undertaken. There shall be provision for space to give flexibility for future re-planning and / or re-modelling and replacement of the services.

8.1.1.11. The Board requires the buildings to be designed to achieve a very efficient level of energy and utility utilisation in accordance with the energy targets noted in Appendix M&E4 .

8.1.1.12. The Contractor shall take cognisance of all the building services implications of the requirements described in the Employers Requirements.

8.1.1.13. The power distribution systems and final circuits where required shall incorporate, IPS and UPS systems to meet the requirements of (S)HTM06-01 together with full compliance where appropriate with the MEIGaN requirements.

8.1.1.14. UPS to be provided from resilient platforms with N+1 redundancy with ability to transfer to shunt by-pass without loss of load, these shall be distributed throughout the works to ensure that reliable interruptible supplies are provided to suit the hospital operations.

8.1.1.15. Open protocol industry standard format must be used for all elements of the Electrical, Mechanical, Public Health Medical Gases, Security and Specialist systems.

8.1.1.16. All systems shall be warranted for support for an extended period and all software shall be retro compatible.

8.1.1.17. All Mechanical, Electrical, Public Health and Specialist system plant shall be designed and installed in modular arrangements incorporating plant N+1 redundancy to minimize disruption during planned maintenance.

8.1.1.18. All Mechanical, Electrical, Public Health and Specialist systems shall be designed and installed in resilient arrangements with dual distribution paths and appropriate isolation facilities to ensure that the completed installations meet all operational, maintenance, servicing together with plant replacement requirements and that local maintenance does not disrupt adjacent areas.

8.1.1.19. Where contradictory advice is apparent, the most recent guidance shall generally take precedence; unless indicated otherwise in the main compliance section of the Employer's Requirements – Volume 2.1 Section 5.1.

8.1.2. Engineering Services Interface with Building Fabric and Service Routes

8.1.2.1. The Contractor shall ensure that co-ordination of the Electrical, Mechanical and Communication services shall form an inherent part of The Works design.

8.1.2.2. Services provision, e.g. luminaires, fire alarms, security and mechanical services, shall be co-ordinated with the ceiling layout and allow simple relocation if required.

8.1.2.3. Access to services shall be provided and the services clearly identified at regular intervals and at all locations where maintenance access is required, for example at valves and electricity connection points. Access to building services shall be in accordance with SHTM 2023 "Access for Engineering Services".

8.1.2.4. It shall not be acceptable to require other services to be removed to allow access to services.

8.1.2.5. The positioning of sockets, light switches, alarm buttons and fire “break-glass” panels etc shall be consistently located throughout the hospital buildings and to specifications set out in BS8300, unless specific clinical needs take precedence.

8.1.2.6. Structural design shall ensure that structures are co-ordinated to ensure the logical and sequential installation and maintenance of services. For example the use of columns adjacent to vertical service voids shall be avoided.

8.1.2.7. All Mechanical, Electrical, Public Health and Specialist systems shall be fully co-ordinated in 3D with prefabricated plant, escalators, lifts, the building fabric and structural frame, secondary steelwork, façade systems, fit out to ensure that the completed installations meet all operational, maintenance, servicing and plant replacement requirements.

8.1.2.8. The Contractor shall provide secure utilities services connection to those services which are;

a) to be taken directly from public and other utilities; and

b) to the point of supply (inc connection) for those utilities which are to be taken from the Board.

8.1.3. Service Routes

8.1.3.1. All service voids, risers and other spaces shall allow for installation of additional services and shall provide a defined reserve of a minimum 25% of useable area through routing cross sectional area. All isolating valves and other items requiring particular access shall be positioned at convenient locations with permanent access provision and which do not impede execution of the clinical functions of the space.

8.1.3.2. The Contractor shall provide a compliance matrix indicating the level of provision of each service together with the means of calculation of the required 25% reserve capacity.

8.1.3.3. Services shall be arranged in a clearly zoned spatial hierarchy in ceiling voids, risers and plant spaces.

8.1.3.4. Generally access to services shall not be given in clinical areas, where this is unavoidable due to the requirement for local access the Contractor shall ensure that all services are co-ordinated and grouped to minimize the number of access hatches.

8.1.3.5. Ceiling void depths in Theatres shall be minimized, and in all cases be less than that required for void protection, with all power and data wired in a loop in basis to allow rewiring without the requirement to access the ceiling void, where access is required to allow periodic inspection of fixings, this shall be accommodated by the apparatus trims and via light fitting openings.

8.1.3.6. Services shall be configured to ensure local maintenance and isolation can be carried out in each room without the requirement to take other rooms out of use.

8.1.3.7. All service voids, risers, plant rooms and other service / plant spaces shall be designed to easily facilitate the future removal and replacement of building services within each space.

8.1.3.8. In order to minimise potential disruption to the Board due to maintenance of building services, The Contractor shall route services through common spaces such as corridors and avoid through routing within department areas.

8.1.3.9. All ductwork shall be provided to allow cleaning of internal surfaces and components to be undertaken in accordance with the Health and Safety Approved Code of Practice 33, and as detailed in the HVCA Document TR17 Cleanliness of Ventilation Systems.

8.1.3.10. Plant rooms shall be configured and constructed to minimize the risk of water penetrating into Critical operational areas. This is a pre-requisite of the design and the Contractor shall provide a detailed strategy document indicating the risk assessments and mitigation measures proposed e.g. water tanks not located above Critical operational areas, plant room floors constructed to prevent water seepage, tanking to be integrated in construction detailing rather than ad hoc post installation details, appropriate location of floor gulleys and sensitive routing of water and drainage pipework.

8.1.4. Server and Nodal ICT rooms

8.1.4.1. Major leak detection shall be incorporated complete with automatic zoned shut off valves.

8.1.4.2. Water proof ceilings to be provided in all Server and Nodal ICT rooms.

8.1.4.3. Resilient redundant environmental engineering services shall be provided within the Server and Nodal ICT rooms. The rooms shall be configured and located to minimise the risk of water damage from all sources with the following minimum requirements:

a) No overhead water, condensate or drainage pipework allowed within ICT rooms; and

b) No water tanks, tea points, DSR's, Cleaners rooms, toilets or showers etc. to be located directly above ICT rooms.

All ICT rooms to be clinically cleaned prior to the installation of active equipment, this deep clean shall be carried out by the Contractor's specialist cleaners to an agreed Board specification by the relevant Board Representative and a certificate issued. Special care shall be taken in advance of the deep clean with ongoing general cleaning being carried out at regular intervals to ensure that the cable termination works are carried out in accordance with the manufacturer's recommendations.

8.1.5. Engineering Flexibility and Zoning

8.1.5.1. All Mechanical, electrical, public health and specialist systems including medical gas zoning shall be configured to promote flexibility in order to enable re-modelling, re-planning and replacement to be undertaken at a future date.

8.1.5.2. All engineering services shall be zoned with isolation and safety provision for the whole of the the Works and for individual wards and departments. The Contractor shall also ensure that zoning accounts for:

a) The requirement for “dirty” / “clean” separation;

b) Solar movement; and

c) The necessity for isolation of part of the Works without affecting the entire facilities e.g. all theatre suite services including, ventilation, water, power, medical gases, lighting and controls etc. shall be capable of being independently isolated for maintenance with the remaining theatres still in service.

8.1.5.3. The Contractor shall ensure that all sections of the services distribution can be taken out of service for maintenance without interruption of the water, gas, medical gas and electrical supplies to the adjacent areas; this shall be detailed in the systematic plant replacement strategy noted in the introduction 8.1.1.

8.1.5.4. It is a pre-requisite of the design that all services to individual Theatres and other Critical operational areas can be isolated for maintenance, repair and replacement without the need to effect the ongoing operation of the other facilities.

8.1.5.5. Specifically each Theatre shall have individual air handling units and associated controls. The air handling strategy in Critical Care areas shall be developed with the design layout to minimize disruption during maintenance and each air handling unit must not serve more than one Critical Care pod. Also Air handling units in isolation facilities in Critical Care and general areas shall be configured in accordance with SHBN04.

8.1.5.6. Air handling strategy for the large recovery areas shall be developed with the design layout to minimize disruption during maintenance with the provision of interwoven duplicated systems and sectional controls.

8.1.5.7. Air handling strategy for the large decontamination areas shall be developed with the design layout to minimize disruption during maintenance with the provision of interwoven duplicated systems and sectional controls.

8.1.5.8. Air handling strategy for all large areas shall be developed with the design layout to minimize disruption during maintenance with the provision of interwoven duplicated systems and sectional controls.

8.1.5.9. No exposed pipework shall be visible in clinical areas.

8.1.5.10. Controls at nurse bases shall be co-ordinated with all alarm panels to improve aesthetics and ensure simple operation.

8.1.5.11. Patients operated environmental controls shall be provided to allow set point variation via a graduated slider with arrow type legend (rather than temperature levels); the local set point bandwidth adjustment shall be controlled from group settings at the BMS front end.

8.1.5.12. Emergency shut offs shall be provided at appropriate locations for all services.

8.1.6. Energy Targets

8.1.6.1. The buildings and building services solutions shall provide sustainable, low carbon, low energy facilities in accordance with Appendix M&E 4.

8.1.6.2. The Contractor shall comply with the requirements relating to energy targets as specified in Appendix M&E 4.

8.1.6.3. The Contractor shall provide a breakdown of how the target energy consumption shall be achieved. In particular, the Contractor shall provide details of the anticipated electrical and gas consumption of The Works.

8.1.6.4. In order to assist in meeting this target, the Contractor shall incorporate a high level of innovative building automation and equipment monitoring. The Contractor shall ensure that a central Building Management System (BMS) for The Works is in place, providing linked control and monitoring of the estate functions. Refer to Appendix M&E 5 for details.

8.1.6.5. The Contractor shall note that the Building Volume used in the calculation of Energy Consumption Performance Indicators shall be the “Heated Volume” as defined in Encode. The Contractor shall also include services within the calculation for determining the energy consumption.

8.1.6.6. The Contractor shall calculate the energy consumption for the new buildings using weather data from CIBSE Guides, and degree-day data. The Contractor shall submit all assumptions used to the Board for comment.

8.1.6.7. In order to assist in achieving the water consumption target noted in Appendix M&E 4. The Contractor shall use water saving measures including but not limited to:

a) Low Flush Toilets;

b) Automatic Sensor Taps;

c) Flush Controls to Urinal Facilities;

d) Major Leak Detection and Automatic Shutdown; and

e) Flow restrictors (if risk assessment accepted)

8.1.6.8. Consideration shall also be given to the possible use of borehole water.

8.1.7. Thermal Comfort

8.1.7.1. It is a requirement of the Contractor's Bid Submission that a maximum temperature (28 degree C) solution be considered for the whole of the Works. This will be discussed with bidders during the bid process. Such a solution would require to be produced with the following supporting information;

a) Capital Costs;

b) Lifecycle & Maintenance Costs;

c) Additional Electrical etc loadings; and

d) Projected Energy costs.

8.1.7.2. Where maximum internal summer time temperature calculations of ventilated rooms indicate that the internal temperature will exceed those limits set out in the Appendix M&E 3 for frequent periods, the Contractor shall provide means of reducing the temperature rise.

8.1.8. Air Quality

8.1.8.1. Internal

8.1.8.2. Air quality in all areas shall take account of occupancy levels, internal pollutants, heat gains, external pollutants, atmospheric conditions and shall be controlled to provide adequate comfort and fresh air levels appropriate to the functions of each department area.

8.1.8.3. Particular attention should be given to the risk of cross infection within the hospital / healthcare environment and shall be such as to minimise the spread of infection, all systems to comply with Hai-Scribe and infection control requirements.

8.1.8.4. The Contractor shall demonstrate how their proposals facilitate the control and management of an outbreak and spread of infectious diseases, and in particular shall comply with the requirements of SHTM 2025 (Ventilation in Healthcare Premises) and Hai-Scribe. In order to reduce cross-contamination, the design of The Works shall incorporate 100% fresh air supply systems only.

8.1.8.5. The Contractor's demonstration shall cover all aspects of the building, its services, spatial relationships, PPM Regime and incorporate requirements of the Board's Infection Control Team.

8.1.8.6. Consideration shall be given to the odours from the adjacent sewage works and appropriate filtration shall be included to reduce odours entering the facility.

8.1.8.7. Special consideration shall be given to the reduction of strong smells within the Children's hospital in accordance with SHPN23.

8.1.8.8. External

8.1.8.9. The Contractor shall comply with the requirements of Glasgow City Council and other Statutory Bodies regarding airborne emissions from the Site and shall undertake all studies necessary to prove that emissions and their dispersal will not have any adverse impact on the local community or staff, patients and visitors to the Site.

8.1.8.10. All works shall comply with the Clean Air Act. 1993.

8.1.8.11. The Contractor shall ensure that all Cooking Odours/Fumes are disposed off and do not cause a nuisance to the local community or staff, patients and visitors to the Site in accordance with Planning Condition 17 (see Outline Planning Conditions documents in Appendix D).

8.1.9. Vibration

8.1.9.1. The Contractor shall ensure that Building Services Plant and Equipment are suitably isolated from the building structure in order to prevent the transmission of vibration. The Contractor shall comply with the guidance on the satisfactory magnitude of building vibration with respect to human response given in BS 6472. The Contractor shall comply with the following vibration limits detailed below:

a) Plant rooms on occupied floors 0.015 m/s^2;

b) Plant rooms above and below occupied floor levels 0.050 m/s^2; and

c) Remote plant rooms 0.100 m/s^2.

8.1.9.2. All mechanical ventilation, air conditioning and electrical plant shall be suitably isolated from the structure of the building and fan units positioned in a ducted system shall be isolated from the ducting by means of flexible connections in accordance with Planning Conditions 12 (see Outline Planning Conditions documents in Appendix D).

8.1.9.3. To minimise structure borne noise or vibration lifts and/or hoists, including doors, guide rails and ancillary plant shall be suitably isolated from the structure of the building connections in accordance with Planning Conditions 13 (see Outline Planning Conditions documents in Appendix D).

8.1.9.4. The Contractor shall establish, in consultation with the Planning Authority, whether Best Practicable Means shall be employed as an approach to control noise or whether a baseline noise survey is required. If the latter is deemed necessary the procedures to be adopted shall be agreed in writing with the Planning Authority and thereafter implemented in the agreed manner. When detailed method statements for construction are available an assessment of hospital noise and vibration sensitivity should be undertaken and adequate controls put in place prior to the commencement of any construction demolition works in accordance with Planning Conditions 15(see Outline Planning Conditions documents in Appendix D).

8.1.9.5. All plant and systems shall be installed to meet the vibration requirement of the Clinical Equipment, including theatres and micro biology microscopes etc.

8.1.10. Acoustics

8.1.10.1. The Contractor shall ensure effective control of building services noise and provide a satisfactory acoustic environment in accordance with the following levels as per (S)HTM 08-01. This shall be developed with the Contractors Acoustician to ensure that a holistic approach is taken to prevent nuisance noise, as detailed in Appendix S – Acoustic Requirements.

Table 2 Criteria for internal noise from mechanical and electrical services		
Area type	**Example**	**Noise from mechanical and electrical services**
Ward areas, sleeping areas	Single-bed ward, multi-bed ward, on-call rooms, relatives' overnight stay	NR 30
Recovery	Recovery rooms	NR 35
Small office-type spaces	Private offices, treatment rooms, interview rooms, consulting rooms	NR 35
Open clinical areas	A&E	NR40
Circulation spaces	Corridors, hospital street, atria	NR40
Public areas	Waiting areas, dining, playroom	NR40
Personal hygiene (en-suite)	Toilets, showers	NR40
Personal hygiene (general access)	Toilets, showers	NR45
Small food-preparation areas	Ward kitchens	NR40
Large food-preparation areas	Main kitchens	NR 50 (NR 55 below extract hoods)
Large meeting rooms (>35 m2 floor area)	Lecture theatres, meeting rooms, seminar rooms, board rooms, classrooms	NR30
Small meeting rooms (≤35 m2 floor area)	Meeting rooms, seminar rooms, board rooms, classrooms	NR35
Operating theatres (excluding laminar flow theatres)	Operating theatres	NR40
Laminar-flow theatres	Ultra-clean theatre	NR50
Laboratories		NR 40 where laboratory has no fume cupboards NR 60 at 1 m from fume cupboard with open sash
Table 2 Criteria for internal noise from mechanical and electrical services		
Area type	**Example**	**Noise from**

		mechanical and electrical services
Utility rooms	Clean utility, dirty utility	NR40

8.1.10.2. As well as complying with the technical requirements noted within the various hospital documents, the Contractor shall develop a managed approach with all designers and the acousticians to provide a holistic solution in areas where low level noise could create potential problems e.g. courtyards, entrance halls etc.

8.1.10.3. The Contractor shall include active solutions were these are deemed appropriate e.g. provide piped music in atria, changing rooms to assist acoustic performance.

8.1.10.4. Noise from, or associated with the completed development (the building and fixed plant) shall not give rise to noise level, assessed with windows closed, within any dwelling or noise sensitive building in excess of that equivalent to Noise Rating Curve (NRC) 35 between the hours of 0700 hours and 2200 hours and Noise Rating Curve (NRC) 25 at all other times in accordance with Planning Conditions 11 (see Outline Planning Conditions documents in Appendix D). Refer to appendix M&E3 and the general acoustic requirements noted in section 7.8 - Acoustics.

8.1.11. Plant Life Cycle Costs

8.1.11.1. The Contractor shall ensure that all plant and systems are selected and configured to provide high quality, efficient, resilient, modular flexible and maintainable Building Services solution.

8.1.11.2. The Contractor shall provide evidence of plant life cycle costings including:

a) Capital Cost;

b) Energy Running Cost;

c) Maintenance Cost;

d) Replacement Cost.

8.1.11.3. Warranty costs for each of the building systems shall be benchmarked against industry standards and backed up by detailed costings in the extended warranty schedules.

Sustainability, Renewables, Low, Zero Carbon Technologies

8.1.11.4. The Contractor shall provide evidence of compliance with the Energy Target requirements as detailed in Appendix M&E4 and section 10 and shall develop the sustainability brief in conjunction with the Local Authority to ensure compliance with:

a) Building Regulations;

b) BREEAM Healthcare Excellent requirements;

c) Building Control;

d) Glasgow City Council requirements;

e) Scottish Government Planning Policies including SPP6;

f) Advice Notes including PAN84;

g) NHS/Board objectives.

8.1.12. Design Criteria

8.1.12.1. The Building Services shall be designed in conjunction with the development of the Architectural and Structural packages to ensure a holistic approach to minimise energy use while maintaining user comfort, fabric protection and statutory compliance.

8.1.12.2. All Mechanical, Electrical, Public Health and Specialist system plant shall be designed in modular arrangements incorporating plant N+1 redundancy.

8.1.12.3. All Mechanical, Electrical, Public Health and Specialist systems shall be designed and installed in resilient arrangements with dual distribution paths and appropriate isolation facilities.

8.1.12.4. The lighting levels shall be in accordance with CIBSE guides and Building Control requirements.

8.1.12.5. Power shall be configured to meet the Target Energy demands and also the design peak load plus 25% capacity for future growth.

8.1.12.6. The growth shall be provided in a modular configuration to allow plant cycling and high efficient running.

8.1.12.7. Fire safety systems shall be provided in accordance with the Fire Strategy.

8.1.12.8. Fire alarms shall be Fire Code and BS5839 CAT L1.

8.1.12.9. Refer to Appendix M&E 3 for Room Design criteria and internal temperature frequency periods.

8.1.13. Compliance with Health Service Notes and Memorandums

8.1.13.1. The Mechanical, Public Health, Electrical, Life Safety and Lift Services shall be designed and installed in accordance with the relevant SHTM's, HTM,s, SHBN's, HBN's, SHGN's and HGN's to meet the Employers Requirements.

8.1.13.2. Refer to Volume 2.1 Section 5.0 General Design & Construction Requirements for document hierarchy and Compliance Requirements.

8.1.14. Compliance with Planning/Building Regulations

8.1.14.1. The Building Services Installations shall generally comply with the Building Regulations and Planning Requirements.

8.1.14.2. If any deviations are proposed these must be highlighted in the contractors return documentation together with the details of the proposed mitigation strategy.

8.1.15. Incoming Services - Utility Connections

8.1.15.1. General

8.1.15.2. Discussions with the supply company have been commenced by the Client and contract details are included in Appendix M&E 1.

8.1.15.3. The Contractor will be responsible for the provision of all utilities and the energy supply infrastructure to and from The Works (whether this is internal or external to the Site boundary), including:

a) Confirmation of the capacity of the proposed system;

b) Liaison with potential suppliers;

c) System development and planning;

d) Any supplies modifications to the periphery of the Site;

e) Any supplies modifications within the Site;

f) Metering and sub-metering of power supplies;

g) Metering and sub-metering of heating usage;

h) Metering and sub-metering of cooling usage;

i) Metering and sub-metering of water usage;

j) Metering required for BREEAM;

k) Strategic planning in the context of the site environment;

l) Emergency systems; and

m) Power factor correction.

8.1.16. Security of Incoming Supplies

8.1.16.1. The Contractor shall provide back up to respond to the failure of the incoming supply of Electricity, Gas and Water supplies to The Works. This shall:

a) Provide full standby generator capacity for all electrical services on an N+1 basis in accordance with the requirements and recommendations of (S)HTM 06-01;

b) Ensure that The Works are provided such that all the requirements detailed in (S)HTM 06-01 are satisfied;

c) Ensure that energy, water, power supplies, medical gases and communication supplies to and within The Works are maintained by providing standby sources of supply (eg. dual fuel boilers, standby generators etc);

d) Develop a strategy to ensure the security of the supply. The Contractor shall be required to demonstrate the feasibility of the strategy to the satisfaction of the Board; and

e) Ensure their town's water connection to the Site maintains an adequate and robust service and shall provide connection details with their proposals;

8.1.17. Water

8.1.17.1. A robust alternative town's water supply is to be provided by the Contractor to the Site from a separate sector of the Scottish Water network.

8.1.18. Site Mains Water, Fire Water, Quality & Distribution

8.1.18.1. The Contractor shall develop the Site potable and fire water networks as separate systems each arranged with adequate valving to achieve robustness in continuity of supply.

8.1.18.2. The outcome of the water survey works is awaited, it is anticipated that The Works are to be supplied from dual supplies one from Govan Road and a second from Hardgate Road.

8.1.18.3. The Contractor shall filter the Site potable water to the criteria set out in SHTN02 with 0.2 micron filtration. Pipework shall be stainless steel.

8.1.18.4. The water filtration system shall be established within the Energy Centre to provide resilient filtered water to meet the requirements for The Works.

8.1.18.5. The Contractor shall provide external isolation of water supplies to the new Facilities.

8.1.19. Incoming Power

8.1.19.1. The overall site power systems shall be integrated with the Distribution Network Operator (DNO) incoming arrangement to provide a resilient system.

8.1.19.2. Scottish Power have advised that the existing 11kV network cannot accommodate the New Hospital load; they have been requested to provide proposals to enhance their network for the development. The Contractor shall negotiate with the supplier and ensure that an integrated solution is provided to meet the new building together with the additional site requirements detailed below.

8.1.19.3. The system shall also be configured to provide power for retained estate and new build areas as indicated in Appendix M&E1.

8.1.20. Fossil Fuels

8.1.20.1. The Contractor shall be responsible, in conjunction with SGN in determining the philosophy for the provision of fossil fuels to the Site.

8.1.20.2. Options the Contractor shall consider are;

a) Un-interruptible gas supply;

b) Provision of dual fuel burners and a heating oil standby facility;

c) Installation of CHP for base load;

d) Provision of CHP to provide full campus Electrical and Heating Loads in “Island” configuration with grid as standby.

8.1.20.3. Standalone Heating Boilers are not mandatory if the bidder identifies packaged CHP plant which does not require them to provide the required resiliency and dual fuel capabilities.

8.1.20.4. Irrespective of the option proposed by the Contractor the availability criteria described elsewhere in this document must be strictly adhered to.

8.1.20.5. Natural gas is required for;

a) Space heating;

b) Limited steam generation (for humidification);

c) Combined Heat and Power systems; and

d) Catering.

8.1.20.6. The gas supply shall be provided by a new mains connection from Govan Road. The pipework shall be routed to the Energy Centre to feed the Heating Boilers, CHP plant and routed to serve localised requirements within the Works.

8.1.20.7. Twin regulators shall be provided at the gas meter, non return valves shall be fitted at fire isolation valve to avoid back pressure shutting down regulator valve on activation of the fire valve.

8.1.20.8. Automatic Isolation facility to be incorporated in all gas fire valves during fire alarm testing. Valves shall be capable of being reopened and set to work remotely via the BMS.

8.1.21. Standby Power

8.1.21.1. Electrical Supplies to the Works shall be fully backed up by on site generation as noted above and in item 8.3.31 below. The Contractor shall provide the infrastructure and plant space to allow the extension of the generation capacity to meet the additional site loads as noted above together with a 25% capacity for growth.

8.1.22. Medical Gases

8.1.22.1. A new oxygen VIE compound is to be provided by the Contractor rated to supply the combined demand of The Works and the retained estate.

8.1.22.2. The existing site systems shall be extended by the Contractor to also be capable of supplying the combined site demand, this may be achieved by the expansion of the Maternity accommodation or the establishment of a further VIE compound site, which summated with the existing Maternity storage will meet the combined demand of the the Works and retained estate.

8.1.22.3. For the purposes of the Bid, the bidder shall assume that the latter is required and shall include for a further new VIE compound to be located as per drawing G1274/U(96)01.

8.1.22.4. The Contractor shall provide all civil, builderswork and distribution pipework via a ring main distribution circuit, which should be carried through to the new building risers.

8.1.22.5. The system shall be fully compliant with current SHTM requirements.

8.1.22.6. The Contractor shall liaise closely with the Boards Supplier who will lease the VIE tanks. The contractor shall carry out all builders work, foundations, bases, blast walls together with all pipe and electrical works.

8.1.22.7. Medical gases shall be supplied and configured to suit the new Hospital requirements and retained estate requirements including:-

a) Nitrous Oxide;

b) Oxygen (as above);

c) Vacuum (Split over two systems with valved off link); and

d) Surgical and Medical Air services (Split over two systems with valved off link).

8.1.22.8. Medical air plant should be provided from 2 separate sources of supply via a ring main distribution net work, carried through to the internal risers.

8.1.22.9. Within the Children's hospital special care shall be taken in the location and covering of medical gas equipment to reduce fear while retaining full operational abilities. The proposal shall be robust, simple to use and easily cleanable.

8.1.23. IT

8.1.23.1. IT equipment/server rooms shall be established in both the new Children's Hospital and Adult Acute Hospital. The two new rooms shall be interlinked, together with associated hub rooms via a star/mesh configuration of cabling.

8.1.23.2. Distributed secondary comms rooms shall be established to allow CAT 6A cables to be run to all positions within The Works within the 90m cable length restriction.

8.1.23.3. All new incoming services shall be duplicated and presented individually at the two server rooms. Ducting and manholes to be provided to up to four providers with diverse routes for each network provider.

8.1.23.4. Distributed secondary comms rooms shall be established to allow CAT 6 Augmented (CAT6A) cables to be run to all positions within The Works within the 90m cable length restriction.

8.1.23.5. The Contractor shall ensure that his works have no impact on the security of services to the existing hospital estate during the site construction works.

8.1.24. NHS Model Engineering Specifications

8.1.24.1. The Contractor shall ensure that systems are installed in accordance with all relevant NHS Model Engineering Specifications and amendments to ensure compliance with the Technical Memorandum.

8.1.25. Service Capacity Reserve

8.1.25.1. In accordance with Good Industry Practice, all plant, plant spaces and building services systems shall be specifically designed and provided with defined reserve capacity allowances and future expansion capabilities for The Works (e.g. distribution boards with 25% spare capacity, 25% additional containment, 25% spare capacity in distribution Pipework, 25% additional plant capacity, 25% additional cooling capacity, 25% additional air handling capacity etc. for the buildings as designed). As detailed in 8.1.3.2, the Contractor to provide compliance matrix detailing how this to be delivered.

8.1.25.2. With optimum for maximum temperature variant (MV2).

8.1.25.3. This shall be demonstrated within the calculations, plant room layouts and service route drawings provided with each stage of the design build project to ensure full compliance at project completion.

8.1.25.4. In addition to the reserved capacity allowances the Contractor shall also ensure reserve capacity, service termination, zoning and general arrangement supports any future extension of the building that may be an optional feature of the Contractors Proposals.

8.1.26. Commissioning, Testing and Demonstrations

8.1.26.1. The Mechanical, Electrical, Public Health and Specialist systems shall be fully tested and commissioned in accordance with:

a) CIBSE Commissioning Code;

b) The Institute of Hospital Engineers Guidance to Engineering Commissioning;

c) Requirements of SHTN’s and SHBNs; and

d) Requirements set out in the works documents

8.1.26.2. The Contractor demonstrations are to cover all aspects of the building, its services, and spatial relationships, Soft and Hard FM and incorporate requirements of the Board’s Infection Control Team.

Refer to section 6.8 – Commissioning & Handover for details.

8.1.27. Environmental Proving

8.1.27.1. During the design stage the Contractor shall provide the Computational Fluid Dynamic requirements of SHPN57 e.g. CFD shall be used to model and prove the ventilation strategy for the works.

8.1.27.2. On completion of the commissioning of all individual systems the overall performance of the combined systems shall be demonstrated within every room within the Adult Acute and Children's Hospitals.

The following parameters shall be recorded:-

a) Space Temperature;

b) Space Humidity;

c) Space Sound Levels;

d) Controls Operation & Achieving Set Points;

e) Domestic Hot and Cold Water;

f) Air Velocities (Comfort Criteria);

g) Lighting Levels; and

h) Fire Alarm Sounders.

8.1.27.3. Trend logs from the BMS system are to be used as a record of the local conditions achieved where possible, or hand held instruments with current Calibration Certificates. All readings shall be recorded, tabulated and issued.

8.1.27.4. Measuring instrument Calibration Certificates shall be forwarded for record purposes.

8.1.27.5. Room cooling capacities shall be tested on a department by department basis by introduction of temporary heat loads to prove the system design capabilities.

8.1.27.6. This shall be carried out by the Contractor at their own cost.

8.1.27.7. The Contractor shall also carry out seasonal commissioning as detailed in Appendix U – BREAAM Guidance, to ensure full system performance i.e. Main cooling plant operation in the summer and heating plant in the winter.

8.1.28. Asset Register

8.1.28.1. The Contractor shall include for a comprehensive Asset Register to be compiled on an open protocol industry standard format for all elements of the Electrical, Mechanical, Public Health Medical Gases and Specialist systems.

8.1.28.2. The Contractor is advised that an NHS Scotland (HFS) National asset management package is currently out to tender for development, this should fully developed and implemented by the time The Works are in the construction phase, failing this the Asset Register management package should revert to industry standard current at time of construction.

8.1.28.3. The register shall be linked to the As Fitted drawings via MiCAD drawing mapping, the MiCAD should also integrate with the Labour Management Systems (LMS) to provide a fully integrated system complete with interfaces to the PPM and Board's labour resource software systems (Apollo or Eclipse).

8.1.28.4. For ease of reference, all installed Mechanical, Electrical, Public Health Medical Gases and Specialist systems components shall be asset tagged by the contractor, entered into the PPM system and linked to its full specification and maintenance schedule.

8.1.28.5. IT provision for this functionality should include for server capacity to effectively store all 3 elements, PPM, MICAD & LMS packages.

8.1.28.6. The tagging system shall be capable of simple extension to allow the Bar Coding of Hospital Equipment, and the bidders shall provide technology proposals for Board consideration.

8.1.28.7. The asset tagging system shall be interfaced with the Personal Digital Assistant (PDA) System to be utilised for Managing Building Handover and Snagging.

8.1.28.8. The Contractor shall provide and manage a computer based electronic system for the management of the handover of the building. The system shall allow a file for each room to be established, with drawings linked to the file and marked to highlight snags or defects. This system shall be configured to provide management reports on zoned and room type selection basis.

8.1.29. Planned Preventative Maintenance PPM

8.1.29.1. The Contractor should provide, as part of the contract, a full PPM manual and system (computer based software package) for all the buildings and for all building and building services elements of the project. This system will incorporate the As Fitted drawings (MiCAD format) and specifications. This schedule shall have a full planned maintenance programme of works that the FM & Estates managers can review to plan and establish their annual maintenance schedules and annual budgets. The Contractor will be responsible for the purchase and installation of the full PPM system, including pc work stations, barcode readers and tablets.

8.1.29.2. The system to be compiled on an open protocol industry standard format for all elements of the Mechanical, Electrical, Public Health and Specialist systems.

8.1.29.3. The PPM system shall be compiled at an early date with time and input included for three iterations of comments and workshops with the Estates Department to ensure that the system meets the various requirements of the Hospital Technical Publications, CIBSE,

Clinical Services and Estate's Department. The system shall be fully linked to the As Fitted drawings via MiCAD drawing mapping, to provide a fully integrated system complete with interfaces to the PPM and Board's labour resource software systems (Apollo or Eclipse).

8.1.29.4. It is understood that there may be an iterative process involved in the preparation of the information, however it is a requirement that the Contractor allows for and ensures that all PPM, Asset register, tagging, management systems and MiCAD information is fully updated to "as fitted" condition.

8.1.29.5. The Contractor shall handover a fully working system including PC's hardware, barcode readers, tablets, printers and project specific software together with system training for the Client's operators.

8.1.30. Helipad

8.1.30.1. The Contractor shall include for all services including;

a) Fire fighting systems;

b) Suppressant storage;

c) Associated drainage, lighting and vertical access; and

d) All items required to allow operation of the helipad to ensure full compliance with HBN 15-03 and CAA guides.

8.1.30.2. The Contractor shall liaise with Glasgow City Planning and the CAA to agree the proposed location and height for Energy Centre Flue and ensure that warning lights are fitted to all required parts of the development including the flue.

8.1.30.3. All warning lighting shall be installed in accordance with the CAA requirements and the lamp replacement methodology shall be included in the main Plant Replacement Strategy.

8.1.30.4. The Building Services shall be designed and installed to accommodate Compliant Helipad Operation with the inclusion of:-

a) Lighting to main energy centre flue;

b) Appropriate location and height selected for;

i. Heat rejection plant to avoid flight path;

ii. Heat rejection plant to avoid hot air generated turbulence; and

iii. Air intakes to avoid contamination from downwash; and

c) Extract ducts to avoid contamination of operators and patient's in transit.

8.1.31. Automated Material Transfer System

8.1.31.1. It is anticipated that an Automated Material Transfer System installation will be provided to reduce the requirement for manual handling and increase service efficiency, all as detailed within Appendix M&E7. The Contractor shall set out the building service and vertical transport implications to ensure that space allocation and service requirements are incorporated for docking stations and controls.

8.1.31.2. All power, controls and equipment shall be configured to ensure EMC compatibility with the robotic solution.

8.1.31.3. The building fabric and general building services installations shall be designed to accommodate the Automated Material Transfer System.

8.1.32. Radiation Protection

8.1.32.1. All required protection and amendments to the Mechanical, Electrical, Public Health and Specialist Services shall be provided by the Contractor to suit the radiation protection regime in accordance with the manufacturer's guidance HSE regulations and Technical Memorandums.

8.1.32.2. Contractor to note that all Radiation Protection measures proposed to be discussed and agreed/endorsed with/by the Boards Radiation Officer

8.1.33. Telemedicine

8.1.33.1. The mechanics of Telemedicine system shall be provided by the Contractor via the ICT network cabling infrastructure and field cabling. The PACS equipment shall be provided by the Board.

8.1.33.2. As the principal tertiary children's hospital RHSC Glasgow is actively involved in all aspects of telemedicine and the new hospital requires to be arranged and equipped to facilitate telemedicine as part of normal practice. In practice this will require:

a) The ability to plug in mobile telemedicine units throughout the clinical areas to enable clinical consultations;

b) The equipping of all teaching facilities within the hospital for the transmission and receipt of educational activities;

c) A dedicated telemedicine suite; and

d) An IT infrastructure which will enable engagement in telemedicine activities from individual offices / PCs.

8.1.33.3. Telemedicine and teleconferencing play an increasingly important role in provision of children's hospital services in Scotland through:-

a) The transmission and receipt of educational programmes;

b) Support for networked models of service delivery (regional and national); and

c) Support for direct clinical care in remote locations.

8.1.33.4. Telemedicine and teleconferencing shall also play an increasingly important role in provision of adult's hospital with similar facilities being provided.

SECTION 8.2 – MECHANICAL SYSTEMS

8.2.1. General

8.2.1.1. The Contractor shall design, supply, install, test, commission and maintain all Mechanical Building Services necessary to support the clinical activities of The Works. The following systems are indicative of those anticipated by the Board but are not exhaustive and it shall be the Contractor's sole responsibility to determine that all necessary systems (excluding Medical Equipment) are included.

8.2.1.2. Systems shall be designed, supplied, installed, tested, commissioned, and put into service all in accordance with all relevant Regulations and Standards.

8.2.2. Building Management Systems & Controls

8.2.2.1. The Contractor shall ensure that all plant can be operated in automatic mode or manual mode should a corruption in BMS software occur. Furthermore, physical bypasses shall be provided where appropriate for maintaining service, for example at control valves for critical departments.

8.2.2.2. Network communications equipment for BMS, CCTV, Access Control Systems etc. shall be housed in racks, located within environmentally controlled secure rooms. If it is proposed that these share node rooms with the main network services then suitable control measures and rack locking shall be provided.

8.2.2.3. The system shall be fully integrated with the Building Services, refer to Appendix M&E 5 for BMS requirements.

8.2.3. Metering

8.2.3.1. The Contractor shall ensure the use of meters giving high accuracy at low flow rates and that metering points give consumption in SI units including any time bands as appropriate. The Contractor shall ensure data collection and report production is by electronic systems.

8.2.3.2. The Contractor shall allow sub-metering of electricity, gas, heating and cooling usage for each individual department / ward /unit. With water consumption measured in departments and wards with high usage.

8.2.3.3. Metering shall be provided in accordance with the targeted BREEAM credits.

8.2.3.4. The BMS shall be installed to automatically read and provide trend analysis to a range of energy and water meters. All meters including those of the utility supply companies and internal sub-meters shall be automatically read by the BMS at pre-determined intervals. The Contractor shall ensure that the BMS is capable of reading utility meters on a continuous basis in order to facilitate trend analysis. The energy metering shall include (but not be limited to):-

8.2.4. Electricity

a) Main incoming HV supplies;

b) Main LV Switchboard;

c) External lighting (separate sub-meter for each car parking area);

d) All distribution boards with separate meters for power and lighting;

e) Departmental power and lighting;

f) HVAC control panels;

g) Cooling plant; and

h) Tenant areas;

For the purpose of energy estimates, hours run meters shall be provided by the Contractor for all Air Handling Unit (AHU) fans.

8.2.5. Water, Gas, Oil, Bio Fuel

Water

a) Main incoming water supply; and

b) Internal sub-meters

Gas

a) Main incoming gas supply; and

b) Internal sub-meters

Oil

a) Delivered to Site; and

b) Used on Site

Bio Fuel (if proposed)

a) Delivered to Site; and

b) Used on Site

8.2.6. Asset Management & Tracking (AM&T)

8.2.6.1. The Contractor shall also arrange for the Utility metering systems to interface with the Board's AM&T system for fiscal metering, electronic invoice & validation process.

8.2.7. Heating System

8.2.7.1. The Contractor shall provide all heating systems required to support the Board's Clinical Output Specification and to;

a) Zone and control heating circuits to provide an efficient and comfortable environment;

b) Provide valve isolation such that isolation of circuits and sub-circuits shall have minimal disruption to the remaining departments;

c) Provide 24 hour occupied (and unoccupied) wards and departments with a night set back Facilities;

d) Provide a temperature and ventilation night set-back facilities so that when departments are unoccupied they will have frost and anti-condensation protection;

e) Good quality heat emitters shall be provided to ensure satisfactory heat distribution within the area served. Heat emitters and all heating pipework shall be arranged such that in all areas, the surface temperature limits as laid down in Health Guidance Note "Safe Hot Water and Surface Temperatures" are not exceeded. Heating pipework shall not be utilised as a heat emitter within patient areas;

f) The bidder shall provide catalogue details of all proposed heat emitters; and

g) Particular attention shall be given to effective use of warm air curtains in entrance / draft lobbies.

8.2.7.2. The Heating pipework shall be thoroughly examined and tested prior to the fitting of insulation. Any site welds shall be x-rayed and a certificate issued to confirm the suitability of the completed joint for operation within the test requirements

8.2.8. Water Systems and Filtration

8.2.8.1. Cold Water Supply

8.2.8.2. The water supply system for The Works shall include two new supplies and also incorporate on-site segregated bulk water storage (24-hours). Treatment of potable cold water supplies is not acceptable and the provision of a wholesome supply from Scottish Water's mains with the minimum of storage and handling is required.

8.2.8.3. The Contractor shall design and install the domestic cold and hot water supply installations to fully comply with the requirements of;

a) (S)HTM04-01;

b) SHTM 2027;

c) SHTM 02;

d) SHTM 2040 "The control of legionella in healthcare premises - a code of practice"; and

e) Health Guidance Note "Safe Hot Water and Surface Temperatures."

8.2.8.4. Pipework shall be stainless steel with compatible accessories.

8.2.8.5. The Contractor shall include for all specialist membrane filtration treatment plant (Replaceable cartridge systems are not acceptable). The Contractor shall provide water sampling points throughout the installation in accordance with the SHTM02. Renal water treatment shall be provided by the Contractor in accordance with Appendix M&E6 with due regard for clinical requirements.

8.2.8.6. Secure local isolation via manual shut off valves shall be provided by the Contractor at all sanitary appliances and at final connection points to Equipment.

8.2.8.7. Area leak detection shall be interlinked to zoned automatic shut down valves.

8.2.8.8. Secure external isolation to the buildings shall be provided by the Contractor. Sentinal taps for testing shall be clearly identified on drawings.

8.2.8.9. Pipework and valving shall be configured to allow isolation of local services whilst maintaining adjacent facilities e.g. resilient pipework routing and valve location to ensure that only one Theatre to be off-line at a time, one CCU bed, one renal bed, one standard bed etc..

8.2.8.10. Plumbed in water dispensers shall be provided at ward level and strategic areas including main reception/café areas etc.

8.2.8.11. Plumbed water shall be provided to specialist services such as, but not limited to;

a) Washing machines in specialised units;

b) Catering requirements;

c) Dishwashers in ward areas in accordance with the exemplar layouts and Equipment List; and

d) Retail Units.

8.2.8.12. Plumbed water shall be provided to all vending machines as required throughout The Works in accordance with the Employers Requirements.

8.2.8.13. Attention is drawn in particular to SHTN 02 concerning pipework materials and standards of filtration to be used in Scottish Healthcare Facilities.

8.2.8.14. Cold water system to comply with Hai-Scribe and the Board's infection control requirements.

8.2.8.15. All hand washing facilities to be provided with automatic taps.

8.2.8.16. The Contractor shall carry out a full risk assessment of the complete water systems of the legionella risks and ensure that the system design and equipment selection and installation is carried out to minimise risks.

8.2.8.17. Water shall be provided for fire fighting including sprinklers, wet risers and fire hydrants in accordance with the local authority requirements.

8.2.9. Hot Water Supply

8.2.9.1. Appropriate operational engineering systems for hot water shall be included in the design of The Works.

8.2.9.2. Pipework shall be stainless steel with compatible accessories.

8.2.9.3. Domestic hot water systems shall be designed with plate heat exchangers and buffer vessels to provide adequate flow to satisfy maximum demand whilst minimising stored hot water and energy consumption. The provision of some storage via buffer vessels may be required to minimise the impact of hot water generation on boiler power. (If buffer vessels are required these shall be minimal rating)

8.2.9.4. The adoption of recommended design practices to control of legionella and other bacteria within the systems is critical and is considered mandatory.

8.2.9.5. Type 3 thermostatic mixing valves (TMV's) shall be installed (in accordance with NHS Model Engineering Specification D08) at all HWS outlets to SHTMs and SHGNs except where 60°C water is a particular requirement. Double check valves to be duplicated at TMV's.

8.2.9.6. The Contractor shall carry out a full risk assessment of the complete water systems of the legionella risks and ensure that the system design and equipment selection and installation is carried out to minimise risks.

8.2.9.7. Hot water system to comply with Hai-Scribe and the Board's infection control requirements.

8.2.9.8. Hot water boilers shall be provided in all Staff Rest rooms and Kitchen areas.

8.2.10. Special Water Services

8.2.10.1. The Contractor shall provide all special water services required to support the Employers Requirements, such as but not limited to:-

a) Special supplies such as de-ionised water to specialist Equipment;

b) Special supplies such as de-ionised water to Equipment washers / disinfection Equipment; and

Special supplies for Renal Dialysis (refer to appendix M&E6).

8.2.11. Ventilation & Air Conditioning

8.2.11.1. The heating, ventilation and air conditioning systems shall be logically designed to operate efficiently incorporating heat recovery and provide local control for all areas including single accommodation.

8.2.11.2. The energy and power systems shall be appropriately designed to provide fully integrated designs in terms of the incorporation of engineering services into the building fabric and external spaces.

8.2.11.3. The need to maintain the specified comfort conditions in all areas but particularly in clinical areas is of paramount importance and the Contractor shall develop strategies for achieving the specified environmental conditions with minimum energy consumption.

8.2.11.4. Air Handling Ductwork shall be constructed from galvanised mild steel sheet and not fabricated from any composite board systems. Ductwork shall be manufactured and installed in accordance with DW144.

8.2.11.5. It is essential that the Contractor designs and provides ventilation and air conditioning systems which will ensure occupants comfort. This shall be achieved by use of well tested design principals and suitable plant selection. Air flow problems must be avoided by accurate system balancing, correct selection and location of air diffusers to prevent high air velocities and stratification together with adequate air volumes and accurate temperature control.

8.2.11.6. The Contractor shall comply with the following general criteria for above systems:-

8.2.11.7. Provide natural and mechanical ventilation, comfort cooling, and air conditioning to suit The Works and clinical requirements.

8.2.11.8. Air changes shall be in accordance with CIBSE guides, SHTM's, HTM's and Building Regulations.

8.2.11.9. Provide a climate control facility in clinical and staff areas which are provided with air conditioning (if applicable).

8.2.11.10. Ensure heat gain from all Equipment and personnel is allowed for in sizing and selection of the systems.

8.2.11.11. Demonstrate how their proposals facilitate the control and management of an outbreak and spread of infectious diseases in accordance with SHTM 2025 and SHFN 30 and HAI-SCRIBE. The Contractor demonstration is to cover all aspects of the building, its services, spatial relationships, maintenance regime proposals and incorporate requirements of the Board's Infection Control Team.

8.2.11.12. Ensure that ventilation systems installed in areas classified as hazardous are designed to relevant standards.

8.2.11.13. Where grilles or diffusers are used within rooms the Contractor shall ensure they are:

a) Arranged to avoid draughts;

b) Designed to minimise noise intrusion into the space; and

c) Humidification shall be provided where control of humidity is required for clinical reasons.

8.2.11.14. The Contractor shall provide the resilience requirements of SHPN28 e.g**.** Steam Humidification shall not rely solely on interruptible gas supply.

8.2.11.15. The Contractor shall design the systems set back arrangement in accordance with the requirements of SHPN57 e.g**.** minimum set back temperature in Cardiac CC of 10^{o}C.

8.2.11.16. The Energy Centre shall be adequately ventilated throughout and in compliance with HTM's, SHTN's, CIBSE and Building Regulations current at time of construction.

8.2.11.17. Special consideration shall be given to temperature control and ventilation within transformer rooms, generator rooms, UPS rooms and battery rooms to ensure optimum equipment operation.

Local Exhaust Ventilation Systems

8.2.11.18. The Contractor shall provide all LEV systems including but not limited to that required to support the provision of;

a) Catering;

b) Workshop and maintenance facilities;

c) Plaster rooms;

d) Decontamination suites; and

e) Areas requiring exhaust as noted in SHBN's, SHTN's and SHPN's etc

8.2.12. Fume Cupboard & Micro-biological Safety Cabinets

8.2.12.1. The Contractor shall provide fume cupboard and both CAT II and CAT III microbiological safety cabinet exhaust systems if required to support the Board's Clinical Output Specification, RDS/ADB information. Systems shall comply with NHS Specifications and Guidance documentation which shall include a matched supply system into the room(s) containing fume cupboards and micro-biological safety cabinets. Fume cupboard design and installation shall be to BS 7258. Microbiological Safety Cabinet design and installation shall be to BS 5726.

8.2.13. High Specification Air Conditioning Systems

8.2.13.1. The Contractor shall provide high specification, full function and close control air conditioning systems to support the Board's Clinical Output Specification, such as but not limited to:-

a) Aseptic rooms;

b) Ultra Clean ventilation and / or operating theatres;

c) Pharmacy; and

d) Areas handling radio isotopes or other radiological contaminants.

8.2.13.2. The operating theatre suite within the Adult Acute Hospital shall be provided with five number ultra clean ventilation (UCV) theatres. All other theatres shall be the standard type.

8.2.13.3. This should be verified with the current Architects drawings and Room data Sheets.

8.2.13.4. Each individual operating theatre shall be provided with its own plant, controls and power i.e. One supply and one extract unit, there shall be no sharing of ventilation between the theatre suite.

8.2.13.5. Air conditioning systems installed in the above areas shall be higher specification air conditioning systems with standby motors belted up in accordance with;

a) SHTM 2025;

b) SHTM 2040; and

c) NHS Model Engineering Specification C04.

8.2.14. Ventilation of Isolation Rooms

8.2.14.1. Each 28 bed ward within the Adult Acute Hospital will be provided with a single isolation room.

8.2.14.2. The Children's Hospital will be provided with two isolation rooms per 28 bed ward.

8.2.14.3. This should be verified with the current Architects drawings and Room Data Sheets.

8.2.14.4. The Contractor shall provide air conditioning systems to Isolation Rooms to support;

a) Employers Requirements;

b) Clinical Output Specification; and

c) NHS infection Control standards

With strict positive / negative pressure differentials.

8.2.14.5. A simple to read digital differential pressure gauge shall be provided by the Contractor at the entrance to the isolation suite lobby.

8.2.14.6. Refer to draft SHPN 4 and drawings G1274 M(57)02 & 03.

8.2.14.7. Ventilation and air conditioning systems for these rooms shall be designed and installed in accordance with;

a) SHTM 2025;

b) SHTM 2040;

c) SHPN 4; and

d) NHS Model Engineering Specification C04

8.2.14.8. The Contractor shall demonstrate how their proposals facilitate the control and management of an outbreak and spread of infectious diseases.

8.2.15. ICT Cooling

8.2.15.1. The Contractor shall provide N+1 redundant high specification, full function close control air conditioning systems to support the Board's Technology requirements, such as but not limited to:-

a) Server Rooms;

b) Computer Rooms;

c) Telephone Rooms;

d) CCTV DVR Equipment Rooms; and

e) Entertainment Server Rooms

8.2.15.2. The Contractor shall provide close control cooling systems to support the Board's Technology requirements, such as but not limited to:-

a) ICT Node Rooms;

b) BMS Node rooms (where these are separate from ICT node rooms);

c) Security Node rooms (where these are separate from ICT node rooms); and

d) Entertainment Node rooms (where these are separate from ICT node rooms)

8.2.15.3. No water or condensate generating equipment to be located above racks.

8.2.15.4. All services to be designed to operate on local control from diverse routed automatic change over power supplies to ensure no single point of failure, BMS to monitor plant operation, set points and room environment conditions.

8.2.16. Internal Drainage

8.2.16.1. The Contractor shall provide all necessary drainage to support the Employers Requirements and their aspirations regarding reduced water consumption which shall include but not be limited to:

a) General foul water drainage;

b) General surface water drainage;

c) Kitchen drainage, inclusive of grease traps;

d) Laboratory drainage;

e) Drainage from areas handling radio isotopes, or other contaminants such as silver;

f) Bedpan disposal system; and

g) Harvested rainwater shall not be utilised in clinical areas.

8.2.16.2. The design of the system shall be in accordance with the BS EN 12056 and the Local Authority's Building Inspector's requirements; pipe routing shall be configured to minimize the risk of blockage.

8.2.16.3. Drainage pipework and accessories material shall be selected to suit the appropriate location and type of waste.

8.2.17. Bedhead Services

8.2.17.1. The Contractor shall provide bed head services in line with the ADB sheet requirements together with clinical and operational requirements. The Contractor shall ensure that bedhead services are designed and installed in accordance with SHTM 2015.

8.2.17.2. The units shall be full integrated with the Patient entertainment systems and a dedicated power outlet shall be provided for patient's equipment.

8.2.17.3. The bedhead services shall be provided via high quality proprietary units with integrated lighting and medical gas outlets.

8.2.17.4. Gas Outlets in Children's Hospital to be concealed.

8.2.17.5. The bedhead units at renal locations shall be proprietary type rather than site constructed from standard components provided all in accordance with Appendix M&E6.

8.2.18. CHP Equipment

8.2.18.1. A CHP installation is proposed as part of the low C02 / energy strategy for the new Facilities. The CHP units shall be located within the Energy Centre. The Contractor shall develop the strategy to incorporate the full benefits of tri-generation and select appropriate plant to meet the works requirements.

8.2.18.2. The installation requires to comply with the following general principles;-

a) The system shall be fully integrated with the energy strategy for the new hospital buildings to ensure economical operation;

b) The units shall operate in accordance with the Clean Air Act; and

c) Where biofuels are proposed for the CHP these shall be stored separately from the main fuel storage system and shelf life control regime integrated in the storage facility.

8.2.19. Fire Fighting Systems

8.2.19.1. The Contractor shall provide all fire fighting systems in line with a robust fire strategy for the project as outlined in Volume 2/1 Section 5.11.

8.2.19.2. All elements of the fire fighting systems, such as but not limited to

a) Wet risers;

b) Sprinklers;

c) Gaseous Extinguishants;

d) Fire Hydrants; and

e) Smoke Control Systems etc.

8.2.19.3. The above shall be fully incorporated within the building design at an early date to ensure that all service routes and plant requirements are integrated in the building envelope while maintaining safe, secure access for maintenance and regular system testing of all systems without disturbance to the Clinical operations.

8.2.19.4. Where sprinklers are used special consideration must be given to mitigate infection control issues including risk assessments, water treatment and pre-action systems.

8.2.19.5. All in accordance with (S)HTM 05-01, 05-02 & 05-03.

8.2.19.6. Specialist systems shall be provided by the Contractor for the roof mounted helipad in line with the appropriate standards.

8.2.19.7. Authorised test certificates shall be provided by the Contractor for all life protection systems.

8.2.20. Gas Systems

8.2.20.1. Medical gases

8.2.20.2. The plant shall be rated to accommodate the requirements of the new and retained hospital estate The medical gas pipeline system for the site will require a detailed design package from a specialist consultant including all required co-ordination with existing gas supplies on-site throughout the phasing periods.

8.2.20.3. Contractor to note that detailed design proposals to be discussed and agreed/endorsed with/by Board's Medical Gas Officer.

8.2.20.4. For certification of the works all new developments will require new independent external plant and complete medical gas pipeline systems. The interconnections with the existing and upgraded systems shall be valved off for certification of the main works.

8.2.20.5. The Contractor shall liaise closely with the Boards Supplier who will lease the VIE tanks. The contractor shall carry out all builders work, foundations, bases, blast walls together with all pipe and electrical works

8.2.20.6. The Contractor shall provide all medical gases required to support the Employers Requirements such as but not limited to:-

Oxygen VIE comprising 2 No. Sources (2 fixed manifold rated for the combined load of the new and existing Hospital requirements) (Board provision) Together with connection to existing hospital VIE network and extension of the existing to provide supplies to meet the fall demand requirements of the new works and retained estate;

a) Nitrogen;

b) Nitrous Oxide;

c) Oxygen / Nitrous Oxide mixture;

d) Surgical air 7 bar;

e) Medical air 4 bar;

f) Carbon Dioxide;

g) Helium/Oxygen;

h) Medical Vacuum; and

i) Anaesthetic Gas Scavenging.

8.2.20.7. All medical gas, vacuum, scavenging, and air systems shall be fully maintainable without the requirement to alter other services and a section for each system shall be included in the Contractor's plant replacement strategy detailing the system resilience, redundancy together with the replacement methodology for all vessels, distribution and equipment while maintaining service.

8.2.20.8. All power supplies to medical gas, vacuum, scavenging, and air systems shall be provided from resilient redundant distribution networks with automatic change-overs with

a holistic approach used to minimise disruption to service during electrical testing and maintenance. Isolation and distribution shall be configured to ensure that work on one power stream does not effect other equipment.

8.2.20.9. Medical gas bottles, plant areas and stores shall be accommodated within suitably designed buildings, rooms and enclosures with good access, natural ventilation and satisfactory noise emissions control.

8.2.20.10. All medical gas installations which serve clinical departments shall be connected to essential electrical supplies.

8.2.20.11. The full status of the central medical gas plant shall be monitored by an alarm system with a status signal to an alarm panel located in the FM Control Centre, and local manned office. The panel shall also report the alarm to the BMS.

8.2.20.12. The Contractor shall provide the Medical Gas installation to comply with the following general criteria;

a) Install the piped medical gases in accordance with;

i. SHTM 2022;

ii. (S)HTM 02-01; and

iii. “Model Engineering Specification C11”;

b) Install outlets as required to allow the Clinical operation of each department to be carried out;

c) In accordance with ADB sheets;

d) Within play rooms and recreation rooms all outlets shall be located in lockable area together with masks and flow meters etc;

e) Provide a medical gas distribution system sized to accommodate the demand of The Works as defined in the Room Data Sheets, with the capacity to accommodate an increase in demand (flow and consumption) of no less than 25%;

f) Ensure that the provision of medical gasses to the point of use is continuous. Where the Contractor is providing medical gases via cylinders they shall provide manifold systems with automatic change over from duty to standby to no less than two equal banks of cylinders; and

g) Ensure that adequate points of isolation exist to all medical gas systems in accordance with SHTM 2022, (S)HTM 02-01.

8.2.20.13. The Contractor shall establish duplicate VIE plant compounds within suitable locations to ensure compliance with the Technical Memorandums, Local Approved Person and suppliers requirements. The system shall be rated to accommodate the full site wide requirements and the Contractor shall include for interlinking the new plant with the retained estate systems via valved off interconectors to improve overall site resilience.

8.2.20.14. A ring main will surround the site (NSGH & RHSC) feeding all necessary areas. It will be supplied from primary, secondary and tertiary sources. Compounds shall require an 8m

boundary zone for most activities around the enclosure, going up to 15m for places of assembly and flanges in flammable gas pipes. Allowance should be made for regular large vehicle access for tank refilling.

8.2.21. Medical & Dental Vacuum

8.2.21.1. The Contractor shall provide medical and dental vacuum by duplicate quadruplex vacuum systems each with three pumps and two vessels to provide service as detailed within the relevant ADB Sheets.

8.2.21.2. Medical and dental vacuum plant areas and stores shall be accommodated within suitably designed buildings, rooms and enclosures with good access, natural ventilation and satisfactory noise emissions control.

8.2.21.3. Installations shall be connected to essential electrical supplies.

8.2.21.4. The status of the central medical and dental vacuum plant shall be monitored by an alarm system with a status signal to an alarm panel located in the FM Control Centre, and local manned office. The panel shall also report the alarm to the BMS.

8.2.22. Anaesthetic Gas Scavenging System

8.2.22.1. The Contractor shall provide active AGSS systems in all locations where Nitrous Oxides are used. These shall be duplicate vacuum systems independent of the main vacuum systems.

8.2.22.2. AGSS plant areas and stores shall be accommodated within suitably designed buildings, rooms and enclosures with good access, natural ventilation and satisfactory noise emissions control.

8.2.22.3. The installation shall be connected to essential electrical supplies.

8.2.22.4. The status of the AGSS shall be monitored by an alarm system with a status signal to an alarm panel located in the FM Control Centre, and local manned office. The panel shall also report the alarm to the BMS.

8.2.23. Medical Air

8.2.23.1. Provision of medical air for the New Hospital Buildings would be best provided by duplicate - quadruplex medical air plant, comprising of 4 compressors, 4 dryers and 2 air receivers. It will be located within the Basement plant room area with sufficient air flow for ventilation and cooling of compressors. Each compressor sized for 50% of the design flow – providing the primary and secondary supply. This ensures an N+1 operation allowing full design flow with one compressor out of service. Emergency provision should be an automatic manifold (with cylinders) located within or close to the main building.

8.2.23.2. All supplies will conform to the European Pharmacopoeia standard for controlling air purity, all necessary filters and monitoring systems will be supplied. According to (S)HTM 02, the efficiency of plant, expressed as the volume of air delivered to the pipeline distribution system, a minimum efficiency of 5 m3/kWh at 100% and 10% is required. The power consumption at zero flow should be less than 1% of that at 100% design flow.

8.2.24. Surgical Air

8.2.24.1. The size of the development warrants dedicated duplicate surgical air supply. Surgical air will be provided by a duplex plants, located in each plant room area with sufficient air flow for ventilation and cooling of compressors. An emergency supply from an automatic reserve manifold (with cylinders) will be located in separate accommodation.

8.2.25. Manifold Installations

8.2.25.1. Other gases required throughout the hospital will be supplied by an automatic manifold installation, as in the case of N2O, with an emergency reserve supply connected. Gases used less frequently may be supplied by local cylinders at point of use.

8.2.26. Pneumatic Air Tube Delivery System

8.2.26.1. The Contractor shall provide a pneumatic air tube delivery system as required to the new Facilities to support the Clinical Requirements, as detailed in Appendix M&E7 of the Employers Requirements. The Contractor shall ensure that the pneumatic air transport system shall be designed and installed in accordance with SHTM 2009.

8.2.27. Fuel Storage
