8.2.27.1. The Contractor shall provide fuel storage within steel tanks located in the Basement of the Energy Centre. One of the tanks shall be provided early for beneficial use of the Board during the construction works to allow removal of the existing vertical oil tanks. The system shall include, fill points, delivery systems pumps and controls (this facility shall be integrated with the two other tanks to provide a long term fuel management facility for the boards new and retained estate.

8.2.27.2. The following fuels shall be provided by the Contractor and stored:-

a) 35sec Gas Oil - Main Boiler Plant and retained existing estate; and

b) Diesel – Generators.

8.2.27.3. Fill points for the individual fuel types shall be provided by the Contractor at a suitable location on the external wall of the Energy Centre to facilitate automated fuelling from tankers.

8.2.27.4. Supply points shall also be provided by the Contractor for the individual fuel types at a suitable location on the external wall of the Energy Centre to facilitate automated fuel distribution to the site and for tank management.

8.2.27.5. The quantity of oil storage shall be in compliance with the requirements of Appendix M&E2 Paragraph 3.0.

8.2.27.6. All plant and equipment and installations shall be in accordance with the HTM's, SHTM's and National Health Service Model Engineering Specifications with amendments to the Model Engineering Specifications to meet the requirements of the HTM's and SHTM's.

8.2.28. Testing and Commissioning of Mechanical Services

8.2.28.1. All Buildings, Services and Equipment shall be commissioned by The Contractor to ensure that they are all compliant with the quality and performance specifications,

including manufacturer's recommendations, and that all systems operate to the Board's satisfaction.

8.2.28.2. The Contractor shall appoint an independent Commissioning Engineer to manage the Testing and Commissioning as detailed in Appendix M&E3

8.2.28.3. The Contractor shall as a minimum commission the works in accordance with the 'Guidance to Engineering Commissioning' published by The Institute of Hospital Engineers (1995).

8.2.28.4. The Contractor shall be responsible for demonstrating and certifying to the Board the successful completion of all commissioning, testing and compliance with all relevant standards.

8.2.28.5. The Contractor shall provide a comprehensive hard and soft copy sets of Operations and Maintenance Manuals together with the MiCAD as fitted drawings (hard and electronic) for all installed and commissioned Equipment. 3 number off sets of each to be provided.

8.2.29. Connection to Specialist equipment

8.2.29.1. The Contractor shall include for final connection of all specialist clinical equipment including MRI's Xray, Imaging, Theatre, CCU and general equipment as indicated in the Board's Equipment Schedules.

8.2.29.2. The main services shall be terminated within 1m of each piece of equipment with the final connection being carried out in conjunction with the equipment supplier.

8.2.29.3. Energy for all Board equipment shall be supplied from the most efficient source e.g. MTHW for dishwashers etc.

8.2.29.4. All terminations shall be in accordance with the manufacturers written recommendations.

8.2.30. Water Services Leak Detection

8.2.30.1. The Contractor shall provide leak detection to all external water mains and transfer pipework serving the satellite tanks located within the basements of the other buildings by means of pressure switches and interconnecting controls to provide an audible and visual alarm in the event of major leakage and provide alarm signals at the BMS front end within the FM Control Centre.

8.2.30.2. Leak detection shall also be provided by the Contractor at:

a) Perimeter of all ICT Server rooms;

b) Perimeter of all ICT Node rooms;

c) Plant room bunds adjacent to theatres, radiology and critical care areas; and

d) Tunnel sumps.

8.2.30.3. These shall provide an audible and visual alarm in the event of local leakage and provide alarm signals at the BMS front end within the FM Control Centre.

8.2.31. Smoke Control

8.2.31.1. The Contractor shall provide all Smoke Control and Smoke Extract systems and equipment to meet the agreed fire strategy for the hospital developments. All in accordance with (S)HTM 05-01, 05-02 & 05-03.

8.2.32. Stair pressurisation

8.2.32.1. The Contractor shall provide as required Stair Pressurisation systems and equipment to meet the agreed fire strategy for the hospital developments. All in accordance with (S)HTM 05-01, 05-02 & 05-03.

SECTION 8.3 - ELECTRICAL

8.3.1. General

8.3.1.1. The Contractor shall design, supply, install, test, commission and put into service all Electrical Building Services necessary to support the clinical activities of The Works. The following systems are indicative of those anticipated by the Board but are not exhaustive and it shall be the Contractor's sole responsibility to determine that all necessary systems (excluding Medical Equipment) are included.

8.3.1.2. Systems shall be designed, supplied, installed, tested, commissioned and put into service all in accordance with the relevant Regulations and Standards.

8.3.2. Electrical Distribution Systems

8.3.2.1. MV Systems

8.3.2.1.1 A new Primary Sub- Station shall be established within the Southern General Site, discussions have taken place with Scottish Power. The Contractor shall conclude these negotiations and include for all works associated with the Construction of the Primary Sub-Station.

8.3.2.1.2 Refer to Appendix M&E1 for Utility correspondence.

8.3.2.1.3 The new Primary Sub-station shall incorporate a composite Client/Utility Company outgoing 11kV switchboard; the switchboard shall be configured to meet Scottish Power Requirements together with metered outgoing ways to allow:

a) Two ring mains to be provided for the new Hospital system being designed by the Contractor; and

b) Two further ring mains for the Board's future configuration of the retained and future estates requirements.

8.3.2.1.4 Automatic protection shall be provided to route power through the rings to minimise downtime on all unaffected sub-stations after a cable or sub-station fault.

8.3.2.1.5 Distribution in relation to the Works is to consist of separate closed unit protected auto-switching ring mains dedicated to each hospital. Unit protection shall be by pilot cables and time graded relays.

8.3.2.1.6 A full instrumentation and protection system with multi-function meters, over-current and earth fault protection to the primary ring mains shall be provided complete with remote monitoring via the BMS and FM Control Centre.

8.3.2.1.7 Refer to drawing G1274E(60)01 for indicative schematic.

8.3.2.1.8 The new Primary Sub-Station shall be delivered to allow power to be made available in line with the Laboratory Practical Completion date. Refer to Volume 2.2 documentation for details of fall back scenario if this cannot be accommodated.

8.3.2.2. LV Systems

8.3.2.2.1 All wiring systems shall be of a form defined within BS 7671:2008 (IEE Wiring Regulations 17th Edition).

8.3.2.2.2 Main LV switchgear shall comprise metal cubicle pattern switchgear enclosures containing Air Circuit Breakers (ACB) and Moulded Case Circuit Breakers (MCCB) with electronic protection selected to allow short circuit, over-current and time grading for full co-ordination and discrimination.

8.3.2.2.3 Each LV section shall be fitted with automatic power factor correction to correct the local power factor to no less than 0.95, the correction equipment shall be located closed to the corrected load, with hard wired automatic drop out facility during generator run and reset on return to mains.

8.3.2.2.4 All ACB's and main distribution ACCB's shall be fitted with monitoring units to capture and relay switchgear status, energy consumption. harmonic content, operation counter and fault indication via the Central Power Monitoring System

8.3.2.2.5 The Central Power Monitoring System work-station shall be located within the main FM control room with a second work-station located in the Estates Office.

8.3.2.2.6 The Central Power Monitoring System shall provide hierarchical maps indicating active mimic of the complete power and stand-by power distribution systems.

8.3.2.2.7 Each Main Switchboard shall be fitted with a touch screen PC to provide access to the maps and interactive mimic screens.

8.3.2.2.8 A hard copy cellular wall mounted MV Mimic Diagram shall be provided by the Contractor in the Estates Office to allow system status to be recorded manually.

8.3.2.2.9 All main LV switchboards shall be constructed to Form 4 Type 6.

8.3.2.2.10 Sub distribution and final distribution boards shall be constructed to:

a) Form 4 Type 2 for Clinical Risk Categories 1 & 2; and

b) Form 4 Type 6 for Clinical Risk Categories 3, 4 & 5

8.3.2.2.11 Risk Categories determined as (S)HTM 06-01

8.3.2.2.12 For the Works, most of the areas fall into Clinical Risk Categories 3, 4 & 5. Robust electrical supplies shall be provided to serve:

a) General lighting;

b) Standby lighting;

c) General power;

d) Medical power;

e) Medical IPS power;

f) Mechanical services plant (ventilation, medical gases, water, chilled water etc); and

g) ICT Power

8.3.2.2.13 The tower of the Adult Acute hospital contains general ward areas. For the avoidance of doubt the Board require Building Services for the Wards appropriate to Clinical Risk Category 3.

8.3.2.2.14 Due to the adjacencies, dual transformers and switch panels shall be provided to form part of the dual-unified supply philosophy employed in the distribution design. Like the MV distribution, the LV distribution shall be divided into Side A and Side B circuits. Side A and Side B Main LV switch panels adjacent to transformer substations and separate compartments will be linked together via an automatic `*bus-coupler-bus-tie'* cable way and two ACB's.

8.3.2.2.15 A robust arrangement, shall be provided to ensure that a fault or problem on the Side A switch panel does not affect the Side B panel and vice versa.

8.3.2.2.16 The Contractor shall integrate the distributed transformers, main and secondary low voltage switch rooms within the development to suit the final layout while minimising cable losses and providing simple maintenance / replacement access.

8.3.2.2.17 All plant rooms are to be in accordance with (S)HTM 2023 and (S)HTM-06-01 and the contractor shall provide a detailed Plant Replacement Strategy.

8.3.2.2.18 Distribution of LV power within the tower will be by three-phase bus-bar ducting with full size phase, neutral and earth conductors. Multiple tap off units shall be provided at each floor to serve distribution boards for lighting and power together with 25% spare capacity.

8.3.2.2.19 Each tap off unit shall contain a circuit breaker to provide full electronic time graded fault protection. The energy monitoring strategy may incorporate meters within the tap off units however where split distribution boards are proposed multiple meters shall be incorporated in the split distribution boards. All meters shall be linked back to the central system to allow remote load monitoring and energy management.

8.3.2.2.20 Each rising bus-bar pair shall serve each of the 'wings' of the tower. In accordance with the dual-unified distribution, each bus-bar pair shall comprise separate Side A and Side B bus-bars rising through the building in separate risers.

8.3.2.2.21 The final solution shall provide full system resilience and allow the distribution equipment to be maintained with the minimum of disruption to services at ward and departmental level.

8.3.2.2.22 Final circuit distribution boards shall be Type A or B with miniature circuit breaker (MCB) and (RCBO's) boards to BS EN 60439-3 located within risers or dedicated cupboards. All distribution boards are to be lockable with a suited key system with sheet metal doors to prevent unauthorised access. All boards shall be provided with ASTA certified bus-bars (rated to suit the local prospective fault current) neutral and earth terminals for each single phase way, clean earth facilities, extension spreader boxes for incoming cables separate CPC's, RCBO connections and flexible split metering facilities.

8.3.2.2.23 Distribution boards with plastic enclosures must not be used.

8.3.2.2.24 Power for all Mechanical, Public Health and Specialist systems shall be provided with resilience and redundancy to allow maintenance to be carried out on specific plant and distribution paths without the requirement to take other plant out of service.

8.3.2.2.25 All power circuits to be sized in accordance with BS7671.

8.3.2.2.26 Switchgear, Control panels etc, shall be securely located in plant areas and distribution cupboards not able to be accessed by public, patients or non FM staff.

8.3.2.3. Cables and Containment

8.3.2.3.1 Primary LV sub-main distribution is to be by bus-ducts, bus-bars and multi-core XLPE/SWA/LSF (low smoke & fume) cables to BS6724 carried on ladder rack (larger cables) and/or cable tray/basket (smaller cables). Primary LV cabling and containment is to be concealed within dedicated risers, cable trenches and risers throughout the building.

8.3.2.3.2 Side A and Side B cables and containment will be segregated and run by different routes to the final outlet as far as practicable, this requires Side A and Side B final circuit cabling to be run in separate containment up to bed head trunking units.

8.3.3. Lighting and Power

8.3.3.1. Interior Lighting

8.3.3.1.1 The lighting design must be functional for clinical use in accordance with the CIBSE and Society of Light and Lighting guides together with relevant SHTM's, SHBN's etc., the Contractor shall also ensure that the overall lighting concept is co-ordinated with the building structure and the project aesthetic requirements. Particular attention is required within entrance, circulation and non clinical areas where a mixture of LED's, conventional low energy fittings and retail lighting techniques shall be utilised to enhance the internal and external building experience in line with the architectural intent.

8.3.3.1.2 Where high efficient fluorescent lamps are not appropriate e.g. for aesthetics, signage and lighting of art works etc, the use of high output LED units and compact discharge sources shall be selected in lieu of tungsten lamps.

8.3.3.1.3 The Contractor shall provide and install high efficiency luminaires, utilising high frequency electronic control gear to provide occupiers with improved visual comfort while reducing noise levels and running costs.

8.3.3.1.4 Where VDU's are being used, the Contractor shall ensure that the lighting scheme complies with "CIBSE Lighting Guide LG3 and LG7.

8.3.3.1.5 The Contractor shall ensure that corridor lighting is multi circuited to facilitate use of 100% or 50% of the luminaires. Where the corridor is over 15 metres in length interlaced zoned lighting shall be provided. This resilient strategy must be imposed on the lighting control system design to ensure that lighting in each area is partially retained in use during maintenance of the alternate area distribution board and alternate section of the lighting control system.

8.3.3.1.6 Night lighting shall be provided within all corridors either by individual fittings or by selective switching of the general corridor wall/ceiling luminaires. The Contractor shall ensure night lighting in corridors shall not spill into patient bedrooms, or other bedded areas. Night lighting shall be provided at nurse stations, patient bed areas and locations where call systems are installed.

8.3.3.1.7 Ward night lighting override control to be fitted at nurse stations.

8.3.3.1.8 Luminaires shall be located to provide ready access for lamp changing and maintenance, whilst still providing the recommended level and quality of illumination to the area.

8.3.3.1.9 All signage is to be illuminated to ensure ease of legibility without causing glare.

8.3.3.1.10 Where sealed fittings are required e.g. in treatment rooms, isolation suites, theatres etc. the diffusers shall be composite type with easy clean flat surfaces with the optics incorporated within a stable sandwich construction.

8.3.3.1.11 Treatment Room luminaires which provide the general lighting shall be controlled by at least two circuits depending on the arrangement of fluorescent tubes in each fitting. The design of these luminaires must provide ease of access for lamp changing.

8.3.3.1.12 In ward areas the lighting shall be integrated with the bedhead services solution with combination wall mounted dimmer controlled fittings providing patient rest, watch light, reading light and examination facilities.

8.3.3.1.13 Where bed areas are used for intervention and treatment an overhead lighting scheme supplemented by bedhead units providing patient rest, watch light, reading light and examination facilities shall be provided.

8.3.3.1.14 Light fittings shall not be mounted immediately above patient positions.

8.3.3.1.15 All fluorescent lamps used in clinical areas shall have as a minimum a colour rendering capability of ≥ 85 CRI. For practical reasons consideration should be given by the Contractor to using the same luminaire in both Clinical and Non-Clinical spaces within the same ward. A reading light with an on/off switch shall be provided at each bedhead location and at the door. The Contractor shall provide an additional switch on the nurse call handset.

8.3.3.1.16 Where luminaires of the fully recessed type (modular and / or downlighter) are installed within fire rated ceilings, they should be provided with a one hour rated fire canopy. The Contractor shall also ensure that they maintain the integrity of the ceiling and that the canopies are tested to “BS 476 Parts 20 and 23, clause 5. The Contractor shall also ensure that all canopies meet the requirements of “Class O materials”.

8.3.3.1.17 Hazardous areas shall be provided by the Contractor with the appropriate classified luminaries.

8.3.3.1.18 Luminaires with prismatic diffusers installed on fire escape routes shall be fitted with flame retardant diffusers to TP (a) classification, minimum Class 3 surface spread of flame.

8.3.3.1.19 Each high dependency and recovery bed position shall have a wall or bed-head trunking mounted, examination lamp with integral switch.

8.3.3.1.20 Sealed food factory type luminaires shall be provided by the Contractor in areas in which food is prepared, cooked and stored.

8.3.3.1.21 Accessible plant areas, roof void areas, ducts, lift motor rooms, shafts and similar utility areas shall be illuminated utilising suitably IP rated luminaires.

8.3.3.1.22 Over-mirror lights shall be provided by the Contractor in all en-suites, shower rooms bathrooms and in all Male and Female changing rooms.

8.3.3.1.23 Lighting in toilets accessible to the public shall be fitted with blue light effect to minimise unsocial activities.

8.3.3.1.24 Laser and x-ray warning lights shall be provided by the Contractor outside theatres, major treatment rooms and x-ray rooms interfaced with the laser / x-ray machines.

8.3.3.1.25 Lighting levels to be in accordance with CIBSE guides and SHPN's. Theatre Pendants and lights to be selected by Board. Contractor to allow for all services.

8.3.3.2. Lighting Control & Wiring

8.3.3.2.1 The Contractor shall provide automatic control of lighting using natural light level sensing and the BMS scheduling capability for unoccupied periods (with movement sensing override for safety) primarily in circulation areas and large open workspaces.

8.3.3.2.2 In plant rooms additional controls interfaced with the access control system shall be provided at main plant room entrances to override the automatic off signals, allowing staff to carry out inspection and maintenance outwith the normal reach of the presence detection system.

8.3.3.2.3 The Contractor shall ensure that the lighting design incorporates a flexible switching arrangement to allow for varying activities within each room and for cleaning purposes. Switches for all public areas should be positioned by the Contractor so that unauthorised persons cannot switch the lighting.

8.3.3.2.4 Lighting within all WC's, Staff WC's and changing rooms shall be controlled via passive infrared sensors/movement detectors or similar, with adjustable time control facilities.

8.3.3.2.5 Lighting within clinical areas shall incorporate manual override controls

8.3.3.2.6 The Contractor shall arrange the circuiting of luminaires to control groups of fittings in order to provide flexibility of switching arrangements. Such a facility is particularly

important in large spaces where the level of daylight is not uniform and artificial lighting is likely to be needed for long period in areas remote from windows.

8.3.3.2.7 The Contractor shall provide the luminaire isolation requirements of SHPN57 e.g. all luminaires to be provided with means of safe isolation to prevent isolation of adjacent fittings for replacement.

8.3.3.2.8 The Contractor shall provide alternative circuits together with two-way or intermediate switching at all section doors and corridor direction changes for lighting in corridors and circulation areas.

8.3.3.2.9 Where multi-gang lighting control switches are required the Contractor shall provide a label fixed to the grid under the switch plate, indicating the switches are fed from different supplies.

8.3.3.2.10 The Contractor shall provide the Lighting requirements of SHPN57 e.g. all lighting in Critical Care Areas shall be dimmable with local controls. (This is in addition to the general requirement for dimmable lighting which shall be provided throughout for the purpose of energy control and commissioning setting).

8.3.3.2.11 All small power accessories and Isolation devices shall be engraved with the accessory function.

8.3.3.2.12 Circuit designation labels shall be provided at all electrical accessories.

8.3.3.2.13 All power cables shall be provided with circuit references adjacent to terminations, the references shall be co-ordinated with the MiCAD As Fitted drawings and asset register tags.

8.3.3.3. Emergency Lighting

8.3.3.3.1 The Contractor shall connect the emergency lighting to addressable self-monitoring control panels with each luminaire containing an interface unit that shall be monitored and controlled by the control panel which shall report to the BMS system. The Contractor shall demonstrate that the emergency luminaires are automatically tested in accordance with the requirements of the British Standards.

8.3.3.3.2 Local circuit monitoring shall be provided to protect all areas.

8.3.3.3.3 The emergency luminaires may be of either the maintained or non-maintained variety. The Contractor shall ensure that they are powered by a suitable battery supply connected by an auto-changeover switch or utilise self-contained battery packs within luminaires (3-hour rated). The Contractor shall ensure that the emergency luminaires will be automatically energised in the event of a failure to the local lighting circuit.

8.3.3.3.4 The Emergency Lighting shall comply with BS5266 and (S)HTM2011.

Standby Lighting

8.3.3.4.1 The Contractor shall provide 100% standby lighting via the site generation system to enable normal activities to continue during the loss of a normal mains supply.

8.3.3.4.2 The Contractor shall ensure that the quality of standby lighting is equal to that of the normal lighting at the task points.

8.3.3.5. Wiring

8.3.3.5.1 Wiring will be generally be carried out using LSF insulated single cables run in concealed steel conduit and trunking. Connections to all suspended ceiling mounted fluorescent luminaires and non modular lights shall be made via a plug & socket/ lighting control module arrangement and a reasonable length of flexible heat resisting sheathed cable. Flexible cables shall not be trailed across the top of ceiling grids.

8.3.3.5.2 Modular wiring systems may be considered for lighting in non clinical areas, however if these are put forward the components must be sturdy, proven in use with long lifespan.

8.3.3.5.3 Loop In system in metal conduit to be utilised for wiring in areas with fixed ceilings.

8.3.3.6 Small Power

8.3.3.6.1 Where required small power circuits shall be provided in accordance with the MEIGaN.

8.3.3.6.2 Where required small power circuits shall be provided from Insulated Power Supplies.

8.3.3.6.3 Where required small power circuits shall be provided from Uninterruptible Power Supplies (UPS).Final circuits shall be interlaced fed from either side of the dual power distribution systems.

8.3.3.6.4 All clinical circuits shall be wired in metal conduit and containment.

8.3.3.6.5 Power shall be provided at docking stations for recharge of robotic units.

8.3.3.6.6 The Contractor shall provide the small power requirements of SHPN57 e.g. via ceiling mounted medical supply units rather than wall mounted outlets in Critical Care Areas.

8.3.3.6.7 The Contractor shall provide the power requirements of SHPN28 e.g. All Theatres shall be provided with two articulated pendants

8.3.3.7 External Lighting

8.3.3.7.1 The perimeter, including all entrance canopies and pedestrian walkways, to all buildings shall be lit by the use of energy efficient luminaires mounted in canopies, on walls, columns and/or bollards. All on-site access roads, service yards and areas, footpaths and cycle ways shall be lit to levels compatible with the GCC Highway standards. The lighting shall satisfy the requirements of BS 5489. Lighting shall be provided by the Contractor to all direction signs around the Site where these are not adequately illuminated by external lighting.

8.3.3.7.2 The system shall also provide a welcoming atmosphere to the main entrances.

8.3.3.7.3 All access routes to plant areas shall be lit to provide safe access for maintenance.

8.3.3.7.4 All wall mounted luminaries shall be fed by back entry. Cable runs on the outside of buildings shall not be permitted.

8.3.3.7.5 All external columns, bollards etc. shall be provided with fused cut-outs and adequate termination facilities for cabling.

8.3.3.7.6 When selecting luminaires, the Contractor shall give consideration to light pollution, vandalism, security, energy efficiency and local residents. The Contractor shall ensure that the installed scheme meets the requirements of the Civil Airport Authority (CAA).

8.3.3.7.7 The Contractor shall provide warning lighting on the main building and flue in accordance with the CAA requirements.

8.3.3.7.8 The Contractor shall provide helipad lighting in accordance with the CAA requirements and the Hospital Guides.

8.3.3.7.9 The BMS shall control external lighting to minimise energy consumption, by photocell or movement sensor, the lamp type selected must be sympathetic to frequency of switching dictated by the control means.

8.3.3.7.10 The Contractor shall utilise solar powered lighting where this can be shown to be effective on the site over a reasonable time period; these shall be supplemented by conventional luminaires when the output is not available.

8.3.3.7.11 The Contractor shall wire luminaires on multiple circuits to avoid loss of light to whole areas in the event of a maintenance and mains/circuit failure.

8.3.3.7.12 External lighting installations shall be designed to provide safe lighting levels in accordance with CIBSE guides and “Secure by Design” requirements.

8.3.3.7.13 Back-up floodlighting shall be provided from FM building into yard and buildings onto entrances pathways and roads should the ‘Contractors Street Lighting’ fail.

8.3.4 Fire Alarm and Detection Systems

8.3.4.1 The Contractor shall ensure that the fully addressable automatic fire detection system integrated within the BMS for The Works is fully compliant with the performance criteria laid down under (S)HTM05 and BS 5839. Refer to Fire Strategy Volume 2.1 Paragraph 5.11.

8.3.4.2 The systems are to be designed to BS 5839 category L1 and are generally to be analogue addressable with aspirated detection provided in areas including Theatres, X-ray, MRI, and ICT rooms and all other 'specialist suites'.

8.3.4.3 All aspirating air sampling units shall be located away from public areas, either in service cupboards or accessible services risers. All circulation doors shall be installed with integrated electro magnetic door hold open devices with all security door locks interlocked for evacuation in a zoned fire condition. The locks and hold open devices must not reduce the rated fire integrity of the doors.

8.3.4.4 The aspirated systems shall be capable of providing identification of alarms or faults within individual sampling pipes.

8.3.4.5 The system design shall be integrated with the requirements of the clinical requirements.

8.3.4.6 A Fire Control Station shall be set up within the new FM Building providing command and control for the life safety systems including PC Graphics for:

a) Fire Alarm Detection and annunciation;

b) Sprinklers (monitoring);

c) Smoke dampers (monitoring and control);

d) Fire fighting systems (monitoring and control);

e) Stair pressurisation (monitoring and control);

f) Helipad systems (monitoring);

g) Cold smoke extract (monitoring and control); and

h) All systems provided in accordance with the agreed fire strategy.

8.3.4.7 The Contractor shall liaise closely with the following;

a) Board's Fire Officer;

b) Glasgow City Council; and

c) Strathclyde Fire Brigade

and ensure that an agreed fire alarm cause and effect matrix is provided by the Contractor prior to detailed design to ensure that the systems support the overall fire strategy.

8.3.4.8 Control panels are to be provided in the Control Room and at the main entrances (or at the entrances to which the fire service are to attend, if different), with additional indicator panels provided throughout the building to allow staff to respond in accordance with local evacuation procedures, and to guide the fire service to the source of the alarm.

8.3.4.9 The control panels shall be fully networked with resilient connections to the site based PC font end with map facilities and remote graphics monitoring in Hillington via a dedicated link.

8.3.4.10 The system shall be equipped with sufficient sounders to maintain sound outputs in different areas in accordance with (S)HTM 05, and incorporate visual strobe indicators for a fire condition in accordance with the requirements of the Disability Discrimination Act.

8.3.4.11 The Contractor shall ensure that The Works are divided into zones by ward / department / unit area as well as by floors with mimic or repeater panels at each nurse station (or equivalent) and at least one panel per floor located in a central circulation area. In the event of fire The Works shall be capable of individual zone evacuation with all other zones receiving awareness signalling.

8.3.4.12 The Contractor shall ensure that all fire alarm panels are capable of giving details of system status for fire, fault, and alarm conditions including full text descriptions of location at all nodes and staff base positions.

8.3.4.13 All panels shall be capable of data / event logging and report generation.

8.3.4.14 Manual call points must be provided at every exit and staircase with no point in the building being more than 30m travel from a call device.

8.3.4.15 Fire Alarm Evacuation facilities shall be provided at each main node, these shall require a double action e.g. break frangible lid and then break glass unit.

8.3.4.16 Materials and equipment shall be the catalogued products of manufacturers regularly engaged in production and installation of automatic fire detection systems and shall be manufacturer's latest standard design that complies with the relevant Standards and Regulations.

8.3.4.17 The Contractor shall ensure, and provide necessary documentation to confirm that this system will have a documented history of compatibility by design for a minimum of 15 years. Future compatibility shall be supported for no less than 10 years. Compatibility shall be defined as the ability to upgrade existing systems to current level of technology, and extend new field panels on a previously installed network.

8.3.4.18 The Contractor shall take into account the need for maintaining patient security during alarm testing i.e. the testing regime shall not allow for ordinarily secure doors to open as a result of routine testing.

8.3.4.19 The Contractor to provide fire suppression systems in line with the proposed fire strategy, which shall include provision of gaseous systems in ICT rooms and Electrical Sub-stations together with the special requirements for the Helipad.

8.3.4.20 The Contractor shall provide fire hydrants to meet the Glasgow Council’s Building Control Department and Strathclyde Fire Brigade requirements.

8.3.4.21 Progressive horizontal evacuation in patient areas is to be facilitated by each fire resisting sub-compartment being on a separate alarm zone, and by the use of two stage (evacuate/ alert) alarms. To avoid unnecessary disturbance, staff elsewhere in the building who are required to perform particular tasks in the event of a fire are to be automatically alerted by pagers or electronic communications devices to avoid the sounding of the fire alarm.

8.3.4.22 In areas where patients can escape unaided and in non-patient areas the audibility of the fire alarm should be in accordance with BS 5839. However, in other areas an audible alarm may be unacceptable and the use of visual devices is to be provided in areas such as very high dependency patient areas, these include operating theatres, ITU, audiology, plant areas, service yards, imaging and areas with high ambient noise etc.

8.3.4.23 The fire alarm signal is to be transmitted automatically to an alarm receiving centre via a monitored line to supplement the control room operation.

8.3.4.24 The fire alarm system is to contain links to all necessary ancillary services such as;

a) Automatic Door Releases;

b) Door Control Systems;

c) Access Control Systems;

d) Ventilation Systems;

e) Lifts etc; and

f) Robotics

8.3.4.25 All wiring to be MICC with red LSF sheath.

8.3.5 Telephone Distribution Systems

8.3.5.1 The Hospital requires efficient, high quality telecommunications service provided to both its internal and external customers on a 24-hour basis. The Contractor will provide a robust resilient high quality cabling infrastructure, with appropriately selected switches provided by the Hospital.

8.3.5.2 Cable links with existing Telephone equipment throughout the site will be required, with all necessary underground ducts together with copper and blown fibre provided by the Contractor.

8.3.5.3 Mobility will be covered with wireless handsets on the IP network.

8.3.5.4 Analogue line facility to be provided for faxes rather than VoIP.

8.3.5.5 10% fall back lines to be provided by the Contractor throughout the works, present technology is for PABX and analogue phones. (PABX by the Hospital, This may be simplified by technology improvement but allow analogue distribution in the meantime).

8.3.5.6 The Contractor shall supply onsite paging facilities for the works to meet the standards provided by the current service provider Multitone Electronics plc, Unit 33 Geddes House, Kirkton North, Livingston, West Lothian, EH54 6GU. Space to be allocated in node rooms for Multitone paging equipment.

8.3.5.7 New Aerial/s to be provided to ensure full coverage throughout the works.

8.3.5.8 Emergency Voice patching to be colour co-ordinated (grey).

8.3.5.9 Field cabling racks and cabling to be set up for Power over Ethernet to minimise requirement for power plugs at feature phones.

8.3.5.10 Payphones will be provided under the current managed service Premier Telesolutions, 10 Alexandra Way, Ashchurch Business Centre, Tewksbury, Gloucestershire, GL20 8NB. The contractor shall provide telephone outlets and power at required areas and the managed payphone company shall provide the hardware and service. Space to be provided for node cabinet etc.

8.3.5.11 A separate Comms room and Office shall be provided for the patient telephone lease company to accommodate their switch and billing units,

8.3.5.12 The Contractor shall include for Analogue lines to be provided for all remotely monitored systems including: Cardiac, Fire, Lifts, VIE, BMS, etc. and for all systems provided by the Contractor.

8.3.5.13 Lift cars to have two comms connections, one for remote monitoring of performance and one for interlinking to the Hillington Control Centre.

8.3.5.14 GEMS to be provided with dedicated incoming lines for their network and telephone switch equipment.

8.3.5.15 Contractor to include 6 ducts from each main server room to the main hospital boundary for Voice/Data Use to suit the agreed communications vendors.

8.3.5.16 Contractor to include 2 ducts from each main server room to the Laboratories.

8.3.5.17 Contractor to include 2 ducts from each main server room to the Estates Department.

8.3.6 Information Technology (IT) Equipment and Distribution Systems

8.3.6.1 Overall Requirements.

8.3.6.1.1 The Board recognises the importance of information and communication in all aspects of its work; improved communication enables improved efficiency.

8.3.6.1.2 The continued development of technologies provides an increased potential to simplify systems and reduce duplication allowing the Board a more complex management system of greater value to users and the Board itself.

8.3.6.1.3 This specification is intended to co-ordinate the various aspects of communication systems within the Board's operations. The specification does not describe all individual systems and their operation in great detail, but identifies the various communication systems, the Board's current strategies for their development and maintenance, the obligations placed on the Contractor.

8.3.6.2 The Contractor shall design, construct and put into service a comprehensive and robust infrastructure (e.g. containment, cabling, power, A/C, Racks, raised floors, floor grills, comms rooms and server rooms) for The Works in accordance with the requirements of the Board's Requirements.

8.3.6.3 The infrastructure shall be commissioned, labelled and documented prior to handover to the Board.

The Board will install hardware (e.g. servers, comms hardware, PCs, printers, scanners), make the final connections (at the application and in computer rooms) and commission the operational system.

8.3.6.4 The Contractor shall provide only those systems that are fully compatible with the Board's operational Information Technology systems.

8.3.6.5 The Works will be served by an N+1 server room distribution. These shall be provided internally within the new development. The server rooms should have dedicated air conditioning, fire suppression, generator back up with diverse routed power and redundant UPS systems to maintain resilience in the IT network.

8.3.6.6 The 2 main comms rooms will house servers for local distribution whilst providing diverse links with existing comms rooms throughout the Hospital estate and further a field. The Contractor shall design each room to accommodate 6 comms racks, 10 server racks and 10 equipment racks, sufficient racks for the Contractors field cabling together with sufficient racks for the Contractors BMS, CCTV, and Entertainment equipment etc. together with space provision for access round racks and work bench laptop space. All racks to be provided by the Contractor, racks are to be lockable with a suited key system for Voice, Data, combined Voice and Data, CCTV, BMS etc.

8.3.6.7 Within these principal ICT rooms, telephony servers will be provided by the hospital.

8.3.6.8 As above multiple racks shall be provided by the Contractor allowing sufficient space for network expansion. Racks shall be 42U, 800mm x 1000mm (space for 1200mm) suitable for high velocity through ventilation based on hot/cold isle philosophy.

8.3.6.9 Data risers shall be established to interlink the main server and hub rooms, the risers shall be of sufficient size to accommodate 25% network expansion and modification.

8.3.6.10 The Contractor shall provide the requisite number of hubs to suit their proposed building layout to ensure compliance with the cable length restrictions. Hubs shall be sized to accommodate all of the Contractors Equipment together with a 42U rack dedicated for the Board's use.

8.3.6.11 It is envisaged that the Board will be using voice over IP for telephony.

8.3.6.12 It is envisaged that the Board will be using wireless technology (RFID) for public, staff data, patient monitoring, equipment tracking and automated transfer system connections, access points shall be provided by the Contractor throughout the facility to meet these onerous demands. The access points shall be located to meet the various system demands throughout all areas of the works. The Contractor shall provide a robust system with area coverage overlap and resilient interconnection to the network suitable for supporting the full RFID requirements.

8.3.6.13 The Contractor shall ensure that the lighting in all ICT rooms is sufficient to allow for safe working on plant and equipment. No water, steam or waste services shall be located either in or directly above the ICT room due to risk of water damage.

8.3.6.14 Infrastructure provided by the Contractor shall be fully compliant with the requirements of the NHSIA N3 project.

8.3.6.15 The Infrastructure shall provide the Connectivity requirements of SHPN57 e.g. Wide bandwidth service etc.

8.3.6.16 The Infrastructure shall provide the Connectivity requirements of SHPN28 e.g. all theatres to be provided with cabling to theatre lights to allow for camera connection to seminar room and general telemedicine system, refer to section 8.1.34 for Telemedicine details.

8.3.7 ICT Workshop

8.3.7.1 The ICT staff workshop shall be provided adjacent to each server room; the workshop shall have suitable environment and services to allow equipment to be tested.

8.3.8 Wireless Networks

8.3.8.1 The Contractor shall provide a secure wireless network which supports the Board's requirements as set out below:

8.3.9 External Services (WAN)

8.3.9.1 As noted above multiple ducts shall be provided by the Contractor from the network vendors external access points (ducts) to each of the Server rooms. These shall be of a size suitable for external grade fibre cable(s), and copper multi-core cable(s).Further ducts will be required providing links to existing building within the estate. The Contractor shall ensure that the Board is granted free access to these ducts at all times so that it may access communications services from any third party it wishes to nominate.

8.3.10 Cabling

8.3.10.1 Cabling systems shall be installed to the highest ratified specification for IT wiring systems as defined in EN50173 and EN 50173 or equivalent standard.

8.3.10.2 All Fibres are to be single mode blown type, mesh star configuration with minimum of 20 pairs backbone.

8.3.10.3 The Contractor shall demonstrate that the proposed copper structured cable is suitable for the latest available known technology at the time of tender and be as a minimum CAT6 Augmented.

8.3.10.4 The jacket construction of the cable must be suitable for the application and details must be provided in the tender. The installation shall also cater for two outlets at every workstation being able to support a VoIP installation in line with the agreed schedules.

8.3.10.5 All voice cabling installed shall allow for an agreed spare capacity over and above the spare requirements stated in the general section.

8.3.10.6 Cables, which pass through the infrastructure of the buildings, shall be suitably protected against damage. Through walls and floors this shall involve an appropriate type of sleeve, through any form of metalwork or stiff plastic then a rubber grommet shall be used.

8.3.11 Data Patch Panels

8.3.11.1 The Contractor shall take cognisance of the ICT requirements and provide patch panels to meet the outlet requirements. 100% patch leads shall be provided with colours and lengths to be confirmed.

8.3.12 Data Outlets

8.3.12.1 The data and voice outlets will be RJ45, CAT6 augmented type with angled connector.

8.3.13 Public Address Systems

8.3.13.1 The Contractor shall provide a public address system to allow zoned emergency messaging throughout the hospitals, Lifts, Building links, tunnels, FM and Energy Centre together with external mustering areas, supplemented by local background music and zoned PA to allow entrances, receptions, atria, changing rooms and waiting areas to operate in line with the Clinical Requirements.

8.3.13.2 The emergency messaging shall be controlled from two locations and the system shall incorporate pre-recorded coded messages.

8.3.14 Staff Location System

8.3.14.1 Pagers to be integrated in the BMS and Telephone Systems to suit the Board Requirements.

8.3.15 Patients/Nurse Call Systems/Personal Attack Alarm

8.3.15.1 Nurse Call Systems

8.3.15.1.1 The Contractor shall provide a comprehensive Nurse Call System integrated within the BMS networking systems at all bed locations (and en-suites), Nurse Stations, Toilets and Showers, TV Rooms and all other areas frequented by patients. The system must be capable of emitting both audible and visual warnings for the following situations:

a) To summon a nurse (Patient to Nurse); and

b) To highlight a medical emergency (Nurse to Nurse).

8.3.15.1.2 The installation shall have the following functionality;

Ensure that both visual and audible warnings are sited in positions that enable the appropriate staff to respond to the exact location of the call both efficiently and effectively.

Ensure that the warnings, both visible and audible, should be specific to the type of emergency and must be consistent throughout all areas of The Works.

Provide systems that comply fully with the requirements of relevant S/HTMs and S/HBNs. In addition these systems shall enable on-screen alerts at locations to be agreed with the Board.

Ensure that the nurse call button / cord meet the need of the particular patient that may be required to use The Works. Patients may have cognitive problems or have difficulties with mobility.

8.3.15.1.3 A nurse call system is to be part of every bed head service. A patient hand unit with a call button is to link to an indicator panel at the Ward Nurses Station. The system is also to link to call buttons in other areas such as WC's, Bathrooms and Quiet rooms. The system shall include the following facilities:

a) Ensuite protection;

b) Over-door indicator lights;

c) Ability to link calls between adjacent wards; and

d) Cardiac arrest or 'crash' call alarms taken back to a 24 hour manned point to allow the 'crash' team to be paged

8.3.15.1.4 The Contractor shall provide a flexible system which annunciates within the nurse station with route indicators to the activated unit. Each bed system shall be transferable to adjacent and remote nurse stations via a hierarchical password control system to meet the Nursing requirements of the flexible ward configurations.

8.3.15.1.5 The system configuration shall be interlinked with the central PC based bed management system.

8.3.16 Clinical Equipment Alarms

8.3.16.1 Each clinical drug cupboard shall be alarmed as follows;

a) Light externally over door to room

b) Back to Nurses station

c) Back to local office to warn of unauthorised access.

8.3.16.2 The Contractor shall provide a system by which clinical Equipment alarms can be annunciated at a designated location during working hours but out of hours alarms can be directed to a designated member of staff, off-site. The Contractor shall determine all Equipment alarms of this nature.

8.3.17 Call Systems

8.3.17.1 The call systems or speech transfer systems shall be provided by the Contractor where normal speech is impaired by the use of glass security partitions or similar barriers. These shall generally be at public entrances and secure receptions these should contain staff control unit, speakers and microphones.

8.3.18 Induction Loops

8.3.18.1 The design of The Works shall include a comprehensive system of induction loops (fixed or portable) with suitably located dedicated sockets and signage such as to;

a) Reception areas;

b) Bedded bays;

c) Single Rooms;

d) Treatment Rooms;

e) Consulting Rooms;

f) Counselling Rooms; and

g) Interview Rooms.

8.3.18.2 Additionally, the design shall reflect these requirements in areas such as offices where staff may require this facility.

8.3.18.3 The Contractor shall provide induction loop or infrared systems in accordance with DDA requirements. The final provision and locations are to be agreed with the Board, dependent upon the final design solutions.

8.3.18.4 Portable hand held systems for use by visitors shall be made available at Reception. This shall ensure that the parts of The Works not provided with Induction Loops or infrared systems are made accessible to all users.

8.3.18.5 The “ear” symbol denoting the presence of an induction loop shall be prominently displayed. A sign shall explain clearly to people using hearing aids how they can benefit from the Induction Loop.

8.3.18.6 Alternative, proven systems that do not raise issues of patient confidentiality can be proposed by the Contractor to provide facilities wide coverage as appropriate.

8.3.18.7 The Induction Loop system shall be interlinked with the speech transfer system in order to provide a neat and unobtrusive configuration and an aesthetically discreet installation.

8.3.19 Television Installation

8.3.19.1 The contractor shall negotiate with a patient entertainment system supplier and provide the required backbone broadband cabling and wire ways and control room facilities for a leased patient entertainment system, to be installed at all bed heads in the Adult Hospital. Bed Head systems to provide:-

a) Television;

b) Radio;

c) Telephone; and

d) Game and internet services (optional at point of use)

Together with the associated infrastructure to allow these to be charged on a pre-payment basis.

8.3.19.2 Within areas were a conventional bedside screen is not suitable, the Contractor shall provide an alternative solution for location of the screen.

8.3.19.3 The Contractor shall provide a fully operational patient entertainment systems in the Children's Hospital to provide:-

a) Television;

b) Radio;

c) Interactive games;

d) Music;

e) Art; and

Protected Internet services.

8.3.19.4 In addition to facilities at each bed head, in the Children's Hospital, entertainment systems consisting of TV, DVD and games systems will be provided in the main waiting and play areas. These will require a central TV and radio reception and distribution system provided by the Contractor.

8.3.20 TV & Radio Facilities

8.3.20.1 The Contractor shall provide the infrastructure for reception and distribution of television and radio for use by patients, visitors and staff. This shall include external aerials / dishes, containment and cabling / distribution to enable radio (inc local hospital radio), and both digital satellite / terrestrial TV services to be distributed throughout The Works.

8.3.21 Lightning Protection & Earthing

8.3.21.1 The Contractor shall provide a lightning protection system for the protection of the structure, the contents and occupants. The lightning protection installation shall be in accordance with BSEN62305. The lightning protection system shall comprise of air termination network, down conductors, earth termination network, type 1 and type 2 surge arrestors and all required equi-potential bonds.

8.3.21.2 Surface fixed down conductors are not acceptable.

8.3.21.3 The Contractor shall provide a system of earthing comprising earth electrode systems, main and supplementary earth bars, main and supplementary equi-potential bonding, to ensure sufficient and fast operation of protective systems in the case of earth faults.

8.3.21.4 The earthing system shall comply with (S)HTM 06-01, BS7430, and BS7671 and with the Electricity at Work Regulations.

8.3.22 CCTV/Security Systems

8.3.22.1 General

8.3.22.1.1 The systems shall be closely integrated with the BMS to provide an integrated central monitoring and management facility. The Contractor shall provide security systems specifically designed to meet the requirements of each department / unit.

8.3.22.1.2 The systems shall present a secure and reassuring environment for staff, patients and visitors by providing appropriate security measures within the particular restraints imposed by clinical demand and personal freedom.

8.3.22.1.3 The design for all security systems shall be in line with the general principals of the approach recommended by Secured by Design refer also to section 7.

8.3.22.1.4 Local security systems alarm annunciation shall be provided within wards and at the central security facilities with remote monitoring and control off site at the Hillington Control Centre.

8.3.22.1.5 The main receptions shall also incorporate a CCTV monitor positions each with a flexible control facility to allow a combination of monitoring arrangements over two 20” Flat LCD screens.

8.3.23 Panic Alarm Systems

8.3.23.1 The Contractor shall provide panic alarm systems integrated within the BMS. Staff attack alarms will be provided by activation of a fixed discrete push button, hard wired to the underside of reception desks. All principal reception desks and staff bases will be provided with this facility.

8.3.23.2 Staff mobile panic alarms will be provided with link to receptions and security in the following areas:-

a) Accident & Emergency

b) Imaging (out of hours)

c) Pharmacy

d) Emergency Decontamination

e) Out of Hours Service Areas

8.3.23.3 All panic alarms fixed and mobile shall be monitored by the on site FM Control Centre and the remote Hillington Control Centre this shall provide a description of the alarm activation highlighting the precise location of staff members in distress.

8.3.24 Paging, Personal Attack Alarms

8.3.24.1 The Hospitals shall be installed with a radio-frequency network to facilitate the use of paging and personal attack alarms integrated within the BMS. This radio-frequency network shall include location beacons so that the exact location of pagers and attack alarm devices can be determined.

8.3.24.2 The radio-frequency network infrastructure shall be compatible with the Identicom personal security device, which is used widely across the NHS to provide lone-worker protection.

8.3.24.3 Panic buttons linked back to the FM Control Centre, and with a loud alarm at the scene, are to be installed at Reception desks and in Treatment Rooms

Decontamination room to be secured and fitted with Panic Alarm and two way intercom to adjacent area.

8.3.24.4 Treatment space in the Emergency Department to host CatA prisoners required (incl terrorist suspects transferred from 'G' Div HQ at Helen Street). This as well as decontamination room to have discrete entrance (double bank decontamination facility, have lobbies and two areas and may require armed escorts to be present. Provide lobby, seating, WC etc to support together with controlled ingress and egress and airlock type doors.

8.3.24.5 Police room in Emergency Department area to be fitted with panic alarm facilities.

8.3.24.6 The system shall be networked with the central management system and linked with other systems to allow:

The unlocking of doors along all escape routes to assist evacuation in an emergency.
Possible automatic locking of doors within an area if a panic button is pressed.
Activation of a security camera in a particular location when a door is opened to provide a picture of the person entering.

8.3.24.7 All A&E entrances shall have Video Access Control System for use at night time so that security staff can control entry from the desk positions in accordance with the Secured by Design recommendations.

8.3.24.8 General staff panic alarm system shall be integrated within the Wi-Fi network to allow staff to operate two stage affray facility within the hand held electronic PDA type equipment. This shall be configured to triangulate the location of staff members in distress and provide a department location.

8.3.25 Alarms & Intruder Detection System

8.3.25.1 The Contractor shall provide an IDS System within The Works to provide out of hours security cover. This shall be provided by PIR Detectors located within the corridors, rooms with ground floor windows, and rooms internally adjacent to any roof access points. In addition The Contractor shall ensure that restricted areas have door contacts available for monitoring unauthorised entry.

8.3.25.2 The following areas shall be fitted with local intruder alarm systems:

a) Pharmacies (to prevent the theft of controlled drugs)

b) X-ray department areas used for storing silver chemicals

c) Patient record offices

d) Stock rooms

e) Plant rooms

f) FM areas

g) All external doors

8.3.25.3 The intruder alarm systems shall link centrally back to the FM Control Centre.

8.3.25.4 The Contractor shall ensure that the proposed alarm systems for The Works include lifts, refrigeration equipment and all other critical equipment.

8.3.25.5 The Contractor shall ensure that the alarm systems can be securely monitored on Site and also remotely at the Hillington Control Room.

8.3.26 Security Access Control

8.3.26.1 The Contractor shall provide a comprehensive access control system to all external access doors and to internal doors requiring restricted access including access control doors to each ward and departments integrated within the BMS and plant area lighting controls to prevent unauthorised access. Control will be via a hierarchical proximity card system. Some departmental systems may only be activated outside normal working hours.

8.3.26.2 Ward access control doors shall also be fitted with CCTV camera and door access system. The CCTV camera shall be suitable for viewing of visitors in wheel chairs.

8.3.26.3 The Contractor shall provide the Entry requirements of SHPN57 e.g. Entrance to be controlled by use of entry-phone intercom system with CCTV linked to the reception/clerical office and communications base with access control provided across the full Critical Care Accommodation including changing room doors

8.3.26.4 Controlled access shall be provided by the Contractor to the Estates and FM vehicle hard standing and parking facilities for vehicles and pedestrians, traffic management lights and barriers shall be provided to control the yard and the associated slip road.

8.3.26.5 The Contractor shall ensure the system includes all necessary power supplies, card readers, actuators, egress buttons and emergency “break-glass” release units and fire alarm interfaces.

8.3.26.6 The system shall utilise the BMS LAN with separate field cabling and all necessary central controls / network cards provided suitable for future extension.

8.3.26.7 The system shall be interfaced with the robotics system to ensure that controlled access is provided while maintaining system integrity.

8.3.26.8 The system shall be interfaced with the theatre system to ensure that controlled access is provided while maintaining operational integrity.

8.3.26.9 The Contractor shall provide door entry video intercom systems to the designated main entrance doors and the delivery entrances with local control and facility to transfer to the main security room.

8.3.27 External CCTV

8.3.27.1 The Contractor shall provide a comprehensive colour CCTV system integrated within the BMS covering all external access points, car parking and external pedestrian/cycle circulation routes around the full Site including FM, service yards, car parks, walkways, boundary of/entrances to Site, boulevard, service tunnel etc, and the general road network.

8.3.27.2 The design shall also take cognisance of the Board's security requirements as detailed in the Boards operational requirements.

8.3.27.3 The Contractor shall ensure that the system comprises a multi-channel digital recorder with a recording frame per second for each camera which is in accordance with a detailed engineering specification to be agreed with Strathclyde Police.

8.3.27.4 The digital recorders shall also control playback of images onto a CCTV monitor.

8.3.27.5 The cameras shall be fully functional set up with stops to avoid over viewing adjacent properties, the RAID storage shall be 25 frames per second and all equipment shall be selected to provide good quality viewing and reproduction for use in prosecutions.

8.3.27.6 The external PA system shall be linked to cameras so operator can 'speak' to persons in external spaces in emergency or to reprimand/warn.

8.3.27.7 The system shall be fully integrated with the new Laboratories system and shall be configured to allow migration of the retained estate equipment without downtime.

8.3.28 Internal CCTV

8.3.28.1 The Contractor shall provide a comprehensive colour CCTV system integrated within the BMS covering all corridors, reception, lift lobbies and other areas where members of the public gather or areas where access is to be restricted i.e. wards.

8.3.28.2 CCTV cameras shall be installed at the main entrances, waiting and circulation areas of both hospitals where the security and safety of hospital staff and patients is a concern but where free access for the visiting public is allowed. The CCTV systems are also to cover:

a) All Exits and Entrances;

b) Ambulance Parking;

c) Vehicle Bays;

d) Fill points;

e) Cycle sheds;

f) All vehicle and cycle routes within the works;

g) All footpaths within the works;

h) Pharmacy Counters;

i) Ward Entrances;

j) Children's Play Areas;

k) Ambulance Entry Points;

l) A&E Departments;

m) Car Parks, Estates Yards, Public Spaces;

n) Generator Plant rooms;

o) Main Heating Plant rooms;

p) Corridors;

q) Receptions;

r) Lift lobbies; and

s) Other areas where members of the public gather or areas where access is to be restricted.

8.3.28.3 All CCTV cameras will be IP-based. They will be linked back to local hubs by fibre or Cat.6A cabling. Local data hubs will be connected back to a number of CCTV servers adjacent to electrical risers, which will in turn be linked to the main server room via a looped optical fibre network. CCTV servers will include input modules, processors and RAID storage. The system shall record at 25FPS per camera and provide 31 days storage. Each CCTV server will also be provided with an independent broadband connection to provide connectivity in the event of a network failure.

8.3.28.4 All cameras shall be linked back to the FM Control Centre and the off site facility at Hillington with local supplementary monitors in accordance with the Clinical Requirements.

8.3.28.5 The Police room in Emergency Department area to be fitted with CCTV monitors, to receive feeds from the Emergency Department cameras and any other surveillance as provided under the control of the main CCTV monitor position.

8.3.28.6 The CCTV system shall be linked to the intruder alarm and access control systems to provide specific viewing functions, such as presenting a picture on a monitor when an access card is presented to a reader, or when a movement detector activates.

8.3.29 Automatic Barriers

8.3.29.1 The Contractor shall provide all vehicle access barriers including associated power and control wiring. For Vehicle control at the A&E, FM to suit the developed traffic philosophy. Facilities shall be provided for audio visual links to the security desk to provide assistance. The Contractors shall also provide additional ducts and network cabling to strategic areas for future pay stations.

8.3.30 Uninterruptible Power Supplies (UPS)

8.3.30.1 The provision made for interruptible/ uninterruptible power supply (IPS/UPS) solutions to provide electrical safety in the patient environment shall be based on IEC 6034 for Electrical Installations in Medical Locations, (S)HTM-06-01 and the recommendations of Guidance Note 7 to BS7671 Wiring Regulations published by the Institution of Electrical Engineers.

8.3.30.2 UPS solutions shall also be provided by the Contractor to support Grade A standby lighting in Group 1 and Group 2 locations within areas of clinical risk 4 and 5.

8.3.30.3 The Contractor shall provide the UPS requirements of SHPN57 e.g. all patient supplies in Critical Care areas shall be UPS backed, dedicated plug arrangements shall be provided rather than colour coding to differentiate.

Lighting in Critical Care areas to be UPS backed, this element of the requirement may be provided from of series of resilient redundant "lighting off line" battery inverter units rather than from the main series of "on line" UPS sets.

8.3.30.4 UPS units shall be located to suit the load requirements and the Contractor shall allow for UPS resilience, redundancy, automatic by-pass and ensure that the equipment is provided with the appropriate environment to ensure full design life is achieved from all equipment and batteries.

8.3.30.5 Consideration shall be given to UPS island mode operation with measures taken to ensure that the output neutral is referenced to earth at all times e.g. bypass and isolation transformers permanently in circuit with local connection or reconstituting the UPS neutral –earth bond as required.

8.3.30.6 Batteries shall be minimum ten year design life type in accordance with British Standards, these shall be provided in cabinets and battery monitoring and battery isolation devices shall be linked to the central monitoring system.

8.3.30.7 Battery cabinets shall be located in separate plant rooms from all heat generating equipment with appropriate environmental conditions to provide a safe steady state environment for maximum battery life.

8.3.31 Generators

8.3.31.1 The site generation shall be sized to provide stand-by power for The Works and Laboratory with provision for integration of the retained estate.

8.3.31.2 The system shall comply with the distribution requirements of (S)HTM-06 as set out in the schematic drawing ref G1274/E(60)01 and the generators shall have sufficient capacity to pick up the load and meet the minimum frequency and stability requirements for the Emergency System after loss of mains power taking into consideration the site load including Medical equipment, UPS and HVAC variable speed drives.

8.3.31.3 Load management control shall be utilised to ensure that the lighting and small power are reinstated within 15 seconds of power failure. All other loads including Mechanical Services and Lift power shall be re-instated in a controlled manner within 25 seconds of power failure. The Contractor shall include for all load management software and hardware including automated motorised ACB's and MCCB's to ensure that the load management matches the generator status. The Control shall be run over twin redundant PLC's with automatic change over in the event of fault. All control circuits shall be constantly monitored for healthy operation and communication with faults indicted at the Plant rooms with remote indication via the BMS.

8.3.31.4 Active mimics shall be provided via touch screen PC's within each main switchroom to indicate the status of all main electrical plant and emergency systems.

8.3.31.5 All power for controls and monitoring equipment shall be provided from resilient supplies with UPS/ Battery backup, with back up to allow maintenance without system downtime.

8.3.31.6 A full load analysis shall be carried out to ensure that the appropriate generator sets are selected to meet the active power, reactive power and apparent power requirements and that change-overs are bump free with a maximum permissible voltage dip of 2% on load acceptance.

8.3.31.7 The alternators shall be selected to match the inrush current of the transformers which shall be brought on line (with lighting and small power loads connected) when one of the generators in each group is available on the bars. The remaining generators shall synchronise to the first unit in their group and signal to the load management controls when sufficient units are available to take the remaining loads.

8.3.31.8 Generators shall be rated as ISO8528 (2005) Continuous Operating Power COP.

8.3.31.9 Full load management shall be provided by the Contractor to allow isolated island running and parallel utility operation.

8.3.31.10 The engines shall comply with ISO 3046-1 and generators comply with ISO 8528.

8.3.31.11 To improve system resilience the generators shall be located in groups with Fire and Blast Separation.

8.3.31.12 Digital Automatic Voltage Regulations (AVR) shall be provided with optimized transient response to suit site load.

8.3.31.13 A stringent series of “Black Building Tests” shall be developed by the bidder to indicate cause and effect for all of the system fault scenarios, this shall be build up in iterations with simple single system faults escalating to major inter system failures in a matrix.

8.3.31.14 An override facility shall be provided via Castel interlocking to allow a controlled manual engine start up procedure to be available in the event of PLC failure.

8.3.31.15 Once the Matrix is agreed the tests shall be integrated in the overall commissioning strategy.

8.3.31.16 The fuel storage shall be integrated with the standby heating fuel system to provide a modular storage facility as described elsewhere.

8.3.31.17 Each generator shall be provided with a dedicated gravity feed day tank capable of tuning the set at maximum load for 10 hours.

8.3.31.18 A resilient dual piped, multiple pumped supply system shall be provided from the Modular Storage to deliver to the day tanks.

8.3.31.19 All engines should incorporate lean burn technology to minimize NOx, flues shall be run to the energy centre stack and discharged at high level.

8.3.32 Plant Rooms

8.3.32.1 The plant rooms shall be configured to ensure optimum environmental conditions to ensure efficient operation.

8.3.32.2 All walls, ceiling and floors within generator rooms, transformer rooms, MV and LV switchrooms shall be painted to minimize problems associated with dust.

8.3.32.3 All floors and roofs to be of water proof construction with all penetrations formed in bunded up-stands incorporated in the water proof design.

8.3.33 Theatre Panels

8.3.33.1 The Contractor shall provide proprietary theatre panels of touch screen design to meet the Clinical Requirements and provide a centralised control and monitoring position within the Theatre for all Electrical and Environment Systems including Mains power, Generator power, UPS power, fire alarms, temperature, humidity, theatre lights, room lights etc.

8.3.34 Lifts and Escalators

8.3.34.1 The Contractor shall provide bed passenger lifts (suitable for inclusion of at least one hospital bed (orthopaedic bed), goods lifts, service lifts, general passenger lifts, clean goods lifts, dirty goods lifts, FM robotics lifts, dumb waiters and evacuation lifts within the buildings in accordance with (S)HTM 2024 and EN 81. Evacuation lifts for emergency conditions will be considered within the fire strategy and shall be provided if required as part of that agreed strategy. All lifts provided for the movement of patients shall be supplied from the essential services supply in accordance with (S)HTM 2011.

8.3.34.2 The Contractor shall give consideration to the following in the provision of lifts:

a) The lifts shall be vandal / damage resistant but aesthetically pleasing and appropriately sized (lifts designated as passenger bed lifts shall be sized to accept as a minimum a bed and associated equipment);

b) Banks of lifts shall be appropriately controlled to maximize movement;

c) Collective controls of groups of lifts shall be used;

d) All floors including plant levels shall be served;

e) Control rooms shall be easily accessible and designed to minimise the need for artificial cooling;

f) All Lift power shall be via automatic changed over units with power fed from either side of the dual power distribution systems;

g) Emergency hands free telephones in lifts shall be accessible to the blind, partially sighted, deaf and wheelchair users. The Contactor shall link each lift car emergency phone directly to an individual emergency line at the Boards central communications centre, to facilitate emergency clinical support and communication, this shall be in addition to the lift remote fault reporting system provided by the lift suppler;

h) Remote lift operation monitoring shall be provided;

i) Lifts for people and goods shall be separated;

j) Dedicated lifts are required for theatres or swipe controlled staff access override;

k) Key operated Priority Control shall be provided for bed movement and a local controller shall be provided within the helicopter recovery area;

l) Manual Handling shall be reduced with the introduction of Automated transfer Systems which shall be integrated in the vertical transport solution. The Contractor shall clearly set out the number of lifts indicating if these are dedicated to Automated Transfer System or shared with the FM units;

m) All lift car levelling requirements shall be in accordance with the British Standards and also be in accordance with the Automated Transfer System step capabilities if this is less tolerant than the British Standard;

n) Lifts shall be conventional type rather than machine room less type to ensure operation of the Boards passenger evacuation procedures;

o) Escalators to be selected to meet the traffic flow in accordance with the Bidders scheme, units shall be designed and installed in accordance with BS5655;

p) The Bidders shall carry out vertical transport analysis for passenger, bed movement and FM movements and automated material transfer systems based on their proposed scheme and the clinical and operational requirements;

q) Lift and escalator ratings speeds shall be selected to ensure excellent service complete with inbuilt redundancy to allow for unit breakdown and planned maintenance;

8.3.35 Tagging

The Contractor shall provide a full asset tagging system in accordance with the NHS Scotland (HFS) National asset management requirements.

All installed Electrical, Mechanical, Public Health Medical Gases and Specialist systems components shall be asset tagged by the contractor, entered into the PPM system and linked to its full specification and maintenance schedule.

The tagging system shall be capable of simple extension to allow the Bar Coding of Hospital Equipment, and the bidders shall provide technology proposal for Board consideration.

The asset tagging system shall be interfaced with the PDA System to be utilised for Managing Building Handover and Snagging.

8.3.36 Service Tunnels

Full resilient building services shall be provided in the service tunnels including, ventilation, smoke control, heating, small power, lighting, emergency lighting, illuminated signage, fire alarms, leak detection, access control, public address/background music and CCTV etc. to allow the tunnels to continue to operate during sectional maintenance.

The tunnels shall be configured to meet the developed traffic flow requirements, with full consideration of the Automated Material Transfer System operation requirements including power, ventilation, unit recovery, weight, gradient and step limitations.

Special consideration shall be given the risk of single point of failure within the tunnel and the main services shall be separately routed with dedicated maintenance access provided to allow ongoing operation during maintenance.

8.3.37 Laboratory Services

All specialist services e.g. security, access control, CCTV, fire alarms BMS etc within the new hospitals shall be fully compatible with building the services to be provided in the Laboratory Building.

8.3.38 Future Proofing

The Contractor shall ensure that all systems are future proofed and shall provide a compliance matrix indicating measures taken in their supply chain to indicate the level of future proofing included in their bid.

Section 9.0 Civil & Structural Engineering Requirements

The Contractor shall in carrying out the Works comply with the following non-exhaustive list of civil & structural engineering requirements.

9.1 General Requirements

9.1.1 The Contractor shall ensure that the design and construction of the civil and structural engineering elements of the buildings and external works meets the following criteria:

a) Be designed observing due skill, care and attention to the requirements of the brief;

b) Be fully co-ordinated with the design of the building fabric, finishes, services, facades, internal walls, medical equipment and existing Site features, including buildings / structures;

c) Provide adequate space for the distribution of services, while maintaining the required finished floor levels and the floor to ceiling heights called for in the Room Data Sheets; and elsewhere in the Employers Requirements documents;

d) Maximise the clear zone above the ceilings for services to the degree consistent with overall economy for the Board;

e) Be economically adaptable to meet changing clinical needs; and

f) Require minimum maintenance and be designed to accommodate maintenance requirements for services, equipment and building fabric.

9.2 Minimum Design and Construction Standards

9.2.1 Unless otherwise agreed with the Board the Contractor shall ensure that all structural and civil engineering elements are designed in accordance with current revisions of the following standards and guidance documents:

a) BS6399 - Loading for buildings or Eurocode 1 (incl. Eurocode 0);

b) BS5950 – Structural use of steelwork in building or Eurocode 3;

c) BS8110 - Structural use of concrete or Eurocode 2;

d) BS5628 – Code of practice for the use of masonry or Eurocode 6;

e) BS5268 – Structural use of timber or Eurocode 5;

f) BS8002:1994 – Code of practice for earth retaining structures;

g) BS8004:1986 – Code of practice for foundations;

h) BS8102:1990 – Code of practice for protection of structures against water from the ground;

i) BS8007:1987 – Code of practice for design of concrete structures for retaining aqueous liquids;

j) BRE Special Digest 1:2005: Concrete in Aggressive Ground;

k) BS5606:1990 – Guide to accuracy in building;

l) BS8000 – Workmanship on building sites;

m) BS8500 – Guide to specifying concrete;

n) Glasgow City Council Roads Development Guide;

o) Design Manual for Roads and Bridges;

p) Specification of Highway Works, published by The Stationary Office as Volume 1 of the Manual of Contract Documents for Highway Works;

q) The Traffic Signs Regulations and General Directions 2002;

r) The Traffic Signs Manual;

s) Sewers for Scotland 2nd Edition;

t) BS EN 752:2008 – Drain and Sewer Systems outside buildings;

u) BS EN 12056 – Gravity drainage systems inside buildings;

v) BS EN 1825 – Grease Separators;

w) BS EN 1295 – Structural Design of Buried Pipelines Under Various Conditions of Loading;

x) CIRIA C624: Development and Flood Risk – Guidance for the Construction Industry;

y) CIRIA C635: Design for Exceedance in Urban Drainage – Good Practice: 2006;

z) CIRIA C697: The SUDS Manual: 2007;

aa) CIRIA R168: Culvert Design Guide;

bb) The Water Environment (Controlled Activities) (Scotland) Regulations 2005;

cc) SPP7 – Planning & Flooding;

dd) Glasgow City Council – ENV 3 – Flood Prevention and Land Drainage;

ee) ICE specification for piling and embedded retaining walls, 2nd Edition;

ff) CIRIA 66S: Assessing Risks posed by hazardous ground gases to buildings: 2008; and

gg) WRAS information and Guidance Note No. 9-04-03. The selection of Materials for Water Supply Pipes to be laid in Contaminated Land.

9.2.2 The Contractor shall deliver the Works set out in accordance with BS5606 – Guide to Accuracy in Building Critical dimensions and setting out points shall be clearly marked on drawings.

9.2.3 Construction tolerances, unless otherwise stated by the Board shall be no greater than those specified in Tables 1 and 2 of BS5606. Where the operational constraints of the building require special levels of construction accuracy then The Contractor shall be responsible for establishing and designing for these.

9.2.4 The performance of components shall be in accordance with the appropriate British Standards.

9.2.5 The Contractor shall ensure that building structures are designed to resist imposed, roof and wind loads not less than those required by current revisions of BS6399, Loading for Buildings.

9.2.6 The Contractor shall ensure that building structures are designed to carry the loads of heavy plant or medical equipment (including ceiling mounted tacking hoist systems) in their permanent positions and any loads that will be imposed upon the structures during the installation, removal or replacement of such heavy items. This requirement may involve the design of 'strong routes' through the buildings and/or specially strengthened areas of the roof onto which heavy items can be lifted.

9.2.7 The Contractor shall ensure that any measures considered necessary shall be taken to protect the building from ingress of naturally occurring ground gases e.g. carbon dioxide, carbon monoxide, methane and hydrogen sulphide.

9.2.8 In addition to reference to the above Performance Standards the Contractor shall take cognisance of the comprehensive list of relevant compliance documents as detailed in Section 5.1 of Employers Requirements: Minimum Design & Construction Standards.

9.3 Loadings & Structural Flexibility

9.3.1 The Works shall be designed to cater for the dead loadings associated with the chosen materials for the structure, finishes, partitions and cladding to the buildings. As a minimum, it shall also be designed for the imposed loads as specified in current British Standards. The design shall also take into account the need for specialist measures to allow for the installation, replacement and removal of Special Equipment and associated services. Structural deflections shall be limited as necessary for the proper installation and functioning of specified equipment.

9.3.2 The Contractor shall account for (but not be limited to) the following loading schedule

a) General floor loadings – Dead and Live loads;

b) Point loads for Clinical equipment and Services;

c) Impact loads;

d) Vibration loads;

e) Special plant foundation loads; and

f) Service loads

9.3.3 The Contractor shall take account of concentrated point loads from both mobile and stationary plant and Equipment. The structure should incorporate reasonable measures to accommodate updated versions of such machinery without major disruption. In addition, the Contractor shall ensure that floors and supporting structures have the capacity for retro-fitting lifting devices for all fixed items of plant and Equipment weighing 35kg or more.

9.3.4 The Contractor shall take cognisance of the requirements in designated patient areas for ceiling mounted tracking hoists etc and such measures to allow for the installation of Special Equipment and associated services.

9.3.5 The Contractor shall ensure that specific areas of the Works satisfy particular requirements of the Board's operations or Equipment in those areas. Relevant constraints may include but are not limited to maximum allowable (structural deflections) differential settlement, (vibration) and the meeting of any constraints.

9.3.6 The Contractor shall take account of dynamic loads from general movement of people through to activities such as aerobics, dance or other rhythmic activities that can give rise to harmonic effects in poor design.

9.3.7 Lateral stability bracing systems shall not obstruct or hinder Clinical or Non-Clinical operations and shall not obscure the windows or doors.

9.3.8 The vibration response of the buildings shall comply with the requirements of SHTM 2045 and be compatible with the requirements of the Equipment to be installed.

9.3.9 With respect to the Works, the Contractor shall:

a) Take due account of future flexibility of the Works (in terms of future change of use and/or relocation of equipment);

b) Specifically make allowance for future flexibility of ceiling mounted lifting equipment in designated patient areas, including the requirement for re-configuration, extension and/or retro-fitting of lifting equipment i.e. the whole of the designated area shall be capable of accommodating re-configuration or retro-fitting;

c) Make specific allowance for items of particularly heavy equipment and/or other onerous loading conditions; and

d) Make specific allowance for installation, transfer and/or removal routes for heavy equipment throughout the Facilities.

9.3.10 Parts of the structure potentially subject to damage from trolleys or vehicles shall be designed with adequate protection to prevent such damage from occurring.

9.3.11 Structural deflections shall be limited as necessary for the proper installation and functioning of special mobile, rail mounted, or fixed Equipment.

9.3.12 The Contractor shall include, within their design, provision for removal, replacement and upgrading of installed plant and Equipment. As part of this element of design, a comprehensive replacement strategy shall be prepared for implementation. This strategy shall, wherever possible, consider how these activities can be undertaken whilst minimising disruption to the function of the completed Works.

9.4 Foundations & Sub-Structure

9.4.1 The foundations shall be designed and constructed in accordance with the relevant Codes of Practice, recognising the prevailing ground conditions at the site as identified in the Ground Investigation Report (contained in Appendix N) and historical ground investigation information issued with the tender. Where the Contractor considers there is insufficient ground investigation information within the information issued for tender purposes, he shall identify this and allow for carrying out further investigation as he considers is required.

9.4.2 The Contractor shall take due cognisance of:

a) Recognition of applied loading;

b) Settlement and its effect on new buildings, links to adjacent buildings, existing adjacent foundations and existing services;

c) Dewatering and its effect on new buildings, links to adjacent buildings, existing adjacent foundations and existing services;

d) Earthworks;

e) Basement construction and waterproofing category;

f) Possibility of uncharted services and existing buried structures; and

g) Utilities Diversions.

9.5 **Basements & Tunnels**

9.5.1 The Contractor shall refer to the Masterplan, Acute Adult and Children's Hospital, Laboratory and Energy Building drawings contained in appendices for proposed locations of basements and tunnels. Basements structures in the main hospitals will generally be provided for FM/distribution and plantroom/service areas. Basements areas in the laboratory building are generally for access to the labs and mortuary as well as services distributions. It is intended that significant size tunnels will be provided between and connecting basement areas. The tunnels will provide routes for distribution of services and movement of staff.

9.5.2 Basement and Tunnel structures should be designed in accordance with the recommendations of BS 8102. The Contractor should provide designs appropriate to use of these elements i.e. he is to confirm categories of design A, B or C and identify where each is employed

a) Category A – Technical Protection;

b) Category B – Structural Integral Protection; and

c) Category C – Drained Protection.

9.6 Movement Joints

9.6.1 Structural/movement joints shall not be located through:

a) Kitchen and food preparation areas;

b) Treatment and surgery rooms;

c) Any room that HAI~Scribe prevents a floor joint from being provided in (including Theatres for example);

d) Rooms requiring a sterile environment; and

e) Any room with (now or in the future) tracking hoists or other similar lifting equipment

9.7 Superstructure

9.7.1 The Works primarily comprise the following elements:

a) Acute Adults and Children's Hospital;

b) New Laboratories Building;

c) New Energy Centre; and

d) External works and roadways/infrastructure, including utilities.
(Multi-storey car parks by others).

General

9.7.2 The Contractor shall provide designs appropriate to the type of buildings and in appliance with all SHBN's, SHTN's HBN's and Codes of Practice. The design of each building should demonstrate.

a) Ability to withstand loads and load combinations imposed on the building, vertical, horizontal, dynamic, temporary etc;

b) Compliance with robustness (tieing) requirements of current Codes of Practice and Technical Standards (Scotland) i.e. progressive collapse requirements;

c) Provision of movement must be included in designs, horizontal, vertical, shrinkage, temperature effects etc;

d) Vibration sensitive equipment will be in use throughout the new faculties. Designs should take cognisance of vibration categories;

e) Integration of building services with structure will be a highly important part of the design process. The Contractor shall demonstrate how design coordination will be achieved;

f) All material used in the design of structures shall be compatible with each other and such things as finishes (e.g. Painted); and

g) The Contractor shall prepare and supply an overall Design Philosophy Statement which should include as a minimum, General Project information, The Site, Design Team Parties, Construction Programme, The Structural Scheme, Design Standard and Sources of Reference, Modelling and Analysis and Calculations and Checking.

Acute Adults & Children's Hospital

9.7.3 The building will comprise basements, large area footprint storied structure (podium decks) and ward block multi-storey towers in 4 wings with associated cores. The Contractor shall demonstrate load paths through the building, identifying such things as transfer structures, stability cores, basements, retaining walls and foundations.

9.7.4 It is anticipated that a Helipad will be provided at roof level. The Contractor shall demonstrate a design in compliance with HBN 15-03 Hospital Helipads and identify in particular,

a) Size of helipad;

b) Size of helicopter designed for a loading applied to roof structure;

c) Load transfer of helipad structure to hospital roof structure;

d) Ramp access from/ to pad/ roof; and

e) Integration with emergency services requirements, such as fire fighting systems.

New Energy Centre

9.7.5 The Contractor is required to provide a building structure housing the new equipment that will service the overall hospital development. It is anticipated that large heavy equipment, boilers, generators, CHP plant etc. will be integrated into the design. Large spaced, double storey heights etc. will be required.

New Multi-storey Car Parks (by others)

9.7.6 The Contractor is required to provide a road and drainage and external works design that reflects and takes cognisance of the overall site, including the provision of new multi-storey car parking. Refer to Masterplan Layout for locations and sizes/ capacity of new car parking requirements.

9.8 Fire & Corrosion Protection

9.8.1 The Contractor shall provide fire protection to all elements of structure and ensure fire ratings are in compliance with space used and the more onerous of Building Regulations/the Board's requirements.

9.8.2 The Contractor shall provide a corrosion protection system appropriate to the various structural elements and their location of the buildings.

9.8.3 The corrosion protection system used shall be relevant to type of structure and its structural function and its material and location within the overall building frame. All materials used shall be compatible with each other and with surface finish materials. Reference should be made to the design life of the building structures and finishes, refer Section 5.0.

9.9 Durability & Maintainability

9.9.1 All elements of the structure shall be capable of withstanding potential deterioration due to weather, ground conditions, wear and tear, and accidental damage relevant to their location and environment.

9.9.2 Where the requirement for maintenance is less than the required life expectancy of the element(s) practical and realistic arrangements shall be designed into the construction of the Works to allow for any necessary repairs, replacements and painting etc. to be carried out safely without compromising the operational activities within and around the Works.

9.9.3 Contractor to provide a strategy statement on maintenance and replacement.

9.10 Other Performance Requirements

9.10.1 The Contractor shall ensure that all building elements and retaining structures shall incorporate appropriate means to resist the passage of dampness, both into the building structure and fabric, and into the accommodation, including the resistance to any hydrostatic pressure. The Contractor shall ensure that all such construction shall be in accordance with the requirements of the Building (Scotland) Regulations 2004, BS8102 and Code of Practice CP 102 for Protection of Structures against Water from the Ground.

9.11 Underground Drainage

9.11.1 A 'Drainage Impact Assessment and Strategy Report' has been prepared (see Appendix L) and is prescriptive in outlining the requirements which are to be assessed and met in respect of the foul and surface water drainage from the development. The report covers, *inter alia*:-

a) The proposed surface water drainage strategy and the resulting surface water drainage network design considerations and projected amendments to existing culverted watercourses;

b) The proposed foul water drainage strategy, projected foul flows and the drainage network anticipated. The Contractor is required to confirm by calculation their own assessment of flows for the development;

c) Sustainable Urban Drainage criteria which require to be met for each element of the development. Again, the Contractor is required to review the requirements and develop appropriate methods for implementation of the treatment required;

d) The management and maintenance of the designed drainage systems shall be accompanied by a summary which details the residual requirements for maintenance of each element of the drainage system, including parts of the network prospectively vestable in Scottish Water; and

e) The criteria for assessment of Flood Risk for the designed drainage networks and the development as a whole. The requirements for mitigation of the assessed flood risk and the appropriate finished floor levels for access, egress and buildings are also outlined for the Contractors to address.

9.11.2 In the development of the guidance within the 'Drainage Impact Assessment and Strategy Report', the Contractor shall be responsible for liaison with the relevant stakeholders in agreeing connection requirements to the surrounding public sewers, watercourses and drainage networks. The Contractor is responsible for the design and construction of a drainage solution that meets all the requirements of and satisfies the relevant regulatory authorities including, but not limited to, GCC, SEPA and Scottish Water.

9.11.3 All phases of the development shall treat the disposal of surface water in accordance with the principles of 'The SUDS Manual' Report no C697 published by CIRIA (March 2007)

9.11.4 The Contractor shall provide, where necessary within the on-site drainage network any isolators, retention traps, interceptor tanks and other such devices necessary to prevent the discharge of any potentially dangerous or otherwise contaminative materials to the public sewers.

9.11.5 The Contractor shall design and provide separate foul and surface water drainage systems in accordance with the requirements of the Building (Scotland) Regulations 2004.

9.11.6 All drainage shall be designed to avoid the risk of local flooding and flooding of the system into which they discharge. Flooding of electrical equipment areas and areas where stray current leakage may occur in the presence of water shall be prevented.

9.11.7 Drainage shall be sufficient to ensure that no areas of standing water occur outwith extreme storm events. The drainage systems shall be capable of coping with, as a minimum, the foul loading and the storm event specified by the relevant authority and shall be considered an integral part of

the public sewerage system. This shall include any storage required on the public network to offset the assessed impact of the development.

9.11.8 The drainage system shall be capable of taking such detritus as may normally arise during the operation of the system and during normal and winter maintenance conditions and those within the design criteria of the relevant authority.

9.11.9 The Contractor shall design the drainage system in such a way as to minimise the requirement for internal manholes.

9.12 Roads, Footpaths, Cycle paths and Car Parking

9.12.1 The extent of adoptable and non-adoptable roads is shown on the Exemplar layout drawings.

9.12.2 The Contractor shall provide a network of internal roadways providing;

a) a spine road network through the site between Govan Road and Hardgate Road to facilitate the increased levels of Hospital traffic;

b) a road network through the site between Govan Road and Hardgate Road with designated provision for blue light ambulances, related and relevant to the position of A&E services at all phases of the development;

c) a public transport hub served independently served from (a) or (b) above and in keeping with the requirements of the 'Clyde Fastlink' proposals being promoted by Glasgow City Council;

d) service access to the relevant areas as indicated on the Masterplan, which will be independent of any of the networks in (a) – (c) above;

e) sufficient Ambulance provision at A&E as outlined elsewhere in these requirements, and separate provision for temporary private vehicle layover in the same environs; and

f) a taxi / car drop-off and layover bay at an appropriate location and geometry to effect the efficient and safe pick-up and dropping off of visitors and other users of the hospital facilities.

A maximum of 3,500 car parking spaces, comprising 2400 staff and 1100 visitor / patient spaces are being created on site by others. The Contractor shall require to liaise with the Board and the consultant teams and contractor(s) carrying out this work in order to establish common routes, levels and other relevant co-ordination requirements.

9.12.3 The layout and geometry of the network of internal roads shall be generally in accordance with the Masterplan and exemplar layout provided to the Contractor.

9.12.4 The Contractor will provide details of junction upgrades including priority control measures for blue light ambulances and provision for 'Clyde Fastlink' shall be developed by the Contractor in consultation with Glasgow City Council.

9.12.5 The Contractor shall design the construction of new roads in accordance with the Glasgow City Council 'Roads Development Guide' for a Traffic Distributor Road. Pavements shall provide a residual design life at the year of completion of the works of no less than 40 years.

9.12.6 The Contractor is responsible for all approvals and consents in relation to all on-site and any off-site road, footpath, cycleway or other transport requirement.

9.12.7 The Contractor shall ensure that all roads, delivery and refuse collection areas have sufficient headroom above them to allow for the passage of appropriate emergency, servicing, delivery or refuse collection vehicles and are designed to provide sufficient space to allow efficient manoeuvring of such vehicles without undue difficulty, risk of impact or adverse effect of exhaust fumes on occupants of the buildings.

9.12.8 All structures which support roads / footpaths / cycleway shall be designed in accordance with the relevant provisions of the Design Manual for Roads and Bridges, and assume design loadings equivalent to the maximum permitted vehicle on the public highway.

9.12.9 The Contractor shall ensure that all roads, car parks and other areas that may be used by fire appliances shall have sufficient headroom for such vehicles and are designed to allow their efficient manoeuvring. The Contractor shall agree with the Board the types of delivery vehicles, which require to be considered in the design. Refer to briefing paper, facilities service yard/compound in Appendix L.

9.12.10 New car parks within the Site shall be designed by The Contractor to comply with applicable SHTM, HTM, HBN 45, HFN 20, HFN 21 and the requirements of Glasgow City Council Roads Development Guide.

9.12.11 Details showing the phased construction of all temporary and new car parking facilities constant with the masterplan shall be provided by the Contractor.

9.12.12 Where areas of surface car parks are required to be traversed by vehicles heavier than 2500kg for maintenance or access purposes, the sub-base and surfacing of these areas shall be specifically designed by The Contractor for these heavier loads.

9.12.13 Roads, delivery and refuse collection areas, and car parks, together with their supporting groundworks and structures, shall be designed by The Contractor to provide full and sufficient access for inspection, maintenance and repair of roads, car parks, delivery and refuse collection areas, structures, underground and underground drainage, including existing drainage items such as manhole covers and drains. Where access for maintenance, repair or replacement of underground services is required under the terms of an easement, the design of all elements affecting the exercise of such an easement shall also be in accordance with the requirements of the company that has the right to exercise the easement.

9.12.14 The Contractor shall also comply with the following criteria:

a) To roads, footways, footpaths and cycleways, construction is to be bituminous and in accordance with Glasgow City Council's Roads Development Guide appropriate for a Traffic Distributor Road;

b) Proposals for differential surfacing to pedestrian crossing areas are sought and shall be submitted by the Contractor for approval. Surfaces shall provide 20 years life before replacement form the date of completion of the works;

c) Cycleways shall include green surface finish utilising a recognised surfacing material which will provide 20 years life before replacement form the date of completion of the works;

d) Pedestrian crossings: types, locations, lighting and controls shall be agreed with the Board (controlled crossings to be included, exact locations to be agreed at design development stage);

e) Kerbs: to comply as a minimum standard with BS7263, Part 1: Pre-cast Concrete channels and edgings;

f) Traffic Signs and Markings to be designed to The Traffic Signs Regulations & General Directions 2002 and The Traffic Signs Manual (part of the Design Manual for Roads &

Bridges), and for the Board's approval. Markings and signage shall dimensioned apposite to a road with a design speed equivalent to 30mph;

g) Supplementary signage to support the management of traffic to preserve the provisions in (a) to (g) above shall be submitted for the Boards approval. Furthermore, the Contractor shall design and provide appropriate signage external to the car parking and other facilities to ensure ease of navigation around the Site for intermittent or infrequent users;

h) Gradients outwith carriageways shall comply with the provisions of HBN 45 and the Building (Scotland) Regulations 2004 as applicable. No gradient in excess of 1:20 shall be allowed in parking areas (other than access roadways), and 1:15 on pedestrian staff, patient and visitor access paths from parking areas to the building entrances;

i) Parking bays: comply with the reference documents, HBN 45, HBN 20, HFN 21 and the item on gradients above. The minimum parking standard parking bay shall be 2.5 x 4.8 m. Variation from the standard (to make optimum use of the space for example) may be desirable and allowed subject to agreement with the Board; and

j) Traffic parking restrictions and parking management: to be agreed with the Board.

9.12.15 Designs shall cater for the access and parking needs of pedestrians and the physically disadvantaged. This shall involve catering for visitors and staff using different modes of transport in adapted vehicles and with multiple aids / equipment.

9.12.16 This is to allow tailgate access by disabled people without the need to set ramps or lifts down within the main circulation routes of car parks. The first and last accessible parking bays in a row of 'in line' spaces shall be provided with a minimum clear area of 1.2m to both sides.

9.12.17 Parking for the transport requirements of deliveries and waste disposal, ambulances, fire appliances and other specialist and emergency vehicles shall be segregated from public and staff parking.

9.12.18 Car parking provision shall take into account the following requirements:

a) Dedicated parking for those with disabilities, the elderly and those with small children located close to the clinical areas, especially for those with limited mobility and eyesight;

b) Space for larger vehicles, which may be fitted with wheelchair ramp or carrying specialist mobile equipment from / to the Works (such spaces will be larger than the normal car parking space);

c) Appropriate zoned parking for night staff as near as practical to the controlled night entrance for staff; and

d) Electric car charging facilities in a minimum of 20nr bays.

9.13 Other External Works

9.13.1 The Contractor shall design the external works for ease of navigation and progression around the site by staff, patients and visitors.

9.13.2 The Contractor shall seek advice from the Board to seek to minimise the risk of crime and vandalism on the Works. This advice shall be pro-actively sought by the Contractor as part of the design process.

9.13.3 The Contractor shall seek advice from Strathclyde Police's crime prevention representative on the proposals for external works to minimise the risk of crime and vandalism on the Site and the Works, including compliance with Secure by Design.

9.13.4 The Masterplan and accompanying landscape drawings demonstrate the general arrangements of the external works.

9.14 Hard Landscaping Requirements

9.14.1 The Contractor shall incorporate into the Works all associated hard landscaping for the Site, including but not limited to, the following:

a) Access and hardstanding for emergency and delivery vehicles;

b) Access for building maintenance and window cleaning;

c) Access and circulation for, visitors and patients on foot, bicycles, in cars or on public transport;

d) Parking for vehicles and bicycles including disabled facilities;

e) Drop-off facilities including lay-bys and bus/transport stops;

f) Service areas, as appropriate;

g) Accommodation for building services plant, waste and materials management, as appropriate;

h) Amenity areas for staff, patients and visitors;

i) Suitable pathways and paving;

j) Protection against noise and environmental pollution;

k) Security provisions, as appropriate;

l) Appropriate Site boundary treatment;

m) Walls, fencing, gates / barriers and hedgerows as appropriate along the Site Boundary and at particular locations inside the Site;

n) CCTV surveillance to all car parks, pedestrian routes, cycle paths, therapy gardens and other specified external areas;

o) External lighting;

p) Suitable means of shelter against adverse weather conditions at entrances, bus/transport waiting, and drop-off locations and covered links provided, as appropriate;

q) Automatic vehicle access barriers; and

r) Fire hydrants.

Section 10.0 Sustainability

10.1 Sustainability

10.1.1 The consideration and implementation of sustainable facilities is a key concern and requirement of the Board in all its functions and activities.

10.1.2 The particular low carbon and sustainability considerations and requirements of the Board are provided in Section 8.0 and Appendix M.

10.1.3 The carbon management plan of the Board is contained for reference in Appendix P.

10.1.4 Guidance with regard to the consideration and assessment of BREEAM points are contained in Appendix U for reference.

Section 11.0 Community Engagement

11.1 Community Engagement

11.1.1 The consideration and implementation of Community Engagement (CE) initiatives is of great importance to the Board. The requirements of the Contractor with regard to CE in relation to the Works are contained in Appendix V.

Section 12.0 Bid Return Requirements

12.0 Bid Return Requirements

12.1 The particular bid return requirements of the Board are identified and listed, along with the evaluation process, in Volume 3 of this ITPD.

12.2 It is anticipated that the bid return information will allow the Board to assess the bids and select a private sector partner to contract with.

12.3 The Contractor will then work with the Board through the Stage 3 Design Development period to produce the FBC design requirements as identified in Appendix K.

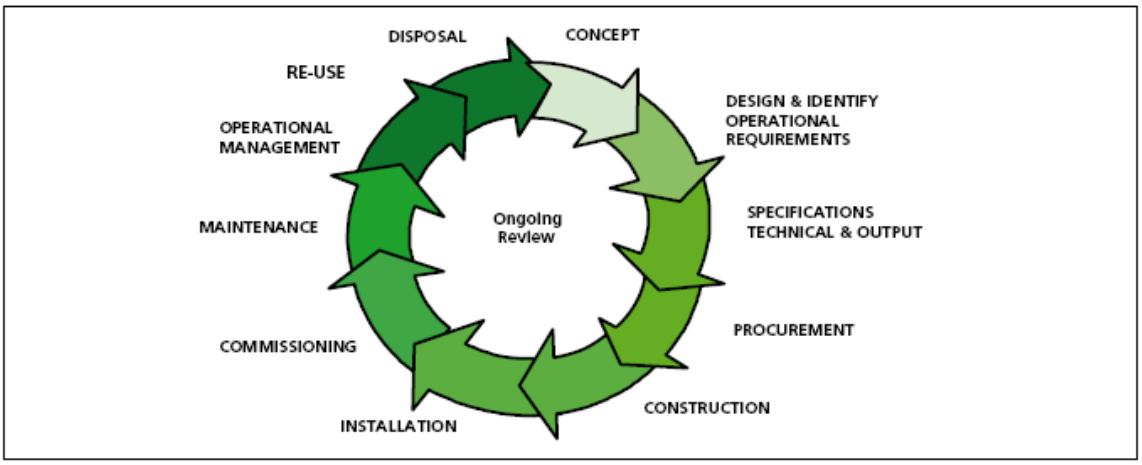
Preface

About Scottish Health Technical Memoranda

Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of SHTM guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle:



Healthcare building life-cycle

Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

It is not the intention within this suite of documents to unnecessarily repeat international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The new core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- Provides a structured reference for healthcare engineering.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Structure of the Scottish Health Technical Memorandum suite

The new series of engineering-specific guidance contains a suite of nine core subjects:

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Scottish Health Technical Memoranda in this series)

Scottish Health Technical Memorandum 01: Disinfection and sterilization

Scottish Health Technical Memorandum 02: Medical gases

Scottish Health Technical Memorandum 03: Ventilation systems

Scottish Health Technical Memorandum 04: Water systems

Scottish Health Technical Memorandum 05: Reserved for future use

Scottish Health Technical Memorandum 06: Electrical services

Scottish Health Technical Memorandum 07: Environment and sustainability

Scottish Health Technical Memorandum 08: Specialist services

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc. Example: Scottish Health Technical Memorandum 06-02 Part A will represent: Electrical Services – Safety – Low Voltage. In a similar way Scottish Health Technical Memorandum 07-02 will simply represent:

Environment and Sustainability – EnCO_2de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

Executive summary

Introduction

A medical gas pipeline system (MGPS) is installed to provide a safe, convenient and cost-effective system for the provision of medical gases to the clinical and nursing staff at the point-of-use. It reduces the problems associated with the use of gas cylinders such as safety, porterage, storage and noise.

This Scottish Health Technical Memorandum is divided into two parts. Guidance in this part (Part A) covers piped medical gases, medical and surgical air, and medical vacuum installations: it applies to all medical gas pipeline systems installed in healthcare premises and anaesthetic gas scavenging disposal systems. Specifically, it deals with the issues involved in the design, installation, and validation and verification (testing and commissioning) of an MGPS. Part B covers operational management.

The guidance given in this document should be followed for all new installations and refurbishment or upgrading of existing installations. All new works should be subject to a design review / validation prior to installation by the AP, AE or CSO.

It is not necessary to apply the guidance retrospectively unless patient or staff safety would be compromised. In this case, the guidance given in this document should be followed.

Existing installations should be assessed for compliance with this guidance document. A plan for upgrading the existing system should be prepared, taking account of the priority for patient safety. Managers will need to liaise with medical colleagues and take account of other guidance published by the Scottish Government Health Directorates in order to assess the system for technical shortcomings.

Scottish Health Technical Memorandum 02 supersedes all previous versions of Scottish Health Technical Memorandum 2022. Where SHTM 2022 has been used as the contractual document within current projects, SHTM 2022 would be applicable.

Sources of supply for pipeline installations

Oxygen

Oxygen is generally supplied from:

- a liquid source such as a large vacuum insulated evaporator (VIE);
- liquid cylinders or compressed gas cylinders; or
- a combination of these to provide the necessary stand-by/back-up capacity.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Oxygen can also be supplied from an oxygen concentrator (pressure-swing adsorber). Such systems are usually installed where liquid or cylinders are expensive, unavailable or impracticable.

Medical air

Medical air is usually supplied from a compressed air plant that includes high-quality drying and filtration equipment. Blending oxygen and nitrogen on-site to provide a high-quality product with minimum maintenance can also provide medical air. Where such systems are installed to provide both oxygen and medical air, nitrogen can be used for the power source for surgical tools.

Other gases

All other gases are supplied from cylinders.(On-site blended oxygen/nitrous oxide mixture is a possibility if bulk liquid supplies of nitrous oxide are available, although this system is unlikely to be adopted in the UK.)

Basic principles of design

Patient safety is paramount in the design, installation, commissioning and operation of medical gas pipeline systems. The basic principles of safety are achieved by ensuring quantity of supply, identity of supply, continuity of supply and quality of supply.

Quantity of supply

This is achieved by ensuring that the design of the pipeline installation and capacity of the supply plant is sufficient to provide the required flows of gases and vacuum for the intended number of patients to be treated at any one time. Adequacy of supply is established during commissioning of the systems.

Identity of supply

This is achieved by ensuring that all points to which the user can connect medical equipment (terminal units) and user-replaceable components are provided with gas-specific connectors. Such connectors are also identified by symbol and often colour. The gas specificity is maintained by comprehensive tests and checks during installation and commissioning, and during any work or maintenance on the systems.

Continuity of supply

This is achieved by installing, as a minimum, duplex components and providing additional means of supply provision in the event of failure of the primary and secondary plant supply system. Systems are also connected to the essential electrical supply.

Quality of supply

Quality of supply is ensured by the use of gaseous or liquid sources that are provided to an appropriate product specification, usually a recognised European

© Health Facilities Scotland, a division of NHS National Services Scotland.

Pharmacopoeia (Ph. Eur.) monogram. In the case of compressor-based systems, filtration equipment to a known and agreed standard is installed. To ensure that the product is not adulterated in the distribution system, pipeline installations and components are required to meet agreed specifications. There are strict Ph. Eur. requirements for medical gases.

General uses of gas and pipeline installations

- oxygen is one of the most extensively used gases for respiratory therapy and life-support and is additionally used in anaesthetic procedures;
- medical air is mainly used in respiratory therapy as a power source for patient ventilators, and for blending with oxygen; it is also used as the driving gas for nebulised drugs and chemotherapy agents;
- surgical air (of medical air quality) is also used, at a higher pressure, to power a variety of surgical tools and other devices such as tourniquets. (As an alternative, nitrogen can be used for this purpose.);
- nitrous oxide is used for anaesthetic and analgesic purposes, being mixed with air, oxygen, and nebulised agents;
- pipeline systems for a 50% mixture of oxygen and nitrous oxide are widely installed in the UK for analgesic purposes, particularly in maternity departments;
- helium/oxygen mixture is used to treat patients with respiratory or airway obstruction and to relieve symptoms and signs of respiratory distress; guidance on pipeline systems is now included;
- carbon dioxide is used less commonly now as a respiratory stimulant, and for insufflation during surgery. Pipeline systems for respiratory use have not been installed in the UK but they are now being installed for this latter purpose;
- piped vacuum is provided in most clinical areas by means of centrally sited vacuum pumps;
- the control of occupational exposure to waste anaesthetic gas (nitrous oxide) and nebulised agents is a legal requirement under the Control of Substances Hazardous to Health (COSHH) Regulations 2002. Where nitrous oxide is provided for anaesthetic purposes, scavenging systems are installed.

1. Scope

Guidance in this document

1.1 This Scottish Health Technical Memorandum is divided into two parts. Guidance in this part (Part A) covers piped medical gases, medical and surgical air, and medical vacuum installations; it applies to all medical gas pipeline systems installed in healthcare premises. Anaesthetic gas scavenging disposal systems are also included. Specifically, it deals with the issues involved in the design, installation, and validation and verification (testing and commissioning) of an MGPS. Part B covers operational management.

1.2 The guidance given in this document should be followed for all new installations and refurbishment or upgrading of existing installations.

1.3 It is not necessary to apply the guidance retrospectively unless patient or staff safety would be compromised. In this case, the guidance given in this document should be followed.

1.4 Existing installations should be assessed for compliance with this guidance document. A plan for upgrading the existing system should be prepared, taking account of the priority for patient safety. Managers will need to liaise with medical colleagues and take account of other guidance published by the Scottish Government Health Directorates in order to assess the system for technical shortcomings.

1.5 Throughout this document, “medical gas pipeline system(s)” will be described by the term MGPS.

Other guidance

1.6 Model Engineering Specification C11: ‘Medical gases’ It is anticipated that this publication will be subject to review for compliance with current standards.

1.7 Guidance on the provision of MGPS is given in the Scottish Health Planning Notes (SHPN’s) Health Building Notes that are still applicable in Scotland and other relevant British, European, and International standards.

© Health Facilities Scotland, a division of NHS National Services Scotland.

2. General principles

Introduction

2.1 An MGPS is designed to provide a safe and effective method of delivering medical gases, medical air and surgical air from the source of supply to the appropriate terminal unit by means of a pipeline distribution system. Medical vacuum is also provided by means of a pipeline system. Anaesthetic gas scavenging disposal systems are provided to control occupational exposure to waste anaesthetic gases and agents.

2.2 It is essential to ensure that there is no possibility of a cross-connection between any system and that all parts of each system to which connections can be made by users are gas-specific.

2.3 Dental compressed air and vacuum systems have differing requirements, and these are covered in Scottish Health Technical Memorandum 2022, Supplement 1: 'Dental compressed air and vacuum systems'. Scottish Health Technical Memorandum 2022 Supplement 2 is concerned with piped medical gases in ambulance vehicles.

2.4 During the installation stage, extensive tests are carried out to verify that there is no cross-connection.

2.5 Medical gas systems may be extended to those departments where respiratory equipment or surgical tools are serviced, such as in electronic and biomedical equipment (EBME) workshops and sterile services departments (SSDs). Specific additional uses of air systems are covered in Sections 7 and 8.

2.6 MGPS should not be used to supply university, pathology and dental laboratories or workshops, steriliser equipment, seals, chamber ballast or controls, washer/disinfection and endoscope drying procedures, air conditioning or other mechanical services. Consideration can be given to the use of MGPS where a university theatre or room teaching medical procedures forms part of the hospital complex.

2.7 Separate installations should be provided for pathology and general laboratories and workshops, although it is recommended that they be constructed to the same specification as MGPS. They should not be provided with medical gas terminal units. Scottish Health Technical Memorandum 08-06 refers.

Note 1: Portable suction devices should be used in infectious disease units.

Quality requirements for medical gases and air

2.8 Medical gases supplied from cylinder or liquid sources comply with the appropriate sections of the current edition of the European Pharmacopoeia (Ph. Eur.). The Ph. Eur. also specifies the approved testing methods to be adopted for gas identity.

© Health Facilities Scotland, a division of NHS National Services Scotland.

2.9 The quality specification for medical, surgical and synthetic air, and oxygen-enriched air produced from a pressure swing adsorber (PSA) system, is as given in Table 42. The medical air and synthetic air should also comply with the appropriate sections of the current edition of the Ph. Eur. (see Table 43).

2.10 The quality of piped medical compressed air, and the particulate content, dryness and concentration of impurities should comply with the requirements for maximum concentrations given in Table 43. Information on testing procedures is given in Section15 “Validation and verification”.

2.11 Bacteria filters should be included in medical and surgical compressor systems to reduce the risk of delivering spores or other infectious material to vulnerable patients.

2.12 Micro-organisms can penetrate a bacteria filter if the material is wet. Therefore it is essential that the dryness of the medical air supplied to a bacteria filter is checked regularly (at least every three months) at the test point, using the test equipment specified in Section15.

Sources of supply

2.13 Both BS EN 737-3: 2000 and BS EN ISO 7396-1: 2007 + A2: 2010 (which replaced the former standard from 30 April 2009) propose that all medical gas supplies should comprise three sources of supply identified as “primary”, “secondary” and “reserve”, although the latter is more commonly referred to as a third means of supply. The supply system should be designed to achieve continuity of supply to the terminal units in normal condition and in a single fault condition. A single fault condition is where a single means for protection against a safety hazard in equipment is defective or a single external abnormal condition is present. Loss of supply due to maintenance of a supply source (or a component within it) is not considered a single fault condition. Failure of the pipeline is considered a catastrophic event and is not regarded as a single fault condition.

2.14 With respect to individual banks of a cylinder manifold installation, this Scottish Health Technical Memorandum (SHTM) refers to separate banks of an automatic manifold as primary and secondary supplies as prescribed within BS EN ISO 7396-1: 2007 + A2: 2010. This SHTM will classify an automatic manifold as a single source of supply, when applied to liquid oxygen, medical and surgical air systems.

2.15 Regardless of these classification differences, the choice of central source will be defined by the ability of the source not only to provide a continuous supply of gas over a range of possible flow rates but also to offer security of supply by virtue of adequate capacity.

2.16 For these reasons, types, capacities and locations of primary, secondary and reserve sources of supply will be based on both system design parameters and the need for supply security, identified by a risk assessment during the planning stage. Security of medical air supplies must be given a high priority. Tables 1–9

© Health Facilities Scotland, a division of NHS National Services Scotland.

describe the various options for gas supply. For each, the primary, secondary and reserve sources are identified.

Primary supply	Secondary supply	Reserve supply (third source of supply
Duty bank of a fully automatic manifold. Number of cylinders based on system design.	Standby bank of a fully automatic manifold.	Manual emergency reserve manifold - to come on line automatically via a non-return valve in the event of a single fault condition and to act as a reserve supply during maintenance / repair works. Type and capacity of supply to be determined by risk assessment.

Table 1: Compressed gas cylinder manifold systems

Primary supply	Secondary supply	Reserve supply (third source of supply)
Simplex VIE (vacuum insulated evaporator) vessel system	Automatic cylinder manifold system. To come on-line in the event of plant failure	Automatic cylinder manifold system. May be sited to support high-dependency areas or whole site OR Locally-based integral valved cylinders with regulators/flowmeters attached.
One vessel of a duplex VIE (vacuum insulated evaporator) vessel system (on same plinth).	Second vessel of a duplex VIE system.	Automatic cylinder manifold system. May be sited to support high-dependency areas or whole site.
One vessel of a duplex VIE vessel system (on separate plinths).	Second vessel of a duplex VIE system (on separate plinths). NB split-site systems are intended primarily for systems where the risk assessment has identified that the site for the primary supply is limited in size or presents too high a risk having both tanks on the same site. These supply systems should be fitted with appropriate non-return valved connections to prevent gas loss in the event of one tank/system failing.	Type and capacity of supply to be determined by risk assessment. May not be required when remote dual supplies are connected to a ring main or to a mains (linked) pipeline distribution system. (Note: a ring main or distribution pipeline is not regarded as a reserve supply (third source of supply)

Table 2: Bulk liquid oxygen VIE systems

© Health Facilities Scotland, a division of NHS National Services Scotland.

Primary supply	Secondary supply	Reserve supply (Third source of supply)
Liquid cylinder or liquid cylinder manifold system. NB: The latter is NOT a changeover manifold. All cylinders are on-line simultaneously.	Automatic cylinder manifold system. To come on-line in the event of plant failure.	Automatic cylinder manifold system. May be sited to support high-dependency areas or whole site OR Locally-based integral valved cylinders with regulators/flow meters attached.

Table 3: Liquid oxygen cylinder system

Primary supply	Secondary supply	Reserve supply (Third source of supply)
Multiplex compressors and columns (adsorbers). Subject to design.	Automatic cylinder manifold system. To come on-line in the event of plant failure. May be fitted with third party cylinders, or filled from compressor of main plant. Number of cylinders should have sufficient connected capacity to supply the site for at least 4 hours. Locally filled cylinders or gas suppliers' cylinders can be used.	Type and capacity of supply to be determined by risk assessment.

Table 4: PSA plant

Primary supply	Secondary supply	Reserve supply (Third source of supply)
First compressor of a duplex compressor system.	Second compressor of a duplex compressor system.	Automatic cylinder manifold system. To come on-line automatically in the event of plant failure. Type and capacity of supply to be determined by risk assessment.
First compressor of a triplex compressor system.	Second compressor of a triplex compressor system.	Third compressor of a triplex compressor. In addition, an automatic cylinder manifold system to support a dedicated department(s) or whole site.
Two compressors of a quadruplex compressor system.	Other two compressors of a quadruplex compressor system.	Automatic cylinder manifold system to support whole site.

Primary supply	Secondary supply	Reserve supply (Third source of supply)
First pump of a triplex pump system.	Second pump of a triplex pump system.	Third pump of a triplex pump system with additional portable suction equipment available.
Two pumps of a quadruplex pump system.	Other two pumps of a quadruplex pump system.	Portable suction equipment.

Table 9: Central medical vacuum systems

© Health Facilities Scotland, a division of NHS National Services Scotland.

Notes to Tables 1-9: General guidance on vacuum systems is contained in Appendix L. a) Where duplex vacuum plant is currently installed, a risk assessment should be carried out to establish if a third vacuum pump or replacement plant is required to meet the recommendations of this Scottish Health Technical Memorandum;

b) for duplex and triplex compressor systems and triplex vacuum pump systems, each compressor/pump will be sized to provide the system's full design flow;

c) for quadruplex systems, each compressor/pump will be sized to provide half the system design flow;

d) for all compressor systems with a design flow greater than 500 litres/min, two receivers, each able to be isolated individually, should be installed. For compressor systems with a design flow less than 500 litres/min with a single receiver, a valved bypass line should be installed;

e) all plant is to be connected to the essential electricity supply;

f) for vacuum provision during total electricity supply failure, cylinder – or medical-gas-system-powered vacuum generators can be used;

g) the use of venturi-type vacuum generators is recommended only for emergency use, as these units are generally driven from the medical oxygen system and use large amounts of gas. This can lead to oxygen enrichment and present a potential fire hazard and may result in the emission of pathological material;

h) the emergency reserve manifold supporting a fully automatic manifold is usually sited with the manifold system. If a risk assessment indicates that this is not in the interests of supply security, they may be sited remotely from the manifold. In all circumstances, care should be taken to ensure that appropriate backflow protection (or non-return valves) are used to protect the system from failure of either manifold;

i) manifolds supporting medical air, surgical air and PSA systems should be sited remotely from the compressor systems. Appropriate backflow protection should be provided, as above;

j) surgical air plant may be used as an emergency supply to the medical air 4 bar system;

k) a valved by-pass arrangement around compressor and VIE-plant non-return valves should be considered to facilitate valve replacement or servicing of the non-return valve to avoid disruption to the service without plant shutdown;

l) fitting non-return valves one pipe size larger will reduce flow resistance, if this is shown to be a critical factor in system design;

m) all sources of supply should be fitted with a test point consisting of a terminal unit and lockable isolating valve. Where the test point is located externally, this should be located within a weatherproof enclosure.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Sizing information for gas supply sources

2.17 Table 10, below, provides guidance on suggested maximum sizes for gas sources. Final decisions on plant and manifold capacities will depend on both available accommodation and risks to supply security.

Source	Service	Number of cylinders	Cylinder size	Notes
Automatic manifold	Oxygen	2 x 10	J	Used as a stand-alone manifold or support for cryogenic system / PSA plant
	Medical air	2 x 10	J	Used as a stand-alone manifold or support for compressor plant
	Surgical air	2 x 6	J	For nitrous oxide, a 2 x 2 or 2 x 4 installation may be adequate in some cases – cylinder sizes should be subject to local manual handling operations.
	Oxygen/nitrous oxide mixture	2 x 8	G	
	Nitrous oxide	2 x 6	G	
	Carbon dioxide	2 x 4	VF	
	Helium/oxygen	2 x 4	H	
	Nitrogen	2 x 6	W	
Manual manifold	Oxygen	2 x 2	J	As reserve supply for an automatic manifold system
	Medical air	2 x 2	J	
	Surgical air	2 x 1	J	
	Oxygen/nitrous oxide mixture	2 x 2	G	
	Nitrous oxide	2 x 1	G	
	Carbon dioxide	2 x 1	VF	
	Helium/oxygen	2 x 1	H	
	Nitrogen	2 x 2	W	

Table 10: Suggested sizes for gas sources

© Health Facilities Scotland, a division of NHS National Services Scotland.

Source	Service	Plant size	Receiver / Reservoir Capacity
Duplex compressor system	Medical air	Each compressor sized at full design flow capacity	Receiver water capacity sized at 50% free air delivery (FAD) in 1 minute
Triplex compressor system	Medical air	Each compressor sized at full design flow capacity	
Quadruplex compressor system	Medical air	Each compressor sized at half design flow capacity	
Simplex compressor system	Surgical air	Compressor sized at 1/3 design flow (when design flow <500 litres/min). For design flows >500 litres/min, refer to Table 33.	Refer to Table 33 (para. 8.9)
Duplex compressor system	Surgical air	Each compressor sized at 1/3 design flow (when design flow <500 litres/min). For design flows >500 litres/min, refer to Table 33.	
Triplex pump system	Medical vacuum	Each pump sized at full design flow capacity	Water capacity of reservoir sized at design flow in 1 minute
Quadruplex pump system	Medical vacuum	Each pump sized at half design flow capacity	

Table 10: (cont'd) Suggested sizes for gas sources

2.18 Sizing of vacuum insulated evaporator (VIE) systems, liquid cylinder storage systems, PSA plant and synthetic air plant should be based on historical consumption data and appropriate risk assessments carried out with the medical gas supplier. Allowance should be made for increases in the use of medical gases and changes to the gas demands caused by local developments and strategic issues. For a completely new site, the proposed gas supplier will need to be consulted so that a review of their historical data can be conducted for similar sites. The graph shown in Appendix M will give an approximate indication of expected annual consumption, based on the number of hospital beds. It should be noted that higher consumption could be expected when, for example, high numbers (>20) of continuous positive airway pressure (CPAP) machines are in frequent use (>40 hours per week).

Note 2: a) Automatic cylinder manifolds are generally expected to hold a minimum of two days' supply on each bank.

b) Sufficient cylinders for changing one complete bank should be stored in the manifold room for all gases except nitrous oxide/oxygen mixture, for which two complete changes should be stored in the manifold room;

c) Sufficient additional cylinders should be held in the medical gas store to ensure continuous supply for one week.

Pipeline distribution system design

2.19 The following general information is required to design an MGPS:

© Health Facilities Scotland, a division of NHS National Services Scotland.

- schedule of provision of terminal units;
- design flow rates and pressure requirements at each terminal unit;
- diversified flows for each section of the pipeline system;
- total diversified flow.

2.20 Guidance on deriving and calculating the above parameters is given in Sections 3 and 4 of this Part A.

2.21 The definition of “departments”, which may comprise several wards, treatment rooms etc, should be agreed at the project design stage to avoid confusion.

Safety

2.22 The safety of an MGPS is dependent on four basic principles:

- identity;
- adequacy;
- continuity;
- quality of supply.

2.23 **Identity** is assured by the use of gas-specific connections throughout the pipeline system, including terminal units, connectors etc, and by the adherence to strict validation and verification procedures of the system.

2.24 **Adequacy** of supply depends on an accurate assessment of demands and the selection of plant appropriate to the clinical/medical demands on the system.

2.25 **Continuity** of supply is achieved by:

- the specification of a system that (with the exception of liquid oxygen systems which may include a secondary vessel) has duplicate components;
- the provision of a reserve (third means of) supply;
- the provision of alarm systems; and
- connection to the emergency power supply system.

2.26 **Quality** of supply is achieved by the use of gases purchased to the appropriate Ph. Eur. requirements or produced by plant performing to specific standards, by the maintenance of cleanliness throughout the installation of the system, and by the implementation of the various validation and verification procedures.

Installation/supply of equipment/maintenance

2.27 The installation of an MGPS should be carried out only by specialist firms who are either registered to BS EN ISO 9001: 2008 /BS EN ISO 13485: 2003 or who can demonstrate that they are actively working towards registration with the scope of registration appropriately defined.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Modifications

2.28 Special precautions are required when existing installations are to be modified or extended, to ensure that all sections of the pipeline system remaining in use are not contaminated, and that the supply to patients is not compromised. The section to be modified should be physically isolated from the section in use. Closure of isolating valves is insufficient for this purpose. Where area valve service units (AVSUs) and/or line valve assemblies (LVAs) have been installed, blanking spades should be used. On older installations where the valve design does not include blanking spades, the pipeline must be physically isolated from the valve with the open ends protected to prevent ingress of dust etc.

2.29 Modification of existing systems may be detrimental to the overall performance of the system. In the case of older systems, there may be insufficient capacity to permit the system to operate safely with the flows typically encountered in use today. Any proposal to extend the system should be subject to a design review to ensure the system has sufficient capacity for adequacy of performance.

2.30 Any work involving alteration, extension or maintenance work on an existing system should be subject to the permit-to-work procedure (see Part B, Section 8).

Removal of pipework

2.31 Removal and cutting out of redundant medical gas pipelines and equipment can present as great a hazard to patient safety as any other modification. All such removal (including cutting into existing pipelines, and capping off and removal of redundant pipework and equipment) should be carried out by specialist medical gas contractors only. General demolition contractors should not carry out this work.

Note 3: Removal of vacuum systems may present additional microbiological hazards and should be undertaken in accordance with routine hygiene practices, that is, covering of open wounds and immediate cleansing and dressing of cuts/scratches received while carrying out the work. Immunisation against certain diseases may be required by the Hospital's occupational health department or the employer of tradespeople, therefore, all operatives should ensure that this requirement has been met. Further advice should be sought from the Hospital's Infection Control Team.

Validation and verification

2.32 The objective of validation and verification is to ensure that all the necessary safety and performance requirements of the MGPS will be met. Validation and verification procedures will be required for new installations, additions to existing installations and modifications to existing installations. The scope of work will dictate the specific programme required. This is described in Section15.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 4: The concept of the existing quality assurance BSI scheme schedule QAS 3720. 1/206/A1 is currently under review. Further guidance will be given when appropriate

General fire precautions

General

2.33 The siting and general structural principles for the design of liquid oxygen storage accommodation are given in Section 6, and the requirements for plantrooms and gas manifold rooms in Section14.

2.34 Guidance on cylinder storage and handling is given in Part B.

Fire detection system

2.35 Smoke or heat detector heads should be installed in the plantrooms, medical gases manifold rooms and (when internal) medical gases cylinder stores in any hospital having a fire detection system in accordance with Scottish Health Technical Memorandum SHTM 85: 'Firecode: alarm and detection systems'. External stores may also require fire detection systems.

Electricity supply to medical gas installations

General

2.36 Electrical installations should be carried out in accordance with the current edition of BS7671 wiring regulations and associated guidance documents.

2.37 Provision of electrical supply and distribution should take account of guidance issued in Scottish Health Technical Memorandum 06-01: 'Electrical services: supply and distribution'.

Resilience of supply

2.38 Medical gas pipeline systems, associated equipment and alarms are a critical service within a healthcare establishment. Due consideration should be given to ensure the continuity of service under mains power failure conditions.

2.39 Each item of plant with respect to medical / surgical air and medical vacuum should be supplied from a dedicated, final sub-circuit which is considered "essential" within the electrical distribution strategy. Alternative means of supply should be considered in the event that internal sub-distribution is compromised.

2.40 In the event of power failure or interruption, all systems should continue to function as they did before the interruption occurred. For example, except for automatic cycling compressors, dryers, pumps etc, the same compressor and dryer (or vacuum pump) set should be on-line, and for manifold systems the same bank should be running.

2.41 All electrical systems, including plant control systems, alarm interfaces etc, should be designed in accordance with electromagnetic compatibility (EMC)

© Health Facilities Scotland, a division of NHS National Services Scotland.

directives. For further details, see the “EMC section” within Scottish Health Technical Memorandum 06-01: ‘Electrical services: supply and distribution’.

2.42 It is important that operational managers and designers are fully aware of stand-by electrical supply arrangements and availability and that plans are available to deal with the total loss of electricity under adverse circumstances.

Electrical installation

2.43 Wiring systems for medical gas installations should be selected in accordance with BS7671 wiring regulations with particular regard to the environment and risk from mechanical damage. In this regard, PVC-insulated MICS (mineral-insulated copper-sheathed) cable for external/ internal locations and heat-rated singles cable in galvanised conduit for plantrooms are considered suitable. For large equipment, fire-rated SWA (steel wire armoured) cable may be appropriate.

2.44 Care should be taken when installing both electrical systems and medical gas pipeline systems to avoid occasional contact between pipework and electrical cables, conduit or trunking. When physical separation is impractical or contact with extraneous metalwork occurs (for example where the pipeline is carried in metal partitions or where terminal units are mounted on metal bed-head units), the pipeline should be effectively bonded to the metalwork in accordance with BS7671 wiring regulations.

2.45 The final connection to any equipment (for example alarm panels or control panels) should be made using a key operated (double pole) fused connection unit should be available to permit work authorised on the equipment.

2.46 Where electrical systems and medical gas pipeline systems are enclosed in a boom, rigid pendant or multi-purpose-type enclosure, care should be taken to ensure that Low Voltage (LV), Extra-Low Voltage (ELV) and communications and data systems are maintained together but separate from pipeline systems. There should be no access to unprotected live parts within the pendant except by the use of a tool. Reference should be made to BS EN ISO 11197: 2009 which gives clear guidance on the requirements for such separation and segregation.

Earthing

2.47 Medical gas pipelines should be bonded together and bonded to the local electrical distribution board in accordance with BS7671 wiring regulations. The pipelines should not in themselves be used for earthing electrical equipment.

2.48 Flexible pipeline connections, wherever used, should be bonded across the fixed points to ensure earth continuity.

2.49 Where a medical gas outlet or pipeline system is present within a group 2 location as defined by IEE Guidance Note 7: ‘Medical locations’, care must be taken to ensure the resistance of the bonding connection is in accordance with the required value.

© Health Facilities Scotland, a division of NHS National Services Scotland.

3. Provision of terminal units, and the location of AVSUs, area alarm panels and LVAs

General

3.1 Terminal unit provision, location of area valve service units (AVSUs) and area alarm panels are given in Table 11. Medical treatment policy is evolutionary, however, and the project team should review requirements for individual schemes.

Terminal units

3.2 Terminal units should be mounted in positions that result in the shortest practicable routes for flexible connecting assemblies, between the terminal unit and apparatus. Terminal units may be surface or flush-mounted. They may also be incorporated with electrical services, nurse call systems, televisions, radio and audio services, in proprietary fittings such as medical supply units, wall panel systems and pendant fittings etc. When they are installed within such fittings, it is essential to maintain the concentricity of the terminal unit bezel with the fascia plate aperture; if the installation is highly eccentric, the bezel will bind on the fascia plate and the terminal unit will not function properly.

3.3 When planning the installation of operating-room pendant fittings, the location of the operating luminaire and other ceiling-mounted devices should be taken into consideration. When the operating room is provided with an ultra-clean ventilation (UCV) system, it may be more practicable (and cost-effective) to have the services (both medical gas and electrical) incorporated as part of the UCV system partial walls. It is particularly advantageous in the case of surgical air systems as rigid pipework can be used, thus avoiding pressure-loss problems that can occur with flexible assemblies used within pendant fittings.

3.4 The following are not permitted:

- floor-mounted terminal units;
- vacuum systems in which body or other fluids are drawn through a fixed pipeline connecting a terminal unit or other connector to a remote suction jar.

3.5 All terminal units should conform to BS EN ISO 9170-1: 2008. Terminal units intended for wall mounting where directly connected equipment such as flow meters are to be used must include a non-swivel device. Terminal units intended for installation with the socket axis vertical, for example on the under-surface of a pendant and intended for use with indirectly connected equipment by means of a flexible connecting assembly, do not require a non swivel device. Dimensions of probes are given in BS5682: 1998. It is essential that probes be machined from stainless steel.

© Health Facilities Scotland, a division of NHS National Services Scotland.

3.6 An anaesthetic gas scavenging (AGS) terminal unit should be provided whenever nitrous oxide and anaesthetic agents are available for anaesthetic procedures. In recovery areas, where nitrous oxide is not provided, there is no primary source of anaesthetic gas pollution; thus, no anaesthetic gas scavenging system (AGSS) is required. Guidance on operating departments requires such areas to be mechanically ventilated. Where nitrous oxide mixed with oxygen is provided for analgesic purposes, scavenging is not generally practicable and pollution should therefore be controlled by mechanical ventilation. Details of ventilation requirements are given in Health Building Note 26 (Volume 1): 'Facilities for surgical procedures'. For dental departments, scavenging is possible by means of nasal masks at a reduced flow of 45 litres/min, and reference should be made to Scottish Heath Technical Memorandum 2022 (Supplement 1): 'Dental compressed air and vacuum systems' (see also Section10).

3.7 The terminal unit (AGS) is specified in BS EN ISO 9170-2: 2008. AGSS's are covered in Section10.

Note 5: Reference should be made to the Department of Health's (1996) 'Advice on the implementation of the Health & Safety Commission's occupational exposure standards for anaesthetic agents'. Further guidance is given in the Health & Safety Executive's (1996) 'Anaesthetic agents: controlling exposure under COSHH'.

3.8 Where respiratory equipment or surgical instruments are serviced, such as in EBME workshops, it is normally necessary to install the full range of medical gas terminal units. AGS should be provided as a dedicated system.

3.9 The fixing of terminal units into medical supply systems or to wall surfaces etc. should be such that the following forces can be applied:

- a lateral force of 20 N applied at 50mm from the surface of the terminal unit without dislodgement or breakage;
- an axial force of 500 N without dislodgement or breakage.

3.10 Where an array of terminal units is provided at a location, they should be arranged as follows (see Figure 1):

- for a horizontal array, when viewed from the front, left to right: oxygen, nitrous oxide, nitrous oxide/oxygen mixture (50% v/v), medical air, surgical air, vacuum, anaesthetic gas scavenging, helium/oxygen mixture. If this arrangement is impracticable, a number of rows can be used;
- for a vertical array, with oxygen at the top and in the sequence as for a horizontal array. In many cases a vertical array is impracticable and a more convenient arrangement will comprise a number of rows/columns;
- for a circular array, for example where terminal units are installed on the under-surface of a pendant, with the sequence as for a horizontal array, in a clockwise direction when viewed from below. The AGS terminal unit may occupy the centre of such an array;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- On occasion, the user may require the configuration of outlets to be out of sequence from that shown in Figure 1 a) to d), however, this should be agreed in line with contractual requirements.

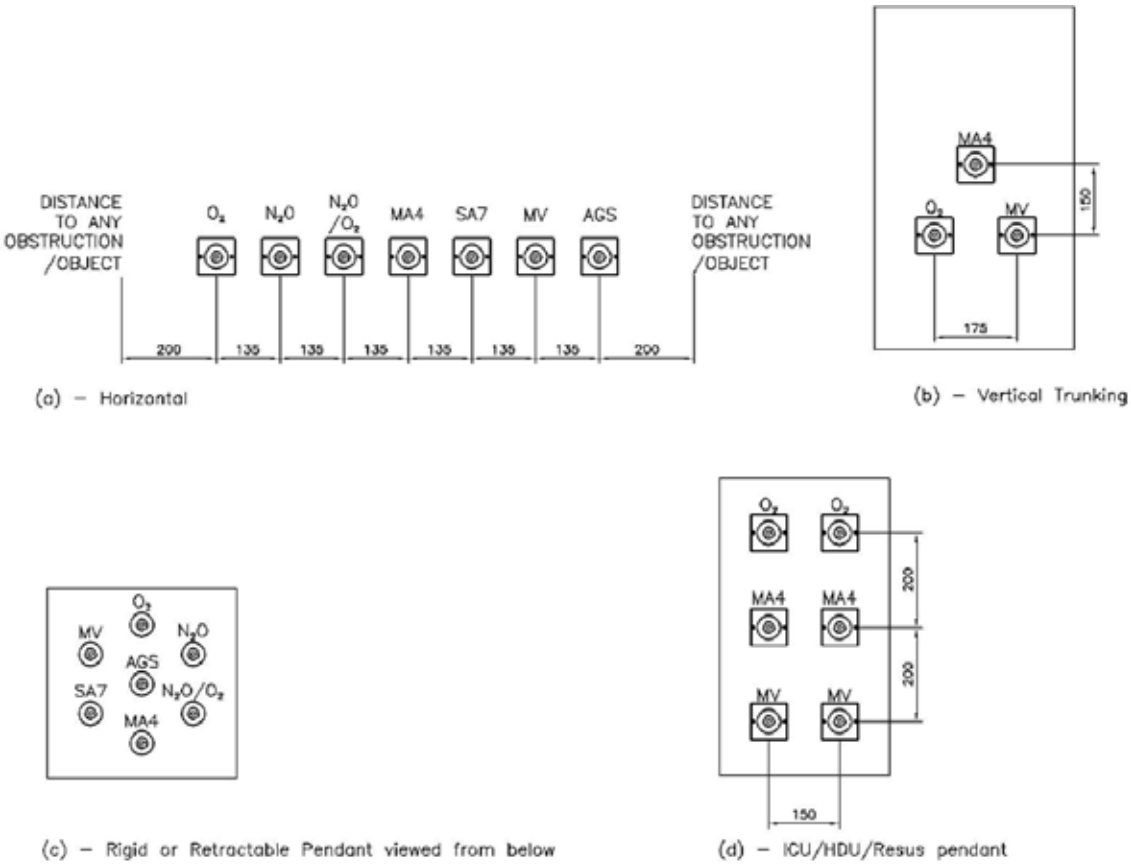

Figure 1: Terminal unit mounting order

3.11 Oxygen/carbon dioxide mixture systems have been installed, but are no longer covered by this Scottish Health Technical Memorandum.

3.12 Helium/oxygen mixtures may be required to be supplied by pipeline in some critical care areas. Systems for these are included in Section 11.

3.13 Mounting heights for terminal units should be between 900mm and 1,600mm above finished floor level (FFL) when installed on walls or similar vertical surfaces – the optimum height for the convenience of users of the medical gas system is 1,400mm (see Figure 2). When terminal units are incorporated within a horizontal bedhead service trunking system, which also provides integrated linear lighting for general room and/or patient reading illumination, it should be of a design that does not compromise the convenience of the medical gas facility. Where there is a desire to mount terminal units below 900mm e.g. below worktops in some dental surgery configurations, prior agreement should be sought from the User.

3.14 When installed in pendants or similar, terminal units should be of a type suitable for mounting within the specified fitting.

3.15 Pressure losses across terminal units should be in accordance with BS EN ISO 9170-1: 2008. The standard does not give pressure loss data for surgical air at 350 litres/min, but this can be ≥150 kPa when connected via a ceiling NIST

© Health Facilities Scotland, a division of NHS National Services Scotland.

(non-interchangeable screw thread) connector and 5m of hose. This pressure drop could be reduced by removing the non-return valve within the NIST connector and installing a line valve directly upstream of the NIST connector to facilitate future servicing / repair / hose replacement.

3.16 Terminal units that are wall mounted should be located as follows (Figure 2 refers):

- the distance between the centre of the terminal unit and a potential obstruction on either side (for example when installed in a corner) should be a minimum of 200mm on either side;
- distance between centres of adjacent horizontal terminal units should be;
  - 135 ± 2.5mm for three or more terminal units;
  - 150 ± 2.5mm for two terminal units only;
- distance between centres of adjacent horizontal terminal units;
- care should be taken to ensure that connected medical gas equipment and hoses do not foul other nearby equipment and services during use. Particular attention should be given to terminal unit positioning with respect to worktops, electrical sockets, cupboards, equipment rails, ventilation flaps and door openings. A minimum radial clearance of at least 200mm from these items is suggested, but this may have to be increased depending on the nature of connected equipment.

Note 6: To promote a more “domestic” environment, some in-patient accommodation is provided with terminal units installed in recesses behind covers/decorative panels etc. To accommodate this it is necessary to allow an additional 100mm on each side of the outermost terminal units and 200mm from centre to top of recess and 300mm from centre to bottom of recess. The depth of the recess should be 150mm. The surface should be clearly marked with suitable legend denoting medical equipment is installed within.

© Health Facilities Scotland, a division of NHS National Services Scotland.

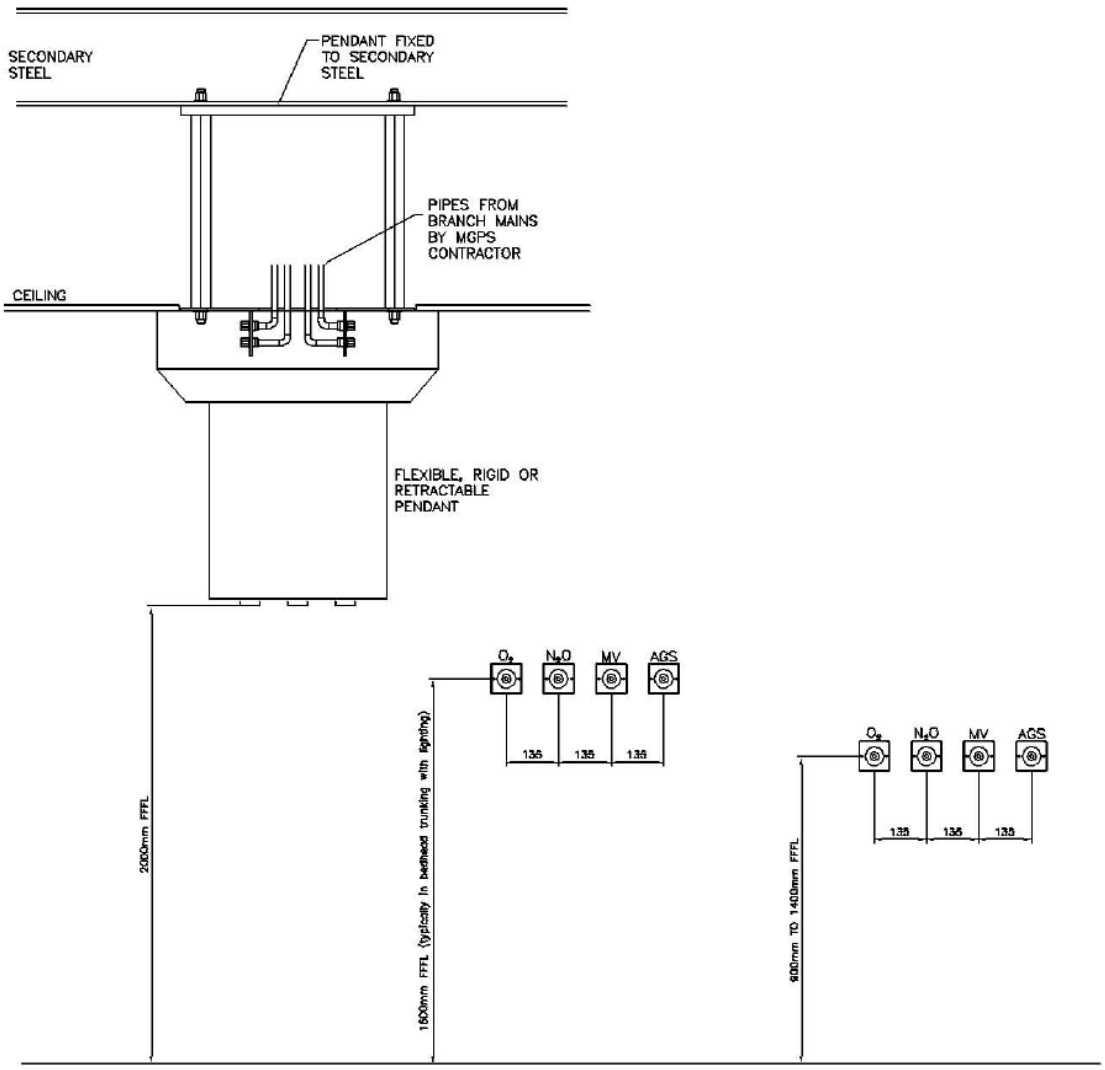

Figure 2: Terminal unit mounting heights

Terminal units for helium/oxygen mixture

3.17 BS EN ISO 9170-1: 2008 does not include a terminal unit for helium/oxygen mixture. They will be included in a new edition of BS5682:1998.

Nitrogen for surgical tools

3.18 BS EN 739:1998 gives details of connectors for nitrogen for driving tools. The body of the NIST connector should form the wall outlet.

Area Valve Service Units (AVSUs)

3.19 AVSUs should be mounted at a convenient height (typically between 1, 000 – 1,800mm) such that they can be operated comfortably by staff without their needing to stoop or overreach (see Figure 3). The order of the location of individual valves in an array should follow that for terminal units, for example: O_2, N_2O and/or N_2O/O_2, MA4, SA7, MV, He/O_2. If the array exceeds 1,000mm in height from top to bottom, it may be preferable to arrange them in two columns. Care must be taken to ensure that AVSUs cannot be obscured by opening doors etc. Details of the design of AVSUs are given in Section13.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 7: The minimum height of 1,000mm is the optimum. In critical care areas where dual circuits are installed, it may be necessary to reduce this to 800mm to avoid an excessive number of columns of AVSUs.

Area alarm indicator panels

3.20 The placing of area alarm indicator panels should be such that they are readily visible by staff. Notices, partitioning, screens, etc. should not obscure them. The mounting height should be such that in the event of an audible alarm sounding, staff can activate the “mute” switch without overreaching, and be a maximum 1,800mm above finished floor level (see Figures 3a and 3b).

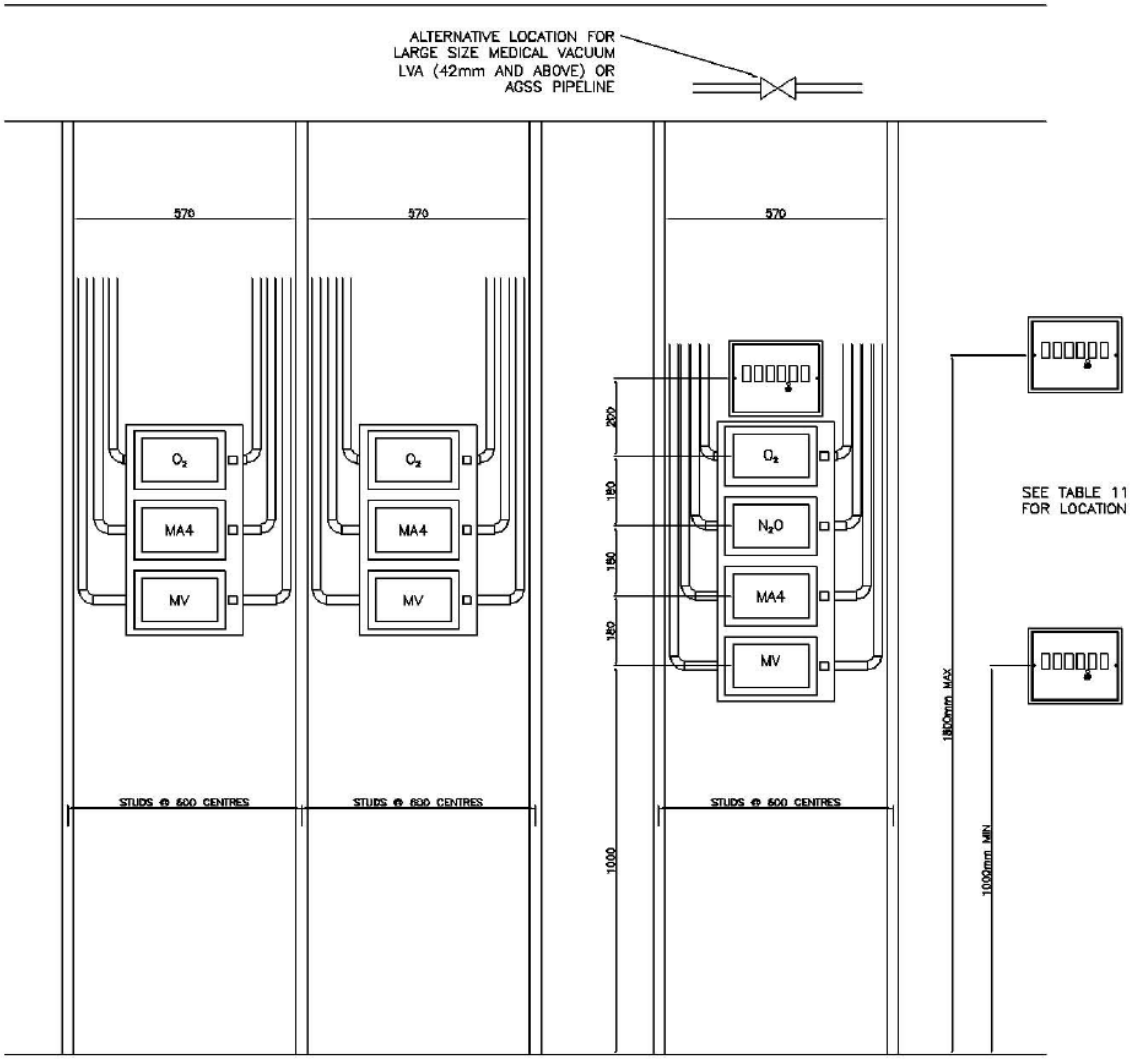

Figure 3a: AVSU and alarm panel mounting heights

© Health Facilities Scotland, a division of NHS National Services Scotland.

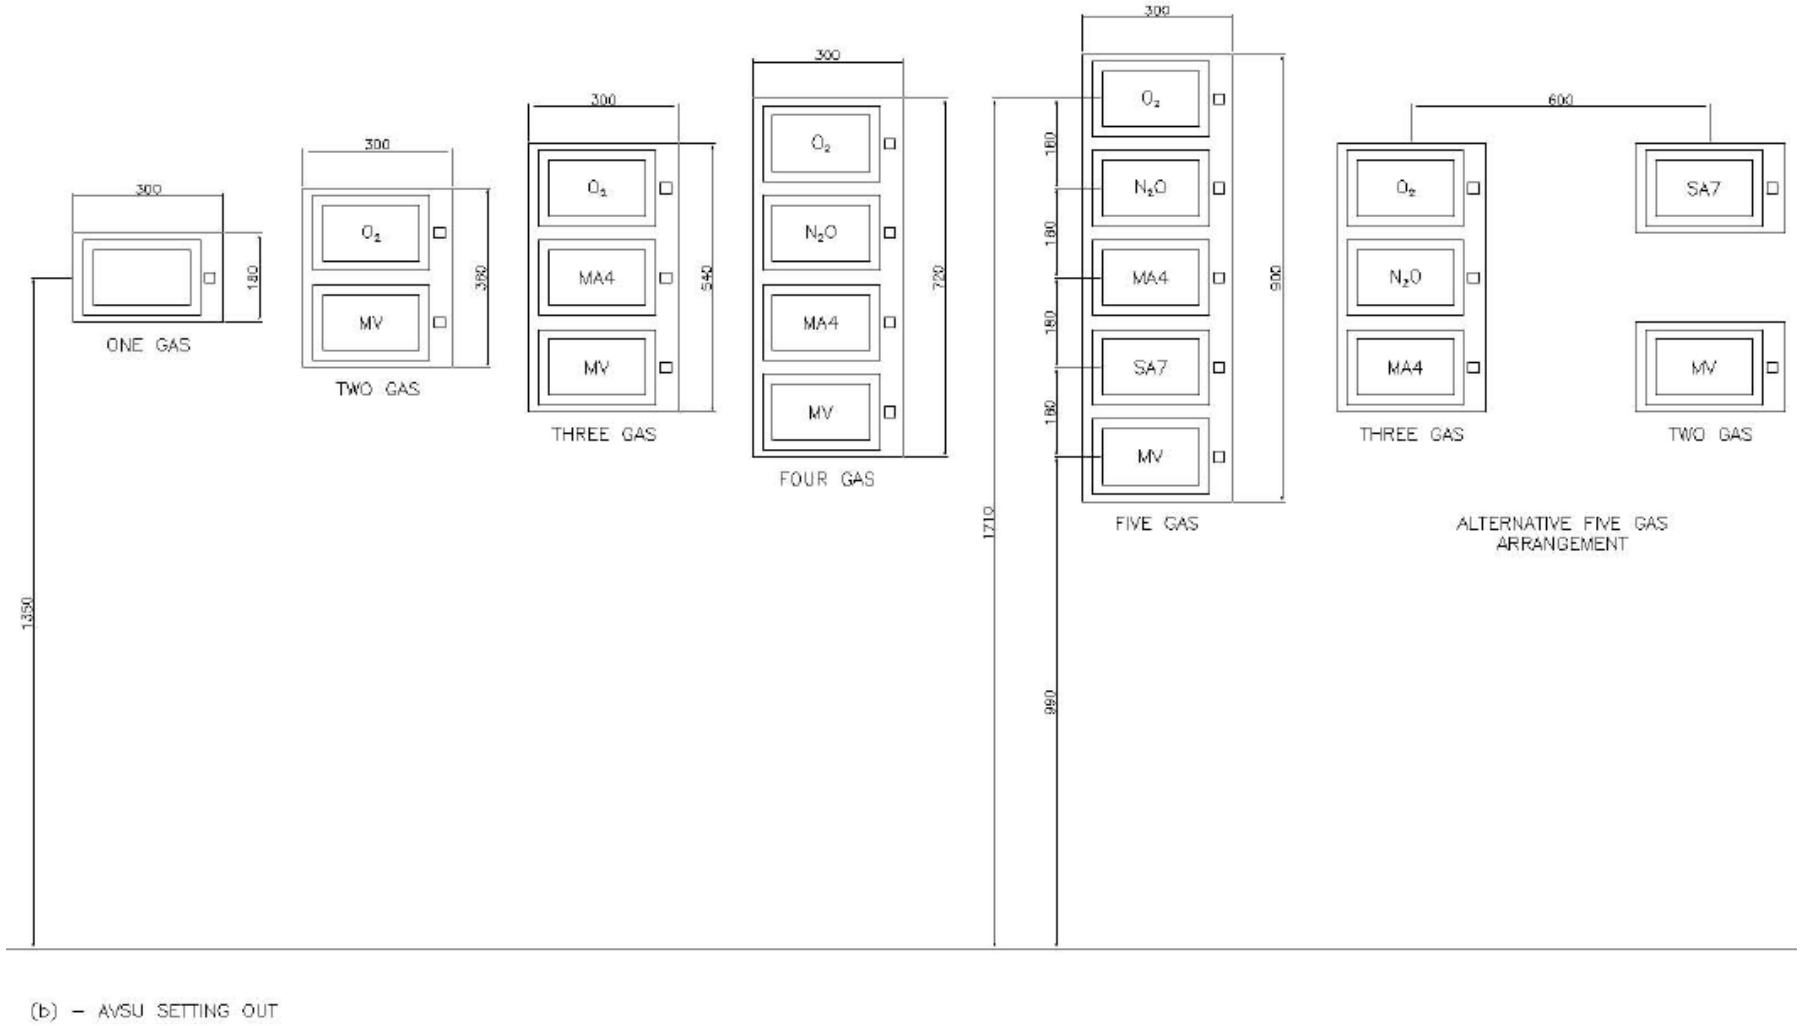

Figure 3b: AVSU and alarm panel mounting heights

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

Line valve assemblies (LVAs)

3.21 LVAs should be installed at branches from risers, branches from main runs, and where pipelines pass into or out of a building. Details of the design of LVAs are given in Section13.

Specific labelling requirements

3.22 All AVSUs should be labelled to identify the individual rooms, sets of terminal units, etc. controlled. They should be provided with flow direction arrows.

3.23 In critical care areas where dual circuits and/or subdivision of circuitry occur, terminal units require to be identified as associated with the specific AVSU. Correspondingly, AVSUs should be similarly labelled to identify the terminal units controlled.

Notes applicable to Table 11:

*	Dual circuits
**	Where the delivery and neonatal units are in close proximity, the equipment service room can be shared.
†	Dental vacuum only
p	Project team option
hp/lp	high-pressure and low-pressure alarms..
lp	low pressure alarm.

Ref: (1)	Departmental AVSUs installed on the hospital street side of fire compartment doors – due consideration should be given to the security of these valves in public areas.
Ref: (2)	Installed immediately outside the room.
Ref: (3)	Where air is used to control movable pendant fittings, it should be taken from the 700 kPa surgical air system. However where surgical air is not available medical air 400 kPa may be used if suitable for the particular pendant manufacturer's requirements.
Ref: (4)	In addition to the dual circuits, additional AVSUs will be required to sub-divide the number of terminal units controlled (typically between 4-8 bed spaces). This subdivision should be based on the layout of the accommodation: for example, if the recovery area is divided into a number of separate room/areas, each would have a separate sub-set (see Figures 4 and 5).
Ref: (5)	This is intended to provide some flexibility and the exact number will depend on the total number of rooms within the department.
Ref: (6)	If a high-dependency unit is included within general in-patient accommodation, a separate set of AVSUs should be provided for the unit. In addition to the departmental valves or the ward as a whole, an additional set will be required to control the single-bed, multi-bed and treatment rooms.
Ref: (7)	Department AVSUs may be required if the units are large and separate from, for example, the critical care area.
Ref: (8)	Additional AVSUs may be required in a large unit: the aim should be to have about 8-12 rooms controlled by a set of AVSUs – discretion is required to arrive at the logical number.
Ref: (9)	Installed in reception area.
Ref: (10)	Installed in the operating room in the "main panel" or within the room, or an ante-room, e.g. control room of an MRI device.
Ref: (11)	Installed at the main staff base (nurses' station).
Ref: (12)	Installed in the room space with the AVSUs.
Ref: (13)	Separate AVSUs will be required if endoscopy room is included.
Ref: (14)	Carbon dioxide is used for insufflation during some surgical procedures. A pipeline installation is a project team option and is covered in Section 11. Two NIST connector bodies units should be installed.
Ref: (15)	Where medical gases are required in Decontamination rooms, such as in A&E, the medical gas should be provided by a dedicated source e.g. gas cylinder or portable vacuum pump.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Ref: (16)	Where grouping of similar type rooms are possible, e.g. Renal departments, Diagnostics (e.g. ultrasound, general purpose rooms) the grouping should be to have an even number of rooms controlled by a set of AVSUs – discretion is required to arrive at the logical number.
Ref: (17)	Where medical gas terminal units are to be provided in areas such as; en-suite bathrooms/shower rooms, etc. the location of the terminal unit should not be in direct contact with water, or cleaning fluids (soaps, etc.). The designer and User should liaise to establish an acceptable location.
Ref: (18)	Dedicated medical/surgical air and vacuum plant should be provided separately for this department.
Ref: (19)	The medical gases provision and method of supply for dedicated clinical / surgical training facilities should be determined in consultation with the training facility management.

General

Normally, departmental AVSUs would be installed at the hospital street side of the entrance doors to a department and would reflect the method of horizontal evacuation in the event of an emergency. In some large departments, for example an operating department, the clean-service corridor is likely to cross one or more fire compartment walls. Additional AVSUs may therefore be required to reflect the evacuation route.

If a department includes one or more floors, a set of AVSUs should be provided for each floor, which will act as emergency overall fire valves.

AVSUs for zones within critical care areas should be located where they can be seen by staff – not necessarily at the staff base.

Area alarms within critical care areas should be provided for the individual space; that is, if a critical care area of, say, 18 beds is sub-divided into three separate six-bed wards, there should be one alarm only for each space (not one for each of the dual circuits).

Where an anaesthetic room is directly linked to an operating room, the anaesthetic room shall be controlled by the theatre AVSUs. Where the anaesthetic room is remote from a theatre(s) separate AVSUs with area alarm panel should be provided.

When an anaesthetic room forms part of a special procedures suite then one set of AVSUs serving both rooms is permissible. Consideration should be given to the general department layout with regard to the degree of valving required where procedures will not require anaesthetics to be applied.

4. Gas flow

General

4.1 Various layouts of an MGPS are shown throughout this document, and each will need to be designed to take into account the anticipated design flow. Appendix N provides a conversion table for various units of measurement that may be encountered.

4.2 There are several aspects of gas flow to consider when designing the pipeline distribution system:

1. the test flow that is required at each terminal unit for test purposes (this flow is essentially to establish that the terminal unit functions correctly and that there are no obstructions; see Table 12);
2. the typical flow required at each terminal (this is the maximum flow likely to be required at any time in clinical use; see Table 12);
3. the likely numbers of terminal units in use at any time;
4. the flow required in each sub-branch of the distribution;
5. the total flow to the ward/department;
6. the flow in the main branches/risers, that is, the summation of all diversified flows;
7. the flow required at the plant, that is, the sum of all diversified flows to all like departments and wards, plus individual or dissimilar departments.

4.3 The pipeline system should be designed so that the flows given in Table 12 can be achieved at each terminal unit: the flows are expressed in free air. Diversified flows are used for the purposes of pipe size selection.

4.4 The designer should always ensure that due account is taken of the stated use of a particular department.

4.5 There is a limited range of pipe sizes, and where there is any doubt about flow requirements, a larger pipe size should be selected.

Note 8: When calculating diversified flows, it is the number of bed spaces, treatment spaces or rooms in which the clinical procedure is being performed that is used; this is not the individual number of terminal units since, in many cases, more than one is installed. For example, a bed position in a critical care area may have four or more oxygen terminal units.

4.6 The overall pipeline design should be based on a 5% pressure drop from the plant/source of supply to that measured at the rear of the terminal unit outlet at the specified test flows. For multi-movement pendant hoses the 5% pressure drop is only applicable to the pipeline up to the inlet of a NIST connector (refer to Figure 8). For vacuum, this should be 50mmHg pressure loss.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Terminal unit flows

4.7 At the design stage, the project team should define the individual room/space requirements. Departments usually comprise several ward units, treatment rooms and other spaces. In order to avoid confusion, the nomenclature for each clinical space should be clearly defined so that the appropriate gas flow requirements can be established at the commencement of the design stage.

Pipeline flows

4.8 Precise prediction of pipeline flow is not possible, but there are guidelines that can be used which have been shown to be adequate in practice.

4.9 For vacuum systems, the minimum vacuum should not fall below 300 mmHg at the front of each terminal unit at a design flow of 40 litres/min.

4.10 The design of the pipework system is based on the diversified flows and the permissible pressure loss from the source of supply to the terminal unit excluding the terminal unit pressure loss. The pipe sizes should be selected to ensure that the pressure loss is below 5% of the nominated pipeline pressure. (See Figures 6–9 and Appendix G).

4.11 Pressure requirements for surgical air are based on the requirement that the minimum pressure should be 700 kPa at the terminal unit at a flow of 350 litres/min.

4.12 Details of pressure requirements for all systems are described in paragraphs 4.42–4.49.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Service	Location	Nominal pressure (kPa)	Design / Test flow (Litres/min)	Typical flow required (Litres/min)
Oxygen	Operating rooms and anaesthetic rooms in which N_2O is provided for anaesthetic purposes	400	100[a]	20
	Continuous positive airway pressure (CPAP)	400	75	30
	All other areas	400	10	6
Nitrous oxide	All areas	400	15	6
Nitrous oxide/Oxygen mixture	LDRP(labour, delivery, recovery, post-partum) rooms	400[b]	275	20
	All other areas	400	20	20
Medical air 400 kPa	Operating rooms	400	40[c]	40
	Critical care high dependency units	400	80[c]	80
	Neonatal	400	40	40
	Other areas	400	20	10[c]
Surgical air/nitrogen	Orthopaedic and neurosurgical operating rooms	700	350[d]	350
	Where multi-movement pendants are installed	900[e]	350	350
	Other areas	700	350	350
Vacuum	All areas	400mmHg – 47 kPa absolute (53 kPa below atmospheric pressure). All further figures will be in 'below atmospheric pressure'	40	40 maximum, further diversities apply
Helium/oxygen mixture	Critical care areas	400	100	40

Table 12: Gas flow – flows required at terminal units

© Health Facilities Scotland, a division of NHS National Services Scotland.

Notes applicable to Table 12:

(a) During oxygen flush in operating and anaesthetic rooms;

(b) For nitrous oxide / oxygen mixture the pressure at the intermittent patient demand regulator should not be less than 310 kPa;

(c) These flows are for certain types of gas-driven ventilators under specific operating conditions, and nebulisers etc.

(d) Surgical air is also used as a power source for tourniquets;

(e) Surgical air pressure losses across pendant NIST connections, hoses and terminal unit assemblies can be up to 200 kPa (which exceeds the BS EN ISO 9170-1: 2008 requirement) plus regulator and pipeline tolerances. Refer to paragraph 3.15;

(f) Pipeline sizing is designed to meet the total design flow at 5% losses which in practice provides a safety margin over the normal hospital flow demands. For surgical air, some regulator adjustment may be required.

Oxygen

In-patient accommodation

4.13 Oxygen is used at a typical flow of 5–6 litres/min. Each terminal unit should, however, be capable of passing 10 litres/min (at standard temperature and pressure (STP)) at a supply pressure of 400 kPa (nominal) as shown in Table 12, in case nebulisers or other respiratory equipment are used. Table 13 contains the formula for arriving at diversified flows.

4.14 For a 28-bed ward unit comprising single and four-bed rooms and a treatment room, the diversified flow is calculated on the assumption that one bed space requires 10 litres/min, and one in four of the remainder require 6 litres/min. For the purpose of pipe size selection, the diversified flow at entry to the ward is

© Health Facilities Scotland, a division of NHS National Services Scotland.

taken as 50 litres/min (strictly 50.5 litres/min).It is assumed that a patient will use oxygen in a ward or in the treatment room but not both.

4.15 A department may comprise several ward units as above. The diversified flow for each department Qd is based on Qw for the first ward unit, plus 50% of the flow for the remaining ward units. For the purposes of this calculation, the first ward unit is taken as the largest within the department.

4.16 If one ward unit is significantly larger than the others, the flows from the ward units should be averaged to obtain a more realistic value.

Operating departments

4.17 The diversified flow for operating departments is based on 100 litres/min required for the oxygen flush. Therefore each oxygen terminal unit in the operating room and anaesthetic room should be able to pass 100 litres/min. It is unlikely that an oxygen flush will be administered simultaneously in several operating rooms. The diversified flow Q is based on 100 litres/min for the first operating room and 10 litres/min for the remainder.

4.18 For anaesthetic rooms, each terminal unit should be capable of passing 100 litres/min (it may be necessary to use oxygen “flush”), but the actual flow likely to be used is 6 litres/min or less. As it is unlikely that a patient would be anaesthetised at the same time that a patient in the associated operating room was continuing to be treated under an anaesthetic (and because the duration of induction is short), no additional flow is included.

4.19 In post-anaesthesia recovery, it is possible that all bed spaces may be in use simultaneously; hence, no diversity is applied.

Critical care, coronary care and high-dependency units

4.20 The flow for these units assumes that all bed spaces may be in use simultaneously, hence no diversity is applied.

4.21 Oxygen should not be used as the driving gas for gas-powered ventilators if they are capable of being powered by medical air. The minimum flow that has been shown to be adequate to drive current types of ventilator is 80 litres/min at 355 kPa.

4.22 If oxygen has to be used to power ventilators and/ or ventilators are operating in CPAP mode, the high flows that may be encountered should be taken into account both when designing the pipeline and when sizing the supply vessel. These ventilators use exceptional amounts of oxygen, particularly if adjusted incorrectly. If incorrectly set, they can use in excess of 120 litres/min, but their therapeutic benefit will be effective at lower flows. To allow for some flexibility, and additional capacity, a diversified flow of 75 litres/min for 75% of beds has been included. If significant numbers of beds are required to treat patients using CPAP ventilation, consideration should be given to running a separate pipeline from the source of supply. Care should be taken when calculating air exchange rates in wards/rooms in which large numbers of CPAP machines may be in use simultaneously and where failure of mechanical ventilation could result in raised

© Health Facilities Scotland, a division of NHS National Services Scotland.

ambient oxygen concentrations. Consideration should be given to installation of systems to warn of ventilation failure and oxygen concentrations above 23%.

Maternity

4.23 For LDRP (Labour, Delivery, Recovery, and Post-partum) rooms, the diversified flow is based on10 litres/min for the first terminal unit and 6 litres/min for one third of the remaining bed spaces. Two cot spaces may be provided, each with a terminal unit. Only one will be considered to be in use. The diversified flow for cot spaces is based on10 litres/min for the first and 50% of the remainder at 3 litres/min.

4.24 In the event of multiple births, the additional gas usage will have negligible overall effect on the total flow.

4.25 Maternity department operating rooms are designed as a suite; that is, it is presumed that oxygen will be provided either in the anaesthetic room or in the operating room. In post-anaesthesia recovery, it is possible that all bed spaces may be in use simultaneously, hence no diversity is applied.

Department	Design flow for each terminal unit (litres/min)	Diversified flow Q (litres/min)
In-patient accommodation (ward units)		
Single, 4-bed rooms and treatment rooms	10	$Q_w = 10 + [(n - 1)6/4]$
Ward block/department		$Q_d = Q_w[1+ (nW - 1)/2]$
Accident & Emergency Department:		
Resuscitation room	100	$Q = 100 + [(n - 1)10/4]$
Major treatment / operating procedures	100	$Q = 100 + [(n - 1)10]$

Equipment service rooms, sterile services etc.	100	No additional flow

Table 13 (cont’d): Oxygen: design and diversified flows

Note 9: The main branch line to a department or floor should only allow for 1 oxygen flush of 100 litres/min.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Legend for Tables 13-21:

Q = diversified flow for the department;

Q_w = diversified flow for the ward;

Q_d = diversified flow for the department (comprising two or more wards);

n = number of beds, treatment spaces or single rooms in which the clinical procedure is being performed, not the individual numbers of terminal units where, in some cases, more than one is installed;

*n*S = number of operating suites within the department (anaesthetic room and operating room);

*n*W = number of wards;

*n*T = number of theatres.

Hyperbaric oxygen chambers

4.26 Hyperbaric oxygen chambers should be supplied from a separate branch from the main riser/ distribution pipe. The pipeline system should be from a liquid supply source. Typical flows for a single patient chamber are as shown in Table 14.

	Max. time for one complete treatment	Total consumption for max. treatment time (litres)	Consumption for each additional minute (litres/min)
O_2 atmosphere and recirculation:			
On open circuit	2 hours	30,000	250
On recirculation	2 hours	7,250	40
O_2 only, no recirculation	2 hours	30,000	250
O_2 delivery by built-in breathing mask and overboard pump	2 hours	1,200	10
O_2 delivery by built-in breathing hood and overboard pump	2 hours	7,250	60

Table 14: Gas flow – hyperbaric chambers

© Health Facilities Scotland, a division of NHS National Services Scotland.

Notes: a) The flows for a recirculating unit assume the standard method of operation is recirculation throughout the treatment. It is recommended that the pipeline should be designed for open circuit operation to ensure adequate flow under all conditions.

b) Clinical practice may require the inclusion of air during the treatment. It may also be necessary to switch to air in the unlikely event of an oxygen convulsion. Therefore consideration should be given to the provision of medical air from a separate dedicated medical air plant in accordance with Chapter 7.

c) Some hyperbaric chambers use air as a buffer and consequently less oxygen is consumed. The advice of the manufacturer should be sought. Where this is the case, the air should be supplied from a separate supply system complying with the requirements for medical air systems.

Nitrous oxide

4.27 Nitrous oxide is provided for anaesthetic purposes and occasionally for analgesic purposes. In all cases, each terminal unit should be capable of passing 15 litres/min, but in practice the flow is unlikely to exceed 6 litres/min.

4.28 When calculating diversities in a department, 15 litres/min is allowed for the first outlet and 6 litres/min for the remainder, subject to the appropriate diversity factor being applied (see Table 15).

4.29 It is assumed that, for an operating department, nitrous oxide may be in use simultaneously in all operating rooms. As it is unlikely that a patient would be anaesthetised in the anaesthetic room at the same time that a patient in the associated operating room was continuing to be treated under an anaesthetic (and because the duration of induction is short), no additional flow is included.

Department	Design flow for each terminal unit (litres/min)	Diversified flow Q (litres/min)
Accident & Emergency: Resuscitation room, per trolley space	15	Q = 15 + [(*n* – 1)6/4]
Operating rooms	15	Q = 15 + (*n*T – 1)6
Anaesthetic rooms as part of an Operating suite	15	No additional flow included
Maternity: Operating rooms	15	Q = 15 + (*n*T – 1)6
Radiology	15	Q = 15 + [(n – 1)6/4]
Critical care areas	15	Q = 15 + [(*n* – 1)6/4]
Oral surgery/orthodontic: Consulting rooms, type 1	15	Q = 15 + [(*n* – 1)6/4]
Other departments	15	No additional flow included
Equipment service rooms	15	No additional flow included

Table 15: Nitrous oxide: design and diversified flows

© Health Facilities Scotland, a division of NHS National Services Scotland.

Nitrous oxide/oxygen mixture

4.30 All terminal units should be capable of passing 275 litres/min for a very short period (normally of five seconds' duration) to supply inhalationary "gasps" by the patient, and a continuous flow of 20 litres/min. The actual flow would not normally exceed 20 litres/min.

4.31 The diversified flow in LDRP rooms is based on 275 litres/min for the first bed space and 6 litres/min for each of the remainder, of which only half of the women in labour will be using gas. (The peak inhalationary "gasp" is 275 litres/min, whereas the respirable minute volume will be catered for with a flow of 6 litres/min – it should also be borne in mind that a woman in labour would not continuously breathe the analgesic mixture.) For larger maternity departments with nine or more LDRP rooms, two peak inhalationary "gasps" are included.

4.32 Nitrous oxide/oxygen mixture may be used in other areas for analgesic purposes. The diversified flow is based on 20 litres/min for the first treatment space, and 6 litres/min for a half of the remainder.

4.33 Design and diversified flows for nitrous oxide/ oxygen mixtures are given in Table 16.

Department	Design flow for each terminal unit (litres/min)	Diversified flow Q (litres/min)
Maternity:		
<9 LDRP room(s), mother	275	Q = 275 + [(n – 1)6/2]
≥9 LDRP rooms	275	Q = 275 x 2 + [(n – 1)6/2]
Other areas	20	Q = 20 + [(n – 1)6/2]
Equipment service rooms	275	No additional flow included

Table 16: Nitrous oxide/oxygen mixtures – design and diversified flows

Air

4.34 Air is used to provide power for several types of equipment including surgical tools, ventilators and nebulisers. Oxygen should be avoided as a power source because of fire risk and cost, and should not be used where medical air is available, unless specifically recommended by the device manufacturer.

4.35 Air should be provided at two different pressures but to the same Ph. Eur. Standard:

- a pressure of 400 kPa is required for medical air to drive ventilators and for other respiratory applications;
- a pressure of 700 kPa or higher is required for surgical air to drive surgical tools.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Medical Air 400 kPa

General

4.36 The use of medical air, particularly for respiratory use and during anaesthesia, has increased markedly in recent years. This service is the most critical of the medical gas services, since air-powered ventilators cease to operate in the event of failure of the supply.

4.37 Medical air is also directly inhaled by patients during ventilation. It may also be used to dilute oxygen before administration because of the potentially toxic effects of pure oxygen.

4.38 The supply system for medical air 400 kPa may be a manifold system, a compressor system or a proportioning system (synthetic air), and normally includes an emergency reserve manifold. A compressor plant, or synthetic air supply, should always be specified where air-powered ventilators are to be used.

4.39 One of the major uses of medical air is for patients' ventilators, which fall into two main categories comprising those used during anaesthesia and those used during critical care. Pneumatically-powered ventilators can use up to 80 litres/min free air continuously. The exact flow requirements will depend on the design of the ventilator. The flow and pressure requirements for some typical ventilators are given in Table 17.

4.40 Current models of anaesthetic ventilator are very similar to critical care models, and may require peak flows of up to 80 litres/min and average flows of 20 litres/min. Almost all such units are pneumatically driven and electronically controlled.

4.41 Medical air 400 kPa is also used for other equipment such as anaesthetic gas mixers, humidifiers and nebulisers. The flow rate normally required would not exceed 10 litres/min, and this flow is always in excess of the actual volume respired.

Pressure requirements

4.42 A minimum pressure required at terminal units for respiratory use is 355 kPa.

4.43 Medical air should not be used to supply mechanical services (see paragraph 7.131).

4.44 Some medical gas pendants use the medical air supply for operating the control/retraction system. This is permitted, provided that:

- a flow limiting device is provided to protect the medical air system in the event of failure of any downstream component;
- a non-return valve is incorporated to protect the system integrity;
- appropriate AVSU arrangements are in place (see Section 3).(The surgical air supply should be used to provide the power source whenever possible.)

© Health Facilities Scotland, a division of NHS National Services Scotland.

4.45 The flow requirements should be ascertained and taken into account prior to the installation of the equipment.

Flow requirements

4.46 Flow requirements for medical air are given Table 18. In ward areas and treatment rooms, the use of medical air is most likely to be for nebulisers. In these areas they should be capable of passing 20 litres/min, although typically 10 litres/min will be required in in-patient accommodation where air is used for nebulisers.

Ventilator type	Pressure (kPa)	Flow (litres/min)
Anaesthesia, typically gas-driven, electronically controlled	Nominally 400. Max 600(1)	Pneumatically driven ventilators use up to 80 max. 20 continuous
Critical care, electrically controlled, gas-powered	Nominally 400. Max 600(1)	180 peak (2) 80 continuous
Neonatal, gas-driven, electronically controlled	Nominally 400. Max 600(1)	80 peak(2) 40 continuous
Nebulisers	400	10

Table 17: Typical pressure and flow requirements for ventilators and nebulisers

Notes applicable to Table 17:

(1) It is strongly recommended that ventilators are not connected to the 700 kPa system since blenders only work satisfactorily with a tolerance of about 10%: with high differential pressures for air and oxygen an incorrect mixture could be obtained.

(2) These flows can be achieved under certain clinical conditions. The peak flows are usually of very short duration.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Department	Design flow for each terminal unit (litres/min)	Diversified flow Q (litres/min)
In-patient accommodation (ward units):		
Single / 4-bed and treatment rooms[1]	20	$Q_w = 20 + [(n - 1)10/4]$
Ward block/department		$Q_d = Q_w[1 + (nW - 1)/2]$
Accident & Emergency Department:		
Resuscitation room, per trolley space	80	$Q = 80 + [(n - 1)80/2]$
Major treatment room	40	$Q = 40 + [(n - 1)40/4]$
Plaster room, per trolley space	40	$Q = 40 + [(n - 1)40/4]$
Post-anaesthesia recovery, per trolley space	40	$Q = 40 + [(n - 1)40/4]$
Operating Theatre Department:		
Anaesthetic rooms	40	No additional flow included
Operating rooms	40	$Q = 40 + [(nT - 1)40/4]$
Post-anaesthesia recovery	40	$Q = 40 + [(n - 1)40/4]$
Maternity Department:		
LDRP rooms: Baby[2]	40	$Q = 40 + [(n - 1)40/4]$
Operating suites:

Equipment service rooms (sterile services etc.)	40	No additional flow included

Table 18: Medical Air 400 kPa – design and diversified flows

© Health Facilities Scotland, a division of NHS National Services Scotland.

Notes applicable to Table 18:

(1). It is assumed that a patient will use oxygen / air in a ward or in the treatment room.

(2). Where two cot spaces have been provided in an LDRP room, assume only one will require medical air.

(3). This diversified flow is also used for helium / oxygen mixture (see paragraph 4.70).

Surgical Air 700 kPa

4.47 The pressure requirements of surgical tools are between 600 and 700 kPa and flows may vary between 200 and 350 litres/min (STP; see Table 19). Most surgical tools are designed to operate within this pressure range. Higher pressures are likely to cause damage to tools. Inadequate tool performance, however, is likely to result from the lack of flow at the specified pressure.

4.48 The introduction of synthetic air (from on-site blending of oxygen and nitrogen) leads to the possibility of using nitrogen as the power source for surgical tools.

4.49 The pipeline systems should be designed to provide a flow of 350 litres/min at 700 kPa at the outlet from the terminal unit. Existing systems may not meet this requirement (but should be capable of delivering 250 litres/min at the terminal unit).

Note 11: Some surgical tools require up to 500 litres/min at up to 1,400 kPa. These will require a separate supply, normally from cylinders.

Dual pressure surgical air systems

4.50 In many instances, particularly where multi-movement pendants have been installed, a 10 bar system is insufficient to overcome the inherent pressure losses within such units in addition to the standard losses which can occur over the desiccant dryer / filtration unit, the tolerances required across the regulator and the pipeline pressure loss. To ensure the flow requirements can be met, the compressed air plant should be capable of 13 bar operation.

4.51 Guidance is given on the pressure requirements of alternative methods of control:

- a single plant pressure reduction system that maintains all control within the plantroom and can be simply adjusted once the actual pressure losses are established following a system performance check;
- removal of the NIST check valve, which can vary in pressure loss per pendant, would assist in standardizing the pressure loss within a single regulated system. In the event that the check valve is removed, permanent labelling will be required at the NIST to indicate this. An additional Line Valve should be provided to allow maintenance;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- a double pressure reduction system with the second stage pressure regulator locally sited to each operating room or group of rooms. Some thought should be given to the siting of the regulator avoiding the easy option of installing within the ceiling void which is not easily accessible for maintenance or where entry to the void is hygienically unacceptable.

4.52 In each instance some fine adjustment of the regulators may be required to ensure 700 kPa @ 350 litres/min. flow at the terminal unit outlets. This requirement would most certainly be required at the emergency reserve manifold, the degree depending on it's location in the event of a fault condition arising. In both cases, there is a likelihood of static pressure under no flow conditions above 900 kPa at the terminal unit, therefore it is essential that nurse training covers the engagement and removal of probes at point of use.

Diversity

4.53 Surgical air 700 kPa is only required where surgical tools are to be used. This would typically involve orthopaedic and neurosurgery operating rooms, and, possibly, plaster rooms. For flexibility, and to allow for possible overspill, surgical air should be extended to two to four adjacent operating rooms. It is not required in maternity or ophthalmology operating rooms. The diversified flow is based on the assumption of 350 litres/min for the first theatre and a quarter of the remainder when there are more than four operating rooms (see Table 20).

Note 12: Scottish Health Technical Memorandum 2022, Supplement 1: 'Dental compressed air and vacuum systems' allows for the extension of surgical air into dental departments for tool use only.

4.54 Unlike dental departments, the use of surgical tools in an operating procedure takes place for a limited period of time.

Type of tool	Pressure (kPa)	Flow (litres/min)
Small air drill	600-700	200
Medullary reaming machine	600-700	350
Oscillating bone saw	600-700	300
Universal drill	600-700	300
Craniotome	620-750	300

Table 19: Typical pressure and flow requirements for surgical tools

System capacity

4.55 Unlike respirable equipment, surgical tools are used intermittently, typically for a few seconds, up to a maximum of three minutes.

Terminal units intended for equipment testing

4.56 It may be necessary to provide surgical air at 700 kPa in the equipment service workshop for testing purposes. Unless a surgical air 700 kPa pipeline is available nearby, it may be cost-effective to use portable cylinders, with a two-stage regulator.

© Health Facilities Scotland, a division of NHS National Services Scotland.

4.57 If a pipeline supply is to be provided, each terminal unit should be capable of delivering 350 litres/min. Where several terminal units are provided, it is unlikely that more than one terminal unit will be in use at any time, and therefore the total design flow for the equipment service workshop will be 350 litres/min.

Department	Design flow for each terminal unit (litres/min)	Diversified flow Q (litres/min)
Operating room (orthopaedic and neurosurgical operating rooms only):		
≤4 operating rooms	350	Q = 350 + [(*n* – 1)350/2]
>4 operating rooms	350	Q = 350 + [(*n* – 1)350/4]
Other departments, e.g. equipment workshops, fracture clinic	350	Q = 350
Equipment service rooms	350	No additional flow required

Table 20: Surgical Air 700 kPa – design and diversified flows

Vacuum

General

4.58 In virtually all cases, vacuum is used via a suction control device and fluid is collected in suction jars. On wards these are typically of approximately 1 litre capacity. In operating rooms, two or four 2–3 litre capacity vessels are provided for the suction control regulator.

4.59 Once full, suction jars have to be emptied. Therefore, vacuum cannot be applied continuously.

4.60 The greatest generation of fluid to be aspirated is likely to arise in the operating room, particularly during orthopaedic surgery, where jet lavage to irrigate and cleanse the wound may be in use. The maximum rate of collection is about 4 litres/min, but it is not continuous.

4.61 During induction of anaesthesia, a patient may vomit. Therefore, it is essential that oral and nasal passages can be cleared as quickly as possible. The highest likely amount of fluid to be aspirated in this case will be no more than 0.5 litres.

4.62 In order to aspirate fluid, a suction cannula is normally used, and this will aspirate air as well as the fluid to be removed. The flow required, however, is higher than would be the case if fluid only were to be removed. The ratio of air/fluid aspirated will depend upon the diameter of the cannula.

In-patient accommodation

4.63 For a 28-bed ward unit comprising single rooms, four-bed rooms and a treatment room, the diversified flow is based on 40 litres/min.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Medical supply units/bedhead trunking systems

4.64 When designing vacuum systems, it is expected that the greatest pipeline pressure losses will occur across the terminal units.

4.65 Care must be taken when sizing vacuum pipework within medical supply units with two or more bed/ treatment spaces, where availability of space will often limit the size of pipe. The largest size of pipe that can be accommodated (typically 22mm) should be used, as this will ensure that excessive pressure losses do not occur within the units. Such losses could necessitate the installation of larger diameter pipework within the rest of the system in order to ensure that the system pressure drops prescribed in this Scottish Health Technical Memorandum are not exceeded.

Operating departments

4.66 Vacuum is provided for the surgical team and anaesthetist in the operating room. It is also provided in the anaesthetic and recovery rooms.

4.67 Since it is possible for both the surgical team and anaesthetist to use vacuum simultaneously, each operating room will require 80 litres/min and each terminal unit should be capable of passing 40 litres/min (see Table 21).

4.68 As it is unlikely that a patient would be anaesthetised at the same time that a patient in the associated operating room was continuing to be treated under an anaesthetic, the need to clear an airway is extremely unlikely and no additional flow is included.

Table 21 (cont'd): Vacuum – design and diversified flows

Helium/oxygen mixture

4.69 Helium/oxygen mixture is used by patients with respiratory or airway obstruction and to relieve symptoms and signs associated with respiratory distress. It can be administered by means of a face mask, a demand valve with face mask, a nebuliser, or a ventilator.

4.70 Pipeline supply will be primarily limited to critical care areas, where the gas mixture is used for driving a ventilator. The design and diversified flows should be based on the figures given for medical air (see Table 17).

4.71 Helium/oxygen mixtures administered by means of a face mask and cannula, a demand valve with face mask and cannula attached, or a nebuliser, are normally supplied using cylinders fitted with an integral valve.

Anaesthetic gas scavenging systems

4.72 For anaesthetic gas scavenging systems, it should be assumed that for each operating suite two terminal units could be in use simultaneously, for example in the anaesthetic room and operating room (receiving systems may be left connected when patients are transferred from the anaesthetic room to the operating room). The diversified flows for other departments are as given in Table 22.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Department	Design flow for each terminal unit (litres/min)	Diversified flow Q (litres/min)
Accident & Emergency resuscitation room (per trolley space)	V(1)	Q = V + [(*n* – 1)V/4]
Operating Theatre departments Operating room and anaesthetic room Recovery rooms	 V(1) V(1)	 Q = 2VnT Q = V + [(*n* – 1)V/4]
Maternity operating suites	V(1)	Q = 2VnT
Radiological (all anaesthetic and procedures room)	V(1)	Q = V + [(*n* – 1)V/4]
Oral surgery/orthodontic consulting rooms (type 1)	V(3)	Q = V + [(*n* – 1)V/4]
Other departments	V(1)	Q = V + [(*n* – 1)V/8]

Table 22: Anaesthetic gas scavenging – design and diversified flows

Notes applicable to Table 22:

(1). For the purpose of sizing the AGS disposal system pump, V is taken as either 130 litres/min or 80 litres/min (see paragraph 10.16).

(2). The AGS flow rate should be advised by the clinicians, in absence of such information, 130 litres/min should be used.

(3). With nasal mask application, flow is 45 litres/min.

© Health Facilities Scotland, a division of NHS National Services Scotland.

5. Cylinder manifold installations

5.1 A cylinder manifold installation consists of an automatic manifold control system and manual emergency reserve manifold.

Automatic manifold control system

5.2 The primary and secondary supplies are provided by two banks of equal numbers of gas cylinders which are connected to the pipeline via a control panel. The changeover from the “duty” to the “stand-by” bank of cylinders should be automatic. The reserve supply is provided via a manual emergency reserve manifold. All manifolds should be capable of passing the full pipeline flow. The temperature of the gas may fall as low as –30°C as the gas passes through the regulator at maximum capacity, and the equipment should be designed accordingly. In the case of nitrous oxide and nitrous oxide mixtures it is advisable to specify control panel in-line heaters.

5.3 A schematic layout for a typical cylinder manifold system is shown in Figure 10. Total storage is usually provided on the basis of a risk assessment. Each bank of the manifold should have sufficient cylinders for two days’ use. Additional cylinders for one complete bank change should be held in the manifold room; for nitrous oxide/oxygen mixture, sufficient cylinders to change two banks should be held. Each cylinder bank should be capable of isolation of supply without individual cylinder valve closure in order to facilitate periodic testing in accordance with BS EN ISO 7396-1: 2007 + A2: 2010. Each cylinder bank should be capable of independent selection to facilitate maintenance activity, for example, via a control switch.

5.4 The nominal and usable capacities of the cylinders commonly used on manifolds are given in Table 23 (the figures are the equivalents at STP).

5.5 An automatic manifold changeover from duty to stand-by should occur at a cylinder pressure that will ensure the greatest possible utilisation of the contents of the cylinders in the duty bank. If the normal operation of the changeover control depends on an electricity supply, the design should be such that failure of the electricity supply does not disrupt the flow of gas to the distribution system. In some instances, it will be necessary to provide heaters on the manifold, e.g. for nitrous oxide or nitrous oxide/oxygen mixture. The heater should be selected by the manifold manufacturer to match the range of flows for which the manifold is designed to deliver. The heater should be provided in such a location to limit the build-up of ice on the regulator and to operate only during flow conditions.

Note 13: All systems should be designed so that both banks (duty and stand-by) supply gas in the event of a power failure.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Gas	Nominal capacity (litres) at 137 bar	Usable capacity (litres)[1]
Oxygen J-size	6,800	6,540
Nitrous oxide: J-size G-size	 18,000 9,000	 8,900
Nitrous oxide/oxygen mixture G-size	5,000	4,740
Medical air J-size	6,400	6,220 (400 kPa) 5,550 (700 kPa)
Helium/oxygen mixture K-size	-	7,000 nominal

Table 23: Capacities of medical gas cylinders used on manifolds

Notes applicable to Table 23:

1. The usable figures are for discharge to a gauge pressure of 7 bar. Two sets of figures are provided for air – for 400 kPa systems and 700 kPa systems. The latter is for discharge to 15 bar.

2. Reference should be made to the respective supplier's data charts / sheets for further information.

© Health Facilities Scotland, a division of NHS National Services Scotland.

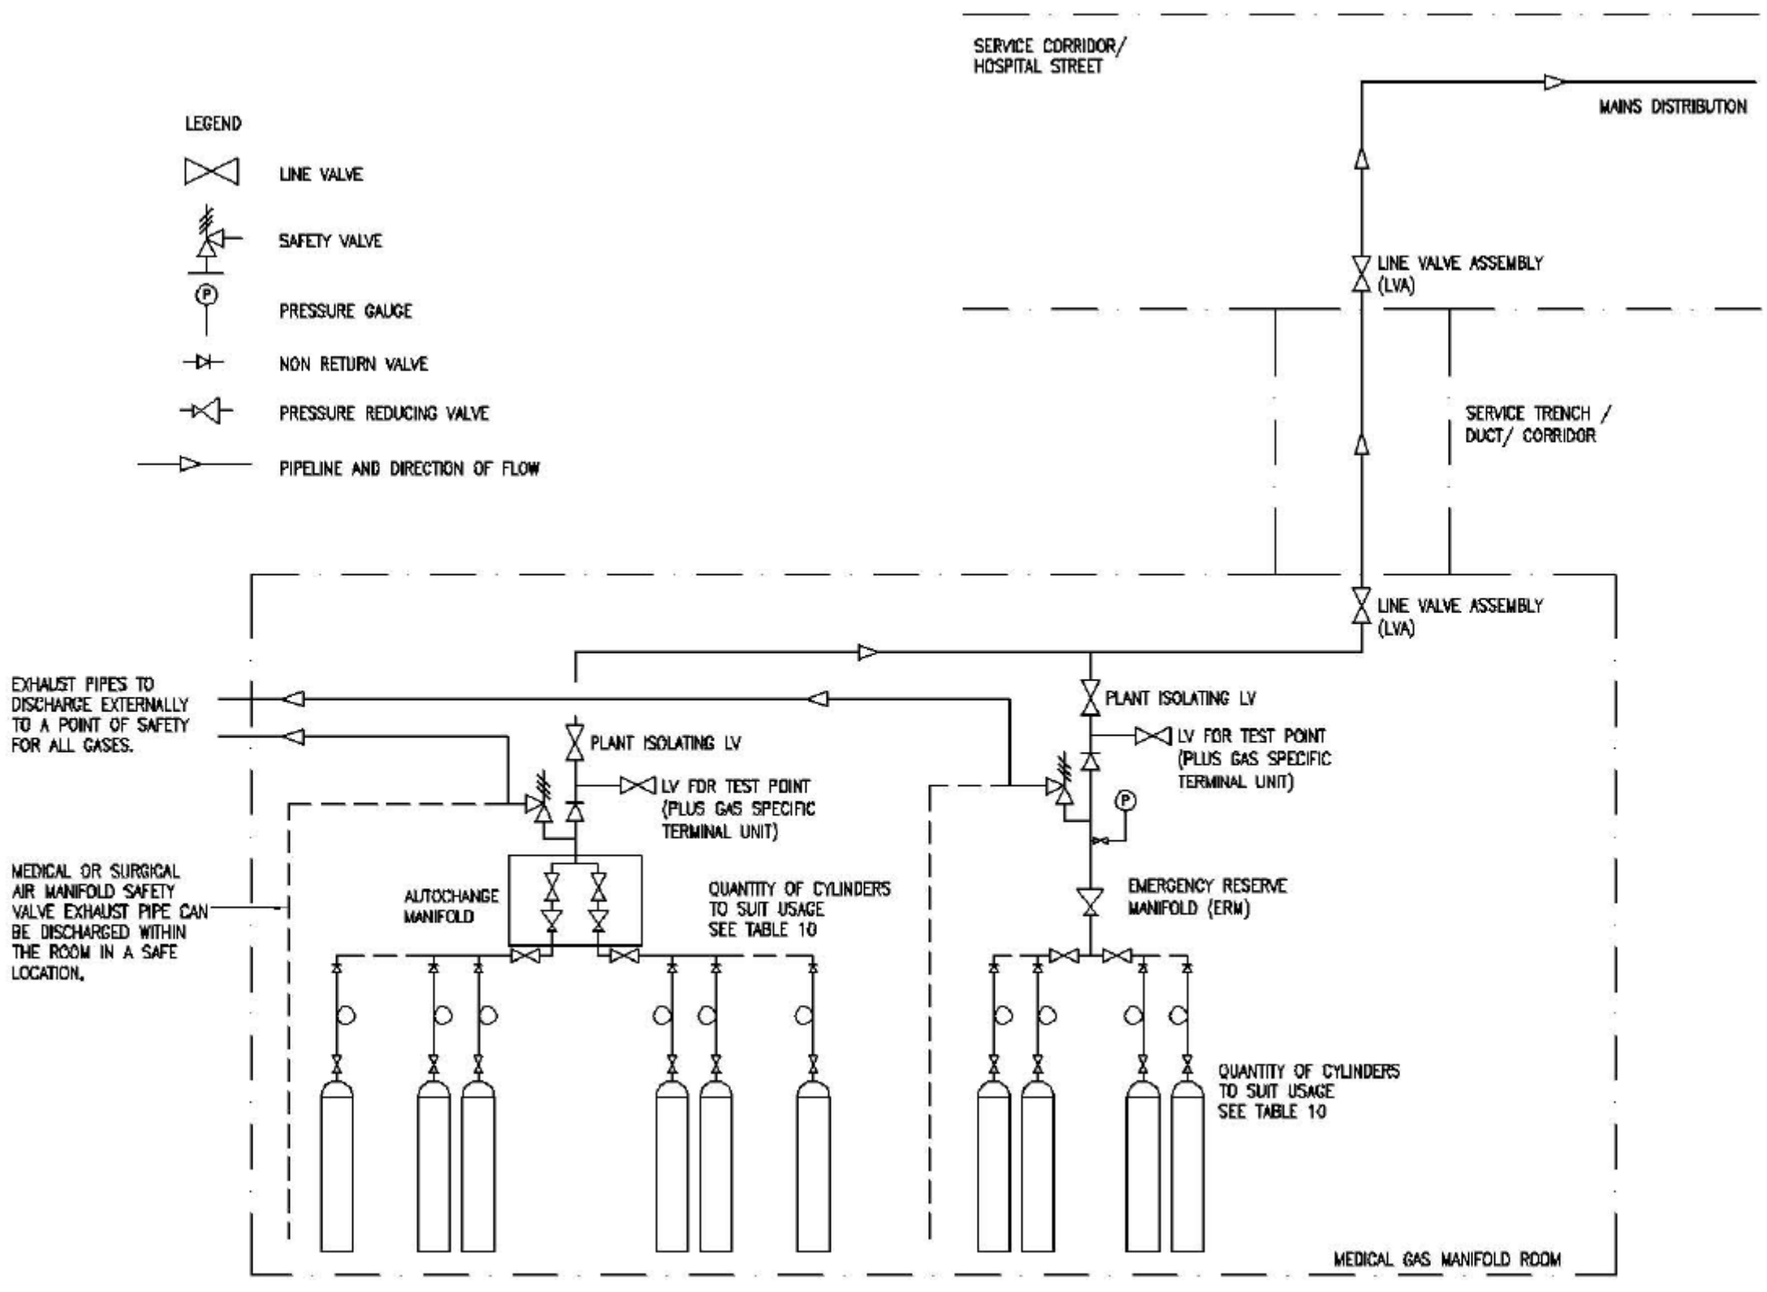

Figure 10: Typical automatic manifold arrangement with manual ERM

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

5.6 In the event of power failure, when the power is restored, the original “running bank” should be on-line, that is, the same bank that was the “running bank” prior to interruption of the supply.

Note14: Some manifolds default to a specific bank following a power failure, regardless of which bank was the running bank prior to interruption of the supply. **NB:** Such units will require manual resetting to the original condition.

5.7 Manifolds and control panels should be designed and certificated for use with 230 bar cylinders. The manifold headers should incorporate a renewable non-return valve to prevent the discharge of a complete bank of cylinders in the event of “tail-pipe” rupture.

5.8 The tail-pipe cylinder connector must be a pin-index yoke connector in accordance with BS EN ISO 407: 2004 for oxygen, nitrous oxide/oxygen mixture (50% v/v) and medical air. Non-metallic flexible connectors shall not be used. The connector for nitrous oxide should be a side outlet valve connector in accordance with BS341-3: 2002. The manifold connectors should be in accordance with Table 24:

Thread	Medical gas
M24 x 2	Medical air
M22 x 2	N_2O/O_2
M20 x 2	O_2
M18 x 2	N_2O

Table 24: Cylinder valve thread sizes

Where it is necessary to use non-metallic materials, consideration should be given to the use of non-halogenated polymers in high pressure systems (>3,000 kPa) delivering oxygen or gaseous mixtures with oxygen concentrations greater than that in ambient air. Consideration should also be given to fitting sintered filters upstream of non-metallic materials to minimise the risk of particle collisions and impacts, which are a potential source of ignition. In addition, there are tests that should be conducted to ensure that the risk of ignition is minimised. Attention is drawn to BS EN ISO 15001: 2010.

Note 15: Studies have shown that inadvertent ignition of halogenated polymers can lead to highly toxic by-products being delivered to the gas stream.

5.9 Pressure indication should be provided to indicate pressure in each cylinder bank and in the MGPS.

5.10 The automatic manifold and ERM should be provided with a test point comprising lockable valve and terminal unit. This should be sited within the manifold room and positioned immediately upstream of the distribution pipeline isolating valve.

Pressure control

5.11 The pressure control should maintain the nominal pipeline pressure within the limits given in Section 4. High-pressure regulators should comply with BS EN

© Health Facilities Scotland, a division of NHS National Services Scotland.

ISO 10524-2: 2006 and be supplied with auto-ignition test results and regulator performance curves for each gas.

5.12 Separate pressure regulating valves should be provided for each cylinder bank. The control system should be designed so that the cylinders of one bank can be changed, or the pressure regulator or any component for one bank can be overhauled, without loss of continuity of the gas supply, refer to Figures 10 and 11 for provision of isolating valves.

5.13 Pressure safety valves should be of the self-closing type and be installed on each distribution pipeline downstream of the manifold line pressure regulator and upstream of the main isolation valve. A pressure safety valve should also be installed between the reserve supply and the pipeline distribution system. It should have a flow capacity at least equal to that of the pressure regulator immediately upstream of it. The discharge pipe should be at least one size larger than the main pipeline and be separate for each safety valve.

5.14 This discharge pipeline should be vented to atmosphere, outside the building, in an area where the discharge of oxygen, nitrous oxide, or nitrous oxide/oxygen mixture will not present a fire hazard or cause injury to personnel. Medical and surgical air may be vented internally normally terminating 50mm above finished floor level. Warning signs should be posted at the discharge positions; access for inspection should be provided.

5.15 Discharge pipelines should terminate at least 3m clear of any door/window that can be opened or other ventilation/air intake. The ends of the discharge pipelines should be turned downwards to prevent the ingress of dirt and moisture, and be placed and protected so that frost cannot form or be collected upon them. Similar safety valve arrangements are required for installations supplied from liquid oxygen cylinders.

Note 16: High pressure cylinders with integral pressure regulation can be used on manifold systems.

Manifold monitoring and indicating system

5.16 The monitoring and indicating system should perform the following functions:

- overall manifold monitoring;
- manifold condition indication;
- overall supply plant indication.

5.17 All functions should be appropriately identified. Indicators should have a design life of at least five years. The system should be capable of automatic reinstatement after restoration of the power supply.

5.18 Manifold monitoring, indicating and alarm systems should be on the essential electrical supply.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Manifold control unit

5.19 The control unit should include a green “mains supply on” indicator.

Manifold monitoring

5.20 Each automatic manifold should be provided with monitoring to detect:

a) duty bank operating;

b) duty bank empty and stand-by bank operating;

c) stand-by bank below 10% capacity, when the duty bank is empty;

d) each emergency reserve manifold bank below nominal 14 bar (for nitrous oxide) and below 68/100 bar pressure for other gases (typically 50% of cylinder contents);

e) pipeline pressure faults outside the normal range.

Manifold indicator unit

5.21 There should be indicators to show the following conditions:

a) for each automatic manifold;

b) a green “running” indicator for each bank. This should display when the bank is supplying gas, irrespective of the pressure;

c) a yellow “empty” indicator for each bank when the running bank is empty and changeover has occurred;

d) a yellow “low pressure” indicator for each bank to be illuminated after changeover, when the pressure in the bank now running falls to the low pressure setting;

e) for each emergency reserve bank, a yellow indicator to be illuminated when the pressure in the bank falls below 14 bar for nitrous oxide or below 68/100 bar for other gases(typically 50% of cylinder contents)- this will require the use of separate pressure sensors – one for each bank);

f) for the pipeline distribution system, a red “low pressure” and a red “high pressure” indicator to be illuminated when the respective conditions occur.

Alarm signal status unit

5.22 The following indication of manifold conditions should be provided:

a) green “normal”: *normal*;

b) yellow “duty bank empty, stand-by running”: *change cylinders*;

c) yellow “duty bank empty, stand-by low”: *change cylinders immediately*;

d) yellow “emergency reserve bank low”: *reserve low*;

e) red “pipeline (high or low) pressure fault”: *pressure fault*.

© Health Facilities Scotland, a division of NHS National Services Scotland.

5.23 Conditions (b) to (e) in Paragraph 5.22 should be transmitted to the central alarm system. Where relays are used, they should be normally energised relays, which de-energise under fault conditions, with contacts having a minimum rating of 50 V d.c. and 50 mA. Volt-free, normally closed contacts rated at 50 V d.c. and 50 mA should be provided for transmission of conditions (b) to (e) to the central alarm system.

5.24 The panel can be incorporated into the manifold control unit or be a separate unit within the plantroom. If mounted separately, the cabling should be monitored for open/short circuit. In the event of such a cable fault, a red “system fault” lamp should be illuminated on the alarm signal status unit, together with the appropriate alarm condition.

Manifold management

5.25 Connections should be provided that allow monitoring of manifold alarm conditions (b) to (e) and manifold running for each “bank”. These connections should be Volt-free contacts normally closed for each condition having a minimum rating of 50 V d.c. and 50 mA. The building management system should not be used to control the manifold.

Emergency reserve manifold

5.26 An emergency reserve manifold system should be provided to form a reserve source of supply, for emergency use or to permit servicing or repair.

5.27 The supply should be designed to provide the design flow of the primary system. When such provision would result in more than ten cylinders on each bank, the additional cylinders should be held in the manifold rooms. A non-return valve and isolating valve should be installed immediately upstream of the reserve manifold connection to the pipeline distribution system.

5.28 The requirements for the emergency reserve supply capacity should be set out in the operational policy document; this should take into account the arrangements for the supply of cylinders and the flow that the system is required to provide. The gas supplier should be consulted.

5.29 The specific requirements will depend on the method of primary supply. Where this results in an unrealistic number of cylinders being kept on site, the operational policy should be set out, giving details of procedures to be followed in an emergency to ensure continuity of supply.

5.30 For large installations, it may be impractical to rely on a cylinder manifold system; thus, consideration should be given to either a bulk liquid or liquid cylinder emergency/reserve supply in the case of oxygen and for two or more compressed air plants sited separately for medical / surgical air applications.

5.31 The operational policy document should set out the location of emergency manifolds, cylinders etc and the action to be taken in the event of loss of the primary source of supply.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Emergency reserve supply for manifold installations

5.32 The reserve supply system for cylinder manifold systems should normally be located in the manifold room adjacent to the automatic manifold. All cylinder valves should be permanently open so that gas is immediately available, but one of the manifold header isolating valves should be closed. A typical system is shown in Figure 10.

© Health Facilities Scotland, a division of NHS National Services Scotland.

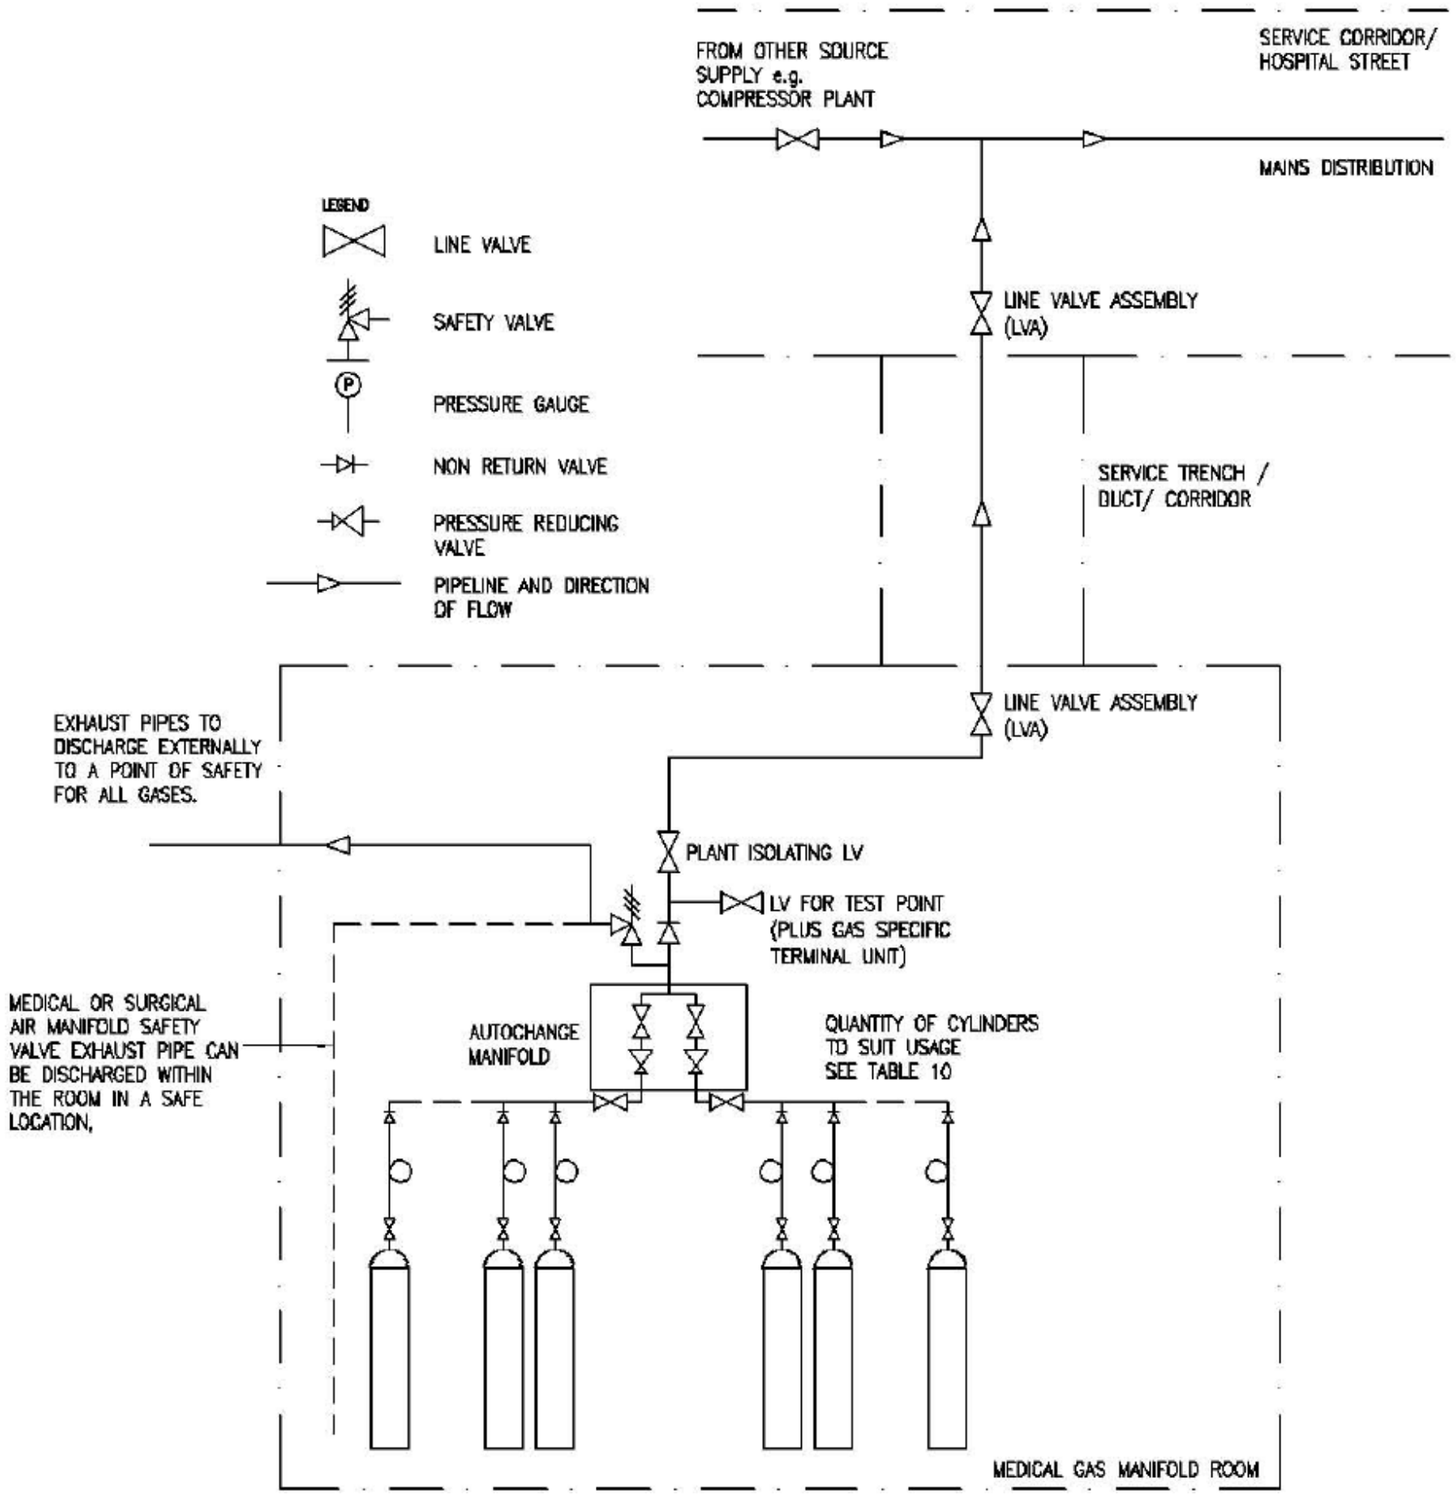

Figure11: Typical automatic changeover emergency reserve manifold for liquid oxygen and medical/surgical air plant

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

5.33 The supply system should go into operation automatically via a non-return valve, and the emergency reserve manifold (ERM) isolating valve should remain open.

Reserve supply for air compressors/liquid oxygen/oxygen concentrators (PSA)

5.34 The supply should comprise a two-bank fully-automatic manifold system as described in paragraphs 5.1–5.24 (except for (d) in paragraph 5.20; (e) in paragraph 5.21; and (d) in paragraph 5.22, which do not apply). The manifold system(s) should be installed in an appropriate manifold room(s) separate from the plant. A typical system is shown in Figure 11.

6. Oxygen systems

Liquid oxygen systems

General

6.1 Over the last ten years, there has been a significant increase in the use of medical oxygen for treating patients in healthcare facilities, with some hospitals seeing annual increases well in excess of 10%. The introduction of the European Standard on medical gas pipeline systems (BS EN 737) has also had implications. Parts 1-4 of BS EN 737 have since been replaced with the standards BS ENISO 9170 and BS EN ISO 7396. Refer to Part B Section 3 for further information.

6.2 The scope of the advice provided by this Section covers the supply of liquid oxygen to healthcare facilities from delivery into bulk storage vessels for the larger hospitals to the supply of liquid oxygen in liquid cylinders to hospitals with lower demands. The guidance given is intended to cover all the aspects of a bulk cryogenic liquid system commonly known as a vacuum insulated evaporator (VIE).

6.3 This chapter also covers the supply of medical oxygen from on-site generation using PSA plant, or in medical cylinders, other than (in the case of the latter) as a means of back-up to the main supply system.

6.4 It does not specifically cover bulk liquid nitrogen installations, but its principles may be applied to hospitals where these gases are used in sufficient quantities to make the use of a VIE cost-effective.

6.5 Significant changes since publication of Scottish Health Technical Memorandum 2022: 2001 include:

- the use of risk assessment as a tool to assist in the development of the medical oxygen installation;
- adoption of the principles outlined in BS EN 737-3: 2000 / BS EN ISO 7396-1: 2007 + A2: 2010;
- new methods of sizing the medical oxygen vessels and back-up manifolds;
- designation of vessel contents as “operational” or “reserve” stock.

A checklist for planning and upgrading an oxygen system is given in Appendix H.

Risk assessment

6.6 Risk assessment is used to assist in the development of the medical oxygen installation to produce a safe and practical design and ensure that a safe supply of oxygen is available for patient use at all times. It is used for all aspects of the process; from the initial concept designs through installation and operation to the routine assessment of the installation, once in service.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.7 Advice is given on setting up risk assessment teams and choosing the correct mix of personnel to ensure that all aspects of the associated risks are considered.

6.8 Throughout this section, non-exclusive risk criteria lists are provided to assist these teams in identifying the unacceptable risks and suggesting how they might be addressed. It recommends that annual risk assessments are carried out throughout the life of the system to ensure that a safe system of supply is maintained and any new risks are identified.

6.9 The prime responsibility to ensure that adequate stocks of medical oxygen are available for patient use should remain firmly with the hospital's management team. However, the hospital may agree with its gas supplier or facilities management supplier that they should manage the supplies of medical oxygen and maintain adequate stocks in the vessel. These arrangements should be clearly documented within the MGPS operational policy and procedures document. The effectiveness of these arrangements will need to be assessed as part of the risk assessment review and be validated to ensure that they can be met.

6.10 Consideration should be given to the operational management consequences of using different suppliers to supply medical oxygen to different supply systems on the same pipeline system.

6.11 Any contracts involving different suppliers should clearly state the obligations and limitations of liabilities; and any facilities management agreement between the hospital and the medical gas supplier must define the responsibilities of each party.

6.12 There must be no modification to the design or any part of the medical liquid oxygen system without written authorisation from the gas supplier.

6.13 This guidance adopts the principles outlined in BS EN ISO 7396-1: 2007 + A2: 2010 'Medical gas pipeline systems – Part 1: Pipeline systems for compressed medical gases and vacuum' which introduces to the UK the concept of having three sources of supply for medical gas systems. This is covered in Section 2.

New methods of sizing

6.14 New methods of sizing the medical oxygen vessels and back-up manifolds are covered, together with advice on appropriate location of vessels on site using principles of risk assessment. This ensures the provision of a secure source of supply that reflects the degree of risk associated with the hospital's location and its level of dependency on medical oxygen.

Designation of vessel contents as "operational" or "reserve" stock

6.15 The operational stock is the volume of product that the gas supplier uses to manage deliveries to the hospital; when this stock is exhausted, the vessel should be refilled under normal conditions.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.16 The reserve stock is the volume of product that is used to provide additional stock to take account of fluctuations in demand or when the supplier fails to make a scheduled delivery.

6.17 Both operational and reserve stock levels are calculated using the risk assessment principles embodied within this document (see Figures 12–17).

Choosing an oxygen supply system

6.18 When designing or reviewing an installation to supply medical oxygen to a hospital, the most appropriate method of supplying the gas will be determined by the potential size and variability of the hospital's medical oxygen demand.

6.19 To determine the most suitable and cost-effective method of supplying medical oxygen and the appropriate size of the installation, comprehensive demand figures should be provided to the designer.

6.20 These demand figures (prepared as a part of the risk assessment) should be based on:

- the current average daily gas usage based on the past twelve months' supplies;
- the maximum potential daily demand volumes based on peak flow conditions, as below;
- any planned extensions to the hospital/pipeline that may affect the demand;
- the expected natural annual growth in the use of medical oxygen.

Portable ultrasonic flowmeters for non-invasive pipeline measurement are a useful tool for arriving at average and peak demand flows.

6.21 The maximum potential daily demand should be based on the peak flow conditions measured between 8.00 am and 6.00 pm, with all operating rooms in use and with maximum demand being provided to pipeline outlets. It should not be based on the theoretical pipeline design flow conditions. Where actual flow monitoring is impracticable, daily cylinder or liquid consumption figures should be used.

Note 17: a) Control panels should be capable of passing the maximum design flow of the oxygen system's pipeline distribution system. This may necessitate installing two control panels in parallel.

b) Plant certification should be issued by the liquid oxygen supply company to demonstrate, on site, the capability of providing the maximum flow as determined as part of the risk assessment process of paragraphs 6.20 and 6.22 within the +/- 4% regulator tolerances required by this Scottish Health Technical Memorandum.

6.22 Additionally, historic consumption records should be reviewed to assess the current usage and the natural growth of the medical oxygen demand. The growth predictions should take into account any planned extensions to the hospital's facilities or pipeline systems and changes in clinical practices in the hospital that could affect the medical oxygen demand. Natural growth in usage of medical oxygen, due to changes in clinical practice, is about 8% to 10% per annum, but individual hospitals will need to establish this growth figure during the risk assessment process. Any planned extensions or estimated natural

© Health Facilities Scotland, a division of NHS National Services Scotland.

growth forming part of the risk assessment process should incorporate a pipeline distribution system reappraisal.

6.23 For new hospitals, where no historic information is available, the estimated demand should be based on the proposed size and type of the hospital and the usage figures of like facilities.

6.24 It is essential to review periodically the average daily demand with the gas supplier and agree either to revise delivery frequencies to maintain the operational stock levels or increase the size of the storage system on site. Any planned increase in demand due to hospital site developments, pipeline extensions or changes in clinical practice should be notified to the gas supplier to ensure that the changes do not jeopardise security of supply.

6.25 The medical liquid oxygen demand should be reviewed with the gas supplier at least annually (or after a significant extension to the pipeline causing increase in demand) to re-assess the size of the installation.

6.26 As the agreed stocks used for the supply of liquid oxygen are all based on an average daily demand, as the demand grows so the storage volume requirements will increase. With the increased volume requirements for the reserve stock, the volume available for operational stock will reduce. Having reviewed the average daily demand with the gas supplier, it is necessary to agree either revised delivery frequencies to maintain the operational stock levels or to increase the size of the storage system on site.

6.27 The review of the medical liquid oxygen installation should also include a review of the risk assessment to ensure that no other conditions on site have been changed that jeopardise the security of the gas supply.

6.28 For smaller hospitals, where the demand is typically below 3,000m^3 per annum, the most cost-effective method of supplying medical oxygen is from a compressed gas cylinder manifold.

6.29 As the demand increases, it becomes less practicable to use compressed gas cylinders and more cost-effective to use medical liquid oxygen. A cylinder manifold larger than 2 x 10 J cylinders is likely to prove impracticable because of the manual handling difficulties with the number of cylinders involved. Liquid cylinders, which are ideally suited to an annual consumption of between 3,000m^3 and 40,000m^3, can be connected together by a manifold to provide adequate storage capacity and flow rate.

6.30 For hospitals with larger demands, a bulk medical oxygen VIE will generally be used. There is a nominal overlap of annual consumption between 27,500m^3 and 40,000m^3, where either a bulk VIE or a liquid cylinder installation could be considered, either to satisfy a particular requirement, or to accommodate possible site restrictions.

6.31 The main benefit of using gas cylinders is that installation costs of manifold systems are significantly lower than those of a liquid oxygen system. However, the cost of the medical oxygen in compressed gas cylinders is higher than the

© Health Facilities Scotland, a division of NHS National Services Scotland.

cost of medical liquid oxygen (supplied either into liquid cylinders or into a VIE). As the demand grows, so the lower unit cost of the liquid oxygen offsets the higher installation costs of the liquid oxygen systems.

6.32 Cryogenic liquid systems are normally used where the demand is high enough to make bulk supplies cost-effective and where the demand makes cylinder supplies impracticable. The demand should be greater than the rate of heat loss to avoid pressure build up.

6.33 Liquid oxygen provides a flexible approach to both the size and the choice of installation design. Its provision is determined by factors such as the size of the hospital, the availability of space for both the installation and the delivery vehicle, the proximity of the gas supplier and the size of the demand for medical oxygen.

6.34 There are a number of operational benefits in using a medical liquid oxygen system over compressed gas cylinders, including:

- greater volume of medical oxygen stored on site;
- improved security of supply;
- reduced storage area for the medical gas cylinders;
- reduced manual handling requirements for cylinder handling.

6.35 When determining the cost-effectiveness of specific proposals from suppliers, the total supply costs should be assessed, including costs for the site preparation and vessel installation, vessel rental and liquid supply over the total period of the contract.

System configurations

6.36 In order to comply with the requirements of BS EN ISO 7396-1: 2007 + A2: 2010, it is necessary for all medical oxygen installations to have three independent supply sources capable of feeding medical oxygen to the pipeline.

6.37 These three sources are referred to as:

- **the primary supply** – the main source of medical oxygen on site, providing gas to the pipeline;
- **the secondary supply** – the secondary source of medical oxygen on site, providing gas to the pipeline and capable of providing the total oxygen flow requirement in the event of a primary supply failure;
- **the reserve supply** – the final source of supply to specific sections of the pipeline, capable of meeting the required demand in the event of failure of the primary and secondary supplies, or failure of the upstream distribution pipework. For the larger development or where the existing hospital acts as the emergency supply source to a PFI/PPP project, refer to paragraph 6.41.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.38 For smaller hospitals, the primary supply can be fed from compressed gas cylinders but as the demand grows, the most practicable supply source will be either liquid cylinders or a VIE system.

6.39 A fully automatic gas cylinder manifold will normally be used as the secondary supply system for smaller VIEs and liquid cylinder systems. Where it is impracticable to maintain supplies to the hospital using a cylinder manifold, a secondary liquid oxygen system will be necessary.

6.40 Emergency supplies will not normally be fed from a liquid oxygen supply system, as it is not possible to prevent the boil-off of the liquid oxygen over extended periods when the emergency system is not in use.

6.41 In major acute hospitals, the foremost consideration of the assessment process should be to locate the primary and secondary supply systems on separate sites. For the larger developments, this consideration can be extended to installing secondary back-up VIEs to each site. Each site should have independent control, monitoring systems and duplex supply routes into the hospital pipeline distribution system and be valved accordingly to ensure that the systems remain independent outwith an emergency situation. The inherent safety of the present control system of a VIE should not be compromised or rely on minimal distribution pipeline pressure differences to determine the primary site, each site should share the hospital load with emergency valving incorporated in the event of a fault condition arising. Alternatively, consideration can be given to each site serving, at high pressure, a common control panel, the secondary supply incorporating an economy circuit, within the hospital manifold room. Section 13 provides additional guidance on dual supply and ring mains.

6.42 Where it is not feasible to utilise two sites, the risk assessment should evaluate the greater level of risk associated with using a single site and define the appropriate actions that should be established to obviate the higher risks, such as using twin or ring-main pipeline systems, siting of the emergency supply manifold or installing suitable protection for the installation.

6.43 The overall ‘same site’ system should be designed so that the primary supply is used first, with the secondary supply automatically switching in when the primary supply is either empty or fails to supply.

Cryogenic liquid systems / VIE

6.44 These systems, commonly referred to as vacuum insulated evaporators (VIEs), are used to store the medical gas as a liquid at cryogenic temperatures and to vaporise it into a gas at ambient temperature for distribution through the hospital pipeline.

Plant

6.45 The VIE system consists of:

- a vacuum insulated cryogenic storage vessel to store the bulk liquid;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- one or more ambient-heated vaporisers to convert the cryogenic liquid into a gas for supply to patients via a pipeline;
- control equipment to control the pressure and flow of gas to the pipeline.

6.46 The liquid oxygen is stored at cryogenic temperatures (down to minus 183°C) and converted to a gas at ambient temperature by passing it through an air-heated vaporiser.

6.47 The cryogenic storage vessel is normally constructed from a stainless steel inner pressure vessel that is supported in a mild steel outer shell. The space between the vessels is filled with a high performance insulating material, maintained under a vacuum, to minimise heat transfer to the inner vessel, which reduces the rate of evaporation of the liquid oxygen.

6.48 A pressure-raising regulator that permits the flow of liquid to the pressure-raising vaporiser, as required, automatically controls the pressure in the liquid oxygen system. The vaporised liquid is fed back to the top of the vessel or liquid cylinder to maintain the pressure in the system.

6.49 Under normal operating conditions for a VIE system, the gas supply to the hospital will be maintained by feeding liquid oxygen to the main vaporiser system where it is converted to a gas and warmed towards ambient temperature. There is a tendency for the vaporiser system to “ice up” where hospital demands are high or continuous, or airflow to the vaporisers is restricted. Under these circumstances the options to be considered should include:

- installation of additional vaporisers;
- an auto-changeover system between vaporizers – refer to Note 18;
- hot water/electrically heated vaporisers;
- increasing size of vaporiser;
- repositioning.

Note 18: In the event of power failure, control valves on all vaporisers should fail “open”.

6.50 Where hospital demands are low or very erratic, the natural heat transfer into the vessel causes the liquid oxygen to boil and the vessel pressure to rise. When the vessel pressure rises to a set point, the hospital pipeline can be fed by valve changeover from the top gas to prevent the vessel pressure rising above the safety-valve setting. On safety-valve operation, oxygen must be able to vent safely to atmosphere. All secondary VIEs should incorporate an economiser circuit which will feed into the hospital distribution system on reaching a predetermined VIE pressure level.

6.51 In all cases, the pipeline pressure is controlled using a system of duplex pressure regulators and valves. It is essential that all materials used in the construction of the vessels, control equipment and pipeline are compatible with

© Health Facilities Scotland, a division of NHS National Services Scotland.

oxygen at the operating temperatures that could be encountered under normal operation with single fault condition. The risk assessment will determine the exact configuration.

6.52 The control panel design should comply with the design requirements specified in BS EN ISO 7396-1: 2007 + A2: 2010 and be sized to provide the system design flow.

Telemetry

6.53 The use of telemetry on the liquid storage system is recommended because it permits both the hospital and the gas supplier to monitor relevant supply conditions continuously, including storage vessel levels and pressure. In addition, it can be used to transmit other operational data from the storage vessel, pipeline and associated equipment for monitoring purposes. It may be beneficial to make this information available to the relevant person(s) in the healthcare organisation. By having continuous monitoring of stock available through the telemetry system, an existing vessel could be retained. This solution is only acceptable provided that an appropriate risk assessment, following the guidance given in this chapter, supports the decision.

Siting

6.54 The Authorised Person (MGPS) will be responsible for agreeing the final location of the liquid oxygen compound(s), taking into consideration any issues raised in the initial risk assessment. It is the supplier's responsibility to assess the space requirements for vehicular access.

6.55 When considering the space requirements for the liquid oxygen compound(s), there may be operational advantages in having two compounds in different areas on the hospital site, rather than one larger site utilising either a single large vessel or multiple tanks. This arrangement may also have benefits with respect to both planning permission and meeting the safety distances specified in the British Compressed Gases Association's (BCGA) Code of Practice 19 (CP19): 'Bulk liquid oxygen storage at users' premises' (henceforth known as BCGA CP19; see Table 25).

6.56 Each supply system should be located in a secure fenced compound, which should be sized to allow adequate access to all of the control equipment.

6.57 The site should essentially be level but designed to have adequate falls to prevent water accumulating beneath equipment.

6.58 The location of drains in the vicinity of the site should comply with the requirements specified in BCGA CP19 (see Table 25).

6.59 Only under extreme conditions should the safety distances specified in BCGA CP19 be reduced. Any relaxation of these safety distances needs to be agreed with the supply company's safety representative and the Authorised Person (MGPS). Both parties must ensure that an equivalent level of safety is achieved, and this should be approved and documented.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.60 The layout of the liquid oxygen installation should provide adequate access to all of the relevant components of the system and permit adequate airflow for the ambient vaporisers.

6.61 The plinth should be of concrete construction. The area in front of the vessel(s) (tanker apron) should be non-porous concrete. Under no circumstances should tarmac be used in the vicinity of the liquid oxygen filling point, or areas where liquid oxygen spillage may occur.

6.62 The location of the liquid oxygen compound should permit the supplier to gain safe access with the appropriately sized tanker. It is the supplier's responsibility to assess the space requirements for vehicular access.

6.63 The design of the liquid oxygen installation should take into account the gas supplier's requirements for discharging the liquid oxygen from the cryogenic tanker. The area directly in front of the vessel should be kept clear to provide access for the delivery vehicle at any time. Under no circumstances should unauthorised vehicles be permitted to park in front of the compound.

6.64 The compound should not be used for the storage of other equipment. For ease of maintenance, the liquid oxygen control panel should be housed in an adjacent bricked room or medical gas manifold room particularly where the secondary supply consists of cylinders.

6.65 Where the secondary or emergency supply system is fed from a cylinder manifold, it should be in a manifold room and have adequate space to permit safe cylinder changeover. Spare cylinders should not be held in the VIE compound or liquid cylinder compound but stored in the nearest medical cylinder store.

6.66 A pipework and installation diagram (P&ID) of the plant should be displayed clearly to indicate the appropriate valves that are necessary to operate the plant safely. The medical gases supplier should make the Authorised Person (MGPS), and others in the hospital that may operate the system, aware of its general operating principles. (Typical plant installations are shown in Figures 18–20.)

Liquid cylinder systems

Plant

6.67 Liquid cylinder systems can also be used to store the medical gas as a liquid at cryogenic temperatures and to vaporise it into a gas for patient use. These systems are used where the demand is too high for compressed gas cylinders to be a practicable option but where it is neither economic nor possible to supply bulk medical liquid oxygen in a VIE system.

6.68 Liquid cylinders are constructed in a similar way to vacuum insulated cryogenic storage units, that is, as double-walled vessels. However, unlike the VIE, the liquid cylinder has an internal vaporiser coil to convert the liquid into a gas.

6.69 The size of the liquid cylinder can vary between 200 litres and 1,000 litres water capacity. To obtain sufficient storage capacity and to meet the hospital's flow requirements, a number of liquid cylinders can be connected together via a manifold.

6.70 The liquid cylinder system consists of:

- a number of vacuum insulated liquid cylinders;
- a system to manifold the liquid cylinders together to store sufficient liquid on site to meet the hospital's demand;
- control equipment to regulate the pressure and flow of gas to the pipeline.

6.71 Although liquid cylinders are suitable for transportation when full, they are normally installed as a fixed installation and remotely filled whilst in situ.

6.72 Liquid cylinders are designed and supplied with gas-specific liquid-fill and gas-use connections (including the connection on the remote liquid-fill connection where the liquid cylinders are filled in situ).

6.73 The connections used are:

- liquid fill: CGA 440;
- gas use: ISO 5145.

Siting

6.74 Where there is no alternative, a liquid cylinder manifold may be installed in a building or confined area, but only if the vent header (to which all liquid cylinder vents will be connected) is piped to a safe area via a back-pressure control valve. This valve should be set at a pressure below that of the liquid cylinder relief valve setting, thus ensuring that any excess pressure is safely vented.

6.75 Where installed in buildings, generous ventilation should be provided by means of fully-louvred access doors to the outside. Additional protection of supply and extract ventilation controlled by oxygen monitoring equipment should be

© Health Facilities Scotland, a division of NHS National Services Scotland.

considered. Further guidance on ventilation requirements is given in BCGA CoP No. 4. The appropriate calculation must be made to ensure adequate ventilation, especially during the filling of the vessels, when they may be venting freely to atmosphere inside the manifold room.

6.76 A P&ID of the plant should be displayed clearly to indicate the appropriate valves necessary to operate the plant safely. The Authorised Person (MGPS) and others in the hospital who may work with the VIE system should be made aware of its general operating principles by the medical gas supplier. (Figure 21 shows a typical liquid cylinder manifold installation with cylinder backup.)

A48235836

Compressed gas cylinder manifolds

6.77 The simplest supply system to provide medical oxygen to a hospital pipeline system utilises compressed gas cylinders, connected together on an auto-changeover manifold. As the demand increases, the number of cylinders fitted to the manifold can be increased to meet the hospital's requirements. The third or reserve supply for this system will usually be a manual changeover compressed gas cylinder manifold, which comes on line automatically (via a non-return valve) in the event of primary manifold failure.

6.78 For a full description of manifold supply systems, see Section 5.

Secondary supply systems

6.79 Where the primary supply system is a VIE, the secondary supply system can be either:

- another VIE; or
- a liquid cylinder manifold; or
- a fully-automatic compressed gas cylinder manifold.

6.80 Where the primary supply system is a liquid cylinder system, the secondary supply system should be a fully automatic changeover gas cylinder manifold that comes into operation automatically.

6.81 There should be a system of backflow prevention to protect either system venting through the other in the event of a single fault in either system.

6.82 Where the secondary supply is fed from compressed gas cylinders, the size of the changeover manifold and the number of cylinders stored on site should be based on the gas supplier's ability to guarantee a delivery service within a defined period.

6.83 Where a liquid oxygen system is used for the secondary supply, the system design should allow any liquid oxygen that has boiled off to be fed to the pipeline system to utilise product.

6.84 Where the feed from the VIE compound to the hospital extends a long distance, or is exposed to potential mechanical damage, particular importance should be given to siting the secondary supply system remotely from the main VIE compound with a separate supply to the hospital pipeline system. In all instances where pipelines cannot be inspected throughout their length, twin pipelines in separate ducts and suitably valved to permit pressure testing whilst maintaining the service should be provided.

6.85 Where the secondary supply is sited remotely, consideration should also be given to the set point of the secondary supply output regulator to ensure that the pipeline dynamic pressure is maintained at a minimum level of 420 kPa. Where a proposal is raised to consider the remote siting of the secondary supply the risk assessment, in consultation with the suppliers, must consider the changes

© Health Facilities Scotland, a division of NHS National Services Scotland.

from a proved but simple control system that would be required to maintain a control link between primary and secondary panels and the requirement of the secondary supply economiser circuit, unless both primary and secondary VIEs on remote sites are served by a common panel or a back-up service is available on each site.

6.86 When the vessels are located on separate sites, a backflow prevention device must be fitted on each leg feeding into the pipeline system. This will prevent loss of product, either from the other vessel or from the hospital pipeline, in the event of failure of or damage to a VIE unit or its feed into the hospital pipeline. The backflow protection should be sited in a secure location where it is not liable to mechanical damage and be as close to the hospital curtilage as possible.

Emergency supply provision

6.87 In the event of total plant and/or main pipeline failure, an emergency supply of oxygen should be available for patient use.

6.88 The emergency supply system should be activated automatically when the primary and secondary system is empty or fails to supply or when the hospital pipeline pressure falls below 375 kPa. It must have the provision to prevent the automatic backflow of medical oxygen into the remainder of the pipeline system should the pipeline fail upstream of the connection.

6.89 A variety of sources are available for the provision of emergency oxygen, and these are detailed in paragraphs 6.96 – 6.105.

6.90 Under most conditions, compressed gas cylinders are the appropriate method of providing an emergency supply source.

6.91 The size and design of the emergency supply system should allow for cylinders to be changed whilst maintaining the emergency supply.

6.92 Where the emergency supply serves the hospital distribution system, the set point of the regulator should be 375 kPa to ensure that the plant low pressure alarm normally set at 385 kPa is activated thus providing warning of plant failure.

Emergency / maintenance inlet ports

6.93 Emergency / maintenance inlet ports are covered in Section 13. In some instances, installation of a fixed manifold system will obviate the need for fitting an emergency inlet port.

6.94 In smaller installations, fitting an emergency inlet port may be dispensed with if the risk analysis indicates that adequate supplies can be maintained via the NIST connectors of AVSUs supplying critical care areas.

6.95 When planning emergency provision for a complete system, vulnerability of the primary and secondary supplies will be a critical factor in determining both the type and the means of supply.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Fixed automatic/manual manifold systems

6.96 Where two VIE units on the same plinth are in use, the emergency supply system should comprise a fully automatic cylinder manifold permanently connected to (one of) the main oxygen riser(s) in the hospital, or directly into a ring-main system. It must be able to feed a riser automatically (without back-feeding to any damaged upstream section) on failure of both primary and secondary plant, or the MGPS upstream of the entry into the hospital. Such an arrangement is particularly suited to situations in which the main feed from the VIE installation to the hospital pipeline is vulnerable to mechanical damage, for example when buried under a roadway. The location and size of the manifold should be determined by the risk assessment and according to the dependency of the patients.

6.97 When two separately sited VIE units are used to provide the hospital supply, the need for emergency manifold provision should be assessed against the likelihood of failure of both VIE systems and their respective feeds into the hospital pipeline.

6.98 Where it can be shown through risk assessment that one or both units are fed into the hospital pipeline in a manner such that the probability of disruption of one or both of the feeds is negligible, the option to waive the fitting of further (manifold) supplies can be considered.

Local manifold provision (critical care areas)

6.99 To offer additional protection against the possibility of a pipeline failure within the hospital, further (manual or automatic) manifolds can be permanently connected, via non-return valves, downstream of AVSUs controlling high-dependency areas. Such units should come on line automatically on failure of the main supply to an AVSU. A further non-return valve must also be added upstream of the AVSU to prevent back-feeding into a failed main supply system.

6.100 The positioning of these manifolds is very important to ensure that the critical care/high dependency areas defined in the risk assessment process have adequate stocks of medical oxygen available in the event of a system failure. However, the risk analysis for the complete system may indicate that the probability of use of such a manifold system is negligible, or that the circumstances causing the system failure would in any event require the evacuation of the area.

6.101 Availability of accommodation, staff and manual handling issues would also need to be considered during the risk assessment process. Where space limitations prevent the installation of such manifolds, the implications of providing discrete cylinder/regulator combinations must be considered.

Gas feed via an AVSU (or terminal unit)

6.102 Oxygen supply to the downstream side of an AVSU (with the valve closed) may be achieved using an “emergency supply kit” consisting of two cylinder regulators and associated supply hoses with gas-specific connectors.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.103 Such an arrangement may be used to support high-dependency departments, albeit the unit will usually be of limited capacity by comparison to a fixed automatic manifold system.

6.104 Storage, maintenance, testing, security and deployment arrangements for the emergency supply kits must be documented in the MGPS operational policy.

Discrete cylinder supplies

6.105 For non-critical care areas where there are no high-dependency patients, it may be appropriate to use individual cylinders as the reserve source of supply. Cylinders fitted with integral valves and having a product-specific terminal unit outlet are suitable for this purpose. The difficulties associated with storing, testing, maintaining, distributing and connecting large numbers of such equipment must not be underestimated. (Such protocols should be referenced in the MGPS operational policy).

Alarm systems

6.106 Installations of the following type should be fitted with alarm systems to provide visual and audible warnings at the plant (each site) and in a 24 hour manned station with slave panels as required for the following conditions. Variations to supply mode are:

- dual VIE vessels on a common site or separate sites feeding into a single control panel; or
- dual VIE vessels on separate sites each with independent control panels;
- single VIE vessel supported by a liquid cylinder secondary supply; or
- single VIE vessel supported by a fully automatic compressed gas cylinder manifold.

The following displays should be presented at the plant and in a 24-hour-staffed position.

Status/fault condition	Indication	Legend
Normal operation System available for use	Green	Normal
Primary supply system's operational stock empty Primary supply system's reserve stock in use	Yellow	Refill liquid
Primary supply system's reserve stock empty Secondary supply system in use	Yellow	Refill liquid immediately
Secondary supply system empty Emergency system in use	Yellow	Emergency supply in use
Pipeline pressure high or low	Red	Pressure fault

Table 26: Oxygen plant alarm conditions

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.107 It is not considered advisable that a single VIE in a remote location has no local back-up – refer to paragraph 6.85. Where the third source of supply is a liquid cylinder or fully automatic cylinder manifold serving separate or singular part(s) of the pipeline system the alarm displayed at the liquid cylinder or manifold and the 24 hour manned station will be independent of the primary and secondary sources of supply but similar to the alarm conditions 1, 2 & 4 laid out in paragraph 6.106 and Table 26. Where the assessment process considered that an additional emergency service manifold is advisable in event of maintenance requirements, alarm condition 3 would apply.

At the primary vessel and a 24-hour-manned position		
Status/fault condition	**Indication**	**Legend**
Normal operation System available for use	Green	Normal
Primary supply system's operational stock empty Primary supply system reserve stock in use	Yellow	Refill liquid
Primary supply system's reserve stock empty Secondary supply system in use	Yellow	Refill liquid immediately
Secondary supply system low	Yellow	Secondary stock low
Pipeline pressure high or low	Red	Pressure fault

Table 27: Oxygen central plant alarm conditions (primary supply)

6.108 When the primary system operational stock has been exhausted and the vessel contents reach the reserve stock level, the first alarm condition will be indicated by a yellow alarm and the legend "refill liquid" illuminated.

6.109 When the primary system reserve stock is empty and the secondary supply system is in operation, the second alarm condition will be indicated by a yellow alarm and the legend "refill liquid immediately" illuminated. This alarm condition continues until the primary supply system is refilled.

6.110 When the secondary supply system is low, the third alarm condition will be indicated by a yellow alarm and the legend "secondary stock low" illuminated. This alarm condition continues until the secondary supply system is refilled or the cylinders are replaced.

6.111 Should the primary supply of medical oxygen to the hospital pipeline fail due to lack of contents or mechanical failure of any of the components, or should a serious leak occur, the pipeline pressure will fall. When the plant output pipeline pressure falls below 385 kPa, the condition will be indicated by the "pressure fault" alarm.

6.112 If the regulator controlling the pipeline pressure should fail "open", the pipeline pressure will rise. This condition will be indicated by the "pressure fault" alarm when the pressure rises above 500 kPa.

© Health Facilities Scotland, a division of NHS National Services Scotland.

At the secondary vessel/liquid cylinder supply/cylinder manifold and a 24-hour-staffed position		
Status/fault condition	**Indication**	**Legend**
Normal operation System available for use	Green	Normal
Secondary supply system's operational stock empty Secondary supply system's reserve stock in use	Yellow	Refill liquid / change cylinders
Secondary supply system's reserve stock empty Emergency supply system in use	Yellow	Emergency supply in use
Pipeline pressure high or low	Red	Pressure fault

Table 28: Oxygen central plant alarm conditions (secondary supply)

6.113 With a correctly installed and commissioned system where the three sources of supply are serving the full hospital distribution system, in the event of a loss of primary and secondary pressure the plant low pressure alarm condition of 385 kPa will be activated with the third source of supply continuing to supply the hospital at 375 kPa. With primary and secondary sources empty, all alarms on both plant and the 24 hour manned station will be activated. In a fault condition the degree of alarm should assist in identifying the problem. The third source should be clearly identified on the alarm panel as the oxygen emergency supply and recognised of having limited capacity. The Operational Policy document emergency procedures should normally ensure corrective action is taken at the first stages of alarm to ensure continuity of supply by arranging a liquid delivery or identify and rectify a fault condition.

6.114 Where the emergency supply is installed on individual zones of the pipeline system, the "emergency supply in use" alarm must be displayed within the pipeline zone area. A separate "emergency supply low" alarm should also be installed on each zone.

6.115 Where more than one VIE is used and the operational and reserve stock is distributed between multiple vessels, a lit "normal" display indicates that the vessel is available for use.

6.116 In the event that the primary (or secondary) vessel should become empty (or suffer from any other fault condition), the "normal" display should be extinguished, indicating that the vessel is not available for use.

6.117 Alarm conditions should be transmitted to the central alarm system.

6.118 Where relays are used, they should be energised relays that de-energise under fault conditions, with contacts having a minimum rating of 50 V d.c. and 50 mA. Alternatively, Volt-free, normally closed contacts rated at 50 V d.c. and 50 mA should be provided for transmission of the conditions to the alarm system.

6.119 Typical alarm trigger points are shown in Figures 12 – 17.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Determining system size through risk assessment

Introduction

6.120 The 2001 edition of Scottish Health Technical Memorandum 2022 defined a (fixed) VIE primary vessel capacity of 14 days' oxygen supply but did not define capacity for a liquid cylinder system. This section addresses the risk factors associated with the supply of oxygen on a hospital site and, with the aid of defined risk criteria, offers guidance on the sizing of VIE, liquid cylinder and compressed gas cylinder manifold installations for any specified location.

6.121 The risk assessment should take into account all issues concerning the safety and continuity of the medical oxygen supply. It is suggested that identified risk factors and criteria be evaluated using both qualitative and quantitative measures, and that all results be recorded in a logical manner that will support the decisions being made. The record of the risk assessment will also act as a reference document when the system is reviewed.

6.123 Additional local factors and requirements identified by the project team will also need to be considered when carrying out the risk assessment to take account of site-specific issues concerning how the product is stored, distributed and used.

6.124 Any risk control procedures identified by the risk assessment process which are designed to minimise any identified risks must be recorded and incorporated into the relevant hospital standard operating procedures (SOP) or work instructions (WI).

6.125 When sizing the vessels and cylinder manifolds to provide adequate storage of medical oxygen on site, the stock should be distributed between the three sources of supply as defined in BS EN 737-3: 2000 / BS EN 1SO 7396-1: 2007 + A2: 2010; that is, the medical oxygen supply system should normally consist of:

- a primary supply;
- a secondary supply;
- emergency third or reserve supply.

6.126 The capacity of the primary and secondary supply system will consist of:

- operational stock;
- reserve stock.

6.127 The operational stock is the volume of product that the gas supplier uses to manage deliveries to the hospital, and its exhaustion signals the point at which the vessel should be refilled under normal conditions.

6.128 The reserve stock is the volume of product that is used to provide additional stock, to take account of fluctuations in demand, or when the supplier fails to make a scheduled delivery.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.129 The system should be designed so that the primary and secondary supply system stocks are kept separate from each other. Under no circumstances can the primary supply system operational stock be stored in the secondary supply system vessel.

6.130 However, where it is not possible to install a single large VIE vessel for the primary supply (such as where planning permission restrictions prevent the use of a single large vessel), it may be appropriate to hold all or some of the primary supply system reserve stock in the secondary supply vessel. Under these circumstances the primary supply vessel should retain a minimum level when changing over to the secondary supply system. The volume retained in the primary supply vessel should equate to the secondary supply system reserve stock. This should provide adequate stock on site to enable the gas supplier to resupply product to the primary vessel in the event of failure of the secondary supply. This level should be determined by the risk assessment process but should be at least one day's usable stock.

Review of risk assessment

6.131 The documented risk assessment should be reviewed after the installation is complete, prior to commissioning, to assess whether any parameters or circumstances have changed since the initial assessment. The risk assessment must also be reviewed at least annually (or when there is any significant change to the medical oxygen supply system or usage pattern) to ensure that the details are current. At this review, all changes should be considered that might have an effect on the safety of the system or the security of supply.

Sizing plant – general

VIE installations

6.132 The operational and reserve stock for each supply system should normally be held in the same vessel. Where planning restrictions prevent the use of a single large vessel on site, it may be appropriate to utilise multiple vessels to provide adequate stocks on site.

6.133 When sizing VIE systems for the primary or secondary supply, the vessel size will be determined by adding the operational and reserve stock together and allowing for the level of unusable stock left in the vessel when the designed flow rate cannot be maintained.

Liquid cylinder installations

6.134 For liquid cylinder installations, the primary system should be made up of a number of liquid cylinders connected together by a manifold. The secondary system will comprise an automatic compressed gas cylinder manifold system.

6.135 Each liquid cylinder will have a maximum design flow rate for continuous use. The number of liquid cylinders required for an installation may be governed by either the maximum storage capacity required on site or the flow rate required to meet the hospital's maximum demand.

© Health Facilities Scotland, a division of NHS National Services Scotland.

6.136 When determining the number and size of liquid cylinders required for either a primary or a secondary supply to a VIE, an allowance has to be made for the unusable capacity of each cylinder when connected to the manifold system.

Compressed gas cylinder manifold systems

6.137 Where the hospital does not warrant a liquid oxygen system, an automatic cylinder manifold should be considered. This should be sited to facilitate future extension of the manifold banks.

6.138 The reserve supply will normally comprise a manually operated manifold system, connected such that it will come on line automatically (via a non-return valve) in the event of failure of the primary and secondary supply.

6.139 For sizing compressed gas cylinder systems, the size of the manifold will normally be determined by the ability of the hospital to provide adequately trained staff to change over cylinders quickly enough to meet the demand.

The risk assessment process

Risk assessment for management responsibilities

6.140 The risk assessment criteria, when considering management responsibilities for the medical liquid oxygen system, need to include the following:

- the need to document and agree responsibilities for the monitoring of the medical liquid oxygen VIE, and the need to establish a back-up procedure with the gas supplier to ensure that adequate stocks will be maintained in the event of a failure of the fitted telemetry system;
- the hospital should set up procedures to ensure that the VIE system is monitored at regular intervals for any deviation from normal operation (such as safety valves lifting, major leaks, or failure of either the telemetry or alarm system);
- the implications of any decisions to not fit telemetry or to utilise a vessel, or vessels, that do not provide adequate operational and reserve stocks. These decisions should be taken at an appropriate level of management, should be documented, and their implications should be considered as part of the risk assessment;
- consideration of the resources needed to maintain adequate supplies of medical oxygen either under normal, or emergency, conditions. When evaluating these requirements, consideration should be given to the risks that the healthcare organisation would face in the event of supply failure causing disruption of clinical services;
- consideration of the operational management consequences of using different suppliers to supply medical oxygen to different supply systems supporting the same pipeline installation. Any contracts involving different suppliers should clearly state the obligations and limitations of liabilities.

6.141 Where manifolds are used, adequately trained staff should be available, whenever required, to ensure continuity of supply. Consideration also needs to

© Health Facilities Scotland, a division of NHS National Services Scotland.

be given to the manual handling issues concerned with changing cylinders on the manifold and arrangements to store adequate stocks to meet demands.

6.142 Consideration needs to be given to the type of clinical activities carried out in each area of the hospital and the ability to provide emergency back-up to individual areas used for critical care, or within high dependency units.

Initial risk assessment for siting of plant

6.143 The initial risk assessment should consider the requirements to ensure a continuous supply of medical gas to the patient.

6.144 The initial risk assessment criteria related to the complete installation should include:

- the size and location of each source of supply (for example the volume held as operational and reserve stock for each source of supply, located on one site or two independent sites);
- the associated risks with siting tanks at either the same or separate locations (for example physical space availability, accessibility for delivery and maintenance requirements, accessibility to the pipeline system [to tie-in points etc], alarm systems and cabling, pipeline routing and protection);
- the need to site the reserve sources of supply local to the point of use to protect against pipeline failure where high-dependency patients are located;
- safety requirements for the storage of oxygen on site, including compliance with the safety distances specified in BCGA CP19;
- the location and extent of the medical oxygen pipeline system;
- the vulnerability of the hospital pipeline to mechanical damage and whether underground sections of the pipeline system comply with the requirements of this Scottish Health Technical Memorandum and whether the pipeline is capable of being inspected throughout its entire length or pressure tested (whilst maintaining the supply), or otherwise can be tested;
- the space available for the liquid oxygen installation, or cylinder manifold, and the available access for the delivery vehicle;
- the vulnerability of the site to external damage;
- the possibility of interference with the supply system or other security issues.

Risk assessment for sizing of operational stock

6.145 The risk assessment criteria for the sizing of the operational stock should include:

- the average daily demand at the end of the contract period. Any changes to the predicted growth of demand will need to be considered, and changes made to the vessel size or delivery frequency at the appropriate time within the contract period. It may be beneficial to set a daily demand rate at which changes to vessel size or delivery frequency will be considered;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- a review of vehicular access to the VIE, timing of the deliveries, any restrictions due to local planning requirements, and the effect of these factors on the delivery frequency;
- an environmental impact assessment.

Risk assessment for sizing of reserve stock

6.146 The risk assessment criteria for the sizing of the reserve stock should include:

- the average daily demand at the end of the contract period. Any changes to the predicted growth of demand will need to be considered, and changes made to the vessel size or delivery frequency at the appropriate time within the contract period. It may be beneficial to set a daily demand rate at which changes to vessel size or delivery frequency will be considered;
- the delivery frequency guaranteed by the gas supplier that can be provided at short notice should the primary supply system fail;
- the minimum response time from when the primary supply system fails to when the delivery vehicle could be on site to refill the secondary supply VIE, or to provide replacement compressed gas cylinders for the manifold.

Risk assessment for the provision of emergency supply systems

6.147 The risk assessment criteria concerning emergency supply systems should include:

- the need for installation of independent emergency supplies to zones on the medical gas pipeline supplying critical care areas or wards or departments that are remote or vulnerable to interruption;
- the positioning of the manifold to ensure ease of changeover of cylinders with respect to access and manual handling issues;
- the storage of cylinders associated with the emergency manifold to ensure compliance with the appropriate codes of practice and local hospital requirements;
- training requirements for both the relevant clinical and operational staff to ensure correct operation of the emergency supply system.

Stock calculations

Calculation of operational stock for primary and secondary supplies

6.148 The capacity of the operational stock of primary and secondary supply systems should be agreed with the gas supplier and based on the following parameters:

- the current average medical oxygen daily demand, plus any natural growth over the contract period;
- any additional planned growth (above any natural growth) in the usage pattern within the contract period;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- the agreed delivery frequency.

6.149 The current average daily demand can be calculated by dividing the current annual consumption by 365 days.

6.150 The operational stock should be based on an average daily demand predicted for the end of the contract period calculated by:

Average daily demand = Current daily demand + Planned growth + Natural growth.

6.151 The operational stock is calculated as:

Operational stock = Average daily demand x Agreed delivery period.

6.152 If there is significant growth in average daily demand within the contract period, either the vessel should be resized or the agreed delivery frequency should be reviewed to reduce the delivery period and maintain the operational stock level.

6.153 The delivery period for the primary supply will be based on the gas supplier's normal delivery frequency.

6.154 The delivery period for the secondary supply will be based on emergency conditions when the primary supply is not available. Under these circumstances, special delivery response times must be agreed with the gas supplier.

6.155 The supply agreement should commit the supplier to manage the operational stock, based on an agreed delivery frequency and the minimum stock level to be maintained in the vessel.

Calculation of primary reserve stock

6.156 Table 29 provides a matrix for the calculation of primary reserve stock based upon distance from gas supplier and fitting of telemetry.

Kilometres from gas supply depot	No telemetry (no of days' stock)	Telemetry fitted (no of days' stock)
Up to 75	5	3
75-150	6	4
150-300	7	5
Over 300	8	6

Table 29: Requirement for remote indication for stock levels

Calculation of secondary reserve stock

6.157 The minimum level for reserve stock for the secondary supply should allow for circumstances in which the primary supply system is not available for use.

6.158 This secondary supply system reserve stock level will be dependent on:

- the proximity of the supplier's distribution depot;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- the response time that the gas supplier needs to make a delivery under these conditions;
- the delivery frequency that can be sustained under the conditions when the primary supply is unavailable for use.

Calculation of capacity of emergency supply systems (VIE and cylinder manifolds)

6.159 Where an existing hospital VIE acts as an emergency third source of supply to a new hospital installation, the minimum supply available to both hospitals should be in accordance with the suggested stock levels detailed in Table 29, above. The number of cylinders stored locally to the emergency supply system manifold and the number of connections on the manifold(s) should be determined by risk assessment.

6.160 When determining these requirements, the risk assessment needs to consider:

- the maximum demand from the high dependency patients who may be supplied from the pipeline zone that the emergency supply system protects;
- the maximum duration for which the emergency state is likely to last;
- the proximity of the supplier of the compressed cylinders to the hospital;
- the ability of the hospital to connect cylinders to the manifold.

6.161 Consideration needs to be given to the logistics of storing and handling the number of cylinders needed to provide adequate supplies until the primary/secondary supply systems or the hospital pipeline can be re-established.

Oxygen concentrator installations (PSA plant)

General

6.162 Oxygen concentrators or pressure swing adsorber (PSA) systems may be alternatives to the more traditional supply systems (the terms ‘oxygen concentrator’ and ‘PSA’ are interchangeable). Typical installations where PSA systems should be considered are those sites having no access to reliable liquid supplies, such as remote or off-shore locations, or where the safety criteria for a bulk liquid vessel cannot be met (for example, very restricted sites). Otherwise, PSA systems should only be installed when an investment appraisal shows them to be economical.

6.163 When installed, a PSA system will deliver product gas via the “oxygen” pipeline system.

6.164 Oxygen concentrators operate by adsorbing, under pressure, other gases in the atmosphere onto materials which have specific physico-chemical properties, thus freeing the oxygen which is stored and transmitting it for use. The adsorbents are known as artificial zeolites, more commonly referred to as molecular sieves. The sieve units are arranged in pairs, one adsorbing whilst

© Health Facilities Scotland, a division of NHS National Services Scotland.

the other regenerates. The waste product, essentially nitrogen, is discharged to atmosphere during regeneration of the adsorbents. In some systems, the use of vacuum to remove the nitrogen increases the efficiency of the regeneration/adsorption process. Regeneration requires the use of a small proportion of the product gas.

6.165 The PSA process has reached a high level of technical sophistication and is capable of producing oxygen with a concentration of about 95%. (For the UK the minimum level, below which the emergency/reserve manifold will come into operation, is 94%.) The remainder is mainly argon with some nitrogen. The highest concentration is not likely to exceed 97/98%, except when the emergency/reserve manifold is in use, when it will be 100% if these are from a gas supplier.

6.166 The major components of a PSA system and their layout are shown in Figure 22. The typical major components of the system are the compressors, receiver(s), dryers, molecular sieves, vacuum pumps, filters and regulators. Other components are identical to those used for medical air and vacuum plant, which are described fully in the appropriate sections. A suitable operating and indicating system is also required, as specified below. Package supply systems, which should be specified to meet the requirements given in this memorandum, are available from manufacturers.

Note 19: Reference should be made to BS7634: 1993 / ISO 10083: 1992 for further guidance.

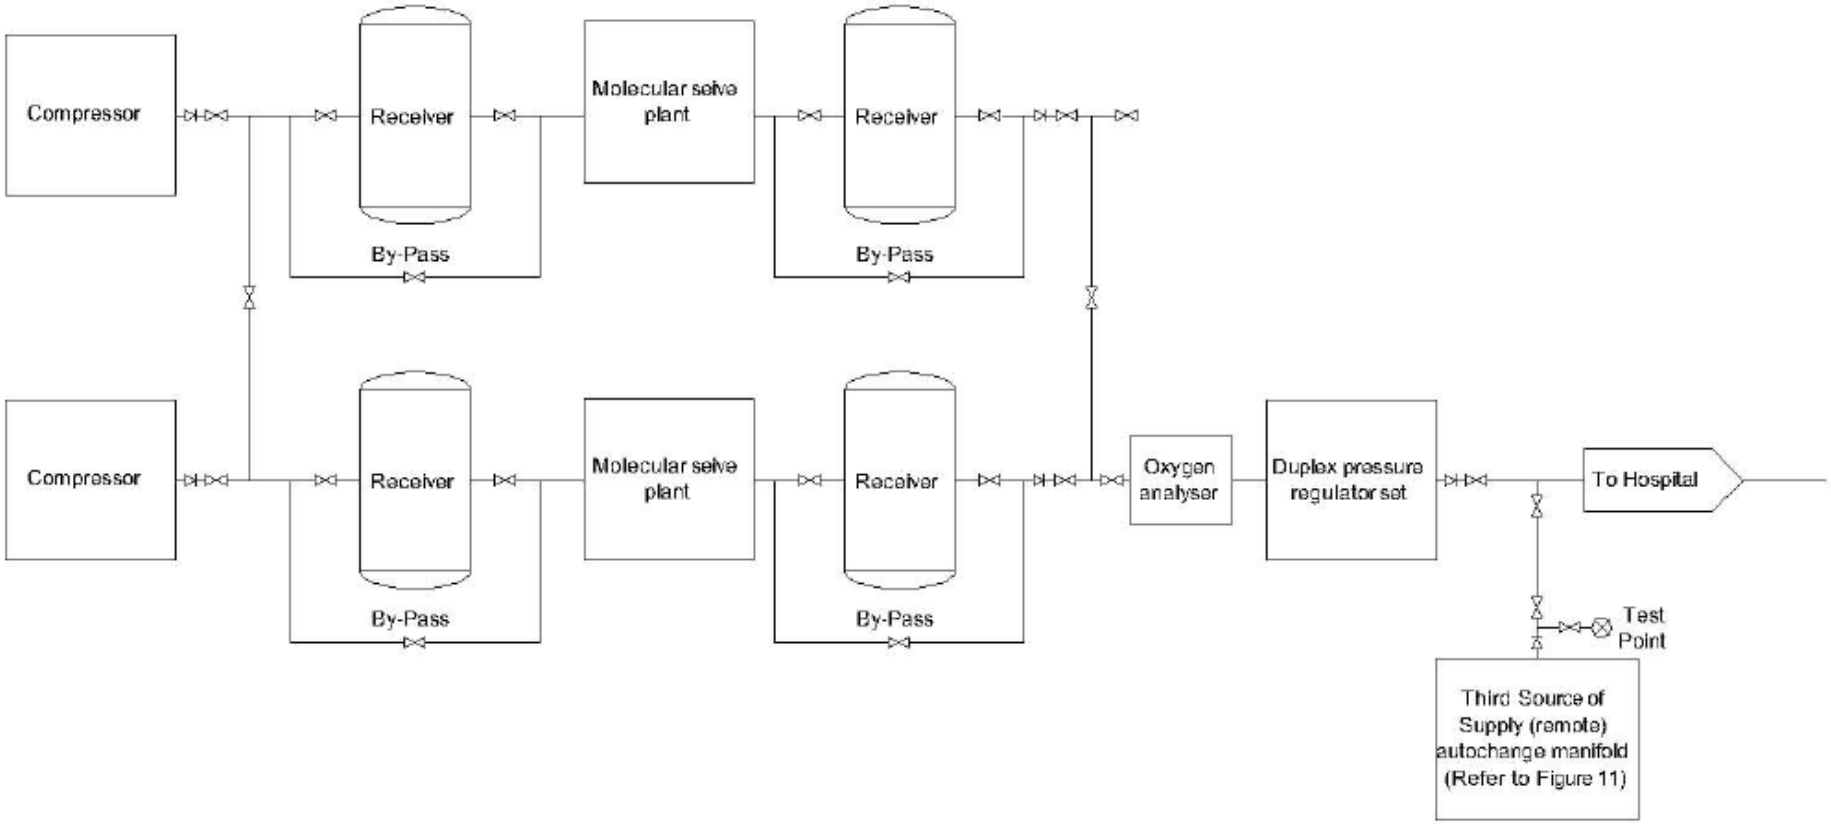

Figure 22: Schematic diagram of a typical PSA installation

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

Siting

6.167 The plant should have all-round access for maintenance purposes, and allowance should be made for changing major components.

6.168 The siting of the plant should allow for adequate flows of air for three different purposes:

- air intake to the compressors;
- cooling of the compressed air by the after-coolers;
- cooling of the compressors.

6.169 Each compressor may require ducting to ensure an adequate flow of cool air. The manufacturer should be consulted over the range of operating temperatures for which the system is designed. In extreme circumstances, refrigeration of the cooling air may need to be provided.

6.170 Air-inlet filters should be fitted either to the compressor inlet or at a suitable point in any ductwork. The filters should comply with BS ISO 5011: 2000 and be either dry medium filters or grade CA paper element filters.

Plant configuration

6.171 The plant should comprise:

- a duplex compressor – if more than two compressors are installed, the plant should provide the design flow with one compressor out of service;
- duplexed air treatment/molecular sieve devices, that is, two sets of filters and a pair of molecular sieves (one adsorbing whilst the other regenerates) and one vacuum pump (if required by the manufacturer).

Note 20: All duplexed components should be capable of independent operation.

Compressors and vacuum pumps

6.172 The compressors for the PSA systems may be any of the type recommended for compressed air systems. It is also possible to provide a combined medical air PSA plant. Generally, the compressed air requirement per litre of product gas is of the order 4:1; as a result the compressor plant will be on longer than that typically seen in hospitals.

6.173 A vacuum pump may be required as part of the system. The vacuum pump, if provided, is utilised during the adsorption/regeneration process. Vacuum pumps may be of any type as for the piped medical vacuum system. It will not generally be practicable to use water-sealed pumps or the medical vacuum plant.

Compressor and vacuum pump noise

6.174 The noise level produced by the compressors will increase with the capacity of the supply system. The maximum free-field noise level for un-silenced

© Health Facilities Scotland, a division of NHS National Services Scotland.

compressed air plant, at 1m from the plant, varies with the type and power of the plant but should not normally exceed the following values:

Reciprocating	Screw	Vane	Power
85 dBA	76 dBA	76 dBA	7.5kW
89 dBA	78 dBA	76 dBA	7.6-15kW
93 dBA	80 dBA	79 dBA	15.1-22kW
97 dBA	92 dBA	90 dBA	22.1-60kW

Table 30: Compressor and vacuum pump noise ratings

6.175 In noise-sensitive areas, an acoustic enclosure should be included in the purchase specification for all compressors. Such an enclosure should produce a reduction of at least 10 dBA in the free-field noise level at 1m.

Molecular sieves

6.176 Duplex molecular sieves should be provided in pairs to permit continuous generation of oxygen. One of the pairs of duplex sieves will be in the adsorbing stage, whilst the other regenerates.

Dryers

6.177 Air dryers of the desiccant type are usually integrated within the molecular sieves and therefore do not regenerate independently. Refrigerant dryers may also be included.

Oxygen monitoring system

6.178 The plant should include a calibrated paramagnetic oxygen monitoring system comprising oxygen analyser, oxygen concentration indicator, oxygen flow monitor and oxygen concentration/flow recorder. Connections for calibration cylinders should also be provided. In the event of the concentration falling below 94%, the monitoring system should isolate the PSA system from the pipeline distribution system so that the emergency/reserve manifold operates. Additionally, an independent monitoring system should be provided to isolate the plant when the concentration falls below 94%. The second system need not be provided with a flow indicator or recorder.

Operating and indicating system

6.179 The operating and indicating system should perform the following functions, as appropriate:

- overall plant control and indication;
- individual compressor starting;
- individual vacuum pump starting (where fitted);
- control of dryers (where installed as a separate component);
- control of molecular sieves;
- plant status monitoring and indication;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- optional indication of the plant alarm status (this function may be considered to be part of the alarm system).

6.180 Provided that the individual compressor starters are housed in a separate compartment, these functions may be carried out by separate units or may be installed in a common panel and located on the plant or on the plantroom wall.

6.181 Control panels containing pneumatic components should have vents to permit release of pressure in the event of component failure. All functions and indicators should be appropriately identified and should have a design life of at least five years. The operating system should be capable of automatically restarting after reinstatement of the power supply.

6.182 All components of the PSA supply system should be connected to the essential electrical supply. The control system should ensure that compressors restart in sequence to avoid overloading the essential power supply.

Plant control unit

6.183 The plant control unit should have a separate power supply for each compressor and vacuum pump, controlled by a separate sub-circuit. The design should be such that no single component failure in the control unit will result in loss of plant output.

6.184 The unit should allow either manual selection of duty/stand-by for each of the compressors or have an automatic sequence selection with a means for manual override. The unit should ensure that two or more compressors do not start simultaneously when power is applied.

6.185 A warning notice that complies with BS5499-5: 2002 should be affixed which indicates the presence of low voltage.

6.186 A further warning notice indicating that the plant starts automatically should also be affixed near or on the plant.

6.187 Each compressor should have a selector switch which, when turned to the “on” position, allows the maximum and minimum pressure switches on the receiver to control the “on” and “off” loading of that compressor. An alternative “auto” position of the selector switch may allow automatic selection of the compressors.

Plant control indication

6.188 There should be indicators for each compressor as follows:

- green “mains supply on”;
- green “compressor called for”, which indicates that the compressor motor is electrically energised;
- an indicator of the pressure produced by the compressor.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Compressor and vacuum starter units

6.189 There should be individual starter units for each compressor and vacuum pump, which should include the features recommended for medical air compressor plants and vacuum plants respectively.

Molecular sieve control unit

6.190 The molecular sieve control unit may be mounted on the molecular sieve columns or may be located with the plant control unit. There should be separate power supplies for the “duty” and “stand-by” sieve assemblies, taken from the same phase.

6.191 The vacuum pump, if provided, forms part of the molecular sieve system.

6.192 The molecular sieve control unit should contain the following:

- a duty selector switch;
- an on/auto selector switch;
- individually-fused, separate cycling systems for each sieve pair;
- a system to control regeneration of the sieves in relation to pipeline demand;
- oxygen concentration, dryness and pressure sensors;
- an automatic changeover to the stand-by molecular sieve system, in the event of failure of the duty unit by oxygen concentration, dryness or pressure. This requires:
  - electrical and pneumatic isolation of the “duty” sub-assembly so that it is taken off-stream;
  - electrical and pneumatic energisation of the “stand-by” sub-assembly so that it is brought on-stream;
  - activation of the appropriate fault indicator and associated Volt-free contacts;
  - the sub-assembly to remain in this mode of operation until the fault has been rectified;
- green function indicators for each dryer sub-assembly to indicate:
  - molecular sieve 1 selected;
  - molecular sieve 2 selected;
  - selected molecular sieve – “normal”;
  - selected molecular sieve – “failed” (this fault indicator should remain until manually reset by means of a reset button);
- closure of all inlet, outlet, exhaust and purge valves.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Plant status monitoring

6.193 A monitoring system must be provided to detect the following faults in the air compressor system:

- plant faults (for each compressor):
  - control circuit failed;
  - overload tripped;
  - after-cooler temperature high;
  - compressor temperature high;
  - compressor run-up time too long;
  - activation of other safety devices supplied by the manufacturers.
- plant faults (for each molecular sieve unit):
  - control circuit failed;
  - “vacuum pump called for”;
  - overload tripped;
  - activation of any of the safety devices supplied by the manufacturer;
  - oxygen concentration failure;
  - pressure fault.
- plant emergency:
  - oxygen concentration failed at below 94% concentration;
  - receiver pressure 0.5 bar (gauge pressure) below the stand-by cut in pressure;
  - dryness above 67 ppm (–46°C at atmospheric pressure).
- pressure fault (cylinder reserve):
  - pressure in either bank below 50% (of normal cylinder pressure).
- pressure fault (pipeline):
  - low pipeline pressure;
  - high pipeline pressure.

Plant status indicator unit

6.194 In addition to the plant control indication, there should be a plant status indicator panel, which may be mounted on the plantroom wall or adjacent to either the compressor starter unit or the plant control unit. It should have a warning notice that complies with BS5499-5: 2002 to indicate the presence of low voltage.

6.195 There should be indicators for each compressor to show the following conditions:

© Health Facilities Scotland, a division of NHS National Services Scotland.

a) green “mains supply on”;
b) yellow “control circuit failed”;
c) yellow “overload tripped”;
d) yellow “after-cooler temperature high”;
e) yellow “compressor temperature high”;
f) yellow for each individual safety device provided by the manufacturers;
g) yellow “compressor failure”.

6.196 There should be indicators for each molecular sieve dryer system to show the following:

a) green “mains supply on”;
b) yellow “oxygen concentration fault”;
c) yellow “pressure fault”;
d) yellow “dryness fault”.

When the stand-by dryer is in operation, conditions (b) and (c) in paragraph 6.195 should be transmitted as a plant emergency either to the alarm system or to the plant alarm signal status unit.

Alarm signal status unit

6.197 An alarm signal status unit should be provided as part of the control system. It should display the following conditions:

Indication	Legends
a. Green “normal”	Normal conditions
b. Yellow “plant fault”	Conditions (b)-(f) (see paragraph 6.195)
c. Yellow “plant emergency”	Conditions (b) or (c), or see conditions (g) (see paragraph 6.195)
d. Yellow “emergency supply low”	Emergency supply bank(s) low (<50%)
e. Red “pipeline pressure fault”	Pressure fault
f. Red “pipeline concentration below 94% O_2”	Oxygen concentration fault
Conditions (b) to (e) should be transmitted to the central alarm system.	

Table 31: Alarm signal status unit

6.198 Where relays are used, they should be normally energised relays, which de-energise under fault conditions, with contacts having a minimum rating of 50 V d.c. and 50 mA.

6.199 Alternatively, Volt-free, normally closed contacts rated at 5 V d.c. and 50 mA should be provided for transmission of conditions (b) to (e) to the alarm system.

6.200 The panel can be incorporated into the plant indicator unit, or be a separate unit within the plantroom. If mounted separately, the cabling should be monitored for open/short circuit. In the event of such a cabling fault, a red “system fault” lamp

© Health Facilities Scotland, a division of NHS National Services Scotland.

should be illuminated on the alarm signal status unit, together with the appropriate alarm condition.

6.201 The alarm signal status unit should be supplied from all individual plant control units, or from a separate common supply.

Plant management

6.202 Connections should be provided that allow monitoring (but not control) of the plant operation. For example:

a) compressor – “on”, “off”, “on-load”, “unloaded”;

b) molecular sieves – “on” or “off”.

6.203 These connections should be used to provide input to the hospital building and energy management systems (BEMS).

© Health Facilities Scotland, a division of NHS National Services Scotland.

7. Medical compressed air systems

General

7.1 Medical compressed air can be derived from compressor systems or by mixing gaseous oxygen and nitrogen from cryogenic liquid supply sources. Air produced by this latter method is referred to as synthetic air.

Compressor systems

7.2 Medical and surgical air can be provided from a single combined system or from separate plants. The choice ultimately depends on the relative consumption.

7.3 In the case of surgical air, consumption is at a high flow at a high pressure (up to 350 litres/min) but for relatively short periods of time (minutes); also, very small numbers of terminal units are in simultaneous use, typically fewer than five. Air for respirable purposes, however, is used at much lower flows (typically less than 80 litres/min) but, particularly in the case of patient ventilation, use can be continuous. Moreover, in the case of medical air there are considerably greater numbers of terminal units in use simultaneously. The installation of separate plants therefore can result in lower running costs. Requirements for separate surgical air systems are given in Section 8.

7.4 Some plant configurations are shown in Figures 23–26: reference should also be made to Tables 5 & 7 in Section 2:

- Figure 23 shows a typical medical air plant with fully automatic emergency reserve manifold;
- Figure 24 shows a combined medical and surgical air plant with emergency reserve manifolds. A combined system would be suitable for a small to medium hospital where separate plant could not be economically justified. In this case, a minimum of three compressors, each capable of supplying the total load should be installed plus automatic air cylinder manifold systems to support both the medical and surgical air;
- Figure 25 shows an option for combined plant with separate dryer and regulator arrangements;
- Figure 26 shows an option for combined plant with common dryer and separate regulator arrangements.

7.5 Other plant configurations are possible depending upon the specific design requirements e.g. for larger hospitals:

- two or three separate plants could be justified each serving a particular area;
- consider surgical air plant acting as an emergency back-up to the medical air plant;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- with synthetic air, however, careful planning is required to take into account the emergency back-up required, the use of nitrogen for surgical use, safety and cost in comparison to the conventional means of supply.

Quality

7.6 The European Pharmacopoeia (Ph. Eur.) specifies maximum impurity levels for carbon monoxide. It may be necessary to make provision to control the levels of contaminants and to monitor the supply to ensure conformance with the specification. European Commission directive 2001/83/EC specifies that medicinal products should be manufactured to the approved standard.

Siting

7.7 The plant should have all-round access for maintenance purposes, and allowance should be made for changing major components.

7.8 The siting of the plant should allow for adequate flows of air for three different purposes:

- air intake to the compressors;
- cooling of the compressed air by the after-coolers;
- cooling of the compressors.

Compressor noise

7.9 The noise level produced by the compressors will increase with the capacity of the supply system. The maximum free-field noise level for un-silenced compressed air plant, at 1m from the plant, varies with the type and power of the plant but should not normally exceed the following values:

Reciprocating	Screw	Vane	Power
85 dBA	76 dBA	76 dBA	0-7.5kW
89 dBA	78 dBA	76 dBA	7.6-15kW
93 dBA	80 dBA	79 dBA	15.1-22kW
97 dBA	92 dBA	90 dBA	22.1-60kW

Table 32: Compressor noise levels

7.10 In noise-sensitive areas, an acoustic enclosure should be included in the purchase specification for all compressors. Such an enclosure should produce a reduction of at least 10 dBA in the free-field noise level at 1m.

Air intake

7.11 The position of an air intake can have a considerable effect on delivered air quality, particularly with respect to levels of carbon monoxide. The air intake for a compressor should be located to minimise contamination from internal combustion engine exhausts and the discharge from vacuum systems, AGSS and ventilation systems or other sources of contaminants. Air intakes should be ducted where necessary to avoid contamination; a minimum height of 5m above ground level should ensure a reasonable quality of intake air. Where this cannot be achieved, additional filtration and/or air treatment may be necessary. If the siting of the compressor, regardless of the air intake location, is considered

© Health Facilities Scotland, a division of NHS National Services Scotland.

subject to a risk of aspirating toxic fumes and smoke as a result of a fire, an automatic shutdown system, linked to local smoke detectors, can be installed. If such a system is planned, it is essential that an automatic emergency supply manifold system is sited well away from the fire-risk area and is arranged to come on-line automatically in the event of plant shutdown.

7.12 Care is needed when extending compressor air intakes. Manufacturers' data should be consulted to ensure that intake flow, and hence compressor performance, are not adversely affected by excessive lengths of intake ducting. Choice of intake material is also important. Often, intakes are constructed from solvent-welded PVC. In a fire, toxic materials from the burning intake could be drawn into the air compressor and distributed throughout the system. In addition, there is a risk that inadequate solvent drying time before use of the intake will result in toxic solvent fumes being drawn into the system. Corrosion-resistant ducting (for example stainless-steel flue liner) is a suitable material.

7.13 Air-inlet filters should be fitted immediately upstream of the compressor. In exceptional circumstances, additional screens, filters and silencers may be required. The filters should comply with BS ISO 5011: 2000 and be either dry medium filters or grade CA paper element filters.

Compressor types

7.14 There are many different types of compressor currently available, the most common types being:

- reciprocating piston compressors;
- rotary vane compressors;
- rotary screw compressors.

7.15 The compressors may be of any type, provided they are suitable for continuous running on load and for high frequency start/stop operation. When selecting compressors the opportunity to maximise energy efficiency should be taken e.g. consideration should be given to the variable speed/ inverter drive motors which are increasingly being used in hospitals particularly on heating systems. In medical compressed air applications, this would reduce the stop/start frequency by maintaining a constant pressure within close limits and it is feasible to consider the eventual removal of the receiver. Research is being carried out into the use of variable speed drives with particularly successful applications in AGSS and Dental Vacuum and the removal of the energy wasteful constant volume exhauster. Now that the range of rotary screw compressors has been expanded particularly to the lower kW sizes, they have generally taken over from the reciprocating compressor in medical air applications. If reciprocating compressors are used, they may be either of the single or of the two-stage type, although for a 400 kPa system a single-stage compressor is usually satisfactory.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Compressor lubrication

7.16 Compressors may be oil-lubricated, provided that suitable arrangements are made to ensure that the air quality specification given in Table 42 is fulfilled (refer to Section 15).

7.17 Rotary screw compressors can be sealed by oil or purified water (reverse osmosis) with cooling by air or water. Water would provide lower operating temperatures with increased efficiency. However, water does introduce another external risk factor to ensuring the service provision. Thus the normal medical application is oil-sealed or air-cooled. Where there is a requirement for ducted intake air, this can be separate from the compressor cooling air. Reciprocating compressors may be oil-lubricated, carbon ring, PTFE ring or diaphragm-sealed type. However, the pulsating frequency of the piston and noise generated would normally require an acoustic enclosure.

7.18 Alternatively, oil-free compressors are available and may be beneficial in reducing filtration requirements.

7.19 Oil-free reciprocating and rotary screw compressors are not necessarily oil-less. Additionally the atmospheric air can carry oil vapours and contaminants and should not necessarily imply a reduction in filtration requirements. Oil-sealed rotary screw compressors have the added advantage of noise reduction, smooth air delivery and are more suited to a variable speed drive.

7.20 There is a danger that PTFE rings and lubricating oils could decompose at high temperatures to form toxic products. It is a requirement of paragraph 7.70 to monitor compressor temperature and to close down the compressor on fault condition. BS EN ISO 15001: 2010 specifies the requirements for selecting materials used in medical supply equipment.

7.21 On start-up, when oil is used as the sealant, moisture condensing at high pressure forms an emulsion with the oil. Once operating temperature is reached, water is readily separated. Because it is impossible to match the varying demand with plant capacity, it may be necessary to include oil heaters to avoid emulsification. If it is intended to omit oil heaters, manufacturers should be asked to confirm the suitability of the compressor for intermittent operation. Oil-lubricated compressors, however, are considered to be satisfactory.

7.22 Where oil-lubricated compressors are used, suitable means of separating oil from condensate is essential.

7.23 Once a compressor installation has been selected:

- the plant should include at least two compressors, but additional compressors may be included in accordance with Table 10;
- the individual compressors should be arranged so that they will supply the system simultaneously if necessary;
- the relative magnitude of the capital and running costs should be evaluated at the time of purchase. Too much emphasis has been placed on low

© Health Facilities Scotland, a division of NHS National Services Scotland.

capital cost at the expense of reliability and high power costs. The running costs should be calculated at realistic levels of usage;

- the control system for the compressor plant should include an “hours-run” counter and should be constructed in accordance with the guidelines given below;
- the efficiency of plant, expressed as the volume of air delivered to the pipeline distribution system (after losses in the drying system and filtration system) per kilowatt-hour (kWh), should be stated by the supplier of the system. The testing procedure should evaluate this efficiency by testing the power consumption over a suitable period of time at 100%, 10% and 0% of the system design flow. A minimum efficiency of 5 m^3/kWh at 100% and 10% is required. The power consumption at zero flow should be less than 1% of that at 100% design flow.

After-coolers

7.24 After-coolers (and inter-coolers) usually form part of the compressor sub-assembly. After-coolers should be fitted to all medical air compressor systems. These will normally be air-cooled, and may need ducting with forced ventilation to ensure an adequate supply of cooling air.

Receivers

7.25 Air receivers should comply with BS EN 286-1: 1998 + A2: 2005 for all vessels up to 10,000 bar litres, and should be supplied with test certificates. The minimum water capacity of the receivers should be 50% of the compressor output in 1 minute, stated in terms of free air delivered at normal working pressure. Receivers should also be fitted with an automatic drain. Electrically operated automatic drains have been found to be more reliable.

7.26 To facilitate the statutory inspection, there should be either two suitably valved air receivers or, for a single receiver, a by-pass arrangement (for use in manual operating mode only) in order to avoid interruption to the supply. Alternatively the tertiary supply manifold can be used. A by-pass arrangement should only apply if rotary screw compressors are provided. Alternatively the tertiary supply manifold can be used provided an adequate supply of cylinders are available and constant monitoring is applied.

7.27 For systems that have a design flow exceeding 500 litres/min, two receivers should be provided with valve arrangements to permit isolation of one or the other for inspection purposes.

Air treatment and filtration

General

7.28 Contaminants can enter the compressed air system from three sources: the atmosphere, the compressor and the pipeline distribution system. Each potential source must be taken into account when specifying the type and location of air treatment equipment. Filtration equipment may include pre-filters,

© Health Facilities Scotland, a division of NHS National Services Scotland.

coalescing filters, adsorption equipment, carbon filters, particulate filters, bacterial filters and any other additional filtration equipment necessary to ensure the quality of the product.

Solid contaminants

7.29 Particles in the environment cover a wide range of sizes, but approximately 80% are less than 0.2µm and are therefore not removed by the intake filter to the compressor.

7.30 Although particles smaller than 40µm are unlikely to cause mechanical damage, a 5µm intake filter is preferred to avoid blockage of internal air/oil separators.

7.31 Filters are specified in terms of performance tests – a sodium flame test, a DOP (dispersed oil particulate) test etc.

Water

7.32 Water is always a contaminant in a compressed air system, regardless of the type and location of the compressor plant, since the air drawn into the compressor intake is never completely free of water vapour. The amount can vary from 2.5 g/m^3 to over 40 g/m^3 depending on the climatic conditions. The after-cooler and receiver remove some of this, but about 20 g/m^3 is likely to remain in the compressed air unless removed by dryers.

7.33 A water content not exceeding 67 vpm (parts per million by volume – equivalent to dew-point –46°C at atmospheric pressure) is specified for medical air pipeline systems. Only desiccant dryers can usually achieve this. A variety of desiccant types are available. Silica gel, although a desiccant, can easily fracture and powder and is not used in medical compressed air applications. Activated alumina is the common type employed. Molecular sieve desiccants employing zeolites can also be used, but on occasions it has been found that this material has produced air with an increased oxygen content, in the order of 24%. Refrigerant dryers can perform satisfactorily down to a pressure dew-point of +3°C (atmospheric dew-point –20°C) and are therefore not recommended as the sole form of drying.

Oil

7.34 With oil-lubricated compressors, it is inevitable that the compressed air will contain oil. Even with oil-free compressors (non-lubricated), complete freedom from oil and oil vapour cannot be positively guaranteed, as hydrocarbon vapours may be drawn into the compressor. Oil levels in the air supply must be controlled to 0.1 mg/m^3 with means of monitoring on a routine basis.

7.35 Oil will exist in the system in three forms: bulk liquid, oil aerosol and oil vapour. Provided that the oil lubricant is appropriate and the after-cooler properly designed, the amount of oil present as vapour should be small and is unlikely to exceed 0.5 mg/m^3.

7.36 The amount of oil that is present as bulk liquid and aerosol is more difficult to predict. With modern, well-maintained oil-lubricated compressors, it is unlikely

© Health Facilities Scotland, a division of NHS National Services Scotland.

to exceed 5 mg/m^3 due to the high-efficiency oil/air separator. A pre-filter/ separator will remove the bulk contaminants which should reduce the remaining oil content to 0.5 mg/m^3, particle removal down to 1 micron and a DOP penetration of less than 0.03%. The coalescing filter should further reduce the remaining oil content to 0.01 mg/m^3, particle removal down to 0.01 micron and a DOP penetration of less than 0.0001%. The preferred practice is to retain the pre and coalescing filter as separate assemblies.

7.37 Oil-contaminated compressor condensate is classified as a trade effluent by virtue of Chapter 14 of the Public Health (Drainage of Trade Premises) Act 1937. An oil condensate separator should therefore be installed.

7.38 Under Scottish environmental legislation, it is illegal to make a discharge of trade effluent to “controlled waters” via a surface water drain without the consent of the Scottish Environment Protection Agency (SEPA).

7.39 Similarly, the Water Authority enforces the limit of oil condensate discharged into the public foul sewer. Prior consent to discharge is mandatory.

7.40 Condensate from oil-free compressors may be discharged to drain.

7.41 Any condensate produced from the compressor/ dryer system must be regarded as trade effluent and is therefore not suitable for discharge to any surface water system draining to any surface water sewer, water-course or soak away; this may not apply if a suitable oil / water separator is installed. Maximum oil content limits range from region to region, from 25 mg/litre up to 500 mg/litre; the water authority should be consulted.

Dryer and filter assembly

7.42 Each dryer and filter assembly should be rated for continuous use at the system demand flow.

Dryer controls

7.43 The dryer control system should ensure that regeneration is operated in proportion to the compressed air usage. The effectiveness of the control system will become apparent when the efficiency of the compressor system is tested at 10% and 0% of the system design flow. Evidence of the reliability and performance of a dryer system should be sought from manufacturers, since these items are critical to the overall performance of the compressor system. The dryer control system should include a dew-point hygrometer and display with a minimum accuracy of ±3°C in a range from –20°C to –60°C atmospheric dew-point, with a set point of –46°C. It should be arranged that in the event of open circuit, a “plant emergency” alarm be initiated.

Dust filters

7.44 There should be a dust filter downstream of the dryers to remove particles down to 1 µm, with a DOP penetration of less than 0.03%, when tested in accordance with BS EN ISO 3549: 2002.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Activated carbon filter

7.45 Duplex activated carbon filters should be installed upstream of the final bacteria filter for odour removal.

Bacteria filters

7.46 Duplex bacteria filters should be fitted upstream of the final pressure regulator with appropriate isolating valves. The filters should provide particle removal to 0.01 mg/m^3 and a DOP penetration of less than 0.0001%.

Pressure control

7.47 The pressure control should maintain the nominal pipeline pressure within limits given in Section 4. Duplex line pressure regulators should be provided with suitable isolating valves. The regulators should be of the non-relieving type.

Safety valves

7.48 Safety valves should be provided in accordance with the requirements given below. All safety valves should conform to BS EN ISO 4126-1: 2004. A safety valve of the certified discharge capacity stated should be fitted in each of the following positions:

- on the delivery pipe of each compressor and upstream of any isolating valve, non-return valve or after-cooler, capable of discharging the total throughput of the compressor;
- on each air receiver and dryer tower, capable of discharging the sum of the throughput of all the compressors. It is not necessary to provide safety valves on the dryer columns where the system is already protected by a safety valve on the receiver and the downstream equipment, that is, if the dryer column is already sufficiently protected;
- immediately downstream of each pressure regulator, capable of discharging the system demand flow.

7.49 All safety valves should be of the closed-bonnet type and connected to suitably sized pipework to allow safe discharge, not necessarily to the outside.

Traps, valves and non-return valves

Automatic drainage traps

7.50 Electrically or mechanically operated automatic drainage traps should be provided on the after-coolers, receiver, separators and coalescing filters. The discharge from these drainage traps should be piped to a suitable gully via an oil/water separator. Co-ordination with building work is required for this provision. A manual by-pass valve should be fitted to each after-cooler and receiver automatic drainage trap to permit a trap efficiency check. Automatic drainage should be fitted to all pre-filter / separators and coalescing filters. Electrically-operated automatic drains have been found to be more reliable.

© Health Facilities Scotland, a division of NHS National Services Scotland.

7.51 Drainage and tundishes are usually provided under the building contract. Separators should be provided under the air compressor contract. Provision of oil/water separators should be supplied by the plant manufacturer and matched to suit the combined plant output.

Non-return valves

7.52 Non-return valves are required to prevent backflow of the air supply in certain situations. These valves should be located as follows:

- between the compressor and the receiver, but downstream of any flexible connector;
- downstream of the dust filter on the dryer;
- upstream of the emergency cylinder reserve connection in the pipeline connecting the plant to the pipeline distribution system, to prevent back-feeding this plant;
- upstream of any inlet point that may be used to feed the system in an emergency;
- downstream of the emergency cylinder manifold regulators.

Isolating valves

7.53 Isolating valves should be provided downstream of non-return valves and upstream of, for example, the connection of the emergency reserve manifold. Isolating valves should be provided in order to facilitate maintenance or replacement of plant items.

7.54 Manually-operated ball isolation valves should be located in the positions shown in Figures 23 – 26 to allow isolation of components such as receivers, dryers, automatic drains, pressure regulators and filters. There should also be a valve on the compressed air plant, downstream of the plant non-return valve and the connection of the cylinder manifold supply.

Pressure indicators

7.55 Pressure indicators should comply with BS EN 837-1:1998 or have an equivalent performance if electronic indicators are used. Calibration should be in bar or kPa. All gauges should have a minimum scale length of 90mm, and the working range should not exceed 65% of the full-scale range except on differential pressure gauges. Pressure indicators should be connected by means of gauge cocks.

7.56 Pressure indicators should be located:

- on the plant control unit indicating receiver pressure;
- on each receiver;
- downstream of each pressure regulator;
- on each dryer tower;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- on the plant pipework, upstream of the plant isolating valve.

7.57 Differential pressure indicators should be provided across each:

- pre-filter / separator;
- coalescing filter;
- dust filter;
- activated carbon odour filter;
- bacteria filter.

7.58 Except for pressure gauges, all control and measuring devices should be connected directly to the pipework via a minimum leak device (to allow removal for servicing) and not isolated by valves.

Operating and indicating system

7.59 The operating and indicating system should perform the following functions:

- overall plant control and indication;
- individual compressor starting;
- control of dryers;
- plant status monitoring.

All pressure switches mounted internally or externally which may require adjustment when 'live' should be designed and operated at extra low voltage.

7.60 Provided that the individual compressor starters are housed in a separate compartment, these functions may be carried out by separate units or may be installed in a common panel and located on the plant or on the plantroom wall. Control panels containing pneumatic components should have vents to permit release of pressure in the event of component failure. All indicators should be appropriately identified and should have a design life of at least five years.

7.61 The operating system of each compressor should be capable of automatically restarting after reinstatement of the power supply.

7.62 All components of the medical air supply system should be connected to the essential electrical supply. The control system should ensure that compressors restart in sequence to avoid overloading the power supply.

Plant control unit

7.63 The plant control unit should have a separate power supply for each compressor, controlled by a separate sub-circuit. Generally, system resilience can be increased through the specification and design of the electrical services by having separate supplies for designated components, for example, two out of four compressors or vacuum pumps being supplied by a separate electrical system / distribution board.

© Health Facilities Scotland, a division of NHS National Services Scotland.

7.64 The unit should:

- allow either a manual selection of duty/stand-by for each of the compressors or preferably have an automatic sequence selection with a means for manual override;
- incorporate an automatic standby control in the event of a printed circuit board failure;
- be capable of manual operation of the compressors in the event of the main and standby central control panel functions failing;
- ensure that two or more compressors do not start simultaneously when power is supplied;
- for each compressor starter unit or if remote from the compressor, incorporate an independent manual start which will permit the compressor to work under load and fitted with an emergency stop.

7.65 A warning notice that complies with BS5499-5: 2002 should be affixed which indicates the presence of low voltage.

Plant control indication

7.66 There should be indicators for each compressor as follows:

- green “mains supply on”;
- green “compressor called for”, which indicates that the compressor motor is electrically energised;
- an indicator of the pressure produced by the compressor.

Compressor starter units

7.67 There should be individual starter units for each compressor which operate a single designated compressor. The starters should be provided with safety interlocks, as specified by the compressor manufacturers, which should inhibit plant operation until manually reset by means of a button. The starters should allow automatic restart after an interruption to the power supply. Each starter unit should contain the following:

- an isolator interlocked with the covers;
- either HRC (high rupturing capacity) fuses to BS88 or suitable circuit breakers to BS EN 60947-2: 2006 + A1: 2009 and/or BS EN 60898-1: 2003 + A1: 2004;
- an industrial grade ammeter to BS EN 60051-1:1999, IEC 60051-1:1997 (digital ammeters of similar accuracy to those compliant with BS EN 60051-1: 1999, IEC 60051-1: 1997 may be used);
- a “total hours” counter if not included in the plant control unit;
- a green “mains supply on” indicator if mounted separately from the plant control unit.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Dryer control unit

7.68 The dryer control unit may be mounted on the dryers or may be located with the plant control unit. There should be separate power supplies for the duty and stand-by dryer assemblies taken from the same phase.

7.69 The dryer control unit should contain the following:

- a duty dryer selector switch;
- a service function – to enable selection of continuous/normal running;
- individually fused, separate cycling systems for each dryer;
- a system to control regeneration of the dryers in relation to pipeline demand;
- a hygrometer and display with a minimum accuracy of ±3°C in a range from –20°C to –60°C (set to –46°C atmospheric dew-point) and a pressure sensor;
- an automatic changeover to the stand-by dryer system in the event of failure of the duty unit by either dryness or pressure. This requires:
  - electrical and pneumatic isolation of the duty sub-assembly so that it is taken off- stream;
  - electrical and pneumatic energisation of the stand-by sub-assembly so that it is brought on-stream;
  - activation of the appropriate fault indicator and associated Volt-free contacts;
- the sub-assembly to remain in this mode of operation until the fault has been rectified;
- green function indicators for each dryer sub- assembly to indicate:
  - dryer 1 selected;
  - dryer 2 selected;
  - selected dryer – “normal”;
  - selected dryer – “failed” indicated by an orange or amber light (this fault indicator should remain until manually reset by means of a reset button).With a duty fault condition existing, the standby dryer will function in the normal alternate drying / regeneration mode.
- a fail-safe system which on failure of the power supply causes the following:
  - closure of the exhaust and purge valves;
  - opening of the inlet and outlet valves.

Plant status monitoring

7.70 A monitoring system should be provided to detect the following faults in the air compressor system:

© Health Facilities Scotland, a division of NHS National Services Scotland.

- plant faults (for each compressor):
  - control circuit failed;
  - motor tripped;
  - after-cooler temperature high;
  - compressor temperature high;
  - compressor failed to go on load.
  - activation of other safety devices supplied by the manufacturers;
- plant faults (for each dryer unit):
  - dryer failure;
  - pressure fault;
- plant emergency:
  - receiver pressure 0.5 bar below the stand- by cut-in pressure;
  - receiver pressure 0.5 bar above cut-out pressure;
  - dryness above –46°C at atmospheric pressure;
- pressure fault (cylinder reserve):
  - as the reserve manifold is a fully automatic cylinder manifold, the full set of standard alarm conditions should apply to the central alarm system.
- pressure fault (pipeline):
  - low pipeline pressure;
  - high pipeline pressure.

Where surgical and medical air are supplied from a standard compressor plant with duplex dryer / filtration unit, each service should be provided with a duplex regulator set. Each set should be fitted in parallel to the other service, each monitored by a high and low line pressure switch. The central alarm panel need only indicate a plant combined line pressure fault, identifying of the service by investigation.

Plant status indicator unit

7.71 In addition to the plant control indication, there should be a plant status indicator panel that may be mounted on the plantroom wall or adjacent to either the compressor starter unit or the plant control unit. It should have a warning notice that complies with BS5499-5: 2002 to indicate the presence of low Voltage.

7.72 There should be indicators for each compressor to show the following conditions:

a) green “mains supply on”;

b) yellow “control circuit failed”;

c) yellow “overload tripped”;

© Health Facilities Scotland, a division of NHS National Services Scotland.

d) yellow “after-cooler temperature high”;

e) yellow “compressor temperature high”;

f) yellow for each individual safety device provided by the manufacturers;

g) yellow “compressor failure”.

7.73 There should be indicators for each dryer system to show the following:

a) green “mains supply on”;

b) yellow “dryness fault”;

c) yellow “pressure fault”.

Alarm signal status unit

7.74 An alarm signal status unit should be provided as part of the control system. It should display the following conditions:

a) green “normal” (normal);

b) yellow “plant fault” conditions ((b)–(g) in paragraph 7.72);

c) yellow “plant emergency” (low reservoir pressure/high moisture: that is, condition (b) in paragraph 7.72);

d) yellow “reserve low” (emergency/reserve banks low (<50%));

e) red “pipeline pressure fault” (pressure fault).

7.75 Conditions (b) to (e) in paragraph 7.74 should be transmitted to the central alarm system. Where relays are used, they should be normally energised relays that de-energise under fault conditions, with contacts having a minimum rating of 50 V d.c. and 50 mA.

7.76 Volt-free, normally closed contacts rated at 50 V d.c. and 50 mA should be provided for transmission of conditions (b) to (e) in paragraph 7.74 to the alarm system.

7.77 The panel can be incorporated into the plant indicator unit or be a separate unit within the plantroom. If mounted separately, the cabling should be monitored for open/short circuit. In the event of such a cabling fault, a red “system fault” lamp should be illuminated on the alarm signal status unit together with the appropriate alarm condition.

7.78 The alarm signal status unit should be supplied from all individual plant control units or from a separate common supply.

Plant management

7.79 Connections should be provided which allow monitoring of plant alarm conditions (b) to (e) in paragraph 7.74 and pump running for each “compressor”. These connections should be Volt-free contacts normally closed for each

© Health Facilities Scotland, a division of NHS National Services Scotland.

condition having a minimum rating of 50 V d.c. and 50 mA. The building management system should not be used to control the plant.

Synthetic air

7.80 This section provides technical details of the process and systems required to generate medical air from mixing gaseous oxygen and nitrogen, derived from cryogenic supplies.

7.81 For the purposes of the Medicines Act 1968, it is considered that the synthetic air is manufactured on-site, for use on that site only, in exactly the same way as for medical air derived from compressor plant. The production of synthetic air implies a manufacturing process, and as such, the process should be subjected to the same safety requirements of any pharmaceutical process. This should include, for example, a HAZOP (HAZard and OPerability) analysis and other safety analyses that may be necessary.

7.82 Synthetic air is generated by mixing gaseous oxygen and nitrogen in a blender or mixing panel at pre-set pressures to ensure that the resultant mixture is always correct. Continuous on-line monitoring of oxygen concentration is provided to check the mixture; the system shuts down automatically if the oxygen concentration varies from the specified value.

7.83 If one mixing system shuts down, the pipeline is supplied from the secondary mixing system to ensure continuity of supply.

7.84 The feasibility study should provide more information on the details of the monitoring and alarm systems required, as well as operational information.

7.85 The VIE system supplying the medical oxygen may be used to supply the synthetic air system, depending on the system demands.

7.86 Nitrogen supplied to the synthetic air system may also be used to provide the power source for surgical tools instead of surgical air at 700 kPa.

7.87 An electrical power supply is required in order, for example, to operate solenoid valves and monitoring instrumentation. Therefore the system should be connected to the essential power supply and via an uninterruptible power supply (UPS) with at least four hours' capacity; this should ensure continuity of supply in the event of power failure.

System description

7.88 The gaseous oxygen and nitrogen are derived from bulk liquid supplies contained in a VIE – asset out in the "Liquid oxygen systems" text within Section 6.

7.89 The oxygen for synthetic air may be taken from the VIE supplying the medical oxygen system or it may be from a dedicated VIE. It would normally be more cost-effective for the oxygen to be taken from the main VIE, although this would obviously depend on the existing VIE capacity, the demand, space constraints etc. The feasibility study should provide more detailed information on whether it

© Health Facilities Scotland, a division of NHS National Services Scotland.

is likely to be more cost-effective to provide a totally separate VIE system or to use the existing medical oxygen VIE. The feasibility study should include a cost comparison against other methods of supply. Unlike the renting of liquid vessels, there can be a high capital cost for the ancillary mixing equipment which may not come under the rental agreement.

7.90 For both the oxygen and nitrogen it is necessary to have a secondary supply system to ensure continuity of supply; the system demands are such that this should be derived from a second – normally smaller – VIE.

7.91 This secondary oxygen supply can also serve the hospital's medical oxygen system.

7.92 Since four VIEs will be required, the space requirements will need special consideration when planning the installation of a synthetic air system.

7.93 The system comprises:

- storage vessels – one main vessel and one secondary supply vessel for both oxygen and nitrogen;
- vaporisers for both oxygen and nitrogen;
- medical oxygen flow control – where used to supply medical oxygen systems;
- surgical nitrogen flow control – where required;
- a control panel for the nitrogen and oxygen supplies to the mixing panels;
- duplicate air mixing panels;
- buffer vessels – each mixer has a buffer vessel to smooth fluctuations in demand;
- a warning and alarm system;
- duplicate oxygen analysers on each mixer.

7.94 A typical system is shown in Figure 27 overleaf which supplies synthetic air with a third source of supply for medical air (remote), surgical nitrogen and oxygen with a third source of supply for oxygen (remote).

Storage vessels

Vessel summary

7.95 The following vessels are required:

- one main oxygen vessel;
- one secondary oxygen vessel with at least 24 hours' capacity;
- one main nitrogen vessel;
- one secondary nitrogen vessel with at least 24 hours' capacity.

Vessel operating pressure

7.96 The following operating pressures are required:

- main vessels: 12.5 bar;
- back-up vessels: 12.5–14 bar.

Main vessel capacity

7.97 The main vessel should normally be sized on the basis of two weeks' supply. This should be calculated as 14 x the average daily usage. This should provide adequate storage and a cost-effective vessel-filling regime. The gas supplier should, however, be consulted as there may be other factors, such as geographical location, space etc, which need to be taken into account when sizing the main vessels.

Back-up vessel capacity

7.98 The stand-by vessel should have 24 hours' capacity at any time; that is, it should be sized on the basis of twice the average daily usage. This will ensure that there is always 24 hours' supply available.

7.99 In addition to the normal instrumentation as set out in the "Liquid oxygen systems" text within Section 6, the vessels should be fitted with a telemetry system to monitor continuously the vessel contents.

7.100 This information should be transmitted direct to the gas supplier and also the hospital. The exact details of how much information, and where it should be received, will depend on each hospital site.

7.101 The main vessel low level alarm is activated at 25% full; the back-up low level alarm is activated at 50% full.

7.102 The safety relief valves and bursting discs should be sized in accordance with BCGA CP19.

7.103 The liquid from the vessels should be supplied to the process at a nominal pressure of 12.5 bar.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Vaporisation

7.104 The main and stand-by vessels should have dedicated vaporisers designed for continuous capacity and 24-hour capacity respectively at 1.5 x the required flows to ensure that the vaporisers are not overdrawn.

7.105 This may be achieved in each case by either a single set of vaporisers or by vaporisers operated on timed or manual changeover.

7.106 It is preferable for the vaporisers to operate on a timed changeover as this avoids the need for hospital staff to manually operate the changeover valves.

7.107 The timed changeover will require a 110 V or 240 V supply; this should be on the emergency supply and a UPS should also be provided, with at least 4 hours' capacity.

7.108 Each vaporiser or set of vaporisers must have a safety relief valve.

Medical oxygen flow control

7.109 A control panel (similar in principle to a C11 panel) should be provided – the only difference is that the secondary supply is taken from a low-pressure liquid source.

Surgical nitrogen flow control

7.110 A control panel to regulate the gaseous nitrogen to between 7.5 and 9.5 bar, depending on the system design, should be provided.

7.111 The pipeline distribution system should be designed in exactly the same way as for surgical air 700 kPa systems, as described in Section 8.

Control panel for the nitrogen and oxygen supplies to the mixing panels

7.112 The control panel should be sized to provide pressure-regulated flows as appropriate for the mixing system; this would typically be up to 200 Nm^3/hr (normal cubic metres per hour).

7.113 The stand-by supply regulation cuts in when the main line pressure falls to 11 bar; there is no regulation on the main supply line.

7.114 A non-return valve should be installed in both the nitrogen and oxygen supply lines within the mixer to prevent cross-contamination.

7.115 A non-return valve should also be installed on both the main oxygen supply and the stand-by oxygen supply to the mixer to prevent the medical oxygen line becoming contaminated with nitrogen.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Air mixing panels

7.116 A range of sizes of mixing panels is available with, typically, nominal capacities of 50, 100 and 200 Nm^3/hr.

7.117 A regulated supply of nitrogen and oxygen is blended in a mixing valve. The differential pressure at the inlet to the mixing panel is critical and should not exceed 0.5 bar. A pressure-switch-operated solenoid valve opens and shuts on a 0.5 bar differential.

7.118 The main mixer solenoid valve opens when the line pressure falls to 4.2 bar; the stand-by mixer solenoid valve will open if the line pressure continues to fall to 4.0 bar.

7.119 Two independent paramagnetic oxygen analysers are provided on each mixer to give continuous on-line measurements.

7.120 If the oxygen concentration falls outside 20–22% as measured by either analyser, the mixer solenoid valve is held closed and the mixer is shut down. In addition, a signal is relayed downstream to close the solenoid valve on the buffer vessel associated with that mixer.

Buffer vessels

7.121 Each mixer has associated with it a buffer vessel to smooth fluctuations in demand.

7.122 In the event that the oxygen concentration differs from the specification (that is, 20–22%), the solenoid valve downstream of the buffer vessel will also close, preventing air from the buffer vessel from entering the distribution system.

7.123 The buffer vessel, together with appropriate means of safety relief, should be sized to match each mixing panel to provide stable operation.

Alarm signal status unit

7.124 The same alarm conditions for liquid oxygen should also be transmitted and displayed for the liquid nitrogen system. The following conditions should be displayed for the mixing panels:

a) green “normal” (normal);

b) yellow “plant fault” (low gas pressure to any mixer);

c) yellow “plant emergency” (analysis out of specification on any mixer);

d) yellow “reserve low” (operating on final mixing panel/buffer vessel only);

e) red “pressure fault” (pressure fault).

7.125 Conditions (b) to (e) of paragraph 7.124 should be transmitted to the central alarm system. Where relays are used, they should be normally energised relays that de-energise under fault conditions, with contacts having a minimum rating of 50 V d.c. and 50 mA.

© Health Facilities Scotland, a division of NHS National Services Scotland.

7.126 Volt-free, normally closed contacts rated at 50 V d.c. and 50 mA should be provided for transmission of conditions (b) to (e) of paragraph 7.124 to the alarm system.

7.127 The panel can be incorporated into the mixing panel control unit or be a separate unit within the plantroom. If mounted separately, the cabling should be monitored for open/short circuit. If such a cabling fault occurs, a red “system fault” lamp should be illuminated on the alarm signal status unit together with the appropriate alarm condition.

Emergency supply provision

7.128 A risk assessment should be carried out to establish the vulnerability of the main supply system of both oxygen and nitrogen. Further information is given in Section 2 on sources of supply and in Section 6.

Additional use of medical air systems

7.129 It is possible to use medical/surgical air as a power source for pendant control and braking systems.

7.130 These additions must not compromise either the medical air system or operation of connected equipment. They must be connected via a non-return valve and flow-limiting device, and be capable of isolation by means of an AVSU labelled to identify the equipment controlled.

7.131 Medical air systems must not be used for applications referred to in paragraph 2.6.

© Health Facilities Scotland, a division of NHS National Services Scotland.

8. Surgical air systems

General

8.1 Surgical air at 700 kPa is only used as the power source for surgical tools. These tools typically require high flows – up to 350 litres/min – at 700 kPa at the point of use. Where nitrogen is available on site, it may be used as an alternative source of supply.

8.2 Supply systems for surgical compressed air may be a cylinder manifold system, a dedicated 700 kPa compressor system or a compressor system capable of supplying both the 700 kPa and the 400 kPa supplies. In practice, the decision about which compressor system to install needs careful consideration because of the flow rates required and total usage (see Section 7).

8.3 A compressor system will be required for large operating department complexes specialising in orthopaedic and/or neurosurgery that require the use of pneumatically-powered surgical tools. An automatic reserve manifold located in separate accommodation should be provided. A typical system is shown in Figure 28 overleaf.

© Health Facilities Scotland, a division of NHS National Services Scotland.

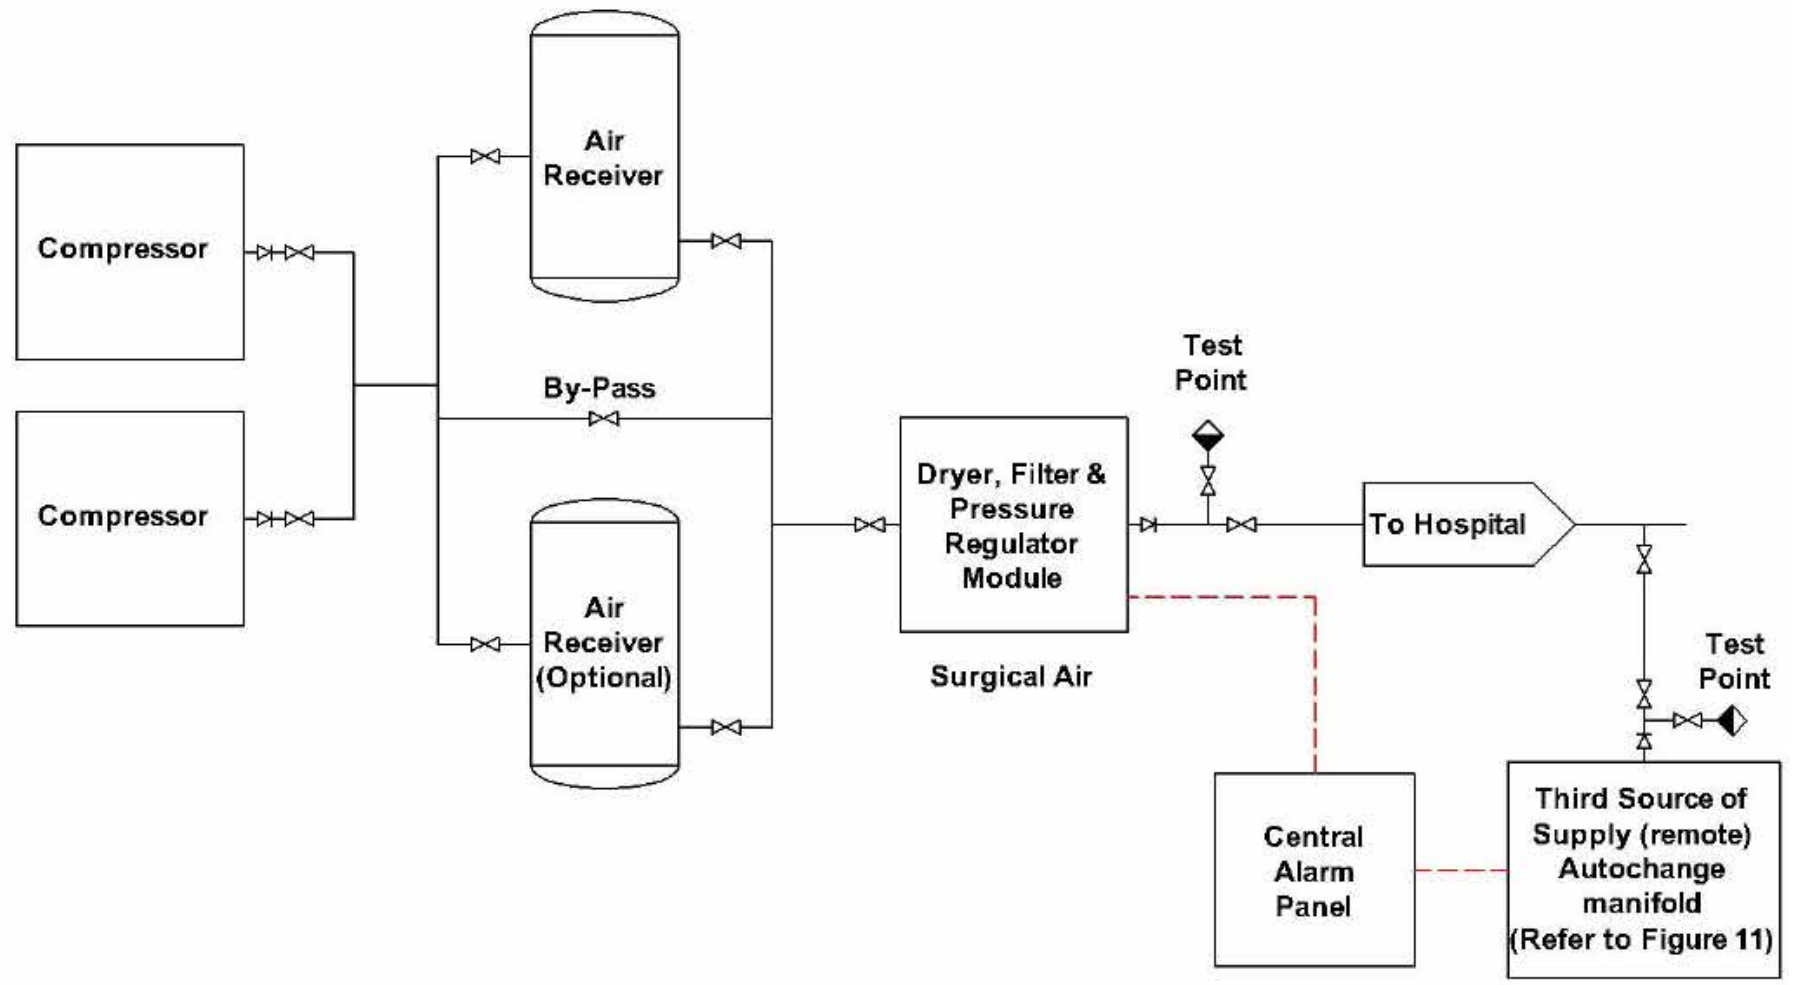

Figure 28: Typical surgical air plant and automatic emergency reserve manifold

.

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

8.4 It is possible to use nitrogen instead of air as the power source for surgical tools. This may be derived from either a liquid source or cylinders. In either case, the terminal units must be different from the existing medical air 700 kPa terminal units. A NIST connector is already specified for nitrogen and should be used.

8.5 The pressure control equipment should comprise duplex regulating valves with upstream and downstream isolating valves, pressure gauges and pressure relief valves.

8.6 Whatever supply system is installed, the overall system should be designed to provide a minimum of 700 kPa at the front of each terminal unit at a flow of 350 litres/min.

Note 21: Systems designed to meet requirements of earlier editions of Scottish Health Technical Memorandum 2022 may not provide 350 litres/min at 700 kPa. Information on upgrading surgical air systems in given in Appendix J.

8.7 The maximum pressure at the terminal unit under “no flow” conditions should not exceed 980 kPa.

8.8 Cylinders of medical air or nitrogen stored locally should always be available for use in an emergency.

8.9 Vessels should be selected as follows:

Design flow (Litres/min)	Vessel size	Compressor output (litres/min)
< 500	1 x 200% design flow	0.33 x design flow
500 - 2000	2 x 66.6% design flow	0.66 x design flow
2001 - 3500	2 x 50% design flow	0.66 x design flow
> 3500	3 x 33.3% design flow	0.50 x design flow

Table 33: Air receiver vessel selection

Extension of surgical air systems into dental departments

8.10 The preferred option for dental surgeries is a dedicated compressor system often purchased as Group 3 equipment. However, some surgical air systems, where pipelines are reasonably located, have been extended into the surgeries. When such extensions are made, a duplex regulator set incorporating upstream and downstream isolating valves, safety relief valves, pressure gauges and flow restrictor to provide 50/60 litres/min per chair per regulator should be fitted, located in a suitable plantroom secure from unauthorised access with gauges visible to the eye. Monitoring of low and high pressure by an area alarm panel should be in place. There should be no need to include a non-return valve or back feed protection. The following must be taken into account:

- the extra demand on the existing system must not compromise patient safety or operation of either the existing system or its extension. In

© Health Facilities Scotland, a division of NHS National Services Scotland.

particular, the ability of an existing emergency supply system to cope with potentially very high demands must be carefully assessed;

- the Authorised Person (MGPS) with responsibility for the existing surgical air system will automatically assume responsibility for the whole of the dental compressed air and vacuum system. Both the Authorised Person (MGPS) and Quality Controller (MGPS) must appreciate that extending a surgical air system into a dental unit for dental instrument use will introduce “non-standard” pipework terminations, for example crimped or compression-fitted connectors, in addition to non-degreased components. Failure of these “non-standard” components could lead to a serious de-pressurisation of the existing surgical air system and, if provided from the same source, the associated medical air system. Under no circumstances should the surgical air system at original or reduced pressure be extended into a dental laboratory;
- a test point should be available at each chair;
- if the medical air is derived from a plant that supplies surgical air, the medical air supply should have a separate manifold reserve supply when space and system design makes this practicable.

© Health Facilities Scotland, a division of NHS National Services Scotland.

9. Medical vacuum systems

General

9.1 The medical vacuum pipeline system provides immediate and reliable suction for medical needs, particularly in surgical accommodation.

9.2 The medical vacuum pipeline system consists of the vacuum supply system, the distribution pipework and terminal units. The performance of the pipeline system is dependent on the correct specification and installation of its component parts. This chapter describes the requirements of the vacuum supply system.

9.3 The medical vacuum pipeline system should be designed to maintain a vacuum of at least 300 mmHg (40 kPa) at each terminal unit during the system design flow tests.

9.4 To ensure continuity of supply, the vacuum plant should be connected to the essential electrical power supply.

9.5 The capacity of the vacuum supply system should be calculated in accordance with the design and diversified flow data provided in Table 21.

9.6 With the exception of the vacuum discharge to atmosphere, the pipeline distribution system for vacuum has traditionally been constructed of copper. PVC pipework can be considered where cost-effective. Pressure testing of PVC pipework should be carried out at 150 kPa. Pressure testing of copper pipework should be carried out at 500 kPa.

9.7 The major components of a medical vacuum system and their layout are shown in Figure 29 overleaf. A suitable operating and indicating system with alarms is also required. The location of the components should allow adequate space for access for maintenance. Packaged supply systems are available from manufacturers that should be specified to meet the requirements given in this memorandum.

© Health Facilities Scotland, a division of NHS National Services Scotland.

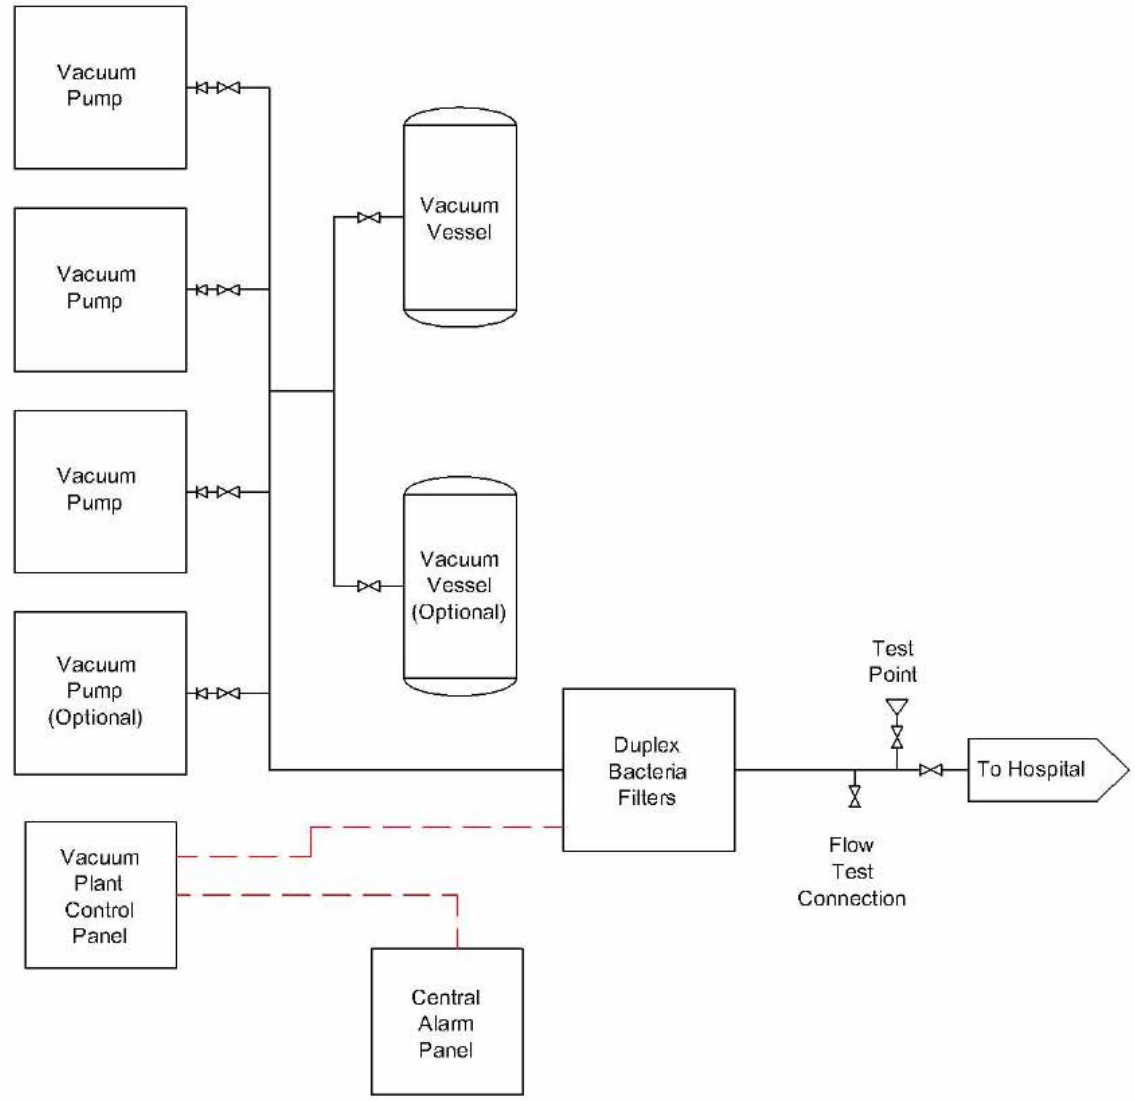

Figure 29: Typical medical vacuum plant

9.8 The plant should consist of at least three identical pumps, a vacuum reservoir(vessel) with by-pass facilities, duplex bacteria filters with drainage traps, appropriate non-return valves, isolating valves, gauges and pressure switches, an operating and indicating system, an exhaust system and a flow test connection. For capacities in excess of 500 litres/min, two vessels that can be independently isolated should be installed.

Note 22: The third means of supply for a vacuum installation will comprise of portable suction equipment and/or the third vacuum pump of a triplex pump system.

Siting

9.9 The plant should have all-round access for maintenance purposes, and allowance should be made for changing major components.

9.10 The siting of the plant should allow for adequate flows of air to cool the pumps. The manufacturers should be consulted over the range of operating

© Health Facilities Scotland, a division of NHS National Services Scotland.

temperatures for which the supply system is designed. In extreme cases, refrigerator cooling may be required.

Pump noise

9.11 The noise level produced by the pumps will increase with the capacity of the supply system. For larger systems this can result in an unacceptable noise level at the pump. The maximum free-field noise level at 1m from the un-silenced pump should not exceed the following values for individual pumps:

Power (kW)	Noise level (dBA)
5	75
5.1 -15	82
15	89

Table 34: Vacuum pump noise levels

9.12 A suitable acoustic enclosure may be required in the purchase specification for all pumps with a free-field noise level at 1m of 80 dBA or over. An enclosure should produce a reduction of at least 10 dBA in the free-field noise level at 1m. Vacuum pumps should be mounted on anti-vibration mounts, where necessary, to minimise transfer of noise and vibration to the building structure.

Vacuum plant exhaust

9.13 The position of the termination point should be carefully chosen to be clear of windows, ventilation intakes and the intake of air compressors and other equipment, since for oil-lubricated pumps the vacuum exhaust is likely to be polluted with oil fumes.

9.14 Noise from the exhaust should be considered and a silencer fitted if necessary.

9.15 The construction should conform to the following criteria:

- the exhaust should be sized to give a back pressure at system design flow which is matched to the pump performance;
- the termination point should be turned down and provided with protection to reduce the effect of wind pressure and prevent the ingress of rain, snow, insects or animals;
- weatherproof notices should be fixed at the discharge point(s) with the legend “medical vacuum discharge point – do not obstruct”;
- the exhaust pipe should be provided with a drainage valve and transparent collection jar at its lowest point;
- a silencer should be fitted in the exhaust pipe from each pump. This may be integral with the pump unit.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Efficiency

9.16 The pump should be capable of producing a higher vacuum than that required in the pipeline, so that the resistance of the bacteria filter and back pressure in the exhaust system can be overcome.

9.17 The capacity of the vacuum pump should be specified in terms of the free air aspirated (FAA) in litres/min when the pump is operating at a vacuum of 475 mmHg (63 kPa) and at 450 mmHg (60 kPa) at the plant pipeline connection.

Vacuum pumps

9.18 Any type of pump apart from water-sealed pumps can be used.

9.19 Pumps should normally be oil-lubricated. Vapours from the lubricating oil are unlikely to be a significant component of the exhaust gases if correctly maintained. “Dry running” rotary vane pumps are available at increased capital cost and with lower efficiency than oil-lubricated pumps of comparable performance.

9.20 At least three pumps should be provided. The actual number is at the discretion of the plant manufacturer to ensure optimum cost benefit of the system. All pumps should be designed for high frequency stop/start or continuous operation. The opportunity to maximise energy conservation should be taken into consideration. Variable speed / frequency inverter drive motors are being increasingly used in industry with consumption being electronically controlled to give rapid response to any output change and avoiding the energy wasteful start/stop frequency within the present wider pressure change corridor. Dental centralised systems and AGSS are obvious applications for such systems but could equally apply to medical vacuum systems with the larger capacity pipe sizing in many instances avoiding the need for a reservoir.

9.21 All systems should comprise pumps and motors of identical type that are suitable for continuous running and stop/start operation.

9.22 Pump motors should comply with the Model Engineering Specification C51 – ‘Electrical requirements for specified equipment’ with the addition of Class F insulation and Class B temperature rise.

Vacuum reservoirs

9.23 In conventional pump control a vacuum reservoir should be provided so that the duty pump does not run continuously for low loads. The reservoir should be manufactured in accordance with BS EN 286-1:1998 + A2: 2005, with test certificates provided to the user. The minimum test pressure should be 400 kPa / 4 bar. For variable speed applications seek advice from the manufacturer.

9.24 The water capacity of the reservoir should be equal to the plant design flow at 450 mmHg (60 kPa) in terms of free air aspirated in one minute with the pump operating at 475 mmHg(63 kPa).

© Health Facilities Scotland, a division of NHS National Services Scotland.

9.25 Provision should be made for draining the reservoir under vacuum conditions. By-pass facilities should be provided so that the reservoir can be drained and inspected without interruption to the vacuum supply. The reservoir should be fitted with suitable lifting lugs and feet.

9.26 If multiple reservoirs are provided, they should be arranged in parallel.

Bacteria filters

9.27 The bacteria filters and drainage trap should comprise two identical sub-assemblies with manually-operated isolating valves, arranged to allow either sub-assembly to be on stream. Each sub-assembly should contain a bacteria filter rated at the plant capacity.

9.28 The bacteria filter should be marked with the legend “bio-hazard”, together with a description of a safe procedure for changing and disposing of the filters and emptying the drainage trap. Refer to Part B of this SHTM – Appendix D.

9.29 The bacteria filters should have a filter efficiency, when tested by the sodium flame test in accordance with BS3928:1969, of greater than 99.995% at the system design flow.

9.30 The pressure drop across a clean filter at the system design flow should not exceed 25 mmHg (3 kPa) at a vacuum of 475 mmHg (63 kPa).

9.31 The drainage trap may be integral with the bacteria filter and should be fitted with a transparent bowl to collect liquid. The bowl should be suitable for steam sterilization at 134°C.

9.32 Although there is no firm evidence that has demonstrated the need for bacteria filters, it is recommended that such devices are included as precautionary measures.

Pressure control

9.33 The cut-in setting for the vacuum pumps should be adjusted to allow for the pressure drop across the pipeline distribution system and the bacteria filters. The cut-in may be expected at about 500 mmHg (67 kPa).

9.34 The cut-out setting should be at an appropriate point on the performance curve of the pump, which minimises stop/start operation but is at a vacuum which is economically attained by the pump. This cut-out setting may be expected at about 650 mmHg (87 kPa).

Valves

9.35 Non-return valves should be fitted, when necessary, at the inlet and outlet of each pump to prevent backflow when a common discharge pipe is used. (Some vacuum pumps include integral non-return valves).

© Health Facilities Scotland, a division of NHS National Services Scotland.

9.36 Manually operated valves should be arranged in the positions shown in Figure 29 to allow isolation of components such as pumps, reservoirs, by-pass pipework, drainage traps and bacteria filters.

Pressure regulation of vacuum system

9.37 A minimum vacuum level of 300 mmHg (40 kPa) is required at the connection point of each terminal unit with a flow of 40 litres/min whilst the system is operating at system design flow.

9.38 This performance is tested by the procedures carried out in accordance with Section15.

9.39 A maximum pressure drop of 100 mmHg (13 kPa) is allowed across the terminal unit at a free air flow of 40 litres/min to provide a minimum pressure of 300 mmHg at a pipeline pressure of 400 mmHg. At lower negative pressures, the volumetric flow would increase by expansion and be represented by a larger pressure drop across the terminal unit. Such tests must be qualified by the pipeline pressure at the time of test. The minimum pressure permitted at the front of the furthest terminal unit on each branch line should be 300 mmHg (40 kPa) at a flow of 40 litres/min. When the system is subjected to the total design flow, the minimum dynamic pipeline pressure from the plant should be 450 mmHg (60 kPa).

Vacuum indicators

9.40 Vacuum indicators should comply with BS EN 837-1:1998 or have an equivalent performance if electronic indicators are used. Calibration should be 0–760 mmHg (0–101 kPa). All gauges should be a minimum scale length of 90mm.

9.41 Vacuum indicators should be located on:

- the plant control unit indicating the vacuum in the pipeline (that is, on the pipeline side of the bacteria filter);
- each reservoir.

9.42 A differential vacuum indicator (to indicate filter blockage rather than quantitative pressure drop) should be located across the bacteria filter and have a service isolation valve.

Electrical supply

9.43 The electrical supply to the medical vacuum plant should be connected to the essential electrical supply. The control system should ensure that pumps restart in sequence to avoid overloading the power supply.

Pump operating and indicating system

General description

9.44 The operating and indicating system should perform the following functions:

© Health Facilities Scotland, a division of NHS National Services Scotland.

- overall plant control and indication;
- individual pump starting;
- plant status monitoring and indication;
- alarm signal status unit.

9.45 Provided that the individual pump starters are housed in a separate compartment, the operating and indicating system may be housed in separate units or may be installed in a common panel and located on the plant or on the plantroom wall.

9.46 Pneumatic components should have ventilation. All functions should be appropriately identified. Indicators should have a design life of at least five years. The operating system should be capable of automatically restarting after reinstatement of the power supply.

Plant control unit

9.47 The control unit should have a separate power supply for each pump controlled by a separate sub-circuit. It should be manufactured and installed in accordance with IEE regulations, and the design should be such that no single component failure in the control unit will result in loss of plant output.

9.48 The unit should allow either manual selection of duty/stand-by for each of the pumps or have an automatic sequence selection with a means for manual override. The control unit should ensure that two or more pumps do not start simultaneously when power is applied.

9.49 A warning notice which complies with BS5499-5: 2002 should be affixed which indicates the presence of low voltage.

9.50 For testing purposes, each pump should have a selector switch which when turned to the “on” position allows the pump to run continuously.

Plant control indication

9.51 There should be indicators for each pump as follows:

- green “mains supply on”;
- green “pump operating”, which indicates that the pump motor is electrically energised;
- green “pump operating”, which indicates that the pump is drawing vacuum;
- an analogue or digital gauge registering the vacuum level within the pipeline.

Pump starter units

9.52 There should be individual starter units, each one operating a single designated pump. The starters should be provided with safety interlocks as specified by the

© Health Facilities Scotland, a division of NHS National Services Scotland.

pump manufacturers, which should inhibit plant operation until manually reset by means of a button. The starters should allow automatic restart after an interruption to the power supply. Each starter unit should contain the following:

- an isolator interlocked with the covers;
- an emergency stop;
- either HRC fuses to BS88 or suitable circuit breakers to BS EN 60947-2: 2006 + A1: 2009 and/or BS EN 60898-1: 2003 + A1: 2004;
- starter;
- an industrial grade ammeter to BS EN 60051-1: 1999, IEC 60051-1:1997 or an electronic digital instrument of comparable, or higher, standard;
- a total hours run counter, if not included in the plant control unit;
- a green “mains supply on” indicator, if mounted separately from the plant control unit.

Plant status monitoring

9.53 A monitoring system must be provided to detect the following faults in the vacuum supply system:

- plant faults for each pump:
  - control circuit failed;
  - motor tripped;
  - pump failed to go on load;
  - activation of other safety devices supplied by the manufacturers;
- plant emergency – receiver vacuum has fallen, for example, by 50 mmHg below the cut-in setting for the pump;
- pressure fault (pipeline) – pipeline vacuum less than 360 mmHg.

Plant status indicator unit

9.54 In addition to the plant control indication, there should be a plant status indicator panel that may be mounted on the plantroom wall or adjacent to either the pump starter unit or the plant control unit. It should have a warning notice that complies with BS5499-1: 2002 to indicate the presence of low voltage.

9.55 There should be indicators for each pump to show the following conditions:

a) green “mains supply on”;
b) yellow “control circuit failed”;
c) yellow “motor tripped”;
d) yellow for each individual safety device provided by the manufacturers;
e) yellow “pump failure”.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Alarm signal status unit

9.56 The following indication of plant conditions should be provided:

a) green “normal” (indicator normal);

b) yellow “plant fault” conditions (b)–(d); see paragraph 9.55;

c) yellow “plant emergency” condition (e); see paragraph 9.55;

d) red “pipeline pressure fault” (pressure fault).

9.57 Conditions (b) to (d) of paragraph 9.56 should be transmitted to the central alarm system. Where relays are used, they should be normally energised relays, which de-energise under fault conditions, with contacts having a minimum rating of 50 V d.c. and 50 mA.

9.58 Volt-free, normally closed contacts rated at 50 V d.c. and 50 mA should be provided for transmission of conditions (b) to (d) of paragraph 9.56 to the alarm system.

9.59 The panel can be incorporated into the plant status indicator unit or be a separate unit within the plantroom. If mounted separately, the cabling should be monitored for open/short circuit. In the event of such a cabling fault, a red “system fault” lamp should be illuminated on the alarm system status unit together with the appropriate alarm condition.

Plant management

9.60 Connections should be provided which allow monitoring (but not control) of plant alarm conditions (b) to (d) of paragraph 9.56 and pump running for each vacuum pump. These connections should be normally closed, volt-free contacts for each condition having a minimum rating of 50 V d.c. and 50 mA.

9.61 Plant should be operated in accordance with the manufacturer’s instructions and be covered by a sound, effective planned preventative maintenance (PPM) policy.

© Health Facilities Scotland, a division of NHS National Services Scotland.

10. Anaesthetic gas scavenging disposal systems

Terminology

10.1 An active system, as specified in either BS6834: 1987 or BS EN ISO 7396-2: 2007 is one in which a high air flow generated by an electrically driven pump is used to exhaust air through the system's fixed pipework. This in turn entrains waste gases from the patient, or patient ventilator, via a transfer hose and receiving system.

10.2 The transfer and receiving system form part of the anaesthetic/breathing system.

10.3 The receiving system is designed to match the variable flow in the breathing system to the constant flow of the disposal system and ensure that very low induced flows are imposed (0.5 litres/min in the case of BS6834:1987 and 0.05 litres/min in the case of BS EN ISO 7396-2: 2007).

10.4 In the UK, only systems complying with the BS or EN Standards above are considered appropriate for scavenging waste anaesthetic gases from accommodation in which general anaesthesia is taking place.

10.5 Active scavenging for dental installations is an entirely different concept. An active system is one in which there is a flow generated through the patient's nasal mask and this carries away the waste gases exhaled by the patient. This flow is in the order of 45 litres/min and is achieved by connection of the mask (via a suitable flow-limiting adaptor or terminal screw adjustment) to an active scavenging system (BS/EN) wall terminal unit. Alternatively, a Group 3 local active unit is available designed for dental purposes. Consideration should be given to providing additional room ventilation i.e. high level supply and low level extract.

General

10.6 Anaesthetic gases are considered to be substances hazardous to health for the purposes of the Control of Substances Hazardous to Health Regulations 2002 (COSHH), except where they are administered to a patient in the course of medical treatment.

10.7 Detailed guidance on compliance with COSHH is given in the Department of Health's (1996) 'Advice on the implementation of the Health & Safety Commission's occupational exposure standards for anaesthetic agents'. Further guidance is given in by the Health & Safety Executive's (1996) 'Anaesthetic agents: controlling exposure under COSHH'.

10.8 The COSHH regulations set out very specific duties that apply to anaesthetic gases, and employers have a legal obligation to ensure that these duties are discharged. It is therefore the responsibility of the general manager or chief

© Health Facilities Scotland, a division of NHS National Services Scotland.

executive to implement the requirements of the COSHH regulations with respect to anaesthetic gases. This subject is covered in Part B.

10.9 For new installations, an assessment should be made of the transfer and receiving equipment currently in use and intended for use with the new installation. Where the transfer and receiving equipment has been designed to BS6834:1987, the disposal system design should be to BS6834:1987. Where the transfer and receiving equipment in use has been designed to BS EN 740:1999, the disposal system should be designed to BS EN ISO 7396-2: 2007. Where a mixture of equipment is in use, the system should be designed to BS6834:1987. Where both types of equipment are required to be used on the same disposal system, a restrictor should be provided for the BS EN 740:1999 equipment to restrict the flow to its design flow rate. The system should be installed in all operating departments and other areas, as required, in accordance with the levels of provision given in Table 11.

Note 23: BS6834: 1987 covered all aspects of the anaesthetic gas scavenging systems. BS EN 737-2: 1998 and BS EN 737-4: 1998have now been replaced with BS EN ISO 7396-2: 2007 and BS EN ISO 9170-2: 2008 respectively.

10.10 A typical system schematic is illustrated in Figure 30a and 30b and shows the terminology used.

© Health Facilities Scotland, a division of NHS National Services Scotland.

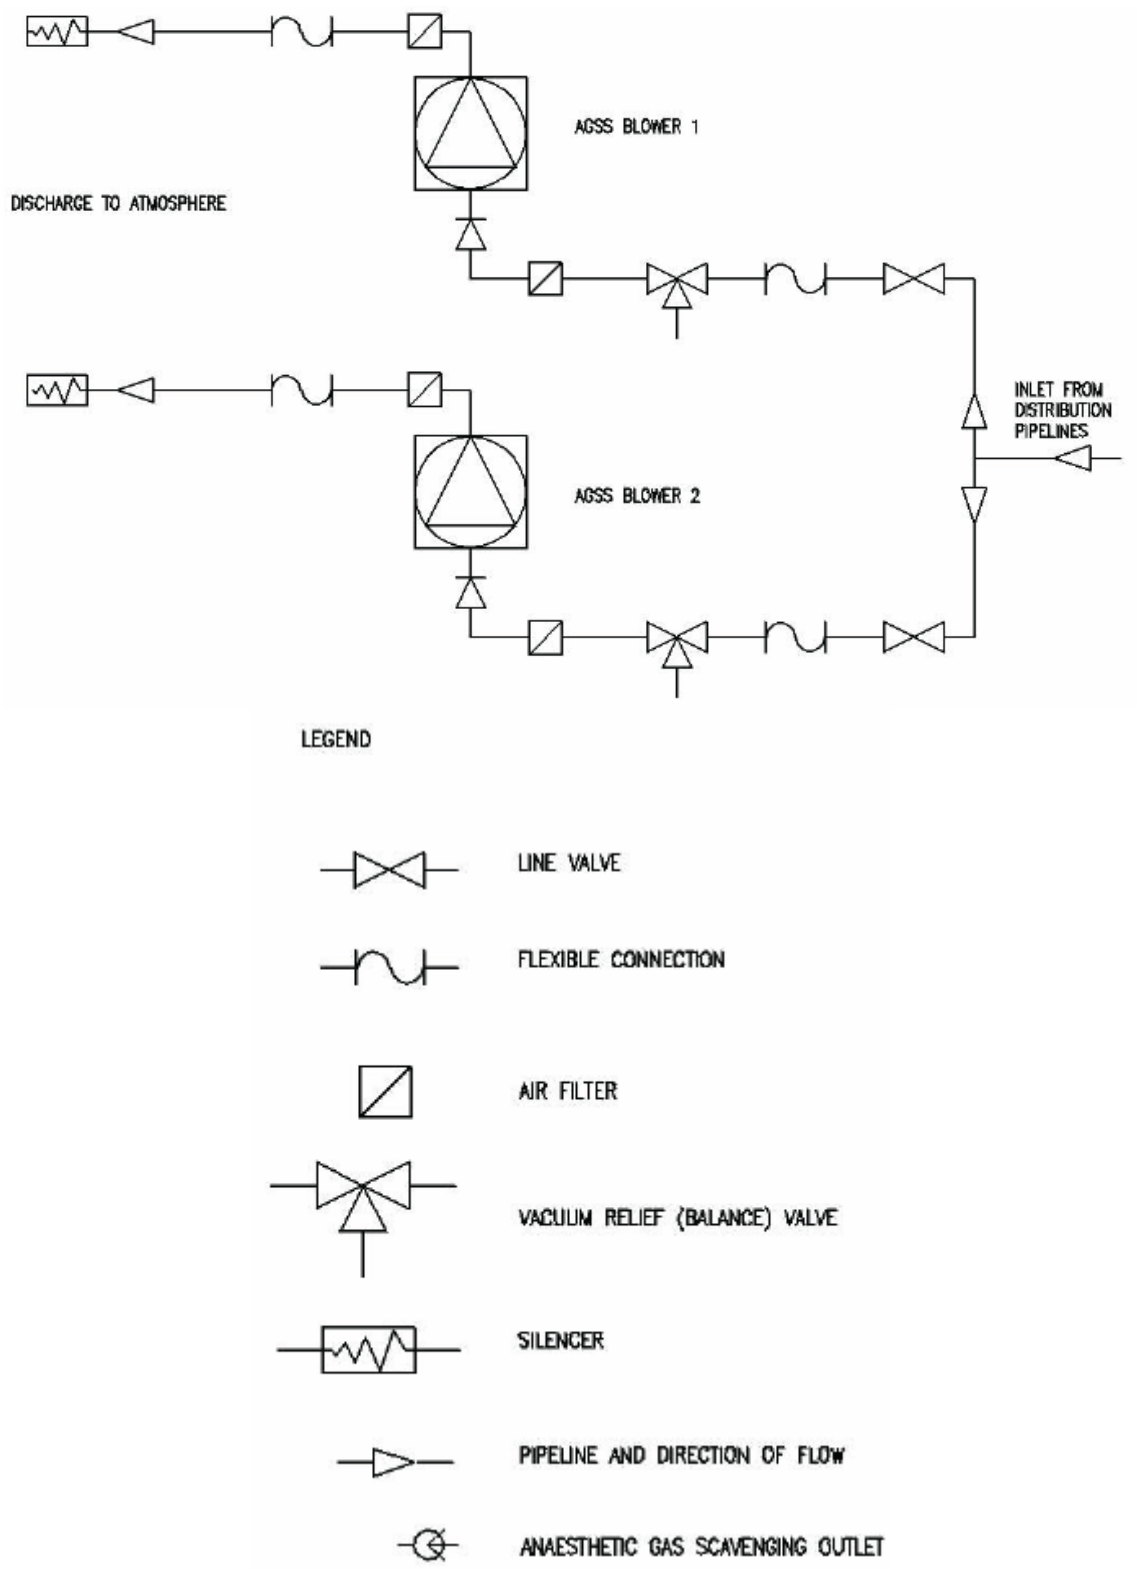

Figure 30a: AGSS Plant schematic (duplex blowers shown)

© Health Facilities Scotland, a division of NHS National Services Scotland.

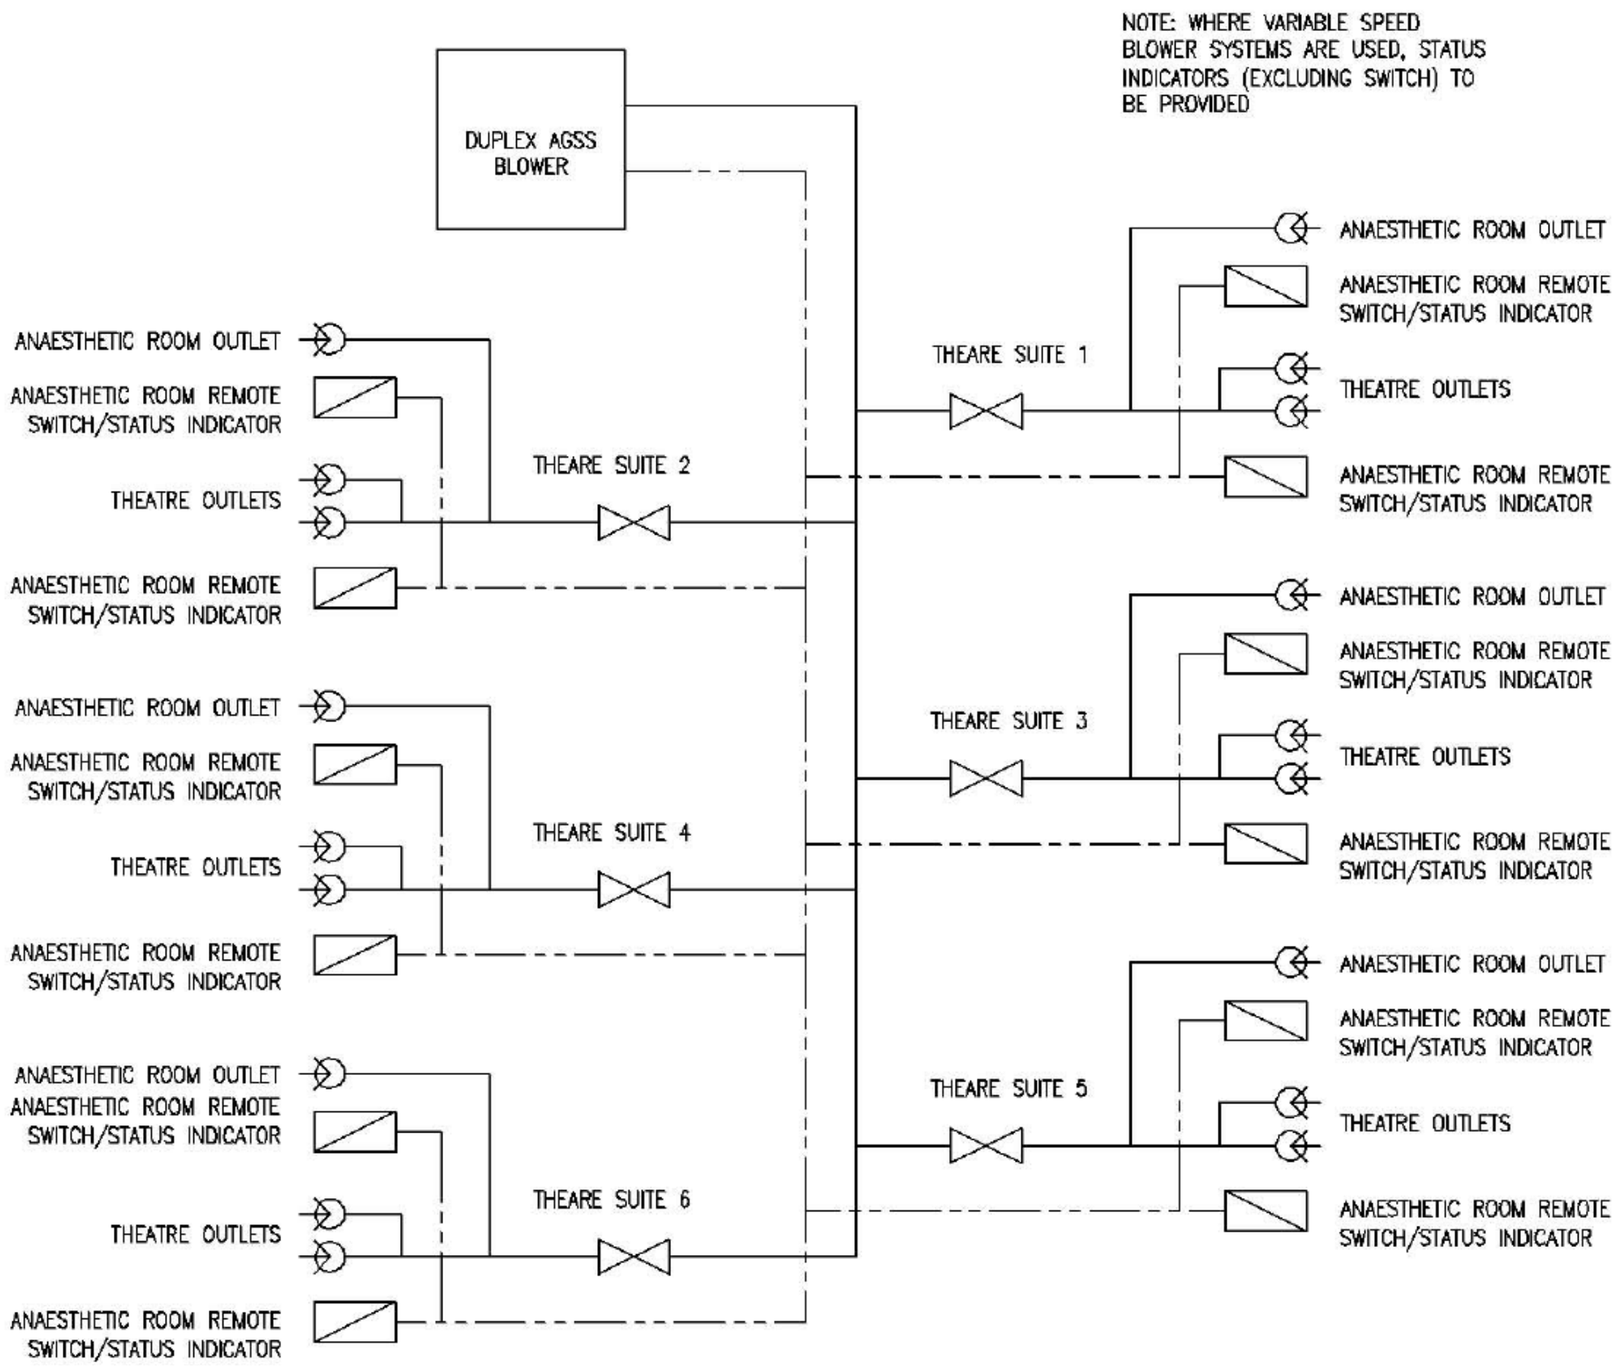

Figure 30b: Pipeline schematic, including remote AGSS switching

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

10.11 The internal components and pipework of AGS disposal systems are in contact with a patient's expired breath. Even though there is considerable dilution by virtue of the receiving system that forms part of the anaesthetic equipment, there is, however, potential for bacteriological contamination. The materials should be reasonably resistant to corrosion and should withstand cleaning, disinfection or sterilization as appropriate.

10.12 The fixed pipework may be of copper or other suitable material such as PVC. Where copper pipework is installed at the same time as the MGPS, it is desirable to use degreased pipework to the same specification as that used for the MGPS (see Section13) in order to avoid confusion. Pipeline pressure testing and loss allowances should be in accordance with the requirements for medical vacuum pipeline pressure tests.

10.13 Where PVC pipes larger than 38mm diameter pass through a fire compartment, they should be protected with metal sleeves extending for 1m either side of the compartment in accordance with the Building (Scotland) Amendment Regulations 2006. The recommendations of Firecode and Scottish Health Technical Memorandum 81 should be followed.

Selecting the number of disposal system pumps

10.14 The number of disposal system pumps selected for operating theatre suites should be determined through consideration of a number of factors including: the number of theatres concerned; the layout of the department; the degree of difficulty associated with the pipework installation; a cost comparison between systems; together with an evaluation of the impact and level of disruption likely to be realised in the event of a fault condition occurring which could result in the loss or partial loss of the system. The following selections could be considered:

- An individual pump per theatre suite will not maintain the system under a fault condition. Spare pumps can be carried in store, however, the disruption factor and outage time must be taken into consideration.
- A duplex pump set will ensure continuity of supply in the event of a single fault condition. When applied in conjunction with other control measures, such as the mechanical ventilation system providing the specified number of air changes for the room, the exposure to anaesthetic agents should be maintained below the prescribed occupational exposure standards in compliance with the COSHH requirements being achieved.
- When specifying a simplex or duplex pump set providing AGS to a number of areas, consideration must be given to future maintenance requirements which will require all rooms with an AGS outlet on the system to be accessed almost simultaneously for the purposes of carrying out a system performance test either as a ppm activity or following modification of the system.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 24: Anaesthetic gas scavenging systems when installed, commissioned and operated should maintain the service in normal use and on a single fault condition. To ensure continued service under a fault condition as required by European Standards, a minimum of a duplex pump plant assembly would be required. The single pump arrangement with a replacement pump in store would not meet the requirement for maintaining the service under a single fault condition. The impact and level of disruption to service in the event of simplex plant failure should be carefully evaluated when finalizing the plant selection.

10.15 Historically a fixed volume exhauster was installed which generated noise, at times unacceptable depending on location and was not energy efficient. With respect to patient safety, the air admittance valve imposed a further risk factor and in most instances staff failed to switch off the system when not in use, resulting in 24/7 exhauster operation and premature replacement of plant. In order to avoid such problems, variable speed/ frequency inverter vacuum pumps should be considered as a first option. As described in other sections of SHTM 02–01 the electronic control will give optimum efficiency with virtual instantaneous response to any output demand. If required the controller will automatically engage the standby pump within preset parameters, however, normally the duty pump would be sized for the design flow taking account of the appropriate diversity factors.

10.16 With variable speed control, tight pipeline pressure loss tolerances, pipe sizing and a terminal unit with variable screw adjustment, the system can be designed to meet the performance requirements of both BS6834: 1987 and BS EN ISO 7396-2: 2007. Protection of the system should include a safety relief valve set to suit system requirements.

10.17 The number of operating theatres and departments served by any one system should be estimated by plant location to departments. Eventually separate switching at each terminal unit should not be a requirement, however, it remains a requirement of BS6834, therefore switching should remain for the present even though the variable speed motor will adjust or automatically closedown at no demand. Further consideration should be given to the location of the plant control indication which rather than individually located at each plant control switch, can be incorporated within the area alarm panel.

Flow and diversity

10.18 Although more than one AGS terminal unit may be installed in an operating room or anaesthetic room for convenience, it may be assumed that only one terminal unit in each room will be in use at any given time. The AGS terminal unit in the anaesthetic room and operating room, however, may on rare occasions be in use simultaneously; therefore, the plant is sized for two AGS terminal units for each operating suite.

10.19 The performance criteria for the disposal system are specified in the relevant British, European and International Standards in terms of the extract flows at specified resistance. The disposal system should meet the requirements set out in the table

© Health Facilities Scotland, a division of NHS National Services Scotland.

	Disposal system standard			
	Pressure drop		Flow rate	
	BS6834: 1987	BS EN ISO 7396-2: 2007	BS6834: 1987	BS EN ISO 7396-2: 2007
Maximum	1 kPa	1 kPa	130 Litres/min	80 Litres/min
Minimum	4 kPa	2 kPa	80 Litres/min	50 Litres/min
Maximum static pressure	20 kPa(-ve)	15 kPa(-ve)		

Table 35: Disposal system pressure and flow rates

Notes applicable to Table 35: a) Since the preparation of BS6834:1987, developments in anaesthesiology have resulted in reduced flows being used. Depending on local circumstances, it may be possible to commission systems for different flows in accordance with BS EN ISO 7396-2: 2007.

b) Details of the test flows should be recorded in the commissioning documentation.

c) The pump inlet should include a vacuum indicator for commissioning and servicing purposes.

Discharge outlet

10.20 Careful consideration should be given to the siting of the discharge from the disposal system. It should preferably be sited at roof level, well away from ventilation inlets, opening windows and other apertures, to prevent pollution re-entering the building. Signage should be provided in accordance with Appendix K.

Plant control indication

10.21 There should be indicators to show the following conditions:

- green “mains on”;
- green “air flow” normal;
- yellow “duty pump failed” (plant fault) – applies to duplex plant only;
- red “system failed” (plant emergency).

10.22 Indicator panels should be installed in operating rooms and at other locations where gas scavenging is available.

10.23 The “air flow normal” indication should be initiated by either a pressure switch or air flow detection device at the pump when vacuum is established within the pipeline.

© Health Facilities Scotland, a division of NHS National Services Scotland.

11. Other medical gas pipeline installations

General

11.1 It is possible to extend medical gas system design concepts to other gases used from cylinders and still maintain the elements of gas specificity that are essential requirements together with all other relevant safety considerations.

Helium/oxygen mixture

11.2 Helium/oxygen mixture is used by patients with respiratory or airway obstruction and to relieve symptoms and signs associated with respiratory distress. It can be administered by means of face mask and cannula, a demand valve with face-mask with cannula attached, a nebuliser, or by a ventilator.

11.3 Its main use will be in Accident & Emergency (A&E), supplied from portable cylinders with integral control valve and regulator, and in critical care areas.

11.4 When provided by means of a pipeline installation, all the elements of a manifold supply system for other medical gases should be installed.

11.5 The manifolds will be designed to operate at low pressure (10 bar), and connection to K-size cylinders will be made by means of a low-pressure flexible assembly to a terminal unit integral with the cylinder regulating valve. The connection to the manifold will be by means of a NIST connector.

11.6 The individual cylinders will include pressure transducers to monitor the pressure upstream of the integral control valve. (Cylinders do not necessarily discharge simultaneously.)

11.7 The manifold should be located close to the facility that it supplies.

Compressed Gas Cylinder Manifold Systems		
Primary supply	**Secondary supply**	**Tertiary supply (third source of supply)**
Duty bank of a fully automatic manifold. Number of cylinders based on system design.	Standby bank of a fully automatic manifold.	Manual emergency reserve manifold - to come on-line automatically via a non-return valve in the event of a single fault condition and to act as a reserve supply during maintenance / repair works Type and capacity of supply to be determined by risk assessment.

Table 36: Compressed gas cylinder manifold systems

Oxygen/carbon dioxide mixture

11.8 Oxygen/carbon dioxide mixture has been supplied by pipeline in at least one installation in the UK for anaesthetic purposes in cardiothoracic procedures.

© Health Facilities Scotland, a division of NHS National Services Scotland.

11.9 There has been little interest shown in installing others and, therefore, this medical gas is no longer included within the scope of this Scottish Health Technical Memorandum.

Carbon dioxide

11.10 Carbon dioxide is now not generally used as a respiratory stimulant post-operatively. Pipelines have not been installed in the UK for respiratory applications. Its main use today is for insufflation during surgery, and to date there have been some installations in the UK.

11.11 When pipeline systems are installed for such purposes, the general requirements for other medical gas pipelines should be followed. The terminal unit should comprise a NIST connector with integral check valve contained in the surgeon's pendant. The level of provision of AVSUs should be provided as for other medical gas pipelines.

11.12 A semi-automatic manifold will normally be satisfactory and it should be installed "locally". A 2x4 VF-size manifold will provide adequate capacity. The safety valve discharge should be taken outside the department. The warning and alarm system indicator will normally be installed in the operating room control panel.

Nitric oxide

11.13 Treatment using nitric oxide is subject to specific Ph. Eur. requirements. Distribution of the gas by pipeline systems is not considered appropriate.

© Health Facilities Scotland, a division of NHS National Services Scotland.

12. Warning and alarm systems

General

12.1 The provision of a warning and alarm system is essential to monitor the safe and efficient operation of an MGPS. There are three reasons for this monitoring:

- to indicate normal function of the pipeline system by means of visual indicators;
- to warn by visual and audible indication that routine replacement of cylinders or other engineering action is required;
- to inform the user by visual and audible emergency alarms that abnormal conditions have occurred which may require urgent action by the user. This alarm condition will require a rapid response by the various departmental staff.

12.2 To date, practice has been to have a “dedicated” medical gas warning and alarm system and this approach will remain in many situations. With the development of computer-based integrated patient/ management systems, nurse call and other alarm systems, however, there is considerable scope for including medical gas system information including text action prompts etc. Additionally, building management IT-based systems will play an increasing role in the operation and management of an MGPS.

Dedicated systems

12.3 The requirements of “dedicated” warning and alarm systems are covered in paragraphs 12.3 to 12.62 and a schematic diagram of a typical central system layout is shown in Figure 31. Warning and alarm systems are required for all medical gas and vacuum systems. A simplified system is required for AGSS, with the warning/indication panel located in the operating room or other area where AGSS is used.

12.4 Warning and alarm systems comprise pressure sensors, a central system providing information on all monitored functions, with repeater panels located where information is required to ensure the necessary action is taken. Area alarms should be provided to give warning to users downstream of the designated departmental AVSU (see Section 3).

12.5 Pressure sensors should be connected to the pipeline by means of a minimum leak device. Whenever possible, pressure sensors should be installed outwith the ceiling space e.g. within wall mounted AVSU panels, within individual AVSUs or within a dedicated panel or box. Where this cannot be achieved, ventilation of the space will be required.

12.6 All MGPS warning and alarm indicating panels should comply with the requirements of this Scottish Health Technical Memorandum, including all operating room panels.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Panel location

Central indicator panel

12.7 Warning and alarm conditions for all medical gas supply systems should be displayed on a central panel located in a position where there is continuous 24-hour occupation, such as the telephone switchboard room or the porters' lodge.

Repeater indicator panel

12.8 Repeater panels should be provided in other locations to display all or some of the information on the central alarm so that appropriate action can be taken to ensure the continuing operation of the system. Some warning system information may be appropriate for display in specific departments, for example cylinder manifold status information in a porters' room, and oxygen concentration in the pharmacy department when a PSA plant supplies the hospital pipeline installation. The inclusion of a repeater alarm panel within critical care areas (ITU, CCU, HDU, SCBU etc.) should be considered to advise staff of high / low pressure fault conditions and whether the emergency supply is in use.

Area warning and alarm panel

12.9 Area panels to display "high" and/or "low" gas pressure should be installed in the locations given in Section 3. The sensors for these panels should be located downstream of the designated AVSUs, normally the departmental AVSUs. It should not be possible to isolate the sensor with a separate shut-off valve and they should be connected to the pipeline by means of a minimum leak device.

System components

12.10 Warning and alarm systems include the following functional elements:

- interfaces/transmitters that convert the signal from the plant or manifold Volt-free alarm contacts into a form which can be transmitted via multiplexed cable (for example using pulse-width modulation). The transmitter may be a separate unit or may be incorporated:
  - in plant or into a manifold control panel;
  - into an indicator panel. Line-fault monitoring devices should be included in both cases;
- indicator panels which display the transmitted signals;
- interconnecting multiplex wiring which connects all interfaces/transmitters to all indicator panels.

© Health Facilities Scotland, a division of NHS National Services Scotland.

System layout

Central plant alarm system

12.11 A typical system layout is shown in Figure 31, which shows initiating devices at remote locations such as the VIE compound, medical air and vacuum plantrooms, manifold rooms and emergency/reserve manifold rooms. The transmitters are normally located close to the initiating devices. Central / repeater alarm panels are typically located at the telephone exchange, the security room, the porters' room and the engineer's office to provide information requiring action by engineering and other support staff.

© Health Facilities Scotland, a division of NHS National Services Scotland.

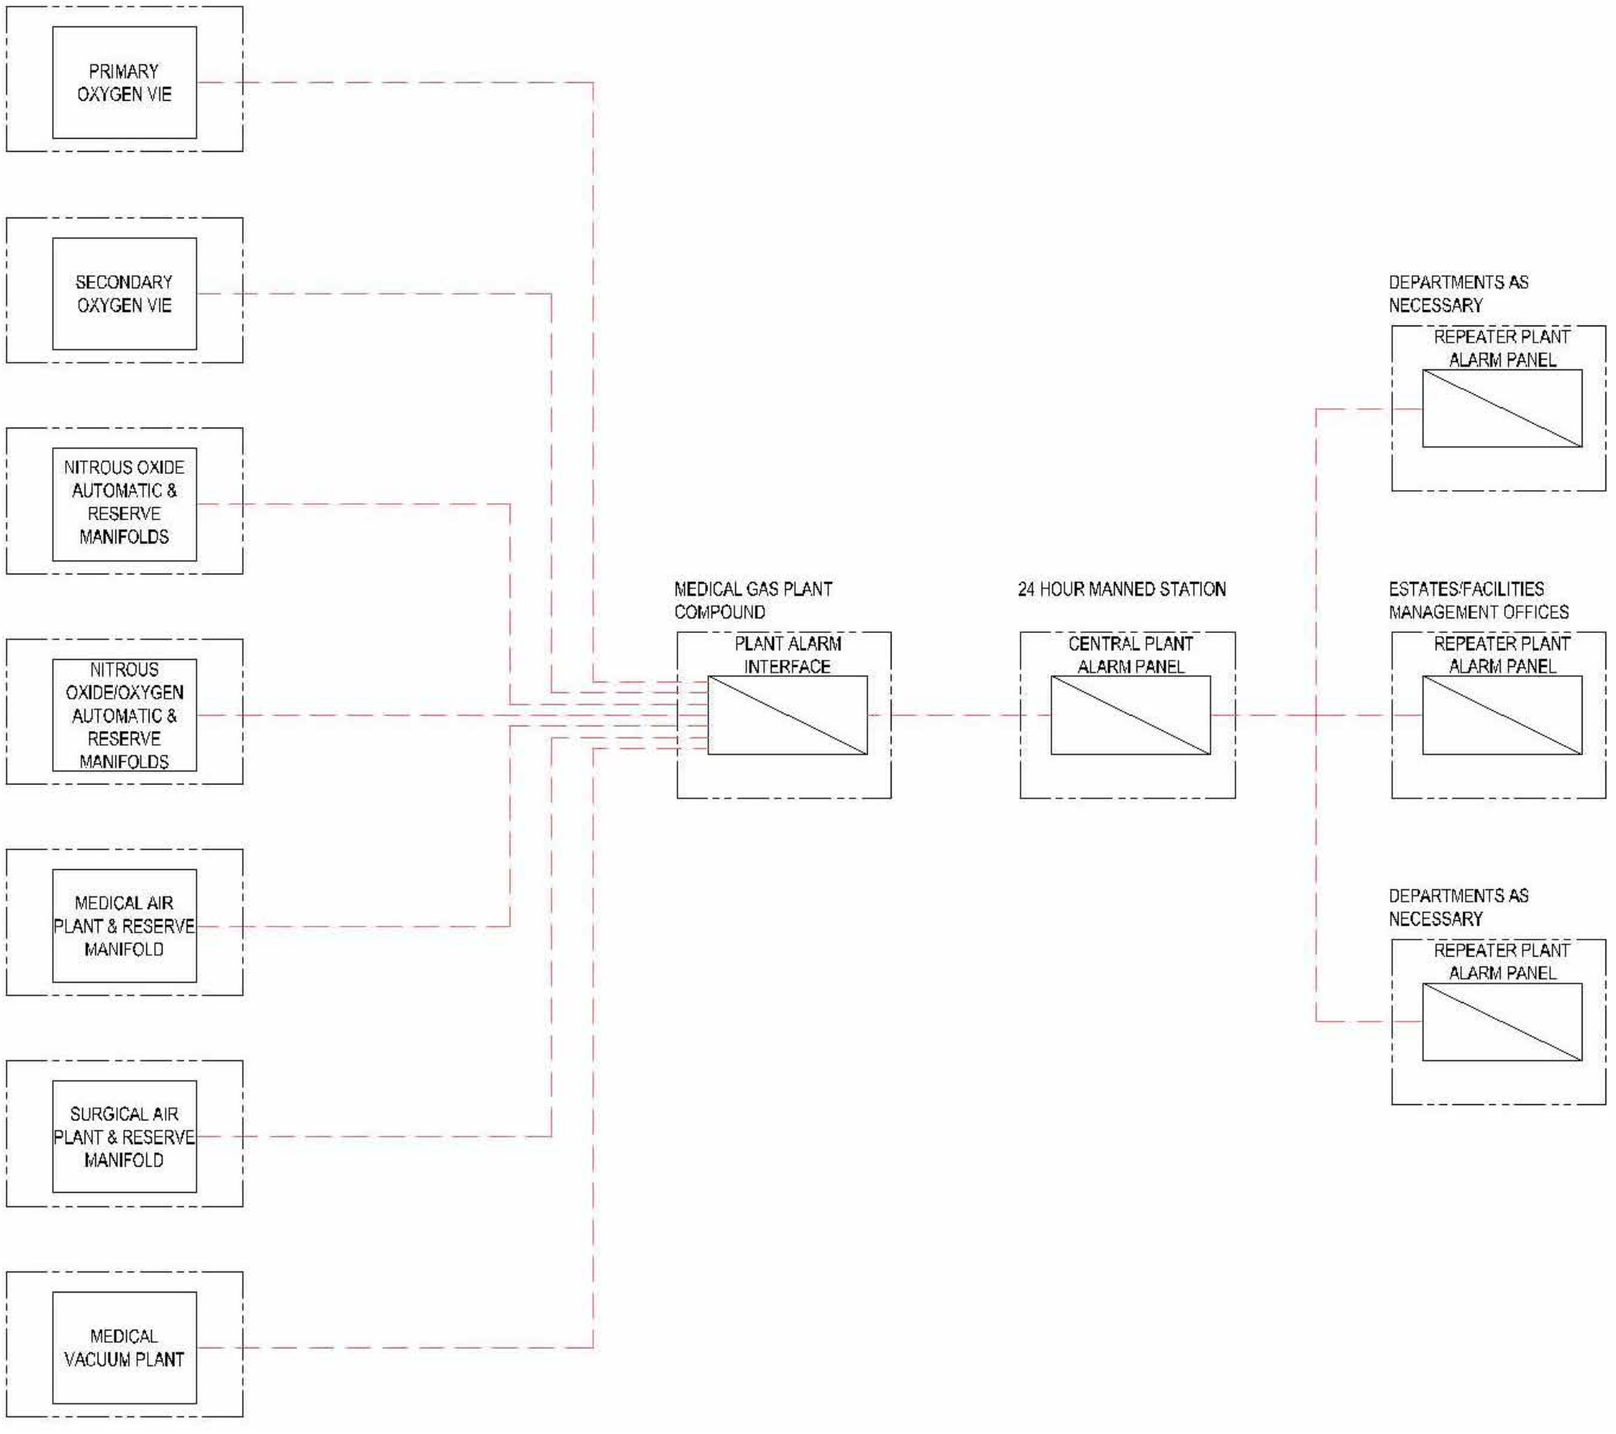

Figure 31: Central plant alarm

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

Area alarm systems

12.12 A typical layout of an area alarm system is shown in Figure 32 for illustration purposes. For each gas service there should be local pressure switches for low pressure; high pressure switches are also required when there is any combination of oxygen, nitrous oxide and medical / surgical air installed together. These conditions should be indicated on a locally-mounted indicator panel, with the facility to provide a common alarm condition for connection to other repeater alarm panels. In situations where the staff base is not in close proximity to the AVSU module / pressure switches, the area alarm panel should be located where it will be both audible and visible from the staff base. Area panels carry no indication of the warnings for cylinder replacement and plant functions that are given on central indicator panels.

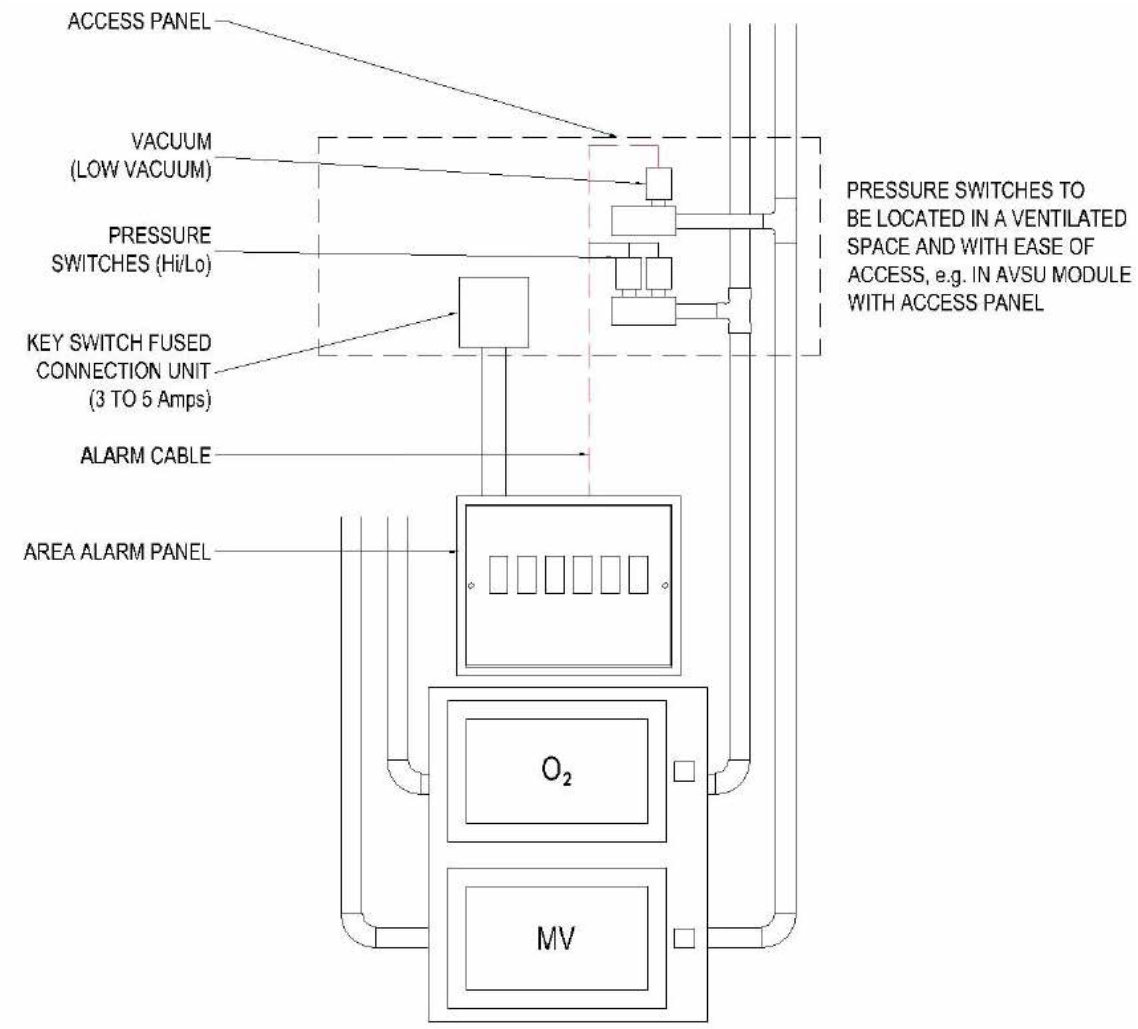

Figure 32: Area alarm panel arrangement (2-gas service shown)

© Health Facilities Scotland, a division of NHS National Services Scotland.

General requirements

Labelling

12.13 All visual signal panels should be permanently labelled according to their function, including clear identification of the areas, rooms or departments served.

Visual signals

12.14 Flashing visual signals should have alternate “on” and “off” periods, each of equal duration between 0.25 and 0.50 seconds.

12.15 There should be two separately energised light sources for each signal, arranged so that the failure of one source does not affect the other.

12.16 The light sources should have a design life of at least five years of continuous operation.

Audible signals

12.17 All audible signal tones should be modulated equally at a rate of 4 Hz ±10% between two tones of 440 Hz ±10% and 880 Hz ±10%.

Automatic resetting

12.18 When a warning or alarm signal occurs and the system condition subsequently reverts to normal, the corresponding visual and audible signals should automatically reset to normal.

Temporary muting

12.19 Means must be provided on each panel for the user to mute the audible signal. The signal must re-sound after a nominal 15-minute period if the fault condition still exists. The process of muting and reinstatement of the signal should be repeated until the fault condition has been rectified. Operation of the mute on the central panel should be accompanied by change from flashing to steady illumination of the corresponding visual indicator irrespective of the number of alarm conditions displayed on the central and any repeater panels. Operation of the mute on area alarm or repeater panels should not be accompanied by a change from flashing to steady illumination.

Continuous muting

12.20 An internally-mounted switch should be provided to allow continuous muting during periods of maintenance. When the system condition returns to normal, the continuous muting should automatically reset to normal operation. When the continuous muting is in operation on any alarm condition, it should not prevent the operation of the audible signal on other alarm conditions when a fault condition arises.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Electrical wiring

12.21 All electrical wiring should be in accordance with IEE Regulations.

System integrity

12.22 If extra low voltage (ELV), maximum 50 V, is superimposed on the signal or communication circuit (for example by cross-connection), the system design should ensure that any damage to the system is limited to replaceable panel components and that such damage is indicated as a system fault.

12.23 The performance of the system should not be compromised by the use of multi-core cabling that carries ELV and communication signals in adjacent cores.

12.24 The system should be designed to reject spurious radio frequency (RF) or mains noise typically arising in hospitals, examples being diathermy equipment and current spikes caused by plant start-up etc.

Relay conditions

12.25 If relays are used to transmit alarm signals, the relays should be energised in their normally closed condition.

Mains power supply

12.26 The mains electricity supply should be derived from the essential power supply (that is, it must be on the emergency system).

Safety extra low voltage/functional extra low voltage power supply

12.27 The panel power may be designed either as a safety extra low voltage (SELV) system or as a functional extra low voltage (FELV) system, as defined in Part 4 of the IEE Wiring Regulations.

12.28 The ELV power supply may be housed either in the alarm panels or in a separate metal enclosure.

12.29 The power supply should be rated for the full load of the panel, with visual and auditory signals on all normal and alarm conditions.

Test facility

12.30 Each panel should be provided with a means to test all visual and audible signals on that panel. The power supply should be capable of sustaining all indicators and audible signals.

Warning and alarm system faults

General

12.31 A flashing red visual indicator and an audible signal should operate on all panels when any of the following conditions occur:

© Health Facilities Scotland, a division of NHS National Services Scotland.

- line fault from the initiating device;
- communication fault or other wiring fault;
- mains power failure.

Line fault

12.32 The system should monitor the integrity of the lines between the initiating devices and the panel or transmitter units. The “alarm system fault” condition should be indicated on loss of integrity, for example open or short circuits, together with the visual alarm indicator(s) associated with the faulty wiring.

Communication/wiring fault

12.33 The system should indicate an alarm system fault in the event of loss of data transmission between panels and transmitters.

Mains power failure

12.34 Failure of mains power should be shown by a flashing red indicator and an audible signal, which should be powered from an internal battery. The audible signal may be muted and not automatically reinstate as required under normal power supply (see paragraph 12.19), but the visual indicator should continue to flash until either the fault has been rectified or the battery has discharged.

Stand-by battery

12.35 A battery should be provided with sufficient capacity to power the visual and audible “alarm system fault” signal for a minimum period of four hours. The battery should be sealed and exchangeable, and should automatically recharge within 72 hours.

Legend

12.36 The legend on this indicator should be “alarm system fault”.

Indicator panel requirements for all systems

Indicators

12.37 Panels should be provided with all indicators for the gas services in local use.

12.38 The visual indicators should be arranged vertically in priority order, with the normal indicators at the top. The sequence of gas services should be, from left to right:

- medical oxygen (cryogenic and cylinders/ pressure swing adsorber (PSA) systems);
- nitrous oxide;
- nitrous oxide/oxygen mixture;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- medical air 400 kPa (compressor plant, cylinders and synthetic air);
- surgical air 700 kPa;
- medical vacuum plant;
- helium/oxygen mixture.

12.39 In addition to the gas service signal indicators, each panel must include:

- a green “power on” indicator without an audible signal;
- a red “alarm system fault” indicator with an audible signal.

Labelling

12.40 Panels should be labelled as follows:

- medical gas alarm;
- with the identification of the medical gas services indicated, and the areas and departments served.

Construction

12.41 The fascia panel should be removable to allow access to the rear of the fascia or to the panel for maintenance purposes.

12.42 Access to the interior of the panel should be tamper-proof.

12.43 It should be possible to replace the source of illumination without removing the legend.

12.44 Panels should have electrical sections with protection at least equal to IP4X as defined by BS EN 60529:1992.

12.45 Panels and their housings should be of adequate strength for their purposes and be manufactured from corrosion-resistant materials.

12.46 If gas services are brought into the panel, they should be housed in separate, enclosed compartments, which are vented to the outside.

12.47 There should be gas-tight seals where electrical services pass through any gas compartment.

Remote audible sounder

12.48 All panels should have provision for connection to a remote audible sounder.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Central indicator panel requirements

Displays

12.49 The central panel should display all signals for all MGPS which are generated by the warning and alarm system, as described in paragraphs 12.50–12.53, below.

Normal

12.50 The normal condition for all piped MGPS should be displayed as a steady green visual signal. The “normal” indicator should extinguish in warning and alarm conditions.

Warnings

12.51 Warning conditions appropriate to each MGPS should be displayed as a flashing yellow visual signal that may be accompanied by a mutable audible signal (see Table 37).

Emergency alarms

12.52 Emergency alarms are generated by loss of pipeline pressure or vacuum and are indicated by flashing red visual signals accompanied by mutable audible signals.

Alarm system fault

12.53 The “alarm system fault” condition should be displayed as a flashing red visual signal accompanied by a mutable audible signal.

Mute functions

12.54 The temporary mute should cancel the audible signal for about 15 minutes and change the visual indicators from flashing to continuous on all central and repeater panels.

12.55 Operation of the continuous mute should inhibit the 15-minute reinstatement of the audible alarm.

12.56 Operation of the mute should not inhibit the visual or audible indication of any subsequent alarm conditions.

Panel legend and display

12.57 Panel legend and display should be as shown in Table 37.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Repeater indicator panel requirements

Displays

12.58 The repeater indicator panel should always display “normal”, “emergency alarm” and “alarm system fault” conditions as given above. The repeater panel should display some or all of the warning conditions that are displayed on the central indicator panel. The extent of the display of warnings should be varied to suit local clinical requirements.

Mute functions

12.59 The temporary mute should cancel the audible signal for about 15 minutes whilst the visual indicator continues to flash. Operation of the temporary mute (on the central panel) should change the visual indicator to continuous illumination on the central and any repeater panels.

12.60 Operation of the continuous mute must inhibit the 15 minute reinstatement of the audible alarm.

12.61 Operation of the mute should not inhibit the visual or audible indication of any subsequent alarm conditions.

Panel legend and display

12.62 The panel legend and display should be as shown in Table 37.

Area alarm panel

Panel displays and legend

12.63 Area alarm panels should display the conditions listed in Table 38.

Mute functions

12.64 The temporary mute should cancel the audible signal for about 15 minutes whilst the visual indicator continues to flash.

12.65 Operation of the mute should not inhibit the visual or audible indication of any subsequent alarm conditions.

Integrated systems

12.66 The introduction of computer-based systems for a range of functions such as patient information, nurse call and other alarm conditions provides an opportunity to further include certain provisions of medical gas pipeline warning and alarm conditions. This concept is totally new and, at this stage, the applications have not been thoroughly evaluated or analysed. One of the advantages of the concept is that text prompts can be displayed on the computer display when changes in the status of the pipeline occur, and these prompts can advise staff of the need to take specific action.

© Health Facilities Scotland, a division of NHS National Services Scotland.

12.67 The advantage of a computer-based system is that the advice given in the text message can be varied to take account of specific circumstances, changes in operating procedures and functional changes within individual departments. Such systems are likely to be of most use in in-patient ward accommodation; it may not be appropriate for central warning and alarm conditions or in individual operating rooms and other accommodation in which anaesthetic procedures are taking place.

12.68 It will be necessary to change the perception of users in that with this approach the “normal” conditions of the pipeline systems that are continuously displayed on alarm indicator panels will not exist – audible emissions and displayed messages generated by the computer-based system will be in response to changes from the “normal” situation. To ensure the long-term viability of the system, any supplier or installer of such a system must supply sufficient information about the system to allow modification, expansion or replacement of sections of the system by a third party. This must include source code for any software, passwords and details of any other security device, and details of any communication protocols. This information must be handed to the end-user before the system is accepted by the end-user.

Note 25: No further information can be given at this stage until further development and consultation takes place.

13. Pipeline installation

General

13.1 Generally, MGPS should be kept away from areas where they may be subject to any of the following:

- mechanical damage;
- chemical damage;
- excessive heat;
- splashing, dripping or permanent contact with oil, grease or bituminous compounds, electrical sparks etc.

13.2 Service ducts, ceiling spaces or voids containing pipelines that include valves etc. should have adequate ventilation to prevent gas build-up in the event of any leakage. Where piped medical gas services are installed of all welded, brazed or joint-free construction, it is generally not necessary to provide ventilation in service ducts, ceiling spaces or voids provided the piped systems are subjected to the rigorous testing imposed by this SHTM. Service ducts, ceiling spaces or voids containing mechanically connected valves or pressure switches will require ventilation in line with the requirements of BS8313:1997.

13.3 Exposed pipelines should not be installed in lift shafts, kitchens, laundries, boilerhouses, generator rooms, incinerator rooms, storage rooms designed to house combustible materials, or in any other fire-risk areas. Additionally, medical gas pipelines should not be installed in fire escape compartments (e.g. stair wells, fire exit lobbies). Where pipelines in hazardous areas are unavoidable, they should be enclosed in non-combustible, non-corrosive materials that have no electrolytic reaction with copper in order to prevent the possibility of the liberation of gases into the room in the event of pipeline failure. Medical gas pipelines should not be run in the same duct as flammable substances, oils, cryogenic or hot services such as steam, condensate, high or medium temperature hot water. Allowance may be made for steam and hot water services where they can be regularly inspected and are routed clear of the medical gas pipelines. Corrosion of copper pipe through chloride deposits from steam pipe leakage could result in the loss of the supply.

13.4 External pipe runs should be avoided when possible. Where external runs are necessary, they should be protected as follows:

- **on external vertical surfaces up to the maximum height of exposure to possible damage (for example vehicular movement):** by means of galvanised, profile-section steel of sufficient thickness to afford adequate protection. The protection should cover the entire space taken up by the pipeline(s), but stand off the surface such that the pipes can be inspected visually. The armour should be readily detachable to permit more detailed inspection;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- **when crossing horizontal surfaces, roofs etc:** similar protection as detailed previously should be provided to withstand “stepping” damage using profiled section.

13.5 Pipework should be protected from lightning strikes by ensuring that they are run within a 60º cone beneath the lightning conductor, for example when run along parapet walls, or when penetrating parapet walls. When run across roof surfaces, a copper lightning conductor should be run on the top surface of the pipework cover providing physical protection, and should be bonded to it.

13.6 Internal pipelines should be suitably protected where there is a possibility of physical damage, for example from the passage of trolleys, tugs etc.

13.7 Wherever practicable, a clearance of at least 25mm should be maintained between each service and 150mm should be the separation distance between the medical gas pipeline and the outer surface of insulation of heating pipes, hot water service and steam pipelines to prevent heat transfer. Where pipelines cross over services and a clearance of 25mm cannot be maintained, they should be electrically bonded and wrap-insulated, in accordance with IEE Regulations. They should be bonded to the main earth at building entry and exit. Care is required when selecting pipeline routes to prevent the pipes coming into contact with electric cables and wiring, and to minimise the risk of electric shock in the event of a fault on adjacent cables (see Section 2).

13.8 Underground pipelines should be run in properly drained ducts not less than 450mm x 450mm which have removable covers to facilitate installation and subsequent inspection. Where it is not possible to provide removable covers, two pipes should be run in separate ducts / trenches with valves provided in a convenient location at either end. The valves should comprise LVAs with NIST connectors for the purposes of pressure and other tests. The separation distance between the two trenches should be not less than 2m where practicable (see Figure 33). The two pipes should each be sized for the design flow. One or more different gas pipelines can be run in each duct / trench. The route of the pipeline should be identified on the surface and should be clearly shown on site layout drawings. The possibility of installing a “ring-main” (see Figure 34) or double-end supply should also be considered for both air and oxygen within the curtilage of the building.

A48235836

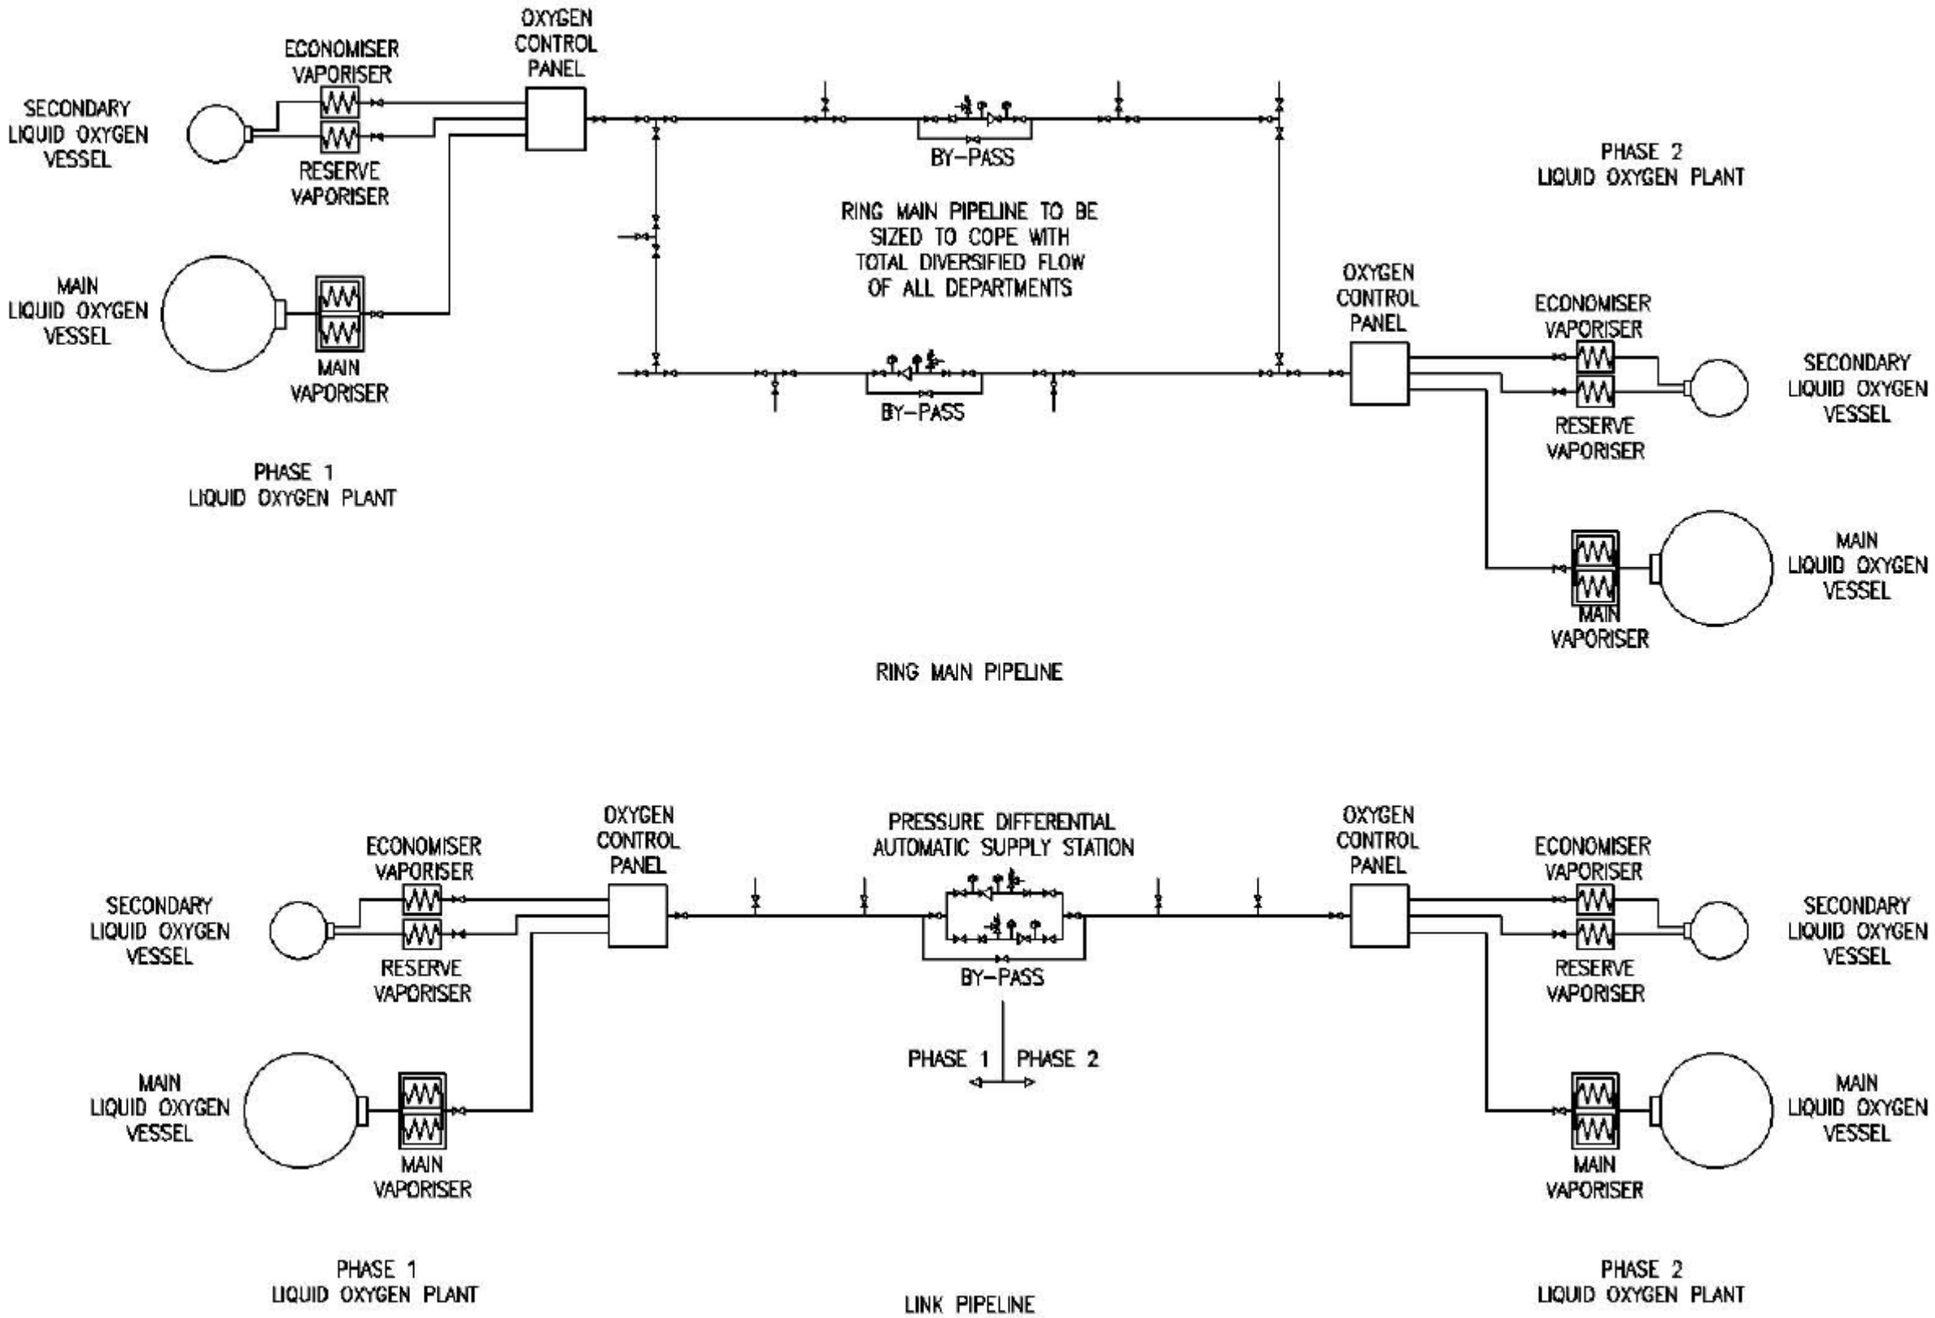

Figure 34: Typical ring main and link pipeline arrangement

© Health Facilities Scotland, a division of NHS National Services Scotland.

A48235836

13.9 Pipelines concealed within walls should have their route clearly shown on “as-fitted” drawings. Pipelines should not be encapsulated in floors, and any joints should be kept to the minimum practicable. Pipelines in stud or plasterboard walls or partitions are acceptable, but the pipeline should be protected from corrosion. If the enclosure of pipelines within plaster wall finishes is unavoidable, they should be wrapped in protective grease-free tape.

13.10 Pipelines need further protection in certain circumstances as follows:

- where pipes pass through walls, partitions or floors, they should be provided with sleeves of copper pipe (with fire stopping), which should extend at least 50mm from the surface of the wall, partition or floor. Since it is normal for other trades to seal the pipe sleeves at the penetration the medical gas contractor should ensure that the pipe sleeves are secured temporarily in place during the construction phase, e.g. by adhesive tape;
- where penetrations are exposed to general view, be provided with appropriate wall or ceiling plates;
- in radio-diagnostic procedure rooms etc., radio frequency (RF) screening wave guides may be required (the advice of the equipment manufacturer should be sought);
- corrosion of pipes can occur where they are in contact with timber that has been treated with fire-resistant or flame-retardant compounds, for example some timber used for roof trusses and floor joists.

13.11 This contact should be avoided by the use of impermeable non-metallic materials in the area where contact may occur. PVC spacers or adhesive PVC tape may be used for this purpose. If spacers are used they should not be liable to drop out due to shrinkage or subsequent movement of the pipe or timber.

13.12 Such precautions are not required where untreated timber is used or where the treated timber is effectively sealed with paint or varnish before the pipes are fixed to it.

Pipeline materials

Quality

13.13 The manufacturer should comply with BS EN ISO 9001: 2008 for pipes and for all materials including fittings, terminal units etc.

13.14 Where materials are obtained from suppliers from other countries, the suppliers should be registered in accordance with BS EN ISO 9001:2008.

Pipes

13.15 Material for pipes should be manufactured from phosphorus deoxidised, non-arsenical copper to BS EN 1412:1996 grade CW024A (Cu-DHP) in metric outside diameters and to:

- BS EN 13348: 2008 – R250 (half hard) for sizes up to 54mm; or

© Health Facilities Scotland, a division of NHS National Services Scotland.

- BS EN 13348: 2008 – R220 (annealed) for larger sizes.

Pipe jointing fittings

13.16 In addition to the above, pipe jointing fittings should be end-feed capillary fittings to BS EN 1254-1:1998.

Other fittings

13.17 Other fittings (oxygen compatible) for connection to copper pipes (for example valve and control panel fittings) may be of copper, brass, gun-metal, bronze or stainless steel.

Cleaning

Pipes

13.18 All pipes must be cleaned and degreased for oxygen service and be free of particulate matter and toxic residues in accordance with BS EN 13348: 2008. They must be individually capped at both ends and delivered to site identified as medical gas pipes.

Pipe jointing fittings

13.19 All pipe jointing fittings and sub-assemblies of fittings for connection to pipes must be cleaned and degreased for oxygen service and be free of particulate matter and toxic residues. They must be individually sealed in bags or boxes and delivered to site identified as medical gas fittings.

13.20 Although it is not essential to use degreased pipelines and components for vacuum and AGSS installations, these are frequently installed by the contractor simultaneously with the medical gas pipelines. Degreased pipe and fittings should therefore be used for the vacuum and AGSS installations to avoid confusion. PVC pipework may also be used for vacuum and AGSS but is unlikely to be of benefit other than for exhaust discharges.

Note 27: Pipes should only be cut with wheel pipe cutters, not hacksaws, to prevent the ingress of copper particles.

Pipeline jointing

General

13.21 Except for mechanical joints, only copper-to-copper joints will be permitted on site, made with brazing filler rods that can be used without flux.

Note 28: Brazing is performed at a higher temperature than in the case of silver soldering with capillary fittings; the exterior of the pipe will therefore have considerably darker oxide deposits.

© Health Facilities Scotland, a division of NHS National Services Scotland.

13.22 Copper joints to brass or gun-metal fittings will require the use of flux, with subsequent cleaning to remove the flux residues and oxide deposits.

13.23 Heating of the joint for brazing should be carried out with oxygen/acetylene, liquid petroleum gas/oxygen torches. Additional heating may be required for larger pipe sizes / fittings, for example, by means of a second torch.

Note 29: Oxygen / acetylene has an excellent safety record when used on site by the specialist MGPS contractor. This fuel-gas provides a narrow controlled flame with the higher flame temperature providing rapid heat transfer to the pipe and is generally the most suitable method for brazing pipelines in close proximity to other services and building fabric. In view of the unstable nature of the fuel-gas, brazing equipment must be in excellent condition with all component parts checked daily and subject to the correct lighting procedure prior to going on site. The control of cylinders on site should be governed by specific site procedures. The cylinders should be removed from site at the end of the working day. Oxygen / propane has a lower flame temperature and a wider spread of flame making it unsuitable for work in enclosed spaces or close to other unprotected services or building fabric. Small hand-held gas canisters, although limited in terms of their contents, can be useful for 15 / 22mm diameter pipe on a small project or break-in.

13.24 The techniques recommended cover all copper-to-copper joints and all copper-to-brass/gun-metal/ bronze joints in an MGPS, and are explained in more detail below.

13.25 The brazing technique should be used on all medical gas pipeline services.

Pipe preparation

13.26 Pipe ends should be cut square with the pipe axis, using sharp wheel cutters whenever possible, and be cleaned to get rid of any cuttings or burrs. Where a pipe shows a deformation or the pipe ‘cut’ shows a significant ragged burr, that pipe section and the pipe wheel cutters should be replaced. On no account should de-burring be attempted unless the burr is at the lower end of the pipe when in a vertical position, the likelihood by doing so when horizontal could leave deposits within the pipeline. All installation teams should carry spare wheel cutters.

13.27 Evidence of such burrs during examination of selected cut-out connections would be classed similarly to oxidation of pipelines and would result in additional joint removal for inspection until satisfied that a quality standard was being achieved. The use of a hacksaw for copper pipe should mean instant degrading of any certificate of competency of the individual and removal from site.

13.28 When brazing copper-to-copper joints:

- the brazed joints should be made using a silver-copper-phosphorus brazing alloy CP104 to BS EN ISO 17672: 2010. No flux should be used;
- ensure adequate protection of adjacent pipe runs and other services.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note30: Brazing copper to brass/gun-metal/bronze is not performed on site. Manufacturers use copper-silver-zinc brazing alloy AG203 to BS EN ISO: 17672: 2010 with an appropriate flux. The flux residues created by the process are chemically removed and, if necessary, the complete assembly is cleaned and degreased for oxygen service. Where brass/gun-metal/bronze fittings are required to be installed they should be supplied complete with copper "tails" of adequate length to ensure that the brazing process does not damage the components.

Use of N_2 internal inert gas shield

13.29 Brazing should be carried out using oxygen-free nitrogen (OFN) as an internal inert gas shield to prevent the formation of oxides on the inside of the pipes and fittings. This method leaves a bright, clean bore. Some slight burnishing may occasionally be observed on sectioned joints. Purging is still required to remove the internal shield gas and the other particulate matter not associated with the brazing operation.

13.30 Oxygen-free nitrogen (OFN) should be supplied to the inside of the pre-assembled, unbrazed pipework through a pressure regulator and flow controller or flow-regulating device.

Application

13.31 OFN should be used as an internal inert gas shield for all positive pressure gases, vacuum and AGSS pipelines.

Note 31: During the first-fix (carcass) stage of pipeline installation, particularly when installing in confined locations such as medical supply units or running pipework within partitions, etc. to individual terminal unit drops, it is possible to inadvertently crossover a pipeline. This is usually discovered at an early stage and, so that the pipe section can be re-assigned and the fault can be corrected, it is essential to use the shield gas to maintain the cleanliness of the internal bore.

13.32 By agreement between the health facility management and the medical gas contractor, the use of a purge gas may be waived on joints such as break-ins to old pipeline systems, where pipe joints will not have been made in accordance with this technique.

13.33 It is recommended that the pipeline to be brazed should first be subject to a high flow of oxygen free nitrogen (OFN) to remove air, followed by a period of 'pickling' at a low flow prior to brazing whilst maintaining the flow.

13.34 Cleanliness of the pre-brazed joint is important. Prepared joints will pick up surface tarnish or moderate oxidation if left and can influence the quality of braze particularly when the permitted depth of braze is 3mm. Failure to braze within the day can be accepted, however any delay should not extend beyond the third day. The nitrogen purge must be maintained during the cool-down of the joint. Adjacent pipes should preferably be subjected to an OFN purge for the duration of the work and cooling period. If it is not possible to introduce OFN

© Health Facilities Scotland, a division of NHS National Services Scotland.

into an adjacent pipe, e.g. pipeline with a live working gas, a heat resistant blanket(s) wrapped round the adjacent pipe(s) should be made available in proximity to the pipeline being brazed.

13.35 Pipe ends may be capped if desired to direct the flow of nitrogen into sections of the pipe or pipes to be brazed. Particular attention should be given to the gas shielding of T-joint fittings. It is essential that there is a leak-free connection between the pipework to be brazed and the OFN supply.

13.36 On completion, all pipes should be maintained under pressure following tests. The pressure to be maintained to ensure internal cleanliness should be agreed on site, however, 1 bar (max) (100 kPa) has been recognised as an accepted pressure.

13.37 Internal oxidation of pipes could mean replacement of pipe thus careful preparation is normally repaid. Purging on completion will remove dust particles or possibly the odd copper particle. It is not intended to remove oxides developed during the brazing stage.

Safety

13.38 If working for prolonged periods in very confined spaces, precautions must be taken to avoid excessive build-up of nitrogen by ventilating the space or by piping the shield gas safely out of the space. The oxygen content of the ambient air should be monitored when brazing in a confined space.

Control of cylinders

13.39 The contractor and the site engineer must keep a record of nitrogen cylinders held on a site. Nitrogen cylinders should be accounted for and removed from the site at the end of the contract, and must not become mixed up with medical gas cylinders.

Inspection of joints

13.40 Inspection of joints should be carried as a “rolling” procedure on a monthly basis as work progresses for each team performing the installation in accordance with the following procedure:

- the Contract Supervising Officer (CSO) or Authorised Person (AP), whoever is responsible for the inspections and validation, should identify a number of fittings to be cut out for examination in order to establish the quality of the finished joint. The exact number to be cut out will vary with the size of the installation: as a guide, a ratio of one fitting per 200 should be cut out; a minimum of ten for all systems should be cut out for examination (it is preferable to perform these checks before pressure-testing sections of pipeline). The actual removal of the joints should be witnessed by the CSO or AP (MGPS). It is generally not necessary to request cut-outs from vacuum and AGSS pipelines;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- the fittings cut out should be cut open (quartered longitudinally) and examined. If unacceptable joints are found, adjacent fittings should be cut out until the extent of any faulty workmanship has been established. This may require extensive removal of sections of the installation;
- In order to maintain a record of the inspected joints, consideration should be given to photographing the joint, recording the pipeline section the joint was removed from, the Competent Person (MGPS) who made and cut out the inspection joint and finally comments by the CSO or AP on their findings, e.g Passed or Failed and reasons for failure. This method of recording is more viable now with the availability of digital photography and electronic file storage systems, particularly on larger projects. The above will also act as a means to assess the competence of the individual Competent Person (MGPS) and act as a tool for the CPs employer to validate the CPs competency under the company's quality management system.

Internal cleanliness

13.41 The tube and fitting should be internally clean and free from oxides and particulate matter. Some heat burnishing may be apparent and is acceptable.

Penetration

13.42 Penetration of brazing alloy:

- due to tolerances of the capillary space on these pipes and fittings, full penetration of the brazing alloy may not occur and is not necessary;
- the minimum penetration at any point on the joint must be three times the wall thickness of the tube or 3mm, whichever is greater;
- the pipe should be fully inserted up to the shoulder of the fitting.

Note 32: These tests can be carried out on a sectional basis.

Jointing methods (mechanical)

13.43 It is not envisaged that mechanical joints, with the exception of NIST connections, will be required for new works. In exceptional situations, such as when brazing could impose an unacceptable risk or in situations when patients cannot be transferred to alternative accommodation, should mechanical connections be used. They may also be used for connecting pre-piped bedhead trunking and wall units to the pipeline distribution system. In which case they should be of the permanent swaged type, not contain elastomeric materials, and if located within ceiling voids, that void should be subject to adequate ventilation to prevent any gas accumulation in the event of any leakage.

13.44 Mechanical joints in keeping with paragraph 13.43 should only be viewed as a non-permanent emergency connection, with each connection number tagged and marked up on the record drawings with all remaining work fitted with brazed copper end caps. The installation should be made good as soon as possible in

© Health Facilities Scotland, a division of NHS National Services Scotland.

accordance with paragraphs 13.29 – 13.35.Mechanical joints will in all instances be subject to, prior to fitting, approval by the Authorised Person and be located readily accessible for periodic inspection.

13.45 PTFE tape is not an acceptable sealing material on oxygen systems or elsewhere downstream of final filters on supply plants.

Note 33: PTFE tape, if applied, can enter the gas system and fragments can block terminal units and present a fire hazard with high-pressure oxygen. Also, when applied by hand, traces of oil and grease can contaminate the inside of the pipeline.

13.46 Liquid or gel-sealing media should be used only if they have been tested and proven safe when subjected to the tests specified in BS EN ISO 15001: 2010.

Capping

13.47 Sections of pipeline should be capped and pressurised with medical air as soon as they are completed so as to prevent the ingress of debris.

Pipeline supports

13.48 The pipeline should be adequately supported at sufficient intervals in accordance with Table 39, below, to prevent sagging or distortion. Supports for surface-mounted pipework should provide clearance to permit painting of the surface. Where it is essential for pipes to cross electric cables or conduit, they should be supported at intervals on either side of the crossing to prevent them from touching the cables or conduit. Supports should be of suitable metallic, non-ferrous material or suitably treated to minimise corrosion and prevent electrolytic reaction between pipes and supports. Supports for vertical drops to terminal units within medical supply units can be of a suitable non-metallic material.

Pipeline outside diameter (mm)	Maximum interval between supports (m)
Up to 15	1.5
22-28	2.0
35-54	2.5
>54	3.0

Table 39: Intervals between copper pipe supports (horizontal and vertical)

Note 34: Consideration should be given to additional supports near LVAs, elbows, etc. where the potential effects of inadvertently applied torque can result in severe pipeline distortion or fracture.

13.49 In situations where medical gas pipelines are required to span building movement joints, consideration should be given to the method by which pipelines are supported to prevent mechanical damage.

© Health Facilities Scotland, a division of NHS National Services Scotland.

13.50 Pipelines need not be laid with falls. In the case of vacuum, the sub-atmospheric pressure will result in the evaporation of any moisture entering the system.

13.51 The connection of individual, or a number of vacuum terminal units into branches, should be taken into the top of the pipeline to avoid flooding other vertical pipe drops should liquid carry-over occur. Within trunking systems and medical supply units etc, vacuum pipes should connect into the underside of terminal units.

13.52 Each vacuum main riser should be provided with a drain leg consisting of a single full bore flanged valve up to pipe diameters of 42mm - pipe diameters in excess of 42mm can reduce to accommodate a 42mm valve followed by a pipe extension of similar bore to valve off a minimum length 0.5m extension terminating in a capped screwed connection. The extension should have a clear sight glass throughout its length or alternatively be fully transparent. Robust flexible hosing, providing it is of sufficient clarity and capable of withstanding 150 kPa positive pressure and 100 kPa negative pressure is a further alternative and has the advantage of being easily replaced. A double valve arrangement increases cost and has no advantage. It is not recommended that such a drain leg be cleaned in situ. This should be bagged and taken to a safe environment for cleaning, disinfection, sterilization or disposal as appropriate in accordance with the Hospitals' infection control / clinical waste procedures.

13.53 Competent persons carrying out work on vacuum or AGSS systems should be suitably clothed and protected in accordance with SHTM 02-01 Part B, Appendix D or as directed by the Infection Control Officer.

Identification of pipelines

13.54 Pipelines should be identified in accordance with BS EN 1710: 2005 + A1: 2008, and colour banding for the pipelines should be used. Colour band identification (see Figure 35) should be applied adjacent to valves and on either side of walls, obstructions such as ventilation ducted services when they obscure pipe run, junctions and change of direction. A label applied every 3m and bearing 6mm size letters should identify each gas. Self-adhesive plastic labels of approved manufacture may be used for this purpose. A band 150mm wide is usually adequate. All colour-coded tapes applied by the pipe manufacturers should be removed before the systems are identified, in accordance with this paragraph.

© Health Facilities Scotland, a division of NHS National Services Scotland.

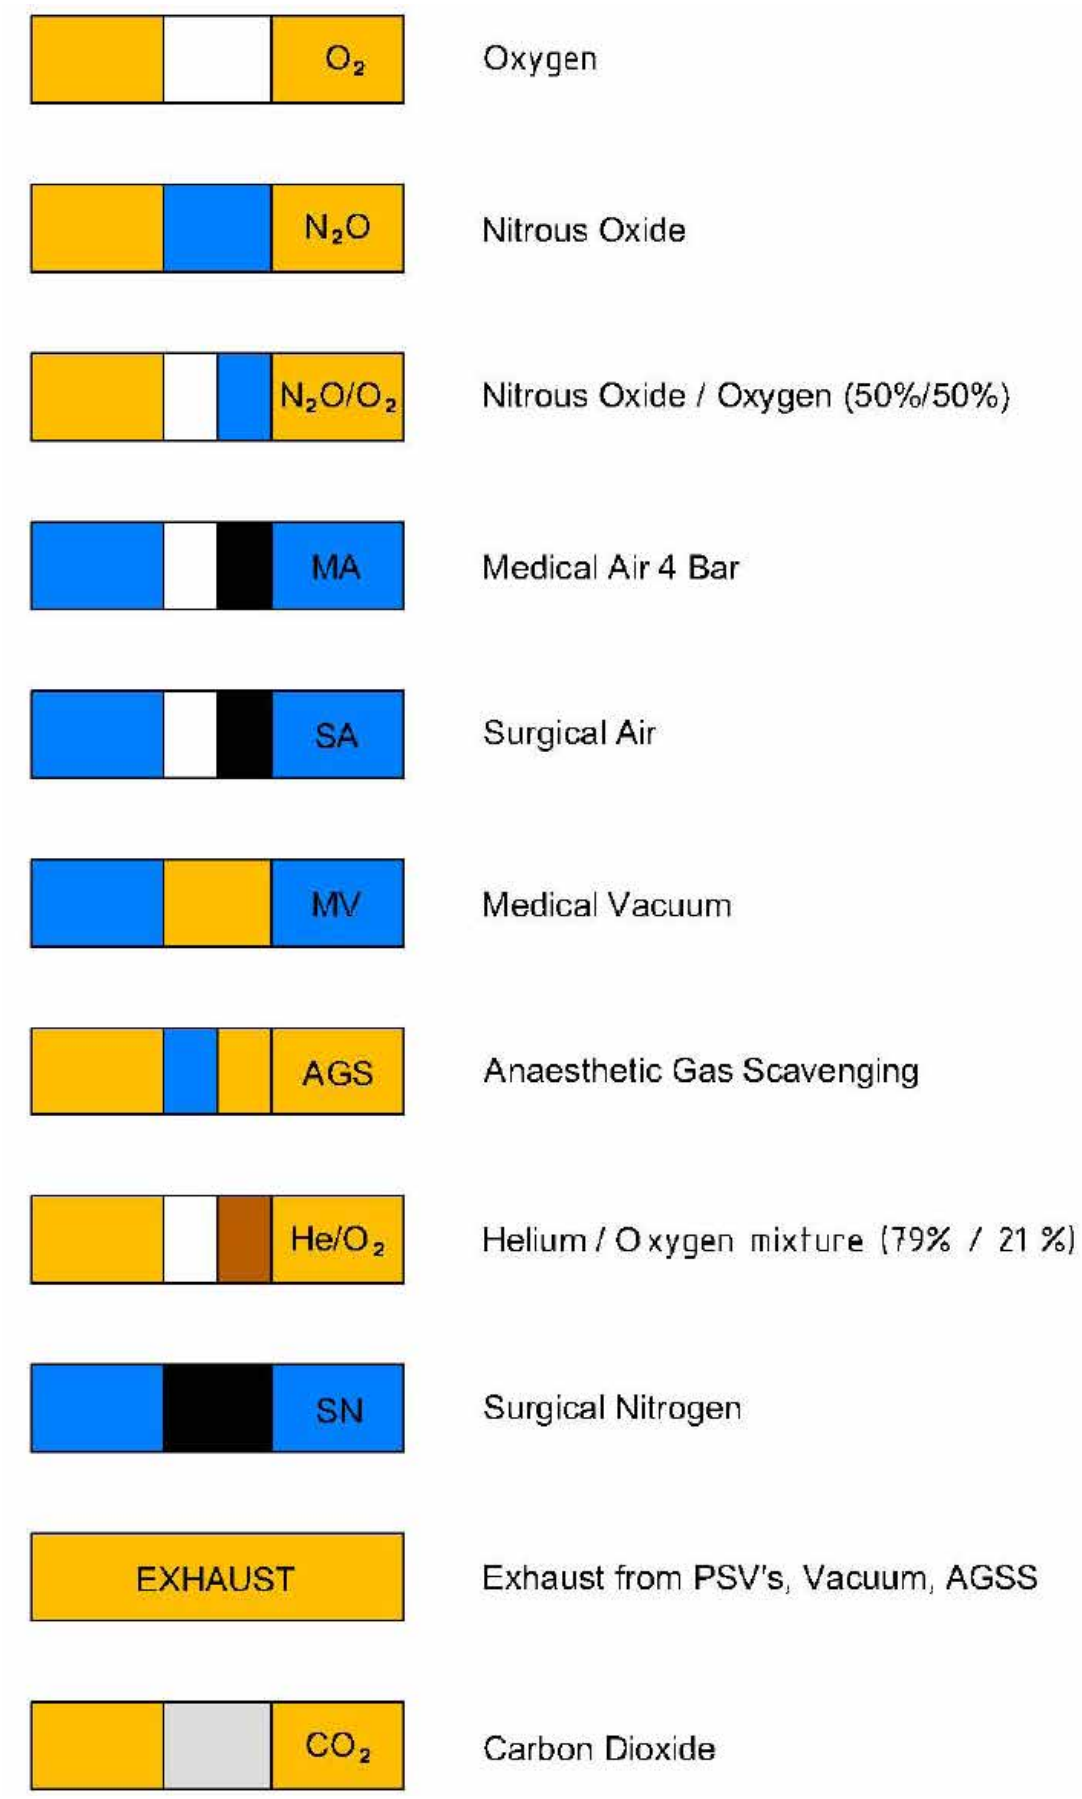

Figure 35: Pipeline identification colours

© Health Facilities Scotland, a division of NHS National Services Scotland.
A48235836

13.55 Care should be taken to maintain pipeline identification when periodical re-painting is undertaken. The direction of flow should be indicated. Where a pipeline is used as a link between two systems or is part of a ring main, direction flow arrows should indicate bi-directional flow. Alternatively, the pipeline can be labelled to indicate the purpose of the pipe, e.g. Ring Main or Link Pipeline.

Pipeline components

13.56 Pipeline components, which may be attached to an MGPS, include various types of terminal unit, AVSUs and other components such as emergency inlet ports and pressure control equipment.

Medical supply units

13.57 These should comply with BS EN ISO 11197: 2009. The construction should provide segregation of FELV electrical services by means of partitions or flexible conduit as appropriate. Access to “live” components should be via panels that are removable by means of tools only.

13.58 All rigid medical supply units should be piped in copper, which will avoid the higher pressure losses, leakage, probable volatile contaminants, regular inspections and replacement associated with flexible hoses. Exceptions will be motorised and multi-movement pendants which should be constructed in such a manner to ensure that the flexible hoses are not subjected to kinking or twisting.

13.59 The flexible hoses should be free from volatile or organic compounds and certificated to that effect by the pendant manufacturers or suppliers by QC tests conducted at manufacturers’ premises prior to pendant assembly.

13.60 Where the pendants incorporate flexible hose assemblies, the hoses should only be of sufficient length to provide connection to the fixed pipeline and terminal unit by means of the appropriate NIST connection in accordance with BS EN ISO 9170-1: 2008

13.61 Excess hose length is a contributory factor in surgical air system pressure drops across the pendant which may exceed this Scottish Health Technical Memorandum 02-01 and BS EN ISO 9170-1: 2008. Where Ultra-clean canopy systems are in place, consideration should be given for surgical air to be piped in copper within a custom built support utilising the canopy structure.

13.62 All equipment incorporating gases suspended from the ceiling structure or wall mounted should provide sufficient venting to allow the escape of gas to the room in the event of leakage/rupture of one or all of the medical gas services.

13.63 The recommended height for rigid pendants is 2,000mm above FFL. The maximum height for pendants capable of vertical movement should be 2,000 mm above FFL in the fully retracted position.

13.64 The use of medical air for pneumatically actuated pendants is covered in Section 3 Table 11, note 3.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 35: In cases where medical or surgical air terminal units are not required to be included in these pendants, an AVSU will still be required "locally" for emergency isolation and servicing of the air-braking mechanisms of some units.

The pendant manufacturer should advise the designer of the requirements for the particular pendant, i.e. the pressure required.

Flexible pendant fittings

13.65 These should comply with the requirements of BS EN ISO 9170-1: 2008 and BS EN 739: 1998. In particular, all loose assemblies should be provided with appropriate NIST connectors.

Bed-head trunking/walling systems

13.66 These fittings should generally be in accordance with BS EN ISO 11197: 2009. Separate compartments should be provided for electrical services, nurse call/radio, etc. and medical gas pipelines.

13.67 The medical gas compartment should be provided with ventilation by means of louvres, slots, etc. to prevent the accumulation of any gas in the event of leakage of the medical gas pipeline services. Unit construction should prevent the accumulation of gas in event of leakage from any of the medical gas system components. Ventilation by any other means, such as natural gaps in trunking sections, are not acceptable as such gaps are dependent on the quality of manufacture and/or fitting and can therefore not be relied upon to adequately vent off leaked gas.

13.68 In some departments, to engender a more domestic environment, medical gas and other bedhead services are installed within concealed recesses (or behind decorative panels, paintings etc). In such cases, adequate provision must be made for ventilation, and the required space to permit connection and disconnection of equipment should be considered. The covers should be clearly labelled to indicate that medical gas equipment is installed within/behind.

13.69 There are three possible installation procedures:

- the introduction of prefabricated units carrying services will require a technical specification, co-ordination of services and procedures. As a minimum to ensure the cleanliness and integrity of the medical gas pipeline systems is retained, brazed copper end-caps or temporary mechanical connections should be a requirement for all pipe terminations;
- providing the bedhead trunking or wall panel is accompanied by a test certificate, the joints can be subjected to a completed installation (2nd fix) pressure test;
- any temporary emergency connection should be removed at the earliest date when a permanent brazed connection should be made.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 36: After any such disconnection and reconnection, it will be necessary to carry out the full range of anti-confusion tests.

LVAs and AVSUs

13.70 All valves should be of the lever-ball type, having flanged O-ring seal connections which open and close with a 90º rotation: the handle should be in line with the pipeline when open.

LVAs

13.71 LVAs should be capable of being locked with the valve in the open or closed position. Means of physically isolating and blanking the pipeline both upstream and downstream of the valve should be provided. The means of isolation should be in the form of a spade that can be readily deployed. It should blank both the pipeline and the valve port and be visible when deployed. Each valve should be provided with a set of “through” and “blanking” spades; they should be coloured white and red respectively. The valve flange should include the thread, and the bolts should be of sufficient length to permit loosening to allow removal/replacement of the spades without loss of structural integrity of the connection. Union-type connections with O-rings are permissible, but the securing nut must also have sufficient thread length to permit venting while maintaining the structural integrity of the connection. A single key for each service is considered to provide sufficient security.

13.72 In the event of leakage of the through or blanking spade, gas must be capable of venting to atmosphere and must not be able to enter either the valve port or the pipeline section blanked.

13.73 The appropriate NIST connector bodies with self-sealing check valves and lockable blanking nuts should be provided upstream and downstream of the flanges. Gas identity and flow direction arrows should be provided for each valve.

Note 37: A single NIST connector will suffice in ring-main branch connections between the three closely spaced valves.

13.74 LVAs should be provided as follows:

- at the connection of the pipeline to any source of supply;
- at the emergency inlet port (that is, it forms the emergency inlet point);
- at the pipeline entry to a building;
- at the pipeline exit from a building;
- at the connection of branches to the main pipeline run;
- at the connection to risers;
- at branches from risers to serve a number of similar departments;
- upstream, downstream and in the branch connection to a ring-main.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 38: a) Good practice with respect to patient safety should ensure that the oxidising medical gases, each capable of vigorously supporting combustion, in each department, ward area and floor can be speedily shutdown in an emergency fire situation.

b) Where departments on a floor are functionally very different, for example wards and diagnostic areas, each area when branching off the main floor pipeline should have a fire valve (AVSU) installed together with AVSUs within the area as detailed in Section 3.

c) Where a risk assessment has evaluated that the installation of an AVSU located at the riser would give cause for concern from tampering by unauthorised persons, an LVA can be installed in the riser at an accessible height.

d) Individual pipelines radiating from the riser to functionally different departments is not seen as a benefit towards higher fire safety practices.

e) Restrictions are placed on permitting mechanical connections for oxidising gases in ceiling spaces or voids, with or without elastomeric o-rings or materials, in the event of a leak resulting in an accumulation of gas. Where this possibility exists, mechanical ventilation would be required.

f) Installation of line valves, LVAs, pressure switches, etc. in risers can be considered if there is adequate movement of air within riser compartments.

AVSUs

13.75 AVSUs are provided for user access in an emergency (or for maintenance purposes). They should be in accordance with the requirements above for LVAs except that security is achieved by installing them in an enclosure with a lockable door designed such that it can be closed with the valve either in the “open” or “closed” position.

Note 39: The views of the building operator should be sought as to the level of security that will be required and hence the range of keys. The medical gas operator, e.g. Estates Department or Facilities Management provider’s views should be sought in determining the number of MGPS keys required per building:

a) One key and duplicate per service;

b) One key and duplicate per valve;

In either case, a key cabinet and valve schedule should be provided. The schedule should provide information of gas service, key and valve numbers and department and/or terminal units controlled by the valve.

Crossover pipelines above AVSUs should be avoided wherever possible.

13.76 In an emergency, the user must be able to gain access in order to operate the isolating valves quickly and simply without the need for a key. There are several

© Health Facilities Scotland, a division of NHS National Services Scotland.

methods of providing such emergency access, for example break-glass panels and plastic push/pull-out inserts. Whichever method is used must be safe and secure and must clearly act as a deterrent to tampering without introducing undue risk of injury to the user. Float glass must not be used. The method of emergency access must be obvious and clearly labelled, and its use must be evident.

13.77 AVSUs may be designed for a single pipeline service for each gas type or combined within a multi-service module. Single AVSU covers should be gas specific, while multi-service AVSU module covers should only require a door for each valve, the covers need not be gas specific. However, access to each valve in a single AVSU or multi-service AVSU module should be by a unique lock and key. In the instance where a hose is to be connected to a NIST, for example to back feed a gas service during a system closure or for emergency supply to a department/room, the protocol for such a requirement would be for the connected cylinder to be permanently supervised by a suitably qualified person. In this case, the door would remain open during the temporary cylinder connection, thereby negating the need for hose access slots.

13.78 The enclosure should have adequate ventilation to prevent the accumulation of gas in the event of a leak. Pipe entries and other penetrations should be sealed to prevent gas escape by routes other than the vents or openings into the user space. The enclosure should be designed to facilitate sealing of these entries on site. Gas identity and flow direction arrows should be provided for each valve.

13.79 Provision and location of AVSUs is covered in Section 3.

Note 40: AVSUs should not be installed in positions where they can be obscured or damaged, for example within the “swing” of a department door or behind partitions.

Specific labelling requirements

13.80 All AVSUs should be labelled to identify the individual rooms, sets of terminal units etc controlled. The upstream and downstream NIST connectors should be clearly identified by a permanent label, securely fixed.

13.81 In critical care areas, where dual circuits and/or subdivisions of circuits occur, terminal units need to be correspondingly identified with the specific AVSUs (see Figures 4 and 5).

13.82 In the case of pneumatically-powered pendant fittings where, typically, medical air or preferably surgical air should be used for the power source that controls the pneumatically-powered devices, the appropriate controlling AVSU should be identified.

Pressure control equipment

13.83 Medical gases may be distributed at a higher pressure than the eventual nominal pipeline distribution pressure at terminal units. Where this is the case,

© Health Facilities Scotland, a division of NHS National Services Scotland.

the maximum pressure should not exceed 980 kPa, and the local pressure "control" equipment should be installed in an area that has good ventilation and be housed in a clear-fronted lockable cabinet, fully identified for service and area served. It should be in a position where it is readily accessible for maintenance/service.

13.84 The pressure control equipment should include duplex pressure-regulating valves, each with upstream and downstream isolating valves, safety valves, up and downstream pressure gauges and NIST connectors. The safety valve discharges should be run to the exterior of the building; medical air and surgical air may be discharged within a plant space, for example a plantroom above an operating department, provided it is terminated in a safe position.

Pressure sensors

13.85 Pressure sensors to provide the alarm function will need to be fitted to pipeline distribution systems. In all cases they should be installed in a location which is adequately ventilated and having access for maintenance. They may be incorporated downstream of AVSUs. Where not incorporated into an AVSU, the pressure sensor should be close to the AVSU so that it is accessible for maintenance. Pressure sensors should be factory-set and be a replacement item. They should be connected to the pipeline by means of a minimum leak connector. Suppliers, contractors and training course providers must be fully aware of the difference in settings between HTM 02-01 and this Code of Practice.

Pressure switches can be installed within:

- AVSUs valve boxes;
- AVSU modular wall panels;
- individual wall box;
- pressure switches need not be installed close to an alarm panel, but appropriately located pressure switches can aid setting alarm conditions visually.

Pressure gauges

13.86 Pressure gauges are not usually required outside the MGPS source plantroom unless they form part of a remote regulating set. If provided, however, they should similarly be installed in an adequately ventilated location. They may be incorporated within AVSUs, operating room supply fittings etc. They should be installed with isolation cocks.

Test points

13.87 Each supply plant, that is, liquid facility, manifold (main and ERM), compressor plant, PSA and blending plant, should be provided with a test point comprising lockable valve and terminal unit. This should be within the plantroom or

© Health Facilities Scotland, a division of NHS National Services Scotland.

enclosure, and be sited immediately upstream of the distribution pipeline isolating valve.

Emergency / maintenance inlet port

13.88 Medical oxygen and 400 kPa medical air systems should be provided with an emergency inlet port to the pipeline distribution system. This should be located downstream from the main source of supply line valve isolation point, in a remote location to permit connection of a temporary supply plant. The emergency inlet should comprise a 28mm dia. LVA, an additional non-return valve on the emergency inlet side and a connection that can be blanked, to which the emergency inlet can be made.

13.89 An emergency inlet port is not required for 700 kPa surgical air systems.

Line pressure alarms and safety valves

13.90 The purpose of the line pressure alarm is to warn users that the nominal line operating pressure is out of limits and that gas mixtures, whether supplied by a blender/mixer, an anaesthetic machine or patient ventilator, may deviate from the clinically desired proportion. Local action can then be taken to adjust the mixture, or when an anaesthetic machine is in use the reserve cylinders can be brought into use. The low-pressure alarm for nitrous oxide/oxygen mixture supply pipelines will warn of possible demand valve regulator failure so that a portable cylinder can be made available. The high/low pressure limits have been set to accommodate the design of most types of anaesthetic equipment where differential pressure or low pressure may affect performance.

13.91 The line pressure safety valve provides limited safety from differential pressure effects since the pressure at which maximum discharge occurs will result in a differential much greater than that for which the anaesthetic equipment has been designed. They are therefore strictly system protection devices. All safety valves should have a separate discharge pipe that is run to a safe position which – except for air – should be external.

13.92 The commissioning of medical gas pipeline line pressure regulators, warning and alarm systems, and pressure settings is crucial to the performance of anaesthetic equipment and patient safety; once commissioned, medical gas pipelines are subject to strict permit-to-work procedures. Decommissioning a complete system is highly disruptive to patient care and introduces considerable risk.

13.93 The Pressure Systems Safety Regulations 2000 require pressure safety devices to be tested periodically. It is not appropriate to test an MGPS by either raising the line pressure regulator setting or manually unseating the relief valve. Such action could result in failure of anaesthetic equipment and – if the safety valve fails to reseat – it could result in considerable gas loss and further hazard. Medical gas pipeline distribution systems should be provided with a pressure relief device downstream of the line pressure regulator connected by means of a three-way cock so that the safety device can be exchanged for a “certificated” replacement in accordance with the frequency required by the Regulations.

© Health Facilities Scotland, a division of NHS National Services Scotland.

14. Design and construction of plant and manifold rooms

Location of manifold rooms

14.1 Cylinder gas/liquid supply systems should not be located in the same room as medical air compressors, PSA systems or vacuum plants.

14.2 Manifold rooms, emergency/reserve manifold rooms for PSA systems, VIE installations and medical compressed air systems should be located to take account of the risk assessment, but should also take account of the location of the medical gas cylinder storage area.

14.3 All manifolds, including the emergency reserve manifolds, may be located within the same room. Manifold rooms should be located on an external wall(s) to facilitate ventilation, which will be required at high and low level. Internally sited manifold rooms for gases other than medical air and cylinder stores may require mechanical ventilation.

14.4 The emergency/reserve manifold for liquid oxygen systems has traditionally been located within the VIE compound, but it is preferable to site the manifold separately. For new installations, these emergency/reserve manifolds should be located separately.

14.5 In the case of surgical air the volume of gas used is relatively small even though the instantaneous flow rates are high. Therefore, it may be more convenient to include the manifold within the operating department.

14.6 Where a surgical air 700 kPa manifold room is provided it may be used as the ready-use store for a small number of spare cylinders to be used on anaesthetic machines.

Note 41: It is permissible to accommodate medical compressed air plant, vacuum plant and AGS disposal system pumps within general plant areas accommodating such equipment as air handling units, water service systems etc. They should not, however, be located with heating or hot water service equipment or equipment likely to produce any fumes or odour.

Access

14.7 Access to manifold rooms should be from the open air, not from corridors or other rooms.

14.8 Normal commercial lorry access is suitable for gas cylinder delivery vehicles, but consideration should be given to the provision of a raised level loading bay to reduce cylinder handling hazards.

14.9 Two doors should preferably be provided in a manifold room. One should be large enough to facilitate cylinder handling and must be in an outside wall. Exits

© Health Facilities Scotland, a division of NHS National Services Scotland.

must be free of all obstructions. Doors must open outwards. All doors must normally be locked to prevent unauthorised access, but should be provided with means of entry and exit in an emergency (for example by a push-bar arrangement on the inside).

14.10 Internal walls and ceilings, including any internal doors of the manifold room, should be of a suitable non-combustible two-hour fire-resistant material as defined in BS476-4:1970 and BS476 Parts 20–23 (1987). Internal doors should be avoided where practicable. Smoke detectors should be provided. The provision of automatic fire suppression / gas leak detection should be considered as part of a risk assessment which reflects local conditions.

Construction and layout of manifold rooms

14.11 The manifold room will contain the manifolds as well as cylinder racks holding sufficient spare cylinders to replace one bank of each manifold and the emergency/reserve manifold. (For nitrous oxide/oxygen manifolds, sufficient spare capacity for two banks of cylinders should be provided.) Further replacement cylinders should be supplied from the medical gas cylinder store. The size of the manifold room should therefore be determined by risk assessment. Adequate space should also be allowed for cylinder handling.

14.12 A typical automatic manifold with two duty and two stand-by cylinders is approx. 1,800mm long and 600mm deep. One extra cylinder on each bank adds approximately 500mm to the overall length, so that a 2 x 6 manifold is approximately 4,500mm long.

14.13 All medical gas manifolds may be installed in the same room. Additional floor area should be provided to accommodate separate storage racks for each gas. The racks should be designed along the lines of those on the manifolds, but the stored cylinders may be closer together. Racks should conform to ISO 32:1977. With the exception of small cylinders of N_2O/O_2 mixtures, under no circumstances should rooms contain gas cylinders other than those appropriate to their manifolds.

Heating and ventilation

14.14 Ventilation louvres should be provided at both high and low level for all manifold rooms, to allow circulation of air. A risk assessment should be carried out to assess the potential risk of staff being exposed to leaking gas within manifold rooms. BCGA Code of Practice 4 provides methods to calculate either oxygen depletion or enrichment and appropriate ventilation rates. Further consideration could require the inclusion of gas leak detection systems. However, these systems would only be required if the risk is high or the organisation responsible for accessing the manifold room deems it necessary.

14.15 Air intakes for compressor inlets should, if possible, be located externally. However, they should not be installed as an alternative to the provision of adequate ventilation for cooling purposes.

14.16 All ventilation louvres should be vermin/bird-proof.

© Health Facilities Scotland, a division of NHS National Services Scotland.

14.17 PSA and medical air compressors liberate, under maximum flow conditions, considerable heat. Moreover, these plants aspirate air for breathing purposes. Generous natural ventilation should be provided, and where this is not possible if the plantroom is deep-plan, mechanical ventilation should be provided. The ambient temperature of manifold rooms and plantrooms should be maintained within the range of 10–40°C. The ventilation rates should ensure that the plantroom temperature does not exceed ambient temperature by more than 10°C.

14.18 Manifold rooms may be used to store small numbers of nitrous oxide/oxygen cylinders intended for portable use; these are taken from the main cylinder store for the purpose of temperature equilibration, before being delivered to wards etc.

14.19 To achieve temperature equilibration, additional heating may be required; the natural ventilation must not be reduced. Where such heating is provided, it should be by indirect means, for example steam, hot water or warm air. Naked flames and exposed electric elements should not be used, and excessive surface temperature should be avoided. If necessary, cylinders should be protected from excessive heat. Any primary heat source should be located in a safe position, preferably remote from the manifold room.

14.20 Cylinder recognition charts, supplied by the medical gas supplier, should be prominently displayed as appropriate.

Lighting

14.21 Manifold rooms and medical gas plantrooms should be provided with lighting to an illumination level of 200 lux by means of lighting fittings to BS EN 60529: 1992.

Noise control

14.22 Plantrooms should be designed and constructed to ensure the satisfactory control of noise emission. The effect of two vacuum pumps or compressors running together, in the case of duplex installations, and three or more in the case of multiplex installations, will be to increase the free-field noise level outside the plantroom by 5 dB(A) for each additional pump or compressor operation over and above the specified limits. Consideration should be given to providing acoustic enclosures to reduce the free-field noise levels in noise-sensitive areas adjacent to plantrooms.

14.23 Acoustic enclosure and/or plantroom design must not inhibit normal cooling functions or maintenance activities.

14.24 Free-field noise levels should be given to the architect to assist in acoustic design of the plantrooms.

14.25 The discharge from some vacuum pumps may require silencing.

© Health Facilities Scotland, a division of NHS National Services Scotland.

14.26 Compressors and pumps should be mounted on properly-selected anti-vibration mounting, where necessary, to minimise transfer of noise and vibration to the structure of the building.

14.27 All pipework and electrical conduits connected to the plant should be fitted with flexible connectors where necessary to prevent the transmission of noise and vibration along the pipelines and conduits. Electrical bonding will be required.

Labelling/signage

14.28 Labelling for medical gas systems, equipment and accommodation should be in accordance with Appendix K.

© Health Facilities Scotland, a division of NHS National Services Scotland.

15. Validation and verification

General

15.1 This chapter covers the validation and verification and filling for use of MGPS. Validation and Verification is required to determine that the designer and MGPS contractor have fulfilled all the necessary conditions by confirming and verifying the initial design data and substantiating that the contractor has installed the medical gas pipeline systems in accordance with the specification and to an acceptable standard. For this purpose the designer will supply the specification, drawings, isometrics and pipeline design calculations at an early stage of the contract. This ensures any design discrepancy can be rectified, preferably prior to installation work commencing.

15.2 This chapter describes the tests required and the test methods. The contractor should provide instrumentation for the engineering tests. The Quality Controller (MGPS) normally provides instrumentation for the gas quality and identity tests. Calibration certificates should be available for all instrumentation. Tests are listed in Appendix A with the associated forms.

15.3 The objective of testing and commissioning is to ensure that all the necessary safety and performance requirements of the MGPS will be met. Testing and commissioning procedures will be required for new installations, additions to existing installations and modifications to existing installations. The scope of work will dictate the specific test programme required. This is described in more detail in paragraphs 15.12 – 15.14.

15.4 For modifications and extensions (except for the final connection), all work should be performed with an inert gas shield; thus, it is essential that a physical break is employed between the pipeline being modified/extended and the system in use. This will usually be by deploying “spades” in AVSUs and LVAs, or by cutting and capping the pipe. Prohibition labels should be affixed to all terminal units of the system affected in occupied areas.

15.5 For small extensions comprising fewer than 20 brazed joints per gas service, all the tests may be performed with the working gas – the carcass pressure tests being replaced by a system leakage test of the complete extension. An extension comprising more connections would, however, be deemed to be a small installation, requiring all the appropriate tests to be carried out, up to the final connection; the final connection would be tested at pipeline distribution pressure. For the purpose of ascertaining the number of joints, a straight coupling comprises two joints and a “T” comprises three joints. On a minor modification, from which existing terminal units would not be removed, the carcass pressure test can also be omitted. All other tests would be required, including a working pressure test.

15.6 The programme of tests is divided into the following phases:

- validation of design

© Health Facilities Scotland, a division of NHS National Services Scotland.

- tests and checks on the pipeline carcass;
- engineering testing, commissioning and purity of the medical and surgical air plant and the testing and commissioning of the vacuum plant;
- tests and commissioning of the complete pipeline system (with terminal units installed) for safety, performance and particulate contamination using test gas;
- filling of the systems with specific gases for the purposes of identity and quality tests of the specific gases prior to use for patient care;
- gas identity and quality tests.

Note 42: a) Systems that are not to be taken immediately into use should be filled with medical air and maintained at operating pressure. Systems other than medical, surgical or dental air supplied from compressors should be filled with medical air from cylinders.

b) Commissioning of liquid supply systems prior to handover should be avoided. (Under “no flow” conditions, liquid will evaporate and oxygen will blow off to atmosphere.)

15.7 The personnel and test equipment needed for these tests are listed together with the test requirements in Table 40. The particulate contamination test for all pipeline systems may be checked using medical air to establish that the pipeline has been constructed correctly and is not contaminated. Successful completion of the commissioning tests normally indicates the end of the installation contract. The systems may then be left under pressure, filled with medical air, for an indefinite period. Responsibility for the system during this period needs to be clearly defined in the contract; the Authorised Person (MGPS) under a conventional build hospital ultimately responsible for the day-to-day management of the MGPS after handover should be permitted access during contract work. This should be included in the contract agreement. For PFI/PPP projects, to ensure there cannot be a conflict of interest, the Contract Supervising Officer preferably from an independent organisation, can be appointed in accordance with Scottish Health Technical Memorandum 00, Scottish Health Technical Memorandum 02-01 Part B and be acceptable to all parties.

Note 43: In some circumstances an MGPS may not be taken into use immediately after construction and will be left filled with medical air. In these circumstances, the particulate contamination and odour/taste tests may be carried out before purging and filling with the working gas (see paragraphs 15.95 – 15.101).

Table 40: Personnel and test equipment requirements

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 44: Refer to Scottish Health Technical Memorandum 02-01 Part B for description of the duties and responsibilities of the various parties included in Table 40.

15.8 All supply systems and their major components should have certificates (as specified in Model Engineering Specification C11 – 'Medical gases') which show that they meet the design requirements of the pipeline system.

15.9 Only contractors who are registered to BS EN ISO 9001: 2008/BS EN ISO 13485: 2003 with their scope of registration defined to include commissioning should undertake engineering validation and verification. Contractors who may not be registered as such, but who can actively demonstrate that they are working towards registration may also be considered for this work.

Note 45: BS EN ISO 9001: 2008 registration is also recommended for independent medical gas testing agencies but is not necessary for appropriately trained and appointed hospital-based QCs (MGPS).

15.10 All relevant tests should be carried out by the persons listed in Table 40 and witnessed by the appropriate persons, who must record the results of the tests in writing for the hospital authority.

Summary of tests

Tests and checks on the pipeline carcass

15.11 The following tests must be carried out after installation of the pipeline carcass but before concealment:

- visual check of pipeline labelling, marking, sleeving and supports;
- leakage test;
- tests for cross-connection;
- valve tests for closure, zoning and leakage. (These tests will be repeated as part of the pipeline system tests and the contractor may wish to defer closure and leakage, but may choose to carry out a zoning check.)

Tests on the pipeline system

15.12 The following tests and checks must be carried out after complete installation of the pipeline system:

- tests for leakage on each MGPS;
- tests of AVSUs for closure, correct service and control of the terminal units in the zone: checks for correct labelling of AVSUs for zone reference and identity of terminal units controlled and flow direction indication;
- tests of LVAs for closure and identification;
- tests for cross-connection, flow, pressure drop, mechanical function and correct identity of the terminal units: checks for correct labelling and

© Health Facilities Scotland, a division of NHS National Services Scotland.

association with AVSUs (this is only required when, within a specific area, there are separate circuits for the same service, for example dual/ split circuits);

- tests for mechanical function and identity of NIST connectors;
- performance tests of the pipeline system;
- functional tests of all supply systems;
- checks of safety valve certification;
- tests of warning systems;
- tests for particulate contamination should be carried out by the contractor and the AP or CSO during the course of the engineering tests. Where it is shown that a high degree of oxide particles were present within the piped system (this would indicate a deficiency in the initial oxygen free nitrogen purging) the AP or CSO would decide whether to continue with the medical air purging or reject the system. At this stage the Quality Controller (MGPS) would not be required. If the AP or CSO is satisfied with the cleanliness and depending on the contract programme handover date, the QC (MGPS) could be invited to carry out particulate contamination, odour and taste tests using the working gases. An advantage in programming these tests at this stage is the use of the medical air which avoids the high usage of the working gases and risk factor to site staff. The CSO particulate test does not negate in any way the role and responsibility of the QC to repeat the test;
- tests for anaesthetic gas scavenging disposal systems.

Note 46: Nitrous oxide and nitrous oxide/oxygen mixture are not tested for odour.

Tests before use

15.13 The following tests must be carried out after purging and filling with the working gas:

- tests for particulate contamination (see para 15.94 and 15.131 to 15.137);
- tests for gas identity;
- tests for gas quality.

General requirements for testing

15.14 The tests described in this document are generally carried out, in the order given, for new installations. It may be necessary to amend the test programme for modifications or extensions to existing systems. Care must be taken, however, to ensure that the basic principles are followed. Para 15.33 to 15.46 give details of the tests required for modifications/extensions to existing systems.

© Health Facilities Scotland, a division of NHS National Services Scotland.

15.15 In all cases involving plant, the medical air and vacuum plant should be tested during or immediately following carcass tests. This test will include the QC certification of the medical / surgical air plant.

15.16 On major projects the availability of the following plant is essential to progress the commissioning programme:

- vacuum plant to allow vacuum leakage and flow tests to be carried out on the completed system.
- medical air plant certificated by CSO or AP and QC to enable its use during the testing of all gas systems. Cylinder supply will not typically provide sufficient capacity when testing large MGPS installations.

Note 47: When tests and/or purging are/is carried out on systems fed by sources serving an operational hospital, it is essential to ensure that the flows generated during any tests do not result in interruption of continuity or impairment of adequacy of supply within the operational areas.

15.17 Testing for leakage is normally carried out in two stages: the first to the pipeline carcass, the second to the completed distribution system, which will include terminal units and medical supply units as appropriate.

15.18 Purging and testing must be carried out with clean, oil-free, dry air or nitrogen, except for those tests where medical air or the specific working gas is prescribed. All test gases must meet the particulate contamination requirements set out in paragraphs 15.131 – 15.137. The shield gas may be used for the tests on the pipeline carcass described in paragraphs 15.50 – 15.57. Cylinders of medical air will normally be used as the source of test gas for oxygen, nitrous oxide, nitrous oxide/oxygen mixture and helium/oxygen systems in order to prevent the possibility of contamination with oil.

15.19 However, in the case of a large oxygen system, for example a new-build, the use of cylinders will be impracticable for the total system performance test. As it may be undesirable to commission the liquid supply system, the total system performance test can be carried out by using the medical compressed air plant, provided that the quality tests have been satisfactorily carried out to demonstrate that the criteria set out in Table 43 have been met and that the air supply plant is continuously monitored for moisture during the test.

15.20 The medical compressed air plant can also be used for the single point performance tests etc and for initial purging and particulate testing of these systems. Once tests have been completed, the system should be maintained under pressure by means of air supplied from medical gas cylinders until filled with the working gas, when full QC checks will be carried out.

Note 48: The use of portable, non-medical air compressors is not appropriate. Not only should a Quality Controller (MGPS) check all compressors before use, but also QC checks during use are important. Preferably, an on-line dew-point meter should be fitted to the plant or pipeline system.

© Health Facilities Scotland, a division of NHS National Services Scotland.

15.21 When employing medical compressed air plant for this type of test, it is important that the system demand should not exceed the maximum flow capacity of the dryers, otherwise wet air will result. It is suggested that the total flow required by the system under test should not be more than 75% of the flow capacity of the dryers.

15.22 It is also important not to introduce such a compressor after identity checks have taken place.

15.23 Special care will be required when carrying out QC checks, as some synthetic oils cannot be detected using portable equipment.

15.24 Special connectors will be needed to introduce test gas into different pipeline systems. These must be of distinctive construction and permanently labelled with their function and the contractor's name. The location of special connectors on the site must be recorded and should be subject to routine inspection under a planned preventive maintenance (PPM) system. They should be removed from site when work is complete and the contractor should record their removal.

15.25 New terminal units are supplied with "Do not use" labels. These labels should remain in place until the final identity and quality tests have been completed. They are then removed by the Authorised Person (MGPS).

15.26 In the case of existing systems, "Do not use" labels should be affixed to all terminal units within the section being modified.

15.27 The results of all tests must form part of the permanent records of the hospital and should show details of the services and areas tested. Examples of the appropriate forms are given in Appendix A. All signatories are entitled to copies of the test forms. The procedure for filing and retaining these forms should be included in the local MGPS operational policy.

15.28 For total system pressure tests on oxygen, nitrous oxide and nitrous oxide/oxygen mixture, the system under test must be physically isolated from the source of supply (for example by the use of spades). In the case of compressed air and vacuum systems, the pressure at the plant must be respectively below and above pipeline distribution pressure.

15.29 All errors found during testing must be rectified, and the relevant systems must be retested as appropriate before the records are signed.

15.30 The contractor (MGPS) must provide all engineering forms, labour, materials, instruments and equipment required to carry out the tests described in this chapter. In the case of engineering tests, this must include all cylinders of test gas together with "open" bore NIST connector probes, pressure-measuring equipment and gas specificity/ flow pressure testing device(s), metered leaks and AGS disposal system test equipment. The Quality Controller (MGPS) will be responsible for supplying all QC forms, unless otherwise requested by the Hospital Authority, calibrated test equipment, connections etc.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 49: If there is to be a delay between completion of the MGPS and when it is taken into use, it will be necessary to carry out the particulate and odour test prior to purging and filling with specific gases. In such cases the contractor must also provide labour, materials and equipment to carry out these tests.

15.31 The Quality Controller (MGPS) should provide the test equipment specified in Appendices D, E and F. The Quality Controller (MGPS) should provide all equipment for gas quality and identity testing. It should be regularly serviced and calibrated to an appropriate standard and the Quality Controller (MGPS) should maintain calibration records. On-site pre and post-testing calibration of equipment against an appropriate standard will be performed at the discretion of the Quality Controller (MGPS).

15.32 In a completely new installation, flow meters, anaesthetic trolleys etc should not be moved into rooms until validation and verification tests have been satisfactorily completed.

Note 50: In existing installations, particular care must be taken to ensure that medical gas equipment left in areas where work or testing is taking place is, and remains, disconnected from the system. Medical and nursing staff should be made aware of this situation by the posting of appropriate exclusion notices and terminal unit “Do not use” labels.

Modifications, extensions or repairs to existing systems

15.33 Where modifications, extensions or repairs to existing systems are carried out, the tests and the sequence of tests summarised in paragraphs 15.12 – 15.14 should be followed as far as possible.

15.34 The permit-to-work system should always be followed whenever any work is carried out on an existing system. The Authorised Person (MGPS) should act on behalf of the management and therefore would not normally be a member of the installation contractor’s staff.

15.35 Whenever modifications or extensions are carried out, it may be advisable but not always possible to test both the existing system and the new system separately before the break-in is made. Existing systems should, if possible, be tested to determine their performance and to identify any potential limitations that may arise as a result of modifications.

15.36 Where there is any doubt as to the cleanliness, it is in the interest of both the contractor and management for particulate tests to be carried out on the existing system prior to any break-in, and it is the responsibility of the hospital authority to ensure that these tests are carried out prior to the design phase of any modifications or extensions.

15.37 It is the responsibility of the hospital’s management to ensure that any required remedial work is carried out on an existing system before extensions are added.

© Health Facilities Scotland, a division of NHS National Services Scotland.

15.38 No system should be modified during the process of testing. It is important that any modifications are documented and that any additional testing required, as a consequence of those modifications, is performed.

15.39 A permit-to-work (or another form of appropriate document) must be issued if additional works are to be carried out during the commissioning process, even though a permit will not have been issued for the original commissioning.

15.40 The tests for particulate contamination of any extension or modification may be carried out with medical air, prior to connection and handover to the Quality Controller (MGPS), although in extensions comprising fewer than 20 joints, the working gas will generally be used to perform all tests.

15.41 The Quality Controller (MGPS) will normally carry out all checks, including a repeat of the particulate matter test, using the working gas.

15.42 The exact tests to be carried out will depend on the nature of the modification/extension. A specification should be prepared for the performance of the completed system. This specification should be as close as possible to that given in Table 41.

15.43 Some older compressed air systems will have been designed to provide 250 litres/min at the terminal unit in accordance with Health Technical Memorandum 22 (1978). It may not be possible for such systems to provide 350 litres/min, as specified in Table 19, and there may be circumstances where this would be acceptable. This should be clearly stated in the specification for the performance of the completed system. However, every effort should be made to comply with the performance and quality specifications given here, although particular care must be taken to avoid degradation of air quality arising from dryer units working at flow rates above their design specification.

15.44 It may be necessary to repeat some of the system performance tests (such as flow and pressure drop) at selected terminal units on the completed system to demonstrate satisfactory performance (see paragraph 15.78). To ensure a valid result from such a test, it should be performed when flows in the system are representative of typical maximum demands.

15.45 The break-in to the existing system should be carried out with an inert gas shield where possible, for example where AVSUs have been installed, and a downstream blanking spade has been deployed. A leak test must be carried out using a suitable leak detection fluid on this final joint at working pressure, and the joint purged with the working gas.

15.46 Connection of the upstream side of the AVSU into the existing system will usually be made without use of the shield gas. This joint can be purged with the working gas (exiting via the AVSU upstream NIST).

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 51: In some articulated pendant fittings, it is not always possible to achieve the specified pressure requirements for surgical air and vacuum. In the case of surgical air, it is most likely to be a potential problem in orthopaedic operating rooms. As these normally include an ultra-clean system into which can be incorporated surgical air (and other terminal units), supplied by rigid pipework, there may not be a problem in practice. If the static pressure exceeds the nominal pressure during flow by more than 25%, the possibility of installing hoses with a greater bore should be considered. In the case of vacuum, the flows required during surgery are less than those used during testing.

Medical gas	Plant Regulator Setting +/- 4% (kPa)	Distribution pressure (kPa)	Allowable pipeline losses to rear of terminal unit 5% (kPa)	Test flow (litres/min) (measured at terminal unit outlet)	Minimum pressure at design flow (kPa)
O_2	440	420	400	40*	380
N_2O	440	420	400	40*	380
O_2/N_2O mixtures	440	420	400	275 (LDRP) 40* (others)	310(2) 380
Medical air (400 kPa)	440	420	400	80 (critical care) 40* (others)	380
Surgical air (700 kPa) Wall outlet	860	825	784	350*	700
Surgical air (700 kPa) Pendant	940	900	854	350*	700
He/O_2	440	420	400	80 (critical care)	380
Vacuum	67 – 88 (500-660 mmHg)	60 kPa (450 mmHg)	55.3 kPa (400 mmHg)	40	40 kPa (300 mmHg)

Table 41: Validation and verification: pressure during pipeline system tests

Requirements for pipeline carcass tests

15.47 If sectional testing is performed, it is essential that as-fitted drawings are available so that the extent of the system(s) under test can be identified. For the purpose of the leakage test, all pressure gas systems may be interlinked, provided that the test can be performed at the highest pressure required. This also has the advantage that the pipeline carcass could be assigned to a different service.

Note 52: In the event of a leak, it will be necessary to test each system separately. It is advantageous to perform the tests with nitrogen, since – in the event of a leak or cross-connection – remedial action can be taken immediately. When connecting systems together, vacuum systems should not be included, as particulates from an un-purged vacuum system may be drawn into any part of any pressure gas system by venturi effects.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Labelling and marking

15.48 A visual check must be made on each pipeline system to ensure that the pipelines are labelled in accordance with the contract specification, and that the terminal unit base blocks are marked in accordance with. BS EN ISO 9170-1: 2008. The results of the checks are recorded on Form A2.

Sleeving and supports

15.49 A visual check must be made on each pipeline system to ensure that the pipelines are sleeved, where required, and supported in accordance with Table 39. The results of the checks are recorded on Form A2.

Leakage

15.50 The aim of the test is to establish that there is no leakage from the piped medical gas systems. This is demonstrated by the use of electronic pressure measuring equipment with a minimum resolution of 0.2 kPa in 1,000 kPa and 0.5 kPa in 2,000 kPa. If the performance of the measuring equipment is in doubt, recourse can be made to a test period extension of between 2 - 24 hours.

Note 53: With suitable equipment, it is possible to carry out this test during a relatively short period to minimise the effect of temperature change. To ensure fairness of the test, it is essential that temperature measurements are taken and recorded at the start and finish of the test irrespective of the period of the test. Over a one hour period with an allowance of 0.2 kPa, a small temperature change may be sufficient to fail the test. Appendix B provides information on the method of calculation. Temperature measurements should be taken throughout the area of test at the beginning of the test and the average temperature should be calculated. Temperature measurements should be taken at the end of the test at the same measurement points. The resulting temperature difference can be used to establish if a pressure loss/increase is acceptable.

15.51 During a test period of one hour, the maximum pressure loss should be ≤ 0.2 kPa for 400 kPa systems, plastic or copper vacuum and ≤0.5kPa for 700 kPa systems. Systems should be tested at a working pressure of

- For medical compressed air systems for surgical use - 18.0 bar (1,800 kPa);
- For all other compressed medical gas systems - 10.0 bar (1000 kPa);
- For vacuum systems constructed in copper 5.0 bar (500 kPa);
- For vacuum systems constructed in plastic 1.5 bar (150 kPa):
- Leakage tests for AGSS systems, the pressure should be set at 70 kPa (± 10%) with a pressure loss of no more than 10 kPa over a period of 15 minutes.

15.52 This test should be carried out with AVSUs, LVAs and other service valves open; any safety valves and pressure-sensing devices installed may be

© Health Facilities Scotland, a division of NHS National Services Scotland.

removed and the connections blanked off. The results of the test may be recorded on Form A2.

Cross-connection

15.53 Before performing these tests, any links between systems should be removed and all pipelines should be at atmospheric pressure with all AVSUs etc open.

15.54 A single pressure source should be applied to the inlet of the system to be tested and at least one terminal unit base block on all other systems should be fully open.

15.55 Each terminal unit base block on the pipeline under test should be opened in turn, checked for flow and then re-blanked. (To permit refitting of blanking caps, it is necessary to partially open at least one base unit – but it is still necessary to achieve a detectable flow.) When the test on one pipeline has been completed, the pressure source should be removed and the pipeline should be left open to atmospheric pressure by removing at least one base block blanking plate.

15.56 The test is repeated for other systems, one at a time.

15.57 The results may be recorded on Form A2.

Requirements for pipeline system tests

15.58 There must be no links between the pipeline systems. Engineering (pressure) tests should be carried out with electronic pressure-measuring equipment with a minimum resolution of 0.2 kPa in 1,000 kPa, and 0.5 kPa in 2,000 kPa.

15.59 The scope of the system and scale of provision of terminal units, AVSUs, LVAs and warning and alarm system panel indicators should be checked for compliance with Table 11 and any deficiencies noted.

Leakage from total compressed medical gas systems

15.60 This test must be carried out on the completed system at working pressure with all terminal units, AVSUs, pressure safety valves and pressure transducers fitted. Once the test pressure has been applied, the system should be physically isolated from the plant. For the purpose of this test, the supply system extends from the last valve(s) nearest to the plant detailed on the appropriate schematic drawing. This point should be identified on the contract drawings. The test is performed at pipeline distribution pressure.

15.61 During a test period of one hour, the maximum pressure loss should be

- ≤ 0.2kPa for 400 kPa systems;
- ≤ 0.5kPa for 700/900 kPa systems.

The test results may be recorded on Form A3.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Leakage into total vacuum systems

15.62 Prior to testing, the vacuum plant should be operated to allow any moisture in the system to evaporate. With the system at pipeline distribution pressure and with the source isolated, the pressure increase in the pipeline must not exceed 1 kPa (7.5 mmHg) after one hour. There is no additional allowance for temperature correction in this test.

15.63 The test results may be recorded on Form A3.

Closure of area valve service units and line valve assemblies

15.64 For pressurised systems, the system upstream of the closed AVSU under test must be maintained at pipeline distribution pressure and the downstream line pressure should be reduced to about 100 kPa. The downstream pressure must be recorded, and there should be no change in pressure over a period of 15 minutes.

15.65 For vacuum systems, the systems on the supply plant side of the closed valve must be maintained at pipeline distribution pressure and the terminal unit side should be at about 15 kPa (115 mmHg). The upstream (terminal unit side) pressure must be recorded, and there should be no change in vacuum over a period of 15 minutes.

15.66 For LVAs, a similar test procedure is adopted. There is no change in the time for vacuum.

Note 54: The reduced residual pressure is intended to take into account any potential terminal unit leakage on the assumption that it is unlikely any such leakage would equate to that of the valve under test; there would be less certainty if the pressures were reduced to zero.

15.67 The test results may be recorded on Forms A4 and A5.

Zoning of AVSUs and terminal unit identification

15.68 This test is performed to ensure that each AVSU in the pipeline controls only those terminal units intended by the design. Each terminal unit must be checked to ensure that it is for the correct service and that it is in accordance with BS EN ISO 9170-1: 2008; unambiguous cross-referenced labelling of AVSUs and terminal units controlled by them, is essential. It is particularly important to establish correct identification where dual or separate circuits have been installed; often it is not obvious by the spatial relationship of AVSUs and terminal units which of the AVSUs controls which terminal unit arrays.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 55: a) The contractor may wish to carry out this test as part of the carcass tests before any section of the pipeline is "enclosed".

b) Terminal-unit first-fix back blocks inadvertently fitted upside-down will result in inverted second-fix components, unless gas-specific components are deliberately removed. Therefore, a selection of terminal unit second-fixes, for example one per ward area, should be removed and examined to ensure that no gas-specific components have been removed.

15.69 The test is performed by turning off an individual AVSU and venting the zone to atmospheric pressure. A check is then made to establish that only those terminal units controlled by the AVSU are at atmospheric pressure. All other terminal units, including those for other gas services, should be at the operating pressure. Once a zone has been vented, it is not necessary to re-pressurise. The other AVSUs are then tested successively.

Note 56: a) These tests can be performed at the same time as the cross-connection/terminal unit pressure drop tests.

b) Where pneumatically activated pendant fittings are installed, a check should be made to ensure that the source of air has been taken from the correct AVSU zone.

15.70 The test results may be recorded on Forms A4 and A5.

Cross-connection

15.71 All systems must be checked to ensure that there is no cross-connection between pipelines for different gases and vacuum. The tests should not commence until all installations are complete and plant operational. The tests can be performed using "test" gas or "working" gas.

Note 57: Oxygen and vacuum can be tested simultaneously, followed by medical air and surgical air simultaneously, followed by the other gases, that is, nitrous oxide and nitrous oxide/oxygen mixture. Helium/oxygen mixture usage is increasing, and pipeline systems may be encountered. Also, carbon dioxide pipelines are being installed.

15.72 The sequence of the test is, first, to open all valves on all systems (for example AVSUs, LVAs and any other valves). For oxygen and vacuum systems, the main plant isolation valves should be opened (the main plant isolation valves on other systems remain closed). A check must be made to ensure that there is a flow at every oxygen terminal unit and suction at every vacuum terminal unit, and that the systems are at the correct operating pressure; there must be no flow at any other terminal unit for the other gases.

15.73 For the next stage, the main isolation valves for medical air and surgical air, if present, are opened. (It is not necessary to return the oxygen and vacuum systems to atmospheric pressure.) A check is made to ensure that there is a flow at every medical air terminal unit and every surgical air terminal unit and

© Health Facilities Scotland, a division of NHS National Services Scotland.

that the operating pressure is correct; there must be no flow from the nitrous oxide and/or nitrous oxide/oxygen mixture terminal units, if present, and helium/oxygen, if present.

15.74 The process is then repeated for nitrous oxide – again there is no necessity to return any of the previously tested systems to atmospheric pressure. A check is made to ensure that there is flow at every nitrous oxide terminal unit and that the operating pressure is correct; there must be no flow from the nitrous oxide/oxygen terminal units and helium/oxygen terminal units (if present).

15.75 The process is then repeated for nitrous oxide/oxygen mixture, and finally helium/oxygen mixture. If other medical gases are encountered, for example carbon dioxide, the sequential testing methodology will continue. As before, there is no necessity to return any of the previously tested systems to atmospheric pressure. Checks are made to ensure that there is no flow from any system that is still isolated at the plant.

Note 58: The tests can be carried out on a total system basis, departmental basis or sub-departmental basis, having previously checked for cross-connection up to the appropriate AVSUs. When carrying out the tests on a sectional basis, it is essential that as-fitted drawings are available such that the extent of the system(s) can be established.

15.76 This test must be repeated in full if any subsequent modifications are made to the pipeline system.

15.77 The test results may be recorded on Form A7/1.

Flow and pressure drop at individual terminal units, mechanical function and correct installation

15.78 These tests can be carried out as part of the cross-connection tests above using appropriate test devices as described in Appendix C with the correct probes inserted for the pipeline(s) under test. The pressure must achieve the values given in Table 41 at the specified flows.

Note 59: When performing these tests as part of the cross-connection tests, there is the possibility that the 400 kPa and vacuum test devices could be connected to the incorrect service, particularly a vacuum and oxygen reversal. The instruments used, therefore, should include appropriate directional check valves. (There is a possibility of damaging the gauges. Alternatively an open probe can be used to determine pressure or vacuum.)

15.79 It must be demonstrated for each terminal unit that the appropriate gas-specific probe can be inserted, captured and released, and it should be visually confirmed that an anti-swivel pin is present, or absent, in terminal units with a horizontal or vertical axis, respectively. Terminal units should be challenged by the test probes of all other gases within the department or ward to ensure non-interchangeability.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 60: a) Terminal units to BS EN ISO 9170-1: 2008 need not be challenged with the full complement of BS 5682:1998 test probes.

b) The terminal unit should be fitted complete with bezel plates etc. The clearance hole should be reasonably concentric with the terminal unit rim – it must not be in contact.

c) By connecting a flowmeter to the terminal unit, the terminal unit should be standard throughout by being proud of the wall, slightly greater than the movement necessary for the release action and sit parallel to the wall on a vertical axis.

15.80 The results of the tests may be recorded on Form A8.

15.81 All NIST connectors, including those provided on AVSUs, LVAs and pendants / flexible hoses, must be checked to ensure that gas flow is achieved when the correct NIST probe is inserted and mechanical connection made. The correct identification of gas flow direction should be confirmed for AVSUs (that is, which are the upstream and downstream NIST connectors). NIST connectors can be checked when performing other tests on AVSUs and LVAs.

Note 61: a) In certain circumstances factory-assembled units are dismantled for installation purposes and can be subsequently incorrectly re-assembled. In the case of LVAs (whether or not CE marked), disassembly and subsequent incorrect re-assembly or, indeed, insertion into an incorrect line, is also possible. The primary purpose of the test is to ensure that whenever it is necessary to make a connection, the appropriate connectors will be to hand; the test is a further safety aid, although it is assumed that personnel making connections to NIST fittings are appropriately qualified and authorised to do so.

b) All NIST connectors should have the manufacturer's certificate of test provided for fitted terminal units within pendants.

15.82 It must be demonstrated (except for vacuum) for each NIST connector that the self-sealing device substantially reduces the flow of gas when the connector is removed without hazard to personnel or reduction in pipeline pressure. This will not apply where the surgical air pendant hose self-sealing device of the NIST has been removed and replaced by an in-line valve.

Note 62: Personnel should take care not to stand in front of the NIST connector when performing this test.

15.83 The results may be recorded on Form A8.

Performance tests on the pipeline system

15.84 The performance of individual pipeline systems is measured by introducing a sufficient number of calibrated metered leaks (with orifice sizes providing different flows that replicate the range of medical devices for which the pipeline is designed; see Table 12) to represent the total "diversified" system design flow, less the flow generated by the test device. Thereafter, a representative

© Health Facilities Scotland, a division of NHS National Services Scotland.

number of terminal units (see note below) are tested for pressure and flow: the diversified flows should be derived from the data in Tables 13, 15, 16, 18, 20 and 21.

Note 63: a) In a 28 bed ward module, metered leaks equal to the total design flow of the ward should be distributed through the ward. A pressure reading should be taken at the furthest located terminal unit and nearest to the entrance to give the pressure loss across the unit. No noticeable loss should occur with ward gases

b) This procedure is applied systematically for a total system design flow by applying metered leaks equal to the hospital diversified design flow. Pressure readings can be taken throughout the system from source to furthest terminal units from source. Normally an index run is selected based on the heaviest diversified flow demand concentration rather than distance from source.

c) In a ring main distribution system the total flow is designed by measurement in turn in each direction from the source. Requirement for sectional or phased testing to be included.

15.85 The metered leaks should be stamped or similarly be identified to show the flow (air equivalent) at, for example, 10, 20, 100, and 275 litres/min for 400 kPa systems, and 350 litres/min for 700 kPa systems.

Note 64: In principle it is permissible, although unlikely to be practicable for large installations, to test all systems simultaneously, particularly oxygen and vacuum, where terminal units are installed in pairs and where they require different metered leaks (this includes vacuum when testing oxygen will not significantly increase the time needed).

Functional tests of supply systems

15.86 All supply systems must be tested for normal and emergency operation, according to the manufacturers' manuals and contract specifications. For the purpose of the tests, the systems must be connected to both the normal and stand-by power supplies. The results of these tests should be recorded on Forms A9 - A13 and A17.

Pressure safety devices

15.87 Pressure safety valves are not tested. They should be examined to ensure that they are correctly rated for the pipeline system and are in accordance with the contract specification. Each should be provided with a test certificate confirming the certificated discharge pressure. Records of safety valve details should be noted on Forms A9 to A12 inclusive.

15.88 Check that the specified pressure safety valves have been fitted.

15.89 Verify that the pressure safety valves are certified to operate in accordance with the contract specification and conform to BS EN ISO 4126-1: 2004.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Warning and alarm systems

15.90 The operation of warning and alarm systems should be tested in all normal operating and emergency modes. Particular attention should be paid to the following:

- that all systems operate within the specified tolerance limits at all operating parameters and fault conditions, and can be seen and heard as specified in Tables 37 and 38;
- that systems react correctly following return to normal status;
- that all indicator panels and switches are correctly marked;
- that all functions on all indicator panels operate correctly;
- that the system will operate from the essential supply stand-by power source;
- that all indicator panels are labelled to show the areas they serve, or as detailed in the contract specifications.

15.91 The following tests should also be carried out:

- for central indicator panels, check that the operation of the mute switch cancels the audible alarm and converts the flashing signals to steady, for all systems and conditions;
- for repeater indicator panels, check that the mute switch cancels the audible alarm and that the flashing signals are converted to steady only on the central alarm panel, for all systems and conditions;
- for area alarm panels, check that the operation of the mute switch cancels the audible only, for all systems and conditions;
- check power failure operates red “system fault” indicator and the audible alarm;
- check that a contact line fault operates the “system fault” indicator, the main alarm displays and the audible alarm;
- check audible reinstatement for each alarm panel;
- check that the audible signal can be continuously muted via operation of the internal push-button for gas service alarm conditions only;
- check for correct identification of each gas service on alarm panels and “departmental” or plant specifying labels;
- check that each alarm panel emits the correct (two-tone) audible alarm. (Some manufacturers supply panels set for a single tone – in use, staff may confuse this sound with that emitted by some models of patient monitoring equipment.)

15.92 The results of the tests are recorded on Form A14.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Verification of as-fitted drawings

15.93 The as-fitted drawings should be checked to ensure that all variations from the contract drawings have been recorded and the results may be recorded on Form A18.

Filling with medical air

15.94 An indefinite time may elapse after completion of the MGPS before the system is taken into use. The installation contract may be written in the expectation that this will happen. In such circumstances the contract should require that the particulate contamination and odour tests, specified in para 15.131 to 15.137 are carried out as an interim measure, using medical air as the test gas. Satisfactory completion of these particulate contamination and odour tests may then signify the completion of the construction contract.

15.95 It is the responsibility of the contractor to ensure that proper provision is made in a specific contract for the maintenance of the systems, their integrity, and any special connectors that may be required during this interim period.

15.96 All MGPS should be left filled with medical air at pipeline distribution pressure until they are filled with the specific working gas shortly before use. The medical vacuum pipeline need not be maintained under vacuum.

15.97 Provision should be made for regular running and maintenance of all supply plant during such an interim period.

15.98 Details of the work carried out, as well as records of the system pressures, should be recorded. This information is required in order to demonstrate that the systems have been satisfactorily maintained under pressure during this interim period. Tests for particulate contamination should be carried out after the systems are filled with the specific gas. The extent of the tests is at the discretion of the Quality Controller (MGPS).

15.99 The “Danger – do not use” label should remain affixed to each terminal unit until all testing is completed.

15.100 When the construction contract has finished, the contractor should record the removal of all special connectors and cylinders from site.

Note 65: Special connectors and cylinders may be required to maintain the systems under pressure. This may be some time prior to the admission of patients. In such circumstances some contracts require systems to be completed and certificated for the purpose of practical completion and handover to the client.

Purging and filling with specific gases

15.101 Each pipeline system must be purged with the specific working gas shortly before use. The following conditions should apply:

© Health Facilities Scotland, a division of NHS National Services Scotland.

- all sources of test gas must be disconnected;
- all special connectors must be removed from site;
- each pipeline system must be at atmospheric pressure with all AVSUs open;
- each system must be filled to pipeline distribution pressure with the specific gas from the supply system;
- with the supply system on, each terminal unit must be purged at a known flow with a volume of gas at least equal to the volume of the pipeline section being tested;
- all oxygen, nitrous oxide, nitrous oxide/ oxygen mixtures and helium/oxygen mixture discharged during the process must be released to a safe place.

15.102 The results of the purging process may be recorded on Form A19.

15.103 Purging is not necessary for vacuum systems.

Note 66: It may be possible to carry out the tests outlined in para 15.59 to 15.92 with the working gases, either sequentially or consecutively, followed by the appropriate pharmaceutical test. After the tests, “certification” arrangements should be put in place such that the client takes over responsibility for managing the system.

Pharmaceutical testing

15.104 When modifying existing systems, the test programme is agreed by the Quality Controller (MGPS) and Authorised Person (MGPS) and the system is taken back into use only after testing has been completed satisfactorily under a permit-to-work system.

15.105 Three types of work are identified:

- new;
- extension/upgrade; and
- repair.

For new installations, for example a new ward, a new department, or a complete hospital, the Quality Controller (MGPS) will prepare a report containing details of tests carried out and an inventory of outlets tested.

15.106 For extensions, upgrades and repairs, the permit will provide the minimum report, although a longer report may be provided at the discretion of the Quality Controller (MGPS).

15.107 Inclusion of details such as the mounting order of terminal units observed at the time of test should be confirmed by signature of the Authorised Person (MGPS) on the report.

© Health Facilities Scotland, a division of NHS National Services Scotland.

15.108 This inventory should be checked by the Authorised Person (MGPS) to ensure that all terminal units have been identified and tested. NIST connectors will also need to be identified. The Authorised Person (MGPS) should then amend a copy of the Quality Controller (MGPS) report, confirming in writing that the system can be taken into use.

15.109 Although a structured approach to testing should be adopted, access and time limitations to parts of the MGPS may lead to some disruption of proposed test regimes.

Note 67: Important: These tests are described in the context of commissioning and repair/alteration to existing systems. However, it must be remembered that quarterly testing is also required by this Scottish Health Technical Memorandum and in accordance with Tables 41 and 42 for medical air generated by on-site air compressors, synthetic air from gas blending plant, and oxygen from oxygen concentrators using compressor plant. The Authorised Person (MGPS) should liaise with the Quality Controller (MGPS) to ensure that these tests are carried out and recorded.

Note 68: a)The role, responsibilities and relationships of Authorised Persons (MGPS) – in the context of both existing and new installations, where the Authorised Person (MGPS) may not have responsibility for the systems when in use – is covered in Part B.

b) Although precluded by adherence to the procedures recommended in this Scottish Health Technical Memorandum, there have been instances when a system undergoes further modifications after a Quality Controller (MGPS) has started testing. It is very important that any modifications are documented and that any additional testing required as a consequence of those modifications is performed. Use of the permit-to-work form should be considered in these cases.

c) If it is necessary to modify systems during or after completion of testing, the Authorised Person (MGPS) and Quality Controller (MGPS) will identify the extent of retesting that is required. If the system has been completed and all documentation handed over to the client or operator of the building, any further modification must be carried out strictly in accordance with the permit-to-work procedure.

d) The importance of NIST connectors in facilitating engineering and pharmaceutical testing and their value during shutdowns and emergency situations should not be underestimated. All LVAs are fitted with upstream and downstream NIST connectors.

Quality of medical gas systems

General

15.110 The objective of these tests is to establish whether the pipeline has been contaminated during construction or modification. The tests indicate whether

© Health Facilities Scotland, a division of NHS National Services Scotland.

work has affected a gas, but they are not tests that indicate compliance with pharmaceutical specifications for licensed products.

15.111 Particulate contamination and odour tests may have been carried out prior to filling with the working gas, particularly if the system has been left for some time before use. However, the Quality Controller (MGPS) will define the extent of repetition of these tests, after the systems have been filled with the specific working gas.

15.112 The Quality Controller (MGPS) will also define the extent of all other pharmaceutical testing, depending on such factors as the extent and nature of the work and the age and condition of the existing systems.

15.113 The Ph. Eur. should be seen as a basic minimum standard when examining medical gas quality, as its principal application is to the manufacture and distribution of medicines according to well-established manufacturing processes. It is not intended to deal with the endless possibilities for contamination that are introduced by an MGPS, or the types of failure that might occur with on-site generation of gases.

15.114 Occasionally, the Quality Controller (MGPS) may need to resort to more sophisticated testing than is permitted by the use of portable equipment.

15.115 Oxygen, helium/oxygen mixture, nitrous oxide, and nitrous oxide/oxygen mixtures discharged during the process must be released to a safe place. These tests are not required on a vacuum system for any work including modifications or new works.

15.116 These test procedures are based on existing practice. The particulate contamination test is subjective in that it requires the QC to make a judgement on whether or not particles are visible on the filter.

15.117 The oil, water, carbon monoxide and carbon dioxide, sulphur dioxide and oxides of nitrogen tests can be carried out with detector tubes, but advances in detection technology have produced a range of suitable alternative instruments. The use of detector tubes giving a quantitative response is recommended but is not intended for re-use. If other equipment is used for validation purposes, it must provide a level of repeatability, resolution and accuracy at least equivalent to that of detector tubes and must be calibrated to appropriate Standards.

15.118 An electronic dew-point meter should be used in preference to water content measurements.

15.119 Detector tubes should be agent-specific. Non agent-specific (polytest) tubes can respond to various agents without identifying or quantifying the contaminants. Nevertheless without their use the degree of release of chemicals from hosing into the gas stream would never have been realised. Although BS5682 did not recommend tests on flexible plastic hosing, this related to theatre pendants where patients were subjected to the medical gases over a short period of time. The introduction of multi-movement pendants within the critical care departments requires research into the effects of prolonged exposure of the

© Health Facilities Scotland, a division of NHS National Services Scotland.

patient to the leaching of contaminants from the flexible hosing into the gas stream.

15.120 However, it is recommended that the use of the polytest tube be considered as a general test for contamination of pipelines. It would be advantageous for the QC to record and transfer such readings to graphical form.

15.121 Users must be aware of the limitations of all types of detection equipment, including ambient operating conditions and cross-sensitivities specified for each type of detector tube.

15.122 These tests must be carried out on a representative sample of terminal units/NISTs in each system at the discretion of the Quality Controller (MGPS).

15.123 If terminal units are being tested, the sample must include, as a minimum, the most distant terminal unit on each branch. This may be the first terminal unit to be tested, but care must be taken to ensure, for example, that a new extension connected to old pipework is first well purged via a terminal unit/NIST connector as close as possible to the junction of the systems so as to avoid the spread of any contamination into the extension.

15.124 It will not normally be necessary to test the most distant terminal unit if distal NIST connectors are provided.

15.125 Depending on the results of this test, the Quality Controller (MGPS) should decide the number and location of additional terminal units/NISTs to be tested.

Note 69: Provision of NISTs throughout an MGPS is to be encouraged, as this will greatly facilitate testing, particularly QC testing.

15.126 These tests are summarised in Table 42.

15.127 All sources of supply should be tested for quality before the pipeline distribution system is filled with the working gas. This test is not intended as a test of certificated gases but is to ensure that supply source equipment (manifolds, compressors, VIEs etc) does not compromise the quality of such gases when delivering them to the pipeline systems.

15.128 When extending existing systems, supply sources will not normally be retested before being used to fill the extension with the working gases.

15.129 For new installations, quality tests should be carried out on the plant as well as on the pipeline distribution system.

15.130 The results of the test may be recorded on Form A21.

Particulate matter

15.131 MGPS should be free from particulate contamination, as they have been constructed using chemically cleaned, capped components and joined in a controlled process using a filtered shield gas.

© Health Facilities Scotland, a division of NHS National Services Scotland.

15.132 However, on-site contamination can occur from ingress of building materials, dust etc. The presence of such particles can adversely affect the quality of the delivered gases. Therefore, tests to indicate their absence are important.

15.133 New systems should be purged until the particulate filter is completely clear of visible particles when viewed in a good light.

15.134 Older systems may exhibit particulates, even after considerable purging, as they can be released or carried along by the gas stream after disruption of the system, reverse gas flow, pressure waves down the pipe, or physical vibration.

Note 70: When connecting new pipework to an older (possibly contaminated) system it may be advisable to perform the first purge via the inlet NIST of the first AVSU, or the first terminal unit of the new system, in order to reduce the possible spread of contamination into the new system.

15.135 Where it is evident that extended purging may not completely clear the system of particulates, a decision to accept the level of contamination present, agree a cleansing procedure or, in very exceptional circumstances, condemn the system will be made.

15.136 The test for particulate matter should be carried out at every terminal unit on a new system. It can be carried out either after completion of the construction phase using medical air (see paragraph 15.94) or after the system has been filled with the specified gas. Once the system is filled with working gas, it would not normally be necessary to repeat the test at every terminal unit. The actual number of terminal units sampled is at the discretion of the Quality Controller (MGPS). It would, however, be necessary to repeat the test in full where there is insufficient evidence to show that the system has been satisfactorily maintained under operating pressure with medical air for the interim period.

15.137 When tested with a membrane filter at a flow not less than 150 litres/min for 30 seconds, the filter must be free from visible particles when viewed in good light. A suitable test device is described in Appendix D.

Note 71: a) When testing surgical air terminal units, a flow of 350 litres/min for 30 seconds should be used.

b) When testing nitrous oxide/oxygen mixture terminal units, a flow of 275 litres/min for 30 seconds should be used.

c) When testing helium/oxygen mixture systems, oxygen-free nitrogen is used at the manifold and this will require special connectors.

d) When tests and/or purging is carried out with the sources of supply serving an operational hospital, it is essential to ensure that the test flows used are not detrimental to the continuity or adequacy of supply in operational areas. When a flow rate of 150 litres/min or more may not be possible without compromising the hospital system, a lower flow rate should be used at the discretion of the Quality Controller (MGPS).

© Health Facilities Scotland, a division of NHS National Services Scotland.

Oil

15.138 This test should be carried out at the plant test point of all newly installed medical/surgical compressed air plant and for all medical/surgical compressed air plant on a quarterly basis.

15.139 When break-ins to a tested (and compliant) medical/surgical air system have been completed, repetition of this test will not normally be required.

15.140 Work involving strip-down of compressor plant and subsequent replacement of oil-sealing components may require a follow-up oil test, at the discretion of the Quality Controller (MGPS).

15.141 Oil may be present as liquid, aerosol or vapour, and an appropriate test device is described in Appendix E.

15.142 The total oil content should be in accordance with Table 42.

15.143 It is desirable to carry out this test at a plant test point before any pipeline system is supplied by that plant so as to prevent inadvertent contamination of the distribution system.

15.144 A representative sample of terminal units on both new and modified medical compressed air and oxygen concentrator systems supplied by compressor plant may be checked at the discretion of the Quality Controller (MGPS).

15.145 Care should be taken in siting the test point to ensure a representative sample.

Water

15.146 This test is intended to identify contamination of the pipeline system by moisture. It should not be confused with the test for compressor plant dryer performance, although it may indicate a failure in the dryer system.

Note 72: a) When testing terminal units supplied via low pressure, flexible connecting assemblies, it is often found that – on initial testing – moisture levels exceed the 0.05 mg/litre limit; this is the result of desorption of minute quantities of moisture into the gas stream. This is particularly noticeable where the test flow is low, and should not cause undue concern. The Quality Controller (MGPS) should establish, however, that the elevated readings at such terminal units result from this effect and not water contamination of the pipeline. (For example, the results should be compared with the readings achieved at nearby terminal units supplied by copper pipework.) New developments in hose materials may lead to hoses with reduced water vapour permeability characteristics.

b) The effects of flow rate through dryer units and sampling times on detection equipment indications should also be taken into account when measuring water content.

15.147 The plant test point and a representative sample of terminal units distributed throughout the pipeline systems should be tested for total water content. The

© Health Facilities Scotland, a division of NHS National Services Scotland.

water content must not exceed 67 vpm (equivalent to an atmospheric pressure dew-point of approximately –46°C). The typical water content of medical gas cylinders is normally below 5 vpm. Water vapour content may be measured using the appropriate test device described in Appendix E (see also paragraph 15.119).

Note 73: Older compressor/dryer combinations may fail to meet the Ph. Eur. requirement of 67 vpm. In these circumstances, the Quality Controller (MGPS) will decide whether application of the older atmospheric dew-point limit of –40°C (127 vpm) is acceptable (Scottish Health Technical Memorandum 2022: 2001).

Carbon monoxide

15.148 The most distant terminal units on each branch of a medical/surgical air pipeline system supplied from a compressor plant and PSA systems must be tested for carbon monoxide, although it would not normally be necessary to test more than five terminal units. The concentration of carbon monoxide should not exceed 5 ppm v/v. This may be measured at up to five terminal units in each system using the appropriate test devices described in Appendix E.

15.149 When break-ins to a tested (and compliant) medical/surgical air system have been completed, repetition of this test will not normally be required.

Carbon dioxide

15.150 The most distant terminal unit on each branch of a medical/surgical air pipeline system supplied from a compressor or an oxygen concentrator plant must be tested for carbon dioxide.

15.151 The concentration of carbon dioxide must not exceed 500 ppm v/v in medical air or 300 ppm v/v in oxygen from an oxygen concentrator plant.

15.152 When break-ins to a tested (and compliant) medical/surgical air system have been completed, repetition of this test will not normally be required.

Note 74: a) Increasing or fluctuating carbon dioxide readings in air or PSA-generated oxygen can be an early indication of dryer failure or poor compressor maintenance.

b) Carbon dioxide is no longer used as an inert shield gas during pipeline brazing.

c) If carbon dioxide has been installed (see Section11), the test methodology should be at the discretion of the Quality Controller (MGPS).

Sulphur dioxide

15.153 The most distant terminal units in medical/ surgical air pipeline systems supplied from a compressor plant, together with oxygen terminal units supplied from a PSA plant, must be tested for sulphur dioxide. It will not normally be

© Health Facilities Scotland, a division of NHS National Services Scotland.

necessary to test more than five terminal units in a single system. The concentration should not exceed 1 ppm v/v.

15.154 When break-ins to a tested (and compliant) medical/surgical air system have been completed, repetition of this test (and those in para 15.112 to 15.115) will not normally be required.

Oxides of nitrogen (NO and NO_2)

15.155 The most distant terminal units in medical/ surgical air pipeline systems supplied from a compressor plant, and oxygen terminal units supplied from a PSA plant, must be tested for oxides of nitrogen. It will not normally be necessary to test more than five terminal units in a single system. The concentration should not exceed 2 ppm v/v.

15.156 When break-ins to a tested (and compliant) medical/surgical air system have been completed, repetition of this test (and those in para 15.112 to 15.115) will not normally be required.

Important: See Note (d) applicable to Table 42 on disparity between Ph. Eur. and EH40 with reference to acceptable levels of sulphur dioxide and oxides of nitrogen.

Nitrogen

15.157 Oxygen-free nitrogen is used as the inert gas shield, and all terminal units of all gas systems should be tested to ensure that the systems have been adequately purged.

15.158 For oxygen systems and nitrous oxide/oxygen, an oxygen analyser must be used to ensure that the oxygen concentration is not less than that given in Table 43.

15.159 For nitrous oxide systems, an instrument based on thermal conductivity, or an infrared meter, must be used to check that the system has been adequately purged at every terminal unit.

15.160 If a thermal conductivity meter is used, it will be necessary to prove absence of carbon dioxide (which could have been used inadvertently as a shield gas) by the use of a chemical reagent tube.

Pipeline odour/taste

15.161 An odour test is performed because it incorporates, qualitatively, many impurity checks, as several contaminants are detectable by odour. This test is normally carried out as the final test with the working gases, except for nitrous oxide, nitrous oxide/oxygen mixture and carbon dioxide, which should not be inhaled.

15.162 In certain circumstances (see paragraph 15.94), it may be carried out as the first test after completion of construction of the pipeline installation using

© Health Facilities Scotland, a division of NHS National Services Scotland.

medical air as the test gas. In such circumstances, a pipeline odour/taste test can be carried out on nitrous oxide and nitrous oxide/oxygen systems.

15.163 In addition to all new terminal units, a representative sample of terminal units on existing parts of the systems must be checked.

Note 75: a) For some time it has been known that materials used in the construction of low-pressure connecting assemblies can present an odour. This was recognised in the 1984 version of BS5682:"Plastics materials currently in use will release small quantities of volatile organic matter into the gas stream throughout the life of the plastics components of the material. The quantities released appear to be below the levels normally considered toxic but, as yet, insufficient research has been carried out to be able to identify and quantify these components, therefore no tests are recommended."

b) More recent work has shown that the quantities of those agents that can be identified are significantly below levels considered to be toxic. It is possible that developments in hose material structure will result in the reduction of odour (and moisture retention).

c) The Quality Controller (MGPS) should perform additional oil and polytest analyses if indistinct odours are detected where flexible hoses are not involved.

d) New developments in hose materials may lead to hoses that are odour-free and do not leach chemicals into the gas stream. Until such hoses are available, present tests including moisture and polytest should continue on flexible hosing with findings recorded.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Gas and source	Particulates	Oil	Water	CO	CO_2	NO and NO_2	SO_2	Poly-test tube	Odour
Oxygen from PSA plant	Free from visible particles in a 75 litre sample	≤0.1 mg/m^3	≤67 vpm (≤0.05 mg/ litre, atmospheric dew-point of -46°C)	≤5 mg/m^3; ≤5 ppm v/v	≤300 ppm v/v	≤2 ppm v/v	≤1 ppm v/v	No discoloration	None
Nitrous oxide	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/ litre, atmospheric dew-point of -46°C)	≤5 mg/m^3; ≤5 ppm v/v	≤300 ppm v/v	≤2 ppm v/v	-	No discoloration	SAFETY Not performed
Nitrous oxide/oxygen mixture	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/ litre, atmospheric dew-point of -46°C)	≤5 mg/m^3; ≤5 ppm v/v	≤300 ppm v/v	≤2 ppm v/v	-	No discoloration	SAFETY Not performed
Medical and surgical air	Free from visible particles in a 75 litre sample (for medical air) and 175 litre sample (for surgical air)	≤0.1 mg/m^3	≤67 vpm (≤0.05 mg/ litre, atmospheric dew-point of -46°C)	≤5 mg/m^3; ≤5 ppm v/v	≤900 mg/m^3; ≤500 ppm v/v	≤2 ppm v/v	≤1 ppm v/v	No discoloration	None
Dental compressed air	Free from visible particles in a 75 litre sample	≤0.1 mg/m^3	≤1020 vpm (≤0.78 mg/ litre, atmospheric dew-point of - 20°C)	≤5 mg/m^3; ≤5 ppm v/v	≤900 mg/m^3; ≤500 ppm v/v	≤2 ppm v/v	≤1 ppm v/v	No discoloration	None
Synthetic air	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/ litre, atmospheric dew-point of -46°C)	-	-	-	-	No discoloration	None
Oxygen from bulk liquid or cylinders	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/ litre, atmospheric dew-point of -46°C)	≤5 mg/m^3; ≤5 ppm v/v	<300 ppm v/v	-	-	No discoloration	None
Helium/oxygen mixture O_2, < 30%		-	≤67 vpm (≤0.05 mg/litre, atmospheric dew-point of -46°C)	≤5 mg/m^3; ≤5 ppm v/v	<300 ppm v/v	≤2 ppm v/v	-	No discoloration	None

Table 42: Quality specification for medical gas pipeline tests (working gases)

Notes applicable to Table 42: a) The quality of the gases delivered at the terminal units should also comply with the specifications given in Table 42, above, which is inclusive of the current edition of the Ph. Eur. (see Table 43). Additionally, contamination introduced by the MGPS, and not limited by the Ph. Eur. specification, should not exceed levels that might pose a threat to patients. It should be borne in mind that the safe levels for medical gases delivered to patients are likely to be significantly lower than those permitted for healthy individuals. In addition to the monograph, the official standards section of the general notices should be read.

b) The tests for oil, carbon monoxide, carbon dioxide, sulphur dioxide and oxides of nitrogen are not normally carried out when the source of supply is from cylinders or cryogenic systems, although it should be noted that rare instances of oil contamination arising from the pipeline have occurred.

c) Synthetic air will be tested for identity as shown in Table 43. A GLC (gas-liquid chromatography) test for nitrogen is possible but not without practical difficulties. Nitrogen content will, therefore, usually be inferred from oxygen analyser test results.

d) The Health and Safety Executive has revised its guidance on exposure limits for sulphur dioxide, nitrogen monoxide and nitrogen dioxide. Occupational exposure standards (OESs) for nitric oxide, nitrogen dioxide and sulphur dioxide were removed from EH40 in the Amendment of April 2003.Time-weighted averages (TWAs) for nitrogen monoxide and nitrogen dioxide are now suggested as no greater than 1 ppm, and limits for sulphur dioxide exposure as less than 1 ppm for both 8-hour TWA OES and 15-minute STEL (short-term exposure limit).Some breathing air standards seek to limit the levels of such contaminants to 10% of the 8-hour TWA, as medical gases are intended for use by people who are not in the best of health. Therefore it is suggested, when testing for these specific compounds, or any contaminants not listed in the Ph. Eur., that a limit of 10% of the OES should be confirmed.

e) See Note following paragraph 15.147.

Gas identification

15.164 The identity of the gas must be tested at terminal units on medical gas pipeline systems. This would include all new terminal units, whether on a new installation or a modification or extension, and a representative sample of terminal units on an existing system, which may have been affected by the work. All systems must have been filled with the specific gas according to paragraph 15.101.

15.165 The composition of all compressed gases must be positively identified. This can be accomplished using an oxygen analyser for oxygen, nitrous oxide/oxygen and air, and a thermal conductivity or infrared meter for nitrous oxide.

15.166 When checking the identity of nitrous oxide and nitrous oxide/oxygen mixture, the gas should be discharged in a manner that minimises pollution and personnel exposure.

15.167 When testing pipelines for helium/oxygen mixture, an initial test is carried out with nitrogen connected after completing the particulate test. An oxygen analyser is used and all terminal units are tested. After a zero reading is achieved, product cylinders are connected and the system is purged. A second test is performed with an oxygen analyser; the oxygen content should be as in Table 44.

15.168 The nominal gas concentration at specific terminal units is given in Table 44; vacuum must be identified by observation of suction at the terminal unit.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Gas and source	Paramagnetic oxygen analyser reading	Thermal conductivity (TC)/infrared (IR) instrument reading	Carbon dioxide detector tube indication if TC meter used	Vacuum probe
Oxygen from liquid or cylinders	Minimum 99.5%	-	-	-
Oxygen from concentrator	Minimum 94.0%	-	-	-
Nitrous oxide	-0.2%	Indicates “nitrous oxide” or gives a reading of 100% ± 2.0% (TC), ≥98% (IR)	≤300 ppm v/v	-
Nitrous oxide/oxygen mixture	50.0% ± 2.0%	50.0% ± 2.0%	-	-
Medical, surgical and dental air	20.9% ± 0.5%	-	-	-
Synthetic air	95-105% of nominal value of 21.0-22.5%	-	-	-
Vacuum	-	-	-	Suction present
Nitrogen shield gas	0%	0% (IR)	-	-
Helium/oxygen mixture: Test 1. Test 2.	 0% 20.9% ± 0.5%	 0% 20.9% ± 0.5%	-	-

Table 44: Gas concentrations for identification purposes

Note 77: The tolerance of the measuring instrument should be allowed in addition. For oxygen concentrator plant (PSA) supplied system, the minimum concentration must be 94% oxygen. A vacuum gauge may be used to obtain a quantitative reading of vacuum level and verify terminal unit performance.

Test results

15.169 The test results for gas identity may be recorded on Form A20.

AGS disposal systems

General

15.170 BS6834:1987 specifies the tests to be carried out on AGS disposal systems that comply with the British Standard. The tests specified are designed to ensure adequate performance and that the safety provisions of receiving systems will be met.

15.171 The responsibility for the tests should be clearly identified at the contract stage for new installations, in the same way as for the medical gas pipeline system. In general, the contractor should carry out the tests, which should be witnessed by the Authorised Person (MGPS).

© Health Facilities Scotland, a division of NHS National Services Scotland.

Performance tests

15.172 All equipment should be tested to ensure that it performs satisfactorily during continuous operation under full load for one hour.

15.173 All electrically powered equipment should be tested as follows:

- check for correct rotation;
- check the current through the powered device at full load.

15.174 The disposal system should be tested to ensure that it meets the requirements set out in the table below, with the number of terminal units for which it has been designed in use.

	Disposal system standard			
	Pressure drop		Flow rate	
	BS6834: 1987	BS EN ISO 7396-2: 2007	BS6834: 1987	BS EN ISO 7396-2: 2007
Maximum	1 kPa	1 kPa	130 litres/min	80 litres/min
Minimum	4 kPa	2 kPa	80 litres/min	50 litres/min
Maximum static pressure	20 kPa (-ve)	15 kPa (-ve)	This check is made before performing the flow tests	

Table 45: AGS disposal system standards

Note 78: Since the preparation of BS6834: 1987, developments in anaesthesiology have resulted in reduced flows being used. Depending on local circumstances, it may be possible to commission systems for different flows in accordance with BS EN ISO 7396-2: 2007. Details of the test flows should be recorded in the commissioning documentation.

15.175 The test should be carried out as described in Appendix K of BS6834:1987. The test device is inserted into each terminal unit in turn and checked for pressure at flows of 80 litres/min and 130 litres/min for BS systems, and 50 litres/min and 80 litres/min for ISO systems. Adjustment is then made if necessary.

15.176 The test device and a number of metered leaks are then inserted into the system to replicate the design flow. The measurements above are repeated. If the test results are satisfactory, the test device is removed and substituted by a metered leak.

Note 79: The test device is designed to replicate either type of receiving system for which the disposal system has been designed.

15.177 The other terminal units are then tested in turn by substituting the test device for each metered leak including the test device.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Note 80: For the purposes of diversity, it may be assumed that in any operating department only one receiving system for each operating room is in use at any time. In a typical theatre suite with two terminal units in the operating room and one in the anaesthetic room, the total number of metered leaks used for testing is two; that is, one being placed in an operating room terminal unit and the other in the anaesthetic room terminal unit.

15.178 The operation of user-controlled switches, power-on indicators and alarm systems should also be checked.

15.179 AGSS terminal units should be checked for correct mechanical operation and that the check valve operates satisfactorily. All AGSS terminal units will incorporate an adjustable flow valve.

Requirements before a medical gas pipeline system is taken into use

General

15.180 Before a system is used, the appropriate persons must certify in writing that the tests and procedures required in para 15.48 to 15.100 and 15.109 to 15.179 have been completed, and that all systems comply with the requirements. This must include certification that all drawings and manuals required by the contract have been supplied and as-fitted drawings are correct (see Form A22).

15.181 All certificates must be dated and signed by the appropriate witnesses, by the CSO and by the representative of the contractor.

15.182 For modifications or extensions to existing systems, the performance tests for flow and pressure drop (as described in paragraphs 15.43 to 15.45) should be carried out on the completed system if practicable. If the performance is in accordance with the specification prepared (as described in paragraphs 15.34 to 15.46), the system may be taken into use, provided that all the other tests have been satisfactorily completed.

Note 81: In many cases, the extension/modification will be relatively small and unlikely to significantly affect the performance of the system.

Operational policy

15.183 A procedure must be available in accordance with Part B, and must ensure continuity of supply of cylinders and bulk liquid. This will incorporate a procedure for recording delivery, handling and storage of full and empty cylinders, with an indication of who is responsible for these activities. The supplier must certify the composition of the cylinder contents. All deliveries of bulk liquid oxygen should be tested for conformance to the product licence specification before dispatch by the supplier, and should be supplied with a certificate indicating compliance.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Cylinder storage and handling

15.184 There should be recorded visual checks for correct labelling, including batch numbers (see Part B).

Removal of construction labels

15.185 When all tests have been completed satisfactorily, the “Danger – do not use” labels affixed to terminal units should be removed on the authority of, or by, the Authorised Person (MGPS).

Central Alarm Panel Test – A15

Hospital:	……			Test by:	……
Project No:	……	Date:	……	Witnessed by:	……

Alarm Panel Location: ……

Service	1	2	3	4	5	6	7	8	9
Oxygen									
Nitrous Oxide									
Nitrous Oxide/Oxygen (50/50)									
Medical Air 4 Bar									
Surgical Air 7 Bar									
Medical Vacuum									

List of tests:

1. for central alarm panels, check that the operation of the mute switch cancels the audible alarm and converts the flashing signals to steady;
2. for repeater alarm panels, check that the mute switch cancels the audible only, and that the flashing signals are converted to steady via the central alarm panel;
3. for area alarm panels, check that the operation of the mute switch cancels the audible only;
4. check power failure operates red system fault indicator and audible;
5. check that a contact line fault operates the system fault indicator, the alarm indicator and the audible;
6. check communication/wiring faults between central and repeater alarms operate the system fault indicator and audible;
7. check audible reinstatement for each alarm panel;
8. check that the audible can be continuously muted via operation of the internal push-button for gas service alarm condition only;
9. check for correct identification of each gas service on alarm panels.

Medical Gas Quality Tests– A21

Hospital:	……..	Date:	……..	Project No:	……..

Quality specifications for medical gas pipeline tests (working gases). This is to certify that medical gas systems have been tested in accordance with paragraphs 15.111 – 15.164as follows:-

Gas and Source	Particulate	Oil	Water	CO	CO_2	NO & NO_2	SO_2	Poly-test tube (optional)	Odour	Pass / Fail
Oxygen from bulk liquid or cylinders	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/l, atmospheric dew point -46^{0}C	≤5 mg/m^3 ≤5 ppm v/v	≤300 ppm v/v	-	-	No discolouration	None	
Nitrous Oxide	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/l, atmospheric dew point -46^{0}C)	≤5 mg/m^3 ≤5 ppm v/v	≤300 ppm v/v	≤2 ppm v/v	-	No discolouration	SAFETY Not performed	
Nitrous oxide / oxygen mixture	Free from visible particles in a 75 litre sample	-	≤67 vpm (≤0.05 mg/l, atmospheric dew point -46^{0}C	≤5 mg/m^3 ≤5 ppm v/v	≤300 ppm v/v	≤2 ppm v/v	-	No discolouration	SAFETY Not performed	
Medical and surgical air	Free from visible particles in a 75 litre sample	≤0.1 mg/ m^3	≤67 vpm (≤0.05 mg/l, atmospheric dew point -46^{0}C	≤5 mg/m^3 ≤5 ppm v/v	≤900 mg/m^3 ≤500 ppm v/v	≤2 ppm v/v	≤1 ppm v/v	No discolouration	None	
Dental compressed air	Free from visible particles in a 75 litre sample	≤0.1 mg/ m^3	≤1,020 vpm (≤0.05 mg/l, atmospheric dew point -20^{0}C	≤5 mg/m^3 ≤5 ppm v/v	≤900 mg/m^3 ≤500 ppm v/v	≤2 ppm v/v	≤1 ppm v/v	No discolouration	None

Medical Gas Pipeline System – Completion Certificate – A22

Hospital:	……	Client:	……
This is to certify that the following tests have been performed.			
Mechanical Carcass and Functional tests:		Forms A2 to A19 inclusive	
Quality and gas identity tests:		Forms A20 to A21 inclusive	
Validation of MGPS Design: The tests have been performed in accordance with Scottish Health Technical Memorandum 02-01 Part A Section 15, and that the test results are satisfactory.			

Contract Supervising Officer (MGPS) / Authorised Person (MGPS)

Appendix B: Gas pressure variation with temperature

General

1 Tests are specified for leakage of the pipeline carcass and the pipeline systems. During these tests, pressure changes may occur that are caused by temperature changes rather than leakage.

2 Pressure changes due to temperature difference may be calculated according to the Gas Laws (see the 'Glossary' in Part B).

3 It is assumed that the temperature in the pipeline is uniform in all branches. If substantial runs are external, an average temperature should be chosen.

Calculation

4 The change in gas pressure with temperature is as follows:

$P_1/T_1 = P_2/T_2$

where:

P_1 = the initial absolute pressure of a fixed volume of gas;

P_2 = the final absolute pressure of a fixed volume of gas;

T_1 = the initial absolute temperature;

T_2 = the final absolute temperature.

Therefore:

$P_2 = (P_1 \times T_2)/T_1$. (1)

5 Care must be taken to express pressure and temperature in absolute values.

6 Pressure is normally expressed in "gauge" pressure: Absolute pressure = gauge pressure + atmospheric pressure.

7 Temperature is normally expressed in K.

Examples

8 The carcass of a surgical air pipeline is tested for leakage at a working pressure of 13.5 bar. The temperature is 13°C at the beginning of the test and 17°C at the end of the test:

P1 = 13.5 + 1.0 = 14.5 bar

© Health Facilities Scotland, a division of NHS National Services Scotland.

T1 = 273 + 13 = 286 K

T2 = 273 + 17 = 290 K.

9 Therefore, using Equation (1):

P2 = (14.5 x 290)/286

= 14.7 bar (absolute pressure)

= 13.7 bar (gauge pressure).

10 That is, gauge pressure should read 13.7 bar at the end of the test, assuming that no leakage has occurred.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix C: Pressure-drop test device

General

1 Special test devices are required to measure the pressure at specified flows at each terminal unit.

2 Suitable test devices are commercially available or may be constructed in accordance with the outline specification given below.

Measurement principle

3 Flow at a specified pressure may be measured either with a calibrated orifice or with a flowmeter.

4 Pressure may be measured with a bourdon gauge.

5 A gas-specific probe conforming to BS5682:1998 should be used to connect the device to the terminal unit.

6 The test device is connected to the terminal unit by the gas-specific probe and the pressure at the specified flow is read on the gauge.

Functional requirements

7 The test device should consist of the following components:

- gas-specific probe to BS5682:1998;
- body on/off valve pressure gauge;
- orifice or flowmeter.

8 The body may be of a design that allows exchange of the following components:

- gas-specific probes;
- calibrated orifices;
- pressure gauges.

9 An on/off valve may be incorporated into the body.

10 The complete assembly should be tested for leaks.

Orifices

11 The orifices should be selected from the information on the manufacturer's data sheets or from practical testing.

© Health Facilities Scotland, a division of NHS National Services Scotland.

12 These devices should be checked against a flowmeter before use.

Flowmeter

13 A bobbin flowmeter calibrated to a flow of 40 litres/min may be used to measure flow under vacuum.

Pressure gauge

14 A 50mm bourdon gauge with an appropriate full scale reading and interval should be used as follows:

Test pressure kPa	Scale	Scale interval
400	0-7 bar	0.1 bar
700	0-11 bar	0.5 bar
Vacuum	0-100 kPa(0-760 mmHg)	5 kPa /50 mmHg
1 bar = 100 kPa approximately		

Table C1: Test pressure gauge scales

Note 82: Generally it is found that three separate test devices for 400 kPa, 700 kPa and vacuum provide greater convenience. Because the test methodology in Section 15 has the potential for exposing the 400 kPa and vacuum devices to pressure or vacuum, it is desirable that they include an appropriate directional check valve.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix D: Membrane filter test device

General

1 The function of this test device is to collect particulate material which may be present in the pipeline.

2 Filter holders appropriate to the pressure encountered are commercially available.

3 The filter holder should be specified for use at pipeline-distribution pressure and be oxygen-compatible.

Measurement principle

4 A known volume of gas is passed through a membrane filter that will collect all visible particles.

5 Hydrophobic membrane filters of pore size 0.45µm should be used.

Test equipment

6 The following equipment is required:

- a membrane filter holder;
- a supply of white hydrophobic membrane filters of not more than 0.45µm pore size and with high mechanical strength;
- a means of connecting the filter to the pipeline;
- a means of controlling the flow through the filter, which is connected downstream of the filter. One method of achieving this is to use the appropriate Amal jets to achieve a minimum flow of 150 litres/min at 400 kPa and 350 litres/min at 700 kPa;
- all equipment must be oxygen-compatible and hoses should be antistatic.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix E: Equipment for contaminant testing

General

1 The function of these tests is to establish whether the pipeline has been contaminated during construction or modification. The specifications for the permissible concentrations of each component are summarised in Table 29.

2 Simple equipment that is of the required sensitivity and is suitable for use on site is commercially available.

Measurement principle

3 A known volume of gas is passed through a tube packed with an absorbent, which is coated with specific colorimetric reagents. The reagents react quantitatively with the compound to be measured and produce a colour change along the length of the tube, which is proportional to the concentration of the compound being measured.

4 Tubes are available with appropriate sensitivities for the measurement of oil, water, carbon monoxide and carbon dioxide, sulphur dioxide, and higher oxides of nitrogen.

Note 83: Non-agent-specific detector tubes are difficult to interpret and are not recommended because of their qualitative and non-quantitative response.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix F: Equipment for gas identification

General

1 The function of these tests is positively to identify medical gases by measuring their oxygen, nitrous oxide and nitric oxide content.

2 Portable equipment of the required specificity and sensitivity is commercially available.

3 Thermal conductivity meters do not give a positive identification of nitrous oxide in the presence of carbon dioxide, and should not be used as a sole means of identification of nitrous oxide. A specific nitrous oxide meter should be used. If carbon dioxide pipelines are present, for example in IVF (in vitro fertilisation) clinics, a carbon dioxide detector tube should be used.

Specificity

Oxygen

4 Oxygen-specific sensors using different measurement principles are currently in manufacture. The oxygen sensor should not give greater than ±1% response in the presence of 100% nitrous oxide or 100% nitrogen.

Note 84: A paramagnetic meter is the specified instrument for identity of oxygen.

Nitrous oxide

5 The nitrous oxide sensor should not give greater than ±1% response in the presence of 100% oxygen, 100% nitrogen or 100% carbon dioxide. An infrared/fuel cell meter is now commercially available.

Specification

6 The equipment should be portable, preferably battery-powered, with digital or analogue indication of 0–100% to one decimal place. The battery should give at least eight hours' continuous running between recharging or replacement.

7 Accuracy better than ±1% is required, with a zero stability of 2.5% per day.

8 The response time must be not more than 15 seconds to 90% of the final reading.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix G: Pressure loss data

Pipeline pressure-drop calculations

1 Example: Calculate the pressure drop in a 15mm diameter pipe, 11m in length, with two 90o elbows, carrying medical air at a design flow rate of 800 litres/min.

Solution

2 The pressure drop Δp across the pipe can be calculated from the formula:

$$\Delta p = \frac{TL_{ACTUAL}}{L_{TABLEG1}} \times \left[\frac{Q_{ACTUAL}}{Q_{TABLEG1}}\right]^2 \times \Delta p_{TABLEG1} \qquad (2)$$

where:

Δp = Pressure drop across pipe section (kPa)

$\Delta p_{TABLE\ G1}$ = Pressure drop from Table G1 (kPa)

TL_{ACTUAL} = Measured length of pipe, plus total equivalent length for fittings, valve, etc. (m)

$L_{TABLE\ G1}$ = Nearest length of pipe from Table G1 (m)

Q_{ACTUAL} = Design flow (litres/min)

$Q_{TABLE\ G1}$ = Nearest flow from Table G1 (litres/min)

3 Total length of pipe including fittings.

TL = L + EL

Where:

L = Measured length of pipe (m)

EL = Sum off all fitting equivalent lengths from Table G6

TL = Total length

Therefore;

TL = 11 + (0.47 x 2)

TL = 11 + 0.94 = 11.94m

© Health Facilities Scotland, a division of NHS National Services Scotland.

4 From Table G1, the nearest length to 11.94m is 15m and the nearest flow rate to the design flow of 800 litres/min is 711 litres/min in the 15m column, at which there is a pressure drop of 21 kPa across a 15mm diameter, 15m length of pipe.

5 Using these values, Equation (2) gives a pressure drop across the pipe of:

$$\Delta p = \frac{11.94}{15} \times \left[\frac{800}{711}\right]^2 \times 21$$

Δp= 21.16 kPa

6 If this loss is unacceptable, use the next (higher) pipe size, that is 22mm. The nearest flow rate to 800 litres/min is now 1135 litres/min, representing a pressure loss of 7 kPa over 15m.

7 In this instance:

Note that due to the increase in pipe diameter the fitting equivalent lengths will change thus;

TL = 11 + (0.63 x 2)

TL = 11 + 1.26 = 12.26m

$$\Delta p = \frac{12.26}{15} \times \left[\frac{800}{1135}\right]^2 \times 7$$

Δp = 2.84 kPa

Table G6: Equivalent lengths (in metres) for copper fittings

8 It is possible to insert the above formula into a spreadsheet and use mathematical functions to calculate required pressure drops (see Tables G2-G5).

9 Another alternative is to derive graphs from the tables, although it may be necessary to draw several graphs, at different scales, to obtain accurate results.

10 The graphs of flow versus pressure drop provide a pressure loss per metre of pipe, not a total pressure loss. This figure must be multiplied by the length of the pipe in order to find the actual total pressure drop.

© Health Facilities Scotland, a division of NHS National Services Scotland.

11 Because a pipe and the fittings in the system cause frictional resistance to the gas flow, a pressure loss occurs that is greater than that which would occur if the gas were flowing through the same distance of straight pipe.

12 Each valve, fitting etc is allocated a “length” equivalent in frictional resistance to a straight piece of pipe of the same diameter. This length is hence known as the equivalent length of the fitting.

13 To calculate design pressure drops, the sum of the lengths of the straight runs of pipe plus the sums of the equivalent lengths of all of the fittings etc. in that run are added.

14 In practice many designers simply add 25–30% to the total measured length or use only 60–75% of the allocated pressure drop when sizing.

15 Equivalent lengths of some fittings are given in Tables G6 and G7.

Table G2: Pipeline pressure loss: 400 kPa (4 bar) pipelines

Examples:

1. 122m of 28mm pipe would carry 706 litres/min of free air per minute with a pressure loss of 0.07 bar (7 kPa), or 1287 litres/min with a loss of 0.21 bar (21 kPa). ie: $122/122 \times (706/706)^2 \times 7$
2. A flow of 1,200 litres/min in 122m of 28mm pipe would result in a pressure loss of 18.26 kPa. ie: $122/122 \times (1200/1287)^2 \times 21$
3. 140m of 28mm pipe would carry 800 litres/min with a pressure loss of 9.92 kPa. Ie: $140/152 \times (800/912)^2 \times 14$

Table G3: Pipeline pressure loss: 700 kPa (7 bar) pipelines

Examples:

1. 122m of 28mm pipe would carry 929 litres/min of free air per minute with a pressure loss of 0.07 bar (7 kPa), or 2232 litres/min with a loss of 0.34 bar (34 kPa).
2. A flow of 1,800 litres/min in 122m of 28mm pipe would result in a pressure loss of 22.11 kPa. i.e: $122/122 \times (1800/2232)^2 \times 34$
3. 140m of 28mm pipe would carry 1,100 litres/min with a pressure loss of 10.78 kPa. i.e: $140/152 \times (1100/1203)^2 \times 14$

Table G5: Pipeline pressure loss (vacuum)

Examples:

1. 122m of 28mm pipe would carry 71 litres/min of free air per minute with a pressure loss of 10 mmHg (1.3 kPa), or 187 litres/min with a loss of 50 mmHg (6.5 kPa). ie 122/122 x $(71/71)^2$ x 1.3
2. A flow of120 litres/min in 122m of 28mm pipe would result in pressure loss of 2.99 kPa. ie: 122/122 x $(120/137)^2$ x 3.
3. 140m of 28mm pipe would carry 90 litres/min with a pressure loss of 2.20 kPa. ie: 140/152 x $(90/94)^2$ x 2.6

Appendix H: Checklist for planning/installing/upgrading a cryogenic liquid supply system

1 Information given in this Appendix can be used to determine the need for a particular capacity or type of supply system. Many of the factors described will also apply to planning an upgrade to an installation by way of increase in system size or a change of system type.

2 Some factors that should be considered are outlined below.

Delivery frequency

- Does current frequency cause logistical problems for the supplier/your site?

Calculating consumption

- Consumption is rising at approximately 10% per annum. It doubles in seven years.
- Use pharmacy records for cylinder/liquid consumption. Look for peaks in demand, for example winter influenza epidemics.
- When average and peak flow rates are known, calculate the required size of the emergency supply.

Age of current system

- The secondary supply of older VIE systems will be a compressed gas cylinder manifold, which may have very limited capacity. Consideration should be given to either a single VIE plus fully automatic manifold or, preferably, a dual VIE system.

Siting of system and the site survey

- what planning restrictions apply (vessel size, noise etc)?
- what are convenient locations for cylinder/ liquid delivery?
- advantages of separating primary and secondary supplies, if space is available;
- will other facilities be lost/reduced, for example car-parking space?
- it will be less economical in terms of delivery charges and unit gas costs to deliver large loads (for example 20 tons) using rigid vehicles (maximum 12 tons). Articulated vehicles will deliver the largest loads but may require roadway/access modifications;
- cranage access for vessels;
- when choosing liquid cylinder systems, will adequate ventilation be available?

© Health Facilities Scotland, a division of NHS National Services Scotland.

- emergency supply location;
- pipeline protection and possible need for dual feeds;
- pipeline extension into other sites if applicable, for example two hospitals supplied from the same VIE system. There are possible insurance issues with this arrangement;
- modifications to the alarm system may have to be made;
- alarm panel + telemetry in waterproof enclosures;
- are alarms compatible with the existing system?
- alarm arrangement for dual (but separate) tank installations;
- cable ducts and trays: examine possible routes;
- possible need to move gates/fences to install new pipework;
- clearance of trees/building;
- sealing windows of adjacent buildings;
- position of frame for valve tree (fix to fence for rigidity?);
- position of emergency gate;
- position of fill couplings must allow driver to see tank gauges;
- cabling and alarm runs for the emergency supply manifold (ERM);
- availability and presentation of alarms for ERM;
- power and lighting during work;
- drainage – catch pits, diversions, pad resizing;

Costs

- Make sure a**ll** costs are allowed for, for example:
  - site inspection;
  - cost of continuing delivery using rigid and non-articulated vehicles;
  - gas charge/HCM (hundred cubic metres) and any inflation likely;
  - facility charges (rental);
  - delivery charge for equipment;
  - loan charges and changes in interest rate on any loan if the installer funds any part of the installation;
  - road/compound loans will be seen as £x added to gas price over y years;
  - climate change levy;
  - professional fees (consultancy);
  - planning permission;
  - building Regulations clearance;

© Health Facilities Scotland, a division of NHS National Services Scotland.

  - all civil engineering work;
  - quoted price for gas/facilities/delivery charges may be dependent on payment by direct debit;
  - introduction/modification and maintenance of services, for example lighting, power supplies, drainage;
  - engineering and pharmaceutical testing;
  - additional emergency provision and any associated cylinder charges;
  - modifications to alarm and telephone systems;
  - security;
  - charges for ERM cylinders during installation (may have to be charged and then recovered);
  - cranage charges;
  - contingency 10%
  - what, if any, commitment is required by the gas company?
- how will gas prices vary during this period?
- is there any agreement to provide, for example, modified roadway facilities if rigid vehicular deliveries are too frequent to be convenient to supplier? Or if such roadway modifications take place within a defined timescale, new rates etc may need to be negotiated;
- check defects liability (usually 12 months).

Emergency provision

- examine the vulnerability of current system and main feeds to hospital;
- consider minimum size of manifold plus cylinder storage to meet four-hour supply requirement. Is a second VIE a better option?
- operational requirements of ERM;
- protection/housing/security of ERM;
- alarm/monitoring systems and power supplies for ERM and its accommodation.

System shutdown during installation

- often it will be necessary to interrupt site supplies during connection of new plant. How will this be managed?
- disruption of two hospitals simultaneously if plant to be upgraded is supplying both sites;
- examine planned plant and pipework systems carefully to ascertain the best way of minimising downtime and facilitating engineering and pharmaceutical testing;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- while installing, fit extra valves to allow for future expansion and emergency supply manifolds to protect vulnerable parts of the system;
- fit NIST fittings wherever this will facilitate system purging;
- fit test points/emergency inlet ports as recommended in this guidance or investigate any likely requirement for additional (local) manifolds to support high-dependency areas.

Paperwork

- site survey details;
- register of contractors with contact names/ telephone numbers;
- keep a record of all dates, for example:
  - tender invitation;
  - tender open;
  - tender close;
  - award and regret letters to tenderers;
- copies of all letters to/from contractors;
- NICEIC (National Inspection Council for Electrical Installation Contracting) test certificate for electrics;
- validation and verification results (engineering and pharmaceutical);
- Health and Safety policies of contractors;
- method statements from contractors;
- insurance agreement with gas supplier for VIE system(s);
- MGPS operational policy protocols.

Health and safety

- Health and Safety policy (contractors and their employees, and subcontractors and their employees, must comply when employed by the trust and working on trust properties);
- inform contractors of specific site hazards;
- Hazard notices on site and on final installation;
- lighting during installation and for completed compound;
- road markings and signage.

Preparation

- carefully plan phasing of building work to maximise efficiency of installation programme. (Remember concrete plinths will take three days to harden before vessels can be sited.);

© Health Facilities Scotland, a division of NHS National Services Scotland.

- plan phasing of engineering and QC testing to avoid wasting APs'/QCs' time;
- consider methods of maintaining supplies during essential shutdowns. Cylinder supplies may be needed during commissioning. Gas supplier may be able to arrange multi-cylinder pallets;
- road base preparation, if required, must be completed in an early phase of the work to allow necessary access for cranes and, eventually, delivery vehicles;
- road surfacing/kerbing/drainage/lighting;
- retaining walls around compound if required, for example on sloping sites;
- maintaining rights of way;
- oxygen compound civil engineering work;
- if you are changing supplier, your original supplier will need to remove old equipment before plinth can be extended to fit new vessels;
- electrics for alarms, tank, lighting and, possibly, vehicle pump;
- floodlighting and telephone line;
- plan vehicular parking during (and after) work;
- the old plinth may require skimming to provide a reasonable surface.

Installation

- if an ERM (as a third means of supply) is installed first, this can be used to supply the hospital system during vessel replacement;
- decide who arranges emergency cylinder supplies for ERM. When plinth extensions are required, specify oxygen-compatible sealant for gaps between old and new plinth sections;
- remember to post health and safety notices during the work;
- alarm systems will not be fully functional until system is fully commissioned. Therefore, all staff must be kept aware of the different alarm situation;
- concrete will need two to three days to harden on any pad extension;
- the first vessel filling is a very noisy procedure with much vapour and can take several hours (consider restrictions);
- concrete sample testing will be required during new plinth construction;
- use temporary steel sheeting to support a new vessel on tarmac alongside the plinth;
- access for cranage must be kept open (car parking control);
- drainage (may have to move existing drains/ soakaways and create new pipe runs; remember oxygen separation distances);
- road markings and signage;
- possible new kerbs/footpaths;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- electrical supplies: single phase can be used for lighting, alarms etc but a three-phase 60 A supply will be needed for delivery vehicle pump if appropriate;
- earth bonding/lightning protection for fences;
- alarm interface/telemetry boxes at a sensible height for viewing;
- lagging of liquid lines;
- if using 200 bar unregulated cylinders for supply during installation or on ERM, take care that they are not mixed up with 137 bar cylinders;
- proximity of flammables and vital services during installation – vulnerability to mechanical damage (cutting discs, etc.), welding and cutting flames/sparks;
- power and lighting supplies during work;
- water supply (washing and concrete) during work.

Follow-up

- routine maintenance and monitoring of complete installation;
- cylinder changes and stock management for ERM;
- establish system management arrangements for vessels supplying more than one site (see Part B, Appendix G);
- update MGPS operational policy and any relevant insurance policies.

Appendix J: Upgrading surgical air systems

Background

1. An increasing number of surgical air pipeline systems are designed to operate at a line pressure above the nominal 700 kPa, for example 1,000 – 1,100 kPa. This enables the system to deliver 350 litres/min (at 700 kPa) at the front of the surgical air terminal unit.

2. Such a system will comprise a high-pressure supply pipeline installation, in the order of 1,000–1,100 kPa and local pressure regulation (for example adjacent to the operating suite) such that the maximum static pressure does not exceed 900 kPa.

3. Existing Health Technical Memorandum 22 systems run at a line pressure of 700 kPa and will provide a flow of 250 litres/min at the front of the terminal unit.

4. Users must be made aware (preferably by written report) that such systems will not meet the demands of some modern air tools and that use of such tools may result in both a lack of tool performance and frequent low-pressure alarms on the surgical air system.

5. Tools are available that require a flow up to 500 litres/min at an operating pressure of 1,400 kPa. Such tools will require discrete cylinder supplies.

Modifying “old” systems

6 Increasing line pressure to meet the latest recommended flow rates is often proposed, but needs to take account of the following:

- **is the compressor receiver suitable for use at the proposed pressures?** A typical “old” 700 kPa system will employ a receiver operating at typically 10 bar pressure. A “new” system, with a typical line pressure of 10.5 bar, requires a receiver operating at a typical pressure of 13 bar. Ensure that the test, design and working pressures of the current receiver are acceptable, and that the capacity of the receiver is appropriate to the new demand;
- **is the compressor plant capable of meeting the increased duty cycle?** Overheating and premature plant failure may result if this is not the case. The system may be supplying both surgical and medical air. Plant failure/flow reduction resulting from an overburdened surgical air system may have serious consequences in terms of medical air provision, particularly as this is the recommended driving gas for patients’ ventilators;
- **are the pressure safety valves (PSVs) suitably rated?** PSVs on pipelines and the receiver will need to be changed to meet the new operating conditions. Certificated replacement PSVs should be used;
- **Are pressure switches suitably rated and adjusted?** Pressure switches on plant and pipelines will need to be changed or adjusted accordingly;

© Health Facilities Scotland, a division of NHS National Services Scotland.

- **has the pipeline been suitably pressure-tested?** There may be occasions when existing 4 bar systems (or parts thereof) are proposed for use at 7 bar or higher. 4 bar systems are only tested to 10 bar; they will need to be retested at 18 bar to ensure a leak-free high-pressure system;
- **will you still be insured?** If the pipeline system contains large diameter pipe (120mm or above), the insurance company should be consulted to ascertain whether the system would be capable of withstanding not only the pipeline operating pressure but also any test pressure that may be applied during system refurbishment or extension. A new Written Scheme of Examination will have to be prepared for the new system;
- **labelling.** Ensure that all relevant labels are in place before the system is accepted;
- **other issues.** There may be other system defects discovered during the upgrading process, for example lack of pipeline support/protection. There may also be a potential contamination issue resulting from the transfer of particulate matter from older, silver-soldered systems into new inert gas shield brazed pipework, although it should be noted that this is not an issue limited to air systems. These issues will need to be addressed before the system is accepted for use. Ensure that any system amendments and changes in working practices are documented in the MGPS operational policy.

Appendix K: Signage requirements

Location	Wording	Notes
Plantroom	Medical Gas Plant Room – No unauthorized Entry	Adjacent to or on external door
	Fire action	On door/wall External or internal
	Keep locked	On door(s)
	Noise Hazard (+ ear defender symbol) Electric shock hazard Permit-to-work must be used	Adjacent to, or on, external door
	Plant is connected to essential electricity supply	"E" symbols can be used on switches etc
	Danger 400 Volts	On plant/switchgear
	Danger 240 Volts	On plant/switchgear
	Danger rotating machines Warning: These machines stop and start automatically without warning Guards must be in position Do not isolate without a Permit	Posted adjacent to plant
	Biological symbol	Vac filters and exhausts Also for AGSS units/exhausts/drain Flasks
	Medical air intake Do not obstruct	On external intakes only
	Emergency Tel No Gas Supplier Estates Pharmacy Porters	External wall
	Health and Safety Law	Internal wall
	First aid	Internal wall

Table K1: General Plantroom Signage

Notes applicable to Table K1: "Bacteria filter change procedure" sign is not available commercially and will have to be made locally.

No "Danger medical gas/vac/AGSS exhaust" sign is commercially available but "Danger explosive gases, no smoking, no naked lights" is available and would suffice.

"Danger 400/240 Volts", "Warning: These machines stop and start automatically/without warning" and "Biohazard" labels would need to be added to AGSS plant remote from main plantroom, plus any relevant plantroom notices.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Location	Wording	Notes
Manifold room	Medical gases manifold room – No unauthorised entry	Adjacent to or on external door
	No parking	Adjacent to or on external door
	Approved personal protective equipment must be worn	Adjacent to or on external door
	Fire action	Internal/external wall
	Cylinder status tag	On manifold cylinders
	Valve open	On line valves/ERM cylinders
	Valve closed	On line valves/ERM cylinders
	Make sure cylinders are secure at all times	Internal, near cylinders
	Danger No smoking	External (on door or wall)
	Danger compressed gas	External (on door or wall)
	Warning oxidizing agent	External (on door or wall)
	Danger oxygen	External (on door or wall)
	Emergency Tel No Gas suppliers Estates Pharmacy Porters	External (on door or wall)
	Keep locked	On door

Table K2: Manifold Room Signage

Notes applicable to Table K2: Also required:

Cylinder ID charts, manifold cylinder change procedure, emergency manifold operating procedure.

Check with fire officer for any local fire brigade requirements for fitting “HAZCHEM” signs e.g. “HAZCHEM 2SE Cylinders”

© Health Facilities Scotland, a division of NHS National Services Scotland.

Location	Wording	Notes
Main cylinder store	Medical gases cylinder store – No unauthorised entry	Adjacent to or on external door
	No parking	Adjacent to or on external door
	Keep loading bay/doors clear	Adjacent to or on external door
	Approved personal protective equipment must be worn	Adjacent to or on external door
	Make sure cylinders are secure at all times	Adjacent to cylinders
	Fire action	Internal/external wall
	Full cylinders	On bays
	Empty cylinders	On bays
	Emergency exit keep clear	May be already fitted
	Danger No smoking	On door
	Danger compressed gas	On door
	Warning oxidizing agent	External (on door or wall)
	Danger oxygen	External (on door or wall)
	Emergency Tel No Gas suppliers Estates Pharmacy Porters	External wall
	Keep locked	On door
	Push bar to open	Emergency exit and main door(s)

Table K3: Main Cylinder Stores

Notes applicable to Table K3: “Danger liquid nitrogen” sign is available for a separate liquid nitrogen store (see BCGA CP30).

Cylinder ID chart(s) to be posted

Check with fire officer for any local fire brigade requirements for fitting “HAZCHEM” signs e.g.

“HAZCHEM 2SE Cylinders”.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Location	Wording	Note
Ready to use cylinder store	Medical gases cylinder store – No unauthorized entry	Adjacent to or on external door
	Make sure cylinders are secure at all times	Adjacent to cylinders
	Emergency Tel No Gas suppliers Estates Pharmacy Porters	External wall
	Danger No smoking	On door
	Danger compressed gas	On door
	Fire action	Internal/external wall

Table K4: Ready to Use Cylinder Stores

Notes applicable to Table K4: Post cylinder ID chart(s) and cylinder change procedure.

Check with fire officer for any local fire brigade requirements for fitting "HAZCHEM" signs, eg "HAZCHEM 2SE Cylinders"

Location	Wording	Notes
Ward (Cylinder parking bay)	Medical gas cylinder parking area	Defines cylinder parking as per new Scottish Health Technical Memorandum
	Emergency Tel No Gas suppliers Estates Pharmacy Porters	External wall
	Gas leak action	On nurses' station

Table K5: Ward cylinder parking bay

Notes applicable to Table K5: Post cylinder chart(s) and cylinder change procedure.

Operational policy may dictate posting of AVSU emergency operation and MGPS alarm responses.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Location	Wording	Notes
Work area	Maintenance in progress	There may be other site safety notice requirements to fulfil
	Medical gas test area	
	Confined space	
	Hot work in progress	
	Danger pressure test in progress	
	Danger nitrogen purging in progress	

Table K6: Medical equipment workshop (EBME)

Notes applicable to Table K6: These signs should be posted during installation/modification/maintenance of an MGPS. Multiple signs may be required.

Location	Wording	Notes
Pipework	Gas identity	
	Flow direction	

Table K7: Pipeline identification

Location	Wording	Note
Line Valves& Lockable Valve Assembly	Gas identity	On pipeline label
	Flow direction	
	Valve No	Sequential number system
	Key No	

Table K8: Line Valve & Line Valve Assembly identification

Location	Wording	Notes
AVSUs	In emergency break glass and shut off valve	On/off positions to be shown on AVSU body
	Gas identity	
	Flow direction	
	Area controlled	
	Key No	
	Valve No	Sequential number system

Table K9: AVSU identification

Appendix L: Important notes for use of medical vacuum and anaesthetic gas scavenging

Infectious disease units

1 Medical vacuum should neither be extended to an Infectious Diseases Unit (IDU) nor provided to such a unit from a central vacuum system.

2 Portable suction units will be required. Decontamination will require specialised protocols and the advice of the infection control officer should be sought.

Note 84: Systems already exist whereby an IDU is, by local agreement, serviced via a central vacuum system. If such agreements exist, or are to be accepted, great care must be taken to ensure that the exhausts of such a plant are kept well away from all air intakes and the plant is labelled to indicate its function. Ideally, the plant should be housed in separate accommodation but, where this is not possible, safety signage and strict operational protocols are extremely important. Personnel changing filters, or carrying out work on such a system, should wear personal protective equipment and follow protocols that have been devised in liaison with the infection control officer.

Laser/surgical diathermy smoke extraction

3 An additional contamination hazard can arise if smoke from procedures employing laser or surgical diathermy equipment is exhausted using a cannula attached to the vacuum system.

4 Clinical staff should be advised against this practice and either instructed to use dedicated laser smoke removal units (incorporating dedicated, filtered, portable vacuum pumps) or a specially designed laser smoke filter fitted to a medical vacuum system terminal unit.

Dental vacuum systems

5 Medical vacuum systems operate at relatively low flow rates at the terminal units (~40 litres/min). Such flows are unsuitable for use as dental vacuum, which operates at much higher flow rates (typically 300 litres/min). Medical vacuum systems should not be used to provide dental vacuum.

Anaesthetic gas scavenging (AGS)

Active AGS systems (medical)

6 Active anaesthetic gas scavenging systems operate at relatively high flow rates (80–130 litres/min in a BS6834:1987 system; and 50–80 litres/min in a BS EN ISO 7396-2: 2007 system).

7 It is unlikely that receiving systems designed for use with these scavenging systems will operate correctly with a medical vacuum system. Severe spillage of

© Health Facilities Scotland, a division of NHS National Services Scotland.

waste gases into the operating area may occur. Therefore, medical vacuum systems should not be used as waste anaesthetic gas disposal systems.

Active AGS (dental)

8 Active AGS systems for use with dental nasal scavenging masks operate by maintaining a flow of air through the outer layer of a specially designed concentric nose mask. Waste gases from the patient pass from inner to outer layers of the mask and are carried away to the exhaust termination by this air stream.

9 The flow rate necessary to achieve effective removal of waste gases by such a method is in the order of 45 litres/min, which is less than the flow rate achieved at a dental vacuum system terminal.

10 Active dental scavenging systems using this type of mask must therefore be driven (via a special flow adjuster) from the dental vacuum system, a dedicated separate high-flow vacuum system, or an active medical AGS system. In the case of a medical AGS system, the special flow adjuster would be plugged directly into an AGS system wall terminal. A receiver (air break) system would not be used between the wall terminal and the special flow adjuster.

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix M: Oxygen usage data

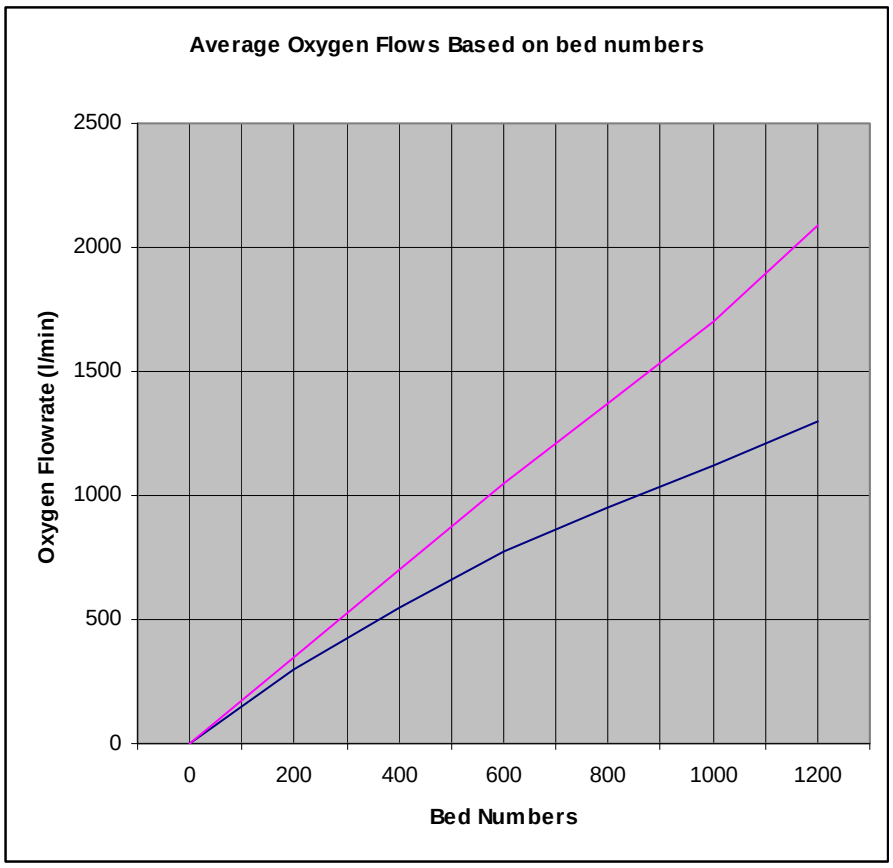

Figure M1: Oxygen usage nomogram

Lower graph shows average flows to be expected in a typical acute hospital.

Upper graph shows flows to be expected when the hospital has specialties using larger amounts of oxygen, e.g. those with multiple large critical care areas (>20 beds) and an increased use of CPAP (>5 machines).

NB. These graphs are issued for guidance only. There will be hospitals for which average flows will, for a given number of beds, be higher or lower than the maxima and minima shown here.

NB. The flows are representative of oxygen provided from a VIE plant and do NOT take into account additional consumption from compressed gas cylinders.

Table N1: Pressure conversion table

© Health Facilities Scotland, a division of NHS National Services Scotland.

Appendix O: Pressure testing procedure

The following provides guidance in relation to the safe procedures related to pneumatic pressure testing of medical gas pipelines. The guidelines are based upon the Health and Safety Executive guidance note GS4; 1998. Note that the appropriate method statements and risk assessments should always be prepared for all pressure testing. All necessary safety warning signs should be posted throughout the test area. All unauthorised personnel should vacate all areas under test.

First Fix Pressure Test

Prior to First Fix test being carried out a leak test should be performed; all pipeline ancillaries which can be affected by the higher pressures should be removed or blanked, e.g. safety valves, pressure switches.

First fix pressure tests should be carried out in the following manner:

1. An initial leak test pressure should be set at no more than 100 kPa. This test should allow significant leaks to be detected and rectified prior to the main pressure test.

2. The pressure should be increased gradually over a period of time, e.g. 200 kPa increments and leave for 10 minutes, while monitoring the pressure reading. If the pressure drops during this period, retest for leaks.

3. If the pressure is stable, continue to increase to the agreed test pressure, leave for 1 hour as indicated in 15.51 and 15.52.

4. The test pressure(s) and temperature(s) should be witnessed by the Authorised Person (MGPS) or CSO at the start and at the end of the test period with all necessary test sheets completed and signed.

5. The pressure should be reduced in a safe manner to a maximum pressure of 100 kPa, or to the pressure agreed on the particular site.

Service	Test Pressure	Pressure Drop (max)	Timescale
Oxygen	10 bar / 1,000 kPa	0.2 kPa	1 hour
Nitrous Oxide	10 bar / 1,000 kPa	0.2 kPa	1 hour
Nitrous Oxide/Oxygen (50/50)	10 bar / 1,000 kPa	0.2 kPa	1 hour
Medical Air 4 Bar	10 bar / 1,000 kPa	0.2 kPa	1 hour
Surgical Air 7 Bar	18 bar / 1,800 kPa	0.5 kPa	1 hour
Surgical Air 9 Bar	18 bar / 1,800 kPa	0.5 kPa	1 hour
Medical Vacuum	5 bar / 500 kPa	0.2 kPa	1 hour
AGSS	70 kPa	10 kPa	15 mins

© Health Facilities Scotland, a division of NHS National Services Scotland.

Second Fix Pressure Test

Second fix pressure tests should be carried out in the following manner:

1. All pipeline ancillaries such as; terminal units, pendant hoses, pressure switches, etc. should be connected and tested for leakage in the same manner as indicated in 1st fix Pressure Test procedure item 1.

2. The pressure should be increased gradually over a period of time, e.g. 200 kPa increments and leave for 10 minutes, while monitoring the pressure reading.

3. If the pressure drops during this process, retest for leaks.

4. If the pressure is stable, continue to increase to the agreed test pressure, leave for 1 hour as indicated in 15.62 and 15.63.

5. The test pressure(s) and temperature(s) should be witnessed by the Authorised Person (MGPS) or CSO at the start and at the end of the test period with all necessary test sheets completed and signed.

6. If the remaining functional tests are not to be performed immediately after the 2nd fix pressure test, the pressure should be reduced in a safe manner to a maximum pressure of 100 kPa or to the pressure agreed on the particular site.

7. The pressure for each service should be monitored over the period until the pipelines are to be set to working pressures for functional tests.

Service	Test Pressure	Pressure Drop (max)	Timescale
Oxygen	4 bar / 400 kPa	0.1 kPa	1 hour
Nitrous Oxide	4 bar / 400 kPa	0.1 kPa	1 hour
Nitrous Oxide/Oxygen (50/50)	4 bar / 400 kPa	0.1 kPa	1 hour
Medical Air 400 kPa	4 bar / 400 kPa	0.1 kPa	1 hour
Surgical Air 700 kPa	7 bar / 700 kPa	0.5 kPa	1 hour
Surgical Air 900 kPa	9 bar / 900 kPa	0.5 kPa	1 hour
Medical Vacuum	450 – 700 mmHg	1 kPa / 7.5 mm Hg	1 hour

1. Introduction

1.1 Scottish Health Technical Memorandum 2027; *Hot and cold water supply, storage and mains services,* is published in four separate parts. It is equally applicable to both new and existing sites and gives comprehensive advice and guidance to healthcare management, design engineers, estate managers and operations' managers on the legal requirements, design applications, maintenance and operation of hot and cold water supply, storage and distribution systems in all types of healthcare premises.

1.2 Current statutory legislation requires both "management" and "staff" to be aware of their individual and collective responsibility for the provision of hot and cold water supplies, storage and distribution in healthcare premises.

1.3 Healthcare premises are dependent upon water to maintain a safe and comfortable environment for patients and staff, and for treatment at all levels of clinical and surgical care.

1.4 The development, construction, installation and maintenance of hot and cold water supply systems are vital for public health. Water quality is influenced by political, environmental and technical issues. It is governed by legislation, water byelaws, building regulations, approved codes of practice and technical standards intended to safeguard quality.

1.5 Interruptions in water supply can disrupt healthcare activities. The design of systems must ensure that sufficient reserve water storage is available to minimise the consequence of disruption, while at the same time ensuring an adequate turnover of water to prevent stagnation in storage vessels.

1.6 While some guidance on the water services applications mentioned below is given in this memorandum, reference should be made to:

laundry – see Health Building Note 25; Health Building Note is suitable for use in Scotland subject to the amendments contained in the Management Executive Letter MEL 94/108

sterile supply departments – see Health Building Note 13; Scottish Hospital Planning Note 13 issued with MEL 94/63

hydrotherapy pools – see Public Health Laboratory service booklet, *Hygiene for Hydrotherapy Pools.*

SHTM 2040; *The control of legionellae in healthcare premises – a code of practice* should be consulted for guidance on the prevention of legionnaires' disease.

NHSScotland Property and Environment Forum

2. Management responsibility

Management accountability

2.1 Management has the overall responsibility for implementing procedures to ensure that reliable hot and cold water supply, storage and distribution systems operate within the organisation.

2.2 These procedures should demonstrate that any person on whom the statutory duty falls has fully appreciated the requirement to provide an adequate supply of hot and cold water of suitable quality. Though compliance with this guidance may be delegated to staff, or undertaken by contract, accountability cannot be delegated.

2.3 Regular assessments should be made at least annually, using this guidance, to establish the extent of the risk. Shortfalls should be clearly recorded and the proposed control measures, with timescales, developed. A review should be undertaken whenever there is a substantial change in physical or environmental conditions.

2.4 The objective must be to institute management procedures to ensure that compliance is continuing and not notional. The prime purpose of the assessment is to be able to demonstrate that management has identified all the relevant factors, has instituted corrective or preventive action and is monitoring the plans being implemented.

2.5 This guidance should be applied to all healthcare premises, however small, where there is a duty of care under the Health and Safety at Work etc Act 1974.

ARCHIVE

Statutory requirements

2.6 It is the responsibility of management to ensure that their premises comply with all statutes.

2.7 Management (owners or occupiers) of healthcare premises have an overriding general duty of care under the Health and Safety at Work etc Act 1974. Therefore, they should ensure that the water supply, storage and distribution services can be provided within the terms of the following legislation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Health and Safety at Work etc Act 1974

2.8 Employers have a general duty, under the Health and Safety at Work etc Act 1974 to ensure, so far as is reasonably practicable, the health, safety and welfare of their patients, employees and visitors who may be affected by workplace activities.

2.9 These duties are legally enforceable and the Health and Safety Executive have successfully prosecuted employers including Health Authorities and Trusts under this statute. It falls upon owners and occupiers of premises to ensure that there is a management regime for the proper design, installation and maintenance of plant, equipment and systems. Failure to have a proper system of work and adequate control measures can also be an offence even though an outbreak of, for example, legionnaires' disease or other such incident has not occurred.

The Management of Health and Safety at Work Regulations 1999

2.10 These regulations require every employer to make a suitable and sufficient assessment of all risks to health and safety of employees and the public caused by work activities. In addition to legionella, other risks from a hot and cold water distribution system include deterioration of water quality, scalding at hot water outlets and danger due to bursting at excessive pressures.

Control of Substances Hazardous to Health (COSHH) Regulations 1999

2.11 In the context of hot and cold water supply, storage and mains services, these regulations apply to micro-organisms, such as legionellae and to the chemicals which may be used to control the growth of micro-organisms in water supply. Employers have a duty to assess the risks from exposure to these substances to ensure that they are adequately controlled.

Public Health (Infectious Diseases) (Scotland) Regulations 1975

2.12 These regulations require that a properly appointed officer shall inform the chief medical officer, of any serious outbreak of any disease which to his knowledge has occurred.

For further reference refer to: Public Health (Notification of Infectious Diseases) (Scotland) Regulations 1988, Public Health (Notification of Infectious Diseases) (Scotland) Amendment Regulations 1989. The Scottish Office, Department of Health, Advisory Group on Infection, Scottish Infection

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Manual. Guidance on core standards for the control of infection in hospitals , healthcare premises and at the community interface (1998).

Water Supply Regulations

2.13 The Water Supply (Water Quality) (Scotland) Regulations 1990 (as amended), apply to water supplied to any hospital which is used for domestic purposes such as drinking, washing or cooking. Two additional sources of advice on drinking water quality are:

a. the Director of Public Health;

b. the World Health Organisation 'Guidelines for drinking water quality' 1993.

2.14 The Private Water Supplies (Scotland) Regulations 1992 (Statutory Instrument 1992/574) cover private water supplies such as boreholes and wells.

Food Safety Act 1990

2.15 The Food Safety Act 1990 covers water used for food preparation or food manufacture and also includes water used for drinking. Food Safety (Temperature Control) Regulations 1995 will also apply as will the Food Safety (General Food Hygiene) Regulations 1995.

Approved Code of Practice

2.16 The Health and Safety Commission have published an, 'Approved Code of Practice (ACOP)' and the Health and Safety Executive have produced a guidance note (HS(G)70) entitled, 'The control of legionellosis including legionnaires' disease'. The onus is on management to demonstrate that procedures in place are as good as, or better than, those required by the ACOP.

2.17 Compliance with the guidance given in SHTM 2040 will satisfy the ACOP requirements for the control of legionellosis.

2.18 The health service, with responsibility for the wider aspects of public health and the operation of NHS in Scotland premises, is expected to be particularly vigilant. The number of outbreaks of legionnaires' disease is relatively small, but outbreaks are considered to be avoidable. Management must also acknowledge that incidents or outbreaks cause widespread concern, especially if associated with healthcare premises. Investigation of these outbreaks has shown that they are generally related to a breakdown in management systems. Design flaws and defects have also been implicated as the cause of some outbreaks.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.19 Hence, managers need to satisfy themselves by monitoring, that effective control procedures are being implemented. It is not sufficient merely to devise procedures.

Model Water Byelaws

2.20 All water authorities responsible for water supply have a statutory duty to enforce their byelaws for the prevention of waste, undue consumption, misuse and contamination of water supplied by them.

2.21 In 1989 new model water byelaws came into effect and these are set out, along with the water industry's interpretation of these provisions, in the 'Water Supply Byelaws Guide 1989'. The WRc (Water Research Centre) operates the Evaluation and Testing Centre which provides advice on byelaws on a national basis and administers the Water Byelaws Scheme which tests and lists water fittings and materials for compliance with the byelaws. The 'Water Fittings and Materials Directory' contains information on suitable fittings and materials and is updated every six months.

Building Regulations

2.22 Part P of Schedule 1 of the Building Standards (Scotland) Regulations 1990 provides the functional requirements for the unvented hot water storage systems.

Building Services Research and Information Association

2.23 Application Guide AG4/94 Guide to legionellosis - temperature measurements for hot and cold water services. A practical guide which sets out the main activities which are essential for compliance with the HS(G)70 guidance on water temperatures. Its principle on planning, measurement and site procedure are equally applicable to healthcare premises.

British Standards

2.24 BS 6700: 1997 is the British Standard specification for design, installation, testing and maintenance of services supplying water for domestic use within buildings and their curtilages.

2.25 BS 1710: 1984 is the British Standard specification for identification of pipelines and services.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operational management

2.26 Managers should ensure that an operational plan is in place for each site under their control. This document should comprise:

a. up-to-date drawings and descriptions of all the supply storage and distribution systems within those premises;

b. step-by-step instructions to operate, maintain, control and shut down the water supply, storage and distribution systems within those premises;

c. a schedule of possible emergency incidents causing loss of the water supply from the water authority. Each item in the emergency incident schedule should include guidance on operational procedures to re-establish a stable wholesome water supply. In re-establishing the water supply, input from the infection control team and the Consultant in Communicable Disease Control may be required.

2.27 A routine of staff training should be implemented by management on the systems' basic operational procedures, and also on those system procedures required during an emergency.

2.28 Only properly trained nominated persons should be appointed by management to control the operation of emergency equipment.

ARCHIVE

Designated staff functions

Management

2.29 Management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the safe operation of healthcare premises.

2.30 A person intending to fulfil any of the staff functions specified below should be able to prove that they possess sufficient skills, knowledge and experience so as to be able to perform safely the designated tasks.

Infection control officer

2.31 Infection control officer-or consultant microbiologist, if not the same person, nominated by the management to advise on monitoring infection control policy and for the maintenance of water quality.

Nominated person

2.33 A nominated person (water), possessing adequate professional knowledge and with appropriate training, should be nominated in writing by management to devise and manage the necessary procedures to ensure that the quality of water in healthcare premises is maintained. The person will be required to liase closely with other professionals in various disciplines.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

In addition, the person should possess a thorough knowledge of the control of legionellae and would ideally be a chartered engineer.

2.34 This person's role, in association with the infection control officer and maintenance staff, involves:

a. advising on the potential areas of risk and identifying where systems do not comply with this guidance;

b. liaising with the water authorities and environmental health departments and advising on the continuing procedures necessary to ensure acceptable water quality;

c. monitoring the implementation and efficacy of those procedures;

d. approving and identifying any changes to those procedures;

e. ensuring that equipment which is to be permanently connected to the water supply is properly installed;

f. ensuring that adequate operating and maintenance instructions exist and adequate records are kept.

2.35 Implementation of an effective maintenance policy must incorporate the preparation of fully detailed operating and maintenance documentation and the introduction of a logbook system. The "nominated person" should appoint a deputy to whom delegated responsibilities may be given. The deputy should act for the nominated person on all occasions when the nominated person is unavailable.

2.36 The nominated person should be fully conversant with the design principles and requirements of water systems and should be fully briefed in respect of the cause and effect of water-borne organisms, for example Legionella pneumophila. The appointment of an engineer as the nominated person is appropriate in that the responsibility can extend to the operation and maintenance of associated plant. It is recognised that the nominated person cannot be a specialist on all matters and must be supported by specialists in specific subjects such as water treatment and microbiology, but he/she must undertake responsibility for calling upon and co-ordinating the activities of such specialists.

Maintenance technician

2.37 A person who, in the opinion of the nominated person, has sufficient technical knowledge and the experience necessary to carry out maintenance and routine testing of the water, storage and distribution system.

Tradesperson

2.38 A person who is appointed in writing by the nominated person to carry out, under the control of the maintenance technician, work on the water, storage and distribution system.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Installer

2.39 A person or organisation responsible for the provision of the water, storage and distribution system.

Contractor

2.40 The person or organisation designated by management to be responsible for the supply and installation of hot and cold water services, and for the conduct of the installation checks and tests.

Contract supervising officer

2.41 The person authorised by the hospital management to witness tests and checks under the terms of contract. He/she should have specialist knowledge, training and experience of hot and cold water supply, storage and mains services and SHTM 2027.

Record keeping

2.42 Management should ensure that an accurate record of all assets relating to the hot and cold water distribution systems is set up and regularly maintained. They must also ensure that records of all maintenance, inspection and testing activities are kept up-to-date and properly stored.

Water economy and energy management

2.43 Managers should ensure that water economy and energy management policies are set up and adhered to. The requirements of such policies are briefly outlined in Chapter 4.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3. Description of systems

3.1 The following sections give a brief description of hot and cold water systems.

Source of supply

3.2 Normally, the source of water supply to a health building is by one or more service pipe connections from the mains of a water authority. If the quantity and rate of flow is inadequate, or if the cost of providing the service connection appears to be uneconomical, alternative sources of supply such as boreholes or wells may be investigated.

3.3 The feasibility of a private supply should be decided by comparing the capital and revenue costs with the long-term cost of water supplied from the statutory authority. Due consideration should be given to the long-term costs of a private supply and account should be taken of potential deterioration in water quality and/or capacity of the private supply source.

3.4 Provision should be included for alternative water supply arrangements to meet an emergency, regardless of the source or sources of supply finally adopted. Alternative arrangements would include the provision of a second service connection from the statutory water authority or a private supply. The water quality requirements applicable to the main supply apply also to any alternative supplies.

3.5 Physical interconnection of pipework and valves of a statutory water authority's supply with any private supply is normally prohibited by water byelaws in order to eliminate backflow from one supply into the other. The statutory water authority should be advised of the NHS need to use any private supply as well as the statutory water authority's supply, and advice should be sought on the limitations imposed in respect of break cisterns and interconnection thereafter.

3.6 All water intended for human consumption is required by legislation to comply with the quality standards laid down in the Water Supply (Water Quality) Scotland Regulations 1990. These regulations apply to water sampled at the point where the water is available for use and embrace not just drinking water but also water used for domestic purposes.

Water treatment

3.7 While potability is not normally affected by such characteristics as hardness, colour, and (within limits) smell and/or taste, a measure of treatment may be necessary to provide a more acceptable supply, for example to protect equipment from deterioration.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

3.8 Treatment may also be considered necessary where the water is to be used in humidification plant, steam boilers, laundries or other heating processes.

Water storage

3.9 Water is stored in large developments like health buildings for three basic reasons:

a. to provide reserve supply during failure of the source cold water supply to the development;

b. to reduce the maximum demand on the cold water main;

c. to provide accommodation for displaced cold feed water resulting from the expansion of any water subjected to heat.

3.10 The purpose for which the storage is used can vary, but this has only a minor effect on design. The range of uses is generally covered by the following:

a. cold water for drinking, washing and cooking;

b. cold water feed to hot water services;

c. treated cold water for laundries, heating, cooling, etc. when local supplies are unsuitable;

d. supplies to equipment or areas deemed to present a backflow contamination risk;

e. feed and expansion for heating service;

f. fire-fighting.

3.11 The water byelaws and BS 6700 specify minimum standards for cold water storage cisterns to ensure that the stored water is retained at a potable standard suitable for domestic use.

3.12 Guidelines on the prevention of legionnaires' disease (see SHTM 2040) must also be considered in relation to water storage.

3.13 In general terms, water storage should be designed such that stored water is regularly used and not allowed to stagnate. These aims would be realised by ensuring that the stored volume is no more than the volume of water used within the building on a daily basis. However, the storage capacity should be sized to cover a 12-hour interruption on the assumption that measures will be taken to minimise water usage during any prolonged disruption.

3.14 In the event of an interruption to the supply, staff should be informed of the need to economise on water use, so extending the duration of the stored supply.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.15 Storage cisterns should be located to minimise heat gains. To restrict microbiological growth it is important that the temperature of stored water is kept as low as practical, not more than 20°C.

Cold water distribution system

3.16 The design and installation of the cold water distribution system should comply with the water byelaws and BS 6700.

3.17 The design of the pipework should ensure that there is no possibility of a cross-connection between installations conveying potable water and installations containing non-potable water or water supplied from a private source. There should be no possibility of backflow towards the source of supply from any tank, cistern or appliance, whether by gravity backflow, back-pressure backflow or backsiphonage. A schematic drawing of a hot and cold water services distribution system can be found in Figure 1.

Hot water storage and distribution

3.18 Hot water services should be designed and installed in accordance with the water byelaws and BS 6700. The hot water system may be of either the vented or the unvented type.

3.19 The components of a hot and cold service system as used within hospitals are shown in Figure 1; some installations may have fewer, or additional, features or components.

3.20 A vented system usually consists of a cold water storage cistern situated above the highest outlets, which feeds a hot water storage vessel (for example a calorifier or direct-fired boiler).

3.21 An unvented system usually has the hot water storage vessel connected to the mains water supply via a pressure-reducing valve. The components of a directly-heated unvented hot water system are shown in Figure 2 .Refer to BS 7206: 1990, ‘Specification for Unvented hot water storage units and packages’.

3.22 The hot water taken from the top of the storage vessel will be circulated around the building in a piped distribution system. The individual outlets, taps, mixing valves or other outlet devices will be served from the distribution system.

3.23 Particular attention is drawn to the requirement to incorporate within the design, measures to ensure the water is retained in a wholesome condition. Guidance on the control of legionellae in healthcare premises is given in SHTM 2040. In order to ensure that the temperature of the water in the distribution system is within acceptable limits, a hot water secondary circulation will be required in which hot water is continuously circulated between the storage vessel and the various outlets. Alternatively, the

ARCHIVE

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

distribution system may be electrically trace-heated to maintain the required temperature in the pipework.

3.24 Recommendations regarding safe hot water and surface temperatures, given in Scottish Health Guidance Note, 'Safe hot water and surface temperatures', apply to all ward accommodation, residents' rooms and those areas to which patients, residents and visitors have free access (including public areas). Until the recommended precautions are put into effect, staff should be made aware of the potential danger and should take the necessary steps to protect patients, residents and visitors. Areas which do not meet these recommendations should be identified and plans to comply as soon as reasonably practicable should be devised. Reference should also be made to the Model Engineering Specification (MES) DO8 Thermostatic Mixing Valves (Healthcare premises).

Materials of construction

3.25 Systems should be in accordance with BS 6700 and BS 6920 and materials used in hot and cold water distribution should be listed in the latest edition of the Water Fittings and Materials Directory, published by the WRc.

NHSScotland Property and Environment Forum

Validation and verification

3.26 Pre-commissioning, commissioning and testing are activities that must be carried out once the hot and cold water systems have been installed or repaired, to ensure that the systems comply with the specification before handover.

3.27 Commissioning involves setting a static system into motion and adjusting the system so that it operates within specified tolerances.

3.28 Testing involves the checking of pipework, plant, equipment and controls to ensure that they operate within specified limits of temperature, pressure etc.

3.29 Further information on this subject can be found in Part 4 ‘Validation and verification’ of this SHTM.

Operational management

3.30 Operating staff need to be provided with the necessary operation and maintenance manuals and record drawings for any new or refurbished hot and cold water systems, clearly identifying what actions must be carried out to ensure that the system will operate as intended throughout its working life.

3.31 Operation and maintenance manuals should be produced in accordance with established guidelines.

3.32 Further information on this subject can be found in Part 3 ‘Operational management’ of this SHTM.

ARCHIVE

NHSScotland Property and Environment Forum

4. Management summary

General

4.1 The water supply, storage and distribution service should be periodically re-assessed by management and improved where necessary to ensure that it maintains an adequate water supply to the healthcare premises facilities.

4.2 Where new healthcare premises are to be built in separate phases, the water supply, storage and distribution service for the whole premises should as far as possible be planned and evaluated at the design stage. This will enable the total water supply requirement to be assessed in the planning stages, and appropriate areas of accommodation to be allocated.

4.3 Within this general guideline, the aim should be to keep water services as simple as practicable.

4.4 Where existing facilities do not meet the standards recommended in this SHTM, management should carry out a risk assessment which should involve the infection control team to establish the extent and priority of action required for compliance. Action must then be taken to meet standards recommended in this SHTM.

4.5 A procedure of routine checks to ensure a potable and adequate water supply is recommended in Part 2 'Operational management' of this SHTM. Managers should ensure that tests are done even if they cause minor disruption to hospital services.

Water management

4.6 A water management policy should be set up to define actions which should be taken to ensure that water is used economically and wastage is minimised. Such a policy should include the recommendations of the report of the Audit Commission for local authorities and the NHS entitled, 'Untapped Savings: Water Services in the NHS' and NHS Estates, 'A strategic guide to water and sewerage policy for general managers and chief executives'.

Energy management

4.7 An energy management policy should be set up to define actions which should be taken to minimise energy consumption. An effective maintenance plan will also contribute to minimising energy consumption. Further guidance is given in 'Encode' and 'A strategic guide to energy management for general managers and chief executives'.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

Maintenance

4.8 Management is ultimately responsible for the provision of a wholesome water supply in the premises under its authority. An effective maintenance policy will be instrumental in achieving this end.

4.9 Regulation 6 of the Provision and Use of Work Equipment Regulations 1998 requires that every employer shall ensure that work equipment is maintained in an efficient state, in efficient working order and in good repair. The employer's COSHH assessment should have identified maintenance, examination and control measures to reduce the risk from exposure to hazardous substances. Regulation 9 of COSHH requires those control measures to be implemented.

4.10 Planned maintenance can be divided into two distinct policies:

a. operate plant until failure occurs, where:
   (i) the consequences of failure will not create a safety hazard;
   (ii) the consequences of failure will not affect the business operation of the building occupants;
   (iii) the costs of repair/replacement are not excessive;
   (iv) the reaction to failure can be planned in advance;
b. preventative maintenance: this involves a series of inspections at regular intervals and monitoring operating parameters in order to avoid failure by implementing timely remedial work. Further information on this topic can be found in Technical Note TN14/92, 'Decisions in Maintenance' by the Building Services Research and Information Association (BSRIA).

Maintenance responsibility

4.11 Once a maintenance policy has been decided upon, a maintenance engineer must be given the responsibility for implementing it. Maintenance responsibilities include:

a. the provision of adequately trained and supervised manpower;
b. clear definitions of the equipment and services to be maintained, together with the procedures to be carried out on them;
c. monitoring of the quality of the work carried out to ensure that it is consistently acceptable;
d. the implementation of financial control procedures.

ARCHIVE

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Contract maintenance

4.12 The increasing complexity of building services equipment has resulted in a growing reliance on contractors for the provision of maintenance services. The decision to use either a contractor or direct labour must be taken in the light of local circumstances. BSRIA Application Guide 4/89 provides advice on aspects to be considered when obtaining contract maintenance. The guidance contained in PROCODE should also be implemented for the appointment of contractors.

Maintenance brief

4.13 The maintenance manager requires a brief from the management which sets out in a clear and unambiguous manner the following requirements:

a. scope of work;
b. budgeting – overall and single-item limits;
c. level of reliability;
d. response time required to correct faults;
e. criteria for quality of service;
f. reporting procedure;
g. accountability and responsibility;
h. energy-saving policy;
i. health and safety policy.

4.14 The above requirements are necessary regardless of whether the work is carried out by contractors or in-house staff.

ARCHIVE

Performance monitoring

4.15 This involves the inspection of systems and records at a frequency, and in such detail, as to enable management to form an opinion regarding compliance with the agreed criteria.

4.16 If a contractor is commissioned to carry out maintenance and in-house expertise is not available to monitor their performance, an independent professional adviser should be retained to carry out this function. Using another maintenance contractor in a monitoring role could lead to a conflict of interest. An appropriate consultant may be appointed and reference should be made to PROCODE for such an appointment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.17 A performance monitoring checklist follows:

a. Is the required level of service being met?
b. Is all the required plant being maintained?
c. Are environmental conditions being maintained?
d. Is maintenance carried out to the agreed standard?
e. Are proper replacement parts being used?
f. Are agreed spares being held on site?
g. Are records being correctly maintained?
h. Is the maintainer using the agreed standard of staff and number of staff, and making the agreed number of visits?
i. Is the plant being operated to achieve optimum energy usage?
j. Are health and safety requirements complied with?
k. Are only agreed sub-contractors being employed?
l. Are the client and typical users of the building satisfied?
m. Where maintenance is on a labour-plus-parts basis do invoices accurately reflect work carried out?
n. Are breakdowns occurring too often?
o. Is adequate consideration given to the potential environmental impact of contractors action, for example discharge of chlorinated water, discharge of water treatment chemicals either to river or sewerage systems?

Preface

About Scottish Health Technical Memoranda

Engineering Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of SHTM guidance remains on healthcare- specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle: Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Engineering Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

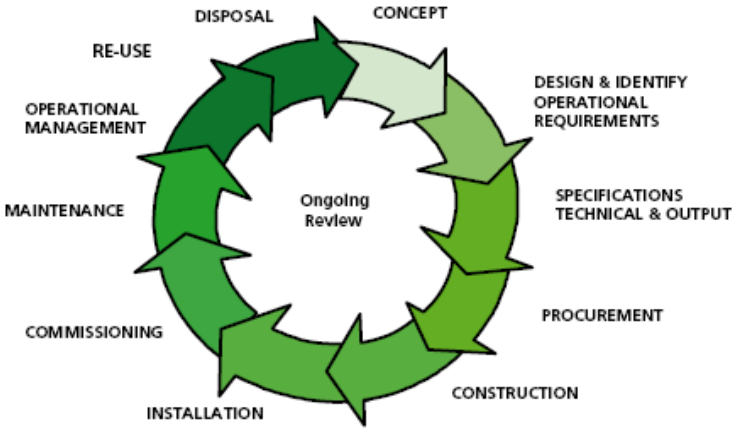
It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of nine subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.

© Health Facilities Scotland, a Division of NHS National Services Scotland



Healthcare building life-cycle diagram

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of nine core subjects:

Scottish Health Technical Memorandum 00 Policies and principles (applicable to all Scottish Health Technical Memoranda in this series)

Scottish Health Technical Memorandum 01 Decontamination

Scottish Health Technical Memorandum 02 Medical gases

Scottish Health Technical Memorandum 03 Heating and ventilation systems

Scottish Health Technical Memorandum 04 Water systems

Scottish Health Technical Memorandum 05 Reserved for future use

Scottish Health Technical Memorandum 06 Electrical services

Scottish Health Technical Memorandum 07 Environment and sustainability

Scottish Health Technical Memorandum 08 Specialist services

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent:

Electrical safety guidance for low voltage systems

In a similar way Scottish Health Technical Memorandum 07-02 will simply represent:

Environment and Sustainability – EnCO_2de.

© Health Facilities Scotland, a Division of NHS National Services Scotland

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

Health Facilities Scotland wishes to acknowledge the contribution made by professional bodies, engineering consultants, healthcare specialists and NHS staff who have contributed to the review.

Executive summary

Preamble

Scottish Health Technical Memorandum (SHTM) 2027: – 'Hot and cold water supply, storage and mains services' and SHTM 2040: – 'The control of *Legionella* in healthcare premises: a code of practice' have both been revised, and have, at the same time, been combined into this single document: SHTM 04-01 – 'The control of *Legionella*, hygiene, 'safe' hot water, cold water and drinking water systems'.

The guidance has been revised in line with changes to relevant regulations, standards and other guidance, and also technical developments.

SHTM 04 now supersedes SHTM 2027 and SHTM 2040 and absorbs information from Scottish Hospital Technical Note 6 – 'The safe operation and maintenance of thermostatic mixing valves' and Scottish Health Guidance Note – 'Safe' hot water and surface temperatures.

Introduction

The development, construction, installation and maintenance of hot and cold water supply systems are vital for public health. Healthcare premises are dependent upon water to maintain hygiene and a comfortable environment for patients and staff, and for clinical and surgical care.

Interruptions in water supply can disrupt healthcare activities. The design of systems must ensure that sufficient reserve water storage is available to minimise the consequence of disruption, while at the same time ensuring an adequate turnover of water to prevent stagnation in storage vessels and distribution systems.

This Scottish Health Technical Memorandum gives comprehensive advice and guidance to healthcare management, design engineers, estate managers and operations managers on the legal requirements, design applications, maintenance and operation of hot and cold water supply, storage and distribution systems in all types of healthcare premises. It is equally applicable to both existing and new sites whether procured conventionally (i.e. owned by the NHS) or via PFI/PPP funding. It is equally applicable to modifications and changes to existing premises and a risk assessment should be carried out to determine, highlight and record where it may not be reasonable or technically possible to implement the SHTM 04-01 guidance.

©Health Facilities Scotland, a division of NHS National Services Scotland

Aims of this guidance

This guidance has been written to:

- provide an overview for developing and maintaining a risk register;
- provide information on thermostatic mixing valve configurations, usage and maintenance requirements;
- outline how quality and hygiene of water supply can preserve system components and safe use by occupants;
- provide a point of reference to legislation, standards and other guidance pertaining to water systems;
- provide a basic overview of possible bacterial contaminants;
- outline key criteria and system arrangements to help stop bacteria proliferating;
- give an overview of some of the different water systems components and their safe installation and operation;
- provide typical system layouts and individual component location;
- illustrate the importance of 'safe'delivery of hot water;
- illustrate temperature regimes for sanitary outlets used in healthcare premises to reduce risk of occupant injury;
- identify key commissioning, testing and maintenance requirements for referral by designers, installers, operators and management.

Recommendations

In healthcare facilities, there is a risk of scalding for vulnerable patients, the very young, older people and mental health patients. Therefore, this guidance strongly recommends that thermostatic mixing devices should be considered for many hot water outlets. It is stressed that staff should not be discriminated against and hot water outlets throughout for staff use should also be fitted with thermostatic mixing devices unless otherwise recorded in a risk register. Safe water and delivery devices are summarised as follows:

Area/Activity	Recommended temperature (°C)	Type of device (see MES D08 for explanation of valve types)
Staff bases, ward and consulting rooms etc basinsIn-patient, out-patient hand-wash basins	41	Type 3 Thermostatic
General areas to which patients and visitors may have access	41	Type 2 Thermostatic

©Health Facilities Scotland, a division of NHS National Services Scotland

Area/Activity	Recommended temperature (°C)	Type of device (see MES D08 for explanation of valve types)
Paediatric baths	40 - to allow for the cold paediatric bath/sink NB: paediatric nurses should always use a thermometer	Type 3 Thermostatic
General baths	43	Type 3 Thermostatic
Showers	41	Type 3 Thermostatic
Assisted baths	46 - to allow for the cold mass of bath NB: Nurses should always use a thermometer before immersing patients	Type 3 Thermostatic
Hair-wash facilities	41	Type 3 Thermostatic
Bidets	38	Type 3 Thermostatic
All sinks, kitchens, pantries, slop sinks etc	55 - minimum required for food hygiene and decontamination purposes	Separate hot and cold taps or combination tap assembly Type 1; no preceding thermostatic device
Office, staff-only access areas hand-wash basins	43	Type 1

Hot water outlets provided for food hygiene and decontamination purposes should be provided with a notice ‘CAUTION – VERY HOT WATER’

It is preferable that thermostatic mixing devices are fitted directly to the mixed temperature outlet, or be integral with it, and be the method of temperature and flow control.

Because of the complexity of hot and cold water systems found in healthcare facilities and the responsibility of maintaining a temperature control regimen at all times, this guidance suggests that chemical and other water treatments that have been shown to be capable of controlling and monitoring *Legionella* may also be considered (for example chlorine dioxide or silver/copper ionisation)

©Health Facilities Scotland, a division of NHS National Services Scotland

Note: As well as complying with the recommendations outlined in this document, the design and installation of the hot and cold water services, new or extended, in any NHS premises must also comply with the Water Byelaws 2000 (Scotland).

a. 1999, recommendations of the water suppliers in the Water Regulations Advisory Scheme's (WRAS) 'Water Regulations Guide', and any other requirements of the local water authority;

b. the Health and Safety Commission's Approved Code of Practice and guidance document 'Legionnaires' disease: the control of *Legionella* bacteria in water systems' (commonly known as L8), which requires that there must be a written scheme in place in respect of controlling *Legionella* in water systems.

©Health Facilities Scotland, a division of NHS National Services Scotland

1. Introduction

Preamble

1.1 Scottish Health Technical Memorandum (SHTM) 2027: – 'Hot and cold water supply, storage and mains services' and SHTM 2040: – 'The control of *Legionella* in healthcare premises: a code of practice' (NHSScotland Property and Environment Forum, 1999) have both been revised, and have, at the same time, been combined into this single document: Scottish Health Technical Memorandum 04-01 – 'The control of *Legionella*, hygiene, 'safe' hot water, cold water and drinking water systems'. The guidance has been revised in line with changes to relevant regulations, standards and other guidance and also technical developments and absorbs information from Scottish Hospital Technical Note 6 – 'The safe operation and maintenance of thermostatic mixing valves and Scottish Health Guidance Note – 'Safe' hot water and surface temperatures'.

1.2 Scottish Health Technical Memorandum 04 now supersedes Scottish Health Technical Memorandum 2027 and Scottish Health Technical Memorandum 2040, and absorbs information from Scottish Hospital Technical Note 6 and Scottish Guidance Note regarding 'Safe' hot water and surface temperature.

1.3 This Scottish Health Technical Memorandum gives comprehensive advice and guidance to healthcare management, design engineers, estate managers and operations managers on the legal requirements, design applications, maintenance and operation of hot and cold water supply, storage and distribution systems in all types of healthcare premises. It is equally applicable to both new and existing sites.

1.4 In its new form, the document is divided in two parts. This part (Part A) outlines the principles involved in the design, installation and testing of the hot and cold water supply, storage and distribution systems for healthcare premises. Some variation may be necessary to meet the differing requirements for the water authority (see Note 1); Part B covers operational management.

General

1.5 Current statutory legislation requires both 'management' and 'staff' to be aware of their individual and collective responsibility for the provision of wholesome, safe hot and cold water supplies, and storage and distribution systems in healthcare premises. This applies whether premises are NHS owned or procured via PFI/PPP and operated by Consortia Facilities Management staff or subcontractors.

1.6 Premises used for the delivery of healthcare are dependent upon water to maintain hygiene through a safe and comfortable risk assessed environment for all who may interface and support functional care delivery.

©Health Facilities Scotland, a division of NHS National Services Scotland

1.7 The development, construction, installation and maintenance of hot and cold water supply systems are vital for public health.

1.8 Interruptions in water supply can disrupt healthcare activities. The design of systems must ensure that sufficient reserve water storage is available to minimise the consequence of disruption, while at the same time ensuring an adequate turnover of water to prevent stagnation in storage vessels and distribution systems.

1.9 Measures to control the spread of micro organisms in healthcare premises include the regular use of alcohol-based hand-rubs, and this can result in a significant reduction in the use of hand-wash basins. Under-use of taps encourages colonisation with *Legionella* and other micro organisms. Designers should be aware of this and, accordingly, consider how local infection policies with regard to hand hygiene and the use of alcohol-based hand-rubs might impact on the frequency of use of hand-wash basins (see also paragraphs 5.7–5.12 in Part B on the extent of utilisation).

Legislation, standards and guidance

1.10 As well as complying with the recommendations outlined in this document, the design and installation of the hot and cold water services, new or extended, in any NHS premises should also comply with:

a. the Water Byelaws 2000 (Scotland), recommendations of the water suppliers in the Water Regulations Advisory Scheme's (WRAS) 'Water Regulations Guide', and any other requirements of the local water supply authority (see Note 1);

b. the Health and Safety Commission's Approved Code of Practice and guidance document L8, which requires that there must be a written scheme in place in respect of controlling *Legionella* in water systems.

Note 1: since April 2008 this has been the private water supplier, following deregulation.

Note 2: The Water Byelaws 2000 (Scotland) are set out, along with the Department for Environmental, Food and Rural Affairs (DEFRA's) (1999) guidance (see References) and with the water industry's interpretation of these provisions, in the WRAS 'Water Regulations Guide'. The WRAS is funded by the water suppliers to provide advice on the Water Byelaws 2000 (Scotland) on a national basis. WRAS also administers the WRAS "approval scheme" that assesses and lists water fittings and materials for compliance with the Regulations. The 'Water Fittings and Materials Directory' contains information on suitable fittings and materials and is updated every six months.

1.11 Designers and installers of hot and cold water distribution systems are required by the Water Byelaws (Scotland) 2000 to notify the water supply authority of any proposed installation of water fittings and to have the water supply authority consent before installation commences. It is a criminal offence to install or use

©Health Facilities Scotland, a division of NHS National Services Scotland

water fittings without their prior consent. Liaison with the local water supply authority is strongly recommended at an early stage to avoid problems of compliance in the design.

1.12 All materials used in the construction of systems referred to in this SHTM must comply with the requirements of the Water Byelaws (Scotland) 2000(Regulation 4: "Requirements for water fittings") and be in accordance with relevant British Standards and codes of practice. All materials in contact with wholesome water supplies must be listed in the 'Water Fittings and Materials Directory'.

1.13 Water quality is governed by the Water Supply (Water Fittings) Regulations 1999, building regulations, approved codes of practice and technical standards intended to safeguard quality.

Model Engineering Specification

1.14 Model Engineering Specification C07, which is a procurement specification, supports this SHTM and provides details of the extent of the work required.

Exclusions

1.15 Although many of this SHTM's recommendations will be applicable, it does not set out to cover water supply for fire-fighting services nor water supply for industrial or other specialist purposes, other than to indicate precautions that should be taken when these are used in association with "domestic" water services. The point at which a "domestic" activity becomes an industrial process, for example in food preparation, has not been defined, and the applicability will need to be considered in each case.

1.16 This SHTM does not cover wet cooling systems such as cooling towers. Guidance on these systems is given in the Health & Safety Commission's Approved Code of Practice and guidance document L8.

1.17 While some guidance on other water-service applications is included, it is not intended to cover them fully. i.e:

- for sterile services departments, see SHPN 13: – 'Decontamination';
- for hydrotherapy pools, see the Public Health Laboratory Service's 'Hygiene for hydrotherapy pools';
- for spa pools, see the Public Health Laboratory Service's 'Hygiene for spa pools: guidelines for their safe operation. The report of a PHLS spa pools working party'.

Definitions

1.18 Definition of terms is as those contained in the Water Byelaws (2000).

©Health Facilities Scotland, a division of NHS National Services Scotland

The water industry

Water supply

In Scotland, the various water supply authorities were not 'privatised' as in England. The various regional authorities were combined into a single entity 'Scottish Water', remaining in the public sector and hereinafter referred to as 'the water supply authority' (see Note 1).

Regulatory authorities

The Water Act 1989 provided for the establishment of several regulatory bodies whose functions are now set out in the Water Industry Act 1991 and the Water Resources Act 1991 and are summarised below:

a. the Office of Water Services (OFWAT), which regulates the prices set by the water companies, oversees the standards of service provision and protects the interests of water consumers. OFWAT also has ten regional Water-Voice committees that identify customer concerns, pursue them with the companies and report to the director-general of water services;

b. the Environment Agency (EA) regulates the quality and controls pollution of "controlled" waters (that is, most inland and coastal waters) and protects the water resources in England and Wales;

c. the Drinking Water Quality Regulator (DWR) regulates the quality of supply of drinking water.

2. Source of supply

General

2.1 Normally, the source of water supply to healthcare premises is by one or more service pipe connections from the mains of the water supply authority (see Note 1). If the quantity and rate of flow is inadequate, or if the cost of providing the service connection appears to be uneconomical, alternative sources of supply such as boreholes or wells may be investigated.

2.2 Where the constraint is only that of inadequacy of the water authority's (see Note 1) supply, the healthcare building needs could be met by using a private supply as an additional source to the water authority's supply. In such cases, the water authority's supply should be the priority supply for drinking, culinary and special hygienic services. By limiting the use of the private supply to services not requiring the highest level of hygiene, the extent of treatment of the private supply may be reduced. Private supplies used in this way must convey water through a separate pipework system that is clearly labelled. Outlets served by the private supply system should also be appropriately labelled.

2.3 Provision should be included for alternative water supply arrangements to meet an emergency, regardless of the source or sources of supply finally adopted. Alternative arrangements would include a second service connection from the water authority (see Note 1); or a private supply. In either case the alternative supply should not be vulnerable to the cause of loss of the original supply. Direct physical interconnection of pipework and valves of a water authority's supply with any private supply without adequate backflow protection is prohibited by the Water Supply (Water Fittings) Regulations 1999. The water quality requirements applicable to the main supply apply also to any alternative supplies.

2.4 The water authority (see Note 1); must be advised if it is proposed to use any private supply as well as the water authority's supply, and advice should be sought on the limitations imposed in respect of break cisterns and interconnection thereafter as required by the Water Supply (Water Fittings) Regulations 1999.

2.5 In Scotland all water intended for human consumption is required by legislation to comply with the quality standards laid down by the Drinking Water Quality Regulator with powers as laid down in Section 7 of the Water Industry (Scotland) Act 2002. They can force the statutory water authority (see Note 1); to comply with the standards set out in the Water Supply (Water Quality) (Scotland) Regulations 2000. These regulations apply to water sampled at the point where the water is available for use and also embrace water used in the preparation of food and beverages.

2.6 The responsibility for enforcing this legislation for public water supplies rests primarily with the Drinking Water Regulator and the statutory water authority

©Health Facilities Scotland, a division of NHS National Services Scotland

(see Note 1) and the legislation also covers private water supplies. In respect of public water supplies, the statutory water authority has a duty to provide a wholesome supply and to demonstrate – by monitoring – that the supplies meet the standards required.

Supplies from a water supply authority

2.7 The following factors should be taken into consideration in the initial stages of the design:

- the water supply authority's requirements;
- the estimated daily consumption, and the maximum and average flows required, together with the estimated time of peak flow;
- the location of the available supply;
- the quality, quantity and pressure required;
- the cold water storage capacity required;
- the likelihood of ground subsidence due to mining activities or any other reason;
- the likelihood of there being any contaminated land on site;
- the proposed method of storage and probable number and purpose of direct connections to pressure mains;
- the minimum and maximum pressures available at the service connection;
- details of the physical, chemical and microbiological characteristics of the water supply and scope of any possible variations in such characteristics;
- the possibility of an alternative service connection from some other part of the water authority's network, including pressure details;
- the water authority's (see Note 1) contingency plan in the event of no water supply for whatever reason.

Note: Regulations require notification to the water supply authority of any proposed changes and additions to the water supply system in the premises.

2.8 These initial design investigations should normally reveal the need for any further treatment, pressurisation and storage of the water authority's (see Note 1) supply to meet healthcare building requirements and enable an estimate of costs to be made.

2.9 BS 6700:1997 and BS EN 806-2:2005 give further guidance on the procedures that should be followed when carrying out preliminary investigations in relation to new water supplies.

©Health Facilities Scotland, a division of NHS National Services Scotland

2.10 During the design stage, close collaboration with the water supply authority should be maintained, and consent must be sought on the final arrangements before proceeding with the installation. These arrangements should include:

- siting of service connection, access chamber, metering, bypassing, flushing out, physical security of service connection, installation and provisions for the fire-fighting service;
- compliance with the Water Supply (Water Fittings) Regulations 1999.

Private supplies

2.11 Private supplies independent of the statutory water authority (see Note 1); are also governed by the Water Supply (Water Quality) (Scotland) Regulations 2000. A license is required from the Scottish Environment Protection Agency (SEPA) before embarking on any private water supply scheme. If, for any reasons of back-up or security of supply, there is a connection to the public supply (regardless of whether, or how often, it is used), the installations must comply with the Water Supply (Water Fittings) Regulations 1999. Private supplies should be registered with the statutory water authority that has the responsibility to monitor the wholesomeness of the supplies where these are used for domestic or food production purposes.

2.12 The standards for private water supply quality are very similar to those for public supplies. Reference should also be made to the Standing Committee of Analysts' (2002) 'The microbiology of drinking water'.

2.13 SEPA keeps records and maps of all known sources of private water supply together with details of the geological strata and water-bearing characteristics of the area under its control.

2.14 The feasibility of such a private supply should be decided by comparing the capital costs (of the construction of works, including mains, pumping plant, treatment plant etc) and revenue costs (of electricity for pumping, water treatment chemicals, direct and indirect maintenance and associated management costs, regular water analysis tests etc) with the long-term cost of water supply from the water authority over the predicted life-cycle of the installation. Due consideration should be given to the long-term costs of a private supply, and account should be taken of potential deterioration in water quality and/or capacity of the private supply source.

2.15 Where consideration is being given to the use of a private supply, specialist assistance should be sought to:

- confirm the long-term availability of water in sufficient quantity, which is either of proper quality or suitable for treatment;
- confirm the long-term quality of water and define requirements for water treatment;
- design and specify the works needed;

©Health Facilities Scotland, a division of NHS National Services Scotland

- carry out a full evaluation of the costs and practicability of a private supply compared to a connection from the water supply authority.

©Health Facilities Scotland, a division of NHS National Services Scotland

3. Water treatment regimens

3.1 Provided water is supplied from the public mains and its quality is preserved by correct design, installation and maintenance, it can be regarded as microbiologically acceptable for use. It is exceptional, however, for a water supply, either public or private, that is wholly 'potable' to be entirely free from aquatic organisms, and consequently it is important that appropriate measures are taken to guard against conditions that may encourage microbial multiplication.

3.2 Reasons for treatment of water from the supply authority in healthcare premises would be for processing for laundries, domestic hot water systems and steam boiler feed water, where either the degree of hardness proves excessive or exceptional softness causes corrosion. Most private supplies, however, are likely to require some measure of treatment, and in many cases, the installation of pumping and treatment plant needs to be extensive to ensure a constant acceptable quality.

3.3 Treatment systems that are used in conjunction with potable water systems should be selected with care. Addition of any substance must not cause a breach of any requirements in the Water Supply (Water Quality) Regulations 2000. Any substance should be approved in accordance with those Regulations, for example, by being in the Drinking Water Quality Regulators list of approved substances for contact with drinking water, which is included as an appendix in the 'Water Fittings and Materials Directory'.

3.4 Automatic water treatment systems should be fail - safe and have sufficient instrumentation to monitor their operation. The water supply connections to the equipment must be adequately protected against backflow. Monitoring by means of building management systems should be considered.

3.5 In healthcare premises, both hot and cold water are considered to be potable and therefore water treatment supplied to healthcare premises must comply with current legislation on water quality.

3.6 Further details can be found in BSRIA's Application Guide AG 2/93: 'Water treatment for building services systems' (with amendments) and SHTN 2: 'Domestic hot and cold water systems for Scottish health care premises'.

3.7 The continuous chlorination of hot and cold water service systems, after initial disinfection (see section 17), to control the growth of *Legionella* is not recommended because chlorine has a limited ability to penetrate biofilm and inactivate sessile micro organisms.

3.8 Treatment using chlorine dioxide or copper/silver ionisation can be used (see section 15).

©Health Facilities Scotland, a division of NHS National Services Scotland

4. Water softening

4.1 Hard waters are unsuitable for many industrial and domestic purposes. Treatment may therefore be necessary to remove or alter the constituents to render the water suitable for particular purposes.

4.2 Hardness is due to calcium and magnesium salts in the water and is expressed in terms of milligrams per litre as calcium carbonate (CaCO3). Temporary (carbonate) hardness is related to the bicarbonate salts of calcium and magnesium. Permanent (non- carbonate) hardness is related to the other salts of calcium and magnesium, that is chlorides, sulphates, nitrates etc. The generally accepted classification of waters is shown in Table 1.

Description	Milligrams per litre (mg/L as $CaCO_3$)
Soft	0 to 50
Moderately soft	50 to 100
Slightly hard	100 to 150
Moderately hard	150 to 200
Hard	200 to 300
Very Hard	Over 300

Table 1: Classification of water hardness

4.3 When the temperature of water is raised, the hardness will be reduced by some of the dissolved salts (temporary hardness) coming out of solution and forming solids in suspension, some of which will be deposited on heating surfaces to form an adherent lime scale, thus reducing the heat transfer rate.

4.4 The extent of treatment required to prevent scale formation will depend upon the process for which the water is being heated; it may therefore be necessary to achieve one of the following conditions:

- replacement of calcium and magnesium salts by their more soluble sodium equivalents;
- removal of all salts, that is, demineralization;
- Where water of greater purity is required for specialized uses, it can be produced from softened water by reverse osmosis or by demineralization.

4.5 Softening is not considered necessary for palatability. In some instances the softening process makes the water less pleasant to taste without affecting the potability.

4.6 Epidemiological studies have shown that the incidence of cardiovascular disease tends to be higher in areas with soft water supplies than in areas with

©Health Facilities Scotland, a division of NHS National Services Scotland

hard water supplies. The association is clearest where the soft water supplies contain hardness below about 150 mg/L (as CaCO3).

The explanation is not known, but it is considered prudent, where possible, not to drink water that has been artificially softened to concentrations lower than this. Softened water may also tend to dissolve metals from pipes. Water softeners containing ion-exchange resins may be subject to bacterial contamination if not adequately maintained. Softeners using salt-regenerated ion- exchange resins increase the sodium content of the water during softening, and this may be undesirable for children and anyone on strict salt-restricted diets. These concerns can be avoided if water intended for drinking and cooking is not softened.

4.7 Waters having a hardness of up to 400 mg/L have been used for public supplies without preliminary softening. While it is accepted that supplies for domestic purposes need not be softened, partial softening may be carried out by the water supply authority (see Note 1).

4.8 The need for softened water in hospitals for domestic purposes other than drinking and cooking should be considered on the merits of each case; if treatment is considered essential, the extent of softening should be the minimum to achieve an acceptable level. A generally acceptable level is between 80 and 150 mg/L, and not less than 60 mg/L, but this should not be taken as a requirement for hospitals as it may be impracticable to achieve. The cost and difficulties of treatment may be prohibitive for certain waters if the hardness value is particularly high and the content of magnesium is appreciable.

4.9 Generally, within healthcare premises, softening of a hard water supply will be required on feeds to the following:

- boilers and hot water supply systems – to prevent sludge and lime scale building up in pipework and plant (see BS 2486:1997);
- mixing devices and blending valves – to avoid clogging of control ports and showerheads by lime scale;
- laundries – high maintenance costs and the uneconomic uses of soap or detergents are caused by the presence of hardness.

Note: Problems often occur in thermostatic mixing valves whereby scale is deposited as a result of hard cold water being heated in the blending process**.**

4.10 The most common water-softening process used for the protection of hot water calorifiers is base-exchange softening. This process removes permanent and temporary hardness from water. The technique uses an ion-exchange process in which the calcium and magnesium ions in solution are removed and replaced by an equivalent number of sodium ions. This method of water softening is not recommended for drinking water or water for culinary use, since a raised level of sodium is associated with heart disease.

©Health Facilities Scotland, a division of NHS National Services Scotland

4.11 Other water softening methods include physical water conditioning and magnetic water conditioning. Physical water conditioners function by triggering the growth of nuclei or seed crystals in the water. When the water is heated or subjected to pressure change, dissolved salts precipitate onto these seeds to form crystals, which do not adhere to the sides of the pipes and are washed out with the flow. Some hard scale will still form, but it will be dissolved provided sufficient seeds are created. The main problem is to ensure an adequate supply of the seed crystals, which have a relatively short life before they are absorbed back into the water. The efficacy of these water-conditioning measures needs to be considered.

4.12 For further details on processes which control scale formation in hot water services systems, refer to BSRIA's Application Guide AG 2/93: 'Water treatment for building services'.

5. Filtration

General

5.1 Examinations of domestic water systems in a number of Scottish Hospitals where water had been supplied under the chlorine water supply regime, in a number of Scottish hospitals have revealed significant deposits of sediment and debris in pipework. Such deposits can provide an environment conducive to the development of bacteria as well as biofilms. Filtration may be required to:

- ensure that the domestic water supply and associated pipework is maintained at a high standard of cleanliness throughout the system;
- reduce the accumulation of sediments and biofilms that may promote the growth of water- borne organisms. Subsequent examinations of domestic water systems in a number of Scottish healthcare premises following a change to a chloramine regime have revealed significant improvement in water quality in that minimal deposits of sediment and debris were found in pipework and storage tanks.

5.2 Filtration need not be provided for cold water for non-domestic use, for example fire-fighting, boiler-feed or other chemically treated or dosed systems unless there is a significant and regular suspended solid carry over from the public water supply.

Description

5.3 Filtration is normally used to prevent ingress of suspended solids into plant and pipework, and as such may be defined as the process of separating solids from liquids using a porous medium. The medium can consist of granular materials (sand, clay, carbon etc) assisted by chemical and/or bacterial activity, woven meshes and screens made of metals, fabrics, ceramics and polymeric membranes.

5.4 Filtration plant is usually specified by various criteria including minimum particle size retained, expressed in microns (µm). ‘Absolute filtration’ of a given size indicates that the plant can remove 99.9% of all particles above a given size. ‘Nominal filtration’ is normally taken to mean that 95% of all particles above a specified size will be removed.

5.5 As a guide, suspended materials are normally classified according to Table 2.

©Health Facilities Scotland, a division of NHS National Services Scotland

Material	Particle diameter	
	mm	pm
Pebbles	>10	-
Gravel	10 - 2	-
Very coarse sand	2 - 1	-
Coarse sand	1 - 0.5	1000 - 500
Medium sand	0.50 - 0.25	500 - 250
Fine sand	0.25 - 0.10	250 - 100
Silt	0.10 - 0.01	100 - 10
Clay	<0.01	<10
Colloid	10-4 - 10-6	0.1 - 0.001

Table 2: Particle size

5.6 In practice, water will contain a range of sizes of suspended particulates. The rate of blockage by suspended solids for any given filter will depend on a number of factors such as:

- throughput;
- concentration of suspended solids and other fouling debris;
- size distribution;
- shape of particles.

5.7 Particles less than 0.1 µm are invisible microscopically. The smallest visible macroparticle is approximately 40 µm. Particles less than 0.001 µm are considered dissolved and in solution.

Capacity

5.8 To accommodate the variation in flow, and to allow for filter changes etc, the equipment should be installed in association with a storage cistern.

Design features

5.9 The level of filtration where thermoplastic pipework systems are installed should be 5 µm absolute.

5.10 The level of filtration where stainless steel pipework systems are installed should be 0.5 µm absolute. If the stainless pipework manufacturer is prepared to give a guarantee offering a lifespan of the installation that is not less that in CIBSE “Guide to ownership, operation and maintenance of building services”, the level of filtration can be relaxed to 5.0 microns.

©Health Facilities Scotland, a division of NHS National Services Scotland

5.11 For small establishments (those with fewer than 100 beds and all other small premises such as health centres and clinics), it will normally be appropriate to use strainer filters with cartridge or membrane elements (see also paragraph 5.16).

5.12 In larger establishments (those with more than 100 beds), the filtration equipment plant should be fully automatic in operation and include self - cleaning and back-washing modes so that the filter medium does not become a reservoir for organisms capable of contaminating the service pipework. To allow for servicing of the plant, a bypass line with strainer filter should be provided, complete with isolation valves and non-return valves. The bypass should be provided with drains and vents to facilitate disinfection prior to bringing it into service.

5.13 As an alternative to the installation of a bypass strainer, the provision of two units to operate sequentially with automatic changeover on a regular basis will minimise potential failures and maintenance. Precautions should be taken to minimise stagnation of water in the dead-legs that may occur with this arrangement – weekly flushing of dead-legs should take place.

5.14 All items in contact with water must be of materials that comply with the Water Byelaws (Scotland) 2000(for example, materials approved by the Water Regulations Advisory Scheme and listed in the WRAS 'Water Fittings and Materials Directory', having been assessed and shown not to have adverse effects on water quality).

5.15 Parameters essential for the continued performance of the plant should be automatically monitored, for example downstream pressures and automatic cycling of back-washing facilities. These should be relayed to a building management system.

Point-of-use filtration

5.16 Point-of-use filters have been found to provide protection from exposure to *Legionella* by preventing the dispersal of the bacterium from showers and other water outlets. To be effective, the filter membrane needs to have a nominal pore size of no greater than 0.2 µm. Before their use is contemplated, two factors should be considered. First, the filters do not eradicate the organism, but prevent discharge to the environment from the filtered outlet only; secondly, by retaining the organism within the pipework, it may be possible for the organisms to multiply and regressively 'seed' other parts of the distribution system. Filters will also need to be changed routinely, depending on usage of the outlets. Their use, therefore, should be considered only as part of an overall regimen of *Legionella* control to be used where the most vulnerable patients are to be treated. Continuous long-term use of point-of-use filters is not recommended, except where there is no effective alternative.

©Health Facilities Scotland, a division of NHS National Services Scotland

6. Metal contamination

6.1 Copper piping is no longer routinely specified for Scottish hospitals (Scottish Hospital Technical Note 2 refers) and the following section applies to existing installations where extensions are being provided retaining the existing specification or to very small, stand-alone facilities, or to temporary accommodation with a short life-span.

6.2 Analytical results have shown that there can be a serious problem from lead contamination of water supplies. The Water Supply (Water Quality) Regulations 2000 set an upper concentration for lead in drinking water of 0.01 mg/L to be achieved by 2013. This value is likely to be exceeded if lead pipes are present or if copper pipes have been joined with solder containing lead. In general, if hospital drinking water contains more than 0.01 mg/L of lead, remedial action should be taken. The use of lead solder is prohibited on all plumbing installations where water is required to be wholesome.

6.3 Copper concentrations above 1 mg/L may cause staining of laundry and sanitaryware and increase the corrosion of galvanised iron and steel fittings. Whilst the maximum allowable copper concentration in drinking water is 2 mg/L, most supplies will give a level at the tap of less than 1 mg/L.

6.4 Water supplies to certain specialist units such as maternity, neo-natal paediatric, general paediatric and renal dialysis units (see the Renal Association, 2002) should be monitored to ensure that water quality is within acceptable limits. The designer should seek epidemiological advice to ascertain the exact water quality requirements for specialist units.

6.5 Where the water supply is known to dissolve metals (that is, soft water), regular sampling should be carried out at strategic sampling points to ascertain that the level of metal contamination in the water supply to the premises, plus any added during its passage through the distribution system, does not result in limits above the stated safe levels. This will especially apply if the distribution pipework includes a multiplicity of leaded solder capillary joints. In soft water areas, metal contamination can occur by simple dissolution. Pitting corrosion arising in hard water areas, as a result of deleterious carbonaceous films laid down during the manufacturing process, does not normally give rise to elevated copper levels in the water and is not nowadays a problem if independently certified tubes to BS EN 1057:1996 are used. Excessive use of acidic flux in the making of capillary joints can lead to corrosion of copper plumbing, especially if the system is allowed to stagnate after commissioning. WRAS Information and Guidance Note 9-04-02: ‘Solder and fluxes’ (available on its website http://www.wras.co.uk) gives further information on solders and fluxes.

6.6 If the proposed water supply is likely to take up metals in excess of acceptable limits, it will be necessary to consider treatment of the water such as raising hardness.

©Health Facilities Scotland, a division of NHS National Services Scotland

7. Water storage

General

7.1 Where there is an interval of time between final testing and commissioning of domestic hot and cold water systems, the systems should be drained dry until put into use. This will include storage, where provided. The design and installation of the system must be such as to facilitate effective draining.

Water is stored in healthcare premises for the following reasons:

- to provide a reserve supply during failure of the main cold water supply;
- to reduce the maximum demand on the cold water main;
- to provide accommodation for the expansion of any water subjected to heat, that is, hot water and heating services;
- to reduce the pressure from that of the distribution system.

7.2 The purpose for which the storage is used can vary, but has only a minor effect on its design. The following generally covers the range of uses:

- cold water services, domestic, laundry etc;
- cold water feed to hot water services;
- drinking water supplies;
- treated cold water for laundries, heating etc when local supplies are unsuitable;
- break tanks on cold water supplies serving points of use where backflow is, or is likely to be, harmful to health due to a substance representing a serious hazard, for example, supplies to pathology laboratories;
- feed and expansion for heating service;
- fire-fighting.

Extent of storage

7.3 There is a conflict between the water supply authority's desire to have 24 hours water storage and the requirements of HSE L8 which recommends 12 hours, the latter being intended to maximise turnover and avoid stagnation of stored water. The requirements of each individual project require to be risk assessed and discussed with the water supply authority at the earliest possible design stage. Storage should be designed to minimise residence time in the cistern and maximise turnover of water to avoid stagnation and deterioration of water quality. Storage volume should be calculated on the basis of peak demand and the rate of make-up from source of supply. There may be more than one peak

©Health Facilities Scotland, a division of NHS National Services Scotland

period in each 24 hours. The interval between peak periods is important as it affects the storage capacity based on the make-up flow. It also determines the available time for maintenance if twin cisterns are not installed.

7.4 Appendix 1 is based on the results of studies into water consumption in various types and sizes of hospitals. CIBSE's Guide G: 'Public health engineering' gives further guidance on sizing cold water storage. While it is accepted that the desirable minimum for total storage will vary with the classification of the particular health building, the upper limit of storage for a district general hospital is 900 L per bed per day and for a teaching hospital 1350 L per bed per day, excluding provision for the staff residences, laundries and any special storage for fire-fighting purposes.

7.5 It must be borne in mind that the overall pattern of healthcare is changing and the data available now is a best estimate of what is required. The guidance in Appendix 1 is known to overestimate water usage in healthcare premises and, moreover, yields data in litres per second. Reference should be made to SHTN 2: 'Domestic hot and cold water systems for Scottish health care premises'. (As an example, a hospital of between 400 and 600 beds might consume 100,000 m^3 of water annually, that is, about 11 m^3/h over a 24-hour period. Peak hourly demand, however, may reach 50 m^3/h.)

7.6 A summation of the average daily consumption for each ward unit contained in a building should be made. From the requirements of each building, the policy of water storage for the whole complex should be decided. It does not always follow that peak demands for each building will coincide, and therefore there may be scope for applying a diversity factor to the whole site.

7.7 Where the water requirement is to be met from a private supply, the summation for each building may require assessment on the basis of storing and using water according to the minimum treatment of the water for each particular use. Likewise, where the water is hard enough to require softening for certain domestic and/or laundry purposes, separate storage will be required, and this should be taken into account when assessing the total stored water.

7.8 Appendix 1 does not cater for water requirements for staff quarters or such support services as laundries, bulk stores and workshops etc. The staff quarters and industrial areas may be remote from the main hospital and supporting departments. The laundry may serve a number of healthcare buildings as well as the premises at which it is located. The storage requirement for such accommodation should therefore be calculated separately and integrated with the accommodation whenever this is practical. Appendix 1 provides data on typical demands expected from staff residences.

7.9 Where new healthcare premises are to be built in separate phases, the water storage, supply and distribution service for the whole premises should, as far as possible, be planned and evaluated at the design stage. This will enable the total water supply requirement to be assessed in the planning stages, and appropriate areas of accommodation (but not tank storage) to be allocated.

©Health Facilities Scotland, a division of NHS National Services Scotland

Location and form of storage

7.10 It is more convenient and more secure to house water storage cisterns at sufficient height to provide adequate flow to all parts of the development by gravity, thus avoiding reliance on pumps etc. This is achieved by siting cistern rooms at roof level. Where buildings are widely dispersed, it is preferable to install a number of smaller cisterns rather than building a water cistern tower.

7.11 The location of storage will depend on the total volume required, the topography and layout of the site proposed for development, and the sources and adequacy of the water supply. A limited site footprint may call for much higher buildings to achieve the required accommodation. Depending on the supply water pressure, it may be necessary to install pressurisation equipment to boost the incoming supply. The cost of the supporting structure will have an important bearing on the solution adopted.

7.12 A hospital built on a restricted site might need both central and local storage to be provided in each building or in one of the buildings to serve other buildings in the development. Local storage at high level should give an average supply of about four hours if gravity-fed, but if the building structure will economically accept greater tankage this should be adopted. The total supply should be based on the average usage over 24 hours. There are some advantages in locating central storage at low level, for example easier access for maintenance, and reduced structural costs.

7.13 Where such storage is located in individual buildings and an adequate supply is available from the water authority (see Note 1), a connection in accordance with the Water Byelaws (Scotland) 2000 to each point of storage may be the most economical arrangement. In such cases, interconnections between selected points of storage should be provided to deal with emergency and maintenance requirements, always providing that such interconnections do not contravene the Water Byelaws (Scotland) 2000and do not result in water stagnating within the storage or distribution system. Where the development is widespread and a water authority's multiple connections are not the best solution, the general arrangement might consist of a total storage reservoir, strategically sited, serving cisterns located as conveniently as possible to the major centres of usage.

7.14 To maintain good water quality, common practice favours the use of smaller decentralised storage capacity as opposed to large central storage and distribution. The use of smaller local cisterns helps to avoid the problem of water stagnation in cisterns and also avoids long runs of distribution pipework between cisterns and points of use. Shorter pipework runs reduce the amount of heat gain in the cold water service en route to points of use.

7.15 Although the final assessment of the capacities of storage cisterns will emerge from the design requirements of Appendix 1, the building's structural design will influence the number of cisterns required and the cistern layout. Standard sizes of tank should be used where possible.

©Health Facilities Scotland, a division of NHS National Services Scotland

7.16 Cisterns must not be located in any position where there is any likelihood of flooding, excessive heat gain or any other factor that could affect the contents of the cisterns. They should not be installed in any location where access for general inspection or maintenance is restricted.

7.17 Separate systems should be provided for pathology and mortuary departments.

External storage

7.18 The ideal location for external cold water storage cisterns is the roof of the highest building, provided the structural design can support the load. If concrete water cisterns are to be considered, they should be designed to form an integral part of the building structure. The materials of construction, however, must comply with the Water Supply (Water Fittings) Regulations 1999.

7.19 Where storage is below ground, as distinct from being housed within a building, it is essential to ensure that there is no risk of contamination. Investigations of such risk require careful consideration of site conditions and should include such aspects as flooding; subsidence; the location of sewers and drains and other buried services; the maximum and minimum height of the water table in the area; the natural drainage of surface water; ingress of contaminants such as dust, debris etc; and, in the event of storage below a car parking area or roads, the danger of oil/fuel seepage. The future development of the healthcare building and probable extensions should also be taken into account in this respect.

7.20 Storage below ground should be adopted only as a last resort, and cisterns should be installed within a watertight bund allowing sufficient space all around and beneath the storage vessel to permit inspection and maintenance. Any underground construction arrangement, concrete or otherwise, not directly against earth will reduce the risk of contamination. The tank chamber must include provision for a sump to collect drainage water and any piping necessary to pump out tanks to the site drainage. The Water Byelaws (Scotland) 2000 require any buried concrete reservoir to be designed, constructed and tested in accordance with BS 8007:1987.

7.21 The economic depth for reservoirs constructed in concrete is a function of the quantities to be stored. It should be considered at the outset of the planning stage, and will be influenced by load - bearing characteristics of the locality and take account of the outlet main's position and particulars. If it is found necessary to exceed a depth of 3.3 m, a specialist should be consulted. A rectangular or square concrete reservoir will generally provide a more economic proposition than one or more circular reservoirs.

Internal storage

7.22 As in the case of external storage, cisterns should be installed in positions where they can be readily inspected and maintained and where they will not be affected by frost or high temperatures.

©Health Facilities Scotland, a division of NHS National Services Scotland

7.23 It is essential in all cistern installations that a clear working space of not less than 0.5 m – but ideally 1 m – is maintained around the cistern. Minimum clearances of 0.5 m below and 0.75 m above the cisterns are necessary to facilitate erection, inspection and maintenance. A minimum of 0.5 m should be provided between the floor of the catchment basin and the underside of the cistern.

7.24 Roof spaces in which cisterns are to be installed must have adequate trap doors or other means of access and adequate lighting to facilitate inspection and maintenance.

Construction of cisterns

7.25 All storage cisterns should be constructed in accordance with manufacturers' recommendations and should comply with the Water Supply (Water Fittings) Regulations 1999, be WRAS-approved, and comply with BS 6700:1997. Glass-reinforced plastic (GRP) tanks should comply with BS EN 13280:2001. The WRAS Information and Guidance Note 9-04-04: 'Cold water storage systems – design recommendation for mains supply inlets' provides useful advice regarding the design of the inlet arrangements to ensure compliance with the Regulations.

7.26 Depending on size and/or capacity, tankage should be divided into convenient compartments suitably interconnected and valved to facilitate cleaning, disinfection, repair, modification and inspection, without seriously disturbing the cold water service. Tank strengthening shall be by means of stainless steel tie-bars and not baffle plates.

7.27 Separate cisterns should also be provided for storage of different water supplies, for example cold water storage, recovered or recycled water, softened water and fire-fighting water. Precautions must be taken to ensure that mixing does not take place between such supplies, and it should be noted that isolation by means of shut-off valves between them is not acceptable.

7.28 Normally the materials used for storage cisterns serving healthcare premises are predominantly GRP, but concrete or steel may also be considered. The material selected should comply fully with the Water Supply (Water Fittings) Regulations 1999. Pre-insulated sections are recommended where practical.

7.29 Sectional cisterns fabricated from GRP or pressed steel provide a convenient means of bulk storage of water at atmospheric pressure. The components can be readily transported to site and, subject to unit multiples, they can be erected to give varying proportions of length to breadth and depth. It is also possible to make provision for future extension in capacity by an increase in available base area or, within limits, depth.

7.30 If sectional cisterns are selected, designs with external assembly flanges and self-draining profiles should be used, since this arrangement facilitates easy cleaning of internal surfaces of the cisterns.

©Health Facilities Scotland, a division of NHS National Services Scotland

7.31 The Water Byelaws (Scotland) 2000 lay down the minimum requirements for potable water storage cisterns. Recommendations to comply with these are given in the WRAS 'Water Regulations Guide'. The requirements are indicated in Figure 1.

Note: Cisterns should be sited away from heat sources and be protected from heat gains by insulation. Adequate access should be provided for inspection and maintenance (both internally and externally).

7.32 Each storage cistern or its compartment should also be provided with the following:

- internal and external access ladders as necessary to comply with current health and safety requirements;
- a full-way servicing valve at each inlet and outlet connection, except for cisterns providing water to primary circuits or heating circuits, vent pipes, overflow pipes, and warning pipes. Where practicable, all outlets should be taken from the base of the system and be sited opposite to the inlet;
- a suitably-sized drain connection complete with isolating valve. The invert of the drain connection should be positioned so as to provide maximum drainage of the cistern.

7.33 Cisterns should be adequately supported on bearers placed under the longitudinal or lateral cistern section joints. To avoid distortion, a flat section of marine ply or equivalent should be sited between the support structure and the cistern. Final siting should be in accordance with the manufacturers' recommendations.

©Health Facilities Scotland, a division of NHS National Services Scotland

Comment [h1]: Requires to be re-drawen.

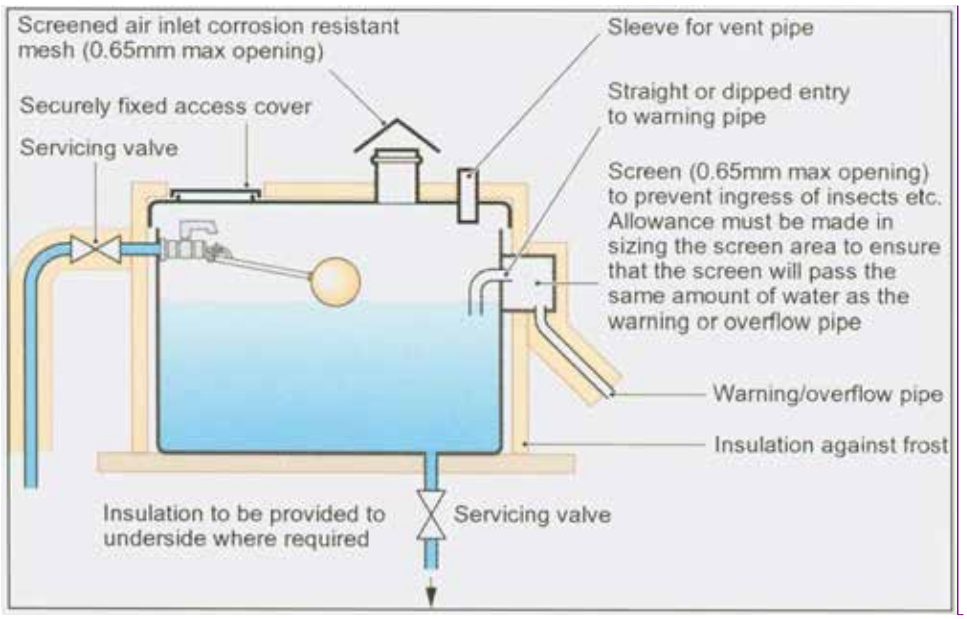

Figure 1: General potable water storage cistern arrangements

7.34 The design may incorporate a watertight drip tray under the cistern to contain condensed water or leakage so as to avoid damage to accommodation below. The necessity of a drip tray or watertight bund with drainage will depend on individual case requirements. The floor of the drip tray or bund should be graded to a drainage sump complete with drain pipe. A single pipe should drain off any overflow water from the sump and lead to a discharge point at ground level where any water flow would be readily noticed. If it is not possible to terminate the discharge pipe from the sump so that any discharge of water can be seen, an audible alarm should be installed to warn of overflow conditions. Cistern support levels should be constructed to keep the valves clear of the water level in the drip tray or bund in the event of cistern leakage. Special requirements apply to the supporting of GRP sectional cisterns on bearers, and manufacturers' recommendations should be observed. The cistern should be provided with a warning pipe or a no less effective device to indicate leakage through the inlet control valve if this should occur.

7.35 On no account should a cistern be installed on a concrete plinth (directly or on steel beams) that is protected by an asphalt membrane. Subsequent irregular settlement into the asphalt may lead to cistern distortion and leakage.

7.36 A consideration in deciding cistern shape and layout is the location of the services duct. Whereas the cistern room may be positioned aesthetically in relation to the building elevation, the duct serving it will be located to suit the internal layout. The pipe route from the system to the service duct will require access for inspection and protection from frost and heat gain.

©Health Facilities Scotland, a division of NHS National Services Scotland

7.37 A typical potable water storage cistern, piping and valve arrangements, for break-tank operation during normal running and maintenance, is shown in Figure 2. The dotted line indicates that the pipe is disconnected. Supply and draw-off connections should be arranged to facilitate good through-flow and turnover of stored water.

Comment [h2]: Figure 4 is on the same section, why is hyperlink required?

Cistern rooms

7.38 GRP or steel cisterns should be installed in well ventilated but draught-proof housings constructed so as to prevent the ingress of birds, rodents and insects. The housing accommodating the cistern and the positioning of the cistern within the room must be designed to permit easy access for inspection and maintenance.

7.39 Prefabricated GRP housings, protected from extremes of temperature by thermal insulation, can provide an economical and aesthetic solution.

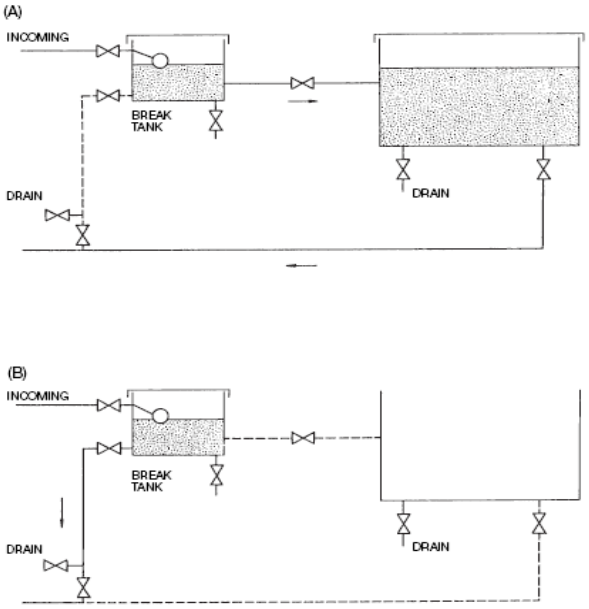
Note: Referring to figure 4, the break-tank can be maintained during rundown of the main tank from full. When not in use 'dotted' piped sections are removed and stored dry.

7.40 The load-bearing capacity of the main structure will limit the distributed load that the cistern room and its contents can impose, and will ultimately limit capacity. If, however, cisterns can be located above main service ducts or stairwells, this will minimise the effects.

7.41 General space lighting should be provided in cistern rooms, together with suitable power points for low voltage small tools and inspection lamps.

7.42 The contents and capacity of all cisterns should be clearly labelled in letters not less than 100 mm high on a white background.

©Health Facilities Scotland, a division of NHS National Services Scotland



Comment [h3]: Requires to be re-drawen.

Figure 2: Piping and valve arrangements for break tank operation. (A) normal running; (B) during maintenance

Ancillary pipework, valves and fittings

7.43 The arrangement of the cisterns in the room should be such that the pipework runs are as short as possible, but accessibility and walkway clearance are ensured. Flanges on parallel runs should be staggered.

7.44 Adequate allowance should be made in the pipework layout for possible future cistern extension.

7.45 All cistern-room pipework and valves should be insulated and clearly labelled to identify their purpose.

7.46 The use of delayed-action ball valves on water storage cisterns should be considered, since these help avoid stagnation of water in the cistern.

7.47 Strainers should be fitted within the water pipework system to protect thermostatic valves etc against ingress of particulate matter. The installation of these fittings should allow adequate access for maintenance/replacement, and they should be provided with means of upstream and downstream isolation. Strainers can be a source of *Legionella* bacteria and should be included in routine cleaning, maintenance and disinfection procedures (see Section 7, Part B).

7.48 Service isolation valves should be fitted to all pipework preceding sanitary tapware and WCs etc for servicing, repair or replacement. Drain-valve provision may also be appropriate for certain installations, for example, service pipework to en-suite facilities etc.

©Health Facilities Scotland, a division of NHS National Services Scotland

Buffer vessels for cold water boosting sets

7.49 Buffer vessels are typically vertical in orientation and normally have a diaphragm to separate the water from the gas space above. They introduce a potential problem of colonisation by *Legionella*, as the plantroom space temperature will exceed that of the incoming water. They should preferably be of a design such that water flows through the vessel, entering at low level, and discharging at a higher level below the water line. Interconnecting pipework should be kept to a minimum, and the vessel should be insulated to minimise heat gain. All materials in contact with water should be WRAS-approved (see also paragraph 9.41).

Water meters

7.50 BS 6700:1997 gives guidance on the design and installation of water meters.

7.51 Revenue meters are normally supplied and installed by the water authority, whereas the consumer may install sub-meters.

7.52 Adequate sub-metering of water supplies should be provided so that supplies can be monitored for individual heavy-use departments. Such monitoring will assist in the detection of leaks or abnormal water demands. Water meters can be connected to a BEMS, which can identify anomalous consumption and lead to the early detection of leaks.

7.53 Appropriate bypass arrangements with valves immediately upstream and downstream should be provided; the bypass loop should be as short as practicable and be arranged to be in the horizontal plane.

©Health Facilities Scotland, a division of NHS National Services Scotland

8. Cold water distribution system

General

8.1 The design and installation of the cold water distribution system should comply with the Water Byelaws (Scotland) 2000and relevant parts of BS 6700:1997 and BS EN 806-2: 2005. A simple cold (and hot) water system is shown in Figure 3.

Comment [h4]: Figure 5, resides in this section, is a hyper link nessasary?

Note: All pipework to be insulated; isolating and control valves not shown; all drains should discharge to waste via a type A "air" gap.

8.2 The installation should be designed to avoid waste, undue consumption, misuse and contamination. Every water fitting through which water is supplied for domestic purposes should be installed in such a manner that no backflow of fluid from any appliance, fitting or process can take place. An assessment of the level of backflow contamination risk (the fluid category) should be made for each fitting, appliance etc. The system should be designed and installed so that each risk is adequately protected against backflow, either by means of the design or by use of backflow prevention devices. Devices are listed in the WRAS 'Water Regulations Guide' together with the degree of backflow protection they provide.

8.3 The design of the pipework should ensure that there is no possibility of a cross-connection between installations conveying potable water and an installation containing non-potable water or water supplied from a private source. There should be no possibility of backflow towards the source of supply from any tank, cistern, fitting or appliance, whether by back-siphonage or otherwise.

8.4 From an early stage in the design process of the water installation, liaison and consultation should take place with the designer of the building, the building owner or his agent, the water supply authority and all other public and private utilities, highway and local authorities, landowners and others involved. There is a legal duty to notify the water authority of proposed installation work and have its consent for the work before installation commences.

8.5 All cold water distribution pipework, mains and cistern down-feeds should be located, as far as is practicable, to minimise heat gains from their environment. Pipework should not be routed through hot ducts or run adjacent to heat sources, such as radiators. Where hot and cold water pipes are run horizontally together, the cold water pipe should be located beneath the hot water pipe to minimise local warming by means of convection.

8.6 All pipework should be insulated, except for any exposed final connections to sanitary appliances, and should be arranged to eliminate or minimise dead-legs.

8.7 The Water Supply (Water Quality) Regulations permit cold water to be delivered at temperatures up to 25°C, although in normal circumstances it will be well below 20°C. As far as possible, the objective should be to design the cold water

©Health Facilities Scotland, a division of NHS National Services Scotland

systems to ensure that the inlet, outlet and surface water temperatures of cisterns and cold water feed/header tanks for the hot water calorifiers are not greater than 2°C above that measured at the main water meter. Also, at cold water draw-off points, a temperature of no greater than 2°C above the temperature measured in cistern and cold water header tanks should be reached within two minutes.

Note: For the control of *Legionella* and other water-borne organisms, 20°C is the quoted upper value above which multiplication of *Legionella* in particular begins to take place (see Part B, Section 4).

8.8 The control of water temperature in the cold water service, however, will essentially rely on good insulation and water turnover. Cold water services should be sized to provide sufficient flow at draw-off points. Stagnation should be avoided.

8.9 Pumped circulation of cold water and refrigerated cold water should only be considered in specialist units where people are at particular risk as a result of immunological deficiency; for example bone marrow transplant units. Such systems require careful design. For other accommodation the aim should be to promote turnover of cold water by means of the design of the distribution circuitry.

8.10 In ward areas provided with en-suite facilities, the aim should be to supply sanitary assemblies in series, with the WC connected to the final element. Elsewhere, pipeline routings should be run so that other outlets are connected with a WC or flushing device, for example sluice hopper or pantry sink, providing the final element at the distal end of the branch – this may require pipe routeing reversal. See Figures 3 and 4.

8.11 In other clinical areas, a similar arrangement for the distribution of cold water should be adopted.

8.12 The cold water distribution system should be designed so that the pressure is the same as that for the hot water service at draw-off points. This may require the inclusion of pressure-reducing valves in the distribution pipework. If unequal pressures exist in the hot and cold water supplies to combination taps where water mixes in the body of the tap, a single check valve is required on each feed pipe to the tap to prevent backflow of water from one to the other.

Drinking water

8.13 When separate drinking water systems have been provided the policy has normally been to distribute directly from the mains without storage, with stored cold water (down service) being used solely for supplies to WCs, hand-wash basins etc. Providing drinking water without storage may not be appropriate in healthcare premises because of the need to have some security of supply. The advantage of separate drinking and cold water services chiefly lie in the possibility of treating the latter (softening or other forms of treatment) without adulterating the drinking supplies. However, low water flows in dedicated Drinking Water piping lead to stagnation, temperature build-up and the possibility of exceeding the 20^0C limits.

Softening will avoid the scale problems associated with thermostatic mixing devices. (Problems often occur when scale is deposited as a result of hard cold water being heated in the blending process.) However, this will be wasteful if the cold water supply is to be used for WC flushing.

8.14 A possible strategy, therefore, is to have a drinking water system that also provides WC flushing and, to some extent, this will assist water turnover and the maintenance of water quality. The disadvantage of the concept, apart from installation cost, is that the use of WCs, particularly in en-suite facilities, as the mechanism for achieving good utilisation in the cold water service no longer becomes possible (see paragraph 8.10). The concept for water turnover in en-suite facilities could still be achieved, however, if the cold water service were run in series to en-suite facilities with minimum dead-legs to draw-offs, with the final connection on the system being a highly utilised outlet, for example a sink.

Many hospitals now store all water in tanks arranged to contain water of drinking quality, having sealed lids and screened vents. This offers complete flexibility avoids problems with stagnation and is recommended practice.

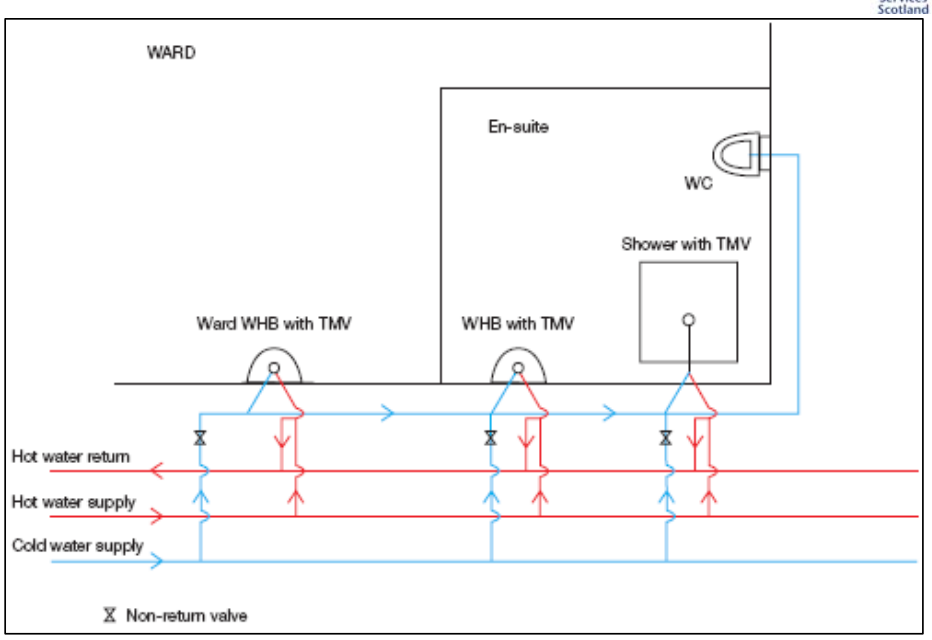

Figure 4: Piping arrangements for an en-suite facility

Comment [h6]: Requires to be re-drawen.

Pumped systems

8.15 Water supply authorities are reducing pressure to reduce mains leakages. Where the pressure of the water supply is inadequate, it will be necessary to utilise pressurisation plant. Similarly, pumping or pressurisation may be required for fire-fighting purposes.

8.16 Various arrangements of pumping system are indicated in BS 6700:1997. Where booster pumps are to be installed, a break cistern will be required between the mains supply pipe and the pumps. This is required in order to comply with the Water Byelaws (Scotland) 2000with regard to prevention of backflow. Any pump delivering more than 12 L/min must be notified to the water authority whose consent is required.

8.17 Control of the pump(s) should be fully automatic in operation and controlled by pressure sensors for the following reasons:

- to reduce energy consumption;
- to prevent heat gain from the pump to the water, which could become significant if large pumps are used;
- to reduce wear on the pumps and hence reduce maintenance.

8.18 Factors to be considered when selecting pumps are:

- quantity and pressure of water to be pumped;

©Health Facilities Scotland, a division of NHS National Services Scotland

- the number of units required to obtain the necessary output and to provide adequate standby capacity;
- the desirability of speed variation;
- the degree of automatic sequence control required;
- the characteristics of the system on both the delivery and suction sides, and in pumping efficiency and priming requirements;
- the type of materials used in manufacturing the pumps relative to the chemical analysis of the water to be pumped.

8.19 The operation and shutdown of pumps may be controlled by various methods depending on the circumstances, such as water-level float switches, pressure switches, flow switches, electrode probes or pneumatic systems. Certain services may also require the pumping equipment to be energised from the emergency electrical service as recommended in SHTM 06-01: Electrical services supply and distribution'.

8.20 Where two or more pumps are installed, the design flow should be achieved with one pump stationary (or out of service). Automatic control should be provided to control all pumps cyclically and sequentially to ensure that each is regularly brought into service.

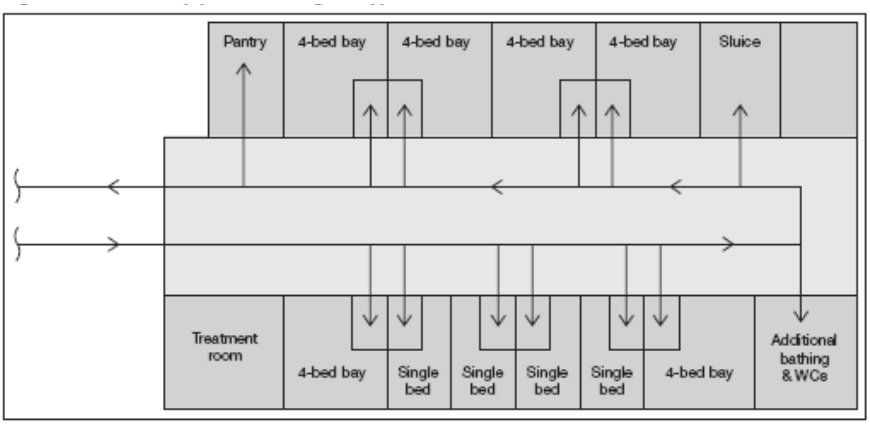

Figure 5: Direction of pipeline routing in a typical ward

8.21 The pumping sets for lifting to higher-level storage should be controlled from the level in the high-level tanks by transmitting sensors, level switches or other suitable devices. A low level alarm should be arranged to give a warning when the storage volume of water falls to a predetermined low level.

8.22 The expansion vessels forming part of the pumping sets are typically pressurisation vessels are typically vertical in orientation and have either a diaphragm or nitrogen fill in the upper space. They introduce a potential problem of colonisation by *Legionella*, as the plantroom space temperature will exceed that of the incoming water. They should be preferably of a design such that water flows through the vessel, entering at low level, and discharging at a higher level below the water line. Interconnecting pipework should be kept to a

©Health Facilities Scotland, a division of NHS National Services Scotland

minimum, and the vessel should be insulated to minimise heat gain. All materials in contact with water should be WRAS-approved. It is important that the expansion vessel is located on the cold feed rather than on the hot water side of the system.

8.23 The plantroom should be constructed with a waterproof and non-dusting type of floor with a slight fall to a drainage trench that should terminate in a trapped gully. The trapped gully should incorporate provisions to either avoid or replenish any trap-water-seal loss. The plantroom will require adequate lighting, ventilation and heating (to prevent freezing or condensation), with electric power points and/or provision for low-voltage supplies for portable lighting and tools.

8.24 If heavy plant is to be installed which may, on occasion, need to be removed for testing, maintenance or replacement, fixed lifting beams of suitable capacity should be provided.

Specialist systems

8.25 Where water supplies are required for specialist systems such as endoscope cleaning installations, dialysis units etc, the designer should consult the hospital infection control team to establish any specific water treatment requirements for the process, and also the local water supply authority to clarify any special precautions that may be necessary, such as backflow prevention devices. The advice of the water supply authority should also be sought as to any possible variation in the quality of supply or possible change in the source of supply (see also Health Building Note 53:'Facilities for renal services: Volume 1 − Satellite dialysis unit').

Vending, chilled water and ice-making machines

8.26 The water supply to this equipment should be taken from a potable supply via a double check valve to prevent backflow and be upstream of a regularly used outlet with the minimum of intervening pipe-run, that is, less than 3m. The supply should not be softened. Additionally, it should be established that the usage is sufficient to avoid deterioration in water quality, for example that the inlet water temperature does not exceed 20°C.

8.27 The equipment should be positioned so that the warm air exhaust does not impinge directly on taps or hoses supplying cold water.

8.28 Reference should also be made to the Food Safety (Temperature Control) Regulations 1995 and Food Safety (General Food Hygiene) Regulations 1995. The Automatic Vending Association of Britain (AVAB) codes of practice should be followed regarding hygiene and water quality and hygienic operation of vending machines (http://www.ava-vending.org). Vending machines dispensing carbonated drinks require special materials of construction which should be WRAS-approved.

©Health Facilities Scotland, a division of NHS National Services Scotland

9. Hot water services

General

9.1 Hot water services should be designed and installed in accordance with the Water Byelaws (Scotland) 2000and relevant parts of BS 6700:1997 and BS EN 806-2:2005. The hot water system may be of either the vented or the unvented type.

9.2 The basic components of a hot and cold service system as used within hospitals are shown in Figure 5; most installations will have additional features and components.

9.3 A vented system usually consists of a cold water storage cistern situated above the highest outlets, which feeds a hot water storage vessel (for example a calorifier or direct-fired boiler).

9.4 An unvented system usually has the hot water storage vessel connected to the mains water supply via a backflow prevention device and a pressure-reducing valve. The components of a directly heated unvented hot water system are shown in Figure 6.

9.5 Hot water is taken from the top of the storage vessel, or water heater, and will normally be circulated around the building in a piped distribution system. The flow temperature should be set to 60°C and the minimum temperature of all return legs to the vessel or water heater should be 50°C. Correct grading of pipework is essential to maintain correct circulation. In all but very small domestic installations, circulation is essential and trace heating should only be used in existing installations to overcome local problems with circulation where rectification would otherwise be disruptive to the operation of the accommodation served. In all but domestic systems, if recirculation is not used, some form of trace heating will be required. Such systems, however, should be restricted to areas where backflow contamination is a potential problem, for example pathology laboratories: these should be supplied from separate systems. The individual outlets, taps, mixing valves or other outlet devices will be served from the distribution system; this should be designed such that the minimum temperature at the most distant taps or outlets is 55°C.

Note: The control of *Legionella* requires there to be a minimum temperature of 50°C in hot water service systems (see Part B of this SHTM). A minimum of 55°C may be required for the operation of suitable fail-safe mixing devices required to provide 'safe' hot water at the upper limit of the recommended range. Hot water at 55°C is required for many applications such as washing in kitchens and laundries.

9.6 A small number of localised hot water distribution systems can have advantages over one large centralised system. With smaller systems, hot water

©Health Facilities Scotland, a division of NHS National Services Scotland

heaters are located closer to points of use and it is therefore easier to maintain hot water distribution temperatures within recommended values. Balancing water flow rates in the hot water secondary distribution system becomes less of a problem, and distribution losses are reduced. A small, localised hot water distribution system may comprise a gas-fired water heater, a storage calorifier, a semi-storage calorifier or plate heat exchanger. The adoption of localised hot water distribution systems will require the provision of local plantrooms.

9.7 With large centralised hot water systems, it is more difficult to maintain secondary distribution temperatures within recommended values; also, water flow rates in large secondary distribution systems can prove difficult to balance. At periods of low draw-off, detritus can lodge within the large horizontal distribution pipes forming part of centralised systems.

9.8 There are also maintenance factors to be considered. With a central hot water system, plant maintenance can be focused in one location, whereas with localised systems there will be a number of plantrooms at remote locations.

Hot water heater types

9.9 In most healthcare premises, hot water storage vessels include the heating source, which can be steam, high- or medium-pressure hot water, or electric immersion heating elements. The flow to the pipeline distribution system is normally taken from the top of the vessel, as too is the open vent, which may or may not be combined. The cold feed is usually taken in towards the base of the vessel and the return water circulation at about one-third of the height. Instantaneous water heaters for distribution systems have similar pipeline connections. All water heaters must be WRAS-approved and listed in the 'Water Fittings and Materials Directory'.

9.10 Traditional design practice has been to provide a non-check-valved cold feed and expansion pipe to the calorifier/water heater and an open vent discharging over the cold feed cistern. Means should be taken to prevent warm water entering the cold feed line and possibly leading to conditions conducive to colonisation by *Legionella*. A check valve can be provided in the cold feed to prevent such circulation, but this will prevent the operation of the cold feed as an expansion pipe. An alternative is to provide a U-bend or S-bend in the cold feed sufficient distance from the connection to the calorifier so that water, which is warm, is not displaced (on heating up) beyond the bend and the vertical pipe rise. Similarly with a need to preserve the potability of water at all times in the storage cistern, the practice of terminating the vent pipe (air vent) over the cistern is no longer permitted by regulations. The vent should be arranged to discharge over a separate tundish arrangement, with visible Type AA air gap, sited at a level that takes account of the hydrostatic head of the system: the tundish should discharge to drain. The calorifier or water heater should be provided with a suitable safety valve of appropriate size and vacuum release arrangement.

9.11 Most vessels have some means of access for inspection, either via a special panel or by removing the heating coils/elements. When new calorifiers are

©Health Facilities Scotland, a division of NHS National Services Scotland

required, it should be specified that they have separate and adequately sized access panels.

9.12 Where water quality indicates the need, cathodic protection from galvanic action by means of sacrificial anodes should be provided.

9.13 The combined storage capacity and heater output must be sufficient to ensure that the outflow temperature, at continuous design flow (at least 20 minutes) from calorifiers or other heaters, should not be less than 60°C. This applies to both circulating and non-circulating hot water systems. The positioning of the control and high limit thermostats, cold feed and return water connections must ensure that these temperatures are achieved.

9.14 There are basically three types of water heater:

- instantaneous heater;
- storage calorifier;
- limited storage calorifier.

Instantaneous water heaters

9.15 This type of heater can be further subdivided into:

- instantaneous water heaters for single or multi- point outlets: these devices are usually either electrically or gas heated. The general principles and limitations of instantaneous water heaters are given in BS 6700:1997. In essence:
    - the hot water flow rate is limited and is dependent upon the heater's power rating;
    - the water in instantaneous water heaters is usually heated to about 55°C at its lowest rate, and its temperature will rise and fall inversely to its flow rate. Where constant flow temperature is important, the heater should be fitted with a water governor at its inflow. Close control of temperature is of particular importance for showers. To attain constant temperatures on delivery, water flow and pressure must also be controlled. Variations in pressure can cause flow and temperature problems when the heater is in use, and when setting up or adjusting flow controls;
    - they are susceptible to scale formation in hard water areas, where they will require frequent maintenance;
    - this form of hot water heating should be considered only for smaller premises or where it is not economically viable to run a hot water circulation to a remote outlet;
- instantaneous-type water heaters for distribution systems: these devices, which normally use steam or high/medium pressure hot water

©Health Facilities Scotland, a division of NHS National Services Scotland

as the primary heating medium, are designed to heat their rated throughput of water rapidly from cold to the design outlet temperature. They can be used either to feed directly into a hot water distribution system, or in conjunction with a storage vessel which reduces the load on the heater during periods of peak demand. This type of heater includes:

- hot water generators: these are vertical instantaneous water heaters that contain modular helical primary coils normally served by steam, medium temperature hot water (MTHW) or high temperature hot water (HTHW). The unit incorporates a temperature control device, which varies the rate of primary energy input so as to maintain a constant hot water flow temperature over a range of secondary flow rates through the heater;

- plate heat exchangers: plate heat exchangers consist of a number of rectangular plates sandwiched between two flat endplates and held together by tie bolts. The plates have ports in all four corners that allow entry and discharge of the primary and secondary liquids. Primary liquid is directed through alternate pairs of plates while the domestic hot water is normally fed in a counter flow direction through the remaining pairs of plates. Each plate is sealed round the edges by a gasketing system, the design of which should ensure that fluids cannot, under normal operating conditions, either leak to atmosphere or mix. This type of heat exchanger can be extended easily, or shortened, to suit changes in hot water demand.

Storage calorifiers

9.16 Storage calorifiers are usually cylindrical vessels mounted either vertically or horizontally; the base of a vertical calorifier can be concave or convex, with the vessel being supported on feet. The latter design is preferred, as it avoids the annular space where the base joins the cylinder wall. Heater batteries are usually located near the bottom of the cylinder, which can give rise to an area of water beneath the battery significantly below the storage temperature. This “dead” area can provide an ideal breeding ground for bacteria. Galvanised cylinders are particularly susceptible to scale formation, which can also provide a source of nutrition and shelter for bacteria.

9.17 As a result of this, galvanised cylinders are not recommended in new hospital installations or for replacement.

9.18 The following points should be considered during the design process (see also paragraphs 9.28–9.29):

- the entire storage volume should be capable of being heated to 60°C without permanent pockets of lukewarm water;

©Health Facilities Scotland, a division of NHS National Services Scotland

- the shell lining should be resistant to bacterial growth;
- sufficient access to ensure adequate cleaning of the shell must be provided;
- a suitably-sized drain should be connected to the base of the calorifier.

Limited storage calorifiers

9.19 These calorifiers can either have an independent heating facility such as oil or gas burners or electric elements, or use primary water/steam from a boiler to heat the water via a heat exchanger. The equipment is available in a range of storage capacities and recovery flow rates. This type of equipment is particularly suitable where systems are being decentralised and water heaters are required close to the point of use.

Sizing of hot water storage vessels

9.20 Storage should be calculated on the requirements of peak demand and the rate of heat input. There may be more than one peak period in each 24 hours. The interval between peak periods is important, as it affects the recovery time.

9.21 The CIBSE Guide G: 'Public health engineering', gives guidance on sizing hot water storage.

9.22 Since the original study set out in Appendix 1 a review of systems indicates that the overall capacity and consumption predicted is excessive (see paragraphs 7.4–7.5).

9.23 Where storage calorifiers are used, the hot water storage capacity should be sufficient to meet the consumption for up to two hours; this must include the period of maximum draw-off. The installed hot water capacity should be sized for current needs and should not be designed with built-in capacity for future extensions.

9.24 Some devices are optimistically rated so that, at a continuous demand equal to their design rating, the flow temperature can fall below 60°C. Semi-storage or high-efficiency minimum storage calorifiers and instantaneous heaters are especially prone to this if under-sized.

Connection arrangements for calorifiers and water heaters

9.25 Where more than one calorifier or heating device is used, they should be connected in parallel, taking care to ensure that the flow can be balanced so that the water temperature from all the calorifiers exceeds 60°C at all times (see also paragraph 9.42).

9.26 Installations must not include for series operation of calorifiers.

©Health Facilities Scotland, a division of NHS National Services Scotland

Stratification in storage vessels

9.27 Stratification will occur in any storage calorifier or heater; the temperature gradient will depend on the rate of draw-off and heat input. In some calorifier designs, stratification is significantly more pronounced and is a feature of their design. There will always be a volume of water in the temperature range that encourages maximum growth of *Legionella*.

Note: Water temperatures in the range 20°C–45°C favour growth of *Legionella*. It is uncommon to find proliferation below 20°C, and *Legionella* do not survive long above 60°C. The optimum laboratory temperature for the growth of *Legionella* is 37°C, that is, body temperature. *Legionella* may, however, remain dormant in cool water, multiplying only when the temperature reaches a suitable level.

Note: Stratification: in a storage calorifier the upper level, above the heating element, will be at operating temperature (60°C) during normal periods of demand. Below this level will be a volume of water between the feed water temperature and operating temperature. This level will vary as draw-off takes place according to the thermal input and rate of demand.

9.28 Storage and semi-storage calorifiers should be provided with independently pumped circulation from the top to the base of the calorifier; this is referred to as a 'shunt pump'. The pump should be run continuously for about an hour during periods of minimum demand to raise the entire contents of the calorifier to 60°C. During periods of low draw-off, the temperature will readily achieve 60°C to effect disinfection. Control should be by a timing device that can be adjusted when the profile of demand has been established.

9.29 Some semi-storage/high-efficiency calorifiers are supplied with an integral pump that circulates water in the calorifier; in this case a second shunt pump is not required.

Provisions for maintenance

9.30 There should be adequate access to calorifiers for inspection and cleaning, removal and replacement of tube bundles and removal and replacement of the entire calorifier.

9.31 All calorifiers and water heaters must be fitted with a drain valve located in an accessible position at the lowest point on the vessel so that accumulated sludge may be removed effectively from the lowest point. The drain should be of sufficient size to empty the vessel in a reasonable time. A schedule of approximate calorifier emptying times is given in Table 3.

Comment [h7]: The table is in the same section.

9.32 Drain valves should be of the ball type to avoid clogging, and a drainage gully should be provided of sufficient size to accommodate the flow from the calorifier drain.

©Health Facilities Scotland, a division of NHS National Services Scotland

Unvented hot water systems

9.33 Hot water storage systems have traditionally been provided with an open vent pipe that relieves any steam generated in the event of failure of temperature controls. The open vent pipe also protects against rupture of the cylinder by expansion of water.

9.34 The use of unvented hot water systems is now permitted in the UK and is covered in Section 4: Safety section of Section 6 Energy in the Non-Domestic Scottish Technical Handbooks, 2007, which covers installation, specification and discharge.

9.35 Where an unvented hot water system is connected directly to the water mains, no back-up will exist in the event of a water supply failure. Such an arrangement may also be unacceptable to the local water supply authority, since they will be required to meet the maximum demand at any time over a 24-hour period.

Calorifier type	Diameter/ length ratio	Capacity: Litres (Gallons)	Drain valve sizes mm (inch)		
			25 (1.0)	38 (1.5)	50 (2.0)
Horizontal	1:2.5	13,500 (3000)	3 hr 00 min	1hr 20 min	45 min
		9000 (2000)	2 hr 10 min	1 hr 00 min	30 min
		4500 (1000)	1hr 10 min	30 min	20 min
		2250 (500)	39 min	17 min	10 min
		1800 (400)	32 min	14 min	8 min
		1400 (300)	25 min	11 min	6 min
Horizontal	1:1.5	13,500 (3000)	3 hr 00 min	1 hr 20 min	45 min
		9000 (2000)	2 hrs 10 min	1 hr 00 min	30 min
		4500 (1000)	1 hr 10 min	30 min	20 min
		2250 (500)	39 min	17 min	10 min
		1800 (400)	32 min	14 min	8 min

		1800 (400)	31 min	14 min	8 min
		1400	25 min	11 min	6 min
			Times assume no hose and simple ball-type valve		

Table 3: Approximate emptying times for calorifiers

9.36 The design and installation of unvented hot water systems should comply fully the Non-Domestic Scottish Technical Notebooks, 2007 of the Water Byelaws (Scotland) 2000.

©Health Facilities Scotland, a division of NHS National Services Scotland

9.37 The key requirements are that the temperature of stored water should be prevented at any time from exceeding 100°C and that discharges from safety devices should be conveyed to a safe and visible place and protected to prevent blockages by the ingress of birds, rodents or insects etc.

9.38 A schematic layout of a typical directly heated unvented hot water system is illustrated in Figure 6 along with a brief description of the main components.

9.39 The discharge pipes from the temperature relief valve and expansion valve should be carefully located so that they are readily visible but do not present a risk to people and protected to prevent blockage by the ingress of birds, rodents or insects etc.

9.40 Where the hot water is heated directly, for example by a steam or LTHW primary coil, a non-self-resetting thermal cut-out wired to a motorised valve on the primary coil must be provided for control of excessive temperature. This should be further protected by a direct-acting protection device, particularly with a plastic pipework installation.

Sealed expansion tanks for unvented hot water systems

9.41 These vessels are typically vertical in orientation and normally have a diaphragm to separate the water from the gas space above. They introduce a potential problem of colonisation by *Legionella*, as the plantroom space temperature will exceed that of the incoming water. It is important that the expansion vessel is located on the cold feed rather than on the hot water side of the system. All materials in contact with water should be WRAS approved.

Hot water distribution system

9.42 To control the possible colonisation by *Legionella*, it is essential to maintain the temperature within the hot water circulating system. To some extent, if properly maintained, the calorifier/water heater will provide a form of barrier to *Legionella* and other water-borne organisms. For premises with intermittent use, the generation of domestic hot water must be continuous unless there is an anticipated prolonged shut down, in which case systems should be drained dry, as occurs between final commissioning and putting systems into use in a new build situation.

©Health Facilities Scotland, a division of NHS National Services Scotland

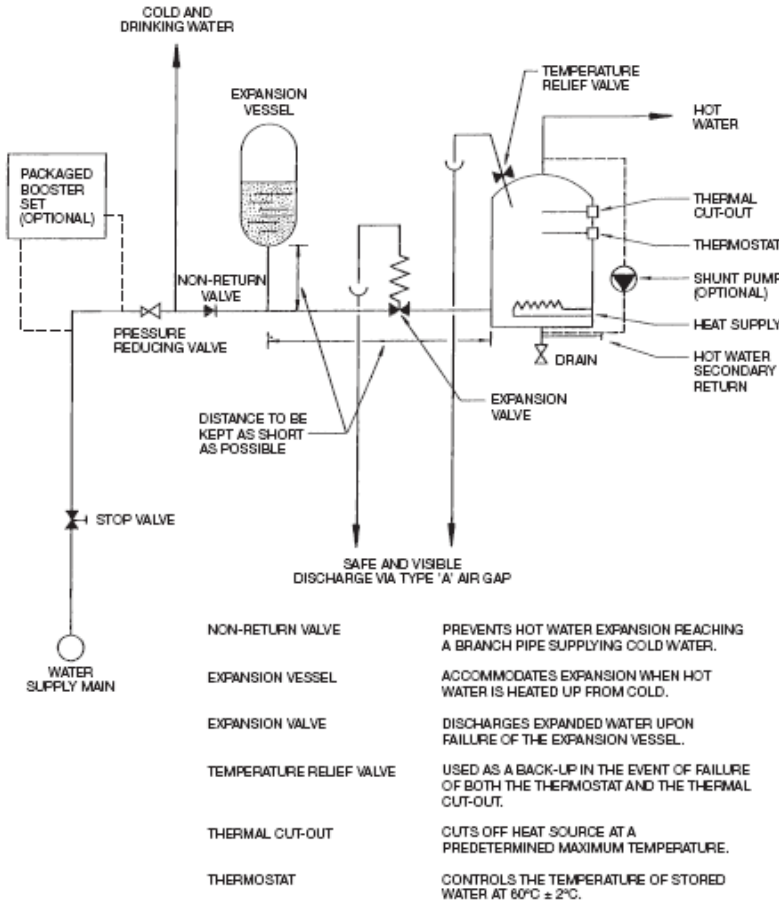

Figure 6: Directly heated unvented systems

9.43 The minimum flow temperature of water leaving the calorifier/water heater should be 60°C at all times, and 55°C at the supply to the furthermost draw-off point in the circulating system. The minimum water temperature of all return legs to the calorifier/water heater should be 50°C.

Note: A minimum of 55°C may be required for the operation of suitable mixing devices required to provide 'safe' hot water at the upper limit of the recommended range.

9.44 To achieve the required circulating temperatures, it will be necessary to provide some form of regulation to balance the flow to individual pipe branches serving groups of draw-off points, for example each washroom/toilet and en-suite facility etc.

9.45 The means of balancing the hot water circulation can be achieved by either manual or thermostatic regulating valves installed in the return. There should be means of isolation, both upstream and downstream. Adequate access for servicing is also essential.

©Health Facilities Scotland, a division of NHS National Services Scotland

9.46 In ward accommodation where en-suite facilities are provided, it is recommended that the hot water circulation be extended to draw-off points in series, for example the supply to a basin, bath and/or shower should be run as one circuit (see Figures 6).

9.47 The operating pressures for both hot and cold water at draw-off points should be the same.

9.48 The domestic hot water system must not be used for heating purposes. This includes all radiators, towel rails, heated bedpan racks etc, whatever the pipework configuration.

9.49 Particular attention should be given to ensuring that pipework containing blended water is kept to the minimum. Generally, the downstream dead-leg should not exceed 2 m, and the complete length of the spur should not exceed 3 m. The length is measured from the centre line of the circulation pipework to the point of discharge along the centre line of the pipework. The same restriction applies to "communal" blending, that is, where more than one outlet is served by one device. Central blending systems should not be used, since the length of distribution pipework containing water in the temperature range that supports *Legionella* growth would far exceed these maximum permissible lengths.

Water temperatures and delivery devices

9.50 The risk of scalding for patients (children and young people, older people, and people with disabilities) and staff is a particular problem in healthcare premises caring for such individuals, and therefore thermostatic mixing devices will be needed for many hot water outlets, with different temperatures required for differing toiletry needs. A risk assessment will be necessary to establish the need and type of device to be installed.

9.51 Hand-washing is best performed under running water in basins/sinks without plugs, as they easily become soiled especially where usage is high – this necessitates the installation of a mixing device.

Note: The Water Byelaws (Scotland) 2000 place limits on the flow of water to draw-offs where plugs are not provided. Spray-type mixer taps are not recommended in healthcare premises; therefore, the type of tap should be carefully selected to minimise the formation of aerosols (With regard to the requirement for plugs, see also the section on baths, sinks, showers and taps in DEFRA's (1999) guidance document to the Regulations.)

9.52 Thermostatic mixing valves should comply with the standards of the MES D08 – 'Thermostatic mixing valves (healthcare premises)'. Thermostatic valves should be tested and accepted by the BuildCert TMV Scheme (http://www.buildcert.com/TMV).

9.53 The types of mixing device are specified in Table 4.

©Health Facilities Scotland, a division of NHS National Services Scotland

Showers

9.54 Showers with fixed heads are preferred for prevention of backflow. Where flexible hoses and moveable shower outlets are provided, the outlet must not be capable of being accidentally immersed into a drain, WC or other potential source of contamination. Some shower heads are provided with a means for adjusting the flow, for example fine spray, pulsating flow etc, selected by utilising different sets of nozzles. As this will exacerbate possible stagnation problems, they should not be installed in healthcare premises. Taps and showers should be flushed at least twice weekly, or the retained water flushed to waste immediately before use without the generation of aerosols.

9.55 To facilitate the required regular removal of shower thermostatic mixing valves for inspection, careful consideration will be required to ensure that these are not recessed in such a way that access can damage thermal insulation on connecting pipework or to the removable panels themselves in wet areas. Surface mounted thermostatic mixing valves with smooth protective panels concealing isolating valves, strainers and check valves will eliminate this problem and avoid repetitive damage to waterproof membranes.

Strainers

9.56 Strainers should be fitted within the water pipework system to protect expansion vessels, mechanical backflow protection devices, thermostatic valves etc against ingress of particulate matter. The installation of these fittings should allow adequate access for maintenance/replacement and they should be provided with means of upstream (and downstream where appropriate) isolation. Strainers can be a source of *Legionella* bacteria and should be included in routine cleaning, maintenance and disinfection procedures (see Chapter 7, Part B).

Cold feed cisterns and tanks

9.57 When separate cold feed cisterns are provided for hot water service installations, they should comply with the requirements for cold water systems.

Note: Hot water cylinders with an integral feed and expansion tank are not recommended.

Service isolation valves

9.58 Service isolation valves should be fitted to all pipework preceding sanitary tapware and WCs etc for servicing, repair and replacement. Drain-valve provision may also be appropriate for certain installations, for example service pipework to en-suite facilities etc.

©Health Facilities Scotland, a division of NHS National Services Scotland

Table 4: Safe water temperatures and delivery devices

Area/activity	Recommended temperature (°C)	Type of device (see MES D08 for example explanation of valve types)
Staff bases, ward and consulting rooms etc basins In-patient, out-patient hand-wash basins	41	Type 3 Thermostatic
General areas to which staff and visitors may have access See note 3 below	41	Type 2 Thermostatic
Paediatric baths	40 - to allow for the cold paediatric bath/sink NB: Paediatric nurses should always use a thermometer	Type 3 Thermostatic
General baths	43	Type 3 Thermostatic
Showers	41	Type 3 Thermostatic
Assisted baths	46 - to allow for the cold mass of the bath NB: Nurses should always use a thermometer before immersing patients	Type 3 Thermostatic
Hair-wash facilities	41	Type 3 Thermostatic
Bidets	38	Type 3 Thermostatic
All sinks, kitchens, pantries, slop sinks etc	55 - minimum required for food hygiene and decontamination purposes	Separate hot and cols taps or combination tap assembly Type 1; no preceeding thermostatic device
Office, staff-only access areas hand-wash basins	43	Type 1

©Health Facilities Scotland, a division of NHS National Services Scotland

Notes:

1. It is preferable that thermostatic mixing devices are fitted directly to the mixed temperature outlet or be integral with it, and be the method of temperature and flow control, i.e. the mixing device should not be separate and supply water via second tap or manual mixer since there will be many cases where draw-off of cold water will not occur. If a separate thermostatic device is used, it should be fitted as close to the outlet as possible, which should be a flow only control. Where “T” type mixing valves are installed they will require access for maintenance and consideration should be given to their location behind sanitaryware partitions.

2. In the case of bidets with ascending sprays, or a handled douche, which may be accidentally immersed in an adjacent WC, water taps must be supplied via a suitable air gap, normally from a storage cistern.

3. Automatic taps should be considered for general public access washroom/toilets, surgical scrub sinks and hand-wash basins in main kitchen/food preparation areas; because the temperature is non-user adjustable they should be supplied from a Type 2 TMV set to 41°C. they are not recommended where the frequency of use of sanitary assemblies is low; part of the operational management regime will necessitate “flushing” of outlets. Such flushing can be time-consuming and is not facilitated by automatic taps that require a continual presence. The proximity detector should include a timer than can be adjusted to take account of the optimum washing time: this is particularly important for scrub sinks.

4. Automatic flushing WCs can also be considered for similar areas.

5. In the case of a dual function delivery device. I.e. shower/bath diverter, a risk assessment will be necessary to establish what temperature setting is required.

©Health Facilities Scotland, a division of NHS National Services Scotland

10. Building and energy management systems

10.1 The continued safe operation of domestic hot and cold water systems requires a number of routine checks to be made by physical means using separate thermometric equipment. A number of the control parameters can, however, be monitored by Building and Energy Management Systems (BEMS) continuously, even though routine checks will still be required for “calibration purposes”. Parameters that should be monitored are as follows:

- incoming mains temperature (at the water meter), inlet, outlet, and surface water temperatures of cisterns and cold water feed tanks for hot water calorifiers;
- calorifier flow and return temperatures;
- hot water service flow and circulation temperatures at the furthermost outlets in individual wards;
- cold water service at the furthermost point from the pipeline entry to the ward/department.

Smaller premises without a Building and Energy Management System will require the same routine checks and monitoring carried out manually with the interval between checks determined by experience and risk assessments.

10.2 In addition to temperature, the BEMS should also monitor pressurisation and circulating pumps, and water treatment systems for fault conditions or change of status likely to result in a fault.

©Health Facilities Scotland, a division of NHS National Services Scotland

11. Materials of construction

General

11.1 Any materials that come into contact with the water in a hot and cold water installation must comply with the requirements of the Water Byelaws (Scotland) 2000. A list of products and materials that have been assessed for compliance with the requirements of these Regulations is given in the current edition of 'Water Fittings and Materials Directory', which is updated every six months. Further information on the selection of materials can be found in BS 6700:1997, BS EN 806-2:2005 and BS 6920-1: 2000.

11.2 Materials of construction should be selected to take account of water quality and its potential corrosive properties. The water supply authority should be asked to provide details of any specific requirements and variability from standard conditions.

11.3 Water supplied by the water supply authority, although remaining uniformly wholesome, will nevertheless differ chemically. Some waters are slightly acidic while others are slightly alkaline, and this affects the choice of materials for pipes, fittings and cisterns. The water supply authority also blends water and accordingly, the character of the water supply may vary from time to time. It will therefore be necessary to consult the water supply authority for advice on what materials should be avoided.

11.4 The choice of materials for buried piping and fittings should also take into account the nature of the soil in which the piping is to be laid. The materials selected should, where necessary, resist possible corrosion both inside and outside. The extent, if any, of anti-corrosion treatment of the outside of the piping will depend on the analysis of the soil. The advice of the water authority (see Note 1); should be sought on the protective measures usually adopted in the area.

11.5 Corrosion (or erosion) can be caused by the motion of water when it is in a turbulent state and thus subject to rapid changes in pressure. Minute vapour or gas bubbles may be released at instants of low pressure; these collapse with implosive force the moment the pressure is increased. The collapse of such bubbles upon a metallic or concrete surface will quickly cause deep pitting or erosion of that surface. The designer should therefore avoid high velocities, the sudden increase of pressures or pulsating pressures.

11.6 Metallic piping should not be installed in contact with corrosive building products and materials.

11.7 Corrosion may result from galvanic action where dissimilar metals are connected. Dissimilar metals should be avoided as far as practicable, but if that is not possible, it should be determined that deterioration through galvanic

©Health Facilities Scotland, a division of NHS National Services Scotland

action is unlikely to occur, or else effective measures should be taken to avoid deterioration.

11.8 The materials generally used for the conveyance of water in healthcare premises are stainless steel or plastics. Copper is only used in exceptional circumstances such as, an extension to existing premises with short life expectancy, or very small stand alone premises. Where this is specified, only lead-free solders should be used.

11.9 Substances leached from materials of construction of pipes, cisterns or other water fittings in contact with water must not adversely affect the quality of water stored or drawn for domestic or food production purposes (Water Byelaws (Scotland) 2000).

11.10 Direct gas-fired water heaters are particularly prone to corrosion and scale formation, and the inside of these heaters should be provided with suitable linings to limit these effects.

Steel pipes and fittings

11.11 Where steel is used for bolts, nuts and slip-on couplings, adequate protection from corrosion should be provided. This usually takes the form of bitumen coating, but bitumen is not permitted in contact with water required to be wholesome (that is, to be used for normal domestic or food production purposes).

11.12 The character of water in Scotland is such that steel, whether galvanised or not, should not be used at all for domestic hot and cold water installations. Any existing premises with such pipework shall have this scheduled for early replacement.

Stainless steel

11.13 Stainless steel is being increasingly used in hot and cold water service systems. Reference should be made to SHTN 2: ‘Domestic hot and cold water systems for Scottish health care premises’.

Copper pipes and copper/copper alloy fittings

11.14 As described previously, careful consideration will be required if copper pipework and fittings are to be specified for healthcare premises in Scotland. Where this is considered to be acceptable either due to the size of the project or the anticipated lifespan of the facility, the following will apply.

11.15 Copper in general is resistant to corrosion. Unless resistant to dezincification, brass fittings must not be used where water conveyed is capable of dissolving undue amounts of zinc from the fitting. External protection from corrosion for buried pipework may be obtained by using copper tube with a factory-applied polythene sheath. Dezincification-resistant material must be used for fittings that

©Health Facilities Scotland, a division of NHS National Services Scotland

are concealed or inaccessible, for backflow prevention devices, and for temperature and pressure-relief devices on heating systems. Copper piping should conform to BS EN 1057: 1996 as appropriate for underground or above - ground installations. When soldering copper tube and fittings, refer to WRAS Information and Guidance Note 9-04-02: 'Solder and fluxes'. If wax-based soldering fluxes must be used, they should be used sparingly. They pose a risk of bacterial contamination to the system, which can be difficult to eradicate.

11.16 Fittings should comply with the requirements of BS EN 1254-1−5:1998. Copper piping may be jointed by means of compression joints or capillary joints. Effective capillary joints in copper pipes can be achieved if care is taken in their construction. Where compression joints are used with fully annealed copper piping, these should be manipulative joints; that is, joints in which the tube ends are flared or grooved.

11.17 Lead-free materials must be used in the formation of all potable water pipe capillary joints.

Plastics

11.18 Most water systems operate at modest pressures and at a maximum temperature of 70°C. Such operating conditions are within the specified performance of plastics being produced in a range of sizes and costs suitable for healthcare premises. Plastic pipework is not suitable for renal dialysis applications where water at a temperature of 95 C is regularly circulated for sanitisation and there is an incompatibility with reverse osmosis treated water used in renal dialysis and in endoscope cleaning.

11.19 Advantages of plastic include corrosion resistance, lightness of weight and ease of handling.

11.20 Disadvantages include poorer mechanical strengths than metals, greater thermal expansion (about seven times that of copper), low temperature (and possible long-term embrittlement [20–25 years]) and shorter distances between pipe supports. The latter can be alleviated by employing the manufacturer's profiled longitudinal tray that snaps into place and extends the distances between supports.

There have also been difficulties with ring seal failures that have required wholesale replacements of all fittings.

11.21 Materials in common use for plastic pipework are medium-density and high-density polythene, the latter being stronger. Unplasticised polyvinyl chloride (PVC-U) pipework has mainly been replaced by the stronger chlorinated polyvinyl chloride (PVC-C) equivalent. All materials used for the transportation of water can give rise to contamination by differing processes. It is therefore important when introducing new materials that care is taken to ensure that appropriate standards are maintained. In the case of plastic materials, this can often be achieved by introducing a suitable "flushing" routine during the commissioning period.

©Health Facilities Scotland, a division of NHS National Services Scotland

11.22 PVC pipes to BS 3505:1986, BS EN 1452:2000 (parts 1−5) and BS 3506:1969 are of a rigid material that has a greater tensile strength than polythene, but is less resistant to fracture. These materials are less susceptible to frost damage than metal pipes. Although freezing is unlikely to damage the pipe, it will result in interruption of supply, and subsequent leakage from joints may occur.

11.23 Polythene pipes are generally not susceptible to corrosion from either the water or the ground in which they are laid. However, they are not recommended in any soils contaminated with organic materials likely to permeate the plastics and taint the water such as coal gas, methane, oils, petrol or other organic solvents. Further advice is available in the WRAS Information and Guidance Note 9-04-03: 'The selection of materials for water supply pipes to be laid in contaminated land'.

11.24 It is essential to consider the locality of exposed plastic pipes to ensure that there is no likelihood of mechanical damage and effects of UV daylight; otherwise suitable protection around the pipe will be necessary.

11.25 Further advice on flushing regimes is given in SHTN 2: 'Domestic hot and cold water systems for Scottish health care premises'.

11.26 Methods of jointing employed include compression joints with insert liners, flanged, screwed and fusion-welded joints, as well as joints of the spigot and socket type. The method of jointing employed is dependent on the bore of the pipe and the applied internal pressure, and should be in accordance with the manufacturer's recommendations. A competent fitter who has been trained under an approved scheme should make joints.

Composite materials

11.27 Less proven, but available on the market, are composite pipes, for example aluminium pipe with an external and internal sheath of plastic. Little evidence on the performance of such pipes is so far available, and questions remain over earth bonding.

Iron pipes and fittings

11.28 Ductile iron is not used nowadays but it may be encountered in the course of a refurbishment project. Iron has good resistance to corrosion, and this is further enhanced if the casting skin on the metal is still intact. Although ductile iron pipes are thinner than grey iron pipes, their resistance to corrosion is at least as good, and there is evidence that they tend to be rather more resistant. In assessing the life expectancy of ductile iron pipelines, account should be taken of any intended higher operating pressures that may be used or permitted. Any iron pipework encountered should be risk assessed with a view to early replacement, dependent upon the anticipated life span of the accommodation served.

11.29 In made ground containing ashes and clinker, or in certain natural soils, such as aggressive waterlogged clays, saline and peat marshes, additional external

©Health Facilities Scotland, a division of NHS National Services Scotland

protection may be required. This may be provided by the use of protective coatings such as bitumen or coal-tar sheathing, by protective tapes, by loose polythene sleeving or, in certain circumstances, by concrete. The water supply authority is using more composite materials in pipework to overcome the risks.

Lead

11.30 No new lead piping should be installed in any building. In the unlikely event of any lead pipework being discovered in existing healthcare premises, it should be removed as soon as practical.

Concrete

11.31 Protection of concrete pipes may be required against sulphate and acid attack. The minimum size available in concrete pipework is 150 mm diameter, and therefore its practical use for healthcare premises is very limited.

11.32 Standard concrete pipes may be used when not subjected to internal pressure. Pre-stressed concrete pipes are available as pressure pipes, but only in larger sizes.

Asbestos cement pipes and fittings

11.33 Asbestos cement pipework should not be used and, if encountered in the course of a refurbishment project, it should be stripped out and replaced as a high priority with modern materials such as medium density polyethylene.

11.34 Specialist advice should be obtained if stripping out materials containing, or suspected of containing, asbestos is carried out.

©Health Facilities Scotland, a division of NHS National Services Scotland

12. Pipework installations

General

12.1 All hot and cold water pipework should be designed and installed in full accordance with the Water Byelaws (Scotland) 2000 and relevant parts of BS 6700:1997 and BS EN 806-2:2005.

12.2 It is essential to include within the system facilities for measuring, regulating, isolating, venting, draining and controlling the flow of water. Regulating valves with built-in pressure tappings or orifice plates with manometer tappings will be required for the measurement of pressure drop, which enables the volume rates of flow to be determined. Care must be taken to ensure that regulating valves or orifice plates are sited well away from bends or fittings.

Sizing

12.3 Mains should be capable of a rate of flow to satisfy the combined maximum demand of all the services to be supplied. All the maximum demands of the separate services may not occur simultaneously, and the actual combined maximum demand may be a proportion of the sum of the separate maximum demands, which will be determined by the number and character of the services.

12.4 Hot and cold water pipework should be sized using the procedure outlined in CIBSE Guide G: 'Public health engineering.

Routeing of pipework

12.5 Pipework in buildings should be designed and routed in a manner that will promote good turnover of water, particularly in cold water service systems (see Figure 5). It should be installed so that it is accessible for inspection, maintenance and repair as far as is practicable. Ducts, trenches and chases containing pipework should be large enough to facilitate repairs.

12.6 Pipework distribution networks should be divided into sections by the provision of isolating valves in accessible locations to facilitate isolation for repairs, maintenance and flushing.

12.7 Underground mains need not be laid at unvarying gradients but may follow the general contour of the ground. As far as possible, however, they should fall continuously towards drain points and rise continuously towards the air vent. They should not rise above the hydraulic gradient; that is, there should always be a positive pressure, greater than atmospheric, at every point under working conditions. The gradient between air release and drainage valves should be not

©Health Facilities Scotland, a division of NHS National Services Scotland

less than 1:500 rising in the direction of flow and not less than 1:200 falling in the direction of flow.

12.8 Underground pipes entering a building should do so with a cover of not less than 0.75 m below the external ground surface and should pass through the wall within a watertight built-in sleeve. The sleeve should be filled in around the pipe with a suitable material for a minimum length of 152 mm at both ends to prevent the ingress of water or vermin. External underground pipes should be at a depth, or otherwise sufficiently protected, to prevent damage by traffic and any consequent vibrations. A minimum depth under roadways of 1 m measured from the top of the pipe to the surface of the roadway is necessary. In other underground locations the depth should not be less than 0.75 m, subject to this depth being sufficient protection against frost; frost penetration depends on the nature of the subsoil and the ground surface. Freezing can occur at depths of up to 1.1 m. Local information on the prevalence of frost should be sought.

12.9 Marker tapes should be laid over the whole length of all underground water services pipework. The tapes should be clearly marked with the description of the service and should be coloured blue.

Vents and drains

12.10 Air-release valves should be provided at summits and drainage valves at low points between summits, unless adequate provision is made for the discharge of air and water by the presence of service connections. Large-orifice air valves will discharge displaced air when mains are being charged with water. When air is liable to collect at summits under ordinary conditions of flow, small orifice air valves, which discharge air under pressure, may be required. “Double-acting” air valves having both large and small orifices should be provided where necessary. Air-valve chambers should be adequately drained to avoid the possibility of contamination.

12.11 Automatic air-release valves should be installed where accessible for maintenance. Installation in ceiling voids is not recommended.

12.12 Drain points should not discharge directly into a drain or sewer or into a manhole or chamber connected thereto without a type A air gap. Where a wash-out discharges into a natural watercourse, the discharge should at all times be well above the highest possible water level in the watercourse. Consent for this discharge may be required from the Scottish Environment Protection Agency. In some cases it may be necessary for the wash-out to discharge into a watertight sump, which has to be emptied while in use by portable pumping equipment.

12.13 In order to minimise quantities of water that may collect in stub pipes at drain points, the length of such stub pipes should be kept to an absolute minimum. This relates in particular to drains from hot water calorifiers, storage cisterns and distribution pipework.

©Health Facilities Scotland, a division of NHS National Services Scotland

Valves

12.14 A clear indication should be given on all valves of the direction of rotation needed to close the valve. Normal practice is to have clockwise closing when looking down on the valve.

12.15 Where blending valves have been installed at the end of a run of hot water pipework, consideration should be given to the inclusion of a drain valve adjacent to the mixer. This should be located upstream of the mixing valve so as to facilitate flushing out and routine temperature testing of the hot water without having to dismantle the blending valve.

Prevention of contamination

12.16 In all cold water installations it is important that adequate protection be provided to all supplies against backflow. In healthcare facilities, there should be a high degree of protection not only to the water in the water supply authority's mains, but also within the installations to protect the patients and staff. In addition to backflow protection at all points of use, the whole installation protection should be provided as required by the Water Byelaws (Scotland) 2000.

12.17 Healthcare buildings and medical premises have been identified as involving Fluid Category 5 backflow risks (see Schedule 1 "Fluid Categories" from the Water Byelaws (Scotland) 2000 which are defined as points of use or delivery of water where backflow is likely to involve fluids contaminated with human waste. Within healthcare facilities, water usage covers a wide range of applications, from domestic use by patients and staff to specialised use in operating departments and pathology laboratories, and with equipment such as bedpan washers and haemodialysis machines. In addition, many apparently "commercial" usages may be classed as high-risk because they are for healthcare purposes, such as centralised laundries.

12.18 The hot and cold water storage and distribution systems should be designed so as to avoid the risk of contamination of the water supply. Such contamination may be caused by backflow, interconnections between potable and non-potable water supplies, stagnation, contact with unsuitable materials or substances, *Legionella* growth etc. The Water Byelaws (Scotland) 2000require the identification, by colour-coding or labelling, of all pipework carrying fluids other than wholesome water.

12.19 Comprehensive guidance on the measures required to prevent contamination of the water supply is given in the WRAS 'Water Regulations Guide' and in relevant parts of BS 6700:1997 and BS EN 806-2:2005.

12.20 Certain departments such as pathology laboratories present particular risks of water contamination. Attention is drawn to section G15.24 in the WRAS 'Water Regulations Guide' on supplementing point-of-use protection by zone protection, where the pipes supplying a high-risk area can be given additional protection by installation of a secondary backflow protection device.

©Health Facilities Scotland, a division of NHS National Services Scotland

12.21 Instances of water use in hospitals where backflow is likely to be harmful to health include bidets, bedpan washers, dental spittoons and equipment, mortuary equipment, and water outlets located in laboratories.

12.22 Where any doubt exists with regard to the level of protection required against water supply contamination, reference should be made to the Water Byelaws (Scotland) 2000 and guidance contained in the WRAS 'Water Regulations Guide', or water supply authority.

Frost protection

12.23 The Water Byelaws (Scotland) 2000 require that all cold water pipework and fittings be adequately protected against damage from freezing.

12.24 In the case of external pipework that is run underground, the Regulations require that consent be sought from the water supply authority if pipes are to be run at depths of less than 750 mm or greater than 1350 mm. Permission from the water supply authority must be sought if any deviation is required.

12.25 Particular care is required when routeing pipework externally above ground or through unheated areas within buildings. The WRAS 'Water Regulations Guide' gives guidance on the minimum thickness of thermal insulating materials that should be applied in such cases.

12.26 Adequate provisions for isolating and draining sections of cold water distribution pipework will ensure that disruption caused by frost damage can be minimised.

12.27 For further guidance on frost protection, refer to the WRAS 'Water Regulations Guide'.

Flushing

12.28 Prior to taking systems into use, they should be subject to a thorough regimen of flushing before disinfection (see paragraph 17.15).

©Health Facilities Scotland, a division of NHS National Services Scotland

13. Noise and vibration

Pump noise

13.1 Noise generated by centrifugal pumps will not cause problems if water velocity in the pipes and the speed of the pumps are low, for example about 1 m/s and 960 rpm respectively.

13.2 Care should be taken in locating water-boosting pumps within healthcare buildings to ensure that they will not cause interference to wards and other quiet zones.

13.3 Such interference may result from break-out noise from the boosting equipment, or noise transmitted through the pipework system or through the building structure. Pump noise may also result from cavitation caused by low suction head.

13.4 Where pumps are located close to sensitive areas, provision for noise and vibration reduction must be incorporated within the design. Such provision will include selection of quiet-running motors, vibration isolation of boosting equipment from pipework and structure and, if required, acoustic lining to the booster plant enclosure.

13.5 Guidance on recommended noise levels for various locations is given in CIBSE Guide A: 'Environmental design'.

Other forms of system noise

13.6 Other forms of nuisance noise that may be generated by hot and cold water distribution systems are listed below:

- noise from pipework due to excessive water velocity;
- water hammer caused by rapid closure of valves or taps;
- oscillation of the float of a float-operated valve;
- tap washer oscillation;
- noise caused by water discharging from float- operated valves into cisterns;
- noise caused by thermal movement of pipes;
- noise due to trapping of air within pipework, particularly on hot water systems.

13.7 Further details on the above sources of noise, including guidance on avoiding such noise problems, are given in the WRAS 'Water Regulations Guide'.

©Health Facilities Scotland, a division of NHS National Services Scotland

14. Water economy and energy conservation

Water

14.1 Hot and cold water distribution systems for healthcare buildings should be designed so as to minimise the use of water. The cold water distribution systems should incorporate an adequate number of water meters to allow for close monitoring of water consumption. Where practicable, consideration should be given to linking water meters to a building management system.

14.2 Measures to minimise water consumption that should be considered at design stage include:

- provision of automatic systems to control flushing of urinals;
- use of showers rather than baths wherever practicable;
- WC pans and flushing cisterns that use more than 6 L per flush are prohibited by Water Byelaws (Scotland) 2000;
- control of water pressure to a level that is not excessive for the purpose required;
- provision of water flow restrictors at hot and cold water taps – these must not be used in conjunction with thermostatic mixing valves unless approved by the manufacturer of such valves; restrictors or regulators should not be installed at the inlets of thermostatic mixing valves;
- use of percussion taps in appropriate circumstances;
- locating warning pipes from cisterns and discharge pipes from relief valves in such a way that any discharge can be readily observed, and/ or fitting alarms on such pipes.

14.3 Further guidance on the prevention of wastage of water is given in the WRAS 'Water Regulations Guide'. Reference should also be made to the Audit Commission's (1993) 'Untapped savings: water services in the NHS'.

Energy

14.4 Energy used in the generation of hot water can be minimised by ensuring that the hot water storage and distribution system is adequately insulated and that thermostats controlling water temperature in hot water storage vessels are set no higher than is necessary for the control of *Legionella*.

14.5 Hot and cold water systems should be designed to operate by gravity as far as possible. Where water - boosting pumps are necessary, the pump motors should be selected to operate at maximum efficiency at the required duty.

©Health Facilities Scotland, a division of NHS National Services Scotland

14.6 The practice of pre-heating of the cold feed to calorifiers should not be carried out. The only time it is acceptable is when under all flow/demand conditions a temperature greater than 45°C can be guaranteed at the entry to the calorifier. Any pre - heater should have a low water capacity.

14.7 Further guidance on energy conservation in relation to hot and cold water systems is given in Scottish Health Technical Memorandum 07-02: EnCO_2de – making energy work in healthcare, environment and sustainability, 2006 (see also the Carbon Trust's website, http://www.carbontrust.co.uk).

©Health Facilities Scotland, a division of NHS National Services Scotland

15. Water treatment

Chlorine dioxide

15.1 Chlorine dioxide is an oxidising biocide that is capable of reacting with a wide range of organic substances and has been shown to be effective in the control of organisms in water systems. Use of chlorine dioxide as a chemical treatment for drinking water treatment is now subject to a European Standard (BS EN 12671:2000).

15.2 The use of chlorine dioxide as a control measure should only be considered strategically on a complete site/campus basis to ensure continuity of control measures. This will depend on the water supply quality and on the design of the systems in use and, in an existing system, their operational history.

15.3 There are two aspects to be taken into consideration:

a. in the cold water distribution system, chlorine dioxide may be injected into the system upstream of all parts of the distribution, storage and boosting equipment or at the break-tank serving the booster set. There must be close monitoring and control of the dose, which should normally comply with the Water Supply (Water Quality) Regulations 2000 for the equivalent use of chlorine dioxide in the treatment of water supplies by the water authority;

b. in the case of hot water distribution systems with calorifiers/water heaters operating conventionally, that is, at 60°C, there will be a tendency for chlorine dioxide to be lost by 'gassing off', especially if the retention time in a vented calorifier/water heater is long. In most cases, however, some total oxidant should be found in the hot water, although at levels far less than the 0.5 ppm injected. The calorifier/water heater should act as a barrier to dispersal of any pathogenic material by the hot water system.

15.4 Where copper supply pipes are used, chlorine dioxide can result in high concentrations of copper being measurable in the water supplies.

15.5 Additional information on chlorine dioxide is given in Appendix 4.

Silver/copper ionisation

15.6 Ionisation systems release copper and silver ions into the water stream by means of electrolytic action. Ionisation as a water treatment method is covered in BSRIA's Technical Note TN 6/96 following a study in which it was shown that copper and silver ion concentrations maintained at 400 µg/L and 40 µg/L respectively can be effective against planktonic *Legionella* in hot water systems. In soft waters a silver level as low as 20 µg/L can be effective.

15.7 The use of ionisation as a control measure should only be considered strategically on a complete site/campus basis to ensure continuity of control

©Health Facilities Scotland, a division of NHS National Services Scotland

measures. This will depend on the water supply quality and on the design of the systems in use and, in an existing system, their operational history.

15.8 The electrodes can be susceptible to accumulation of scale unless effective anti-scaling electrode cells are fitted. The system should be designed to take account of water quality, otherwise additional treatment may be necessary. Copper and silver ion treatment is also sensitive to pH, and thus pH control may be required.

15.9 In hard water areas there have been cases of staining of sanitaryware, but in a properly controlled system where dosing levels of silver are not exceeded, this should not be a major problem.

15.10 The opinion of the Committee on Products and Processes for Use in Public Water Supply concerning the use of silver as a disinfectant in public water supplies can be found on the Drinking Water Regulator website: http://www.dwi.gov.uk/cpp/silver.htm.

15.11 Additional information on copper and silver ions is given in Appendix 5.

Ozone and ultraviolet treatment

15.12 Whereas the previous treatments are intended to be dispersive (that is, they result in a residual agent within the system), ozone and ultraviolet are intended to be effective close to the point of application. They are not, therefore, necessarily effective in hot and cold water service systems.

15.13 Ultraviolet and ozone are methods that are suitable for water systems used for dialysis equipment. However, allowance must be made for the aggressive effects of ozone on materials exposed to it, particularly the degradation of rubber compounds and the corrosion of metallic materials.

15.14 The systems should be fail-safe and have adequate instrumentation to monitor operation. For example, UV systems should be preceded by particle filtration to prevent microorganisms being shielded by particles, and incorporate a detector so that any loss of transmission can be corrected immediately. They require appropriate pre-filtration to remove particulate matter that may shield bacteria from the UV rays.

Purging the systems

15.15 When the system is initially dosed, checks should be made at various parts of the system to ensure that satisfactory concentrations of treatment chemicals are being achieved.

©Health Facilities Scotland, a division of NHS National Services Scotland

16. Testing and commissioning

Introduction

16.1 While testing and commissioning is regarded as a discrete activity, continuous monitoring is required throughout the installation to ensure that:

a. materials and equipment installed comply with the Water Byelaws (Scotland) 2000 and other British Standards, and are not otherwise unsuitable. Equipment that is listed in the latest edition of the 'Water Fittings and Materials Directory' and installed in accordance with any of its relevant conditions will comply;

b. the work is done entirely within the specification for the scheme;

c. all the requirements of current legislation are met, both during construction of the installation and when it is completed, particularly with regard to the Health and Safety at Work etc Act 1974.

Installation checks

16.2 The system should be regularly checked during installation to ensure that open pipes, valve ends, cylinder connections etc are sealed to prevent the ingress of dust/debris that could cause problems during commissioning and subsequent operation. Checks should also be made to ensure that fittings and materials comply with the Regulations and are those listed in the 'Water Fittings and Materials Directory', and that lead solders are not being used. Equipment that requires to be maintained or which is likely to fail or be replaced during the life of the system should be de-mounted and re-instated during the installation process to ensure that it is maintainable and that appropriate isolation is provided to ensure safety and continuity during operational use.

Inspection of joints

16.3 Before pressure testing, the site engineer should identify a number of fittings to be cut out for examination to establish whether the quality of the finished joint meets the specification. The exact number to be cut out will vary according to the size of the installation, but as a guide, a ratio of one fitting per 400 installations should be cut out. In any event, a minimum of two, and not normally more than five, fittings should be cut out for examination.

16.4 The fittings cut out should be cut open (quartered longitudinally) and examined. If unacceptable joints are found, adjacent fittings should be cut out until the extent of any faulty workmanship has been established.

16.5 The pipeline should be made good.

©Health Facilities Scotland, a division of NHS National Services Scotland

16.6 The tube and fitting should be internally clean and free from particulate matter. Some oxidation will be evident when hot “joints” are made on copper piping.

16.7 When copper pipe and capillary fittings are used, because of the viscosity of the brazing filler, full penetration may not be achieved.

16.8 The minimum penetration at any point must be three times the wall thickness of the tube or 3 mm, whichever is the greater.

Commissioning

16.9 Correct commissioning is vitally important for the satisfactory operation of the hot and cold water systems. The designer should prepare a commissioning brief for use by the contractor’s commissioning engineer. This brief should specify fully and clearly the extent of the commissioning and maintenance and the objectives which must be achieved, and should include:

- full design data on temperatures, water flow rates and pressures;
- plant and equipment data;
- number commissioning procedures for thermostatic mixing valves in accordance with specification MES D08;
- drawings and schematics;
- a list of test certificates to be provided.

16.10 The designer’s attention is drawn to CIBSE Commissioning Code W: ‘Water distribution’, which provides guidance on information that will be required by the commissioning engineers.

16.11 In the preparation of commissioning instructions for domestic hot and cold water services, designers should ensure that their work is in accordance with up-to-date guidance from the Department of Health’s Estates & Facilities Division.

16.12 The designer should prepare for inclusion in the contract documents a list of tests and measurements that are to be taken by the contractor and recorded by him/her. These should be witnessed by the contract supervising officer or project engineer on his/her behalf and he/she, if approved, will circulate the results, in accordance with the client’s instructions.

16.13 The commissioning manual should be prepared by the contractor and submitted to the client’s commissioning adviser for review before being issued in final form.

16.14 Typical schedules of checks and performance tests should be included in the commissioning manual together with record sheets. These should be amended and supplemented as the designer/client advisor considers necessary.

16.15 The supervising officer or project engineer, who should countersign any relevant test record documents, should witness commissioning and testing.

©Health Facilities Scotland, a division of NHS National Services Scotland

16.16 'As installed' record drawings, schematic diagrams, operating and maintenance instructions must be supplied at the time of handover. Certified records of pressure testing and disinfection should also be made available.

16.17 The whole commissioning procedure should be carried out under the guidance of a single authority, although the involvement of specialists or manufacturers may be required for specific items of plant.

16.18 Valid calibration certificates should be submitted and checked for all measuring equipment to be used by the commissioning engineers prior to commencement of commissioning.

16.19 The commissioning should be carried out in a logical and methodical manner.

16.20 The installation, on completion, should be operated by the contractor as a whole, and subjected to specified functional or performance tests.

16.21 Once the system meets the design intent, the final completion record sheet(s) should be completed. In the event of performance not being acceptable, the matter should be dealt with in accordance with the contract requirements.

Commissioning and testing checklists

16.22 The following is a summary of the key activities associated with pre-commissioning and commissioning of hot and cold water storage and distribution systems. The list is not intended to be comprehensive.

Cold water installations

16.23 Pre-commissioning checks can be carried out on completion of the system installation, filling and pressure testing.

16.24 Pre-commissioning checks and tests to be applied are as follows. Check that:

- systems have been provided and installed in accordance with specification and drawings, and that the systems are charged with water, vented and free from leaks;
- water storage cisterns are free from distortion and leaks, are properly supported and secured, are provided with correctly fitting covers, and are in accordance with the Water Byelaws (Scotland) 2000;
- distribution pipework is rigidly supported, insulated, and incorporates adequate provisions for venting, draining, expansion, isolation and measurement of flow, temperature and pressure;
- pipework systems have been pressure tested;
- pipework systems and storage cisterns have been flushed, disinfected, appropriate certification received, and that specified residual chlorine levels are attained;

©Health Facilities Scotland, a division of NHS National Services Scotland

- pipework systems and storage/break tanks are correctly identified and marked;
- regulating valves and flow control devices operate freely;
- water meter(s) is/are fitted correctly;
- electrical isolation, cross-bonding and wiring of system components are installed in accordance with the current edition of BS 7671:2008.

16.25 Upon satisfactory completion of the pre-commissioning tests, the commissioning tests can commence.

16.26 Commissioning checks and tests to be applied are as follows. Check that:

- overflows run freely and discharged water does not cause flooding or damage, and that drain- down points flow when released and are free from leaks when shut;
- float-operated valves function satisfactorily and are adjusted to give the correct water level;
- control valves operate correctly and shut-off valves close tightly;
- all electrical circuits are tested and the pump motor direction of rotation is correct, and that electrical controls and alarms function correctly;
- operation of any safety or anti-flood device is satisfactory;
- circulating or lifting pumps are free from excessive noise, vibration and leaks;
- remote control of pumps (if appropriate) is satisfactory;
- the installation is vented and regulated;
- the flow rate into, and out of, storage cisterns is recorded;
- all taps, mixers and outlets operate satisfactorily, and test and record mass flow from outlets in positions shown on contract drawings. (TMVs require hot and cold water for testing and commissioning. Type 3 TMVs are commissioned in accordance with MES D08.);
- temperature of water in storage cisterns and at taps is appropriate;
- full load current of components does not exceed the recommended values;
- the running current of components does not exceed the recommended values;
- pump thermal overload trips are set;
- system schematic is displayed in a frame in the relevant plantroom, complete with valve schedule.

©Health Facilities Scotland, a division of NHS National Services Scotland

Hot water installations

16.27 Pre-commissioning checks can be carried out upon completion of system installation, filling and pressure testing.

16.28 Pre-commissioning checks and tests to be applied are as follows. Check that:

- systems have been provided and installed in accordance with the specification and drawings;
- the system is charged with cold water, vented, and free from leaks;
- hot water storage vessels are free from leaks and are properly supported and secured;
- distribution pipework is rigidly supported, insulated, and incorporates adequate provision for venting, drainage, expansion, isolation, and measurement of flow, temperature and pressure;
- pipework systems, storage cylinders etc have been pressure tested, flushed and disinfected, and appropriate certification has been received, and that specified residual chlorine levels are attained;
- pipework systems, calorifiers and cisterns are correctly identified and marked;
- regulating valves and flow control devices operate freely;
- all control and regulating valves are labelled or marked to correspond with reference numbers on contract drawings;
- electrical isolation, cross-bonding and wiring of system components is installed in accordance with the current edition of BS 7671:2008;
- system schematic is displayed in a frame in the relevant plantroom.

16.29 Upon satisfactory completion of the pre-commissioning checks, the commissioning checks and tests can then be started.

16.30 Commissioning checks and tests to be applied are as follows. Check that:

- drain down points flow when released and are free from leaks when shut, and that air vents and release valves open correctly and are airtight when shut off;
- all temperature and other controls are adjusted and calibrated to agreed design limits of system performance;
- all electrical circuits are tested and the pump motor direction of rotation is correct, and that electrical controls and alarms function correctly;
- control valves operate correctly and shut-off valves close tightly;
- heat exchangers operate satisfactorily;
- primary heating circuits are adjusted and regulated, and thermostatic settings are correct; and that bypass circuits and automatic control valves operate correctly;

©Health Facilities Scotland, a division of NHS National Services Scotland

- circulating pumps are free from excessive noise, vibration and leaks;
- remote and automatic control of pumps (if appropriate) is satisfactory, and there are no leaks at joints under maximum flow conditions;
- secondary circuits are regulated and vented;
- thermostatic mixing devices and regulating valves are adjusted and set to desired values (TMVs require hot and cold water for testing and commissioning, and should be commissioned in accordance with MES D08);
- all taps, mixers and outlets operate satisfactorily;
- water flow quantities at all plant items, regulating valves and flow-measuring valves are recorded;
- mass flow from taps, main and other outlets in positions shown on contract drawings is satisfactory;
- pressure drop at heat exchangers at full design demand flow is tested and recorded;
- hydraulic balancing of hot water secondary circulation system is carried out to ensure that minimum temperatures are achieved in all parts of the circuit;
- full load current of components does not exceed the recommended values;
- the running current of components does not exceed the recommended values;
- pump thermal overload trips are set.

Pressure testing

16.31 Pressure testing must be carried out before disinfection. Except where otherwise specified, testing of underground pipelines should be carried out in accordance with the requirements of the Water Byelaws (Scotland) 2000.

16.32 Open pipes should be capped and valves closed to avoid contamination.

Temperature testing

16.33 These tests should be performed prior to contractual handover and bringing the system into use. Separate thermostatic measuring and recording equipment should be used, that is, independent of any building management system. It will be necessary to have systems fully operational and to simulate typical draw-off of water.

16.34 Tests should include:

- measuring the incoming water temperature at the main water meter;
- testing the inlet, outlet and surface water temperatures of cisterns and cold water feed/ header tanks for the hot water calorifiers. The temperature

©Health Facilities Scotland, a division of NHS National Services Scotland

should not be greater than 2°C above that measured at the main water meter;

- testing the flow and return temperatures at connections to calorifiers and water heaters. These should not be less than 60°C and 50°C respectively;
- testing the temperature in branches of hot water circulating systems installed in all departments to ensure that the system has been balanced, and that under "no draw-off" conditions 55°C is achieved in the circulating system at outlets furthermost from the calorifier/heater;
- testing single hot water outlets and inlets to mixing valves to ensure that a minimum of 55°C is achieved within 1 minute;

Note: The Health and Safety Commission's (2000) Approved Code of Practice L8 permits a period of 1 minute to achieve an equilibrium temperature of 50°C. A minimum of 55°C may be required for the operation of suitable mixing devices required to provide 'safe' hot water at the upper limit of the recommended range. Hot water at 55°C is required in many cases for reasons of food hygiene or decontamination requirements, for example in kitchens and sluice rooms. In a properly balanced hot water circulating system, with the circulation taken close to the draw-off point, achieving temperature should be virtually instantaneous. (At a typical flow to a wash-hand basin of 4.5 L/m, 1 min to achieve temperature would indicate a 25 m dead-leg of 15 mm pipe or that the system is out of balance.)

- testing single cold water outlets and inlets to mixing valves to ensure that temperature equilibrium below 20°C is achieved within 2 min.

Note: The Health and Safety Commission's (2000) Approved Code of Practice L8 permits a period of 2 min to achieve an equilibrium temperature below 20°C. Achieving this minimum requirement would be indicative of an exceptionally under-utilised water system in an unoccupied building. During commissioning, therefore, it is essential to encourage draw-off to simulate normal usage. (At a typical flow to a hand-wash basin of 4.5 L/m, 2 min to achieve temperature would indicate a 50 m dead-leg of 15 mm pipe or that stagnation is occurring.)

- Testing the temperature at hot water draw-off points to ensure that they comply with the recommended temperatures in Table 4. (Note: the maximum temperatures should not exceed those shown in Table 4 by more than 2°C.)

©Health Facilities Scotland, a division of NHS National Services Scotland

17. Disinfection

17.1 Guidance on disinfection is given in BSRIA's (2004) Application Guide 1/2001.1: 'Pre - commission cleaning of pipework systems', which contains recommendations for the design, installation, system-flushing and chemical cleaning of pipework systems. Disinfection should be applied to the complete hot and cold water service systems. When considering a contractor to carry out the work, preference should be given to companies/individuals who are members of the *Legionella* Control Association (formerly, the Code of Conduct Association for the Control of Legionellae).

17.2 Alternative disinfectants may be used, provided satisfactory disinfection is achieved. The infection control team should be consulted, and advice should also be sought from the Drinking Water Regulator.

Note: Disinfection is a requirement of the Water Regulations. Additional advice on the use of alternative disinfectants is given in SHTN 2: 'Domestic hot and cold water systems for Scottish healthcare premises'.

17.3 Proprietary solutions of disinfectant should be used in accordance with the manufacturers' instructions. The COSHH Regulations require that the risks from using the disinfectant for each task be assessed to ensure that the control procedures adopted are suitable for the particular application.

17.4 Disinfection should not be undertaken before materials, for example linings in cisterns, have fully cured. Advice should be sought from equipment manufacturers to ensure that proposed disinfection chemicals will not adversely affect performance. No heat source should be applied during the disinfection procedure, including final flushing.

17.5 Pipework under pressure from the mains should be disinfected through an injection point and the disinfectant residual measured at the end of the pipeline. BS 6700:1997 and the Approved Code of Practice L8 advise 50 mg/L (ppm) for one hour or 20 mg/L (ppm) for two hours; it is usual practice to leave the chlorine solution in the pipes for 24 hours before thoroughly flushing out with fresh water. Junctions that are to be inserted into existing pipelines should be disinfected prior to installation.

17.6 All disinfection of pipework under pressure from the mains must be carried out in accordance with the requirements of the water supply authority. Failure to ensure close liaison between the contractor and the water authority during design, construction, pressure testing or commissioning could present a potential risk of back-flow of contaminated materials or chemicals into the public water supply. Site supervision to ensure compliance with any requirements specified by the local water supply authority is recommended.

17.7 All cisterns should be internally cleaned to remove all visible dirt and debris. Cisterns and distributing pipework should be drained, filled with fresh water and

©Health Facilities Scotland, a division of NHS National Services Scotland

then drained completely. The cisterns should then be refilled and the supply servicing valves closed. On re-fitting it is normal practice to add high doses of sodium hypochlorite to the water in the cisterns, for example, to give a calculated chlorine concentration of 50 ± 10 mg/L (ppm) in the water, and leave the water to stand for one hour. Whatever disinfection method is used, the concentration should be adjusted if necessary. The use of a high dose ensures an adequate residual concentration to allow proper disinfection of the downstream services. Each tap or fitting should then be opened, progressively away from the cisterns, and water discharged until the disinfectant is detected. Each tap or fitting should then be closed, and the cistern and pipes left charged for a further hour. The tap(s) furthermost from the cisterns should be opened, and the level of disinfectant in the water discharged from the taps measured. If the levels set are not achieved, the disinfection process should be repeated.

17.8 As soon as possible after disinfection, the distribution pipework should be drained and thoroughly flushed through with fresh water and refilled (see paragraphs 17.14 and 17.15). Appropriate hazard warnings should be placed on all taps throughout the building during disinfection procedures.

17.9 After disinfection, microbiological tests for bacteria colony counts at 37°C and coliform bacteria, including Escherichia coli, should be carried out under the supervision of the infection control team to establish that the work has been satisfactorily completed. Water samples should be taken from selected areas within the distribution system. The system should not be brought into service until the infection control team certifies that the water is of potable quality.

Discharge of waste water used during disinfection procedures within buildings

17.10 Contaminated water that is run to waste into a natural watercourse or a drain leading to it should be treated in accordance with the requirements of the authority responsible for land drainage and pollution control. The authority responsible for that sewer should be informed.

Thermal disinfection (of hot water service systems)

17.11 The process introduces a serious scalding risk, and it is essential that steps are taken to ensure that access is limited to authorised personnel only until such time that the system has returned to normal operating temperature: it is unlikely to be a practicable alternative for a large system. It also requires the removal of thermostatic elements, thus introducing additional practical difficulties.

17.12 This process can be performed by raising the temperature of the entire contents of the calorifier, or hot water heater, followed by circulating the water throughout the system for at least an hour. The calorifier/heater temperature must be sufficiently high to ensure that the temperature in all parts of the circulating system, and at the return connection, does not fall below 60°C. After this period, each tap or draw-off-point should be run sequentially from the nearest point to the furthermost outlet. At branches it will be necessary to draw-off water to at

©Health Facilities Scotland, a division of NHS National Services Scotland

least one outlet, the nearest, to ensure adequate purging. The draw-off at the tap or outlet should be for a period of at least five minutes at full temperature.

Maintaining control of systems

17.13 Once disinfection has taken place, it is essential to put in place measures to ensure that hot and cold water temperatures are maintained. This will require regular flushing, at least weekly, and possibly more frequently during periods of hot weather.

17.14 Once filled, systems should not be drained unless full disinfection is to be carried out prior to building occupancy and use. However, allowing water in newly installed capillary-jointed copper plumbing to stagnate can result in serious corrosion of the copper. To reduce the risk of this, it is recommended that flushing should take place on a weekly basis to introduce fresh water throughout the system.

17.15 To prevent the accumulation of biofilm during construction and testing, continuous dosing of water systems with appropriate biocides should be considered. Such treated systems should be regularly flushed to ensure that the biocide reaches all parts of the systems, and particularly outlets. Dosing with an appropriate level of biocide as soon as water hits a pipe or storage vessel, along with regular flushing, can control the accumulation of biofilm more effectively.

18. Documentation

General

18.1 It is essential that a full report of all commissioning and testing activities is compiled and handed over to be incorporated within the operation and maintenance manuals.

18.2 These commissioning and testing records will be required so that subsequent maintenance and periodic checks can be made to ensure that the installation continues to operate as intended. Such information will includes results of temperature checks on the cold water supply and hot water circulating systems and commissioning and in-service test data for Type 3 TMVs. The information should also include identification of, and test results for, sentinel taps.

18.3 Where continuous water treatment is installed, the commissioning records should include details of settings of the equipment, dosing rates and requirements for testing.

18.4 Operation and maintenance manuals should be in accordance with BSRIA's (1990) Application Guide 1/87: 'Operation and maintenance manuals for building services installations'.

18.5 As a minimum, for new installations or major refurbishment, the contract should require the following documents and drawings to be supplied:

a. full manufacturing details, including batch numbers of all pipes and fittings;
b. full records and certificates of pressure tests for all sections of pipework;
c. settings of all balancing valves, with readings of flow rates where applicable;
d. full details of each item of plant, including arrangement drawings and appropriate test certificates;
e. as-fitted drawings showing clearly the location of balancing valves, flows and settings, isolation valves, drain valves;
f. schematic drawings for installation in plantrooms showing all valves and items of plant;
g. full details of water treatment parameters and operating modes and settings;
h. full details of maintenance requirements;
i. detailed confirmation of disinfection procedures to BS 6700:1997, and results of post-disinfection microbiological analysis;
j. full records confirming that all materials and fittings hold WRAS or equivalent accreditation.

Appendix 1 Water consumption

Ward unit

For the purposes of this study, a ward unit is defined as a combination of all the rooms which make up the working area for patient care, that is, patients' bedrooms, day spaces, treatment, utility and test rooms, bathrooms, showers, WCs, pantry, staff rooms, cleaners' room etc and circulation spaces. Figure A1 shows the average daily consumption of stored water and Figure A2 shows the rate of supply of mains water to cistern.

Designers should consider the impact on water consumption of such specialist departments such as Renal Dialysis and the dumping of water as part of the filtration processes.

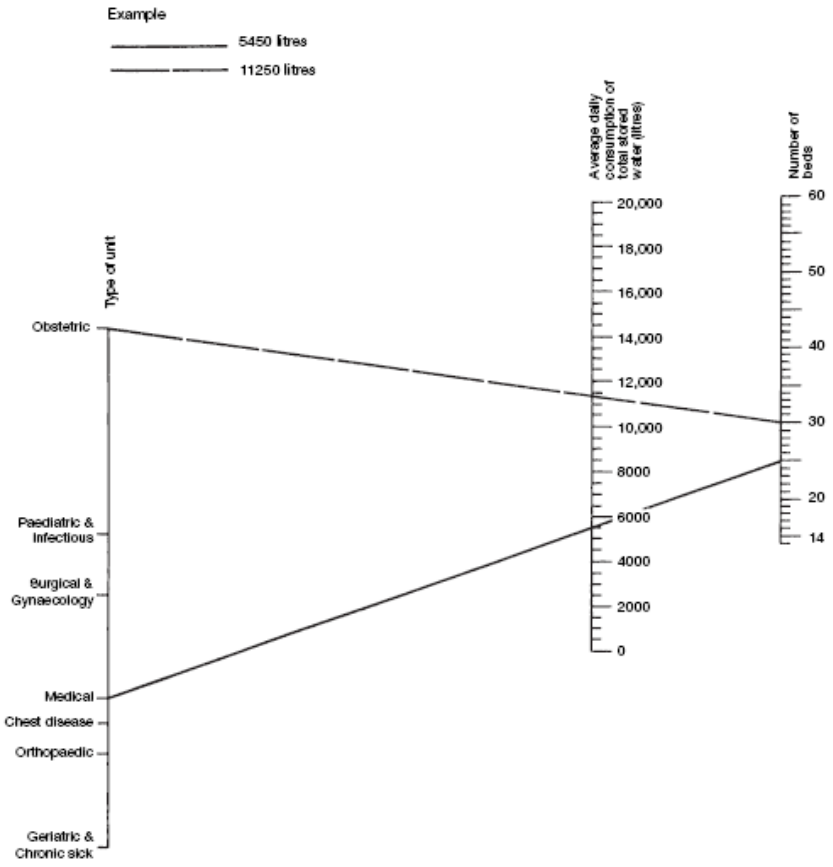

Figure A1: Average daily consumption of total stored water

©Health Facilities Scotland, a division of NHS National Services Scotland

Use of nomogram
Project line from point ⊕ to number of beds. The intersection on 8000 scale gives rate of supply of mains water in litres/hour. The result obtained relates to one ward unit. For a given number of ward units, multiply by the number.

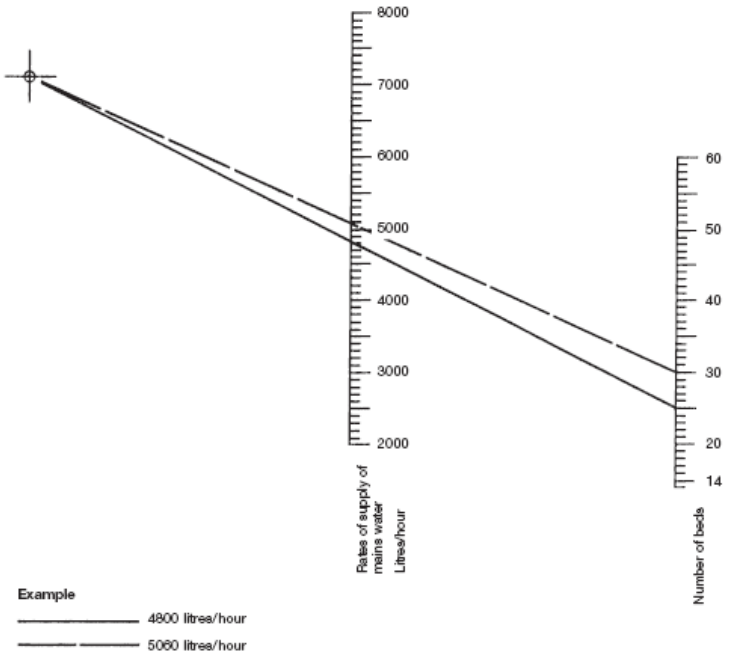

Figure A2: Rate of supply of mains water to cistern

Average water consumption by type and size of hospital

Table A1 (the results of a survey of NHS hospitals by the Department of Health and Social Security in 1974) provides basic data for design guidance on the estimation of water storage and consumption for whole hospitals.

The definitions which have been used for the classification of hospitals are shown in Table A2. 'Excluded departments' are those for psychiatry (mental illness), psychiatry (mental handicap), diseases of the chest, chronic sick, geriatrics and convalescence (including rehabilitation, but not pre-convalescence).

Relative intensity of water consumption

Whilst water consumption per bed content is a convenient estimating and planning yardstick, it does not show the widely differing floor areas which are provided per bed in hospitals of different sizes and type.

To illustrate the relative rates of consumption as seen against a basis of comparable patient density and showing the amount of water consumed − not only directly by the patient but also in the supporting treatment departments − a

Table A1: Average water consumption by type and size of hospital

Type of hospital	Type number	Definition
Acute	1	Hospitals with not more than 15 per cent of their beds allocated to the "excluded departments"
Mainly Acute	2	Hospitals with more than 15 per cent and up to 40 per cent of their beds allocated to the "excluded departments"
Partly Acute	3	Hospitals with more than 40 per cent and up to 60 per cent of their beds allocated to the "excluded departments"
Mainly Long-stay	4	Hospitals with more than 60 per cent and up to 85 per cent of their beds allocated to the "excluded departments"
Long-stay	5	Hospitals with more than 85 per cent of their beds allocated to the "excluded departments"
Pre-convalescent	7	Hospitals with 90 per cent or more of their beds allocated to patients who have already received elsewhere the most intensive part of their treatment, but who still require active nursing care and medical oversight
Convalescent	8	Hospitals with 90 per cent or more of their beds allocated to patients recovering from a disability who no longer require active medical supervision or nursing care in bed though they may need such simple nursing procedures as renewal of dressings or the administration of medicines
Rehabilitation	9	Hospitals with 90 per cent or more of their beds allocated to patients who no longer require nursing care in bed and who, with or without the aid of appliances, can get about and attend to their own needs with occasional assistance but who require remedial and re-educative treatment with a view to attaining the maximum degree of use of functions

©Health Facilities Scotland, a division of NHS National Services Scotland

Maternity	11	Hospitals (including General practice maternity Hospitals) with 90 per cent or more of their beds allocated to obstetrics
Type of hospital	**Type number**	**Definition**
Psychiatric (Mental Illness)	12	Hospitals with 90 per cent or more of their beds allocated to mental disorder and 50 per cent or more of the psychiatric beds allocated to metal illness
Psychiatric (Mental Handicap)	13	Hospitals with 90 per cent or more of their beds allocated to mental disorder and more than 50 per cent of psychiatric beds allocated to handicapped and/or severely handicapped patients
Orthopaedic	14	Hospitals with 90 per cent or more of their beds allocated to traumatic and orthopaedic surgery, including bone and joint tuberculosis
Tuberculosis and Chest	15	Hospitals with 90 per cent or more of their beds allocated to tuberculosis (both respiratory and non-respiratory) or diseases of the chest (including thoracic surgery) or both
Tuberculosis and Chest Isolation	16	Hospitals with 90 per cent or more of their beds allocated to tuberculosis (both respiratory and non-respiratory) or diseases of the chest (including thoracic surgery) or both, and infectious diseases
Children's (Acute)	17	Hospitals with 90 per cent or more of their beds allocated as in Type 1 but for children only
Eye	18	Hospitals with 90 per cent or more of their beds allocated to that one function
Other hospitals	19	These include Dental and ENT hospitals and also: All hospitals with 90 per cent or more of their beds allocated to a single department not specifically named above unless that department is "General Medicine", "General Surgery" or "General Practice (Medical)", in which event the hospital would be classified as "Acute" (Type 1) Type 19 will include Geriatric and Chronic Sick Hospitals

Appendix 2 Water treatment

General

All water supplied to healthcare premises must comply with current legislation on water quality.

The following sections on water treatment are intended to provide a brief overview only. Further details can be found in BSRIA Application Guide 2/93: 'Water treatment for building services systems'. Some of the more common water treatment processes are mentioned below. The extent of treatment will vary for each application depending on water quality, intended usage etc, and specialist advice should be obtained when considering the adoption of any water treatment processes.

The need for water treatment, and the treatment processes used, depend on the purposes for which the water is to be used and the quantity required for each purpose. While potability is not normally affected by such characteristics as hardness, colour, and (within limits) smell and/or taste, a measure of treatment may be necessary to provide a more acceptable supply.

A supply from a water supply authority should not normally require any further treatment when used for hospital purposes other than laundries, domestic hot water systems, humidification plant and steam boiler feed water. Private supplies, however, will require some measure of treatment, and in many cases the installation of pumping and treatment plant needs to be extensive to ensure a constant acceptable quality.

Water is not naturally found in a state of chemical purity. Surface waters in upland reservoirs, rivers and lakes often contain organic matter including algae, tree foliage and silt. River water may also be polluted by sewage and industrial effluents and chemicals leached from agricultural land etc. Groundwaters in springs, wells and boreholes collect impurities from the surrounding strata; shallow wells collect impurities from surrounding soil.

The impurities which must therefore be removed include tree foliage and matter in suspension consisting of mineral particles, algae, organic matter and various kinds of living organisms and bacteria. Other dissolved chemicals may also require removal.

Suspended matter in water covers a wide range of particle size varying from the large organic particles and silt found in fast-flowing rivers, to colloidal matter with a size of 1 micron or less. Natural filtration takes place as water percolates through the permeable strata and generally reduces suspended solids.

©Health Facilities Scotland, a division of NHS National Services Scotland

Water treatment processes

For high quality groundwater sources, the only treatment that may be required is disinfection, which is covered in Chapter 17. However, for other water sources such as grey water, further treatment will be required, and this may be extensive, depending on intended use.

There are a wide range of treatment options available, but the most relevant to health establishments are:

- coagulation and flocculation;
- settlement;
- dissolved air flotation;
- filtration;
- iron and manganese removal;
- pH adjustment;
- solids treatment and disposal.

Coagulation and flocculation

This is the addition of a coagulant (often aluminium sulphate or an organic polymer) followed by gentle agitation. The process is used to destabilise fine particles in the water so that they agglomerate together such that they will settle out more easily in the settlement process or that they can be removed more easily by filtration.

Settlement

In this process, water is passed through tanks in which solid particles settle out. Settlement covers a range of designs from simple horizontal flow tanks to complex upflow sludge blanket clarifiers and lamella flow separators. Settlement is basically a gravity process, although the sludge blanket used in some designs of tank is part of a flocculation process.

Dissolved air flotation

Dissolved air flotation uses fine bubbles of air to lift particles present in water to the surface of a tank, from where they are removed by a skimming system. Water to be treated passes through a rectangular tank. High-pressure water, saturated with air, is introduced into the bottom of the tank. The air in this water comes out of solution because of the pressure drop, and forms fine air bubbles on solids within the water; these solids then rise. The process is particularly suitable for the removal of low-density solids such as algae. It is a sophisticated process and is unlikely to be used except in special circumstances.

©Health Facilities Scotland, a division of NHS National Services Scotland

Filtration

Filtration is a solids removal process that involves passing water through a filtering medium, which is normally sand. The most likely form of sand filter to be found in a modern small treatment plant is a pressure filter; these are normally vertical cylindrical steel or GRP pressure vessels.

Water enters at the top of the vessel and passes down through 50 cm of sand. The sand rests on gravel which, in turn, is supported on a perforated floor. After passing through the sand and gravel, the filtered water leaves through the bottom of the vessel.

As the water passes through the vessel, the sand becomes increasingly clogged with dirt, and the pressure drop across the filter increases. Once the pressure drop becomes excessive, the filter is cleaned. This is done by flow reversal with water, and sometimes air, flowing up through the sand to waste. This expands the bed and frees the dirt from the sand.

The need to clean filters involves a fairly complex system of pipes and valves. On modern filters, cleaning is normally done automatically, with electrically-operated valves.

Filtration removes solids, and for relatively clean waters it may be the only treatment process needed apart from disinfection. For dirtier waters, pre-treatment by settlement or dissolved air flotation is required in order to prevent too great a frequency of backwashing. For sources liable to pollution from animal waste, filtration is essential for the removal of cryptosporidium and/or giardia cysts. The filtering medium may be sand but may also be granular activated carbon, to remove tastes and odours, or a catalytic medium (for example manganese dioxide) to oxidise and remove iron and manganese.

Modern packaged plants may also use other sorts of filtration system.

Iron and manganese removal

A common problem, particularly with ground water, is excessive iron and manganese levels. This problem is often solved by oxidising the iron and manganese to an insoluble form by chlorination, pH adjustment and filtration to remove the iron and manganese. Filtration is often done in pressure filters with a catalytic medium.

pH adjustment

This is often needed either to oxidise iron and manganese or to render water less corrosive to the distribution system.

©Health Facilities Scotland, a division of NHS National Services Scotland

Solids treatment and disposal

It should always be borne in mind that a water treatment plant will produce wastes from settlement tanks and filters. These wastes will need to be disposed of, probably to the site foul sewerage system.

Contaminated water that is run to waste into a natural watercourse or a drain leading to it should be treated in accordance with the requirements of the authority responsible for land drainage and pollution control. The authority responsible for that sewer should be informed. Dechlorination can be achieved using either sulphur dioxide or sodium thiosulphate. 20 g of sodium thiosulphate crystals are required to dechlorinate 500 L of water containing 20 mg/L free chlorine. For water requiring dechlorination, an automated system dosing bisulphite solution or similar solutions can be linked to the BEMS.

Scottish Hospital Technical Note 2

Further advice on filtration methods and standards can be found in SHTN 2.

©Health Facilities Scotland, a division of NHS National Services Scotland

Appendix 3 Chloramine (and chlorine) in public water supplies

The Water Authority in Scotland has been introducing chloramine as a disinfecting agent in water supplies as an alternative to free chlorine. Chloramines tend to be more stable and provide better residual antibacterial activity with lower total chlorine levels. The protection lasts longer and avoids or reduces the need for additional disinfectant dosing stations along the network between water treatment plant and the end–user to ensure that the strict microbiological standards set within the Regulations are met. This explains why chloraminated supplies have been introduced in rural areas.

In Scotland, the drinking water standards are identified in within The water Supply (Water Quality) (Scotland) Regulations 2001, in line with all European community (EC) requirements. This is a legal document with which the Water Authority is required to comply. The Drinking Water Regulators (DWQR) monitor the Water Authority to ensure that the Regulations are complied with and the 2001 Regulations detail the acceptable levels of certain characteristics, elements and substances allowed in drinking water for which these permissible levels are known as Prescribed Concentration of Value (PCV).

It has been recognised by Scottish Water that the secondary disinfection of water supplies with choramine offers a number of benefits, mainly comprising of

- a longer lasting treatment process within the distribution network than would apply if chlorine was used on its own;
- the process helps prevent the formation of trichloramine (THM) compounds that are formed with traditional chlorination;
- it removes the need to add further chlorine further along the pipework distribution network;
- there is the benefit of having no significant taste or odour when correct dosing rations are applied.

There is evidence that the use of free chlorine as a disinfecting agent in surface water supplies containing natural organic residues can combine to form trihalomethanes (THMs), for example chloroform ($CHCl_3$), bromodichloromethane ($CHCl_2Br$) and other compounds that are carcinogenic. (Free chlorine is still preferred for disinfecting borehole waters.)

The local water supply authority carries out chloramination at the water works by introducing both chlorine (Cl_2) and ammonia (NH_3), which combine in aqueous solution to form monochloramine (NH_2Cl), dichloramine ($NHCl_2$) and a small quantity of trichloramine (NCl_3).

The quantities of these depend upon the ratio of chlorine and ammonia and the acidity of the water; it is important to achieve the correct balance, as

©Health Facilities Scotland, a division of NHS National Services Scotland

dichloramine and trichloramine can lead to problems of taste and odour and their formation needs to be minimised.

In the UK there is no standard for chloramines in water. The World Health Organisation (WHO) recommends a maximum concentration of 3 mg/L. This is based on a tolerable daily intake that is derived from the 'no observable adverse effect level' (NOAEL) to which a safety factor of 100 is applied. The levels of chloramine that the UK will use (and dialysis treatments units should be designed to handle) is likely to be in the order of 1 mg/L total chlorine, most of which is present as monochloramine.

Problems associated with aquaria have been reported in the USA, where much higher levels of chemicals are used than is proposed in the UK.

Chloramine is also extensively used in Europe for disinfection of public water supplies.

Implications for healthcare

In systems where free chlorine is rapidly lost, such as typical hot and cold water service systems, chloramines can remain for much longer, posing particular problems for dialysis patients. The effect of chloramine-induced acute haemolytic anaemia and methaemoglobinaemia has been well reported. Little other information is available on chloramine.

Chloramines, and to a lesser extent chlorine, in dialysis water can cause haemolysis – a condition whereby red blood cells are ruptured. In addition, all renal patients suffer from anaemia to some extent because they are lacking in erythropoetin (EPO). This natural hormone, which stimulates bone marrow to produce red blood cells, is not available in sufficient quantities in patients with damaged or diseased kidneys. Synthetic EPO is administered to dialysis patients but, apart from its high cost, can have unpleasant side-effects. Where chlorine or chloramines are present, the need for EPO escalates, and therefore it is imperative to eliminate chlorine and chloramines from water supplies to dialysis equipment to minimise the dosage of EPO.

Dialysis requires a water supply that has the minimum of chemical and bacterial impurities. This requires water treatment – typically reverse osmosis and softening; neither process removes chloramines or chlorine.

Some reduction of chloramine occurs in deionisation equipment because of adsorption onto ion-exchange resin molecules, but performance of the ionisation process is unpredictable in this respect and cannot be relied upon. The Renal Association sets limits of 0.1 mg/L and 0.5 mg/L respectively for chloramines and total chlorine in water for dialysis. (The European Pharmacopoeia specifies a maximum limit of 0.1 mg/L for chloramine: studies have shown, however, that levels as low as 0.25 mg/L can cause haemolysis.) Therefore, it can be seen that the margin for error is low. (See also Health Building Note 53 – 'Facilities for renal services', Volumes 1 and 2 which have not been adapted for Scotland but may be used with general caution.)

©Health Facilities Scotland, a division of NHS National Services Scotland

There remain some concerns about chloramine, but in the main, these are about high concentrations for bathing water disinfection. Further studies are taking place.

Removal of chloramines

The use of granular-activated carbon (GAC; filtration upstream of the reverse osmosis (RO) equipment) is recognised as an effective means of dealing with chloramine. (In hard water areas, water softening will also be required.)

Chemical reduction by use of ascorbic acid (vitamin C), which is capable of neutralising many oxidising agents, is also an effective method. There is some concern about the use of ascorbic acid because of its toxicity for dialysis patients. Management of vitamin C intake has to be carefully monitored in dialysis patients; therefore chemical reduction, particularly for domiciliary patients, is undesirable.

GAC is manufactured from a variety of products, but mostly bituminous coal. The charcoal derived is pulverised and “activated” by exposure to superheated steam. This increases the total surface area for adsorption, which can be as high as 1500 m^2/g. This highly porous substance is formed into disposable cartridges, or used in rechargeable tanks.

The critical factor in the selection of the carbon filter is the empty bed contact time (EBCT), which can be calculated as follows:

$$EBCT = \frac{volume(GAC(L))}{flow(water(L/m))} \times 50$$

The aim should be an EBCT of about 6 min.

As a yardstick, the Drinking Water Regulator has advised the Renal Association to design water treatment systems, whether domiciliary or hospital-based, to remove up to 1 mg/L total chlorine.

Summarising

The following facilities require special attention

a) Renal Departments

The Renal association identifies that dialysis water purification plant should be capable of accepting 1mg/I total chlorine, while setting limits of 0.1 mg/I and 0.5 mg/I, respectively, for chloramines and total chlorine in water for dialysis. Dialysis requires a water supply that has the minimum of chemical and bacterial impurities and to achieve this, further water purification is required, typically reverse osmosis and softening, neither of which is an effective means of removing chloramines and chlorine.

©Health Facilities Scotland, a division of NHS National Services Scotland

The use of Granular Activated Carbon Filtration (GAC – filtration) upstream of the Reverse Osmosis (RO) equipment is recognised as an effective means of chloramines and chlorine and the impact of dealing with chloramines is limited only to the increased contact time within the activated carbon filters associated with the renal water purification plant because chloramines take longer to be absorbed than free chlorine. It has been estimated that an increase in contact time of around 6 to 10 minutes will be required, increasing the total surface are for absorption. The assessment would normally be calculated by the specialist water treatment company specialising in renal water supply and plant selection.

b) Pharmacy Departments

The residual levels of chloramines within a water supply can affect the manufacturing of pharmaceuticals and therefore pharmacy departments within healthcare premises may be more effected by a chloraminated water supply. For this reason, monitoring of the water supply is required and any subsequent review of any existing purification processes and procedures currently operating may have to be enhanced, upgraded or renewed.

c) Laboratories

Areas within healthcare facilities that require specialised water, such as science laboratories, would also require their water treatment and purification to be reviewed and, where necessary, enhanced, upgraded or renewed.

d) Hydrotherapy Departments

Water treatment processes and procedures to hydrotherapy pools, etc., may also require their water treatment processes to be reviewed as the introduction of additional chlorine may induce the production of dichloramine and trichloramine. The water treatment and procedures to these areas may require to be enhanced, upgraded or renewed where necessary.

There have been instances in which chloraminated water supplies have been introduced in Scotland by the Water Authority without advance warning or consultation. To avoid this, the maintenance if close liaison with the Water Authority is essential and that the quality of incoming supplies is monitored at all times to avoid adverse effects, principally on vulnerable patients.

Chloramines and the effect on pipework materials

There is no test data available identifying that a chloraminated water supply affects pipework or pipework components, neither within the various UK water authorities' nor undertakings' infrastructure, nor within industrial, commercial or domestic premises. The Water Research Council (WRc) advise that no recent product testing had been carried out on any plumbing components or material to assess the long-term affects that chloramine may bring.

©Health Facilities Scotland, a division of NHS National Services Scotland

However, the fact that such supplies have been delivered in the Thames Water, Northumbrian and Anglian Water areas for so many years without any reported detrimental affects leads to the confidence that traditional and contemporary plumbing materials and components are unaffected as a result of handling chloraminated water supplies.

©Health Facilities Scotland, a division of NHS National Services Scotland

Appendix 4 Chlorine dioxide

Chlorine dioxide is an oxidising biocide that is capable of reacting with a wide range of organic substances. Its effectiveness in the control of organisms in water systems has been demonstrated in a study carried out by BSRIA (see BSRIA's (1998) TN 2/98: 'Chlorine dioxide water treatment − for hot and cold water services').

For hot and cold water services, chlorine dioxide is usually generated by sodium chlorite reacting with gaseous chlorine or hydrochloric acid:

$5NaClO_2 + 4HCl \longrightarrow 4ClO_2 + 5NaCl + 2H_2O.$

Alternatively, a number of systems use proprietary solutions that release chlorine dioxide on acidification.

Use of chlorine dioxide as a chemical for drinking water treatment is now subject to a European Standard (BS EN 12671:2000). National conditions of use require that the combined concentration of chlorine dioxide, chlorite and chlorate do not exceed 0.5 mg/L as chlorine dioxide. Chlorine dioxide dissolves unchanged in water, but is very slowly hydrolysed to chloric and chlorous acids. In alkali, chlorate and chlorite are formed:

$2ClO_2 + 2OH^-\ ClO_3^- \longrightarrow ClO_2^- + 2H_2O.$

It is essential that the maximum amount of chlorine dioxide is available for reaction with organic molecules and not total chlorite or chlorate.

In water, the oxidising properties of chlorine dioxide result from two reactions. Chlorine dioxide gains one electron to form chlorite:

$ClO_2 + 1e^- \longrightarrow ClO_2^-.$

If available, the chlorite gains four electrons to form chloride:

$ClO2^- + 2H2O + 4e^-\ Cl^- + 4OH^-1.$

The first of these reactions proceeds readily in the range of pH found in potable water.

The latter reaction, to complete the five-electron transfer, does not always occur.

In the inactivation of microorganisms, the chlorine dioxide molecule acts as a free radical (oxidising biocide) that readily bonds with the amino acids − the basic building blocks of proteins − which form the living cells. This results in their destruction.

©Health Facilities Scotland, a division of NHS National Services Scotland

Note: The difference between the chlorine dioxide injected into the system and the levels at the furthermost parts of the system, where its presence can be measured, is an indication of the bio-burden oxidised.

Chlorine dioxide is also effective in the destruction and removal of biofilms, which contribute to the nutrients within the systems and provide protection for bacteria against the effects of heat and chlorine.

©Health Facilities Scotland, a division of NHS National Services Scotland

Appendix 5 Copper and silver ionisation

Ionisation as a water treatment method has been shown to be effective against planktonic *Legionella* in hot and cold water systems at 400 µg/L and 40 µg/L respectively. In soft waters a silver level as low as 20 µg/L can be effective. Ionisation systems release copper and silver ions into the water stream by means of electrolyte action. Copper and silver ionisation involves the release of copper and silver ions by electrolytic generation for use as a water treatment.

Copper and silver ionisation is concerned with releasing silver and copper ions into water by passing an electrical current between two copper electrodes and between two silver electrodes placed in running water.

The copper and silver ions attach, through electrostatic bonds, to negatively charged sites on bacterial cell walls. This distorts and weakens the cell wall, allowing penetration of the silver ions. The silver ions attack the cell by binding at specific sites to DNA, RNA, cellular protein and respiratory enzymes, denying all life support systems to the cell, causing paralysis and death. The copper and silver ions act synergistically to kill bacteria.

Silver/copper ionisation's effectiveness in the control of *Legionella* bacteria in water systems has been demonstrated in a study carried out by BSRIA (1996; TN 6/96: 'Ionisation water treatment for hot and cold water services'). Results show that where silver and copper ion concentrations could be maintained at 0.04 ppm and 0.4 ppm respectively, copper and silver ionisation was effective against *Legionella* bacteria in both cold and hot water systems with reduced water temperatures as low as 35°C. pH levels above 7.6 may affect the efficacy of this technology.

Water analysis certificates-of-analysis results from samples collected from outlets at sites that operate silver/copper ionisation systems in the UK show that where silver and copper ion concentrations are maintained at outlets at between 0.01 and 0.08 ppm and at between 0.2 and 0.8 ppm respectively, *Legionella* contamination is avoided and controlled.

The study carried out by BSRIA also showed that the copper and silver ions not only reduce the biofilm coverage in cisterns and within pipework circuits, they also reduce the number of *Legionella* bacteria present within the biofilm.

Further studies by Walker et al (1997) showed that when copper and silver ionisation was operated at concentrations of 0.04 ppm of silver and 0.4 ppm of copper, it is an effective non-chemical disinfectant for the control of bio-fouling.

Version 2
NHSScotland, Property and Environment Forum Executive, October 2001

Executive summary

SHTM 2030 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of washer-disinfectors (WDs) in use in the National Health Service for processing medical devices, laboratory ware and sanitary products. No guidance is given on WDs intended for use in processing textiles or for dishwashers in general catering applications.

This SHTM is intended as a guide for technical personnel with appropriate training and experience and also for users responsible for the day to day running of WDs. It will also be of interest to architects, planners, estates managers, supplies officers, and others.

Detailed information on the planning and design of a sterile services department, including the provision of WDs, is given in Scottish Hospital Planning Note 13; *Sterile Services Department* and Health Building Note 13 Supplement 1 *'Ethylene oxide sterilization'* section. Guidance for Laboratory installations can be found in Scottish Hospital Planning Note 15; *Accommodation for pathology services*.

Although this edition of SHTM 2030 reflects current WD technology it is recognised that considerable scope exists for improvements in the operational and management standards used with WDs.

NOTE: The term washer-disinfector is abbreviated to WD throughout this publication.

The current British Standards for WDs, although only in force since 1993, are expected to be replaced by European Standards within the next two to three years. These Standards include consideration of the requirements arising as a result of European Union Directives on medical devices which are of concern for WDs in two ways; firstly, some WDs will themselves be considered to be medical devices and therefore must meet the relevant requirements of the Medical Devices Directive and secondly, the manufacturer of a medical device which is intended to be reprocessed is required to specify the method to be used for reprocessing which will include any necessary washing and disinfecting stage.

When practicable the information in this SHTM has been aligned with existing or anticipated Standards and advice is offered when no Standard has yet been formulated.

The WDs described in this SHTM may not be suitable, without modification, for safely processing articles contaminated with either Hazard Group 4 Pathogens or with agents which are unusually resistant to disinfection.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

The guidance previously given in HTM 2030 ‘Management policy’ has been incorporated into SHTM 2030 ‘Operational management’. HTM 2030 is superseded.

1. General

Introduction

1.1 This part of SHTM 2030 covers the specification, purchase and installation of the various types of washer-disinfectors (WDs) used in hospitals, laboratories and other healthcare facilities.

1.2 Terminology used in washing and disinfection has long been inconsistent and this has often led to ambiguities. This SHTM introduces a set of terms which, it is hoped, will provide workers in the field with a vocabulary that will be consistent with the European Union (EU) standards that are to be introduced in the near future. The glossary provides a definition of terms referred to in this part of SHTM 2030.

1.3 Full references for all the documents referred to in this volume and for selected documents providing additional information of which the reader should be aware are listed at the end of this part.

Purpose of washer-disinfectors

1.4 WDs are used to decontaminate items intended for re-use. They may be used in relation to both medical devices and medicinal products as well as other items. For example, they may be used for reprocessing, within their intended use, medical devices, sanitary equipment, laboratory equipment, manufacturing equipment (for use in the manufacture of medicinal products or medical devices) or cutlery and crockery.

1.5 The decontamination process is intended to:

a. make the item safe for staff to handle;

b. make the item safe for use on a patient (after any necessary additional processing) – including when relevant ensuring freedom from contamination that could lead to an erroneous diagnosis.

1.6 WDs may also be used as part of the manufacturing process for medical devices, medicinal products, in-vitro diagnostics or laboratory products – in processing “single-use” products or components such as bottles and vials.

1.7 When items being decontaminated by a WD are intended to be used again without further treatment (such as a terminal sterilization process) before being re-used, the disinfection process in the WD must produce an item which is microbiologically safe for its intended use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.8 When the items being decontaminated by a WD are intended to be subjected to further processing (such as a terminal sterilization process) before being re-used, the disinfection stage must produce an item which is microbiologically safe to be handled during preparation for subsequent processing.

1.9 The decontamination process involves two distinct stages: cleaning and microbial inactivation (disinfection). WDs are used to decontaminate items intended for re-use by subjecting the items to an automated process of cleaning and disinfection.

1.10 The efficacy of the cleaning stage of the process is of crucial importance to the successful outcome of the disinfection stage. This is especially relevant in the circumstances when a liquid chemical disinfection or sterilization process has to be used.

Legal framework for washing and disinfection

1.11 WDs are used in relation to both medical devices and medicinal products as well as for sanitary equipment, laboratory equipment and cutlery/crockery.

1.12 WDs may be used for reprocessing medical devices, sanitary equipment, laboratory equipment, manufacturing equipment (for use in the manufacture of medicinal products or medical devices) or cutlery and crockery, within their intended use.

1.13 WDs may also be used as part of the manufacturing process for medical devices, medicinal products, in-vitro diagnostics or laboratory products in processing ‘single-use’ products or components such as bottles and vials.

Medicinal products

1.14 The manufacture and supply of medicinal products are controlled by extensive legislation based on EU Directives for medicinal products. These are enacted in the UK by the Medicines Act and a number of Regulations.

1.15 The requirements for the manufacture and supply of medicinal products are set out in the ‘Guide to good manufacturing practice for medicinal products’ (GGMP) published in Volume IV of ‘The rules governing medicinal products in the European Community’.

1.16 The GGMP contains guidance on cleaning of components and manufacturing equipment which have implications for the design, installation and operation of WDs. When a WD is to be installed for processing containers, components or manufacturing equipment for use with medicinal products the GGMP should be consulted at an early stage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.17 Guidance on the application of medicines legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medicines Control Agency (MCA) when necessary.

Medical devices

1.18 SHTM 2030 Part 2, 'Operational management' refers to the three EU Directives on the manufacture and supply of medical devices and in-vitro diagnostics.

1.19 Whether, and if so in what circumstances, the Medical Devices Directive (93/42/EEC) applies to medical devices which are being reprocessed for further use – either within a particular healthcare facility or externally under a service contract – is a complex issue beyond the scope of this SHTM. Guidance is given in the Medical Devices Agency (MDA) Directives Bulletin 18. If necessary further advice should be sought from the MDA.

1.20 The essential requirements of the Medical Devices Directive require inter alia:

a. that devices and manufacturing processes be designed to eliminate or reduce as far as possible the risk of infection to the patient, user and third parties (annex I, paragraph 8.1);

b. that devices must be designed, manufactured and packed in such a way as to minimise the risk posed by contaminants and residues, to persons involved in the transport, storage and use of the devices and to patients (annex I, paragraph 7.2).

1.21 There is no direct equivalent of the GGMP for medical devices. The same role is fulfilled by general quality system Standards (the BS EN ISO 9000 series), supplemented by Standards tailoring the requirements specified in the general standard for medical devices (BS EN 46001 and BS EN 46002) and Standards providing guidance on compliance with these Standards (BS EN 724 and BS EN 50103).

1.22 These are mandated Standards and as such compliance with them affords the presumption of compliance with the relevant essential requirements of the Directive.

Published Standards

1.23 British Standard 2745: 1993 specifies requirements for WDs for medical purposes. The standard is in three parts: Part 1: 'Specification for general requirements'; Part 2: 'Specification for human-waste container washer disinfectors'; and Part 3: 'Specification for washer-disinfectors except those used for processing human-waste containers and laundry'.

1.24 There are no European Standards, as yet, for WDs. CEN Technical Committee TC102 is developing a series of mandated Standards relevant to the Medical Devices Directive for WDs. There are four parts with the working titles 'General Requirements', 'Washer-disinfectors for human-

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

waste containers', 'Washer-disinfectors for medical devices and surgical instruments' and 'Washer-disinfectors for thermo-labile medical devices (for example endoscopes)'.

1.25 IEC Technical Committee TC66 is developing Standards for 'Safety requirements for washer-disinfectors'.

1.26 When published, compliance with these Standards may be used to give a presumption of conformance to the relevant requirements of the Medical Devices Directive.

1.27 This edition of SHTM 2030 has been written while the new Standards are in the course of development. The guidance given here is designed to be broadly consistent with the emerging Standards but SHTM 2030 should not be regarded as a substitute for the Standards themselves when ascertaining compliance with the EU Directives and the UK Regulations that implement them.

1.27 If the WD is purchased with the intention of processing both medical devices and components, or equipment for use in the manufacture of medical products, purchasers should ensure that the requirements for both types of load are met.

Washer-disinfectors as medical devices

1.28 The Medical Devices Directive (93/42/EEC) Annex IX, Classification Criteria, Rule 15 classifies as medical devices "all devices intended specifically to be used for disinfecting medical devices" and places them in Class IIa for conformity assessment purposes. It specifically excludes products that are intended to clean medical devices, other than contact lenses, by means of physical action.

1.29 WDs for cleaning and disinfecting medical devices are thus covered by the medical devices legislation and those supplied on or after 14 June 1998 will have to bear the CE marking in accordance with the provisions of the Medical Devices Directive.

This will apply to many of the WDs described in this SHTM.

1.30 Detailed guidance on the application of medical devices legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medical Devices Agency.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Key Personnel

1.31 The following personnel are referred to in this part of SHTM 2030.

Management

1.32 Management is defined as the owner, occupier employer, general manager, chief executive or other person who is ultimately accountable for the operation of the premises.

1.33 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of similar authority. In small autonomous units the user may take on this function.

User

1.34 The user is defined as the person designated by management to be responsible for the management of a WD.

1.35 In a hospital the user could be a sterile services manager, theatre manager, endoscopy clinic manager, ward manager or laboratory manager; in primary care he/she could be a general practitioner, dentist or other health professional. When a WD is used to process equipment or containers for use in the preparation of medicinal products the user is normally the production manager in charge of the manufacturing process.

1.36 The principle responsibilities of the user are as follows:

a. to certify that the WD is fit for use;

b. to hold all documentation relating to the WD;

c. to ensure that the WD is subject to periodic testing and maintenance;

d. to appoint operators where required and ensure that they are adequately trained;

e. to maintain production records.

Competent Person (Pressure vessels)

1.37 The competent person (pressure vessels) is defined as a person or organisation designated by management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a WD described in the ‘Pressure Systems Safety Regulations 2000’. The shorter term “competent person” is used in this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.38 The following guidance on the qualifications for the competent person is based on the HSC Approved Code of Practice, Safety of Pressure Systems:

a. where required to draw up or certify schemes of examination, the competent person should be qualified at least to technician engineer level, with adequate relevant experience and knowledge of the law, codes of practice, examination and inspection techniques and understanding of the effects of operation of the pressure vessel concerned. He or she must have established access to basic design and plant operation advice, materials engineering and non-destructive testing (NDT) facilities. The competent person must have sufficient organisation to ensure a reasonable data storage and retrieval system with ready access to relevant laws, technical standards and codes;

b. where required to carry out examinations, the competent person should have sufficient practical and theoretical knowledge and actual experience of the type of pressure vessel which is to be examined to enable defects or weaknesses to be detected and their importance in relation to the integrity and safety of the WD to be assessed.

1.33 The principle duties of the competent person under the Regulations are as follows (they need not all be exercised by the same individual):

a. advising on the scope of the written scheme of examination;

b. drawing up the written scheme of examination or certifying the scheme as being suitable;

c. carrying out examinations in accordance with the written scheme, assessing the results and reviewing the written scheme for its suitability.

1.34 Most insurance companies maintain a technical division able to advise on appointing a competent person. Advice may also be obtained from Scottish Healthcare Supplies, Trinity Park House, Edinburgh.

Test Person (Washer-disinfectors)

1.39 The test person (washer-disinfectors) is defined as a person designated by management to carry out validation of washer-disinfectors and to provide advice on testing, maintenance and procedures. The shorter terms test person or TP are used in this SHTM. The test person should either:

a. be a Test Person (Sterilizers) (see SHTM 2010 for a definition of this role);

b. be qualified to at least HNC level in engineering or relevant sciences and have at least two years experience in the validation of washer-disinfector processes; or

c. have at least five years experience in the testing of washer-disinfector processes.

1.40 The principle responsibilities of the TP are as follows:

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

a. to advise on programmes of periodic testing and periodic maintenance of WDs;

b. to advise on operational procedures for routine production;

c. to conduct the validation test specified in SHTM 2030 Part 3, 'Validation and verification' and to prepare the validation report;

d. to conduct the periodic tests specified in SHTM 2030 Part 3, 'Validation and verification' and to prepare reports as required by the user;

e. to conduct any additional tests at the request of the user.

Maintenance Person (Washer-disinfectors)

1.41 The Maintenance Person (washer-disinfectors) is defined as a person designated by management to carry out maintenance duties on washer-disinfectors. The shorter terms maintenance person or MP are used in this SHTM.

1.42 The Maintenance Person should be a fitter or electrician with documentary evidence to demonstrate competence in the maintenance of one or more types of washer-disinfector. He or she should be in a position to deal with any breakdown in an emergency and have the ability to diagnose faults and carry out repairs or to arrange for repairs to be carried out by others.

1.43 The principle responsibilities of the Maintenance Person are as follows:

a. to carry out the maintenance tasks outlined in SHTM 2030 Part 2, 'Operational management';

b. to carry out additional maintenance and repair work at the request of the user.

1.44 A Maintenance Person who has a minimum of 5 years experience in the maintenance of washer-disinfectors may, by agreement, perform the duties of the Test Person for the daily, weekly and quarterly tests described in SHTM 2030 Part 3, 'Validation and verification'.

Microbiologist

1.45 The microbiologist is defined as a person designated by management to be responsible for advising the user on microbiological aspects of disinfection.

1.46 The microbiologist should have a degree in microbiology and will normally be a member of the hospital staff.

1.47 The principle responsibilities of the microbiologist are as follows:

a. to provide general and impartial advice on all matters concerned with washing and disinfection;

b. to advise the user on the microbiological aspects of all disinfection procedures;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

c. to arrange for the culturing of biological indicators used in microbiological tests;

d. to audit the documentation from all washer-disinfectors which have been tested by microbiological methods.

Control of Infection Officer

1.48 The Control of Infection Officer is defined as the person designated by management to be responsible for advising the user on all infection control aspects.

Production Manager

1.49 The Production Manager is defined as a person designated by management to be responsible for production of medicinal products and medical devices.

Quality Controller

1.50 The Quality Controller is defined as a person designated by management to be responsible for quality control of medicinal products and/or medical devices with the authority to establish, verify and implement all quality control and quality assurance procedures.

Laboratory Safety Officer

1.51 The Laboratory Safety Officer is defined as a person designated by management to be responsible for all aspects of laboratory safety in respect of equipment, maintenance, personnel and training relating to safety issues, and to ensure compliance with safety legislation and guidelines.

Operator

1.52 An operator is defined as any person with the authority to operate a WD. Their duties may include the noting of WD instrument readings, replenishment of consumable items, such as detergent, and simple housekeeping duties.

Manufacturer

1.53 The manufacturer is defined as a person or organisation responsible for the manufacture of a WD.

Contractor

1.54 The contractor is defined as a person or organisation designated by management to be responsible for the supply and installation of the WD, and for carrying out the installation checks and tests. The contractor is usually the manufacturer of the WD.

Purchaser

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.55 The purchaser is defined as the person or organisation who orders the WD and is responsible for paying for it.

Authorised Person (Sterilizers)

1.56 The authorised person (sterilizers) is defined as a person designated by management to provide independent auditing and advice on sterilizers and sterilization and to review and witness validation (see SHTM 2010 Part 1 for a full definition of the responsibilities of the authorised person (sterilizers) with respect to sterilizers and the qualifications and experience required). AP(S) are also able to provide independent auditing and advice on washing/disinfection and WDs and to review and witness validation of these processes and machines.

Independent Advisor

1.57 The Independent Advisor is defined as a person who may or may not be registered as an AP(sterilizers), but can demonstrate to the satisfaction of management previous training and experience appropriate to carry out the designated tasks in respect of WDs as the AP(S) would carry out in respect of sterilizers. AP(S) is a suitable person to carry out the functions of an Independent Advisor.

Water supply

1.58 All the organisations responsible for water supply have the statutory power to make and enforce byelaws to prevent waste, excessive consumption, misuse or contamination of the water supply. The Model Water Byelaws form the basis for such byelaws. WDs must be designed, constructed, installed, operated and maintained in accordance with the requirements of the relevant byelaws.

Safety

1.59 Guidance on the safe operation of the various types of WD is given in SHTM 2030 Part 2; ‘Operational management’. As far as testing is concerned, normal safety precautions are adequate except in the case of WDs using liquid chemical germicides. In this case users are recommended to operate a permit-to-work system to ensure that such WDs are declared safe to work on, and that personnel working on them have documented authority to do so.

Chemical additives

1.60 Many of the chemical additives used in WDs and their associated ancillary equipment, for example water treatment plant, are corrosive, toxic or otherwise hazardous and require special provision for their storage and use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.61 The 'Control of Substances Hazardous to Health (COSHH) Regulations 1999' place upon management an obligation to ensure that suitable measures are adopted to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a special ventilation system.

1.62 Some of the substances which may be used in WDs, in particular those employing chemical disinfection or sterilization, have Occupational Exposure Limits (OEL) set out in Guidance Note EH40 published annually by the Health and Safety Executive. These limits are statutory maxima but should not be regarded as representing a safe working exposure. Employers have a legal obligation to ensure that exposure is reduced as far as reasonably practicable and to carry out regular Occupational Health review of "at risk" staff..

1.63 The WD, including any special ventilation equipment necessary for its safe operation will be subject to the COSHH Regulations. These Regulations introduced controls on biological agents which are of relevance to purchasers of WDs. Detailed guidance on ventilation systems is provided in SHTM 2025.

Infectious materials

1.64 All WDs have the potential to process infectious materials. The user should therefore ensure that personnel working on WDs wear appropriate protective clothing and are fully informed of any hazards that may be present. In case of doubt the microbiologist should be consulted.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2. Procurement of a washer-disinfector – an overview

Introduction

2.1 This chapter gives a short synopsis of the steps involved in purchasing a WD. More detailed information, including information relevant to specific types of WDs, is given in subsequent chapters.

Purchasing a washer-disinfector

2.2 The first step is to form a consultative group which could consist of User, Control of Infection Officer, Maintenance Person and Independent Adviser.

2.3 The purchase of a WD can be broken down into a stepwise sequence of decisions. These are summarised in the following paragraphs (see also Table 1).

What type of load is to be processed?

2.4 A knowledge of the load(s) which will be processed by the WD is an essential pre-requisite in making the correct decision about which WD to purchase; the difficulty in obtaining a clean product, the standard of cleanliness and the disinfection required vary for different product types. For example, some products with intricate interstices or long narrow lumens require specific provision if they are to be cleaned satisfactorily.

Purchasers should be aware of the need to specify all the items requiring processing to allow the tenderer to offer the most appropriate machine and accessories.

What suitable washing-disinfection processes are available?

2.5 In this SHTM, WDs are classified by:

a. the product range which they are intended to process;

b. their configuration and load handling type;

c. the nature of the cleaning and disinfection process.

Eight product-specific categories are recognised but, in many cases, WDs are available in which a single machine is designed to process two or more of these product categories. Guidance on the selection of a WD is given in Chapter 3.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

What models are available?

2.6 Once the type of WD which will be required has been agreed sales literature and product data sheets should be sought from a number of manufacturers. The development of EU Standards on WDs should widen the choice open to purchasers. Guidance on the information which should be sought is given in Chapter 4.

Where will the washer-disinfector be sited?

2.7 The location available for the WD will have a significant influence on the type of machine which can be used. Many of the larger continuous process machines require considerable space. Guidance on siting is given in Chapter 5.

What services are available?

2.8 A WD will require one or more of the following services: electricity, water, steam, compressed air, drainage, ventilation and chemical additive (detergent, rinse aid etc.) supply. The manufacturer's product data sheets will show which services are required for each model. Determine which of these are available at the proposed site and the capacities of each service. It may be necessary to plan for a new service which would add significantly to the cost of the installation. Further information about services is to be found in Chapter 6. Water supply is crucial and is discussed in detail in Chapter 7.

Who will operate the equipment?

2.9 If the equipment is to be sited in a general area, eg. a ward sluice room, intended for use by a wide range of ancillary and nursing staff the machine should be simple to operate and as foolproof as possible.

Conversely, a machine which will be located in a centralised processing unit under the care of specially trained staff – whose sole or principle activity will be the operation of the WD – may be a more complex machine offering a number of different operational cycles and loading systems to optimise the washing and disinfection of diverse products.

What capacity is required?

2.10 Establish the likely daily and weekly work load, and the peak hourly work load, that the WD will have to process. Calculate the number of WDs required to process the workload. Throughput figures for different manufacturer's machines and different models within any given range vary considerably. For continuous process machines a distinction must be made between the time required to process one load and the total number of loads which may be processed in a period of one hour. Further guidance is given in Chapter 3.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

What ancillary equipment is required?

2.11 A WD may require ancillary equipment such as water softeners, de-ionisation or reverse osmosis (RO) water treatment plant, steam generators, air compressors, extract ventilation (with or without condensers), bulk storage and dispensing facilities for process chemicals.

2.12 In addition some WDs will require load staging facilities, before and after processing, purpose-built load carriers for different categories of product and means for returning load carriers from the unloading side of the WD back to the loading side.

What Standards or published specifications are relevant?

2.13 Most WDs for clinical applications (see Chapter 3) should have been constructed to British and EU Standards. In some cases, eg. for endoscopes, there are no published British or European Standards and additional specifications will be required. Advice on preparing a detailed specification for the WD is given in Chapter 4.

What sort of contract?

2.14 Once the specification has been completed a contract should be drawn up for the supply and installation of the WD. Chapter 4 gives guidance on suitable forms of contract.

Which manufacturer?

2.15 Two or more manufacturers should be invited to tender for the supply of the WD. While no manufacturer should be excluded unnecessarily from the tendering process they should not be invited to tender unless there is a realistic prospect of their being awarded the contract. Guidance on tendering is given in Chapter 4.

What installation and commissioning arrangements?

2.16 Chapter 4 contains advice on the documentation that the manufacturer should provide with the WD. After delivery and installation, the WD should be subjected to a formal documented programme of installation, commissioning checks and validation testing. This is discussed in detail in SHTM 2030, Part 3 ‘Validation and verification’.

What arrangements for service and repair?

2.17 It is common practice for the initial purchase contract to include all service and repair costs for the first year after installation, ie. during the warranty period. A number of manufacturers also offer an “extended warranty” facility which, for an additional fee, provides an all-inclusive service and repair option.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

What are the likely running costs?

2.18 Advice should be sought at the time of tender on the operational costs of the various machines which would be suitable. The operational costs should include the anticipated requirements for services (water, electricity, steam etc.), consumable items (detergents, rinse aids etc.) and maintenance. This data should be used in the evaluation of the tender bids.

NHSScotland Property and Environment Forum

3. Choice of washer-disinfector

Introduction

3.1 This chapter contains information relevant to the choice of a new WD. It discusses the different types of WD and the way in which they are classified in this SHTM. It summarises the loads for which each type is suitable and gives guidance on choosing the size and number of WDs required for a given application.

Classification of washer-disinfectors by nature of load to be processed

3.2 This SHTM groups WDs into two broad categories according to their intended use, ie. the nature of the load which they are intended to process:

a. clinical WDs are designed to process medical devices which may be intended for use without further processing or may be subjected to a terminal sterilization process before further use.

b. laboratory WDs are designed to process equipment for use in the manufacture of medical devices and medicinal products, or to process laboratory goods that are neither medical devices nor medicinal products and are not intended for use in the clinical care of patients.

3.3 WDs can be further classified both by their configuration/load handling system and by the nature of the operational process.

Clinical washer-disinfectors

Human waste containers

3.4 These are intended for use in emptying, cleaning and disinfecting bed pans, urinals, suction bottles and similar containers, and for the rigid supports used to hold disposable bedpans.

3.5 They may have a large volume or mass of material to be removed (faeces, urine, blood, serum, mucous) and many of these materials have a high biomass of potentially infective organisms.

3.6 The processed product will usually be used without further treatment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Surgical instruments and associated products

3.7 These are intended for processing a wide range of products used in clinical practice. WDs may be dedicated for use with one particular category of products or may be intended for use with a range of products, often by the use of dedicated load carriers for each product type.

Surgical instruments

3.8 This includes the whole range of surgical instruments but some particular instruments, such as those with long narrow lumens or intricate interstices, may require disassembly and/or specific adapters if they are to be cleaned effectively.

Anaesthetic accessories

3.9 This includes tubing, face masks and re-breathing bags for both anaesthetic use and for respiratory therapy and diagnosis.

Bowls and utensils (hollowware)

3.10 This includes instrument trays and containers, receivers, gallipots, specula etc.

Endoscopes

3.11 Endoscopes may be considered in two categories based on the method of construction of the endoscope. This will often determine which of the available washing-disinfection processes is suitable. However, in all cases, users should seek advice from the manufacturer of the endoscope on the most suitable method of decontamination.

3.12 Rigid endoscopes and their accessories may often be processed through conventional WDs used for surgical instruments – provided the WD is fitted with appropriate load carriers which direct water and wash solutions through the lumen(s).

3.13 Flexible endoscopes are often unsuitable for processing through a conventional WD – parts of the endoscope may not withstand immersion and valved channels may not be accessible unless the valve is open during the cleaning process. In addition, most flexible endoscopes will not withstand the elevated temperatures used during thermal disinfection and drying in a conventional WD.

3.14 Dedicated WDs are available which are intended specifically for processing endoscopes. These may incorporate a chemical disinfection or sterilization stage or may require that, after processing in the WD, the endoscope is terminally sterilized using a suitable low temperature sterilization process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum
A48235836

Dishwashers

3.15 Dishwashers in general are not covered by this SHTM. However there is an occasional need for the crockery and cutlery used by immunologically compromised patients to be disinfected to a higher standard than is found in standard commercial or domestic dishwashers. Consideration should be given to using a terminal steam sterilization process for items processed through a standard dishwasher or to specifying a dishwasher with a thermal disinfection process as shown in Table 2.

3.16 In the latter case the WD should be fitted with a temperature indicating instrument to show the temperature attained during the disinfection stage.

Laboratory washer-disinfectors

Laboratory equipment

3.17 Laboratory washers are available to process a range of laboratory items. These items may include bottles and vials – either new or after previous use – intended for containing reagents, culture media, etc. and other laboratory equipment, predominantly glassware. Most do not include a disinfection stage except when the WD has been designed for a particular application, eg. animal cage washing and disinfection.

Pharmaceutical equipment

3.18 Laboratory washers specifically intended for processing equipment and containers for use in the manufacture of pharmaceutical or in-vitro diagnostic products may be configured for a single product or family of products, eg. vials, or may be required to process a range of items.

3.19 The process specification may include high requirements for cleaning efficacy and levels of process residuals. This may incorporate a disinfection stage for items to be used without further treatment in the preparation of a non-sterile product.

Classification of washer-disinfectors by configuration/load handling type:

3.20 WDs can also be classified by the construction of the WD and the manner in which the load is processed through the machine.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Cabinet (single chamber) machines (Type 1)

Installed machines

3.21 Type 1 machines have a single chamber in which the full range of process stages are carried out. Type 1 machines may have more than one chamber but the full range of process stages are carried out in each chamber. They are batch process machines in which all stages of the cycle are completed on one chamber load before another load can be processed in that chamber.

3.22 These may have either a single door through which both loading and unloading takes place or double doors with one door being used for loading and the other for unloading.

"Table top" machines

3.23 These are a particular category of Type 1 machines which have only a single door and are distinguished by their small size – having a chamber which will not accommodate two standard sterilization modules (SSMs) each of 600 mm x 300 mm x 300 mm dimensions – and by their limited requirements for connected services. These machines can be operated by connecting to a single phase outlet (normally drawing 20 Amps or less at 230 V), a potable water supply and discharging into a domestic drain or sink.

NOTE: They may be intended to be floor standing or may be placed on a work surface to provide a convenient loading height.

Continuous process machines (Type 2)

Sequential chamber machines

3.24 These all have double doors, ie. a loading door at one end of the machine and an unloading door at the other end of the machine, and also have doors or some other means of segregation between adjacent chambers.

3.25 Sequential chamber machines have two or more chambers through which the load is moved in sequence. Each chamber is employed for one, or more, different stages in the process. Two or more loads may be processed simultaneously, with the loads at different stages in the cycle at any one time. Adjacent chambers are separated by an intervening door.

Conveyor machines

3.26 These may be equipped with double doors, air-flow baffles at each end, or a door at one end and an air-flow baffle at the other.

3.27 Conveyor machines have a continuously, or intermittently, moving load carrier which progresses the load through a series of tanks, chambers or zones – in each of which one stage of the process takes place. Two or more loads may be processed simultaneously, with the loads at different stages in

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

the cycle at any one time. The separation between adjacent stages may be spatial only or there may be baffles (eg. strip curtains) interposed.

Classification of washer-disinfectors by the nature of the process

3.28 WDs can be further classified by the nature of the process employed in each of the three principle processing stages: cleaning, disinfection and drying. A limited range of WDs also provide a chemical sterilization facility.

Cleaning

Flushing machines

3.29 Cleaning is achieved by flushing with water; no detergents are employed.

Washing machines

3.30 Water and detergents are used to clean the product. Detergents act both as wetting agents – in which the reduction of surface tension allows contact with all surfaces – and also as a solvent and/or dispersant of soil. Enzymatic detergent systems are intended to work by converting insoluble soil into a water-soluble form.

3.31 The mass of water and the force with which the water comes into contact with the surface to be cleaned plays a significant part in the soil removal process.

Ultrasonic machines

3.32 Ultrasound energy is used to effect the mechanical removal of soil from the surface of the product.

Solvent cleaning machines

3.33 These machines use cleaning processes which employ specific solvents in which the particular soils to be removed are soluble. An example of this type of process is the de-greasing systems which employ organic solvents to remove mineral oils. These processes are not commonly used in reprocessing healthcare products and are not covered by this SHTM.

Disinfection

Thermal disinfection

3.35 In this process disinfection is achieved by the action of moist heat maintained on the surface to be disinfected at a particular temperature for a particular time (see Table 2) or some other time-temperature relationship of demonstrated equivalence.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chemical disinfection

3.36 Disinfection is achieved by the action of a solution of a microbicidal chemical maintained on the surface to be disinfected at a particular concentration for a particular time at, or above, a specified temperature.

3.37 The removal of the chemical disinfectant after the disinfection stage is of importance also and must be achieved without compromising the microbial quality of the product.

Drying

3.38 Drying may be an integral part of the cycle, usually by the circulation of hot air over the product, or may be provided as a separate drying cabinet. Some products, eg. corrugated anaesthetic tubing, require prolonged drying times and a separate drying cabinet can improve the productivity of the WD.

3.39 Solvent drying systems have also been used but their relevance is limited to specific applications.

3.40 A dry product can also be obtained by the flash evaporation of residual moisture from product items which are hot following a high temperature thermal disinfection stage. This method is often employed in low cost machines, eg. bed pan washers.

Liquid chemical sterilization

3.41 Sterilization by means of solutions of microbicidal chemicals is also employed for a limited range of products which, although required to be sterile for their intended use, cannot be sterilized through conventional terminal sterilization processes (see SHTM 2010; *Sterilization*).

3.42 Key factors in determining the efficacy of the process include:

a. the concentration of the chemical sterilant;

b. the temperature at which it is used;

c. the contact time with the product;

d. the absence of inhibitory materials, such as residual soiling.

3.43 The removal of the chemical sterilant after the sterilization stage is of importance and must be achieved without compromising the microbial quality of the product. The control of the microbial quality of the rinse water is critical in this respect.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.44 The sterile product obtained from a liquid chemical sterilization process is not usually packaged for transport and may not have been dried. Under these circumstances the product is only suitable for immediate use and the machine must be installed close to the point of use. Prolonged storage (eg. for more than two or three hours) may permit contamination to occur followed by the growth of a large microbial population. The storage conditions are also important determinants of contamination.

NOTE: The microbicidal chemicals used for disinfection and sterilization are usually toxic and may also be sensitisers in low concentrations. Many have defined exposure limits (see HSE guidance on occupational exposure). Control of environmental emissions and personnel exposure are important considerations in the design and operation of the processing equipment and in the siting of such equipment. Specific ventilation provision may be required.

When is a washer-disinfector required?

3.45 For many products used in healthcare practice there are two choices available:

a. products which are intended to be re-used after they have been decontaminated and subjected to any necessary reprocessing (eg. terminal sterilization);

b. single-use products – ie. those which are intended to be discarded after use.

3.46 Products which are intended to be re-used may be decontaminated, in accordance with the manufacturer's instructions, by:

a. manual cleaning followed by disinfection and/or sterilization;

b. machine cleaning followed by disinfection and/or sterilization;

c. automated machine decontamination incorporating cleaning and disinfection (or more rarely sterilization).

For further guidance, see Device Bulletin 9501 'The re-use of medical devices supplied for single-use only' published by the Medical Devices Agency.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: The decontamination and subsequent re-use of items intended for single-use requires extensive technical investigation to establish the compatibility of the process and that the performance of the item has not been impaired. To undertake such studies is beyond the competence and expertise of hospital departments and routine laboratories and is rarely justified on economic terms. There are also serious legal implications for both management and user.

3.47 When both re-usable and single-use devices are available a choice may need to be made based on several considerations including: clinical acceptability; economics; local constraints, such as the storage space needed for single-use items or engineering services (electricity, water, drainage) required for a WD processing re-usable devices.

This situation is most relevant in the disposal of human excreta from bed-dependent patients and is discussed in more detail in Chapter 9.

Choice of washer-disinfector

3.48 The choice of WD will be governed by the nature of the loads required to be cleaned and disinfected. Detailed guidance on appropriate processes for different load items can be found in a number of documents: ‘Sterilization, disinfection and cleaning of medical equipment: Part 1 Principles’ published by the Medical Devices Agency; ‘Sterilization and disinfection of thermo-heat labile equipment’; ‘Bed pan washers’ published by the Central Sterilising Club; and in SHTM 2030 Part 2, ‘Operational management’.

3.49 Purchasers should be aware that items suitable for a particular type of WD may still require different operating cycles, which need to be specified before purchase.

Guidance on the modification of operating cycles to suit different loads is given in SHTM 2030, Part 2 ‘Operational management’.

More information about the different types of WD is given in Chapters 10 to 14.

Advice on individual cases should be sought, if necessary, from the AP(S) before any decision is made. When a chemical disinfection process is being considered the microbiologist should also be consulted.

3.50 Once the type of WD has been decided, preliminary enquiries should be made with a number of manufacturers to obtain specifications and price lists. Table 1 indicates some of the information that will be useful for planning purposes and which should be obtained at this stage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 1: Information to be obtained before inviting tenders

Information required	Objectives
The standards to which the WD is designed and constructed and a statement of compliance.	To confirm that the WD meets recognised specifications for design, construction, safety and performance.
Installation data including the overall dimensions and the mass of the WD (fully loaded, the number of supports), floor loading at each. The clearance space required for installation access. The mass of the principle components. Access space required for maintenance. Doors and necessary space for movement of the doors.	To enable the user to establish whether the proposed location is suitable for the WD and the extent of any site improvement work required (see chapter 5).
The usable chamber space expressed as volume, the principle internal dimensions, and the number of standard load carriers or load items which can be accommodated.	To enable the user to determine the capacity of the WD for the load which it is intended.
Specifications for each of the engineering services required by the WD.	To enable the user to establish that the required quality and quantity of each utility required is present or can be provided, and to assess operational costs.
The mean and peak sound power levels generated by the WD (see BS 2745: Part1).	To enable the contractor to confirm that the sound power level after installation will not exceed that specified for the location (see Chapter 5).
A description of the operating cycle including overall cycle time(s) for classes of goods to be processed, length of individual stages: cleaning, disinfection, drying.	To enable the user to determine the throughput of the WD and hence calculate the number of WDs required for the anticipated workload.
The maximum temperature which may be attained during each stage, the range within which cycle variables can be adjusted, the nature and quality of chemical additives required.	To enable the user to assess their compatibility with the load.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Cycle variables

3.51 For the purposes of this SHTM the following definitions have been adopted.

3.52 The **Cycle Variables** are the physical factors – such as time, temperature, water volume, flow rate, pressure, detergent concentration – that influence the efficacy of the cleaning and disinfection processes.

3.53 Most operating cycles have a stage in which the load is exposed to the disinfection conditions for a specified length of time. This period is known as the **Holding Time** (see Table 2).

3.54 The **Disinfection Conditions** are the range of conditions that may prevail throughout the chamber and load during the holding time.

3.55 The holding time may be preceded by a period in which the disinfection conditions are present in the chamber but not yet present on all surfaces of the load which are to be disinfected. This period is the **Equilibration Time**.

3.56 Together the equilibration time and the holding time constitute the **Plateau Period**. The plateau period can always be determined from the indicated or recorded temperature in the chamber during each cycle. The equilibration and holding times cannot be ascertained unless the temperature in that part of the load which is slowest to reach the disinfection temperature is also being recorded or measured.

3.57 For thermal (moist heat) disinfection the disinfection conditions are specified by a **Disinfection Temperature Band**, defined by a minimum acceptable temperature, known as the **Disinfection Temperature**, and a maximum allowable temperature.

3.58 The higher the disinfection temperature the shorter the holding time which will be required to achieve the same level of disinfection.

3.59 For liquid chemical disinfection/sterilization processes the plateau period is equivalent to the **Disinfectant/Sterilant Exposure Time**. The holding time can only be determined by thermometry when the chemical agent is supplied at an elevated temperature to a load which was not pre-heated to the required temperature.

3.60 The disinfection temperature band may also be quoted for liquid chemical disinfection/sterilization processes but is not a complete specification of the disinfection conditions since the efficacy of such processes depends also on the concentration of the chemical agent.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

Table 2: Thermal disinfection temperature bands

Disinfection[a] temperature (°C)	Minimum exposure time (minutes)	Maximum allowable temperature (°C)
65	10	70
73	3	78
80	1	85
90	0.2[b]	95
93[c]	10	98

Notes.

a. The disinfection temperature is measured at the surface to be disinfected.

b. The exposure time of 1 second (as specified in BS 2745 Part1) is too short for reliable measurement and a minimum time of 12 seconds (0.2 min) should be used.

c. This time/temperature relationship is only used for items known to be contaminated with large amounts of pathogenic organisms, for example in laboratories.

3.61 The dispensed volume of the chemical additives (eg. detergents), including the accuracy and reproducibility of the dosing system(s), should be specified.

3.62 For WDs employing jet washing systems, the pump pressure and water flow are also critical variables.

3.63 For ultrasonic cleaners, the frequency, amplitude and power density (Watts/litre of usable chamber space) are critical variables.

3.64 In all cases, the duration of each process stage must be determined with sufficient accuracy to ensure that consecutive cycles have the same efficacy.

Sizes and numbers

3.65 Precise information on the sizes and numbers of WDs required for particular applications is difficult to give since there are considerable variations in patterns of use. The number of WDs required will depend on the cycle time and the loading capacity of the machine and in some circumstances on the flexibility of operation that may be required, eg. whether items to be processed can wait until there is a full load for the WD or need to be processed immediately. Within the clinical applications for WDs, the size and number will also depend on the configuration and load handling type and the operational type. Guidance on calculating the size and number of WDs required for a particular application is given later.

3.66 The methods which may be used to estimate the size and number of WDs varies with the application for which the WD is to be purchased. A detailed description of two approaches is given for WDs intended to be used to process surgical instruments and associated products with brief complementary notes for WDs for other applications. The cycle times quoted by manufacturers of WDs will usually be based on the assumption that the water supply is no less than the mid-point of the specified range for an

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

acceptable supply. It should be noted that lower pressures may significantly extend cycle times.

Assessment of workload and throughput

3.67 A combination of different types of WD and cleaning processes will often be required to deal with the extensive range of instruments to be processed, eg. in an SSD. This needs to be taken into account in calculating the capacity (size and number) of WDs required.

3.68 The provision of separate drying facilities for items which are difficult to dry (eg. corrugated tubing for anaesthetic and respiratory use) can dramatically increase throughput by reducing overall cycle times.

3.69 Bowls and receivers occupy a large volume but are relatively easy to clean. For a large SSD, consideration needs to be given to using a relatively simple washer to process bowls and receivers rather than occupying space in a more sophisticated machine which is better utilised processing more complex instruments.

3.70 Two distinct methods of assessment should be considered:

a. aggregated workload and throughput capacity;

b. throughput time.

Aggregated workload and throughput capacity

3.71 For items in sufficiently plentiful supply, minimising the turn-round time (the time between receipt of the used item and its having been reprocessed and made available for further use) is not a priority. An assessment based on the weekly workload generated by users is appropriate.

Throughput capacity

3.72 Throughput capacity is affected by a number of variables.

These include:

a. The number of operational hours per week for the department in which the WD is located.

b. The machine utilisation factor expressed as a percentage of the number of operational hours. This will be influenced by several factors including:

   (i) delivery schedules from clinical areas;

   (ii) staff availability for loading and unloading (meal and comfort breaks may total one hour/day);

   (iii) start-up and shut-down time each day (approx. one hour/day);

   (iv) planned and breakdown maintenance time (approx four hours/week);

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

(v) routine, periodic and annual testing.

3.73 Precise estimations are difficult to make and may have limited value due to continually changing and developing clinical workloads. SHPN 13 recommends an assumed utilisation factor of 60% for most types of WDs and in practice this is reputed to be appropriate.

Throughput time

3.74 Throughput time may be the controlling factor:

a. for items, usually sophisticated and expensive devices such as endoscopes, where the shortest practicable turn-round time may be required in order to maintain an effective clinical service;

b. for items where anything more than a short delay in initiating processing would be unacceptable (eg. human-waste containers).

3.75 Throughput time is affected by three key factors:

a. cycle time;

b. machine capacity;

c. machine availability.

Sizing calculation

Cycle time

3.76 The processing time varies depending upon:

a. the number and the duration of the flushing and washing stages;

b. the disinfection time;

c. the drying time.

With modern microprocessor-based control systems, several cycle options may be programmed into the same machine.

NOTE: The cycle time may be adversely affected by inadequate services such as low water pressure and low water temperature.

3.77 Some WDs now include a load identification system which reads a label attached to a load carrier in order to identify the nature of the load. The machine then automatically switches to the required process cycle.

3.78 The cycle time may be determined from the WD manufacturer's specification either for the particular item to be processed or for the "worst case" load for which the cycle time will equal or exceed that required for the products to be processed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Machine capacity

3.79 The machine capacity, specified by the manufacturer, will normally be stated in terms of the number of “baskets” or “trays” that can be accommodated in one load.

The EU standard on sterilizers BS EN 285 has standardised 600 mm x 300 mm x 300 mm as a single sterilization module. Rigid re-usable containers for use in sterilizers are also standardised to fit either singly, or in multiples, within the modular unit. Current proposals in the committee draft for the EU Standards on WDs have adopted this size as the basic module for WDs also. However, until these standards are finalised it will be necessary to determine the size of the baskets referred to by the manufacturer.

Aggregated workload for theatres

3.80 An approximate assessment of the workload can be determined from the total actual, or the expected, case load on a weekly basis.

3.81 Each case may be assumed to require the use of at least two baskets in the WD load carrier; one for the instruments and one for the Edinburgh tray, instrument orientation tray or re-usable container used to package the instrument set. Large instrument sets will often require additional baskets – eg. for orthopaedic, cardio-thoracic or large abdominal sets – and careful notes should be made of which specialities may be served by the installation.

3.82 Dedicated load carriers or separate provision (eg. ultrasonics) will be required for particular items eg. micro-surgical instruments, laparoscopes and their accessories.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Workload estimate

3.83 The workload should be estimated from historical records of operational activity or based on proposed work loads.

Theatre case load per week = C_S[1]

Number of acute beds = C_A

Average number of machine baskets:

– per theatre case = B_S[1]

– per acute bed/week = B_A[2]

Workload: W_{TOTAL} (= number of baskets to be processed/week)

$W_{TOTAL} = (C_S \times B_S) + (C_A \times B_A)$

1. It may be necessary to carry out this assessment on the sum of several subsets when there are a number of operating theatres with diverse instrument demands per case.
2. This assessment should be based on the total number of acute beds, including maternity and geriatric, but excluding mental health. If a factor of approximately 0.2 baskets per acute bed is assumed, this should be sufficient to allow for demands from other areas with lower volume requirements such as A&E, community, etc.

Throughput estimate

3.84 The following data are required to estimate the throughput

Machine baskets per load B_N

Machine cycle time (in hrs)[1] C_T

Number of operational cycles per week H

Machine utilisation (%)[2] A

1. If a number of different operating cycles are to be run with widely differing cycle times, it may be advisable to calculate the workload and throughput separately for each category of instruments/process cycle and sum the individual components. Alternatively, a weighted mean cycle time may be calculated from the proportion of each cycle that is expected to be required.
2. An assumption of 60% utilisation is appropriate in most cases (see also SHPN 13).

Then the throughput $T_{TOTAL} = \frac{B_N \times H \times A}{CT}$ baskets per week

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Number of machines required

3.85 The number of machines required may be calculated as follows:

W_{TOTAL} : Workload as machine baskets per week

T_{TOTAL} : Throughput as machine baskets/week/machine

No. of machines required =

$$\frac{[W_{TOTAL}]}{[T_{TOTAL}]}$$

Worked example

If W_{TOTAL} = 1400 baskets/week

and T_{TOTAL}= 1600 baskets/week/machine

then no. of machines required =

$$\frac{[1400]}{[1600]}$$

= [0.875]

i.e. 1 machine

Clinical washer-disinfectors for surgical instruments and associated products

3.86 WDs for this application present the greatest diversity of operational, configuration and load handling types. They range from small table-top models suitable for use in general practice to large, fully automated continuous process models capable of processing the full range of surgical instruments, utensils, containers and anaesthetic accessories with high throughput rates.

3.87 WDs for small units where a single, low volume WD is adequate are considered under WDs for use in general practice.

3.88 Most WDs for surgical instruments and associated products, other than flexible endoscopes, are located in centralised units such as sterile service departments (SSDs).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Clinical washer-disinfectors for human-waste containers

3.89 These machines are equipped with load carriers built to accept standard numbers and/or patterns of specified containers including bedpans, urine bottles, suction bottles and bedpan carriers (for use with disposable bedpans), raised toilet seats, commode bowls, enema and emesis containers.

3.90 The workload will depend on the number of beds to be served, the bed-dependency of the patients in these beds and the nature of the medical or surgical speciality – for example an orthopaedic ward may be expected to have a high level of bed-dependency.

3.91 Human-waste containers need to be processed as soon as possible after use if they are not to become offensive or a potential infection hazard. The peak workload and the maximum throughput are factors that need to be considered. A high proportion of bed-dependent patients may be expected to use a bedpan in the hour following breakfast and the capacity of the WD should be sufficient to process this within an hour.

3.92 Two capacities of WD are widely available: one that will process one bed pan or two urine bottles per cycle; and one that will process two bed pans or four urine bottles. The latter affords more flexibility at times of peak demand.

Clinical washer-disinfectors for anaesthetic accessories

3.93 Many WDs for surgical instruments and associated products can be adapted to process anaesthetic accessories, eg. corrugated tubing, face masks, airways – usually by the provision of a dedicated, interchangeable load carrier.

There are also dedicated WDs intended solely, or principally, for processing anaesthetic accessories.

NOTE: Simple deluge washers (normally used for bowls and utensils) and ultrasonic washers cannot usually deal with anaesthetic accessories or other tubing.

3.94 Current clinical practice makes frequent use of single-use items and/or protects patient connected circuitry from contamination by the use of filters. These have dramatically reduced the throughput of such items. In many SSDs only those items used in respiratory diagnosis, where filters cannot be used, are sent for reprocessing.

3.95 When the projected throughput is low the use of a WD for surgical instruments with a suitable load carrier is to be recommended. However, the drying stage will necessarily be greatly extended beyond that required for surgical instruments leading to a longer cycle time.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.96 When a higher throughput is anticipated but where it is still not economical to provide a dedicated WD for anaesthetic accessories, consideration should be given to the provision of a separate drying cabinet.

3.97 Capacity should be assessed based on the number of items of each type that can be processed in a single load.

Clinical washer-disinfectors for endoscopes

3.98 Users are reminded that they should seek advice from the manufacturer of the endoscope as to the most suitable method of decontamination.

Rigid endoscopes

3.99 Many rigid endoscopes and most of the re-usable surgical accessories used for minimal access therapy (MAT) can withstand steam sterilization and may be processed through WDs employing a thermal disinfection stage to make them safe to handle during packing, etc.

3.100 It is essential that the WD is designed or adapted to ensure that during the flushing, cleaning and disinfecting stages water flows though the lumen(s) of the device.

3.101 Many cabinet WDs and continuous process WDs of the discrete chamber type can be equipped with dedicated load carriers to process rigid endoscopes, gas cannulae, etc. There are also a number of dedicated endoscope cleaners including ultrasonic cleaners.

3.102 The capacity of the WD should be assessed on the number of items of each type that can be processed in a single load.

Flexible endoscopes

3.103 Most fibre-optic endoscopes cannot be processed in conventional WDs used for surgical instruments. Fibre-optic endoscopes are unable to withstand the high pressures generated during the cleaning process or the high temperatures attained during the disinfection process. Dedicated endoscope WDs are available.

NOTE: Many fibre-optic endoscopes are stated by the manufacturer to be incompatible with ultrasonic cleaning.

3.104 In general, the re-usable accessories, biopsy forceps, etc. can be processed through a WD for surgical instruments.

3.105 For most fibre-optic endoscopes, the throughput time is the critical factor. Most endoscope WDs will only accept one endoscope per cycle. Those which will take two endoscopes or more may be of little benefit in reducing

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

throughput time unless each endoscope is accommodated in a separate chamber and cycles can be run independently.

3.106 The disinfection stage of WDs for fibre-optic endoscopes is also critical since there are few suitable terminal sterilization processes with sufficiently rapid cycle times.

Clinical washer-disinfectors for use in general practice

3.107 These are generally small machines, eg. “table-top” cabinet washers, intended for use in dental, medical or veterinary general practice, clinics, mortuaries, etc. where there is a low level demand for thorough cleaning and disinfection of surgical instruments and utensils such as bowls and receivers.

3.108 The maximum anticipated demand and required turn-round time will usually be readily identified by the user for comparison with the loading capacity and cycle times specified for the WD.

3.109 Purchasers should note the importance of the effect of low water supply pressure and, where a hot water supply is required, the effect of low feed water temperature on process cycle times.

Laboratory washer-disinfectors

3.110 Laboratory WDs, whether intended for use in a clinical laboratory or in the laboratory of a manufacturer of a medical device or medicinal product, are equipped with one or more load carriers specific to the nature of the items to be processed.

3.111 The number of each type of item that can be accommodated and the length of the operating cycle may then be used to estimate throughput by comparison with anticipated workload. This can be used to calculate the size and number of machines required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4. Specification and contract

Introduction

4.1 This chapter discusses general specifications for WDs and the steps to be taken in inviting tenders and issuing a contract. The validation procedure which begins on installation of the WD is discussed in detail in SHTM 2030 Part 3, 'Validation and verification'.

Preparing a specification

4.2 Purchasers are strongly recommended to seek assistance from the Independent Advisor when preparing a specification for a WD.

4.3 Standards and other specification documents are continually being updated and purchasers should ensure that they consult the latest editions of such documents, including any amendments issued after publication, to keep abreast of changing requirements. Advice should be sought from the Independent Advisor on this.

4.4 Most WDs are constructed to British Standards or the standards of another European country, eg. the German Standards Authority (DIN). In some cases the Standards specification may not be adequate for WDs to be used in the public service. In these cases additional specifications are listed below for general design considerations and, where appropriate, under an additional specification heading in each chapter.

4.5 Details of the proposed location of the WD should be stated clearly in the specification sent to suppliers.

4.6 Purchasers should specify all of the items requiring to be processed through the WD to allow the tenderer to offer the most appropriate machine and accessories.

4.7 Except where the manufacturer is responsible for installation of the machine the type and standard of packing and delivery of the WD should be specified. When site conditions are likely to be poor and damage could occur a substantial dust proof transit case may be necessary.

General design considerations

4.8 The following design considerations are applicable to all or most types of WD, but are not necessarily required by the current standards. When applicable they should be included in the specification for any WD to be operated in the NHS.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

4.9 All WDs and associated equipment are classed as “work equipment” and should comply with the ‘Provision and Use of Work Equipment Regulations 1998’. Purchasers are reminded that under the Regulations it is the responsibility of the employer, not the manufacturer, to provide a WD that is “suitable for the purpose that it is used or provided”.

4.10 All WDs made or sold in the UK from the 1 January 1996 should conform to the emission and immunity requirements of the ‘Electromagnetic Compatibility Regulations 1992 (as amended)’. This may be achieved by compliance with BS EN 50081 (Emission) and BS EN 50082 (Immunity). The manufacturer should be informed of any local sources of electrical magnetic disturbance which may effect the operation of the WD.

4.11 For maintenance purposes one or more panels of free standing WDs should be easily removable and replaceable.

4.12 Special foundations are not normally required. The weight of the WD, which can be as much as 2500kg for a large continuous process WD when fully loaded, should be borne by at least four pads each measuring at least 150 mm x 50 mm. Floor mountings should be designed to minimise vibration.

Safety features

4.13 Safety features should be designed in accordance with the Standard PD 5304: 2000 and the standard for the ‘Safety of electrical equipment BS EN 61010’.

4.14 The design of the control system should ensure that the door can not be opened until the cycle is complete. When a fault is indicated the door should only be able to be opened by a key code, or tool, when the WD is returned to a safe condition.

4.15 The manufacturer should provide a list of all safety devices together with their settings and methods of adjustment.

4.16 All safety devices should be designed to fail in a manner which does not cause a safety hazard to personnel.

4.17 A safety hazard should not be caused by an error in the control or indication system.

Over pressure protection

4.18 Over pressure safety valves should be fitted to protect components that may be damaged by inadvertent high pressures. This includes any pressure vessel, eg. the steam generator or compressed air reservoir, used within the machine. The discharge from safety valves should be terminated in a safe position.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Instrumentation

4.19 The WD should be fitted with means to verify and/or record the attainment of the specified process conditions. The nature and extent of monitoring should be commensurate with the intended use of the load and the risk arising from the inadvertent use of an improperly cleaned or disinfected load. Particular requirements for different types of WD are described in subsequent chapters.

A “cycle control” recorder may be of value in fault diagnosis but does not provide verification of attainment of the specified operating conditions.

NOTE: WDs may be fitted with either, or both, of two separate recording systems. A “cycle control” recorder which records the values of control variables as seen by the controller; or a “process verification” recorder which, independently of the controller and its sensors, records the values attained for some or all of the critical variables which determine the adequacy of the process.

4.20 Within this SHTM, three levels of process verification are identified:

a. Verification by the operator of the attainment of disinfection conditions – the WD is equipped with a temperature indicator, independent from the controller, to allow the operator to verify attainment of the programmed disinfection temperature.

   This may be used when, because of the intended use of the load, the risk arising from use of the product after an unsatisfactory disinfection process is low. This may include, for example, WDs for human-waste containers.

b. Verification by process record, independent from the controller, of the attainment of disinfection conditions – the WD is equipped with a temperature recorder, with sensors and signal processing independent from the controller, to record the attainment of the programmed disinfection conditions.

   This may be used when, because of the intended use of the load, it is necessary to provide confirmatory evidence that the disinfection process has taken place within the limits established during validation.

c. Verification by process record, independent from the controller, of the attainment of process variables affecting both the cleaning and disinfection processes – the WD is equipped with a multi-channel recorder, with sensors and signal processing independent from the controller, to record the process variables which were determined during validation studies to be critical to the satisfactory outcome of the cleaning and disinfection processes.

   This may be used when, because of the intended use of the load, it is necessary to provide confirmatory evidence that both the cleaning and disinfection processes have taken place within the limits established

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

during validation. This may include WDs for products which will be used without further processing and where the risks arising from an unsatisfactory cleaning and/or disinfection process are unacceptable.

4.21 A temperature indicator, independent of the controller, should be fitted to all WDs having a chemical disinfection stage to enable the user to verify the attainment of the specified disinfection temperature.

4.22 WDs used in SSDs and other similar production environments should be fitted with recorders to record process temperatures and the values of other key variables, eg. volume of chemical additive admitted.

NOTE: The use of recording devices may be required for compliance with the various quality systems under which the WD may be operated but in addition may be cost effective in producing the information to optimise the decontamination process.

4.23 When an instrument has a facility to allow it to be adjusted the adjustment should require the use of a key code, or tool, which is not available to the operator.

4.24 When a fault is indicated in the form of an error message shown on a visual display unit, it should be clearly distinguishable from the normal messages – for example, by use of a different colour or larger size of text. The indicator should remain displayed until cancelled by the operator.

4.25 The contractor should be required to carry out adjustments to the instruments on site so that the accuracy specified at the disinfection temperature can be met with the plant running and under the conditions normally prevailing on site.

4.26 An indicator should show which stage of the operating cycle is in progress and indicate “cycle complete” at the end of the cycle. For continuous process machines, separate indication of the operational status should be provided for each chamber or section.

4.27 A five digit counter should be provided to indicate the cumulative number of cycles started. The counter should be non re-settable, tamper evident or sealed. For continuous process machines the counter should indicate the number of loads which have entered the WD.

4.28 Provision should be made for the attachment of the test instruments required for the tests specified in SHTM 2030 Part 3, ‘Validation and verification’.

For temperature testing – a connection should be provided to permit the entry of sensors into the chamber, as described in BS 2745 Part 1. A suitable form of temperature connection is described in BS EN 285.

For pressure or flow testing – test tees and valve cocks with sealing plugs should be fitted to permit connection of test instruments for the verification

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

and calibration of all pressure and flow instruments permanently fitted to the WD.

When the WD is provided with instruments to monitor other variables – such as electrical conductivity of water supply or ion selective electrodes (ISE) for the determination of detergent concentration – means should be provided to enable test instruments to be connected to verify the readings obtained from the installed sensors.

Programmable electronic systems

4.29 Modern WDs frequently use programmable electronic systems (PES) for control and data recording. Such systems should be designed in accordance with the principles set out in the two parts of the HSE document 'Programmable electronic systems in safety related applications'.

4.30 When a PES is used to control or monitor the process, the values of cycle variables critical to process performance and determined during validation should be documented in the validation report regardless of whether or not they are held in the PES memory.

4.31 The version number of the software used in the PES should be available for display when required.

4.32 Combined control and instrumentation systems that are wholly operated by means of a PES should incorporate at least two timing systems independent of each other. When one timing system is used to control the holding time during the disinfection stage it is verified by the other timer.

Steam supply

4.33 When the WD is fitted with a steam supply, the steam pipework should include a pressure reducing system with a separator on the high pressure side. The system should be fitted with a strainer and trap to prevent condensate accumulating in the system.

Doors

4.34 WDs may have a single door or a door at each end (double door or pass through machines). Double door machines are preferred since they allow full physical segregation of clean disinfected items from dirty contaminated items. However, the increased complexity of a two door system may present additional maintenance requirements. Without special provision these may be inadequate for effective use of the WD as a "pass-through" machine from a "dirty" to a "clean" area since they allow a continuous, large, loss of air from the clean area.

NOTE: Some continuous process machines are fitted only with baffle stops at each end of the machine, and in some cases between sections of the machine.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.35 Other continuous process machines may be in the form of a series of tanks into which the load is moved by an overhead conveyor. Each tank is protected by horizontally hinged spring loaded flaps which are pushed open by the load as it is lowered into, or raised from, the tank.

4.36 Discrete chamber or cabinet type machines (Type 1) may be fitted with manual or power operated doors whereas continuous process machines (Type 2) are normally fitted with power operated doors. Power operated doors will usually be vertical sliding doors. When manually operated doors are used they may be either vertically hinged or horizontally hinged. Horizontally hinged doors which fold down may offer the additional benefit of providing a loading and/or unloading platform.

4.37 The choice of design for any particular installation will depend on the workload, space restriction, price and ease of maintenance. If hinged doors are specified it should be clearly stated whether they are to be hinged on the left hand side, the right hand side or horizontally hinged.

4.38 It should be possible to clean the contact surfaces of the door seal without removing parts of the WD.

Materials of construction

4.39 Those parts of the WD which come into contact with the load should be manufactured from materials which have corrosion and abrasion resistant properties equal to or better than stainless steel.

4.40 The wet and chemically aggressive environment within the WD will cause corrosion and galvanic attack when dissimilar metals come into contact –a fact which should be taken into account when choosing the materials of construction.

4.41 The chamber should be designed to withstand 25,000/T operating cycles where T is the minimum operating cycle time in hours, specified by the manufacturer.

4.42 The method of construction of the chamber should ensure that it is self draining and free from sharp internal corners which cannot be cleaned during the normal cleaning cycle.

4.43 Floor mounted WDs shall be fitted with adjustable feet to compensate for irregular surfaces.

Integral steam generators designed to operate at pressures exceeding 200 mbar gauge

4.44 Steam generators fitted to WDs should be designed and manufactured to conform to BS 5500: 2000.

4.45 The integral steam generator should be equipped with blow down facilities to enable sludge to be expelled.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Integral air compressors

4.46 WDs may require a supply of compressed air for either the operation of valves and powered door systems and/or during the drying stage of the cycle.

4.47 When compressed air is intended to come into contact with the washed and disinfected product the compressed air supplied should be “medical grade” ie. it should be oil and particulate free (see SHTM 2022).

4.48 Built-in air compressors should be suitable for the duty imposed upon them. Current experience suggests that certain small compressors of the type fitted to domestic refrigerators are not suitable for use in WDs. Without meticulous maintenance a small air leak can cause them to run continuously thus causing carbonisation of the oil and a consequent failure of the WD pneumatic system.

Integral calorifiers and tanks

4.49 All integral calorifiers should conform to BS 853: 1996 and should be designed and constructed to allow thermal disinfection to be achieved throughout the calorifier and associated pipework before water and/or steam can be supplied to the WD during the thermal disinfection and subsequent stages.

4.50 Water tanks within the WD should be self draining and located so that they are cleanable by the operator and fitted with a drain down system which either works automatically when the machine is switched off or which is accessible to the user.

4.51 All tanks should be fitted with an overflow (see Water Bye-laws 1989).

When water is to be heated the heat source should be controlled by a thermostat and it should employ a heating medium as specified by the purchaser. The heat sources should be removable for replacement or maintenance purposes.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum
A48235836

Dosing systems

4.52 The WD should be fitted with not less than two systems for controlling the admission of chemicals (detergents, disinfectants, rinse aids, lubricants etc.) and should be provided with the facility for at least one additional dosing system to be fitted.

NOTE: This requirement does not apply to WDs for human-waste containers.

4.53 Each dosing system should be provided with means to adjust the volume admitted. Access to the means of adjustment should require the use of a key, code or tool.

NOTE: The means of adjustment can be manual or automatic.

4.54 The stage(s) in the process cycle at which each dosing system admits chemical to the WD should be under the control of the automatic controller.

4.55 Each dosing system should be provided with means to determine the volume admitted and the time within the operational cycle when the admission occurred. This data should be available to the operator.

Failure to admit the specified minimum volume should cause a fault to be indicated.

4.56 The manufacturer should specify the accuracy and reproducibility of the control of volume admitted for each of the dosing systems used (detergents, disinfectants, rinse aids, lubricants) per cycle.

4.57 The WD should be fitted with a system that will indicate when there is insufficient chemical(s) available for the next cycle.

Door controls

Control of manually operated doors

4.58 An explanation of the manual action required to lock the door should be provided for the operator. In addition, if the unlocking procedure is not the reverse of the locking procedure, there should be an indication to the operator of the manual action required to unlock the door.

The indication should be clearly displayed either on the door or on its handle or handwheel. Explicit instructions should be displayed on the facing panel adjacent to the door or on the operator's control panel.

4.59 The door mechanism should be such that the force to be applied by an operator in order to either lock or unlock the door does not exceed 250N at the intended point of grip.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Control of doors of a double-ended WD

4.60 In double-ended WDs the control initiating the automatic cycle should be at one end only. When the loading door is closed and locked, it should not be possible to open the unloading door until the WD has completed a successful operating cycle – ie. without showing a fault.

4.61 If a fault develops, it should only be possible to open the loading door.

4.62 It should not be possible for an operator to open or close a door at the opposite end of the WD or for more than one door to be open at one time.

4.63 A visual display should be provided at both ends of the WD to indicate when the cycle is in progress.

4.64 The indication “cycle complete”, or an equivalent indication, should be cancelled when the unloading door is unlocked, and the loading door should remain locked until the unloading door has been locked again.

Internal doors and access ports

4.65 Doors between consecutive sections of a multi-section machine and access ports fitted to the outside of the machine for maintenance purposes.

Loading systems

4.66 The WD should be provided with carriers to locate the load during the washing and disinfection process. When interchangeable load carriers and baskets are provided each load carrier should be capable of being fitted and removed without the use of tools.

WD loading systems should be designed with regard to the Manual Handling Operations Regulations 1992. Reference should be made to the Lifting Operations and Lifting Equipment Regulations 1998 (LOLER).

4.67 When the WD is supplied with a system for supporting the load – and/or a system for transferring the load into and/or out of the chamber – the following should apply:

a. the load should be wholly supported and retained within the usable chamber space for the duration of the operating cycle;

b. the force required by the operator, either directly or by the application of a mechanical device supplied with the equipment, to remove the whole, or part, of the load from the chamber should not exceed 250N when loaded and operated in accordance with the manufacturer’s instructions;

c. the load carrier should either be retained in the chamber by a mechanism which is only released when the transfer system is in place, or remain stable when withdrawn for a distance equal to two-thirds of the chamber length, and be fitted with a retaining device, which has to be released if the load is to be withdrawn further.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.68 Means should be provided such that the transfer of the load into and out of the chamber does not cause damage and wear to the chamber.

NOTE: Systems which cause high levels of local stress, eg. point loadings, may also initiate corrosion in stainless steel materials.

4.69 The system used to support the load should be constructed from durable, corrosion-resistant materials and should withstand, without damage, the environment within the chamber.

4.70 The system used should neither prevent the attainment of the pre-set cycle variables nor the free drainage of water from the load and the penetration of water and/or steam into the load.

The load carrier(s) should be designed so that they cannot be mis-positioned in a manner which will prevent such attainment.

4.71 Any accessory used for handling the load which can be used outside the WD (eg. a trolley) should remain stable when it is supporting its maximum design load and a force of 250N is applied horizontally in any direction to the highest point of the load or accessory.

4.72 The trolley should be designed to allow the operator to align the trolley with the WD for ease of loading and unloading.

4.73 The trolley should be provided with means to collect liquid residues from the load to prevent these from dripping onto the floor. The means provided should be detachable for cleaning and for sterilization at 134–137°C in a porous load sterilizer.

4.74 The trolley should be provided with swivel wheels to facilitate manoeuvring.

4.75 The trolley should be provided with a parking brake.

4.76 The trolley should be designed to secure the load carriers on the trolley during loading and unloading, and while traversing a gradient at a slope of up to one in 20.

4.77 Trolleys intended for use with single door machines should be designed and constructed to facilitate cleaning and disinfection of the trolley between use for dirty and clean loads.

4.78 Load conveyors outside the WD which are intended to, or may reasonably be expected to come into contact with, soiled/contaminated goods should be designed and constructed to be easy to clean and disinfect. When practicable the load conveyors should be demountable and be able to be sterilized at 134–137°C in a porous load sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Cleaning the washer-disinfector

4.79 The design, construction and operation of the WD should ensure that during the process the surfaces of the chamber and the load carrier presented to the operator are cleaned and disinfected.

4.80 For manually filled and emptied cleaning machines with no disinfection cycle, eg. stand alone ultrasonic cleaners, the manufacturer should advise on the cleaning/disinfection method.

Invitation to tender

4.81 Once detailed specifications have been drawn up, manufacturers should be invited to tender for the supply and, if required, installation of the WD.

4.82 When inviting tenders purchasers should follow the principles described in Scottish Capital Investment Manual and Scotconcode.

4.83 The purchasers should specify that the WD manufacturer operates a quality system in accordance with the principles described in the BS EN ISO 9000 series and, when applicable, the BS EN 46000 series.

If the manufacturer has both designed and manufactured the WD the quality system should conform with BS EN ISO 9001/BS EN 46001.

If the WD has been manufactured to a design supplied by a third party the manufacturer's quality system should conform to BS EN ISO 9002/BS EN 46002.

In either case the manufacturer should ensure that each supplier of accessories, fittings and other materials also operates an appropriate quality system.

4.84 Prospective contractors should be given the following information:

a. that each WD will be subject to a validation process as described in SHTM 2030 Part 3, 'Validation and verification';
b. unless otherwise specified, that the installation checks and test specified in the validation process must be satisfactorily completed before the WD can be accepted;
c. whether the installation checks and tests are to be witnessed by the purchasers representative (normally the TP);
d. the date by which all services will be available;
e. the date by which the validation process is expected to be completed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.85 Under the Public Supply Contract Regulations an exceptionally low offer may only be rejected after the contracting authority has requested and taken into account any explanation given by the supplier in writing (Statutory Instrument 1995 No 201 Part V 21/71).

Contract

4.86 For procurement of WDs reference should be made to the latest issue of PROCODE and the procedures advised in the Scottish Capital Investment Manual.

Guidance on the various contract types is available from the Property and Environment Forum Executive.

4.87 Consideration may also be given to the use of alternative forms of contract, for example MF/1 (available from the Institution of Electrical Engineers, the Institution of Mechanical Engineers or the Association of Consulting Engineers) or the Joint Contracts Tribunal (JCT) suite of documents (available from RIBA publications) or the New Engineering Contract issued by the Institution of Civil Engineers. Addresses are given in Appendix III.

4.88 Purchasers using other forms of contract are strongly advised to seek legal advice especially where a contract proposed by the prospective contractor is being considered.

4.89 Other contracts – notably for the authorised person, test person, maintenance person, competent person, and microbiologist – may need to be considered at this time (see SHTM 2030 Part 2, ‘Operational management’ and Part 1 of SHTM 2010).

4.90 In awarding these contracts purchasers should ensure that there is no conflict of interest that would compromise the validation process as set out in SHTM 2030 Part 3, ‘Validation and verification’.

Delivery

4.91 On or before delivery of the WD the manufacturer should provide the purchaser with the information specified in Appendix 4. WDs for a particular scheme should not be ordered and stored on site for long periods prior to installation and validation. Disregard of this recommendation may invalidate the manufacturer’s warranty and cause deterioration of the WD prior to installation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5. Siting

Introduction

5.1 This chapter sets out some of the considerations to be taken into account when siting a WD. WDs are commonly installed in sterile service departments (SSDs), operating departments, wards and laboratories. A comprehensive review of the requirements for SSDs is given in SHPN 13 and for operating departments in SHPN 26.

5.2 The room in which a WD is installed and operated should meet the requirements of the Workplace (Health, Safety and Welfare) Regulations 1992. These Regulations have considerable implications for the design of accommodation for WDs.

5.3 Fire safety precautions should comply with NHSScotland Firecode.

Operating department dirty utility room

5.4 This area should be equipped for the storage, preparation for use, and disposal of contents after use, of human-waste containers including vomit bowls, bedpans and urine bottles. Specific guidance is given in SHPN 26.

Endoscope cleaning room

5.5 Provision may be made within the operating department for an endoscope cleaning room to provide facilities for cleaning and disinfection or sterilization of those endoscopes which cannot be returned to the central SSD or TSSU for reprocessing. When practicable this is best provided by means of an automated endoscope WD. Manual cleaning facilities will also be required.

5.6 A toxic vapour extract system at bench level to exclude all possibility of inhalation should be installed whenever a liquid chemical microbicide is to be used other than in an enclosed ventilated automatic WD.

5.7 The same area may also be used to accommodate an automated WD for emptying, cleaning and disinfecting suction bottles.

Specific guidance is given in SHPN 26 Operating Department.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Sterile services department

Decontamination area

5.8 A soiled returns hold area, where collection trolleys containing soiled returns can be marshalled, is normally located adjacent to or within the washing area and adjacent, or with easy access to, the hospital corridor or loading bay.

5.9 The washing area provides space to:

a. off-load soiled returns from trolleys;

b. sort items for disposal or appropriate cleaning and disinfection;

c. clean and disinfect reprocessable items;

d. transfer cleaned and disinfected items to the packing room.

When the transfer is automatic (ie. from an automatic WD) means should be provided to allow for the return of items which, when inspected in the packing room, are found not to have been properly cleaned.

5.10 The necessary cleaning and disinfection processes for the routine range of items to be processed may require several different types of WD. These may include, for example:

a. Single door cabinet WDs which may be used with a pass through hatch to the packing room.

When a hot air drying cabinet is used this should be of the pass through type with interlocking doors for transferring items from the washing area to the packing area.

b. Continuous process “pass through” WDs which will usually be equipped with a conveyor system to return the load carriers from the packing room to the decontamination room.

The conveyors should be designed and constructed to be easy to clean and disinfect (see also paragraph 4.78).

The decontamination room should provide a facility for cleaning trolleys used to transport returned items for decontamination and a suitable holding space for the number of trolleys which will be in use.

The room should also provide sorting benches with sufficient space for unloading trays from the trolleys and transferring items to WD baskets/load carriers.

Proper insulation of WD and exposed pipework from services is essential, together with appropriate ventilation, in order to maintain a comfortable working environment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.11 Manual cleaning facilities may also be required. A stainless steel double sink, double drainer and water gun unit (hot and cold water) should be provided. The manual cleaning area should be provided with a hood and extract ventilation (to microbiological safety cabinet Class 1 – 0.7m/sec face velocity) to protect the operator from aerosols created during the cleaning process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6. Engineering services

Introduction

6.1 A WD installation will require external service connections. These may include water (of various qualities), electricity, steam, compressed air, drainage, ventilation and supplies of process chemicals.

6.2 The manufacturer should make clear at an early stage which services will be needed and give detailed requirements for each service (see Table 3).

6.3 For most WDs the water and drainage services are the most critical although for user comfort, especially in the case of WDs using chemical disinfectant/sterilant, the ventilation and extraction system are also of importance.

6.4 If the services are to be installed by a contractor, other than the contractor installing the WD, care must be taken to ensure that the size and location of terminations are agreed before the contracts are placed.

Electrical services

6.5 The electrical power requirements will depend on a number of factors, such as the type of WD and the method used to heat water, hot air dryers etc. Some WDs will need a three phase supply. The manufacturer should provide details of the type of supply (a.c. or d.c.), number of phases, frequency and voltage, with tolerances and loading.

6.6 Each WD should be connected via an isolator. The type of isolator will depend on the nature of the supply:

a. for small WDs and table top WDs with a maximum current demand not exceeding 13A on a single phase supply, isolation may be provided by a simple plug and socket connection using a correctly fused plug and a switched socket-outlet;

b. when a three phase and neutral supply is required or when the maximum demand from a single phase supply is more than 13A, the WD should be wired directly to the isolator. The switch should isolate all poles simultaneously and each pole should be fused separately. The cable from isolator to WD should be fixed and protected from the effects of heat and water.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 3: Information on services to be obtained from the washer-disinfector manufacturer

Steam	a) acceptable range of supply pressures; b) maximum flow and usage rates; c) usage per operating cycle d) when steam is generated within the WD, the acceptable limits for hardness, pH and conductivity of feed water.
Electricity	a) type of supply eg. a.c. or d.c; b) number of phases (normally one or three) and whether neutral is required for a three – phase supply; c) supply voltage and frequency including nominal and acceptable minimum and maximum values; d) maximum continuous power demand in kW or kVA.
Compressed air	a) acceptable range of supply pressures; b) the flow required at minimum pressure; c) the volume of air used for each cycle; d) the quality or quantity of air required including dew point, maximum size and concentration of particulate material, oil content, and microbial contamination level as relevant.
Water	For each grade of water required, a) the acceptable range of supply pressures; b) the flow at minimum pressure; c) the volume used per cycle; d) the acceptable temperature range for incoming water; e) the quality of water required when relevant: - the maximum permissible hardness expressed as mg/l $CaCO_3$; - the acceptable range of pH; - the maximum permissible conductivity; - the limiting concentration of heavy metals, halides, phosphates and nitrates; - the maximum acceptable microbial population.
Drainage	a) the maximum flow of effluent to the drain; b) the maximum temperature of the effluent on leaving the WD; c) the maximum effective diameter of the discharge orifice from the WD chamber; d) requirement for sealed drainage system if hazardous fumes or gases are produced from chemicals used in the process.
Ventilation	a) the peak value during a cycle and the average value throughout a cycle of the heat in Watts transmitted to the environment when the WD is operated in still air at an ambient temperature of $23 \pm 2\ ^{o}C$; b) the heat in watts transmitted by a full load being unloaded from the WD into still air at an ambient temperature of $23 \pm 2\ ^{o}C$; c) the maximum flow of air extracted from the environment of the WD as exhaust ventilation; d) ventilation requirements for removal of fumes or gases from hazardous chemicals used in the process.
Process chemicals	Details of all process chemicals required (eg. detergents, rinse aids, sequestering agents, descalers, microbicides) for the regeneration of integral water treatment system), the quantity required per cycle, the nature and size of containers in which they are supplied, the necessary storage conditions for safe handling.

6.7 Within the loading area an additional switch should be provided so that the operator can electrically isolate the WD or group of WDs in the event of an

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

emergency. The switch should be placed between the normal operating position and the exit door.

6.8 It is not normally necessary for WDs to be connected to the essential supplies circuit, when this is available. Exceptions might include the decision to ensure that a limited number of WDs within the SSD remains on the essential supplies circuit. Guidance on the supply of electricity in the event of failure of the normal supply is given in SHTM 2011; *Emergency electrical services*.

6.9 All electrical installations should conform to IEE Regulations contained in BS 7671. Further guidance is given in SHTM 2007; *Electrical services: supply and distribution* and SHTM 2020; *Electrical safety code for low voltage systems (Escode–LV)*.

Steam

6.10 Steam may be used to supply a heat exchanger as a source of indirect heating for water or air to be used in the cleaning, disinfection or drying stages of a WD operating cycle.

6.11 Steam may also be used to heat process water directly, or to heat the load directly during the thermal disinfection stage, and for this purpose may be supplied either with an integral steam generator or from an external (“mains”) supply.

Steam for indirect heating

6.12 Steam heat exchangers used for heating water or air may be of the shell, tube or plate design. In all cases, the steam supplied should be substantially free from non-condensable gases and free from oil since these contaminants will seriously impair the efficiency of the heating process. The effect of thin films of air on the surface of the heat exchanger may increase heating costs by 25% or more.

6.13 Suitable steam may be available from the high-pressure hot water systems used in some hospitals.

6.14 The steam service should be designed to meet the maximum demand of the WD, while keeping the fall in pressure before the final pressure reducing system to no more than 10%.

6.15 Except for vertical rises between floors or at intermediate points on long runs, the pipework should have a continuous fall such that any condensate flows by gravity in the same direction as the steam. Air vents and steam traps should be fitted at each vertical rise.

6.16 The condensate discharge system should be sized to ensure that the high volume of condensate found during the initial stages of heating can be discharged without “water-logging” the heat exchanger.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.17 When the steam supply pressure at the inlet to the WD exceeds the maximum value specified by the manufacturer, a pressure reducing valve should be fitted to the supply pipe at least 3 m from the WD (this may be supplied by the manufacturer and be integral to the WD).

6.18 Careful attention should be paid to the siting of all pressure relief valves to ensure that the WD is properly protected.

6.19 Relief valves and their discharge pipes should be large enough to prevent the pressure in the supply pipes rising to more than 10% above the design pressure for the heat exchanger. The discharge pipe should terminate in a safe position outside the building.

6.20 Steel and copper piping traditionally used for steam supply are acceptable for this application.

6.21 Excessive moisture in the steam supply will impair the heating efficiency of the heat exchanger.

Steam for direct heating

6.22 Steam for direct heating should meet the requirements described above but should also be of an appropriate chemical and microbiological quality.

6.23 Any contaminants carried with the steam supply will be transferred to the load being processed either through contact with water which was steam heated or heated directly.

6.24 Filming amines or similar volatile corrosion inhibitors used to prevent corrosion in condensate return pipes should not be employed in steam used for direct heating.

6.25 The quality of steam required will depend on the nature of the load to be processed and, in particular, on the intended use of the load items. In heating for loads intended for use in surgically invasive procedures, the condensed steam should meet the chemical purity Standards specified for Water for Irrigation EP and should contain no more than 0.25 Endotoxin units/ml. Detailed guidance is given in SHTM 2031; *Clean steam for sterilization* and the same Standards are applicable.

6.26 When direct heating of the load by steam is used, the design of the WD should include adequate venting to the chamber to ensure that there is no possibility of pressurisation during a single fault condition.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Integral steam generators

6.27 Some WDs are equipped with small electrically heated steam generators to raise steam to heat the load directly by thermal disinfection.

6.28 They may be of the “open-boiler” type which are so designed and constructed that they are unable to generate an internal pressure above atmospheric pressure. The design should ensure that, under a single fault condition eg. obstruction of the steam discharge port, the boiler cannot become pressurised.

6.29 Integral steam generators which are pressure vessels should comply with the requirements of BS 5500: 2000.

Condensate recovery

6.30 Condensate from steam heating systems (calorifiers, dryers) and steam traps on the pipeline is suitable for recovery and should be returned to the steam generating plant when recovery is economically justifiable.

Compressed air

6.31 A compressed air supply may be required for the operation of controls and also for air drying. When the WD does not contain an integral air compressor (see paragraph 4.45) the air may be supplied from a piped service (mains supply) or from a local compressor.

Mains supply

6.32 If air is supplied by pipeline from a central air-compressor system a pressure gauge of the Bourdon type, complying with BS EN 837, should be fitted on the supply line to the WD via an isolation valve.

6.33 A reducing valve, or other automatic device, should be fitted to reduce the pressure of air delivered to the WD to no more than the maximum supply pressure specified by the manufacturer. A pressure relief valve will normally be required.

Local compressor

6.34 When it is not practical to obtain compressed air from a mains supply, a dedicated compressed air system should be installed to supply the WDs.

6.35 The compressors may be too noisy to install with the WD and may need to be located in a dedicated location away from noise sensitive areas.

6.36 Components of the compressed air system which require servicing and maintenance, such as dryers and filters, should be located where they are readily accessible for service or exchange.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Air quality

6.37 The quality of air may be critical for some applications and some WDs will incorporate appropriate filters. When the purchaser is to be responsible for the provision of filtered air the TP should ensure that the quality of air available meets the WD manufacturer's specification or the requirements given below.

6.38 Air that could come into direct contact with the load, such as air used for drying the load or testing the free-passage of lumens, should be oil-free (ie. should have no more than 0.5mg of oil per cubic metre of free air measured at 1013 mbar and 20°C; see BS EN 554), be filtered to an efficiency of at least 95% when tested in accordance with BS 3928 and be free of bacteria (see SHTM 2022, *Medical gas pipeline systems*).

6.39 Air for control purposes should be free of liquid water, filtered to 25 µm (5 µm for precision controls) and lubricated with micro-fog oil particles of 2 µm or less.

Drainage

6.40 All effluent from a WD is potentially contaminated and should be disposed of to the main drain.

6.41 Effluent may originate from each of the stages of the process which may include:

a. flushing to remove gross contamination;
b. washing with detergent and/or enzymatic cleaners;
c. rinsing, with or without the addition of a neutraliser, rinse aid or instrument lubricant;
d. chemical disinfection or thermal disinfection;
e. post-disinfection rinsing;
f. drying.

6.42 Effluent from the initial stages [(a) and (b) above] of the process may contain significant concentrations of organic contaminants and potentially infective micro-organisms. Effluent from the middle stages [(b), (c) and (d) above] may contain some organic contaminants and potentially infective micro-organisms and high concentrations of process chemicals. Effluent from the latter stages [(d), (e) and (f) above] may be at high temperatures (90–100°C).

6.43 Effluent from WDs (other than WDs for human-waste containers) should pass via an air break into a tundish or tank before being discharged to drain. The air break should be preserved at all times to prevent the WD and its associated pipework being contaminated by reverse flow from the drainage system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: WDs for human-waste containers are connected directly to a soil pipe but are tested to ensure that back siphoning cannot occur under severe operating pressure.

6.44 When a tank supplies water to a pump on the WD, the overflow discharge from the tank should also include an air break.

6.45 The drainage system from the installation should be trapped and designed to pass the flow rate of water, air and condensed steam specified by the manufacturer, with account taken of the peak output during the operating cycle.

6.46 The drainage system should be designed to pass and maintain in suspension the solids removed from the load during the flushing process. The minimum diameter of the drainage system should be greater than the maximum diameter of the most restricted section of the discharge from the WD chamber.

6.47 Means shall be provided to prevent, as far as possible, flash steam being liberated into the atmosphere or causing condensation on electrical equipment.

6.48 The discharge temperature from a WD may be as high as 95°C. The materials used for the construction of the discharge system should be chosen to withstand temperatures up to 100°C.

6.49 Attention is drawn to the legal requirement (Public Health (Scotland) Act) that the maximum temperature of any liquid to be emptied into the public sewer or communicating drain is 43°C. This should be interpreted as referring to the main building connection to the sewer and not to the internal building drain.

Hazardous effluents

6.50 The discharge of soil from WDs should be regarded as being no more, but no less, hazardous than the discharge from any other sanitary appliance eg. a WC.

6.51 The discharge of process chemicals, including detergents and microbicides, may require special attention. The local water undertaking should be consulted before such chemicals are discharged into the drainage system as it may be necessary to neutralise or inactivate them before discharge.

6.52 A sealed and vented drain should be used for the discharge of chemicals with a significant vapour pressure – determined at the maximum attainable temperature of effluent in the drain – which may be hazardous to health or a nuisance. Possible backflow from the drain should be prevented by the inclusion of a check valve and a vacuum breaker.

6.53 WDs should not be used to process items known to be contaminated with high titre pathogens in Hazard Group 3, eg. arising from research activities, or any pathogens in Hazard Group 4 unless the items have been sterilized

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

by an appropriate steam sterilization cycle in a laboratory sterilizer designed and operated for the purpose (Further guidance is given in SHTM 2010 and advice should also be sought from the HSE).

Ventilation

6.54 Ventilation of the area near WDs may be needed to remove excessive heat and humidity, and also vapours from disinfectants such as glutaraldehyde.

6.55 General room ventilation will be sufficient for most WDs, but local exhaust ventilation may be required for chemical disinfection/sterilization systems.

6.56 Electrical systems used in ventilation systems should take account of the high levels of humidity that may be discharged and the potential for this to condense within the ventilation system.

6.57 All ventilation systems should meet the ventilation requirements of the Workplace (Health, Safety and Welfare) Regulations 1992.

6.58 Further guidance on ventilation systems may be found in SHTM 2025; *Ventilation in healthcare premises*.

General room ventilation

6.59 WDs for most healthcare applications do not require a filtered air supply in the room in which they are located unless there is no physical segregation between this area and the packing/sterilizing area.

6.60 The ventilation system in the area of a WD used to decontaminate used items should be a “full fresh air” system without recirculation. In designing the ventilation system reference should be made to SHTM 2025 ‘Ventilation in healthcare premises – Design considerations’.

6.61 Decontamination areas should generally be at a pressure below atmospheric; a 5-10Pa pressure difference is sufficient to minimise the dispersion of potentially infective aerosols into adjacent areas.

6.62 In designing the ventilation system two factors are of particular importance:

a. the provision of adequate cooling so that working conditions remain comfortable for staff;

b. correct sizing of the room ventilation system and/or interlocking with operation of both the room ventilation system and the machine/process specific extraction system(s) when extraction fans on WDs and/or extraction hoods are in operation.

6.63 WDs, particularly those employing thermal disinfection processes and a drying stage, may discharge significant heat energy to the surrounding environment. In designing a ventilation system for single ended WDs,

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

account should also be taken of the heat emitted from the load after it has been removed from the WD.

6.64 Current experience suggests that a 250 litre capacity cabinet WD, with a thermal disinfection stage and hot air drying installed as a free standing unit with the door closed and the machine operating, will release by radiation and convection heat energy at the rate of approximately 1.0 kW. A full load of processed items being removed from the WD will release energy at a declining rate but having a peak rate of approximately 0.5 kW immediately upon removal from the WD. Large multi-cabinet machines can release by radiation and convection energy over their operating cycles at rates up to 4 or 5 kW.

Machine ventilation

6.65 WDs are often run under a slight negative pressure to minimise the potential for the discharge of aerosols into the environment.

6.66 WDs not equipped with an air extract system may require siting under an extraction hood. The capture velocity in the vicinity of the process should be within the range 0.25–0.5m/s to ensure adequate extraction of steam and water vapour.

6.67 The extracted air from WDs is discharged into the atmosphere. In large installations significant quantities of useful energy may be discharged as a result. A heat recovery system may be economically viable and a full assessment of the benefits and costs should be carried out. Additional guidance is given in SHTM 2025 Part 2 ‘Ventilation in healthcare premises – Design considerations’.

6.68 The air extracted from WDs, both during the washing and the drying phases of an operating cycle, will normally have a high moisture level. The extraction system should, therefore, be equipped with a drain to discharge the condensate and should be designed and constructed so that it may be cleaned periodically. The drainage system should be constructed with a continuous fall to discharge, without any upstand at the point of connection to the ventilation system to prevent pooling.

6.69 The extraction system should be constructed from corrosion resistant materials. The discharge from some WD dryer systems is at high temperature (105°C) which is sufficient to melt or distort some lightweight plastic ducting materials. Typical worst case values are temperatures >105°C and 100% saturation.

6.70 Current experience suggests that flow rates for built-in extraction systems are in the order of 100 m^3/hr for a single cabinet 250 litre capacity machine, and up to 800 m^3/hr for a multi-cabinet continuous process machine of 1500 litre total capacity (ie. three 500 litre chambers).

6.71 The output from the extraction system should be considered as potentially containing infective aerosols and should, therefore, be discharged away from

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

opened windows, air intake systems or where down draughts occur. It is important that adequate dispersal is achieved and roof-level discharge is preferred.

6.72 The extraction ductwork connected to the WD is an efficient transmission system for noise originating within either the WD or extraction plant. Care is needed in the design and construction of the ducting to ensure that noise does not become a problem. This may require the use of sound attenuators as part of the ductwork design. Additional guidance is given in SHTM 2025 Part 2 'Ventilation in healthcare premises – Design considerations'.

6.73 Extraction hoods to protect operators against aerosol dispersion of potentially infective material, eg. over a manual washing sink or an unlidded ultrasonic bath, should have extraction velocities at working level of no less than 0.7–1.0 m/s.

NOTE: Although higher velocities will not impair extraction they are wasteful of energy.

6.74 Extraction systems, eg. bench extraction ventilation designed to protect operators against contact with vapours or gases such as those arising from chemical microbicides including glutaraldehyde, should have extraction velocities of 5.0–6 0 m/s.

6.75 Extraction hoods should be provided with local controls, or a control system interlocked with the equipment with which they are intended to work, so that they may be shut down when not required.

6.76 Purpose built work stations for glutaraldehyde disinfection/sterilization with built-in ventilation systems are also available. These are generally installed in a similar manner to laboratory fume cupboards (see BS 5728: 1990).

6.77 Extract from WDs and extraction hoods should not be discharged through general ventilation extraction systems. The extract from two or more WDs and/or extraction hoods should not use common ducting unless provision is made to ensure that there is no risk of contamination of a disinfected load from the cross-connection.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chemical additives

6.78 Safe storage provision is needed for containers of chemical additives used in the WD. These chemicals are frequently corrosive, irritant and toxic and provision should be made in, or adjacent to, the storage area for an emergency eye wash station and a source of running water to dilute any spillage.

6.79 In large installations with two or more Type 2 machines, as may often be required in SSDs, bulk storage tanks for chemical additives required for the process may be preferred with a piped distribution system to each WD.

6.80 For each chemical additive to be used there should be two storage tanks in parallel, one of which may be a small reserve tank, to permit cleaning and maintenance of the system without interrupting the use of the WDs, to facilitate segregation between separate batches of chemical additive and to allow for an orderly change to a different formulation if required.

6.81 The liquid concentrates are often viscous and chemically aggressive. The pipework, valves etc. used for the distribution of these chemicals will need to withstand the corrosive effects of these materials. Advice should be sought from the manufacturer of the chemical additives on suitable materials, construction and pumping systems for the distribution system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7. Water supply

7.1 The number, nature and quality of water supplies required are dependent on the size and type of WD.

7.2 WDs may be supplied with both hot and cold water. When hot water is required as part of the operating cycle, it is generally advantageous to supply hot water to the WD rather than heat cold water to the required temperature within the WD.

7.3 The quality of water used at all stages in the decontamination process is critical to the successful outcome of the process.

7.4 At each stage the water quality should be compatible with:

a. the materials of construction of the WD;
b. the load items to be processed;
c. the chemical additive used;
d. the process requirements of that particular stage.

7.5 The key factors are:

a. hardness;
b. temperature;
c. ionic contaminants (eg. heavy metals, halides, phosphates and silicates);
d. microbial population;
e. bacterial endotoxins.

Water hardness

7.6 Hard water is caused by the presence of dissolved salts of the alkaline earth (calcium, magnesium and strontium) which come out of solution and deposit as hard mineral layers (lime-scale) when water is heated or evaporated.

7.7 The fouling of electrical heating elements or heat exchange components by hard water dramatically reduces the heat-transfer efficiency and can quickly lead to an increase in heating costs of 50–100%.

7.8 The deposition of lime-scale within pipes and around the edges of spray nozzles will seriously impair the performance of a WD. Hard water will cause scaling on the edges of spray nozzles even when fed with only cold water.

7.9 The presence of hardness in water seriously impairs the efficiency of most detergents and disinfectants. If the use of hard water is unavoidable it will be

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

essential to use process chemicals that contain sequestering agents. This adds considerably to the cost of the process.

7.10 Using hard water in the thermal disinfection and final rinse stages of the WD cycle is one of the major causes of white powdery deposits on load items. These are not only unsightly and an unwelcome contaminant but act as a focus for soiling and recontamination of the item in use. In some applications (eg. with optical systems) such deposits may seriously impair the utility of the item.

7.11 Most WDs will operate with water of hardness values up to 125mg/l $CaCO_3$ but are more effective and cheaper to operate when the hardness of the water does not exceed 50 mg/l $CaCO_3$

7.12 Some WDs are fitted with integral water treatment systems (see paragraphs 7.31 to 7.33).

7.13 The temperature at which water is supplied to each stage of the process has a major effect on the efficacy of the process.

7.14 Water at too high a temperature during the initial flushing stage may lead to the coagulation of proteins and thus serve to “fix” proteinaceous soil to the surface of the load items. The British Standard (BS 2745) recommends that the initial temperature should not exceed 35°C. The initial flushing stage should be supplied with water from a cold supply.

7.15 Water at too low a temperature during the washing stage of the cycle will often impair the ability of detergents used to remove soils composed largely of fats, oils or grease.

7.16 When enzymic cleaners are used the water temperature must be maintained close to the optimum temperature specified by the manufacturer; too high a temperature will inactivate the enzymes.

7.17 When chemical disinfectants are used the rate of activity generally increases with increased temperature. Too low a temperature will cause failure to attain the required microbial activation. However, too high a temperature with particular compounds can lead to degradation of the active components, evolution of toxic vapours or adverse reactions with the load items being processed.

7.18 The maximum temperature of rinsing water must be compatible with the items being processed; many items used in medical practice are temperature sensitive or may be damaged by thermal shock.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Ionic contaminants

7.19 Water used in the cleaning and disinfection of stainless steel instruments should have a chloride concentration between 0 and 120 mg/l Cl – to avoid the risk of corrosion. Chloride concentrations greater than 240 mg/l Cl – cause pitting to occur.

7.20 Tarnishing of stainless steel instruments, shown by blue, brown or iridescent surface colouration, occurs when heavy metal ions – such as iron, manganese or copper – are present in the process water. In hot water (over 75°C) magnesium ions and silicates can cause similar discolouration.

Microbial population

7.21 The purpose of the decontamination process is to remove soiling and reduce the microbial contamination to an acceptable level for the intended use of the items to be processed. The water used at each stage of the WD process cycle should not increase the bioburden of the load items.

7.22 For items which are intended to be used without further decontamination processing (eg. terminal sterilization) the nature and extent of the microbial population in the final rinse water should not present a potential hazard to the patient, either through infection or by leading to a erroneous diagnosis. Appropriate treatment to control or reduce the microbial contamination in water may be required.

Bacterial endotoxins

7.23 Bacterial endotoxins are thermostable compounds derived from the cell walls of bacteria which, when introduced into the human body, can cause a fever-like reaction and other adverse effects (for a more detailed explanation see SHTM 2010 *Sterilization*, part 5). They are not readily inactivated at the temperatures used for disinfection or sterilization.

7.24 Water used for the final stages of processing in a WD, where there is a significant risk of residual water remaining on the load items, should not contain more than 0.25EU/ml when the WD is being used to process surgically invasive items or those which are intended to come into contact with parenteral solutions.

Water treatment

7.25 Despite the cost involved in treating water from the public supply to provide the optimum quality for use at each stage in the WD process cycle, this is usually cost-effective.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chemical purity

7.26 There are generally four methods of water treatment available for use on water supplies to be used in WDs:

a. water softeners;

b. water de-ionisers;

c. distillation;

d. reverse osmosis.

Water softeners

7.27 Water softeners, or “base-exchange” softeners, consist of an ion-exchange column containing a strong cation resin in the sodium form. Calcium and magnesium ions in the water are replaced by sodium ions. The column may be regenerated by treatment with a solution of common salt (sodium chloride).

Table 4: Use to which water of various qualities may be put

Types of water	Application
Cold water	Flushing ie. removal of gross soiling
Potable water	Flushing/cleaning
-soft eg. <50 mg/l $CaCo_3$	Cleaning with detergents or enzymatic cleaners Thermal disinfection in WCs for human-waste containers Final rinse water in WDs for human-waste containers
-hard eg. >125 mg/l $CaCo_3$	Flushing for WDs for human-waste containers will require use of descalers
Softened water -base exchange softener	Desirable in all water >50 mg/l $CaCO_3$ Essential in all water >125 mg/l $CaCO_3$ for use in WDs
Purified water	Final rinse water for laboratory WDs
De-ionised water	Thermal disinfection in all WDs Final rinse water
Reverse osmosis	Diluent for chemical disinfection Final rinse water
RO/0.22μm filtered recirculated, heated and or UV disinfected	Post-disinfection/sterilization rinsing of products intended for immediate use in critical applications eg. fibre-optic endoscopes
Sterile purified water	Post-disinfection/sterilization rinsing of products intended for immediate use in critical applications eg. fibre-optic endoscopes

Note: The above table shows suitable applications for the various qualities of water commonly available. Although water of lower quality may be used, this will normally require additional chemical additives and may entail some impairment of the WD performance.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.28 The concentration of total dissolved solids in the water is not reduced by this process. The sodium salts which remain do not readily form hard deposits to foul heat exchangers or spray nozzles but if used as the final rinse will leave white deposits on the load items as they dry.

7.29 The process is simple to operate with an automated in-line system, will handle water with varying levels of hardness, and is simple and safe to regenerate. After regeneration, however, high levels of chloride ions may be present in the initial output from the softener which should be run to waste.

7.30 In common with other water treatment systems, the base-exchange softener needs to run to a minimum volume of out-flow if the required water quality is to be achieved. This volume should be specified by the manufacturer of the treatment plant. The output from the softener should be to a water tank and the volume demanded each time additional water is fed to the tank should exceed the minimum flow.

Integral water softener

7.31 WDs are available with built in base-exchange water softeners although these are generally laboratory WDs.

7.32 Water softeners should be chosen based on the total demand of softened water in the unit eg. SSD including when necessary provision for manual washing facilities and other plant.

7.33 Base-exchange softeners may cause a significant increase in the microbial content of the water.

De-ionisers

7.34 De-ionisation or demineralisation systems can remove virtually all the dissolved ionic material by ion-exchange using a combination of cation and anion exchange resins either in a single column (mixed bed) or in a separate column.

7.35 Operating costs of mixed bed de-ionisers are usually higher than for two-stage systems.

7.36 Systems are available in a range of sizes from small wall-mounted units in which ion-exchange resins are contained in disposable cartridges to large industrial units. Regeneration requires the use of strong acid (hydrochloric acid) and strong alkali (sodium hydroxide). For most types of installation an exchange column service is available from the water treatment suppliers.

7.37 De-ionised water may be heavily contaminated with micro-organisms and de-ionised water will be colonised rapidly because the chloride ions normally present to control microbial growth have been removed. De-ionised water should not be used for the final rinse of products intended for invasive use without further decontamination processing by heating, filtration etc. (see below).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.38 For a given output volume, the initial cost of providing de-ionisation equipment will be lower than for reverse osmosis (RO). However, the inconvenience and cost of the regeneration process for de-ionisers, and the better microbial quality of the RO process, makes RO the preferred option.

Reverse osmosis (RO)

7.39 RO treatment plants remove dissolved contaminants from water by passing the water, under pressure, through a semi-permeable membrane against an osmotic gradient. The process will remove organic material, bacterial endotoxins and micro-organisms, as well as ionic species.

7.40 The initial capital cost of an RO plant is generally higher than for a de-ionisation system supplying a similar volume of water but operational costs are generally lower. When appropriate measures are taken to maintain the microbial quality of the water during storage and distribution, the water is endotoxin-free and has a negligible microbial population.

Distilled water

7.41 Distilled water may equal or exceed the purity of RO water but, despite the relatively low capital cost of the necessary plant, is very expensive to produce due to the high energy usage.

7.42 Distilled water is only used in laboratory WDs and RO is usually an acceptable alternative.

7.43 When indirect steam heating of WD water tanks and air dryers takes place, the condensate formed may provide an acceptable quality of water for use instead of distilled water.

Microbial purity

7.44 Potable water from the public supply has a low microbial content and should be free from pathogenic organisms, other than those which may cause opportunistic infections in immunologically compromised patients.

7.45 On storage in tanks and cisterns, the microbial content may increase considerably.

7.46 Attention is drawn to the requirement under the code of practice for control of legionella that water in intercepting tanks must be stored below 20°C or above 55°C.

7.47 The extent and nature of microbial contamination in the water supplied to a WD will depend on the stage in the process cycle at which it is to be used and the intended use of the decontaminated load at the end of the process.

7.48 Water stored at 60°C or above may be assumed not to have a proliferating microbial population.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.49 When sterile water is required for final rinsing in critical applications, eg. WDs for endoscopes, this should be provided by using a single-use container of sterile water for each cycle whenever practicable. The pipework, valves and pumps through which the water will pass should be subjected to an appropriate sterilization/disinfection process.

7.50 When water is treated by filtration, eg. through a 0.22 μm filter to remove microbial contaminants, rigorous controls are needed to ensure that the system works effectively. This should include:

a. either maintaining the pressure drop across the filter throughout its working life – a decrease in differential pressure being cause for rejection of the process cycle and a change of filter – or, a bubble point test before and after each process cycle (see BS 1752);

b. a continuous recirculation system so that the filter is not left wet in static water;

c. treatment of the circulating water to ensure that proliferation of microbial contamination is inhibited either by use of elevated temperature (eg. >60°C) or by the use of UV irradiation (wavelength 260 ± 10nm; >2J.m^{-2}). (See also report of the Expert Advisory Committee on biocides).

Pipework

7.51 The pipework used to supply the various grades of water should be appropriate to the quality of water carried. Sterilized uPVC or stainless steel pipes are preferred for all qualities of purified water.

7.52 All pipework should be run with a continuous fall to the discharge point so that it is free draining. It should be free from dead ends and other areas where water may become stagnant.

Water supply byelaws

7.53 All the organisations responsible for water supply within the UK have the statutory power to make, and the duty to enforce, byelaws for the prevention of waste, undue consumption, misuse or contamination of the water supplied by them.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.54 Attention is drawn to the following points:

a. Bye-laws 38 to 41 require storage cisterns to be fitted with warning pipes (and an overflow if in excess of 1000 litre capacity). The warning pipe and overflow should not comprise, or have connected to it, a flexible hose.

b. Byelaw 25 Schedule A gives examples of points of use or delivery of water where backflow is, or is likely to be, harmful to health owing to a substance continuously or frequently present (Byelaw 25 (1)(a)).

c. This schedule lists amongst other things water softening treatment plant, bedpan washers, bottle washers, dishwashers and disinfection equipment and clearly applies to all WDs.

d. The required protection is a Type A air gap at the point of use or an interposed cistern.

e. Water softeners, regenerated only by means of sodium chloride solutions, need only be protected by a Type B air gap.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8. Chemical additives (detergents, enzymic cleaners, rinse aids, lubricants and disinfectants)

Introduction

8.1 Chemical additives are not necessary for all applications while they may enhance the removal efficacy they then in turn have to be removed during the rinsing stage. For applications in the laboratory and in the preparation of components and equipment used in manufacturing medical devices and medicinal products, it may be better not to use chemical additives when their use is not essential. Further guidance is given in the chapter on each type of WD.

8.2 In choosing the various chemical additives which may be required for effective cleaning and disinfection, it is important to ensure that the formulation of each chemical additive is compatible with:

a. the materials of construction of the WD;

b. the process being operated in the WD;

c. the quality of water available;

d. the items to be processed and their intended use;

e. any other additives to be used in the WD process;

f. any intended subsequent decontamination process (eg. sterilization).

It is also important that the required concentration can be accurately and reproducibly generated by the dosing system(s) on the WD.

Compatibility with the materials of construction of the washer-disinfector

8.3 The pH, redox potential and ionic nature of the chemical additive is important in determining whether it will cause corrosion or electrolytic attack (either between different materials in the WD or between the WD and items in the load).

8.4 Chemical additives which can be absorbed into, or adsorbed onto, surfaces of the WD (eg. plastic pipework) may be carried over into subsequent stages of the process (see also paragraphs 8.7 and 8.15).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Compatibility with the process

8.5 The performance of the additive must be matched to the physical characteristics of the operating cycle, eg. jet washing action systems require low foam detergents, if the washing action is not to be impaired.

Compatibility with the items to be processed

8.6 The chemical additives used must be compatible with the materials of which the load items are constructed and should not cause chemical or physical damage – eg. phenolic compounds used in detergents and disinfectants may cause material changes in rubber and plastics, while the anodic coating on the surface of anodised aluminium is removed by strongly acid or strongly alkaline compounds. The precise formulation of the chemical additive will affect its compatibility. It is not sufficient to determine only the compatibility of the principle active constituents.

8.7 The chemical additives used must be readily removed from the load items by rinsing with water and should be biologically compatible with the intended use of the load items. Chemical additives which are intended to persist on the surface of items processed through the WD (eg. lubricants) should be biologically compatible with the intended use of the load items.

Compatibility with the quality of water

8.8 Many detergents and disinfectants are seriously impaired in their activity by hard water. If only hard water is available formulations should be sought which are intended for use with water of that quality.

8.9 Detergent formulations intended for use only with soft water may give rise to precipitation if used with hard water, particularly at elevated temperatures. Once this precipitation has occurred on the surfaces of the WD or the load it is particularly difficult to remove (see paragraph 8.7).

Compatibility with other chemical additives

8.10 Many of the chemical additives which might be used are incompatible with one another – eg. quaternary ammonium compounds which are often used as surfactants will rapidly destroy the activity of enzymic cleaners, while many detergents will inactivate chemical disinfectants.

8.11 The additives used should be both compatible with other chemicals used in the same process stage and, as far as may be practicable, with those used in preceding and subsequent stages to minimise the adverse effect of any carryover.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Compatibility with subsequent decontamination processes

8.12 Chemical additives which may persist on the surface of items processed through the WD should be compatible with any subsequent decontamination process which may be required, such as terminal sterilization. An in-process instrument lubricant which deposits a lubricant film on all surfaces of the instrument should only be used if it has been demonstrated to be compatible with any subsequent sterilization process.

General

8.13 In almost all cases, attainment of the specified concentration of chemical additives is essential to effective processing. The addition of too little will impair the process while too much is wasteful, may also impair the process and may contribute to unacceptably high residual levels.

8.14 Suppliers of chemical additives should provide product data sheets and material safety data sheets for the products supplied. These should include details of biocompatibility studies.

8.15 Suppliers of chemical additives should provide details of the analytical methods which may be use to detect residual concentrations of product. The sensitivity of the method should be sufficient to determine the presence of the compound below the level at which any adverse biological reaction may be determined.

Detergents

8.16 For most applications, mild alkaline detergents in the pH range 8.0–11.0 are preferred. Alkalinity improves the efficacy of detergents both by enhancing their inherent cleaning capabilities – neutralising and helping to remove acid soils, emulsifying oils and fats and peptidising proteins – and by synergistic action with other detergent compounds. Many surfactants work better in the presence of alkaline “builders” such as sodium tripolyphosphate (STPP).

8.17 Alkaline detergents inhibit the growth of most micro-organisms. Alkaline detergent residues are readily detected by pH measurement.

8.18 Acid-based detergents should only be used for stainless steel surfaces and then only for limited applications, eg. for de-scaling instruments that have been processed in hard water.

8.19 Cleaning agents for use in WDs should be:

a. liquid – to facilitate accurate dispensing;

b. non-abrasive;

c. low foaming;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. free rinsing;

e. biodegradable.

8.20 Cleaning agents should not contain:

a. artificial colouring agents;

b. optical brighteners;

c. perfumes;

d. halides at an in-use concentration greater than 120mg/l;

e. fatty soaps, glycerine or lanolin.

Enzymic cleaners

8.21 Enzymes are organic catalysts through which the normal metabolism of most living organisms takes place. Although produced by living organisms they are not themselves alive. Enzymes are large organic molecules whose steric configuration (shape) affords them the ability to catalyse many reactions in the living cell.

8.22 Enzymes are classified into groups depending on the nature of the chemical reaction that they catalyse. Generally the enzymes used in enzymic cleaners are hydrolases ie. they promote the hydrolysis of the substrate with which they interact.

8.23 Enzymic cleaners are themselves proteins (often derived from the bacteria B subtilis and B stearothermophilus) and may be sensitising or allergenic agents. A similar adverse reaction is allegedly produced in some people by domestic biological washing powders.

8.24 Many of the developments in enzymic cleaners originated with the pre-soak cleaners and subsequently the biological washing powders used in domestic laundry applications.

8.25 A considerable proportion of the soiling found on medical items contains proteins which act as binding agents. Particulate dirt can be bound by the coagulation of these proteins on the surface.

8.26 If the binder proteins can be broken down into a simpler molecular form this binding action is destroyed and the bound soil, as well as the protein, can be released from the surface.

8.27 Formulations will often include buffering agents to maintain the pH within the preferred range. Most enzymes have an optimum pH at which their activity is greatest and a pH at which the enzyme itself is most resistant to thermal degradation, although these two values are not necessarily the same.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

8.28 For example the proteolytic hydrolase derived from B subtilis, subtilisin A, withstands temperatures up to 60°C and displays its greater stability at pH 9.4.

8.29 The importance of the enzymic solution being at the correct temperature and pH, as well as being used for the specified contact time, cannot be too strongly emphasised.

8.30 Enzymes are not themselves cleansing agents. A properly balanced detergent may still be needed to remove the simpler molecular forms resulting from the enzymic action.

8.31 It is important to ensure that any detergents used are compatible with the enzymes – quaternary ammonium compounds (QACs) deactivate many of these enzymes (the deactivation of enzymes in the bacterial cell is one of the proposed mechanisms of action for the microbicidal action of QACs).

8.32 Enzymic formulations for cleaning solid surfaces are available in two forms:

a. a pre-soak formulation which is used to digest proteinaceous soil and is then followed by normal washing process using detergent;

b. a combined enzyme and detergent formulation.

Cleaning additives for ultrasonic cleaners

8.33 Only detergents specifically intended for use in ultrasonic cleaners should be used. The use of other detergents may impair rather than enhance the cleaning process.

Rinse aids

8.34 Rinse aids are generally formulated from surfactants and are designed to make the water more free rinsing. They are often at low pH in order to remove deposited salts arising from the use of hard water.

Lubricants

8.35 The addition of oil-based compounds to the cleaning process is wrong in principle. They deliberately cause contamination over the entire cleaned surface. If they are to be used the water-soluble type should be used. Mineral oils have poor biocompatibility and may inhibit the penetration of steam or sterilant gases on terminally sterilized product.

8.36 Lubrication should only be applied to those areas where it is required during the inspection/packing process after thorough cleaning of the instrument.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Disinfectants and/or sterilants

Choice of disinfection method

8.37 Thermal disinfection using moist heat is the preferred method and should be used whenever it is compatible with the load to be processed.

8.38 Temperatures in excess of 65°C and up to 95°C (or in some cases 100°C) can be used for disinfection; the lower the temperature the longer the exposure time in order to obtain the same reduction in microbial population. The thermal disinfection process is reliable, reproducible, free from toxic residues and capable of easy and economical physical monitoring and recording.

8.39 Chemical disinfection should only be used for products which cannot be treated using thermal disinfection methods.

Criteria for selecting a chemical disinfectant

8.40 Chemical disinfectants differ in their ability to kill micro-organisms.

8.41 In order to choose a disinfectant for a particular application it is necessary to know the microbicidal activity required – both the number and types of organisms that may be encountered and the assurance that may be required that they have been inactivated. The technical information from the manufacturer of disinfectants should provide the required information about the activity of the product.

8.42 The major application for chemical disinfection is in processing for re-use thermo-abile equipment such as fibre-optic endoscopes. Two distinct standards are applicable: for those instruments that will only come in contact with intact mucosa; and for those that will invade a sterile body space. While the same or similar disinfectant formulations may be used for both applications the operational controls required may be different. This is addressed in Chapter 12. Further guidance is given also in SHTM 2030 Part 3, ‘Validation and verification’.

8.43 Although there are numerous disinfectant formulations available on the market, there are relatively few generic types of disinfectant suitable for chemical disinfection in WDs.

8.44 A solution containing 2% glutaraldehyde is the most commonly used disinfectant. Other aldehydes, quaternary ammonium compounds, hydrogen peroxide, peracetic acid, chlorine dioxide and alcohol solutions have also been recommended by various workers and may have particular benefits in certain applications.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.45 The guidelines from various professional bodies are not in agreement as to the disinfectant contact time to be used and few recognise the need to specify the temperature or minimum concentration. Furthermore, these guidelines may not be in accord with the recommendations from the manufacturer of the item to be sterilized or from the manufacturer of the disinfectant.

8.46 Current guidelines from the UK Departments of Health are given in Health Circular HC (91)33. These recommend:

a. a freshly activated solution containing 2% glutaraldehyde at room temperature for 30 minutes for dealing with contamination with HIV or HBV;

b. a 2% solution of glutaraldehyde for 60 minutes if mycobacterial contamination is suspected.

8.47 'Guidance for Clinical Health Care Workers: Protection against infection from HIV and hepatitis virus' produced by the Expert Advisory Group on AIDS also recommends "endoscopes which will enter sterile body cavities must be immersed for a minimum of three hours".

8.48 While these times may be reduced if the items are processed in a validated automatic WD with appropriate routine monitoring, the exposure time should in all cases be at least that specified by the disinfectant manufacturer. More detailed information is provided in SHTM 2030, 'Validation and verification'.

8.49 Instructions for use supplied with the disinfectant should include:

a. the quality of water with which the product should be diluted;

b. the **storage life** – the life before dilution or activation (or before use if supplied at the required concentration for use);

c. the **use-life** – the storage life after dilution and storage under stated conditions within which the unused disinfectant will retain activity at, or above, the minimum specified by the manufacturer;

d. the **re-use life** – the extent to which the disinfectant may be re-used. This may be specified as time, the number of load items processed or the number of disinfection cycles.

NOTE: This is event related not time related but when a manufacturer specifies a "use-life" this should be based on simulated "worst case" use conditions. Whenever possible, a single use is preferred since it avoids the many problems associated with control of re-use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Materials compatibility

8.50 The disinfectant should not cause damage to either load items or the WD in which it is used. Damage which may occur with incompatible disinfectants includes corrosion, embrittlement or swelling of plastics, degradation of lens cement in optical systems etc. The potential for electrolytic attack to occur as a result of different metals in the load and the WD coming into contact, via a powerful electrolyte, should not be overlooked.

8.51 The material of construction of the WD and of the items in the load should not inhibit the disinfectant.

Safety of disinfectants

8.52 Many of the compounds which are most effective as disinfectants are potentially human health hazards. Employers are required by law to do everything that is reasonably practicable to protect the health of their workers. The safe use of these compounds is covered by the COSHH Regulations.

8.53 Glutaraldehyde has an occupational exposure standard of 0.2 ppm over a 15 minute reference period. This should not be regarded as a permissible limit but as a maximum which should not be exceeded. Further guidance is given in SHTM 2030 Part 3, ‘Validation and verification’.

NHSScotland Property and Environment Forum

9. Washer-disinfectors for human-waste containers

Introduction

9.1 This chapter discusses specifications for WDs intended for emptying, cleaning and disinfecting human-waste containers.

9.2 WDs for human-waste containers are all Type 1 machines.

9.3 Human-waste containers include bed pans, urine bottles, commode bowls, enema and emesis containers, and suction bottles.

9.4 WDs currently available may be divided into two groups: flusher-disinfectors in which there is no detergent wash stage – all soil removal is accomplished by the physical action of water; and washer-disinfectors in which there is a wash stage after the initial flushing stage to remove gross soiling. While the former may be less expensive, the latter design may be used to process a wider range of items such as support frames for disposable bedpans, raised toilet seats, jugs and bowls etc.

Choice

9.5 WDs for human-waste containers are one of two available systems for providing for the needs of bed-dependent patients. The alternative system uses disposable containers, made of cellulose pulp, which are disposed of, complete with their contents, using a macerator. When properly installed, maintained and operated either system can provide a satisfactory solution for the provision of human-waste containers.

9.6 Factors to be considered in making the choice include:

a. the relative capital and running costs;

b. the storage space required for an appropriate working stock of disposables;

c. the peak throughput required;

d. the need to provide for the cleaning and disinfection of support frames used with disposable bedpans;

e. whether the flexibility to clean and decontaminate other sanitary items is required, and so on.

A review of these factors was published in 1991 (Rollnick) and should be consulted for further information.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load handling equipment

9.7 The load handling equipment may be specific for the containers to be processed or may be designed to accommodate a range of different containers without the need to change load carriers.

9.8 When a range of items is to be processed eg. raised toilet seats, jugs, bowls, disposable bedpan support frames, as well as bedpans and urine bottles, the load carrier should be designed to accept these without the need to change carriers or add accessories. This reduces the operator time, the storage space required and the risk of loading errors. When it is necessary to change carriers or add accessories this should be a simple operation not requiring the use of tools.

9.9 The loading capacities from currently available machines are either one bedpan/two urine bottles per cycle or two bedpans/four urine bottles per cycle. The higher capacity machine is the preferred option in most cases because of its increased capability to deal with peak demands. For certain applications (eg. GU wards) designs capable of carrying up to eight urine bottles per cycle are available.

Standard specifications

9.10 WDs for human-waste containers should conform to the specifications in BS 2745: Part 1: 1993 and BS 2745: Part 2: 1993 and the safety specifications in BS EN 61010: Part 1.

Additional specifications

9.11 The WD should be equipped to provide automatic emptying of human-waste containers. Manual emptying prior to, or during, the loading of containers into the WD should not be required.

9.12 When a cold water rinse is used after the disinfection cycle, the water used shall not have been stored in a tank or cistern within the WD at a temperature above 20°C or below 60°C for more than four hours.

9.13 Consideration should be given to specifying an in-built condenser system to obviate the need for an external ventilation connection.

9.14 When required for connection to a hard water supply, a dispensing system should be specified to add detergent-descaler to the water during the washing stage of the process.

9.15 The WD should flush the residual soil from the emptied containers with a discharge volume of no less than 15 litres to ensure adequate clearance of solids from the drainage system. The total volume of water used per cycle may be significantly greater than this value and the volume of water required per load item processed should be a consideration when choosing a WD.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operating cycle

9.16 The WD should perform the following operational stages in each cycle:

a. emptying – this should take place automatically and is usually effected and controlled by closing the door; Some WDs are provided with two chemical additive dispensing systems as standard giving the option to add a detergent wash stage for processing specific items;

b. flushing – removing residual soil from the containers with water at no more than 35°C;

c. washing – removing any remaining soil by washing with water, water and detergent, or water and detergent/descaler;

d. rinsing – removing any residual detergent or detergent/descaler;

e. thermal disinfection – raising the temperature of the load to the preset temperature (using hot water or steam) and maintaining the temperature for the required disinfection holding time.

The following stages may be included if required by the user:

a. cooling – rinsing the hot load with cold water to reduce the temperature of the load;

b. drying – purging the load and chamber with heated air to remove residual moisture.

Disinfection requirements

9.17 Thermal disinfection using moist heat is the preferred method; none of the equipment intended to be processed in this type of WD is unable to withstand thermal disinfection within the specified temperature range and there is no justification for the use of chemical disinfection.

9.18 The WD should be programmable to provide a thermal disinfection process within the temperature range 65-90°C for disinfection times between 10 minutes and one second respectively. The preferred disinfection process is 80°C for one minute.

9.19 A post-disinfection cold water rinse is available on some WDs. This is intended to cool the load so that it can be handled, and/or used, immediately at the end of the cycle. However, the advantage in shortening the time before the item can be re-used is minimal and, since the final product is wet, it has to be dried manually – eg. using paper towels.

9.20 When thermal disinfection is the final stage of the cycle, the hot load at the end of the cycle dries rapidly as the water evaporates from the surface – cooling the load at the same time.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Drying stage

9.21 Although a hot air drying stage is available on many current models, drying by evaporation after the hot disinfection/rinse stage is sufficient in most cases.

9.22 A hot air drying stage should be specified if the WD is to be used to process a range of other items.

Instrumentation/recorders

9.23 The WD should be fitted with a chamber temperature indicating instrument to show the temperature attained during the disinfection stage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10. Washer-disinfectors for surgical instruments and associated equipment

Introduction

10.1 This chapter discusses specifications for WDs intended to be used for cleaning and disinfecting surgical instruments and associated equipment including instrument trays (eg.: Edinburgh trays), bowls and hollowware.

10.2 The guidance given here assumes that the WD is to be used to decontaminate medical devices and that the essential requirements of the EU Directives discussed in Chapter 1 must be met.

10.3 WDs for this purpose may be Type 1 or Type 2 machines.

Type 1 machines

10.4 Single chamber cabinet washers for surgical instruments and associated equipment may be either:

a. simple “deluge” washers primarily intended for bowls and hollowware but also suitable for dealing with simple easy to clean instruments;

b. designed to accept inter-changeable load carriers, typically with rotating spray arms or other devices to ensure a uniform wash action with several layers of load items.

The spacing between layers should be designed to accommodate a number of wire mesh baskets full of instruments or should be more widely spaced to accept and correctly position large bowls, instrument trays, re-usable rigid containers and similar items. Spacing should also allow for anaesthetic accessories to be located and processed, as well as specialist carriers with connections for particular instruments such as rigid endoscopes and MAT instruments.

10.5 Since all stages of the cycle take place in the same chamber, it is not possible to get physical separation between the dirty and clean stages of the cycle. Assurance that the load will not be recontaminated is dependent upon the efficacy of the cleaning and disinfecting stages in decontaminating the interior of the WD as well as the load.

Type 2 machines

10.6 Continuous process washers, other than those designed as automatic ultrasonic cleaners only, are usually designed to accept inter-changeable load carriers (see above).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.7 Compared with Type 1 machines they have a higher throughput and, for a similar process, achieve some decrease in overall cycle time.

10.8 Since the load is moved through the machine as the cleaning and disinfection cycles proceed it is possible to get excellent physical separation between dirty and clean load items.

10.9 There may be some loss of operational flexibility when this type of machine is used for several applications at a time, eg. if it is used to process anaesthetic accessories the increased drying time, necessary for this application, will slow the passage of other loads passing through the WD.

10.10 WDs of this type are large, expensive pieces of equipment and their use is only justified in centralised production units.

Standard specifications

10.11 WDs for surgical instruments and associated equipment should conform to the specifications in BS 2745: Part 1: 1993 and BS 2745: Part 3: 1993 and the safety specifications in BS EN 61010: Part 1.

10.12 An EU standard is in preparation for WDs for surgical instruments and associated equipment and for specific safety requirements for WDs.

Additional specifications

10.13 The automatic controller of Type 2 machines should prevent initiation of any further operating cycles if there is an inadequate supply of the chemical additives required for the next cycle.

10.14 Whenever practicable the WD should be of the double-ended pass through type to facilitate physical segregation of dirty and decontaminated items.

10.15 The design should permit installation through the wall between the decontamination area and the clean area with effective sealing to prevent either passage of air from dirty to clean areas or excessive air loss from the clean area (normally maintained at a pressure above atmospheric).

Load handling equipment

10.16 A number of different types of carrier may be required to accommodate the range of items to be processed. The range of carriers required in an SSD may include:

a. a multi-layer carrier for instruments in wire mesh baskets (wire mesh baskets to include a number with retaining systems for small instruments);

b. a two layer carrier for small hollowware and instrument trays;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

c. a single layer carrier for large bowls, Edinburgh trays etc;

d. a rigid endoscope/MAT instrument carrier;

e. an anaesthetic accessories carrier.

10.17 The load carriers must protect instruments from mechanical damage during the wash process and must also orientate the instruments to facilitate proper cleaning providing, when necessary, a direct connection between the water flow and the lumen of the load item.

10.18 The specification for load handling equipment should include the provision of appropriate tabling to permit sorting of instruments and loading of load carriers and, after processing, the unloading of load carriers.

10.19 When double-ended WDs are specified a conveyor will normally be required to return load carriers from the unloading to the loading end. Where this passes through the wall between the packing room and decontamination room there should be a pass through hatch with interlocked doors.

Operating cycle

10.20 The WD should perform the following operational stages in each cycle:

a. flushing – removing gross contamination from the items in the load with water at a temperature not exceeding 35°C;

b. washing – removing any remaining soil by washing with water, water and detergent, or water and enzymic cleaner. Several sub-stages may be used consecutively to provide a combination of treatments; physical removal of the soil may be by the impingement of water jets or by ultrasonication or both consecutively;

c. rinsing – removing any residual detergent or enzymic cleaner. This stage may be combined with the thermal disinfection stage which follows;

d. thermal disinfection – raising the temperature of the load to the preset temperature (using hot water or steam) and maintaining the temperature for the required disinfection holding time;

e. drying – purging the load and chamber with heated air to remove residual moisture.

Disinfection requirements

10.21 The load, the load carriers and the internal surfaces of the WD chamber should be subjected to a thermal disinfection cycle. This should ensure that all surfaces to be disinfected are exposed to moist heat for a period and at a temperature not less than specified in Table 2.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Drying stage

10.22 The drying of the load is greatly facilitated by the thermal disinfection/hot rinse stage. In Type 1 machines with a low throughput drying by flash evaporation from the hot load may be sufficient. Individual items for which drying is more critical may be transferred to a separate drying cabinet.

10.23 For more critical applications and in Type 2 machines it is normal practice to include a hot air drying stage.

10.24 Thorough drying is of great importance. Products which are to be sterilized must be thoroughly dry as should products which are to be used without further treatment if there is not to be a significant risk of recontamination by, and growth of, micro-organisms.

The drying stage may be omitted on Type 1 machines particularly for small “table-top” machines. Additional chemical treatments may also be included if required by the user.

The addition of “rinse-aids” may be required to assist drying and to minimise “spotting” (deposits of waterborne salts) if purified water is not used for the final rinse.

The addition of instrument lubricants during the final rinse should be avoided whenever possible.

Instrumentation/recorders

10.25 The extent of necessary monitoring depends on the particular application. As a minimum for the thermal disinfection stage the attainment of the required temperature should be monitored independently of the cycle controller, displayed on a temperature indicator or recorder, and recorded.

10.26 When the WD is to be used to decontaminate medical devices – and the technical Standards described in the essential requirements of the EU Directives discussed in Chapter 1 must be met – additional monitoring facilities will be required.

10.27 The WD should be equipped with monitoring and recording devices to monitor the critical variables which affect the outcome of the cleaning and disinfection processes. This may include some, or all, of the following:

a. pump pressure, water flow and temperature at each process stage;
b. the flow or volume admitted of each chemical additive used (or, when applicable, by direct measurement of the concentration);
c. the chemical purity of the final rinse (by measurement of electrical conductivity);
d. the flow and temperature of the hot air used for drying.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: Visual inspection following the decontamination process is not of itself sufficient to determine whether the process was successful. The decontamination process must be subject to validation and then routinely monitored to ensure that the process remains within the validated limits. Further guidance is given in SHTM 2030 Part 2, 'Operational management' and Part 3, 'Validation and verification'.

Test connections

10.28 Test connections should be provided to permit the connection of thermocouples to be used during validation and periodic testing.

10.29 When additional monitoring is provided (see above), a separate test connection should be provided for each sensor to permit periodic verification of the installed system by comparison with a calibrated test sensor.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11. Washer-disinfectors for anaesthetic accessories

Introduction

11.1 This chapter discusses specifications for WDs intended for use in cleaning and disinfecting anaesthetic accessories. These items are often intended for use without further reprocessing.

11.2 The guidance given here assumes that the WD is to be used to decontaminate medical devices and that the essential requirements of the EU Directives discussed in Chapter 1 must be met.

11.3 Dedicated equipment for anaesthetic equipment would usually only be justified when there is a particularly heavy demand; most anaesthetic departments now use single use and/or filter protected patient circuitry.

11.4 Although dedicated WDs for anaesthetic equipment are commercially available their use is declining due to the changing pattern of equipment and accessories used in anaesthetic departments.

11.5 There is still a requirement for this type of equipment to be decontaminated because of its use in respiratory monitoring where the use of filters may not be practicable.

11.6 Dedicated anaesthetic WDs are usually Type 1 machines but when this facility is provided as an option with WDs for surgical instruments they may be Type 1 or Type 2 machines (see Chapter 10).

Load handling equipment

11.7 WDs for surgical instruments which can accept inter-changeable loading racks may be adapted to deal with anaesthetic accessories using a loading rack designed to hold anaesthetic breathing circuits, rebreathing bags and self-inflating resuscitator sets, face masks etc.

11.8 The design of load carrier should ensure that each hollow or tubular item can be connected to a spigot through which flushing, washing solutions and the water for rinsing and thermal disinfection can be directed into the lumen of the load item.

11.9 Whenever practicable the WD should be of the double-ended pass through type to facilitate physical segregation of dirty and decontaminated items.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.10 The design should permit installation through the wall between the decontamination area and the clean area with effective sealing to prevent either passage of air from dirty to clean areas or excessive air loss from the clean area (normally maintained at a pressure above atmospheric).

Standard specifications

11.11 WDs for anaesthetic accessories should conform to the specifications in BS 2745: Part 1: 1993 and BS 2745: Part 3: 1993 and the safety specifications in BS EN 61010: Part 1.

11.12 An EU standard is in preparation for WDs for surgical instruments and associated equipment and for specific safety requirements for WDs.

Operating cycle

11.13 The WD should perform the following operational stages in each cycle:

a. flushing – removing gross contamination from the items in the load with water at less than 35°C;

b. washing – removing any remaining soil using water and detergent or water and enzymic cleaner. Several sub-stages may be used consecutively to provide a combination of treatments; physical removal of the soil should be by flushing through lumens and by the impingement of water jets on external surfaces of load items. Ultrasonication is not effective for items made from flexible rubber or plastic;

c. rinsing – removing any residual detergent. This stage may be combined with the thermal disinfection stage which follows;

d. thermal disinfection – raising the temperature of the load to the preset temperature (using hot water or steam) and maintaining the temperature for the required disinfection holding time;

e. drying – purging the load and chamber with heated air to remove residual moisture.

The drying stage may be omitted if a separate drying cabinet is to be provided. No additional chemical treatments should be necessary.

Disinfection requirements

11.14 Many anaesthetic accessories will be used without further decontamination treatment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.15 The load, the load carriers and the internal surfaces of the WD chamber should be subjected to a thermal disinfection cycle. This should ensure that all surfaces to be disinfected are exposed to moist heat for a period and at a temperature not less than one of those specified in Table 2.

11.16 The use of chemical disinfection is particularly contra-indicated because of the possibility of residuals being absorbed into the polymeric materials, of which the anaesthetic accessories are made, and then being evolved as irritant or toxic gases during use.

Drying stage

11.17 Thorough drying of anaesthetic tubing and other accessories is essential whether or not they are to be subjected to a further decontamination process, eg. sterilization.

11.18 Because of the thermal characteristics of the materials and the structural complexity of the items, drying with a current of warm air is a relatively slow process and may take more than twice as long as an equivalent sized load carrier filled with steel instruments. It is, for example, very difficult to remove the residual water from inside long lengths of corrugated tubing.

11.19 When anaesthetic accessories are processed through a WD for surgical instruments the extended hot air drying stage required will significantly reduce the throughput; if significant quantities of anaesthetic accessories are to be decontaminated consideration may need to be given to the provision of a separate drying cabinet.

11.20 Whether within the machine, or within drying cabinet, the flow of warm dry air should be directed through and over the items to be dried.

Instrumentation/recorders

11.21 The extent of necessary monitoring depends on the particular application. As a minimum for the thermal disinfection stage the attainment of the required temperature should be monitored independently of the cycle controller, displayed on a temperature indicator or recorder, and recorded.

NHSScotland Property and Environment Forum

12. Washer-disinfectors for endoscopes

Introduction

12.1 This chapter discusses specifications for WDs intended for cleaning and disinfection of flexible endoscopes (fibre-optic or video) and rigid endoscopes and their accessories.

12.2 The guidance given here assumes that the WD is to be used to decontaminate medical devices and that the essential requirements of the EU Directives discussed in Chapter 1 must be met.

12.3 WDs for flexible fibre-optic endoscopes are all Type 1 machines; the form of the chamber is often complex and sculpted to provide appropriate support to the endoscope(s) being processed. WDs for rigid endoscopes may be Type 1 or Type 2 machines.

12.4 Disinfection may be achieved:

a. for most rigid endoscopes and other items which are not heat sensitive, by direct contact of the load items with moist heat at a temperature in excess of 65°C and below 95°C. The preferred temperature is 80°C for no less than one minute;

b. for fibre-optic and other heat sensitive equipment, by direct contact of the load items with a chemical disinfectant.

NOTE: Users should seek advice from the manufacturer of the endoscope as to the most suitable method of disinfection and the limiting values of process variables (eg. temperature) for particular endoscopes.

12.5 Automated WDs for endoscopes are preferred to manual cleaning, whether followed by a manual or automated disinfection procedure. This is both for the safety of the user and also because it provides a more consistent, validated process with a higher level of assurance of attaining the required standards than can be achieved with manual cleaning.

Standard specifications

12.6 WDs for rigid endoscopes which can withstand thermal disinfection and steam sterilization are similar to WDs for surgical instruments and associated equipment and should conform to the specifications in BS 2745: Part 1: 1993 and BS 2745: Part 3: 1993 and the safety specifications in BS EN 61010: Part 1.

12.7 An EU standard is in preparation for WDs for surgical instruments and associated equipment and for specific safety requirements for WDs.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.8 There are currently no British Standards for WDs intended for use with thermo-labile endoscopes. An EU standard for WDs for thermo-labile equipment including fibre-optic endoscopes and videoscopes is in preparation.

Additional specifications

12.9 WDs for endoscopes which employ a thermal disinfection stage should meet all the requirements specified for WDs for surgical instruments (see Chapter 10).

WDs with a chemical disinfection stage

12.10 The WD should be an enclosed system. It should be a requirement for the lid to be locked before it is possible to start a cycle, and it should not be possible for the operator to interrupt a cycle before completion.

12.11 The control system should permit regulation of pump pressure and inlet pressure to the various connections to allow the WD to be adjusted for particular types of instrument. It is desirable that this should be a programmable option on the automatic controller.

12.12 The WD should discharge solutions of cleaning agents to drain after each operating cycle unless the WD is equipped with means to verify the concentration of the chemical additive which remains active in the solution. (For some cleaning agents this may be achieved by continuous monitoring of in-use concentration using an appropriate ion selective electrode (ISE).)

12.13 The disinfectant solution should be used once and discarded. Alternatively, when systems which re-use disinfectant solutions for a number of cycles are employed, means should be incorporated to ensure that the automatic cycle will not start when the disinfectant concentration has fallen to, or below, the minimum recommended by the manufacturer or established by independent testing – eg. for a 2% solution of glutaraldehyde a limiting concentration of 1.5% would be recommended (Babb et al 1992).

NOTE: Re-use of the same disinfectant solutions for several operating cycles is often justified on grounds of economy. This may be a false economy if second and subsequent processes with the same batch of disinfectant solution are not subject to the same control as the initial use.

12.14 The rinsing stage should be carried out with water of a quality that does not lead to recontamination of the endoscope with micro-organisms coming from the incoming water supply reservoirs, including pipework within the machine.

12.15 The rinse water from one process should not be retained and used in subsequent cycles but should be discharged to drain.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.16 There should be no static water stored within the WD at a temperature above 10°C or below 55°C for more than four hours if it is intended to come into contact with the load. This should be controlled and monitored by the automatic controller of the WD.

12.17 WDs should be designed and constructed such that they are able to be drained and dried when not in use.

12.18 The available operating cycles on the automatic control system should provide for a WD decontamination cycle to ensure that all pipework, tanks, pumps, water filtration systems and other fittings which are used to carry aqueous solutions intended to come into direct contact with the product are cleaned and disinfected. The decontamination cycle shall be user selectable.

12.19 The automatic controller should control the temperature of the disinfectant solution or monitor the temperature to ensure that it is above a value previously determined during validation studies (see SHTM 2030, 'Validation and verification' for more information).

12.20 The WD should be equipped with a recorder or data logger to record the attainment of the specified value of critical cycle variables throughout the cycle.

12.21 The WD should be equipped with means to contain or vent fumes and gases from the disinfectant solution to ensure that operators are not exposed to hazardous concentrations of the chemicals used. The WD should be provided with means to vent fumes from the chamber before allowing access to the operator.

Load handling equipment

12.22 The loading system should be appropriate to the range of endoscopes which it is intended to process.

12.23 Some endoscopes are not designed to be completely immersed in liquid and the operating head must remain above the liquid level.

NOTE: Endoscopes of this type are being phased out of service.

Some endoscopes require protective caps to be fitted to sensitive components before they can be decontaminated in an automated WD, eg. videoscopes need a protective cap on the video plug.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.24 The load carrier needs to provide connection to the various channels within the endoscope to allow the cleaning and disinfection solutions to flow through the channels and may need to provide holders for disassembled components, valves etc.

Compatibility with items to be processed

12.25 Attention is drawn to the need to ensure that for any particular load item that all cleaning and decontamination processes are carried out in strict accordance with the manufacturer's instructions. All endoscopes, but particularly those incorporating fibre-optic systems, are easily damaged.

12.26 If the process conditions recommended by the manufacturer, including maximum temperatures, internal pressures, nature of any physical treatment such as ultrasonication, and limitations on the chemical additives which may be used, are ignored serious damage can be caused to these expensive instruments.

Disinfection requirements

12.27 The standard of disinfection required should be defined by the user in consultation with the control of infection officer.

12.28 In general:

a. endoscopes which, in use, are passed into sterile body cavities are considered to be invasive and must be sterilized;

b. endoscopes which, in use, come into contact with mucous membranes but do not invade sterile body cavities are non-invasive and can be decontaminated using high-level disinfection.

12.29 The choice of disinfectant should be based on the rigours of the disinfection procedure required, and on the compatibility with the endoscope and WD and the constructional materials of both.

NOTE: There is a potential for electrolytic action between different materials even when one material is part of the load and the other is part of the WD. This may result in corrosion of the load items and/or the WD.

Guidance on suitable disinfectants and exposure times is given in SHTM 2030 Part 3, 'Validation and verification' and in the MDA Bulletin on 'Decontamination of endoscopes and their accessories'.

Rinse water: quality requirements

12.30 For invasive endoscopes the final rinse water should be sterile and for non-invasive endoscopes it is preferable that it is sterile.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.31 The most reliable method of providing water of the quality required for the final rinse is to use sterile “bottled” water.

12.32 Alternatively it is possible to produce water of appropriate quality by treatment of the local piped water supply. This may be provided adjacent to, or within, the WD.

12.33 The nature and extent of treatment will depend in part on the quality of the local water supply but normally should include at least the following steps:

a. pre-filtration to remove suspended particulate matter (this may require one or two filtration stages but the final stage should be with a filter that will retain particles of 5 µm or larger);

b. filtration through a bacteria retentive filter (0.22 µm).

The operating system should include:

a. means to monitor the integrity of the filter or warn of failure;

b. means to disinfect or sterilize the filter and the downstream water distribution system between uses or at four hourly intervals. This should preferably be by exposure to moist heat but a chemical disinfection process may also be used. A demountable system which allows the filter and downstream distribution system to be removed, dried and steam sterilized between sessions provides an acceptable alternative;

c. means to maintain the filter with a constant flow of water (not left wet in static water);

d. means to inhibit microbial growth in water in the storage and distribution system downstream

e. of the filter. This may be achieved by recirculation through an appropriate UV light disinfection system or by maintaining the water at elevated temperature eg. >80°C.

12.34 The design of the pipework, tanks, valves and pumps to avoid dead legs and areas where microbial growth may proliferate is critical to the maintenance of the system from microbial contamination. All fittings and pipe connections should be pharmaceutical grade sanitary fittings.

NOTE: If heated storage is used it will be necessary to cool the water supplied to the WD to ensure that the endoscope(s) are not damaged by exposure to too high a temperature.

Operating cycle requirements

12.35 The following operating cycle presents a general specification which may need to be adapted for particular instruments. It assumes that immediately after use, and before transfer to decontamination, the insertion tube will have

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

been wiped clean and that all channels will have been flushed through to remove gross contamination and ensure that they are free from blockages.

12.36 It is also assumed that any manual dismantling required (including removal of single use items, separation of accessories, removal of valves and covers, and disassembly) has taken place before the instruments are placed into the WD.

12.37 The operating cycle should include:

a. a **leak test** to verify that the endoscope is undamaged and will not suffer irreparable damage during exposure to the cleaning and disinfection process. (This should be a user selectable option);

b. **flushing** with water at a temperature not exceeding 35°C (this maximum temperature is necessary to minimise the coagulation of protein and consequent fixing of the soiling);

c. a **flow test** to ensure that all channels which should be irrigated with cleaning solution and disinfectant solutions are not blocked;

NOTE: Although this should have been verified before the instrument was placed in the WD, blockage can occur during processing when soiling dislodged from one place becomes trapped in a more restricted part of the instrument.

d. **washing** with an aqueous solution of detergent or an enzymic cleaner; when detergent solutions are used this may be at elevated temperature but should not exceed 60°C (see paragraphs 12.25 and 12.26).

The efficacy of chemical cleaning agents (detergents and enzymic cleaners) is affected by concentration, temperature, contact time and the presence or absence of materials/chemicals which will react with, and therefore inactivate, the chemical cleaning agent. The WD should provide means to control all these factors to the extent necessary to obtain satisfactory and reproducible cleaning.

For most rigid endoscopes ultrasonication may be used except for the telescope; ultrasonication generally is not suitable for use with optical or fibre-optic systems.

The pressure at which fluids are pumped through the internal channels of the endoscope should be controlled and maintained within the limits specified by the endoscope manufacturer;

e. **rinsing** to remove chemical additives used during the cleaning process;

NOTE: The rinse stage between cleaning and disinfection may be omitted if the disinfectant and cleaning agents are known to be compatible and the disinfectant preparation is used only for a single cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

f. **drying** to remove excess water before transferring to the disinfection stage where residual water can cause serious dilution of the disinfectant. This stage may be optional unless the load has to be manually transferred to an automatic disinfector;

g. **disinfection**. For rigid endoscopes thermal disinfection may be practicable (see endoscope manufacturer's instructions) and if so should be used. For fibre-optic endoscopes there is usually an upper temperature limit of 60°C for processing conditions; thermal disinfection is impracticable and chemical disinfection should be used.

   The efficacy of chemical disinfectants is affected by concentration, temperature, contact time and the presence or absence of materials/chemicals which will react with, and therefore inactivate, the disinfectant. The WD should provide means to control all these factors to the extent necessary to obtain satisfactory and reproducible disinfection;

h. **rinsing** to remove disinfectant. After an effective cleaning and disinfection process the microbial quality of the final rinse water will determine the microbial contamination which may be present on the endoscope;

i. **drying**.

Drying stage

12.38 Drying may be achieved by purging with heated dry air; means should be provided to ensure that the temperature of the endoscope is not raised above the maximum specified by the endoscope manufacturer. The quality of air used should not contribute to physical, chemical or microbial recontamination of the decontaminated item.

12.39 Drying may also be accomplished by purging the decontaminated item with 70% alcohol and allowing this to evaporate. The quality of the alcohol used should not contribute to physical, chemical or microbial recontamination of the decontaminated item. In particular spore-free alcohol should be used.

NOTE: Most endoscope manufacturers advise that the lens system should not be exposed to alcohol for prolonged periods, although normally two to five minutes exposure will cause no damage.

Decontamination of the washer-disinfector

12.40 Automatic WDs for endoscopes may themselves act as a source of contamination for the decontaminated items.

12.41 The design, installation and operation of the WD, including the quality of connected services, may contribute to the problem.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12.42 The WD should include a flushing stage for the WD pipework after each cleaning cycle to remove dislodged debris, biofilm etc. so that these cannot initiate a contamination problem.

12.43 All tanks used for the storage of water or aqueous solutions should be designed and constructed to ensure that they are free draining and cleanable.

NOTE: The use of hard water, water of inadequate microbiological quality or water stored in tanks at ambient temperatures for prolonged periods will promote contamination and the formation of biofilms within the machine.

12.44 The use of soft water can help alleviate this problem but it should be noted that base exchange softeners, and also de-ionisers, may themselves be a source of microbial contamination and can lead to high microbial counts of water borne organisms. These organisms are typically of species adapted to develop biofilms and the extracellular layers present in these biofilms provide good protection against microbicides.

12.45 Microbial colonisation of pipework may occur if the system is not disinfected regularly or if there is inappropriate cleaning and maintenance of the machine.

12.46 The WD manufacturer should provide information on cleaning and disinfection procedures and compatible chemicals for these purposes.

Requirements for control of the disinfection stage

12.47 The chemical disinfection system must:

a. ensure that the disinfectant solution temperature is either controlled at a pre-set temperature or is above a specified minimum temperature on which the exposure time was based;

b. ensure that all parts of load items to be disinfected are in contact with the disinfectant. This should include means to ensure the elimination of air bubbles etc;

c. avoid the risk of recontamination with micro-organisms from the WD, other load items or the connected services.

NOTE: Some disinfectant formulations have an upper temperature limit beyond which the disinfectant or its adjuvants in the formulation are decomposed or inactive.

Recontamination could lead to transfer of infection or inaccurate diagnosis if the contaminant is erroneously assumed to have come from the patient.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Instrumentation/recorders

12.48 The extent of necessary monitoring depends on the particular application. As a minimum for the thermal disinfection stage the attainment of the required temperature should be monitored independently of the cycle controller, displayed on a temperature indicator or recorder, and recorded.

12.49 When the WD is to be used to decontaminate medical devices and the technical Standards described in the essential requirements of the EU Directives discussed in Chapter 1 must be met additional monitoring facilities will be required.

12.50 The WD should be equipped with monitoring and recording devices to monitor the pump pressure (or water flow) and temperature at each process stage, the flow or volume admitted of each chemical additive used (or, when applicable, by direct measurement of the concentration), the chemical purity of the final rinse (by measurement of electrical conductivity), and the flow and temperature of the hot air used for drying.

Test connections

12.51 Test connections should be provided to permit the connection of thermocouples to be used during validation and periodic testing.

12.52 When additional monitoring is provided (see above) a separate test connection should be provided for each sensor to permit periodic verification of calibration of the installed system by comparison with a calibrated test sensor.

NOTE: Visual inspection following the decontamination process is not of itself sufficient to determine whether the process was successful. The decontamination process must be subject to validation and then routinely monitored to ensure that the process remains within the validated limits. Further guidance is given in SHTM 2030 Part 2, ‘Operational management’ and Part 3, ‘Validation and verification’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13. Laboratory washer-disinfectors

Introduction

13.1 This chapter discusses specifications for laboratory WDs.

13.2 Laboratory WDs may be used to process components or equipment for use in the manufacture of medical devices or medicinal products or they may be used to process apparatus and equipment for use in clinical, or other, laboratories.

13.3 When used to process components or equipment for use in the manufacture of medical devices or medicinal products the design, construction, validation, operation and maintenance of these WDs will need to meet the requirements of the relevant EU Directives for medical devices or medicinal products (see Chapter 1).

13.4 WDs for both these applications may be machines of Type 1 or Type 2.

13.5 Commercially available machines offer a similar range of options to those WDs intended for the decontamination of surgical instruments and associated equipment (see Chapter 10).

Load handling equipment

13.6 The load handling equipment must be specific for the load items to be processed to ensure both that the load items are retained in the load carrier and that the external and any internal surfaces of the load items are reached effectively by the cleaning and disinfecting liquids throughout the cycle.

Standard specifications

13.7 There are no standard performance specifications specifically for laboratory WDs. For most applications the WD should conform to the relevant parts of the specifications in BS 2745: Part 1: 1993 and BS 2745: Part 3: 1993 which includes, for example, specific requirements for WDs used for the decontamination of glassware.

13.8 Laboratory WDs should conform to the safety specifications given in BS EN 61010: Part 1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operating cycle

13.9 The WD should perform the following stages in each cycle:

a. flushing – removing gross contamination from the items in the load with water at a temperature not exceeding 35°C;

b. washing – removing any remaining soil by washing with water, water and detergent, or water and enzymic cleaner. Several sub-stages may be used consecutively to provide a combination of treatments; physical removal of the soil may be by the impingement of water jets or by ultrasonication or both consecutively;

c. rinsing – removing any residual detergent or enzymic cleaner. This stage may be combined with the thermal disinfection stage which follows and normally requires the use of purified (DI, RO or distilled) water;

d. thermal disinfection – raising the temperature of the load to the preset temperature (using hot water or steam) and maintaining the temperature for the required disinfection holding time;

e. drying – purging the load and chamber with heated air to remove residual moisture.

For many applications in laboratories the drying stage may be omitted.

NOTE: Laboratory WDs incorporating a solvent wash stage are also available but are beyond the scope of this SHTM.

Choice of detergent/cleaning agent

13.10 The cleaning agent(s) to be used should be chosen to be appropriate to the materials of the load items, the soiling to be removed, the intended end use of the load items and compatible with the WD. In many cases there are highly specific requirements and a specific formulation is required.

13.11 The use of detergent and other chemical additives may not be appropriate in all cases. For example in the preparation of single-use glass containers for pharmaceutical applications the process is required to remove dust and similar debris which have contaminated the containers during distribution and storage, rather than strongly adherent soiling, and vigorous washing with water alone may be sufficient. Furthermore, if detergents and/or other chemical additives are to be used the process must be designed and operated to ensure that the concentration of residual detergent is reduced to a level where it will not have an adverse effect on the product.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Disinfection requirements

13.12 Disinfection is achieved by direct contact of the load items with moist heat at a temperature in excess of 65°C and below 95°C (see Table 2). The preferred temperature is 80°C for not less than one minute.

Drying stage

13.13 Drying is greatly facilitated by the final hot rinse. In general laboratory applications drying by flash evaporation from the hot load may be sufficient with individual items for which drying is more critical being transferred to a separate drying cabinet. For more critical applications, eg. containers for parenteral products where residual moisture may permit recontamination and unacceptable microbial growth, drying is important. Drying is also important for those products which are to be sterilized subsequently since this will require that the item is thoroughly dry.

Instrumentation/recorders

13.14 The extent of necessary monitoring depends on the particular application. As a minimum when thermal disinfection is required the attainment of the required temperature should be monitored independently of the cycle controller and displayed on a temperature indicator or recorder.

13.15 For critical applications, eg. the preparation of pharmaceutical containers for parenteral products, all key variables of the process should be independently monitored. The WD should be equipped with monitoring and recording devices to monitor the pump pressure, water flow and temperature at each process stage, the flow or volume admitted of each chemical additive used (or, when applicable, by direct measurement of the concentration), the chemical purity of the final rinse (by measurement of electrical conductivity), and the flow and temperature of the hot air used for drying.

NOTE: Visual inspection following the decontamination process is not of itself sufficient to determine whether the process was successful. The decontamination process must be subject to validation and then routinely monitored to ensure that the process remains within the validated limits. Further guidance is given in SHTM 2030 Part 2, ‘Operational management’ and Part 3, ‘Validation and verification’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Test connections

13.16 Test connections should be provided to permit the connection of thermocouples to be used during validation and periodic testing.

13.17 When additional monitoring is provided (see above) a separate test connection should be provided for each sensor to permit periodic verification of calibration of the installed system by comparison with a calibrated test sensor.

14. Ultrasonic cleaners

Introduction

14.1 This chapter discusses specifications for ultrasonic cleaners.

14.2 The guidance given here assumes that the WD is to be used to decontaminate medical devices and that the essential requirements of the EU Directives discussed in Chapter 1 must be met.

14.3 Ultrasonic cleaners may be Type 1 or Type 2 machines.

14.4 Ultrasonic cleaners work by exposing the items to be cleaned to high frequency sound waves in the liquid cleaning medium.

14.5 The high frequency sound waves are generated within the liquid by the vibration of one or more surfaces of the bath; the surface(s) of the bath being caused to vibrate by one or more transducers bonded to the outer surface(s). The transducers convert electrical energy into vibrations of the required frequency and amplitude.

14.6 The highly effective cleaning action occurs as a result of the penetrative agitation caused by cavitation; the rapid formation and collapse of tiny bubbles within the liquid which are generated by the high frequency sound waves.

Applications

14.7 Ultrasonic cleaners are used in a wide range of industries including engineering, jewellery etc.

14.8 Ultrasonic treatment is particularly suitable for cleaning instruments of high grade steel. Delicate instruments such as micro-surgery instruments and dental instruments can be effectively cleaned with little risk of damage.

14.9 Ultrasonic treatment is also particularly effective for cleaning instruments that have deep interstices that may be contaminated with body tissues, eg. reamers, drills and burrs.

14.10 When combined with appropriate connection to an irrigation or flushing system ultrasonicators are also effective for cleaning cannulated instruments.

14.11 Ultrasonic cleaners are less effective when used to clean plastic and similar readily compressible materials since they absorb much of the ultrasonic energy.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Standard specifications

14.12 Ultrasonic cleaners, whether designed as stand alone units or incorporated into continuous process machines, should comply with the requirements of BS 2745: Part 3: 1993 and the safety specifications in BS EN 61010: Part 1.

Additional specifications

14.13 The ultrasonic cleaner should be fitted with means to drain the tank with the cleaner in situ. The tank should be free draining so that no pools of water are left in the tank after draining.

14.14 The tank should be heated electrically and the heaters should be thermostatically controlled.

14.15 The ultrasonic cleaner should be fitted with a timer to control the duration of exposure.

14.16 The ultrasonic cleaner should have a lid; the lid should be interlocked with the operating system to prevent normal operation if the lid is open and should fit securely to prevent the emission of aerosols when the cleaner is in operation.

NOTE: The lid interlock should ensure that no part of the operator's body can be immersed in the ultrasonic cleaner during operation; long term direct exposure to ultrasound is suspected of causing arthritic conditions.

14.17 The ultrasonic cleaner should be effectively insulated to prevent high frequency sound transmission at a power which could cause a health hazard. (Note: High frequency sound is suspected of causing damage to hearing). The casing and lid should provide adequate sound proofing so that harmonic frequencies within the audible range are not obtrusive.

14.18 The manufacturer should specify the chemical additives (detergents and/or enzymic cleaners) which are required and which are compatible with the process.

NOTE: Low foaming detergents are required; liquid detergents used for washing dishes ("washing-up liquid") are generally not suitable. Although an ultrasonicator will work without detergent/cleaner the cleaning action is much less effective.

14.19 The manufacturer should specify the means by which the cleaner may be disinfected. This may be by the provision of a high-temperature, eg. 80°C cycle option, or by means of a suitable disinfectant solution. In the absence of guidance the microbiologist should be asked to advise on a suitable procedure.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14.20 The manufacturer should specify the de-gassing time(s) which should be used on start-up and, when necessary, between each load of instruments processed.

Wash cycle

14.21 The ultrasonic frequency used is typically within the range 35 ± 5 kHz and the energy input used may range from 5.0 to 20.0 Watts/litre.

14.22 Ultrasonic cleaners may be designed to operate at a single frequency, across a frequency range, or with a feedback control system claimed to adjust the frequency in response to the loading conditions.

14.23 For medical applications aqueous solutions are used. Although ultrasonic cleaners containing aqueous solutions may be effective at temperatures up to 90°C it is normal practice to operate those for medical applications at temperatures between ambient and 40°C. This minimises the rate of coagulation of proteinaceous material in the soiling and is compatible with the use of enzymatic cleaners, many of which are rapidly destroyed at higher temperatures.

Type 1 ultrasonicators

Load handling equipment

14.24 A mechanical lifting device should be specified when the ultrasonicator is intended to process heavy sets of instruments.

14.25 The load container, usually a wire mesh basket, should be of appropriate size for the longest instrument to be processed.

14.26 When it is intended to process micro-surgical instruments or instruments with fine points the load handling equipment should provide means of retaining these in position so that the points are not blunted by the impacts resulting from fine mechanical shaking.

Type 2 (continuous process) ultrasonicators

14.27 Continuous process WDs may incorporate an ultrasonic cleaning stage within the cycle programme.

14.28 Ultrasonic cleaners are also available in continuous process format with a thermal disinfection stage and with the option to provide a hot air drying stage.

14.29 Ultrasonic cleaners with a solvent drying stage are no longer commercially available since the solvents used were CFCs which are now prohibited under the Montreal Protocol.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load handling equipment

14.30 If complex tabling or conveyors are required these should be specified, and preferably illustrated with a sketch plan, when seeking tenders.

14.31 When it is intended to process micro-surgical instruments or instruments with fine points the load handling equipment should provide means of retaining these in position so that the points are not blunted by the impacts resulting from fine mechanical shaking.

Instrumentation/recorders

14.32 The ultrasonic cleaner should be fitted with a temperature indicator; provision should be made for a recorder to be fitted if requested by the purchaser.

14.33 The ultrasonic cleaner should be fitted with an indicator to show the power consumption (in Watts), or electrical demand (in Amps) of the ultrasonic transducers; provision should be made for a recorder to be fitted if requested by the purchaser.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Appendix 1: Glossary of terms

Automatic controller: Device that, in response to pre-determined cycle variables, operates the WD sequentially through the required stages of the cycle(s)/process.

Biological indicator: See BS EN 866-1:1997 ‘ Biological systems for testing sterilizers and sterilization processes: General requirements’.

Calibration: The set of operations that establish, under specified conditions, the relationship between values of a quantity indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material, and the corresponding values realised by Standards.

Calorifier: A closed vessel in which water is indirectly heated under a pressure greater than atmospheric.

Chamber: That part of the WD in which the load is processed.

NOTE: The chamber does not include steam generators, pipework and fittings from which it can be isolated.

Chemical disinfection: Disinfection achieved by the action of one or more chemicals; the primary purpose of which is to be microbicidal.

Continuous process machine: A machine which automatically transports the load through each stage of the operating cycle.

Chemical additive: A formulation of chemical compounds intended for use in a WD.

Cycle complete: Indication that the washing and disinfection cycle has been satisfactorily completed and that the disinfected load is ready for removal from the chamber.

Cycle variables: The physical and chemical properties (eg. times, temperatures, disinfectant concentration, pressures and flows) that influence the efficacy of the washing and processes.

Decontamination: The combination of processes, including cleaning and disinfection and/or sterilization, used to render a re-usable item safe for further use.

Disinfection: The reduction of the number of viable micro-organisms on a product to a level previously specified as appropriate for its intended further handling or use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Disinfection temperature: The minimum temperature of the disinfection temperature band.

Disinfection temperature band: The range of temperatures, expressed as the disinfection temperature and the maximum allowable temperature which may prevail throughout the load during the disinfection time.

Disinfection time: The time period at which the cycle variable (eg. temperature of the load, disinfectant concentration in the chamber) is maintained at or above the value specified for disinfection.

NOTE: This includes detergents, surfactants, rinse aids, disinfectants, and enzymatic cleaners.

Door: Device provided as a means of closing and sealing the chamber.

Double-ended washer-disinfector: A WD incorporating separate doors for loading and unloading.

Fail safe: Attribute of WD design, component or its associated services that minimises a possible safety hazard.

Fault: Recognition by the automatic controller that the pre-set cycle variables for the WD cycle have not been attained.

Holding time: the time period for which the cycle variables are maintained at or above the value specified for disinfection.

Hysteresis: The lagging of effect behind cause.

Inoculated carrier: See BS EN 866-1:1997 ‘ Biological systems for testing sterilizers and sterilization processes: General requirements’.

Installation test: Series of checks and tests performed after installation of the WD in the place of use.

Load: A collective term used to describe all the goods equipment and materials that are put into a WD at any one time for the purpose of processing it by an operating cycle.

Loading door: Door in a double-ended WD through which the load is put into the WD prior to processing.

Loading height: The minimum height to which the underside of the load or load container has to be raised for it to enter the loading door.

Medical device: See BS EN 46001: 1997 ‘Specification for applications of EN ISO 9001 to the manufacture of medical devices’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Monitoring: The measurement of physical variables, such as the function of the automatic controller to check the attainment, or otherwise, of the pre-set cycle variables essential to the efficacy of the operating cycle.

Operating cycle: The complete set of stages of the process that is carried out in the sequence as regulated by the automatic controller.

Operating pressure: The gauge pressure at which the vessel is operated during normal use.

Override: The system by which the operating cycle can be interrupted or modified as necessary.

Safety hazard: Potential detrimental effect on persons arising from the load.

Steam generator: Vessel designed to contain water and a heating system (eg. a steam coil or a fully immersed electric element) which is used to heat water to its vapour state.

Sterile: See BS EN 556 ‘Sterilization of medical devices. Requirements for terminally sterilized devices to be labelled ‘Sterile’’.

Sterilization: Process used to render a product sterile (35).

Tank: A process vessel, integral to the WD, designed to hold solutions during processing.

Test organism: See BS EN 866-1:1997 ‘ Biological systems for testing sterilizers and sterilization processes: General requirements’.

Test soil: Substance used to test the washing efficacy of a WD.

Thermal disinfection: Disinfection achieved by the action of moist or dry heat.

Type test: Series of tests to establish the working data for a WD type.

Unloading door: Door in a double ended WD through which the load is removed after an operating cycle.

Usable space: Space inside the chamber which is not restricted by fixed parts and which is consequently available to accept the load.

Validation: See BS EN 554 ‘Sterilization of medical devices. Validation of and routine control of sterilization by moist heat’.

Viable micro-organism: Micro-organisms, including viruses, which are capable of multiplication under specified culture conditions.

Warning pipe: Overflow pipe so fitted that its outlet, whether inside or outside the building, is in a conspicuous position, where the discharge of water can be readily seen.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum
A48235836

Washer-disinfector (WD): Machine intended to clean and disinfect medical devices and other articles used in the context of medical, dental, pharmaceutical and veterinary practice.

NOTE: This type of machine does not include those designed specifically to wash linen or clothing.

Waste outlet: The point from which the chamber discharges the waste fluids.

Works test: Series of tests performed at the manufacturer's works to demonstrate compliance of each WD with its specification.

Appendix 4: Information to be supplied by the manufacturer

A2.1 The following information should be supplied by the manufacturer of the WD at or before the time the WD is delivered.

Standards

A2.2 Statements of, and documentary evidence to substantiate, compliance with relevant British and EU Standards.

Instruction manual

A2.3 The manual should contain complete instructions including:

a. simplified operating instructions in a durable form suitable for fixing next to the WD;

b. guidance on the types of load that may be processed in the WD and the recommended loading patterns/load carriers to be used;

c. operational limits including the maximum working temperature which may be attained within the WD chamber or chambers, and the maximum pressure that may be applied to the lumen of cannulated instruments.

A2.4 When the WD incorporates a pressure vessel (eg. an integral steam generator) the operational limits of the pressure vessel including design pressure, maximum permissible working pressure and maximum permissible working temperature in accordance with the ‘Pressure systems regulations’. A valid test certificate should be provided by the manufacturer for all pressure vessels supplied.

Instruments and controls

A2.5 The manual should include a description of each instrument and control fitted to the WD including:

a. the scale ranges of each and the limits of accuracy;

b. evidence that the calibration of each instrument has been verified and that the instrument is reading correctly within its limits of accuracy.

Operating cycles

A2.6 The manual should give a description of each operating cycle available on the sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Services

A2.7 The manual should give a description of all the engineering services required by the WD, specifying:

a. values of the fluctuating demands placed on each service during the course of a normal operating cycle;

b. the maximum and minimum safe supply pressures, temperatures and voltages.

This should also include specification of the minimum acceptable water quality for each stage in the process (defined as pH, total dissolved solids, redox potential, electrical conductivity).

Safety

A2.8 Safety information should include:

a. description of any safety hazard that may arise in the normal operation of the WD and recommended precautions to avoid them;

b. description of all safety devices including their recommended settings and any means provided to override and reset them;

c. description of the chemical additives with which the WD is intended to be used.

Machine characteristics

A2.9 The manual should include a description of the machine, specifying the total volume of the chamber: This should include the following information:

a. dimensions of the usable space and its capacity expressed either as an integral number of load baskets based on the standard sterilization module (SSM) or as a specific number of identified load items eg. the number of bed pans;

b. parts of the usable chamber space which are fastest and slowest to attain the disinfection temperature, and those parts which are hottest and coolest during the disinfection holding time.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Maintenance manual

A2.10 Two copies should be provided. The manual should include:

a. a planned preventive maintenance programme, consistent with the principles outlined in SHTM 2030 Part 2, ‘Operational management’, together with detailed instructions for the procedures contained within it;

b. a list of any special tools and equipment required for periodic maintenance and testing;

c. diagrams of all electrical, steam, compressed air, water, chemical additive dosing systems, and ventilation and drainage connections;

d. a complete list of all spare parts, indicating all parts which should be held in stock and that may require replacement during the normal working life of the WD together with their usage rates;

e. guidance on tracing and correcting likely causes of malfunction;

f. method of adjusting and calibrating the pressure, temperature and flow rate indicating or recording systems;

g. Specification and source of supply for suitable flexible ducting to enable extracts from WDs to be conveyed to atmosphere.

Version 2
NHSScotland, Property and Environment Forum Executive, October 2001

Executive summary

SHTM 2030 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of washer-disinfectors (WDs) in use in the National Health Service for processing medical devices, laboratory ware and sanitary products.

No guidance is given on WDs intended for use in processing textiles or for dishwashers in general catering applications.

This part, 'Operational management', is intended as a guide for management, technical personnel with appropriate training and experience and also for users responsible for the day to day running of WDs. It will also be of interest to architects, planners, estates managers, supplies officers, and others.

Detailed information on the planning and design of a sterile services department including the provision of WDs is given in Scottish Hospital Planning Note 13, *Sterile services department*. Guidance for laboratory installations can be found in Scottish Hospital Planning Note 15; *Accommodation for pathology services.*

Although this edition of SHTM 2030 reflects current WD technology it is recognised that considerable scope exists for improvements in the operational and management standards used with WDs.

NOTE: The term washer-disinfector is abbreviated to 'WD' throughout this publication.

The current British Standards for WDs are expected to be replaced by European Standards within the next two to three years. These Standards include consideration of the requirements arising as a result of European Union Directives on medical devices, which are of concern for WDs in two ways. Firstly, some WDs will themselves be considered to be medical devices and therefore must meet the relevant requirements of the Medical Devices Directive and secondly, the manufacturer of a medical device which is intended to be reprocessed is required to specify the method to be used for reprocessing which will include any necessary washing and disinfecting stage.

When practicable the information in this SHTM has been aligned with existing or anticipated standards and advice is offered when no standard has yet been formulated.

The WDs described in this SHTM may not be suitable, without modification, for safely processing articles contaminated with either Hazard Group 4 pathogens or with agents which are unusually resistant to disinfection.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

The guidance previously given in HTM 2030 ‘Management policy’ has been incorporated into SHTM 2030 ‘Operational management’. HTM 2030 is superseded.

1. Disinfection in healthcare: an overview

1.1 Decontamination by washing and disinfection is a complex and subtle process. The testing, maintenance and reporting procedures described in this SHTM may seem excessive, but they are based upon good practice in both the UK and Europe, as formalised in European Standards designed to support the EC Directives.

1.2 The main purpose of washing and disinfection is to eliminate the hazard of contamination and infection.

1.3 Disinfection is the reduction of the number of viable micro-organisms on a product to a level previously specified as appropriate for its intended further handling or use.

1.4 The lethality of the process is less than that of sterilization but eliminates virtually all recognised pathogenic organisms, although not necessarily all microbial forms, for example bacterial endospores. Disinfection is adequate for the preparation of many items intended for use in patient care, but should not be used as a substitute for sterilization.

1.5 The hospital infection committee should prepare and implement a disinfection policy. This requires consultation between the microbiologist, infection control officer, engineer, pharmacist, supplies officer and representatives of medical, nursing and domestic staff.

1.6 The use of chemical disinfectants should be avoided when heat can be reasonably used as an alternative, for example in thermal disinfection or sterilization.

NHSScotland Property and Environment Forum

2. Washer-disinfectors and the role of management

Introduction

2.1 This part of SHTM 2030 covers the maintenance and operation of the various types of WDs used in hospitals, laboratories and other healthcare facilities.

2.2 Terminology used in washing and disinfection has long been inconsistent and this has often led to ambiguities. This SHTM introduces a set of terms which, it is hoped, will provide workers in this field with a standard vocabulary and will also be consistent with the EU Standards. The glossary contains defined terms referred to in this part of SHTM 2030.

2.3 Full references for all the documents referred to in this part and also for selected documents providing additional information of which the reader should be aware are listed at the end of the publication.

2.4 The NHS is no longer protected by Crown immunity and is now subject to the full force of the law, notably in health and safety, medicinal products and consumer legislation. Tighter statutory control, brought in by new European Union Directives, will extend to almost every aspect of disinfection, and practices which were common a few years ago will no longer be acceptable.

2.5 The test, maintenance and reporting procedures described in this SHTM are based upon good practice in both the United Kingdom and the rest of Europe, as formalised in new European Standards designed to support the new EU Directives, and are designed to prevent the possibility of gross failure and serious incident.

2.6 Good staff morale is important. Anomalous behaviour which may foreshadow a malfunction of a WD is often first noticed by an alert operator or other relatively junior employee. It is vital that staff feel free to report such observations promptly, and that appropriate remedial action is taken. “Untiring vigilance” demands no less.

Legal framework for washing and disinfection

2.7 WDs are used in relation to both medical devices and medicinal products as well as for sanitary equipment, laboratory equipment and cutlery/crockery.

2.8 They may be used for reprocessing, within their intended use, medical devices, sanitary equipment, laboratory equipment, manufacturing equipment and components (for use in the manufacture of medicinal products or medical devices) or cutlery and crockery.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.9 Users must be clear as to whether the load items they intend to process in a WD are classified as medicinal products or medical devices. While the practical requirements are very similar their implementation is covered by different legislation.

2.10 For the guidance given in this SHTM the various types of WDs are presumed to be used primarily as follows:

a. for medicinal products – laboratory WDs;

b. for medical devices, WDs for human-waste containers, surgical instruments and utensils, for anaesthetic equipment, for heat labile medical equipment eg. endoscopes.

2.11 When a WD is purchased with the intention of processing both medicinal products and medical devices purchasers should ensure that the requirements for both types of product are met.

Medicinal products

2.12 The manufacture and supply of medicinal products are controlled by extensive legislation based on EU Directives for medicinal products. These are enacted in the UK by the Medicines Act and a number of Regulations.

2.13 The requirements for the manufacture and supply of medicinal products are set out in the 'Guide to good manufacturing practice for medicinal products' (GGMP) published in Part IV of the 'The rules governing medicinal products in the European Community'.

2.14 The GGMP contains guidance on cleaning of components and manufacturing equipment which has implications for the operation of WDs. When a WD is to be installed for processing containers, components or manufacturing equipment for use with medicinal products the GGMP should be consulted at an early stage.

2.15 Guidance on the application of medicines legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medicines Control Agency (MCA) when necessary.

Medical devices

2.16 This part refers to three EU Directives on the manufacture and supply of medical devices and in-vitro diagnostics:

a. the Active Implantable Medical Devices Directive (Council Directive 90/385/EEC) covers all powered implants or partial implants that are left in the human body. (Heart pacemakers are the most common example of powered implants.) The Directive was adopted by the EC Council of Ministers on 20 June 1990 and came into effect in the UK on 1 January 1993 as the Active Implantable Devices Regulations 1992 (see paragraph 4.29);

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

b. the Medical Devices Directive (Council Directive 93/94/EEC) covers most other medical devices ranging from first aid bandages and tongue depressors through to hip prostheses and will therefore have a wide impact on disinfection. The Directive was adopted by the EU Council on 14 June 1993 and came into effect in the UK on 1 January 1995 as the Medical Devices Regulations;

c. the In-Vitro Diagnostic Medical Devices Directive will cover any medical device, reagent product, kit, instrument, apparatus or system which is intended to be used in vitro for the examination of substances derived from the human body. Some examples of in-vitro diagnostic devices are blood grouping reagents, pregnancy test kits, and hepatitis B test kits.

2.17 Whether, and if so in what circumstances, the Medical Devices Directive (93/42/EEC) applies to medical devices which are being reprocessed for further use – either within a particular healthcare facility or externally under a service contract – is a complex issue beyond the scope of this SHTM. Guidance is given in the MDA Directives Bulletin 18. If necessary advice should be sought from the Medical Devices Agency (MDA).

2.18 The relevant essential requirements of the Medical Devices Directive are:

a. that devices and manufacturing processes be designed to eliminate or reduce as far as possible the risk of infection to the patient, user and third parties (Appendix 1, paragraph 8.1);

b. that devices must be designed, manufactured and packed in such a way as to minimise the risk posed by contaminants and residues to the persons involved in the transport, storage and use of the devices and to the patients (Appendix 1, paragraph 7.2).

2.19 There is no direct equivalent of the GGMP for medical devices. The same role is fulfilled by general quality system Standards (the BS EN ISO 9000 series), supplemented by Standards tailoring the requirements specified in the general Standards for medical devices (BS EN 46001 and BS EN 46002) and Standards providing guidance on compliance with these Standards (BS EN 724 and BS EN 50103).

2.20 These are mandated Standards and as such compliance with them affords the presumption of conformance with relevant essential requirements of the Directive.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Published Standards

2.21 British Standard 2745: 1993 specifies requirements for WDs for medical purposes. The standard is in three parts: Part 1: 'Specification for general requirements'; Part 2: 'Specification for human-waste container washer-disinfectors' and Part 3: 'Specification for washer-disinfectors except those used for processing human-waste containers and laundry'.

2.22 There are no European Standards, as yet, for WDs. CEN Technical Committee TC102 is developing a series of mandated, Standards relevant to the Medical Devices Directive, for WDs. There are four parts with the working titles 'General Requirements', 'Washer-disinfectors for human-waste containers', 'Washer-disinfectors for medical devices and surgical instruments' and 'Washer-disinfectors for thermo-labile medical devices (for example endoscopes)'.

2.23 IEC Technical Committee TC66 is developing Standards for 'Safety requirements for washer-disinfectors'.

2.24 When published, compliance with these Standards may be used to give a presumption of conformance to the relevant requirements of the Medical Devices Directive.

2.25 This edition of SHTM 2030 has been written while the new Standards are in the course of development. The guidance given here is designed to be broadly consistent with the emerging Standards but SHTM 2030 should not be regarded as a substitute for the Standards themselves when ascertaining compliance with the EU Directives and the UK Regulations that implement them.

2.26 If the WD is purchased with the intention of processing both medical devices and components or equipment for use in the manufacture of medical products purchasers should ensure that the requirements for both types of load are met.

Washer-disinfectors as medical devices

2.27 The Medical Devices Directive (93/42/EEC) Annex IX, Classification Criteria, Rule 15 classifies as medical devices "all devices intended specifically to be used for disinfecting medical devices" and places them in Class IIa for conformity assessment purposes. It specifically excludes products that are intended to clean medical devices, other than contact lenses, by means of physical action.

2.28 WDs for cleaning and disinfecting medical devices are thus covered by the medical devices legislation and those supplied on or after 14 June 1998 will have to bear the CE marking in accordance with the provisions of the

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Medical Devices Directive. This will apply to many of the WDs described in this SHTM.

2.29 Detailed guidance on the application of medical devices legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medical Devices Agency.

Water supply

2.30 All organisations responsible for water supply have the statutory power to make and enforce bye-laws to prevent waste, excessive consumption, misuse or contamination of the water supply. The Model Water Bye-laws form the basis of such bye-laws. WDs must be designed, constructed, installed, operated and maintained in accordance with requirements of the relevant bye-laws.

Safety

2.31 Extensive guidance on the safe operation of various types of WDs is given within this SHTM (Chapters 5 to 11), while guidance on safety practice of testing WDs in given in SHTM 2030 Part 3, 'Validation and verification'.

2.32 Many of the chemical additives used in WDs and their associated ancillary equipment, eg. water treatment plant, are corrosive, toxic or otherwise hazardous and require special provision for their storage and use.

2.33 The 'Control of Substances Hazardous to Health (COSHH) Regulations' 1999 place an obligation upon management to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a special ventilation system.

2.34 Some of the substances that may be used in WDs, in particular those employing chemical disinfection or sterilization, have Occupational Exposure Limits (OEL) set out in Guidance Note EH 40 published annually by the Health and Safety Executive. These limits are a statutory maxima and should not be regarded as representing a safe working exposure. Employers have a legal obligation to ensure that exposure is reduced as far as reasonably practicable.

2.35 The WD, including any special ventilation equipment necessary for its safe operation, will be subject to the COSHH Regulations. These Regulations also include control of biological agents. This is of particular relevance to the operation of WDs which are commonly used to process items that may be heavily contaminated with pathogenic micro-organisms.

NOTE: Detailed guidance on ventilation systems is provided in SHTM 2025.

Summary of management responsibilities

2.36 SHTM 2030 will assist managers and other personnel to ensure that WDs are operated safely and effectively and in compliance with existing and anticipated legislation and standards. To this end, the major responsibilities of management can be summarised as follows:

a. to ensure that washing and disinfection are carried out in compliance with the law and with the policy of the UK health departments;

b. to ensure that all personnel connected with washing and disinfection, whether NHS employees or contract personnel, are suitably qualified and trained for their responsibilities;

c. to ensure that purchased WDs conform to legal requirements, the minimum specifications set out in British and European Standards and any additional requirements of the UK health departments;

d. to ensure that WDs are installed correctly and safely with regard to proper functioning, safety of personnel and environmental protection;

e. to ensure that newly installed WDs are subject to a documented scheme of validation comprising installation checks and tests, commissioning tests and performance qualification tests before they are put into services;

f. to ensure that WDs are subject to a documented scheme of periodic tests at yearly, quarterly, weekly and (in some cases) daily intervals;

g. to ensure that WDs are subject to a documented scheme of preventative maintenance;

h. to ensure that procedures for production, quality control and safe working are documented and adhered to in the light of statutory requirements and accepted best practice;

i. to ensure that procedures for dealing with malfunctions, accidents and dangerous occurrences are documented and adhered to.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3. Statutory Requirements

Introduction

3.1 So far as washing and disinfection are concerned, the chief areas of legislation with which managers should be familiar are health and safety, medicinal products and consumer protection including the medical devices regulations.

Health and safety

3.2 The largest body of law with which managers need to be familiar concerns health and safety, in particular the Health and Safety at Work etc Act 1974 (the HSW Act) and its various Regulations.

3.3 The HSW Act and its Regulations require employers to assess the risks to their employees. Attention is drawn to the following hazards which are implicit in the practice of washing and disinfection:

a. the hazard of scalding from escaping steam or water vapour;

b. the high temperatures (up to 100ºC) at which WDs are operated;

c. the toxic properties of chemicals used in certain WDs;

d. the infection hazard associated with the microbial pathogens that may be handled by personnel using certain laboratory WDs;

e. the hazard of infection to patients and staff by the inadvertent release of an infected load due to the failure of a disinfection and quality control process;

f. the hazards associated with the handling of heavy and hot loads while loading and unloading WDs;

g. the hazards associated with high pressure leaks from piping used for transfer of water or chemical agents.

3.4 The guidance given throughout this SHTM is designed to ensure that these hazards are minimised and that washing and disinfection procedures comply with the relevant legislation and established good practice.

Health and Safety at Work etc Act 1974

3.5 The HSW Act sets out the basic legal responsibilities of employers and employees with regard to health and safety at work.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Management of Health and Safety at Work Regulations 1999

3.6 The Management of Health and Safety at Work Regulations 1999 expand upon the principles of the HSW Act.

3.7 The core of the Regulations is a requirement of employers to make a systematic assessment of the risks to health and safety of their employees and others arising from work activities.

Workplace (Health, Safety and Welfare) Regulations 1992

3.8 The Workplace (Health, Safety and Welfare) Regulations 1992 are designed to ensure that workplaces meet the health, safety and welfare needs of each member of the workforce, including people with disabilities.

3.9 Most of the Regulations deal with the physical requirements of the workplace. Managers concerned with the operation of WDs should pay particular attention to the Regulations on maintenance, ventilation, temperature, lighting, cleanliness, room dimensions and space, floors, doors, and traffic routes.

Provision and Use of Work Equipment Regulations 1998

3.10 The Provision and Use of Work Equipment Regulations 1998 (PUWER) aim to ensure the provision of safe work equipment and its safe use.

3.11 PUWER 1998 replaces the existing Provision and Use of Work Equipment Regulations 1992 and applies to all equipment (including lifting equipment) used at work. PUWER 1992's requirements are carried forward in full but there are important new additions, including a requirement to inspect work equipment where significant risk could result from incorrect installation or relocation; deterioration, or as a result of exceptional circumstances; and to record the results of those inspections (Regulation 6).

Pressure Systems Safety Regulations 2000

3.12 These Regulations apply to steam and compressed air services supplying WDs and to those WDs with a pressurised chamber.

3.13 The Regulations define the duties of the competent person: a person or organisation responsible in law for advising on the scope of a written scheme of examination of a pressure system, drawing up the scheme, certifying the scheme as being suitable, and carrying out examination under the scheme.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Control of Substances Hazardous to Health Regulations 1999

3.14 The Control of Substances Hazardous to Health (COSHH) Regulations 1999 list a number of substances hazardous to health and specify a maximum exposure limit for inhalation, eg. glutaraldehyde.

3.15 The Health and Safety Executive (HSE) publishes an annually updated guidance note on current exposure limits – 'Occupational Exposure Limits (EH40)'.

Until January 1998 an occupational exposure limit for glutaraldehyde had been in force. It has been cancelled and to replace it a Maximum exposure limit (MEL) has been set.

This is in the form of a concentration in air. It is illegal to expose people to concentrations of glutaraldehyde in air above this level.

Source: HSE Guidance EH40 Feb 1999.

3.16 Users of WDs should note that a "substance hazardous to health" may include a micro-organism which creates a hazard to the health of any person. Suitable precautions are required when handling items that may be contaminated with pathogenic micro-organisms.

Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1995

3.17 Commonly known as RIDDOR, these Regulations impose duties on persons responsible for the activities of persons at work, and on self-employed persons, to report accidents resulting in death or major injury arising out of or in connection with work, and to report specified dangerous occurrences. They also require certain particulars of accidents at work to be reported both to the Department of Health and also to the Health and Safety Executive, and require records to be kept.

3.18 Some WDs may contain pressure vessels as defined under Part 1 of Schedule 1 (see paragraph 3.12).

3.19 Poisoning by chemical agents, eg. disinfectants, is a reportable disease listed under Schedule 2.

Manual Handling Operations Regulations 1992

3.20 These Regulations require employers to make an ergonomic assessment of all manual handling operations which involve a risk of injury and to reduce the risk as far as is reasonably practicable. Factors to be assessed include the nature of the task, the load, the working environment and individual capability. Reference should also be made to the 'Lifting Operations and Lifting Equipment Regulations' 1998

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.21 Managers should assess the risks associated with loading and unloading WDs, whether by loading trolleys or by hand. Top-loading WDs can be especially hazardous if lifting equipment is not available. The mass of the load is not the only source of risk; the temperature and other factors should be taken into account. Risks associated with maintenance and overhauling should also be assessed.

Personal Protective Equipment at Work Regulations 1992

3.22 Managers should assess whether the risks associated with washing and disinfection require the use of personal protective equipment (PPE). Some examples include heat-resistant gloves for use when hot loads are removed from WDs, protective gloves for use when loading contaminated material into WDs, eye or face protection when testing WDs containing pumped fluids and chemical agents, and foot protection for operators loading and unloading WDs.

Consumer protection

3.23 In recent years new legislation has been introduced affording protection to persons who may be harmed by unsafe goods supplied to them. In certain circumstances this may include products from WDs.

Consumer Protection Act 1987

3.24 Part 1 implements EU Council Directive 85/374/EEC (the Product Liability Directive) providing for compensation to be paid to persons injured by a defective product. Under the Act a product is defective “if the safety of the products is not such as persons generally are entitled to expect”, taking the circumstances into account. It is likely that civil action for damages could be taken against a hospital for supplying, for example, “disinfected” products that were not in fact disinfected and caused the infection of a patient.

3.25 The Active Implantable Medical Devices Regulations 1992 (SI 1992/3146) and the Medical Devices Regulations 1994 (SI 1994/301) are both issued under the Consumer Protection Act.

Electromagnetic Compatibility Regulations 1992

3.26 The Electromagnetic Compatibility Regulations (SI 1992/2372) (the EMC Regulations) impose requirements concerning the electromagnetic compatibility of most types of electrical and electronic apparatus which must be complied with when such apparatus is to be supplied or taken into service.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.27 A WD (and any ancillary equipment) is a “relevant apparatus” within the terms of the Regulations, and will have to meet Standards for emission of and immunity to electromagnetic disturbance. Note that it is an offence not only to supply but also to “take into service” a WD that does not conform to the Regulations.

3.28 The Regulations do not apply to any WD supplied or taken into service in the EU before 28 October 1992. A WD supplied or taken into service in the UK on or before 31 December 1995 is not required to comply with the Regulations provided it complies with the requirements of the Wireless Telegraphy Acts listed in Schedule 1 of the Regulations.

NOTE: Detailed guidance on the application of the EMC Regulations in healthcare premises may be found in SHTM 2014, *Abatement of electrical interference*.

4. Personnel

Introduction

4.1 This chapter introduces the personnel who share the responsibility for the safe and efficient operation of WDs. It gives guidance on qualifications and training and summarises areas of responsibility.

Training

4.2 It is essential that personnel at all levels should have a sound general knowledge of the principles, design and functions of WDs. They should be trained on those types and models of WD with which they are concerned. They should have some knowledge of the basic elements of microbiology in order to ensure personal safety, safety of others and general safety. Training given to individuals should be recorded and reviewed regularly.

4.3 Users working in relative isolation should take care to ensure not only that they are trained in the use of WDs in their charge, but also that they are aware of the changing requirements of the law and good practice as outlined in this SHTM.

4.4 Further information is available from the Property Environment Forum Executive and the Authorised Person (Sterilizers).

4.5 Detailed training on a particular model of WD is usually available from the manufacturer, either on site (such as during validation) or by courses at their premises.

Functional responsibility

4.6 There have been profound changes in the management philosophy of the NHS over recent years. With the wide range of circumstances in which a WD may be employed, from a busy sterile services department in a major general hospital to a small clinic, it is not possible to prescribe a universally applicable management structure for washing and disinfection.

4.7 The approach chosen for this SHTM is to identify the distinct functions that need to be exercised and the responsibilities that go with them. The titles given are therefore generic; they describe the individual's role in connection with washing and disinfection but are not intended to be prescriptive job titles for terms of employment. Indeed, many of the personnel referred to may not be resident staff but employed by outside bodies and working on contract. Some of them will have other responsibilities unconnected with

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

washing and disinfection and in some cases the same individual may take on more than one role.

4.8 In every case, however, it is possible to identify a user who is responsible for the day-to-day management of the WD. The philosophy of this SHTM is to invest the user with the responsibility for seeing that the WD is operated safely and efficiently.

4.9 In cases where steam is generated in a pressure vessel within the WD, the law requires that a competent person (pressure vessels), who is not the user, be designated to exercise certain responsibilities of inspection (see paragraph 4.17).

4.10 For small installations where the user is qualified to perform all required test and maintenance functions, no other personnel may be necessary. However, it is strongly recommended that in all cases the user receives professional advice from a microbiologist, and that maintenance be carried out by a suitable qualified person and a maintenance person with assistance from the microbiologist when microbiological testing is required.

Key personnel

4.11 The following personnel are referred to in this part of SHTM 2030. Further information including qualifications and areas of responsibility can be found in Part 1 of SHTM 2010.

Management

4.12 Management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the operation of the premises.

4.13 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of similar authority. In small autonomous units the user may take on this function.

User

4.14 The user is defined as the person designated by management to be responsible for the management of a WD.

4.15 In a hospital the user could be a sterile services manager, theatre manager, endoscopy clinic manager, ward manager or laboratory manager; in primary care he/she could be a general practitioner, dentist or other health professional. When a WD is used to process equipment or containers for use in the preparation of medicinal products the user is normally the production manager in charge of the manufacturing process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.16 The principal responsibilities of the user are as follows:

a. to certify that the WD is fit for use;

b. to hold all documentation relating to the WD;

c. to ensure that the WD is subject to periodic testing and maintenance;

d. to appoint operators where required and ensure that they are adequately trained;

e. to maintain production records.

Competent Person (Pressure vessels)

4.17 The competent person (pressure vessels) is defined as a person or organisation designated by management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a WD described in the 'Pressure Systems Safety Regulations 2000'. The shorter term "competent person" is used in this SHTM.

4.18 The following guidance on the qualifications for the competent person is based on the HSC Approved Code of Practice, Safety of Pressure Systems:

a. where required to draw up or certify schemes of examination, the competent person should be qualified at least to technician engineer level, with adequate relevant experience and knowledge of the law, codes of practice, examination and inspection techniques and understanding of the effects of operation of the pressure vessel concerned. He or she must have established access to basic design and plant operation advice, materials engineering and non-destructive testing (NDT) facilities. The competent person must have sufficient organisation to ensure a reasonable data storage and retrieval system with ready access to relevant laws, technical standards and codes;

b. where required to carry out examinations, the competent person should have sufficient practical and theoretical knowledge and actual experience of the type of pressure vessel which is to be examined to enable defects or weaknesses to be detected and their importance in relation to the integrity and safety of the WD to be assessed.

4.19 The principal duties of the competent person under the Regulations are as follows (they need not all be exercised by the same individual):

a. advising on the scope of the written scheme of examination;

b. drawing up the written scheme of examination or certifying the scheme as being suitable;

c. carrying out examinations in accordance with the written scheme, assessing the results and reviewing the written scheme for its suitability.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.20 Most insurance companies maintain a technical division able to advise on appointing a competent person. Advice may also be obtained from Scottish Healthcare Supplies, Trinity Park House, Edinburgh.

Test Person (Washer-disinfectors)

4.21 The test person (washer-disinfectors) is defined as a person designated by management to carry out validation of washer-disinfectors and to provide advice on testing, maintenance and procedures. The shorter terms test person or TP are used in this SHTM. The test person should either:

a. be a Test Person (Sterilizers) (see SHTM 2010 for a definition of this role);

b. be qualified to at least HNC level in engineering or relevant sciences and have at least two years experience in the validation of washer-disinfector processes; or

c. should have received appropriate documented training, and been assessed as technically competent to act as test person (washer-disinfectors). This person will normally have at least three years experience in the maintenance of washer-disinfectors processes.

4.22 The principal responsibilities of the TP are as follows:

a. to advise on programmes of periodic testing and periodic maintenance of WDs;

b. to advise on operational procedures for routine production;

c. to conduct the validation test specified in SHTM 2030 Part 3, ‘Validation and verification’ and to prepare the validation report;

d. to conduct the periodic tests specified in SHTM 2030 Part 3, ‘Validation and verification’ and to prepare reports as required by the user;

e. to conduct any additional tests at the request of the user.

Maintenance Person (Washer-disinfectors)

4.23 The Maintenance Person (washer-disinfectors) is defined as a person designated by management to carry out maintenance duties on washer-disinfectors. The shorter terms maintenance person or MP are used in this SHTM.

4.24 The Maintenance Person should be a fitter or electrician with documentary evidence to demonstrate competence in the maintenance of one or more types of washer-disinfector. He or she should be in a position to deal with any breakdown in an emergency and have the ability to diagnose faults and carry out repairs or to arrange for repairs to be carried out by others.

4.25 The principle responsibilities of the Maintenance Person are as follows:

a. to carry out the maintenance tasks outlined in this part of SHTM 2030;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

b. to carry out additional maintenance and repair work at the request of the user.

4.26 A Maintenance Person who has a minimum of 5 years experience in the maintenance of washer-disinfectors may, by agreement, perform the duties of the Test Person for the daily, weekly and quarterly tests described in SHTM 2030 Part 3, 'Validation and verification'.

Microbiologist

4.27 The microbiologist is defined as a person designated by management to be responsible for advising the user on microbiological aspects of disinfection.

4.28 The microbiologist should have a degree in microbiology and will normally be a member of the hospital staff.

4.29 The principle responsibilities of the microbiologist are as follows:

a. to provide general and impartial advice on all matters concerned with washing and disinfection;

b. to advise the user on the microbiological aspects of all disinfection procedures;

c. to arrange for the culturing of biological indicators used in microbiological tests;

d. to audit the documentation from all washer-disinfectors which have been tested by microbiological methods.

Control of Infection Officer

4.30 The Control of Infection Officer is defined as the person designated by management to be responsible for advising the user on all infection control aspects.

Production Manager

4.31 The Production Manager is defined as a person designated by management to be responsible for production of medicinal products and medical devices.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Quality Controller

4.32 The Quality Controller is defined as a person designated by management to be responsible for quality control of medicinal products and/or medical devices with the authority to establish, verify and implement all quality control and quality assurance procedures.

Laboratory Safety Officer

4.33 The Laboratory Safety Officer is defined as a person designated by management to be responsible for all aspects of laboratory safety in respect of equipment, maintenance, personnel and training relating to safety issues, and to ensure compliance with safety legislation and guidelines.

Operator

4.34 An operator is defined as a person, designated by management, with the authority to operate a WD. Their duties may include the noting of WD instrument readings, replenishment of consumable items, such as detergent, and simple housekeeping duties.

Manufacturer

4.35 The manufacturer is defined as a person or organisation responsible for the manufacture of a WD.

Contractor

4.36 The contractor is defined as a person or organisation designated by management to be responsible for the supply and installation of the WD, and for carrying out the installation checks and tests. The contractor is usually the manufacturer of the WD.

Purchaser

4.37 The purchaser is defined as the person or organisation who orders the WD and is responsible for paying for it.

Independent Advisor

4.38 The Independent Advisor is defined as a person who may or may not be registered as an AP(sterilizers), but can demonstrate to the satisfaction of management previous training and experience appropriate to carry out the designated tasks in respect of WDs as the AP(S) would carry out in respect of sterilizers. AP(S) is a suitable person to carry out the functions of an independent advisor. The principle responsibilities of the Independent Advisor are, independent advice on WDs and audit review of WD documentation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5. Operational management: an overview

Introduction

5.1 It is important that all WDs are effective in achieving the performance required to produce clean and disinfected products, and that they are safe in operation.

5.2 Failure to achieve the required standard of cleanliness may also impair the capability of the process to achieve disinfection and/or subsequent sterilization.

5.3 The cleanliness and microbial safety of all products processed in a WD is ultimately dependent upon the care taken by the personnel responsible for its design, manufacture, installation, operation, test and maintenance.

5.4 Washing and disinfection may appear to be relatively simple processes, but considerable care is needed to consistently achieve satisfactory results. The quality and safety of the product obtained from a WD ultimately depends upon the vigilance of skilful personnel fully trained in the operation of WDs.

5.5 Responsibility for assurance on these points rests variously with the TP, the MP, the microbiologist, the control of infection officer, and the user.

Maintenance

5.6 Decontamination processes are among those processes which have to be validated before use. In consequence the performance of the process has to be routinely monitored (see SHTM 2030 Part 3, ‘Validation and verification’) and the equipment has to be maintained in good working order.

5.7 The maintenance of WDs should, therefore, meet the following requirements:

a. preventive maintenance should be planned and performed in accordance with documented procedures;

b. the procedure for each planned task, and the frequency at which it is carried out, should be specified and documented;

c. the WD should not be used to process contaminated loads until all maintenance tasks have been satisfactorily completed and recorded;

d. records of maintenance should be retained as specified in BS EN ISO 9001: 1994 or BS EN ISO 9002: 1994;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

e. the maintenance scheme, maintenance procedures and maintenance records should be reviewed periodically by a designated person who should be appropriately qualified and experienced.

Safety precautions

5.8 Whether products which have been processed in a WD are safe to handle and/or use, as appropriate, is ultimately dependent on the vigilance of all personnel responsible for its operation.

5.9 Effective decontamination necessitates, in many cases, complex operating cycles. Protection is provided, in the first instance, by fail-safe design principles some of which also serve to protect the product by indicating when an ineffective operating cycle has occurred.

5.10 However fool-proof the design, any safety device can be defeated ultimately, either wantonly or accidentally. To ensure that this does not occur requires the continuing vigilance of skilful personnel fully trained in the operation of WDs.

5.11 Some WDs are only intended to perform an initial step in the reprocessing of soiled re-usable items. Care should be taken to ensure that items which have been cleaned and disinfected in a WD are, when necessary, subjected to terminal sterilization prior to their use on patients.

5.12 To prevent the hazard of burning or scalding the door should be interlocked to prevent it being opened in mid-cycle. In the event of a fault there may be an escape of hot water vapour when the door is opened or hot water (up to 93°C) may be retained within the chamber and load.

5.13 Washing is a wet process and water dropping on to the floor can create a serious hazard of slipping and falling for personnel. Any leaks should receive urgent attention from maintenance staff and any spillages should be cleaned up as soon as possible.

Management should have a safety policy to deal with spillages which considers both the chemical and microbiological hazards that may be posed.

A copy of the documented procedures to deal with spillages should be available in the vicinity of each WD. The user, and all operators who may use the WD, should be trained in the implementation of these procedures.

5.14 Overloading load baskets, and/or load carriers, can cause a hazard and will also impair the efficacy of the disinfection process. Operators and maintenance personnel should ensure that the loading does not exceed the manufacturer’s stated capacity for the loading accessories in use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.15 Detergents and other additives are, or may be, caustic and can cause adverse effects to exposed tissues; operators and maintenance personnel should wear protective gloves, a face shield and water-proof clothing whenever handling chemical additives or servicing the injection pumps or pipework. Contact with the eyes and skin or ingestion of chemical additives should be avoided.

5.16 Operators and maintenance personnel should read and follow the precautions and instructions given in the material safety data sheet and on the label prior to handling any chemical additive, refilling the container or servicing the injection pump and pipework.

All staff who may be exposed to contamination by any chemical additive should be trained in the action they should take to minimise harm to themselves and others in the vicinity. This will include: first aid; alerting emergency services if necessary; methods for cleaning and decontaminating the affected area; and the correct disposal of the materials used. There should be a written procedure detailing the actions to be taken in the event of spillages and contamination of personnel.

NOTE: The training should be part of a documented programme and should include periodic assessment and retraining.

5.17 Any equipment issued to operators should comply with the 'Provision and Use of Work Equipment Regulations (1998)'.

5.18 Operators and maintenance personnel should be issued with appropriate personal protective equipment (PPE) complying with the 'Personal Protective Equipment at Work Regulations (1992)'. In providing protection against, or minimising the risks from, hazards to health and safety priority should be given to engineering controls and safe systems of work; PPE should always be regarded as a last resort.

Equipment damage

5.19 The user should ensure that chemical additives used in the decontamination process are compatible with the materials of which the WD is constructed and also with the items to be processed.

5.20 Most WDs are made partly or wholly of stainless steel; the water supplied to the chamber, and the detergent and other chemical additives used, should have a low chloride content to minimise the risk of corrosion.

5.21 Lubricants for squeeze tubes on peristaltic pumps and other dispensing devices should be chosen and used in accordance with the manufacturer's instructions.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: In the absence of specific instructions silicone-based lubricants should always be used since petroleum-based lubricants can cause serious damage to many types of plastic tube.

5.22 Care should be taken to ensure that the walls of ultrasonic tanks are not scratched as this can cause serious cavitation erosion.

5.23 Operators should be instructed never to drop or rest load items directly on the bottom of an ultrasonic tank.

Performance qualification

5.24 New load items should not be processed until:

a. performance qualification (PQ) tests as specified in SHTM 2030 Part 3, 'Validation and verification' have been conducted by the TP to the satisfaction of the user and the independent advisor; or

b. the user is satisfied that the new load item is represented by one of the existing loading conditions/process cycles for which a PQ report exists; or

c. the instructions from the manufacturer of the item are sufficiently detailed and specific that the appropriateness of the proposed treatment is readily apparent.

5.25 The user, in consultation with the manufacturer(s) of the load items, the Independent Advisor and the control of infection officer as necessary, should ensure that the load is suitable for the process to which it is to be exposed. This should include consideration of the compatibility of all process chemicals used.

5.26 The process selected will depend on the nature of the load and its ability to withstand the environmental conditions present during the operating cycle. The rates of change of cycle variables, such as temperature and pressure, may also need to be considered.

5.27 Before selecting a process it may be necessary to carry out preliminary tests on the product, or on a surrogate product, to determine both the levels and rates of change of the cycle variables necessary to achieve the required result and to determine which can be tolerated by the product without causing unacceptable changes in its performance.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Loading

5.28 The user should ensure that each load is presented to the process in accordance with documented procedures established and tested during PQ.

5.29 Overloaded baskets or load carriers will result in inefficient cleaning and disinfection.

5.30 Cannulated load items, which are intended to be connected to spigots on the load carrier to ensure flushing of the lumen, will not be adequately cleaned and disinfected if they are not properly connected.

5.31 Small and light items should be secured with a hold-down screen or by other means; if they are free to move around there is a serious risk of damage to the instruments. Small sharp instruments which have moved within the load may also represent a hazard to staff who have to subsequently handle the load.

5.32 Load carriers should only be used with the items for which they were intended.

Documentation

5.33 When the WD is used to process medical devices, other than sanitary appliances, intended for use on a patient without further processing, eg. sterilization, each production cycle should be fully documented. The user should ensure that the records are kept securely.

Cycles which were aborted, for whatever reason, should also be noted along with the remedial action taken.

NOTE: Further guidance is given in subsequent chapters on WDs for particular applications.

5.34 Operators should be encouraged to note and report any indication that the WD may not be working as expected.

5.35 A process log should be kept for those products, other than human-waste containers, which will be used without being subjected to further processing (eg. sterilization). This will include items such as anaesthetic accessories and some fibre-optic endoscopes.

5.36 If in doubt as to whether records are required, and if so which records are necessary, the user should consult the Independent Advisor.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Post-decontamination inspection and release for further processing

5.37 The user in consultation with the Independent Advisor should establish and document procedures to ensure that loads are not released for use or further processing, eg. sterilization, until the user is satisfied:

a. that the disinfection stage of the process has been reproduced within the permitted tolerances established during commissioning and PQ; and

b. that the cleaning stage of the process has been reproduced within the permitted tolerances established; and/or

c. that visual inspection of the load shows that an acceptable standard of cleanliness has been obtained.

5.38 The procedures should ensure that:

a. the load has been correctly positioned in the loading basket and/or on the load carrier;

b. that the settings for the operating cycle are in accordance with the specification for that load type;

c. that the instrument/indicator readings and/or chart record for the cycle conforms with the data established during validation within the permitted tolerances;

d. that the decontaminated load shows no obvious defects – such as damage, residual soiling or staining – which may suggest a faulty operating cycle.

5.39 Whenever an operator has cause to suspect that the load may not have been properly disinfected the load must not be released. The user should be informed immediately.

5.40 A small percentage of load items which remain soiled after processing may not be sufficient cause to reject the entire load. The rejected items should be returned for reprocessing. However, the cause of the failure to clean all the items in the load should be investigated.

NOTE: This may be due to improper loading or items which were exceptionally heavily soiled or for which decontamination was unavoidably delayed.

5.41 Documented procedures for reprocessing rejected loads should be agreed between the user and the Independent Advisor. The method by which rejected loads are returned for reprocessing should be chosen to ensure that product flow in a controlled environment is not compromised.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5.42 For loads which are to be used in connection with the manufacture of medicinal products the quality controller will establish the procedures for product release.

5.43 After decontamination and before release of the product for use or further processing, as appropriate, the conditions for storage and handling should not compromise the cleanliness or freedom from microbial contamination of the product.

5.44 When a single-door WD is in use a system to clearly differentiate between processed and unprocessed loads may be required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6. Maintenance

Introduction

6.1 Disinfection, and to a great extent, cleaning are processes whose efficacy cannot be verified retrospectively by inspection or testing of the product before use. For this reason decontamination processes (cleaning and disinfection and/or sterilization) have to be validated before use, the performance of the process routinely monitored, and the equipment maintained.

6.2 Means of ensuring that a WD is fit for its intended purpose will include the validation and testing programme specified in SHTM 2030 Part 3, 'Validation and verification', and also the programme of planned maintenance as described in this chapter.

6.3 The philosophy of maintenance and testing embodies two main principles to ensure that the required standards of performance and safety are met and maintained:

a. all WDs are subject to a carefully planned programme of tests to monitor their performance;

b. all WDs are subjected to a planned programme of preventive maintenance.

Expertise on the maintenance of WDs is available at two levels, the MP/TP and the Independent Advisor.

Testing of WDs is dealt with in SHTM 2030 Part 3, 'Validation and verification'.

Planned maintenance (PM) programme

Design of a PM programme

6.4 The PM programme recommended by the manufacturer should be used when it is available. The maintenance programme may be modified subsequently to take account of equipment use, equipment history and local conditions after a suitable period of operational experience.

If no PM programme is available from the manufacturer a maintenance programme should be drawn up in consultation with the Independent Advisor and MP/TP.

6.5 A set of procedures should be developed for each model of WD, each containing full instructions for a particular maintenance task.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.6 The frequency with which each task will need to be carried out will depend, in part, on the usage level for the WD and also on the quality of the water supplied to the WD. It may be necessary to adjust the programme so that work is carried out more frequently on WDs which are heavily used and/or are supplied with hard water.

6.7 It is important that maintenance is planned so that the WD is out of service as little as possible.

6.8 Systematic records should be kept of all maintenance work undertaken both to demonstrate that the work has been carried out and also to facilitate periodic review of the PM programme.

Maintenance and facilities management software packages (eg. WIMS) may be used to maintain a full technical and financial history of the equipment.

Warranty period

6.9 After the purchase of a new WD the manufacturer may carry out certain inspection and maintenance procedures under the terms of the warranty. This may not be a full PM programme. The user should ensure that the complete PM programme is carried out by the MP during the warranty period.

6.10 The user should also comply with any reasonable instructions from the manufacturer during the warranty period.

Review of a PM programme

6.11 The PM programme should be reviewed at least annually to ensure that the equipment is being fully maintained but without any unnecessary maintenance activity.

6.12 The review should aim to identify:

a. the adequacy of maintenance records and compliance with the PM programme;
b. any emerging defects;
c. any changes required to the PM programme;
d. any changes required to any maintenance procedure;
e. any additional training required by maintenance personnel.

6.13 Proposed changes to the PM programme should be made in consultation with the WD manufacturer whenever possible.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Routine housekeeping

6.14 Certain maintenance tasks may be carried out by the user, or by the operator under the user's supervision, and should be recorded in the WD log.

6.15 Examples of such tasks include:

a. checking that the rotating spray arms are free to rotate;

b. checking that nozzles are not blocked;

c. removal and cleaning of strainers and filters;

d. checking that the supply of chemical additives is sufficient for the day's use and replenishing if necessary;

e. cleaning the inside of the chamber;

f. cleaning the external surfaces of the WD and washing of loading side conveyors and trolleys;

g. for WDs with a built-in water softener, checking the level of salt in the regeneration tank and replenishing if necessary.

Overhauls

6.16 The user should arrange for each WD to receive periodic overhauls. For WDs which incorporate a pressure vessel this should be timed to precede the examination of the pressure vessel by the competent person and the yearly tests.

6.17 Improvements and modifications recommended by the WD manufacturer should be reviewed and considered for implementation before each overhaul.

6.18 The overhauls, and any necessary inspections, should be scheduled so that in any particular installation only one machine needs to be withdrawn from service at a time.

Inspection of pressure vessels

6.19 Under the 'Pressure Systems Safety Regulations 2000' all WDs which incorporate pressure vessels are subject to a periodic inspection by a competent person (see paragraph 3.13).

6.20 The Independent Advisor will advise on the application of the Regulations to any particular installation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.21 The competent person has five principal duties under the Regulations:

a. advising on the scope of the written scheme of examination;
b. drawing up the written scheme of examination or certifying the scheme as being suitable;
c. carrying out examinations in accordance with the written scheme;
d. assessing the results of the examinations;
e. reviewing the written scheme of examination for its suitability.

6.22 The user should liaise closely with the competent person to ensure that the written scheme of examination is accommodated within the maintenance and testing programmes.

6.23 The competent person may require certain examinations to be carried out more frequently than recommended by the manufacturer.

6.24 Each written scheme of examination should specify detailed procedures for, and the frequency of, examination and should be regularly reviewed and updated.

Features requiring special attention

Steam generators

6.25 Steam generators, provided as an integral part of some WDs, are steam boilers and they should be subject to a written scheme of examination for pressure vessels.

6.26 Steam generators constructed from stainless steel will be subject to the risk of stress corrosion cracking. To minimize the risk the manufacturer's guidance on feedwater quality should be followed.

Stainless steel chambers

6.27 Stainless steel is used in the manufacture of many WD chambers. Over a wide range of specifications, stainless steels are susceptible to cracking from crevice corrosion and from stress corrosion initiated by chemical attack.

Leak tightness of doors

6.28 The door(s) of the WD are intended to prevent the escape of fluids into the surrounding environment, ie. to ensure freedom from aerosols which may be potentially infectious in the work place.

6.29 Damaged door seals are the major potential source of leaks and should receive careful attention as advised by the manufacturer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.30 The working life of door seals may be prolonged by regular cleaning.

6.31 Door seals should be renewed with spares provided, or approved, by the manufacturer at recommended intervals or when there is any sign of damage/deterioration.

Door interlocks

6.32 The interlocks on door(s) of the WD are intended to:

a. prevent the operator gaining access to the load during processing;

b. prevent both the loading and unloading doors being open at the same time on “pass-through” WDs;

c. prevent the operator gaining direct access to a load that has not been satisfactorily processed.

6.33 Maintenance and inspection of door safety devices and door interlocks should be carried out in accordance with the WD manufacturer’s written instructions.

6.34 Security and settings of door safety switches and interlocks should be checked at least monthly. The setting should be within the limits specified by the manufacturer.

Chemical dosing systems

6.35 Admission of the correct amount of chemical additive at the right time in the operating cycle is essential to the correct functioning of a WD. The chemical additive dosing system should be subjected to regular (at least monthly) inspection, maintenance and test. This should include:

a. visual inspection of all piping to ensure freedom from leaks;

b. visual inspection and/or testing to determine whether the delivery or pick-up piping is blocked by coagulated or hardened chemical additive (many of the chemical additives used are a viscous suspension) – and cleaning or replacing piping as necessary;

c. lubrication of the pinch tubing on peristaltic pumps in accordance with the manufacturer’s instructions;

d. verification that the volume dispensed is within the specified limits.

Water sprays and jets

6.36 The correct flow and distribution of water and aqueous solutions throughout the chamber and load are essential to the correct functioning of a WD. The spray system should be checked on a daily basis as part of the routine housekeeping tasks carried out by the user.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

In addition maintenance staff should also check the system at least weekly; this should include:

a. checking that the rotating spray arms, both installed within the chamber and located on load carriers, are free to rotate;

b. checking that nozzles are not blocked – clean and/or replace if necessary;

c. checking for wear in bearings of rotating parts – replace any worn parts as necessary;

d. checking the mating of any necessary connection between the load carrier and the water supply in the chamber.

Ultrasonic transducers

6.37 Many ultrasonic cleaners are not fitted with means to provide continuous monitoring of performance. Transducers can fail or become detached from the ultrasonic tank without being noticed by the operator (other than by the deterioration in the cleaning performance).

6.38 Periodic functional testing of ultrasonic cleaners is described in SHTM 2030 Part 3, ‘Validation and verification’.

6.39 The tank of the ultrasonic cleaner should be cleaned with a suitable neutral detergent and soft brush at least weekly.

Instruments

6.40 Each instrument fitted to WDs should be maintained and calibrated in accordance with the manufacturer’s instructions. Any instrument which is reading incorrectly or inconsistently should be repaired by the manufacturer, or scrapped if it is not economical to repair.

6.41 Instruments which are consistent in their readings but are slightly inaccurate compared with a reference instrument should be checked for zero and span and then adjusted to work correctly at the value of interest, eg. at the normal working temperature.

6.42 An instrument case should never be left open and any broken glass should be replaced promptly.

6.43 Temperature measuring systems are subject to both inherent errors and to loss of calibration with use. Temperatures read from an indicator or recorder should be treated with caution and interpreted in the light of the established characteristics of the particular measuring system, the load and data from previous cycles.

6.44 Temperature recorders should be used to record the attainment of thermal disinfection conditions for all critical applications.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.45 The absolute minimum intervention should be made to recording systems which are functioning correctly. Any adjustments should be strictly in accordance with the manufacturer's instructions.

6.46 Persons who change charts, print rolls and other consumables on recording instruments should be authorised to do so by the user. They should be fully trained and should be aware of the delicate nature of the instruments.

Water treatment plant

6.47 The correct functioning of water treatment plant incorporated in, or otherwise supplying, a WD is essential to maintaining the required cleaning performance.

6.48 The system should be inspected periodically to ensure that it is free from leaks.

6.49 The quality of water supplied should be verified by testing at weekly intervals for a period of three months following commissioning or major repair/overhaul of the water treatment system. At the discretion of the Independent Advisor and the microbiologist, the frequency of testing may be reduced to monthly intervals after three months of satisfactory weekly test results.

6.50 For water supplied from a de-ioniser or reverse osmosis plant this should include checking the pH and the conductivity to verify that these remain within specified limits.

6.51 When a water softener is used the water supply should be tested for hardness to ensure it remains below the specified maximum concentration of calcium salts.

6.52 Water intended for use as the final rinse water on items to be used invasively on patients or in the production of parenteral medicinal products should be tested for the presence of bacterial endotoxins.

6.53 Water intended for use as the final rinse water after a chemical disinfection process for load items which will not then be sterilized should be tested both for the presence of bacterial endotoxins and for total viable microbial count.

Ventilation plant

6.54 Correct operation of ventilation plant is essential to ensure:

a. the safe operation of WDs which include a chemical disinfection stage;
b. the efficient operation of the drying stage (where this is included);
c. the maintenance of a comfortable working environment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.55 All ventilation systems associated with a WD should be inspected, serviced and maintained at least every six months. Guidance on maintenance is given in SHTM 2025.

6.56 WDs which include a chemical disinfection stage should have the associated ventilation system examined and tested annually.

6.57 Before undertaking maintenance work on the cabinet, or its associated ventilation system, it may need to be decontaminated and the advice of the designated safety officer should be sought. A permit-to-work system should be in operation.

Returning a washer-disinfector to service

6.58 Whenever any work has been carried out on a WD, whether or not this was part of the PM programme, the user should be satisfied that it is fit for use. Following major repairs, overhauls etc. which may affect the performance of the WD the user and Independent Advisor should draw up a schedule of checks and tests to be carried out before the WD is returned to service. This should include some or all of the recommissioning (yearly) tests specified in SHTM 2030 Part 3, ‘Validation and verification’.

Trouble-shooting

6.59 A failure to clean all the items processed in a load through a WD is the most frequently observed fault. The most common causes of this type of failure, and thus those which should be considered first in any investigation, are:

a. Incorrect loading:
   (i) items which are not correctly located in an appropriate load carrier will not be subjected to the intended washing process;
   (ii) overloaded baskets and load carriers will allow some load items to shield others from spray jets etc;
   (iii) hinged instruments which are not opened prior to washing will not be effectively cleaned.

b. Blocked spray jets, spray arms that are not free to rotate, or a blocked strainer in the chamber base.

c. Soiled instruments which have been stored for prolonged periods before decontamination – blood and protein will coagulate if stored for more than eight hours making this hard to remove.

d. Soiled instruments subjected to heat treatment before decontamination – this will lead to coagulation of blood and protein making this hard to remove.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

e. Incorrect choice or quantity of detergent:

   (i) the detergent chosen must be compatible with the loads to be processed, the soil to be removed and the quality of water supplied;

   (ii) malfunction of the dosing system may cause the wrong quantity of chemical additive to be used – too little will not provide the detergency required but too much may also impair cleaning by causing excessive foaming etc.

f. Inappropriate water quality:

   (i) initial flush with water which is too hot will lead to coagulation of blood and protein making this hard to remove;

   (ii) the hardness of water used during washing must be compatible with the detergent chosen;

   (iii) hard water used in the final rinse will leave deposits on the surface of instruments.

7. Water disinfectors for human-waste containers

Introduction

7.1 This type of WD is used to empty, clean and disinfect human-waste containers (eg. bedpans, urine bottles, suction jars); both those which are not required to be sterile, eg. bedpans (but are required to be disinfected), as well as those which subsequently may be subjected to sterilization, eg. suction bottles.

7.2 Disinfection is achieved by direct contact of the load with water, or steam at a pressure near to atmospheric pressure, to raise the temperature of the surface of the load to a specified temperature for not less than a specified time, or a combination of conditions providing equivalent lethality.

7.3 The key requirement for WDs of this type is the safe emptying of the human waste (faeces, urine, blood etc.) and the effective cleaning and disinfection of the items for re-use.

7.4 Two distinctly separate types of WD are used for this purpose: a flusher-disinfector in which cleaning is achieved by the physical action of jets of water and no detergent is used (although a de-scaling agent may be used); and a WD which incorporates a detergent washing stage.

Safety precautions

7.5 The area in which the WD is located should be provided with appropriate equipment to deal with spillage from the containers during transfer to the WD (see paragraph 5.13).

7.6 At the end of the operating cycle the washed and disinfected containers may be too hot to handle without protective gloves; containers may also retain significant volumes of hot water with the attendant risks of scalding. Operators should be trained in the use of the WD and should be provided with appropriate protective clothing.

7.7 Many of the chemical additives used as anti-scaling agents are toxic, irritant and corrosive. They are potentially hazardous and require careful handling and secure storage (see paragraphs 5.15 and 5.16).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load handling/presentation

7.8 Load carriers are designed for particular types of containers; if it is intended to process a different container the manufacturer's advice on an appropriate load carrier should be sought.

7.9 The use of an inappropriate load carrier may prevent safe emptying of the container and may not permit effective cleaning and disinfection to take place.

7.10 Most WDs for human-waste containers are single-door machines; the area in which they are located should provide facilities for the segregation of containers awaiting processing and those that have been processed. These areas should be maintained in a good state of repair to facilitate the frequent cleaning which is required.

Selection of cycle variables and chemical agents

7.11 WDs which are connected to a hard water supply may need to include the use of a de-scaling agent to prevent the build-up of lime-scale on the containers being processed.

NOTE: A lime-scale deposit on the containers is not only unsightly but also makes the container more difficult to clean.

7.12 WDs for human-waste containers may be provided with a drying stage but this is rarely used for ward installations.

7.13 The operating cycle may combine the disinfection stage with the final rinse leaving the containers at high temperature at the end of the cycle. The operator should be provided with insulated gloves to allow safe removal of these hot items; being hot any residual moisture evaporates very quickly.

7.14 An option to use a cold final rinse, after disinfection, may be employed to facilitate the safe removal of the containers which will usually then require manual drying before use.

Cycle monitoring

7.15 The WD should be provided with either a temperature recorder to monitor and record the temperature attained during the disinfection stage or an indication from the automatic controller that the specified temperature was maintained for the specified time during the disinfection stage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Product release

7.16 Before a product is released for re-use the operator should verify the successful completion of the disinfection stage and visually inspect each load item for cleanliness.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8. Washer-disinfectors for anaesthetic accessories

Introduction

8.1 This type of WD is used to process anaesthetic and respiratory accessories; both those which are not required to be sterile (but are required to be disinfected) as well as those which will be subject to further processing, eg. sterilization.

8.2 Disinfection is achieved by direct contact of the load with water, or steam at a pressure near to atmospheric pressure, to raise the temperature of the surface of the load to a specified temperature for not less than a specified time, or a combination of conditions providing equivalent lethality.

8.3 The key requirement for WDs of this type is the circulation of water (and/or other aqueous solutions), used for washing, and hot air, used for drying, through the lumen of hollow items.

8.4 The facility to process anaesthetic accessories may be provided by a dedicated load carrier using a WD for instruments (see Chapter 9). A separate drying cabinet is often advantageous when a dedicated load carrier is used in a WD for instruments. Drying times for anaesthetic accessories are much greater than for instruments and the use of a separate drying cabinet improves the overall throughput of the WD.

8.5 WDs for anaesthetic accessories may incorporate a drying stage in the automatic process or there may be a separate drying cabinet.

Product compatibility

8.6 The instructions of the manufacturers of the anaesthetic accessories should be followed regarding the suitability of the various items for processing in a WD for anaesthetic accessories.

8.7 A neutral detergent or washing without a detergent may be necessary for some products, eg. laryngeal masks made of silicone rubber.

8.8 The maximum temperature attained during disinfection and drying may need to be controlled to minimise the oxidative degradation of rubber materials.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load handling/presentation

8.9 The use of a load carrier specifically intended for anaesthetic accessories is essential.

8.10 Items with a lumen should be placed over, or connected to, the appropriate nozzle on the load carrier to ensure the free passage of fluids through the lumen during processing.

8.11 Items such as breathing bags and sets and self-inflating resuscitator sets (including valves) may need to be dismantled before being placed in an appropriate load carrier.

8.12 Other items such as Magill forceps and tubing clamps can be decontaminated in a WD for instruments (see Chapter 9).

Selection of cycle variables and chemical agents

8.13 An initial flush (pre-rinse) assists the removal of mucous, blood and other body fluids before washing commences. The water should be at a low temperature to avoid coagulation of proteinaceous material. Organic matter not loosened by the flushing stage may become coagulated during, and not be removed by, the wash cycle.

8.14 Anaesthetic accessories made from plastic may need to be washed, disinfected and dried at temperatures lower than those normally used for instruments and utensils.

8.15 The operating temperature for the drier is a balance between the speed of drying and the longevity of anaesthetic accessories made of rubber.

8.16 The importance of an effective drying stage cannot be over emphasised. Items which are left wet or damp will rapidly become re-colonised with micro-organisms.

8.17 The compatibility of all materials and items to be processed should be established by reference to the manufacturer's instructions, or when necessary by appropriate performance qualification testing.

Cycle monitoring

8.18 WDs used to disinfect anaesthetic accessories intended for re-use without further processing should be equipped with a temperature recorder, independent of the automatic controller, to monitor and record the temperature attained during the disinfection stage.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

8.19 It is desirable that they should be equipped with means of monitoring, directly or indirectly, the flow of water during the flushing and washing stages and the flow of air during the drying stage.

Product release

8.20 Before anaesthetic accessories intended for re-use without further processing are released the recorded cycle variables should be checked to ensure that they are within acceptable limits for the process.

8.21 The load items should be inspected for cleanliness and dryness and to ensure that there are no signs of physical deterioration. For complex items, eg. valves, consideration should be given to function testing using a medical grade compressed air supply.

8.22 Items for use without further re-processing should be packaged to protect them from adventitious contamination.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9. Washer-disinfectors for instruments and utensils

Introduction

9.1 This type of WD is used to process surgical instruments, instrument trays and re-usable containers and hollowware.

9.2 Disinfection is achieved by direct contact of the load with water, or steam at a pressure near to atmospheric pressure, to raise the temperature of the surface of the load to a specified temperature for not less than a specified time, or a combination of conditions providing equivalent lethality.

Safety precautions

9.3 At the end of the operating cycle the washed and disinfected load may be too hot to handle without using protective gloves; bowls and receivers (particularly those made of polypropylene) may also retain significant volumes of hot water with the attendant risks of scalding. Operators should be trained in the use of the WD and provided with appropriate protective clothing (see paragraph 5.18).

9.4 Many of the chemical additives used are toxic, irritant and corrosive. They may be hazardous and will require careful handling and secure storage (see paragraphs 5.15 and 5.16).

9.5 A written procedure should be available for the filling or connection of all chemical additive containers. Staff whose duties include this task should receive formal training.

9.6 Adequate protective clothing, washing and eye washing facilities should be provided. Appropriate hazard labels should be displayed in the vicinity of use.

9.7 When the chemical additive(s) used has a volatile component the measurement of environmental concentrations may be necessary both during commissioning and as periodic routine checks.

9.8 During loading there should be minimal handling of contaminated instruments and equipment. Staff should be trained in the appropriate procedures and provided with suitable protective equipment including gloves and eye protection.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

9.9 Before transferring instruments to the WD operators should carefully check the returned instrument trays for hazardous items, eg. scalpel handles with the blade left attached. When present, hazardous items should be carefully removed using, if necessary, handling equipment such as forceps or cheatals.

9.10 Operators should dispose of any sharps found into a sharps disposal container complying with BS 7320:1990.

Product compatibility

9.11 The compatibility of all materials and items to be processed should be established by reference to the manufacturers' instructions, or when necessary by appropriate performance qualification testing.

9.12 Factors to be considered in determining the compatibility of the load to the WD process include, but are not necessarily limited to:

a. whether or not the load can be immersed in water;

b. the availability of an appropriate load carrier;

c. the maximum operating temperature (this will usually occur during the thermal disinfection or drying stages);

d. the internal pressure to which the lumen of a cannulated instrument may be subjected;

e. the mechanical damage which may occur from the impact of water jets or other items in the load;

f. the compatibility of chemical additives used – both with the instrument itself and in combination with other load items (when acidic chemical additives are used metal items of different composition in the same load may be subject to electrolytic corrosion).

Load handling/presentation

9.13 Load carriers specific to the type of load should be used to ensure that all surfaces to be cleaned and disinfected will be exposed to the action of the water jets, will not be dislodged by the water jets and will drain freely.

9.14 For single-door machines facilities to allow segregation of the handling equipment, eg. trolleys used for clean and dirty items, is required.

Selection of cycle variables and chemical agents

9.15 A flushing (pre-rinse) stage assists the removal of blood and other body fluids before washing commences. The water used for flushing should be at a low enough temperature to avoid coagulation of proteinaceous material.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Organic matter not loosened by the flushing stage may become coagulated during, and not be removed by, the wash cycle.

9.16 The choice of detergent will be based upon a number of factors. These include:

a. the quality of water available;

b. the nature of the soiling to be removed;

c. the nature of the washing process.

Advice should be sought from both the WD and detergent manufacturers.

NOTE: For most applications mild alkaline detergents, up to pH 10.5, are preferred. The alkalinity contributes to the detergent action by the saponification and emulsification of fats and oils, by the peptidisation of proteins and by softening the water. The presence of alkaline builders also has a synergistic effect with surfactants present in the formulation.

9.17 A low foaming detergent will be required for most WDs since foaming will impair the wash action.

9.18 The use of enzymic detergents may be considered. These are most effective when used for soaking instruments since the contact time is of importance. Many enzymic cleaners are inactivated at the high temperatures used in wash cycles with non-enzymic detergent.

9.19 The quality of water used for the final rinse stage is important in ensuring freedom from scaling, process residuals etc.

9.20 The rinse stage may include a neutralising agent to counteract the detergent and/or minimise the effect of hard water which otherwise would cause “spotting” on the instruments.

9.21 The rinse may include an additive to facilitate free draining of water (rinse aid). Additives intended to lubricate hinged instruments (instrument milk) are also available. The use of these lubricants is generally contra-indicated. Instruments requiring lubrication may be identified on inspection after washing and disinfection and individually lubricated.

9.22 The final hot rinse may be combined with the disinfection stage.

9.23 Water purified by de-ionisation or reverse osmosis is preferred for the final rinse stage since this gives the lowest levels of process residuals and minimises the requirement for rinse additives.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Cycle monitoring

9.24 The WD should be equipped with means to provide independent monitoring of all critical cycle variables.

9.25 The following variables may need to be monitored for each of the listed stages – together with the duration of each stage:

a. Flushing stage:
   (i) pump pressure or flow rate for water;
   (ii) temperature of water.
b. Washing stage:
   (i) pump pressure or flow rate for water and/or aqueous solutions;
   (ii) temperature of water and/or aqueous solutions;
   (iii) volume(s) of chemical additives injected.
c. Rinsing stage:
   (i) pump pressure or flow rate for water and/or aqueous solutions;
   (ii) temperature of water and/or aqueous solutions;
   (iii) volume(s) of any chemical additives injected.
d. Disinfecting stage (moist heat):
   (i) pump pressure or flow rate for water;
   (ii) temperature of water.

9.26 WDs equipped to monitor all these variables have become commercially available only in the past two to three years.

9.27 As a minimum, WDs used to process surgical instruments should monitor the temperature during the disinfection stage and the time during which the temperature met or exceeded the specified minimum. There should also be means of ensuring an adequate flow of water within the chamber and load.

9.28 WDs that do not have independent monitoring of the time for which the specified temperature was maintained do not provide adequate assurance that the load was disinfected; a load that has not been disinfected may not be safe for staff to handle or for re-use.

Product release

9.29 Before a product is released for use or further processing it should be visually inspected for cleanliness and dryness. The attainment of the required temperature for the required time during the disinfection stage should be verified.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10. Washer-disinfectors for thermo-labile endoscopes

Introduction

10.1 This type of WD is used to process endoscopes which are thermo-labile and cannot withstand thermal disinfection. They are typically of the flexible fibre-optic or video-endoscope type.

NOTE: Rigid endoscopes capable of withstanding a thermal disinfection process may be decontaminated in WDs for instruments and utensils equipped with an appropriate load carrier designed to provide flushing of the lumen.

10.2 Disinfection is achieved by direct contact of the load with a chemical disinfectant solution at a specified concentration for a specified time either at a specified temperature or within a previously validated temperature range.

10.3 The disinfection facility may be provided as part of the automatic process or as a separate machine intended to disinfect items which have been cleaned. For this reason equipment for chemical disinfection is considered separately (see Chapter 12).

Product compatibility

10.4 Endoscopes may be harmed by some chemical additives or the use of an inappropriate operating cycle in the WD. The reprocessing instructions supplied by the manufacturer of the endoscope should be followed carefully.

Load handling/presentation

10.5 Few, if any, WDs for thermo-labile endoscopes are capable of cleaning the endoscope without any pre-treatment. As soon as the endoscope is removed from the patient, the channels should be flushed in accordance with the endoscope manufacturer's instructions. The outside of the instrument should then be wiped with a swab soaked in an aqueous solution of a suitable detergent.

Instrument/biopsy channels should be brushed through several times with a cleaning brush designed for the instrument in accordance with the endoscope manufacturer's instructions.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10.6 The use of a load carrier specifically intended for the endoscope(s) to be processed is essential.

10.7 The channels of the endoscope should be connected to the appropriate nozzle on the load carrier to ensure the free passage of fluids through the lumens during processing.

Selection of cycle variables

10.8 The cleaning stage should terminate with a rinse stage to remove any chemical agents used in cleaning which may be incompatible with the disinfectant to be subsequently used.

10.9 The automatic process should include means to ensure the removal of residual water which might dilute disinfectants.

Cycle monitoring

10.10 The WD should be equipped with means to provide independent monitoring of all critical cycle variables (see paragraph 9.25).

10.11 This should include means to verify that all channels to be irrigated with cleaning solution are not blocked.

Product release

10.12 Before a product is released for use or further processing it should be visually inspected for cleanliness and dryness. When the process includes a chemical disinfection stage the attainment of the required conditions should be verified (see Chapter 12).

11. Manually-loaded ultrasonic washers

Introduction

11.1 This type of washer is used to process metal instruments with complex interstices. It may be used as a pre-cleaning method before processing through a WD for instruments and utensils.

11.2 Ultrasonic cleaners work by subjecting the load to a high intensity of high frequency sound waves which causes cavitation at the surface of the instruments, loosening the soiling.

11.3 Ultrasonic cleaning is not a disinfection process and loads cleaned by ultrasonication must be subjected to a subsequent disinfection or sterilization process as appropriate.

11.4 The guidance offered in this chapter is, when relevant, equally applicable to ultrasonic cleaning processes included in a WD for instruments and utensils.

Safety precautions

11.5 Ultrasonic cleaners should only be operated in accordance with the manufacturers' instructions. They should only be operated when the lid is in place to avoid the dispersion of aerosols and to protect operators from the noise that may be generated.

11.6 Ear protection may be necessary for operators if the ultrasonic cleaner produces significant audible noise during operation.

11.7 Operators should be instructed not to put their hands, or any other parts of their body, into the ultrasonic tank while it is operating.

11.8 Items washed in an ultrasonic cleaner will only have been cleaned, not disinfected, and should therefore be handled with appropriate precautions.

11.9 Ultrasonic cleaners should never be operated with the tank empty since this can seriously damage the transducers.

Product compatibility

11.10 Ultrasonic cleaners are used to assist in cleaning jointed and serrated stainless steel instruments. Plastics and other similar materials which absorb the ultrasonic energy are not successfully cleaned by this method.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.11 Cannulated instruments can be cleaned by ultrasonication but this is generally successful only when means are provided to ensure that the cannula is also flushed with cleaning solution during the process.

11.12 Cemented glass syringes and optical systems will be damaged if they are subjected repeatedly to ultrasonication.

11.13 The compatibility of all materials and items to be processed should be established by reference to the manufacturer's instructions, or by appropriate performance qualification testing when necessary.

Load handling/presentation

11.14 Instruments should be placed in the basket provided with the machine.

11.15 The cleaner should be located at a convenient height for loading and unloading. When heavy sets of instruments are to be processed the cleaner should be equipped with a mechanical lifting device.

11.16 Cannulated instruments should be connected to the appropriate nozzle on the load carrier to ensure that the cleaning solution can be pumped through the lumen during processing.

11.17 Hinged instruments should be opened before being placed in the cleaner.

11.18 Gross contamination, such as blood and other visible soil, should be rinsed off instruments before they are immersed in the ultrasonic tank.

Selection of cycle variables and chemical agents

11.19 The only variables selectable are the operating temperature (on some machines), the concentration of chemical additives and the exposure time.

11.20 The efficacy of ultrasonic cleaning is improved by the use of a low foaming surfactant or detergent. The choice of detergent and control of the in-use concentration of detergent have a significant effect on cleaning performance. Advice should be sought from both the WD and detergent manufacturers.

Routine operation

11.21 The tank should be filled with the volume of clean cold water recommended in the manufacturer's instructions and the required volume of detergent added. The ultrasonic cleaner should then be brought up to operating temperature (if it is of the thermostatically controlled type) and operated for a period of not less than five minutes to de-gas the solution.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11.22 After de-gassing, the instruments to be cleaned should be loaded into the ultrasonic cleaner using the basket provided and, when the lid is in place, the cleaner operated.

11.23 After the specified time the instrument basket should be removed, the instruments removed and either transferred to a WD for instruments and utensils or thoroughly rinsed in clean hot water (60°C or hotter) before drying prior to sterilization or chemical disinfection.

11.24 The tank should be emptied and refilled with clean solution when the solution has become visibly soiled or every four hours, whichever is the sooner. De-gassing is necessary after each fill, before instruments are processed.

Cycle monitoring

11.25 The user should carry out a daily test to verify the activity of the transducers (see SHTM 2030 Part 3, ‘Validation and verification’).

Product release

11.26 Before a product is released for use or further processing it should be visually inspected for cleanliness.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

12. Liquid chemical disinfectors

Introduction

12.1 Machines for the automatic disinfection of items by liquid chemical disinfectants are intended for use only on items previously subjected to a cleaning process.

12.2 The guidance offered in this chapter is equally applicable when the disinfection process is included in a single machine with the cleaning process.

Safety precautions

12.3 Chemical disinfectants are potentially hazardous. Depending on the formulation they may cause irritation to the skin, eyes, respiratory tract and mucous membranes and may be volatile, flammable and corrosive. A risk assessment should be undertaken in accordance with the COSHH Regulations (see paragraph 3.14).

12.4 Staff training should include specific instruction on the procedures to be adopted in the event of equipment malfunction.

Product compatibility

12.5 The compatibility of all materials and items to be processed should be established by reference to the manufacturer's instructions, or when necessary by appropriate testing.

12.6 Factors to be considered in determining the compatibility of the load to the WD process include, but are not necessarily limited to:

a. whether or not it can be immersed in aqueous solutions;

b. the availability of an appropriate load carrier providing the necessary connection to all channels which require disinfection;

c. the maximum operating temperature;

d. the internal pressure to which the channels may be subjected;

e. the compatibility with the chemical disinfectants used.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load handling/presentation

12.7 Items to be processed should be:

a. clean, to ensure that all internal channels are clear and that the activity of the disinfectant is not compromised by residual soiling;

b. free from process residues from the cleaning process, eg. detergent, which may inactivate the disinfectant;

c. dry or free from significant surface moisture which would cause dilution of the disinfectant solution;

d. verified as undamaged, eg. by means of a leak test;

e. dismantled to the extent necessary, eg. with valves opened or demounted as recommended by the manufacturer;

f. protected with any necessary closure to prevent the ingress of aqueous solutions into the wrong part of the equipment, eg. videoscopes which are only immersible if the protective cap is in place;

g. connected to the disinfector so as to ensure the passage of disinfectant through all channels.

Selection of cycle variables and chemical agents

12.8 The activity of chemical disinfectants is time and temperature dependent. The temperature of the disinfectant solution should, therefore, be either thermostatically controlled or monitored during each cycle to ensure that it is within the temperature range validated during commissioning.

12.9 The exposure time should be controlled to ensure that the predetermined minimum exposure time has been attained.

12.10 As the various disinfectant formulations differ considerably in their properties, the choice of disinfectant should be made in consultation with the manufacturers of the equipment to be disinfected, the disinfector and the disinfectant. Guidance on the properties of commonly used disinfectants is given in ‘Sterilization, disinfection and cleaning of medical equipment, guidance on decontamination from the Microbiology Advisory Committee to the Department of Health Medical Devices Agency’.

12.11 The operating cycle must provide adequate rinsing after the chemical disinfection stage to ensure that residues of the disinfectant have been reduced to a level at which they do not present a hazard to patients.

12.12 The quality of the final rinse water, especially microbial quality, and the means of ensuring that quality are important characteristics of the process if recontamination of disinfected items is to be avoided. The manufacturer’s instructions should be followed precisely.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Cycle monitoring

12.13 For disinfectant solutions which are formulated for multiple or prolonged use the date of preparation and/or activation and the number of operating cycles run should be recorded. Whenever practicable the concentration of disinfectants intended for re-use should be monitored on a daily basis.

12.14 The WD should be equipped with means to provide independent monitoring of all critical cycle variables.

12.15 This should include means to verify that all channels to be irrigated with disinfectant solution are not blocked.

12.16 The disinfectant temperature and exposure time should be monitored for each cycle.

12.17 The means employed to maintain the quality of the final rinse water should be monitored in accordance with the manufacturer's instructions.

Product release

12.18 Before a product is released for use or further processing it should be verified that the chemical disinfection stage was within the limits previously determined during commissioning.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

13. Laboratory washer-disinfectors

Introduction

13.1 This type of WD is used to process laboratory equipment and glassware and may also be used to process containers and equipment for use in the preparation of medicinal products.

13.2 Disinfection is achieved by direct contact of the load with water to raise the temperature of the surface of the load to a specified temperature for not less than a specified time, or a combination of conditions providing equivalent lethality.

Safety precautions

13.3 At the end of the operating cycle the load may be too hot to handle without protective gloves. Operators should be trained in the use of the WD and provided with appropriate protective clothing.

13.4 Many of the chemical agents used are toxic, irritant and corrosive. They are potentially hazardous and require careful handling and secure storage.

13.5 A written procedure should be available for the filling or connection of all chemical additive containers. Staff whose duties include this task should receive formal training.

Product compatibility

13.6 The compatibility of all materials and items to be processed should be established by reference to the manufacturers' instructions, or when necessary by appropriate performance qualification testing.

Load handling/presentation

13.7 Load carriers specific to the type of load should be used to ensure that all surfaces to be cleaned and disinfected will be exposed to the action of the water jets, will not be dislodged by the water jets and will drain freely.

13.8 For single-door machines facilities to allow segregation of the handling equipment, eg. trolleys used for clean and dirty items, is required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Selection of cycle variables and chemical agents

13.9 A flushing (pre-rinse) stage assists the removal of gross soiling and proteinaceous material before washing commences. The water used for flushing should be at a low enough temperature to avoid coagulation of proteinaceous material.

13.10 The choice of detergent will be based upon a number of factors. These include:

a. the quality of water available;

b. the nature of the load;

c. the nature of the soiling to be removed;

d. the nature of the washing process.

Advice should be sought from both the WD and detergent manufacturers.

NOTE: For some applications, particularly where detergent residues would be a significant problem for the intended use of the load, washing without detergent may be used.

13.11 The quality of water used for the final rinse stage is important in ensuring freedom from scaling, process residuals etc.

13.12 Water purified by de-ionisation, distillation or reverse osmosis is preferred for the final rinse stage since this gives the lowest levels of process residuals.

13.13 When the WD does not include a separate drying stage the use of a high temperature final rinse will facilitate the rapid natural drying of the load on removal from the WD.

Cycle monitoring

13.14 The WD should be equipped with means to provide independent monitoring of all critical cycle variables.

13.15 The variables which may need to be monitored include those identified for WDs for instruments and utensils (paragraph 7.25).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Product release

13.16 Before a product is released for use or further processing it should be visually inspected for cleanliness. When disinfection is required the attainment of the required temperature for the required time during the disinfection stage should be verified.

13.17 For loads which are to be used in connection with the manufacture of medicinal products the quality controller will establish the procedures for product release.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Appendix 1: Glossary of terms

Automatic controller: Device that, in response to pre-determined cycle variables, operates the WD sequentially through the required stages of the cycle(s)/process.

Biological indicator: See BS EN 866-1:1997 'Biological systems for testing sterilizers and sterilization processes: General requirements'.

Calibration: The set of operations that establish, under specified conditions, the relationship between values of a quantity indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material, and the corresponding values realised by Standards.

Calorifier: A closed vessel in which water is indirectly heated under a pressure greater than atmospheric.

Chamber: That part of the WD in which the load is processed.

NOTE: The chamber does not include steam generators, pipework and fittings from which it can be isolated.

Chemical disinfection: Disinfection achieved by the action of one or more chemicals; the primary purpose of which is to be microbicidal.

Continuous process machine: A machine which automatically transports the load through each stage of the operating cycle.

Chemical additive: A formulation of chemical compounds intended for use in a WD.

Cycle complete: Indication that the washing and disinfection cycle has been satisfactorily completed and that the disinfected load is ready for removal from the chamber.

Cycle variables: The physical and chemical properties (eg. times, temperatures, disinfectant concentration, pressures and flows) that influence the efficacy of the washing and processes.

Decontamination: The combination of processes, including cleaning and disinfection and/or sterilization, used to render a re-usable item safe for further use.

Disinfection: the reduction of the number of viable micro-organisms on a product to a level previously specified as appropriate for its intended further handling or use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

A48235836

Disinfection temperature: The minimum temperature of the disinfection temperature band.

Disinfection temperature band: The range of temperatures, expressed as the disinfection temperature and the maximum allowable temperature which may prevail throughout the load during the disinfection time.

Disinfection time: The time period at which the cycle variable (eg. temperature of the load, disinfectant concentration in the chamber) is maintained at or above the value specified for disinfection.

NOTE: This includes detergents, surfactants, rinse aids, disinfectants, and enzymatic cleaners.

Door: Device provided as a means of closing and sealing the chamber.

Double-ended washer-disinfector: A WD incorporating separate doors for loading and unloading.

Fail safe: Attribute of WD design, component or its associated services that minimises a possible safety hazard.

Fault: Recognition by the automatic controller that the pre-set cycle variables for the WD cycle have not been attained.

Holding time: the time period for which the cycle variables are maintained at or above the value specified for disinfection.

Hysteresis: The lagging of effect behind cause.

Inoculated carrier: See BS EN 866-1:1997 ‘Biological systems for testing sterilizers and sterilization processes: General requirements’.

Installation test: Series of checks and tests performed after installation of the WD in the place of use.

Load: A collective term used to describe all the goods equipment and materials that are put into a WD at any one time for the purpose of processing it by an operating cycle.

Loading door: Door in a double-ended WD through which the load is put into the WD prior to processing.

Loading height: The minimum height to which the underside of the load or load container has to be raised for it to enter the loading door.

Medical device: See BS EN 46001: 1997 ‘Specification for application of EN ISO 9002 to the manufacture of medical devices’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Monitoring: The measurement of physical variables, such as the function of the automatic controller to check the attainment, or otherwise, of the pre-set cycle variables essential to the efficacy of the operating cycle.

Operating cycle: The complete set of stages of the process that is carried out in the sequence as regulated by the automatic controller.

Operating pressure: The gauge pressure at which the vessel is operated during normal use.

Override: The system by which the operating cycle can be interrupted or modified as necessary.

Safety hazard: Potential detrimental effect on persons arising from the load.

Steam generator: Vessel designed to contain water and a heating system (eg. a steam coil or a fully immersed electric element) which is used to heat water to its vapour state.

Sterile: See BS EN 556 ‘Sterilization of medical devices. Requirements for terminally sterilized devices to be labelled ‘Sterilie’’.

Sterilization: Process used to render a product sterile.

Tank: A process vessel, integral to the WD, designed to hold solutions during processing.

Test organism: See BS EN 866-1:1997 ‘Biological systems for testing sterilizers and sterilization processes: General requirements’.

Test soil: Substance used to test the washing efficacy of a WD.

Thermal disinfection: Disinfection achieved by the action of moist or dry heat.

Type test: Series of tests to establish the working data for a WD type.

Unloading door: Door in a double ended WD through which the load is removed after an operating cycle.

Usable space: Space inside the chamber which is not restricted by fixed parts and which is consequently available to accept the load.

Validation: See BS EN 554 ‘Sterilization of medical devices. Validation of and routine control of sterilization by moist heat’.

Viable micro-organism: Micro-organisms, including viruses, which are capable of multiplication under specified culture conditions.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Warning pipe: Overflow pipe so fitted that its outlet, whether inside or outside the building, is in a conspicuous position, where the discharge of water can be readily seen.

Washer-disinfector (WD): Machine intended to clean and disinfect medical devices and other articles used in the context of medical, dental, pharmaceutical and veterinary practice.

NOTE: This type of machine does not include those designed specifically to wash linen or clothing.

Waste outlet: The point from which the chamber discharges the waste fluids.

Works test: Series of tests performed at the manufacturer's works to demonstrate compliance of each WD with its specification.

Scottish Health Technical Memorandum 2030

(Part 3 of 3)

Validation and verification

Washer-disinfectors

Disclaimer

The contents of this document are provided by way of guidance only. Any party making any use thereof or placing any reliance thereon shall do so only upon exercise of that party's own judgement as to the adequacy of the contents in the particular circumstances of its use and application. No warranty is given as to the accuracy of the contents and the Property and Environment Forum Executive, which produced this document on behalf of NHSScotland Property and Environment Forum, will have no responsibility for any errors in or omissions therefrom.

The production of this document was jointly funded by the Scottish Executive Health Department and the NHSScotland Property and Environment Forum.

Version 2
NHSScotland, Property and Environment Forum Executive, October 2001

Executive summary

SHTM 2030 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of washer-disinfectors (WDs) in use in NHSScotland for processing medical devices, laboratory ware and sanitary products. No guidance is given on WDs intended for use in processing textiles or for dishwashers in general catering applications.

This part is intended as a guide for technical personnel with appropriate training and experience and also for users responsible for the day to day running of WDs. It will also be of interest to architects, planners, estates managers, supplies officers, and others.

Detailed information on the planning and design of a sterile services department, including the provision of WDs, is given in Scottish Hospital Planning Note 13; *Sterile Services Department* and Health Building Note 13 Supplement 1 *'Ethylene oxide sterilization'* section. Guidance for Laboratory installations can be found in Scottish Hospital Planning Note 15; *Accommodation for pathology services*.

Although this version of SHTM 2030 reflects current WD technology it is recognised that considerable scope exists for improvements in the operational and management technology used with WDs.

The current British Standards for WDs, although only in force since 1993, are expected to be replaced by European Standards within the next two to three years. These Standards include consideration of the requirements arising as a result of European Union Directives on medical devices which are of concern for WDs in two ways; firstly, some WDs will themselves be considered to be medical devices and therefore must meet the relevant requirements of the Medical Devices Directive and secondly, the manufacturer of a medical device which is intended to be reprocessed is required to specify the method to be used for reprocessing which will include any necessary washing and disinfecting stage.

When practicable the information in this SHTM has been aligned with existing or anticipated Standards and advice is offered where no Standard has yet been formulated.

The WDs described in this SHTM may not be suitable, without modification, for safely processing articles contaminated with either Hazard Group 4 pathogens or with agents which are unusually resistant to disinfection.

1. General

Introduction

1.1 This part of SHTM 2030 covers the validation and periodic testing of the various types of washer-disinfectors (WDs) used in hospitals, laboratories and other healthcare facilities.

1.2 Terminology used in washing and disinfection has long been inconsistent and this has often led to ambiguities. This SHTM introduces a set of terms which, it is hoped, will provide workers in the field with a vocabulary that will be consistent with the European Union (EU) standards that are to be introduced in the near future. The glossary provides a definition of terms referred to in this part of SHTM 2030.

1.3 References for all the documents referred to in this part and other selected documents that provide additional information of which the reader should be aware are contained at the end of this part.

Legal framework for washing and disinfection

1.4 WDs are used in relation to both medical devices and medicinal products as well as for sanitary equipment, laboratory equipment and cutlery/crockery.

1.5 WDs may be used for reprocessing medical devices, sanitary equipment, laboratory equipment, manufacturing equipment (for use in the manufacture of medicinal products or medical devices) or cutlery and crockery, within their intended use.

1.6 WDs may also be used as part of the manufacturing process for medical devices, medicinal products, in-vitro diagnostics or laboratory products in processing ‘single-use’ products or components such as bottles and vials.

Medicinal products

1.7 The manufacture and supply of medicinal products are controlled by extensive legislation based on EU Directives for medicinal products. These are enacted in the UK by the Medicines Act and a number of Regulations.

1.8 The requirements for the manufacture and supply of medicinal products are set out in the ‘Guide to good manufacturing practice for medicinal products’ (GGMP) published in Volume IV of ‘The rules governing medicinal products in the European Community’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.9 The GGMP contains guidance on cleaning of components and manufacturing equipment which have implications for the design, installation and operation of WDs. When a WD is to be installed for processing containers, components or manufacturing equipment for use with medicinal products the GGMP should be consulted at an early stage.

1.10 Guidance on the application of medicines legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medicines Control Agency (MCA) when necessary.

Medical devices

1.11 SHTM 2030 Part 2, 'Operational management', refers to the three European Directives on the manufacture and supply of medical devices and in-vitro diagnostics.

1.12 Whether, and if so in what circumstances, the Medical Devices Directive applies to medical devices which are being reprocessed for further use, either within a particular healthcare facility or externally under a service contract, is a complex issue beyond the scope of this SHTM. If necessary, further guidance is given in the MDA Directives Bulletin 18.

1.13 The essential requirements of the Medical Devices Directive require inter alia:

a. that devices and manufacturing processes be designed to eliminate or reduce as far as possible the risk of infection to the patient, user and third parties (Annex I, paragraph 8.1);

b. that devices must be designed manufactured and packed in such a way as to minimise the risk posed by contaminants and residues to the persons involved in the transport, storage and use of the devices and to the patients (Annex I, paragraph 7.2).

1.14 There is no direct equivalent of the GGMP for medical devices. The same role is fulfilled by general Quality System standards (the BS EN ISO 9000 series), supplemented by standards tailoring the requirements specified in the general standards for medical devices (BS EN 46001 and BS EN 46002), standards providing guidance on compliance with these standards (BS EN 724 and BS EN 50103) and the Institute of Sterile Services Management (ISSM) guidance document 'Standards & Practice'.

1.15 Other than the ISSM guidance these are mandated Standards and as such compliance with them affords the presumption of conformance with the relevant essential requirements of the Directive.

Published Standards

1.16 British Standard 2745: 1993 specifies requirements for WDs for medical purposes. The Standard is in 3 parts; Part 1: 'Specification for General

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Requirements', Part 2: 'Specification for washer-disinfectors for human-waste containers' and Part 3: 'Specification for washer-disinfectors except those used for processing human-waste containers and laundry'.

1.17 There are no European Standards, as yet, for WDs. CEN Technical Committee TC102 is developing a series of mandated Standards relevant to the Medical Devices Directive for WDs. There are four parts with the working titles 'General Requirements', 'Washer-disinfectors for human-waste containers', 'Washer-disinfectors for medical devices and surgical instruments' and 'Washer-disinfectors for thermo-labile medical devices (for example endoscopes)'.

1.18 IEC Technical Committee TC66 is developing Standards for 'Safety requirements for washer-disinfectors'.

1.19 When published, compliance with these Standards may be used to give a presumption of conformance to the relevant requirements of the Medical Devices Directive.

1.20 This edition of SHTM 2030 has been written while the new Standards are in the course of development. The guidance given here is designed to be broadly consistent with the emerging Standards but SHTM 2030 should not be regarded as a substitute for the Standards themselves when ascertaining compliance with the EU Directives and the UK Regulations that implement them.

1.21 If the WD is purchased with the intention of processing both medical devices and components, or equipment for use in the manufacture of medical products, purchasers should ensure that the requirements for both types of load are met.

Key personnel

1.22 The following personnel are referred to in this part of SHTM 2030.

Management

1.23 Management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the operation of the premises.

1.24 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of similar authority. In small autonomous units the user may take on this function.

User

1.25 The user is defined as the person designated by management to be

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

responsible for the management of a WD.

1.26 In a hospital the user could be a sterile services manager, theatre manager, endoscopy clinic manager, ward manager or laboratory manager; in primary care he/she could be a general practitioner, dentist or other health professional. When a WD is used to process equipment or containers for use in the preparation of medicinal products, the user is normally the production manager in charge of the manufacturing process.

1.27 The principal responsibilities of the user are as follows:

a. to certify that the WD is fit for use;

b. to hold all documentation relating to the WD;

c. to ensure that the WD is subject to periodic testing and maintenance;

d. to appoint operators where required and ensure that they are adequately trained;

e. to maintain production records.

Competent Person (Pressure vessels)

1.28 The competent person (pressure vessels) is defined as a person or organisation designated by management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a WD described in the Pressure Systems Safety Regulations 2000. The shorter term “competent person” is used in this SHTM.

1.29 The following guidance on the qualifications for the competent person is based on the HSC Approved Code of Practice, Safety of Pressure Systems:

a. where required to draw up or certify schemes of examination, the competent person should be qualified at least to technician engineer level, with adequate relevant experience and knowledge of the law, codes of practice, examination and inspection techniques and understanding of the effects of operation of the pressure vessel concerned. He or she must have established access to basic design and plant operation advice, materials engineering and non-destructive testing (NDT) facilities. The competent person must have sufficient organisation to ensure a reasonable data storage and retrieval system with ready access to relevant laws, technical standards and codes;

b. where required to carry out examinations, the competent person should have sufficient practical and theoretical knowledge and actual experience of the type of pressure vessel which is to be examined to enable defects or weaknesses to be detected and their importance in relation to the integrity and safety of the WD to be assessed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.30 The principal duties of the competent person under the Regulations are as follows (they need not all be exercised by the same individual):

a. advising on the scope of the written scheme of examination;

b. drawing up the written scheme of examination or certifying the scheme as being suitable;

c. carrying out examinations in accordance with the written scheme, assessing the results and reviewing the written scheme for its suitability.

1.31 Most insurance companies maintain a technical division able to advise on appointing a competent person. Advice may also be obtained from Scottish Healthcare Supplies, Trinity Park House, Edinburgh.

Test Person (Washer-disinfectors)

1.32 The test person (washer-disinfectors) is defined as a person designated by management to carry out validation of washer-disinfectors and to provide advice on testing, maintenance and procedures. The shorter terms 'test person' or TP are used in this SHTM. The test person should either:

a. be a test person (Sterilizers) (see SHTM 2010 for a definition of this role);

b. qualified to at least HNC level in engineering or relevant sciences and have at least two years experience in the validation of washer-disinfector processes; or

c. have at least five years experience in the testing of washer-disinfector processes.

1.33 The principal responsibilities of the TP are as follows:

a. to advise on programmes of periodic testing and periodic maintenance of WDs;

b. to advise on operational procedures for routine production;

c. to conduct the validation test specified in SHTM 2030 Part 3, ‘Validation and verification’ and to prepare the validation report;

d. to conduct the periodic tests specified in SHTM 2030 Part 3, ‘Validation and verification’ and to prepare reports as required by the user;

e. to conduct any additional tests at the request of the user.

Maintenance Person (Washer-disinfectors)

1.34 The Maintenance Person (washer-disinfectors) is defined as a person designated by management to carry out maintenance duties on washer-

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

disinfectors. The shorter terms maintenance person or MP are used in this SHTM.

1.35 The maintenance person should be a fitter or electrician with documentary evidence to demonstrate competence in the maintenance of one or more types of washer-disinfector. He or she should be in a position to deal with any breakdown in an emergency and have the ability to diagnose faults and carry out repairs or to arrange for repairs to be carried out by others.

1.36 The principle responsibilities of the Maintenance Person are as follows:

a. to carry out the maintenance tasks outlined in SHTM 2030 Part 2, 'Operational management';

b. to carry out additional maintenance and repair work at the request of the user.

1.37 A Maintenance Person who has a minimum of 5 years experience in the maintenance of washer-disinfectors may, by agreement, perform the duties of the Test Person for the daily, weekly, quarterly and yearly tests described in this SHTM 2030.

Microbiologist

1.38 The microbiologist is defined as a person designated by management to be responsible for advising the user on microbiological aspects of disinfection.

1.39 The microbiologist should have a degree in microbiology and will normally be a member of the hospital staff.

1.40 The principle responsibilities of the microbiologist are as follows:

a. to provide general and impartial advice on all matters concerned with washing and disinfection;

b. to advise the user on the microbiological aspects of all disinfection procedures;

c. to arrange for the culturing of biological indicators used in microbiological tests;

d. to audit the documentation from all washer-disinfectors which have been tested by microbiological methods.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Control of Infection Officer

1.41 The Control of Infection Officer is defined as the person designated by management to be responsible for advising the user on all infection control aspects.

Production Manager

1.42 The Production Manager is defined as a person designated by management to be responsible for production of medicinal products and medical devices.

Quality Controller

1.43 The Quality Controller is defined as a person designated by management to be responsible for quality control of medicinal products and/or medical devices with the authority to establish, verify and implement all quality control and quality assurance procedures.

Laboratory Safety Officer

1.44 The Laboratory Safety Officer is defined as a person designated by management to be responsible for all aspects of laboratory safety in respect of equipment, maintenance, personnel and training relating to safety issues, and to ensure compliance with safety legislation and guidelines.

Operator

1.45 An operator is defined as any person with the authority to operate a WD. Their duties may include the noting of WD instrument readings, replenishment of consumable items, such as detergent, and simple housekeeping duties.

Manufacturer

1.46 The manufacturer is defined as a person or organisation responsible for the manufacture of a WD.

Contractor

1.47 The contractor is defined as a person or organisation designated by management to be responsible for the supply and installation of the WD, and for carrying out the installation checks and tests. The contractor is usually the manufacturer of the WD.

Purchaser

1.48 The purchaser is defined as the person or organisation who orders the WD and is responsible for paying for it.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Independent Advisor

1.49 The Independent Advisor is defined as a person who may or may not be registered as an AP (Sterilizers), but can demonstrate to the satisfaction of management previous training and experience appropriate to carry out the designated tasks in respect of WDs as the AP(S) would carry out in respect of sterilizers. AP(S) is a suitable person to carry out the functions of an Independent Advisor.

Water supply

1.50 All the organisations responsible for water supply have the statutory power to make and enforce byelaws to prevent waste, excessive consumption, misuse or contamination of the water supply. The Model Water Byelaws form the basis of such byelaws. WDs must be designed, constructed, installed, operated and maintained in accordance with the requirements of the relevant byelaws.

Safety

1.51 Guidance on the safe operation of the various types of WD is given in SHTM 2030 Part 2; 'Operational management'. As far as testing is concerned, normal safety precautions are adequate except in the case of WDs using liquid chemical germicides. In this case users are recommended to operate a permit-to-work system to ensure that such WDs are declared safe to work on, and that personnel working on them have documented authority to do so.

Chemical additives

1.52 Many of the chemical additives used in WDs and their associated ancillary equipment, for example water treatment plant, are corrosive, toxic or otherwise hazardous and require special provision for their storage and use.

1.53 The 'Control of Substances Hazardous to Health (COSHH) Regulations 1999' place upon management an obligation to ensure that suitable measures are adopted to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a special ventilation system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.54 Some of the substances which may be used in WDs, in particular those employing chemical disinfection or sterilization, have Occupational Exposure Limits (OEL) set out in Guidance Note EH40 published annually by the Health and Safety Executive. These limits are statutory maxima but should not be regarded as representing a safe working exposure. Employers have a legal obligation to ensure that exposure is reduced as far as reasonably practicable.

1.55 The WD, including any special ventilation equipment necessary for its safe operation, will be subject to the COSHH Regulations. These Regulations introduced controls on biological agents which are of relevance to purchasers of WDs. Detailed guidance on ventilation systems is provided in SHTM 2025.

Infectious materials

1.56 All WDs have the potential to process infectious materials. The user should therefore ensure that personnel working on WDs wear appropriate protective clothing and are fully informed of any hazards that may be present. In case of doubt the microbiologist should be consulted.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2. Testing of washer-disinfectors

Introduction

2.1 WDs are used to carry out the processes of cleaning and disinfection consecutively.

2.2 In some instances a visual inspection for residual contamination may be considered sufficient for monitoring the adequacy of the cleaning process before use. However, this is not true in all cases; for example, visual inspection will not detect soiling on the internal surfaces of instruments with lumens and will not detect low, but potentially significant, concentrations of soiling (for example proteins) or residual chemical additives from the WD remaining on load items.

2.3 There is no simple method to verify by inspection or test the efficacy of the disinfection process on a product prior to use.

2.4 In consequence, cleaning and disinfection processes have to be validated before use, the performance of the process monitored during routine use, the calibration of controls and instrumentation verified, and the equipment subjected to a suitable maintenance programme.

2.5 The control protocols described in this part of SHTM 2030 provide the means for ensuring that the WD is fit for its intended purpose and includes tests and checks carried out during manufacture, after delivery, during validation and periodically thereafter. Tests are also required before a WD is returned to service after repairs that affect one or more components which influence the attainment of critical process control variables or after modification.

2.6 The control protocol is based on four key aspects to ensure that the required standards of performance and safety are met and sustained:

a. all WDs are subjected to a planned programme of tests to validate their performance, that is, to provide experimental evidence that, when operated under the specified conditions, the WD will reliably produce cleaned and disinfected items to the standard required;

b. all WDs are subjected to a planned programme of tests to monitor their performance;

c. all WDs are operated in accordance with an agreed procedure by staff trained in the use of the WD;

d. all WDs are subjected to a planned programme of preventative maintenance irrespective of whether a preventive maintenance scheme is operated on the premises.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.7 Expertise on all aspects of the operation and testing of WDs should be available on three levels; the Independent Advisor, Test Person (WD), and Maintenance Person (WD).

2.8 The scheduled test programmes include simple tasks to be undertaken by the user as well as more complex tests undertaken by the MP/TP.

2.9 Schedules for pre-delivery works tests (when necessary), installation checks, validation tests and periodic tests are presented in Chapters 3, 4, 5 and 6 of this document, and discussed below. When appropriate, the schedules refer to detailed test procedures described in later chapters.

2.10 Maintenance of WDs is dealt with in SHTM 2030 Part 2; 'Operational management'.

Responsibilities

2.11 WDs should be subjected to a planned programme of testing both before delivery and on-site. The on-site testing should be carried out using the procedures described in this SHTM and should include installation qualification, operational qualification and process qualification. The purchaser, manufacturer and contractor have distinct responsibilities.

Management

2.12 Management should nominate, when necessary, an Independent Advisor to provide advice on validation and a MP/TP to carry out the checks and tests required.

2.13 The Independent Advisor should review the results of pre-delivery works tests carried out by the manufacturer, and review the test instruments provided by either or both the contractor (see paragraph 1.37) and the MP/TP to ensure that their accuracy, calibration and condition meet the standards for test instruments described in Chapter 8.

2.14 The MP/TP should witness the installation checks and tests carried out by the contractor, including ensuring that the calibration of each test instrument provided by the contractor has been checked on site and is satisfactory and arrange for test loads to be supplied as required.

2.15. The TP should carry out the initial operational qualification and performance qualification tests.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Manufacturer

2.16 The manufacturer should ensure that the WD is designed, manufactured and tested within a quality system complying with the requirements of BS EN ISO 9001 or BS EN ISO 9002.

2.17 The manufacturer should carry out pre-delivery works testing. The extent of testing will depend on whether the product is in serial production or a 'one off' and, for machines in serial production, whether the manufacturer has obtained a certificate of compliance to a relevant British or European Standard by means of a type test for the particular type and size of WD.

Contractor

2.18 The contractor, who may also be the manufacturer, should complete the installation checks and tests specified in Chapter 4 to the satisfaction of the MP/TP before the WD can be accepted for use in accordance with the contract.

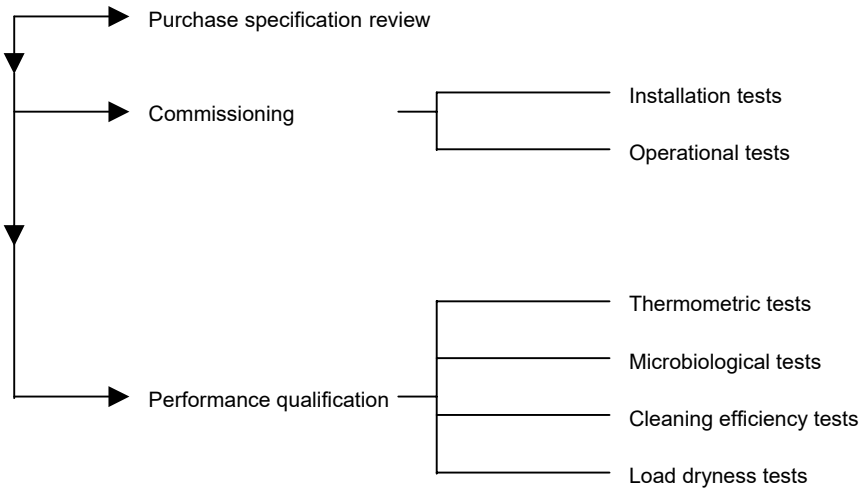
2.19 The contractor should provide the test instruments and equipment (but, unless otherwise specified in the contract, should not be expected to provide the test loads). The test instruments provided should meet the standards for test instruments described in Chapter 8.

Validation

2.20 Validation is the documented procedure required for obtaining, recording and interpreting the results needed to show that a process will consistently yield a product complying with a pre-determined specification. Validation is a total process beginning with a review of the specification against which the equipment is purchased. This is to ensure that it will meet the user's specified production needs including installation qualification, operational qualification and performance qualification. Installation qualification and operational qualification are sometimes referred to jointly as 'commissioning'.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 1: The validation process



Works tests

2.21 Before delivery of the WD, the manufacturer should subject the machine to a programme of factory tests. The extent of these tests will depend on whether the WD is in serial production or is a unique design (a 'one-off'). For machines in serial production the works tests are intended to verify that, in respect of various critical attributes, the WD performs in conformity with the results obtained from type testing. It is rarely necessary to attend the factory to witness works tests but the manufacturer should make the results of these tests available on or before delivery of the WD.

2.22 For 'one-off' designs a more extensive programme of works tests, similar to the programme of type tests for machines in serial production, is required and the purchaser may wish to arrange for their representative (either the Independent Advisor or MP/TP) to attend the factory to witness these tests before accepting delivery of the WD.

2.23 The schedule for type test and works tests is set out in Chapter 3.

Commissioning

2.24 Commissioning is defined as the process of obtaining and documenting evidence that the equipment has been provided and installed within the agreed purchase specification, and that it functions within pre-determined limits when operated in accordance with the manufacturer's instructions.

2.25 Commissioning consists of a series of installation tests to be carried out by the contractor and operational tests to be carried out by the MP/TP.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Pre-Installation checks

2.26 The contractor should verify that the site services are adequate for the operation and performance of the WD before it is delivered.

2.27 The contractor should verify the condition of the water supply and set chemical dosing levels as appropriate.

Installation tests

2.28 The contractor should carry out the required installation checks on delivery of the WD to ensure that the WD has been supplied and installed correctly and is safe to operate.

2.29 Ventilation systems should be checked by the contractor responsible for their installation.

2.30 When these checks have been completed and found satisfactory the contractor should carry out the installation tests necessary to demonstrate that the WD is working satisfactorily. The contractor is not required to carry out any thermometric tests unless these were specified in the purchase contract. Any assistance required from the purchaser should be agreed as part of the purchase contract.

2.31 If any modification, maintenance or repair work is carried out on the steam, water, compressed air ventilation or drainage systems after the installation tests have been completed, the relevant installation tests should be repeated before the operational tests are undertaken.

2.32 The schedule for installation checks and tests is set out in Chapter 4.

Operational tests

2.33 When the WD has been installed and accepted the MP/TP should carry out a sequence of operational performance tests to evaluate the basic performance and safety of the WD. Some of these tests are identical to those specified as installation tests and need not be repeated if operational testing follows within ten working days of the completion of the installation tests.

2.34 For operational tests see Chapter 5.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Performance qualification

2.35 Performance qualification is defined as the process of obtaining documented evidence that the equipment, as commissioned, will produce an acceptable product when operated in accordance with the specification.

2.36 Performance qualification consists of tests designed to show that:

a. soil removal and cleaning have been effective throughout the load and the WD chamber, and the products are of the required standard of cleanliness, free from process residues (when applicable);

b. disinfection conditions have been attained throughout the load and the WD chamber, and to the required standard for the type of load being processed. A thermometric test is sufficient for WDs employing a thermal disinfection process. Additional microbiological tests will be required for WDs that use chemical disinfectants and may be necessary for WDs where the nature of the load or loading conditions do not permit thermometric monitoring which accurately reflects the conditions pertaining in the load.

2.37 In principle, it might be argued that a performance qualification test is required for each loading condition that a WD is required to process. In practice, it is possible to identify reference loads and reference loading conditions which present an equal or greater challenge to the process than the loads which may be encountered in normal use.

Documentation

2.38 Accurate and efficient record keeping is an essential part of the management of a WD. The extent and nature of the records that are necessary varies with the type of WD and the use to which it is put. Guidance is given in SHTM 2030 Part 2, ‘Operational management’.

Summary sheets

2.39 On completion of the validation process the MP/TP should immediately prepare a summary report containing the results of the commissioning and performance qualification tests and essential working data.

2.40 The summary report should be signed by the MP/TP and countersigned by the user to certify that the WD is fit for use.

2.41 Summary reports should be securely retained by the user and be available for ready reference.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Validation report

2.42 Within one month of the completion of the validation process the MP/TP should prepare a full validation report which should include:

a. all the data supplied by the contractor, collected during the installation checks and tests, with written confirmation that they meet the manufacturer's specification;

b. written confirmation that the calibrations of all measuring instruments fitted to the WD have been verified;

c. all the data collected during the commissioning tests, with written confirmation that they meet the specified requirements;

d. data showing the correlation between the performance of the measuring instruments fitted to the WD and the test instruments used;

e. reports containing all the data collected during the performance qualification tests with written confirmation from the MP/TP and the user of the loading conditions and types of load (including when necessary reference to specific individual items) which may be satisfactorily processed in the WD.

2.43 When data is in the form of electronic data files, the report should include copies of disks or tapes containing the data in a format agreed with the user and a printout of the directory of each, annotated to show where the data for each test is to be found.

2.44 The MP/TP should certify that all necessary tests have been carried out and that the results are satisfactory.

2.45 The records of any microbiological tests should be signed by the microbiologist.

2.46 The Independent Advisor should review and countersign the completed validation report.

2.47 The validation report should be retained by the user. Copies may be retained as necessary by the MP/TP, the Independent Advisor, the Microbiologist, Estates Dept. and, where applicable, the Quality Controller.

Periodic tests

2.48 After validation and when the WD is passed into service, it should be subject to a schedule of periodic tests at daily, weekly, quarterly and yearly intervals, refer to (Table 5).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.49 The user, Microbiologist and the MP/TP are responsible for the periodic tests.

2.50 The daily, weekly and quarterly test schedules provide evidence that the WD continues to operate within the limits established during commissioning.

2.51 The yearly test schedule is a revalidation procedure and provides a more comprehensive test programme than the other periodic tests; it serves to demonstrate that data collected during commissioning and the performance qualification remain valid.

Revalidation

2.52 In addition to annual revalidation (Table 5), further revalidation is required in the following circumstances:

a. when the WD is to be returned to service after repair or component replacement of part of the systems which affect satisfactory attainment of the pre-set variables of the operating cycle;

b. when the pre-set values of the cycle variables have been modified;

c. when the software in a programmable electronic system (PES), used for control of the process, has been modified;

d. whenever the user or Independent Advisor advises that revalidation is necessary;

e. whenever it is required by an authorised inspectorate or licensing authority.

2.53 The full revalidation procedure is identical to that specified for the yearly test. See Chapter 7.

2.54 It will not always be necessary to carry out a full revalidation and the advice of the Independent Advisor, Microbiologist or the Control of Infection Officer should be sought on which tests are required following any particular event.

Repeat validation

2.55 Revalidation and periodic tests are designed to establish the continued conformance of the equipment and its performance with data established during the original validation study.

2.56 There are occasions when it may be necessary to repeat the full set of tests carried out during the initial validation in order to obtain a new set of data.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.57 Repeat validation will be necessary:

a. when the WD is modified to such an extent that it must be presumed that the original data is no longer valid;

b. when a WD, other than a table top machine, has been moved and installed at a new site;

c. when the WD has been dismantled or extensively overhauled;

d. whenever the user or Independent Advisor advises that repeat validation is necessary;

e. whenever it is required by an authorised inspectorate or licensing authority;

f. whenever revalidation fails to confirm compliance with the original data and no cause for the discrepancy can be found.

2.58 It will not always be necessary to carry out a full repeat validation and the advice of the Independent Advisor should be sought as to which tests are required following any particular event.

Types of test

2.59 The tests should fall into the following categories:

a. **Automatic control tests** which are designed to verify the correct functioning of the operating cycle from the readings obtained from the instruments fitted to the WD;

b. **Thermometric tests** which are designed to provide assurance that the temperature requirements for disinfection are met by using accurate measuring equipment, independent of the instruments fitted to the WD to monitor the temperatures attained within the chamber and reference loads;

c. **Microbiological tests** which are designed to show that disinfection conditions are attained when thermometric methods alone are inadequate for this purpose;

d. **Cleaning efficacy tests** which are designed to show, by monitoring the removal of a test soil, that the process will effectively clean products of the type to be processed.

2.60 Other performance tests specific to certain types of WD are designed to provide assurance that the WD will perform correctly under the anticipated conditions of use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Procedure on failure of a test

2.61 There should be no difficulty in ensuring that a correctly installed and maintained WD will comply with both the validation tests and periodic tests described.

2.62 Failure of a test generally indicates that a WD is not working to specification and it should be withdrawn from service and the failure investigated.

2.63 In practice, the action to be taken is a matter of judgement and will depend on the nature of the failure and the use to which the WD is being put. It may be acceptable for the WD to continue operating under carefully defined restrictions until the cause of the failure can be established and rectified.

2.64 The Independent Advisor and the user should agree the course of action to be taken.

2.65 The user has the ultimate responsibility for certifying that the WD is fit for use.

Inter-relationship of test programmes

2.66 The tests described in this part of SHTM 2030 are intended for use in type tests, works tests, commissioning (installation and operational tests), and performance qualification (thermometric tests, microbiological tests, cleaning efficacy tests and load dryness tests), and routine periodic tests.

2.67 The inter-relationship of the various test programmes, the place where they would usually be conducted and the responsibility for conducting the tests are shown in Figure 2.

2.68 The circumstances under which each of the test schedules should be applied is given in Table 1: ‘Summary of manufacturer's test programmes for WDs'.

2.69 The programmes of tests should be applied to all WDs where relevant. Details are given under the test schedules for particular types of WD.

3. Schedule of type tests and works tests

Introduction

3.1 The manufacturer carries out type tests on representative samples of WDs in serial production to demonstrate compliance of the WD design with its specification and/or published Standards as appropriate.

3.2 The manufacturer carries out works tests on each WD before it leaves the manufacturing site to ensure that each WD meets specification.

3.3 For WDs in serial production the programme of tests required for the works test is usually a reduced set of the tests in the schedule for type testing.

3.4 For WDs of 'one-off' design the schedule of works tests would necessarily be the same as the schedule for type testing.

3.5 Type tests, and more rarely works tests on one-off designs, may be carried out or witnessed by a third party to allow certification of the product to a relevant standard e.g. BS 2745 Part 2 or Part 3. The product certification scheme run by BSI leads to the award of the 'kitemark' for certified products. A similar scheme is operated through CEN for products complying with European Standards and compliant products may carry the CEN 'keymark'. Those clinical WDs which are classified as medical devices and are supplied on, or after, 14 June 1998 will be required to bear the CEN marking.

3.6 The manufacturer should make available to the purchaser the results of type tests and works tests on or before delivery of the WD.

3.7 It will rarely be necessary for the purchaser, or their representative, to visit the manufacturer's works to witness works testing except, perhaps, in the case of 'one-off' machines. The advice of the Independent Advisor should be sought.

3.8 A summary of the tests which should be included in a programme of type tests and works tests is shown in Table 1.

4. Schedule of installation tests

Introduction

4.1 On delivery of the WD the contractor should carry out the installation checks included in the contract and as set out in this chapter to establish that:

a. the WD has been provided and installed correctly;

b. the WD is safe to operate;

c. the WD does not interfere with other equipment;

d. all connected services are satisfactory and do not prevent attainment of the designed cleaning and disinfection performance of the WD.

4.2 The contractor responsible for installing the WD should carry out installation checks on services and other ancillary equipment. These checks should be completed and all services and ancillary equipment found to be satisfactory before carrying out installation checks on the WD itself.

4.3 The contractor responsible for installing the WD should carry out any additional checks specified by the manufacturer.

4.4 The MP/TP should carry out any checks specified in this chapter which were not included in the purchase contract for the WD.

4.5 As a safety precaution, checks on chemical dosing systems (for chemical additives such as detergents, disinfectants etc.) should be carried out using water. Checks on fume extract systems designed to eliminate personnel exposure to hazardous chemicals (for example gluteraldehyde) should be carried out using a non-hazardous substitute or a smoke test.

Checks on ancillary equipment

4.6 Ancillary equipment should, whenever practicable, be installed and commissioned before validation of the WD begins.

4.7 When the checks on ancillary equipment require the WD to be in operation, the MP/TP should carry them out in co-operation with the contractor for the WD.

4.8 The contractor for the WD is not responsible for the correct functioning of services and ancillary equipment unless this was agreed in the purchase contract.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Engineering services

4.9 Check that the following requirements are met:

a. the engineering services have been installed correctly, they are adequate to meet the demands of the WD, they do not leak and all necessary isolating valves/switches and test points have been installed;

b. drains remove effluent effectively when all plant in the vicinity, including the WD, is connected and operating;

c. the water treatment plant (if fitted) operates correctly and the quality of water supplied for each stage of the process is in accordance with the specification;

d. the provision for storage, handling and connection to the WD for all process chemicals, meets the requirements for safe handling of potentially hazardous chemicals;

e. the exhaust ventilation and/or condenser unit fitted to the WD is adequate to remove the hot, humid air evolved from the washing, thermal disinfection and drying and unloading processes;

f. for WDs employing volatile process chemicals, the exhaust ventilation maintains the environmental concentration below any limit specified for occupational exposure and that the discharge is to a safe place.

NOTE: The maximum permitted concentration and the method of detection and analysis will depend on the chemical being used.

Additional checks for WDs using a chemical disinfectant

4.10 WDs using chemical disinfectants require further tests to the ventilation and safety systems because of the possible emission of toxic gases or vapours.

4.11 For WDs using a chemical disinfectant, check that the ventilation system within the loading (or unloading) area of the WD, the plant room (if applicable) and the storage area for the disinfectant meet the specified requirements. Particular attention should be paid to the following:

a. the installation meets the manufacturer's specifications;

b. air flow is from the operator towards the WD and air does not flow from the plant room (if applicable) or disinfectant storage area into the loading (or unloading) area;

c. exhaust systems are non-recirculating and their discharges comply with relevant safety Regulations.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.12 Check that local exhaust ventilation incorporated in the WD or installed as a dedicated accessory meets the specified requirements. Particular attention should be paid to the following:

a. air flow is from the operator towards the WD;

b. the rate of flow complies with the specified requirements;

c. The exhaust discharge complies with safety Regulations.

4.13 When the disinfectant solution is intended to be discharged to drain ensure that the drainage system is trapped, sealed and vented to a safe position. The drainage system should be checked to ensure that it is not possible for toxic materials to be vented into any other part of the building.

Checks on the WD

Preliminary checks

4.14 Check that the electrical equipment on the WD is correctly connected to the electrical service. Carry out the following electrical tests:

a. insulation resistance;

b. phase sequence (for 3 phase installations);

c. polarity;

d. bonding and earth continuity;

e. emergency stop.

4.15 After the WD has been installed, check that the following requirements are met:

a. the manufacturer has supplied all the documents specified in the contract;

b. the WD has been supplied and installed in accordance with the contract;

c. calibration verification certificates for the measuring instruments and controller(s) on the WD have been supplied;

d. no defects are apparent from a visual inspection of the WD;

e. all supports, bases and fixings are secure and without imposed strain from service connections;

f. thermal insulation is in good condition and securely attached;

g. security and settings of door safety switches are in compliance with data

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

supplied by the manufacturer;

h. keys, codes or tools required to operate locked controls and control over-rides have been supplied, operate correctly and only operate the control for which it is intended;

i. loading conveyors and trolleys, load carriers and load baskets are effective and safe in use.

Functional checks

4.16 During an operating cycle, with an empty chamber, check that the following requirements are met (several cycles may be necessary to complete all the checks):

a. the selection of automatic or manual control is by key, code or tool. The selection of one control mode inactivates the other control modes;

b. under automatic control, water, steam, compressed air or chemical additives cannot be admitted into the chamber, and the operating cycle cannot start until the door is closed;

c. under manual control, the operator can advance the cycle only sequentially through each stage. Any stages designed to remove chemical additives from the chamber and load cannot be circumvented;

d. throughout the cycle, the indicated and recorded values of cycle variables are within the limits specified by the manufacturer;

e. throughout the cycle, there are no leaks of water, steam aerosols, toxics chemicals or effluent;

f. there is no evidence of interference to or from other equipment connected to the same services;

g. there is no evidence of electromagnetic interference to or from other equipment;

h. operation and reading of all instruments appear to be satisfactory;

i. the temperature of surfaces routinely handled by the operator does not exceed those specified in SHTM 2030 Part 2, ‘Design considerations’;

j. the effluent temperature does not exceed that specified in SHTM 2030 Part 1, ‘Design considerations’.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.17 At the end of the cycle check that the following requirements are met:

a. the door opening system cannot be opened until the cycle has been completed, that is, the automatic controller has operated in accordance with its specification;

b. for systems incorporating one or more cycle stages at pressures 200 mbar above or below atmospheric pressure:

(i) the door opening system cannot be operated until the chamber has been vented to atmosphere and the chamber pressure is within 200 mbar of atmospheric pressure;

(ii) the door retaining parts cannot be released until the seal between the door and chamber has been broken, and the chamber is effectively vented to atmospheric pressure.

Response to external faults

4.18 It is necessary to check that the WD reacts correctly and safely when exposed to a number of external fault conditions; that is, a safety hazard is not created and a false indication of satisfactory completion of a cycle is not obtained.

4.19 During an operating cycle, check the response of the WD to the following simulated faults (as appropriate to the type of WD):

a. operation of the emergency stop button;

b. power failure;

c. failure of the disinfection process;

d. failure of extract ventilation (chemical disinfection).

5. Schedule of operational tests

Introduction

5.1 To demonstrate compliance with specifications the contractor should carry out installation checks and tests before operational tests are carried out (see Chapter 4); these may be repeated by the MP/TP if required.

5.2 Operational tests and performance qualification (see Chapters 5 and 6) tests are carried out by the MP/TP.

5.3 Unless otherwise specified in Chapter 8 the tests should be carried out with the WD at normal working temperature, which may require a 'warm-up' run to be carried out before commencement of testing.

5.4 A number of the tests required can be carried out concurrently on the same operating cycle and this is also indicated in Chapter 8.

5.5 The calibration of test equipment should be checked before and after use as described in Chapter 8.

5.6 In principle, performance qualification tests should be carried out after operational tests have been completed. However, for WDs employing a thermal disinfection stage, the performance qualification tests may be performed while the temperature sensors used in the commissioning tests are still in place.

5.7 Although dishwashers generally are excluded from this SHTM, there may be instances where, due to local needs, dishwashers should be tested to verify compliance with current disinfection standards (especially in the case of patients who are immunologically compromised).

5.8 The responsibility for microbiological tests rests with the user, microbiologist and control of infection officer. The scope and contents of any tests will be incorporated in local protocols agreed between the above persons and will take account of local circumstances.

5.9 During the commission of WDs for endoscopes, the Occupational Health Officer should carry out tests on and around the machine for traces of disinfectant vapour, particularly in the vicinity of the door or lid when opening at the end of a process. The frequency of testing will be determined by the local Occupational Health Officer.

6. Schedule of performance qualification tests

Introduction

6.1 Performance qualification (PQ) is the procedure for obtaining documented evidence that the WD, as commissioned, will produce cleaned and/or disinfected goods of the standard required when operated in accordance with the operational instructions.

6.2 PQ tests are performed as part of the initial validation procedure, as part of any repeat validation procedure and whenever the user, acting on the advice of the Independent Advisor, judges that new loading or operating conditions require a new PQ test.

6.3 Circumstances that may lead to new PQ tests would include changes to the quality of the water supply, changes to the chemical additives used in the cleaning and disinfection process, changes to the loading system or the requirement to process a new type of product.

6.4 Performance qualification should not be undertaken on any WD until the requirements of the installation and operational tests specified in Chapters 4 and 5 have been met.

6.5 Soil removal efficacy tests are required for all WDs as part of the performance qualification (see Para 6.24).

6.6 Performance qualification tests are carried out by the MP/TP.

6.7 Tests should be carried out with the WD at normal working temperature which may require a ‘warm-up’ run to be carried out before commencement of the tests.

6.8 Test data obtained from the PQ tests should be recorded in a written PQ report which clearly identifies the loading conditions, the operating cycles, the chemical additives and the water quality used at each stage of the cycle.

6.9 The user should employ the PQ report to confirm the suitability of the process for loads which are to be processed. It should be used by the MP/TP and Independent Advisor as the basis for comparison with subsequent performance requalification tests.

6.10 Performance requalification (PRQ) is the process of confirming that the WD continues to meet the performance standards established during PQ and that the working data established during PQ tests remain valid.

6.11 Performance requalification is carried out annually as part of the yearly test schedule, as part of any revalidation or repeat validation study, or whenever the user requests such confirmation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.12 Before undertaking performance requalification tests the MP/TP should confirm, either by testing or by reference to current test records, that the WD meets the requirements of the installation and operational tests.

Loading conditions

6.13 A **loading condition** is a specified combination of the nature and number of load items, the items of chamber furniture, and their distribution within the chamber. For example, a load placed on the topmost level of a four level load carrier constitutes a different loading condition from the same load placed on the lowest level.

6.14 In principle, validation is not complete until a PQ test has been performed for each loading condition that the WD is expected to process.

6.15 In practice, the loading conditions specified in the tests to be carried out during commissioning are designed to represent the nature of production loads and to present a greater challenge to the process than production loads. In these cases further PQ tests will not be required; the data obtained from the commissioning tests will be sufficient.

6.16 PQ tests are required under the following conditions:

a. when the proposed production loading condition presents a greater challenge to the process than that presented by the commissioning tests; for example, WDs for surgical instruments will require PQ tests if the mass of metal instruments to be processed exceeds that of the standard test load or if it is intended to process instruments with narrow lumens;

b. when the nature of the load is not represented by the commissioning tests; for example, WDs for surgical instruments will require PQ tests if it is intended to process instruments with narrow lumens such as endoscopes.

6.17 When PQ tests are required it is often possible to select a production load that is known to be a greater challenge to the process than any of the others. This **reference load** can then serve as a ‘worst case’ and allow one PQ test to be valid for a range of less demanding conditions.

Surrogate devices

6.18 Many of the devices that constitute the most difficult loads to process in a WD, which therefore require PQ, are difficult to monitor either thermometrically or microbiologically, are in short supply and are extremely expensive; examples include fibre-optic endoscopes, videoscopes, etc.

6.19 A **surrogate device** is a test piece designed and constructed to emulate the characteristics of a device to facilitate appropriate monitoring of the cleaning and disinfecting processes.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.20 An example of a surrogate device might be a rigid endoscope emulated by a similar length of stainless steel tube of appropriate diameter and bore. The surrogate device can be constructed to incorporate the appropriate temperature sensors so that it may be separated into sections to facilitate the evaluation of residual test soil or survivors from a microbial challenge.

6.21 The surrogate device should have similar geometry and thermal mass and, as far as may be practicable, should be constructed of the same materials and the same surface finishes as the device it is designed to emulate. There are several devices available for assessing the efficacy of WD processes, and these can be used in conjunction with the reference loads as part of the testing procedures. Their suitability to a particular process should be verified before use. Advice should be sought from the Independent Advisor.

6.22 When an instrument presents particular problems in validation the manufacturer of the instrument should be requested to provide details of the method by which they recommend that PQ studies should be performed.

Cleaning efficacy tests

Native soiling

6.23 Cleaning efficacy tests are intended to demonstrate the ability of the WD to remove or reduce to acceptable levels, soiling and contamination which occurs during normal use of re-usable items.

6.24 Naturally occurring contamination shows considerable variation both in the nature and proportion of constituents and also in the extent of soiling which may occur during use.

NOTE: These tests should be carried out by the user in conjunction with the Microbiologist.

6.25 Test methods based on the detection of naturally occurring soiling are difficult to standardise and show poor reproducibility due to:

a. the variation in the composition of the soiling which may affect the ease with which soiling is removed;

b. the changes in sensitivity of detection which may occur due to variation in composition of the soiling;

c. the variation in the extent of soiling.

6.26 A number of methods exist for estimating (both qualitatively and quantitatively) the residual levels of some important soils or components of soils. These include detection of blood (Hydrogen peroxide test, Kastle-Meyer test), protein (Ninhydrin test, Biuret test) or bacterial endotoxins (LAL test).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.27 Common practice in the past has been to rely solely upon visual inspection to detect unacceptable levels of residual soiling. This method has poor sensitivity, is very subjective and can be greatly influenced by a number of factors including the intensity and nature of the illumination in the inspection area.

Test soils

6.28 Artificial test soils are designed to simulate the nature of native soiling and to be equally, or more difficult to remove.

6.29 By incorporating appropriate marker substances, they can provide improved sensitivity of detection.

6.30 Test soils can be used to give a quantified loading level, quantified detection and hence a quantified estimate of the soil removal which has occurred.

6.31 Test soils avoid any hazard which may be associated with native soiling (for example blood borne viruses) which may be of particular concern with the more extensive handling necessary for test work.

6.32 Worldwide, many different test soils have been specified for testing WDs but they generally fail to meet the key criteria necessary for a test soil.

NOTE: These tests should be specified by the Independent Advisor.

Standard test soils

6.33 Current proposals for the European standard for WDs are to specify a test method for the validation of test soils. This would allow acceptance of the use of any test soil which meets the defined criteria and is validated as equivalent to a particular native soil, or soils.

6.34 Test soils are specified in BS 2745.

NOTE: These tests should be specified by the Independent Advisor.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Process residues

6.35 The nature of process residues and the level of such residues that may be of concern depend on the chemical additives and quality of water used during the process and the intended use of the washed and disinfected product.

6.36 The water used for the process may give rise to a number of chemical residues on processed items. The most obvious of these is the presence of limescale from the use of hard water.

6.37 The water used for the process may give rise also to contaminants of microbial origin. Bacterial endotoxins, primarily derived from the cell wall of Gram negative bacteria, may give rise to adverse (pyrogenic) reactions when introduced into the mammalian body. Items not autoclaved and intended for surgically invasive use or for the preparation or administration of parenteral fluids should be free from, or have acceptably low levels of, bacterial endotoxins.

NOTE: These tests should be carried out by the user in conjunction with the Microbiologist.

6.38 The chemical additives used during the process (detergents, rinse aids etc.) may not be completely removed by the rinsing process. The residual level which may be tolerated will depend upon the nature of the chemical and the intended use of the product. The supplier of any chemical agent used should provide data on the chemical composition of the chemical agent and the biocompatibility of the components of the chemical agent. The supplier should also provide details of the method of detection, which may be used to determine whether processed items are free from residuals at the specified levels.

Disinfection

Thermometric tests

6.39 Thermometric tests are required for both thermal disinfection processes and chemical disinfection processes.

6.40 For thermal disinfection processes the time temperature relationships which are generally regarded as acceptable are shown in Table 3.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 3: Thermal disinfection temperature bands

Disinfection temperature (°C)[a]	Minimum exposure time (minutes)	Maximum allowable temperature (°C)
65	10	70
73	3	78
80	2	85
90	1[b]	95
93[c]	10	98

Note:

a. The disinfection temperature is measured at the surface to be disinfected.

b. The exposure time of 1 second (as specified in BS 2745 Part 1) is too short for reliable measurement and a minimum time of 1 minute should be used.

c. This time/temperature relationship is only used for items known to be contaminated with large amounts of pathogenic organisms, for example in laboratories.

Microbiological tests

6.41 A microbiological PQ test is required, in addition to the thermometric test, for WDs in which disinfection is carried out using a chemical germicidal agent (see Chapter 10).

6.42 Normally, microbiological testing is not required for thermal disinfection processes. If particular circumstances make such testing necessary or desirable the advice of the microbiologist should be sought. Direct evaluation of microbial efficacy within the WD is difficult. Whenever practicable, microbiological testing should be carried out by:

a. undertaking a laboratory investigation of the inactivation characteristics of the micro-organisms of interest (that is, by determination of the D value and Z value over the range 65ºC to 95ºC);

b. calculating from these data the exposure conditions necessary to give the required assurance of disinfection;

c. determining attainment of the required exposure conditions in the WD by physical measurement (temperature, time etc.).

NOTE: Advice of the microbiologist should be sought for these tests.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load dryness tests

6.43 The presence of residual water on cleaned and disinfected items is undesirable since it may interfere with the correct functioning of the item, promote re-contamination and microbial growth, or prevent attainment of sterilizing conditions. In many cases these data will already be available from the published literature.

6.44 The ability of the WD to dry the load may be evaluated either visually, when appropriate, or by drying to constant weight and determining the mass of residual water present at the end of the WD process cycle.

PQ report

6.45 All the data collected during PQ tests should be filed in a PQ report, a copy of which should be kept with the plant history file.

6.46 The PQ report should contain or refer to the complete specification for the washing/disinfection process. The specification should be sufficiently detailed to allow the loading condition and the operating cycle (including the type and volume of all chemical additives and the water quality) to be replicated on any future occasion.

6.47 The report should include the following:

a. a specification of the loading condition defined by the nature and number of the load items, items of chamber furniture and their distribution within the chamber; photographs taken of the load are valuable for future reference and can minimise the need for extensive descriptive text;

b. a specification of the operating cycle, defined by the settings for the cycle variables; for microprocessor based control systems a copy of the program held independently on electro-magnetic storage media is suitable also;

c. a specification of the service supply, defined by reference to the nature and volume of all chemical additives and the quality of the water service(s);

d. a specification of any pre-test operation of the WD, for example a warm-up cycle;

e. a specification of any pre-treatment of the test load, for example manual cleaning, ultrasonic cleaning etc;

f. all the indicated, recorded and measured data from the test; these should be annotated with the target values and permitted tolerances of elapsed time and other cycle variables at all significant points of the operating cycle, for example at the beginning and end of each stage or sub-stage;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

g. for WDs equipped with process recording, the original of the process record derived from the test should also form part of the record.

Master process record

6.48 A master process record (MPR) is a record of the values and permitted tolerances of cycle variables for a correctly functioning operational cycle against which test and production cycles can be checked.

6.49 It is derived from the process records obtained during a PQ test, or during commissioning when no PQ test was required.

6.50 The MPR may be a 1:1 copy of the process record from a chart recorder, a template derived from the process record or data stored in a computer system and compared automatically with the data from each production run.

6.51 An MPR is intended to facilitate production control on WDs when the attainment of the validated standards of cleanliness and disinfection are critical to the safe subsequent use of the product.

6.52 When a number of different processes and different loading conditions are to be used for production it will be necessary to prepare an MPR for each operational condition.

Tests for performance requalification

6.53 Performance requalification (PRQ) tests are performed once a year to ensure that the established criteria for cleaning and disinfection are still being met. The PRQ tests should follow the yearly schedule of tests and checks listed in Chapter 7.

6.54 For a given operating cycle it is necessary to perform the PRQ tests only for those reference loads for which a PQ test was performed and reported.

6.55 The need for additional PQ tests in the light of changes in the nature of loads being processed should be agreed between the user and the TP.

6.56 The procedure for the PRQ test is essentially the same as that used for the corresponding PQ test. The operating cycle and the loading conditions used should be identical with those used previously for the PQ test.

6.57 The PRQ test should be considered satisfactory if the values of the measured variables are within the tolerances stated in the PQ report.

6.58 The results of the PRQ tests should be linked with the relevant PQ report and retained securely.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.59 The PRQ test should meet the specified requirements without difficulty for a WD which has passed the yearly test programme. If the PRQ test is not satisfactory the advice of the Independent Advisor and/or the WD manufacturer should be sought.

7. Schedule of periodic tests

Introduction

7.1 Periodic tests are carried out at daily, weekly, quarterly and yearly intervals. They are the shared responsibility of the MP/TP, microbiologist and the user.

7.2 The yearly test schedule is identical to that required for revalidation. It contains the tests required for re-commissioning and for re-qualification of the performance of the WD.

7.3 Tests should only be undertaken after completion of the planned maintenance tasks described in SHTM 2030 Part 2; 'Operational management'.

7.4 Unless otherwise specified in Chapter 9 the tests should be carried out with the WD at normal working temperature, which may require a 'warm-up' run to be carried out before commencement of testing.

7.5 A number of the tests required can be carried out concurrently on the same operating cycle and this is also indicated in Chapter 9.

7.6 The results of periodic tests, whether carried out by the MP/TP, microbiologist or the user, should be filed securely, for example in the plant history file.

7.7 Although dishwashers generally are excluded from this SHTM, there may be instances where due to local needs, dishwashers should be tested to verify compliance with current disinfection standards (especially in the case of patients who are immunologically compromised).

Weekly safety tests

7.8 The user should examine the door seals as a safety check before starting the sequence of weekly tests.

7.9 For WDs which include a pressure vessel or pressure system (for example steam or compressed air), make any check required by the competent person in connection with the written scheme of examination for the pressure vessel.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Yearly safety tests

7.10 In order to ensure the continued safe functioning of the WD the MP/TP should conduct a series of safety tests before starting the yearly tests.

7.11 The Independent Advisor should draw up a documented programme of the yearly safety tests necessary for a particular installation.

7.12 The original installation checks and tests may be used as a basis for the yearly safety test paying particular attention to those factors which affect safety and especially to those which may have changed since the previous annual safety test (or installation test).

7.13 The adequacy and safe connection of all engineering services should be verified.

7.14 The responsibility for microbiological tests rests with the user, microbiologist and control of infection officer. The scope and contents of any tests will be incorporated in local protocols agreed between the above persons and will take account of local circumstances.

7.15 During the commission of WDs for endoscopes, the Occupational Health Officer should carry out tests on and around the machine for traces of disinfectant vapour, particularly in the vicinity of the door or lid when opening at the end of a process. The frequency of testing will be determined by the local Occupational Health Officer.

Schedule of typical periodic tests

Daily Test (where applicable)
- automatic control test
- check spray arm for rotation (if fitted)
- check spray nozzles for blockage
- remove and clean strainers/filters

Weekly Test (where applicable)
- carry out daily test
- cleaning efficacy

Quarterly Tests (where applicable)
- daily and weekly tests
- safety checks
- basic function of engineering services
- thermometric tests for disinfection
- chemical purity (water system)
- doors and interlocks (start, in cycle etc)

Yearly Tests and Revalidation (where applicable)
- daily, weekly and quarterly tests
- automatic control test (each cycle)
- verification of WD instrument calibration
- water system purity
- chemical dosing (reproducibility/low level detection)
- channel patency
- self disinfection
- ultrasonic activity
- load carrier temperature
- over temperature protection
- cleaning efficacy (consult Microbiologist/Independent Advisor)

The precise schedule of periodic tests should be agreed with the independent advisor, microbiologist and the control of infection officer, recognising the manufacturer's recommendations.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8. Test equipment and materials

Introduction

8.1 This chapter reviews the major items of portable test equipment necessary to carry out the test procedures described in this SHTM.

8.2 Instrumentation technology continues to advance rapidly making it increasingly difficult and undesirable to provide detailed specifications for the equipment to be used in testing WDs. There is a trend towards computer controlled data loggers with software which enables the system to verify attainment of the required conditions and then to produce a detailed written report accompanied by tabulated and/or graphed data. Although these new systems may offer advantages, the traditional instruments, such as chart recorders, remain the accepted standard.

8.3 The objectives of this chapter are both to ensure that traditional measurement methods are supported adequately and to define clearly the essential requirements that apply to the test equipment whether it is a traditional system or the latest technology.

8.4 When it is proposed to use measurement and/or recording techniques that are not covered in this SHTM the advice of the Independent Advisor should be sought.

8.5 It has been assumed also that there will be ready access to standard laboratory equipment and supplies.

Calibration and sources of error

8.6 The integrity of the measuring system is essential in order to obtain meaningful results. Significant errors can arise through improper use of calibration instruments and it is therefore important that staff are trained and skilled in their use. Two types of errors exist: Intrinsic and Introduced. Intrinsic errors relate mainly to the instruments best capability and usually cannot be improved upon without modification. Introduced errors may be very small or great, depending upon the skill used in the process.

Careful attention to detail including the location of the test instruments, effective maintenance and the skill of personnel trained in the application, handling and use of the instruments are required to eliminate or minimize errors. Systematic errors can be reduced by careful calibration.

8.7 Instruments should be subjected to a planned maintenance and calibration programme in accordance with the instrument manufacturer's recommendations. The drift status of instruments should be monitored to ensure that they remain within their intrinsic specification. Each instrument

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

should be labeled with a unique reference number, a calibration date, date due and a reference to a UKAS/NAMAS laboratory reference from which its current calibration status may be traced. If being transported, a suitable protective carrying case should be used.

8.8 The calibration of all test instruments should be verified at a frequency defined by the stability of the equipment. In the first instance the period should be at least yearly. Calibration should be carried out against reference instruments with a valid certificate of calibration provided within a NAMAS or ISO/EN17025 scheme of accreditation. A written procedure that describes the calibration method should be prepared and made available for the Independent Advisor to review. A history record should be kept for each instrument.

8.9 All test instruments should be located in a position protected from draughts and not subjected to rapid temperature variations. Test instruments should be allowed a period of time to stabilize within the environment of the test site prior to use. The instrument manufacturer's instructions should be followed.

Recorders

8.10 Test recorders are required to measure temperature in all types of WD and may also be required for the measurement of pressure, flow rates and humidity. They should be designed for use with the appropriate sensors, independent of those fitted to the WD. Most of the tests described in this SHTM may be conducted with a single recorder combining both temperature and pressure functions showing both records on the same chart or printout. For WDs incorporating humidity control or humidity monitoring of a hot air drying stage, the measurement of humidity is desirable but not essential.

8.11 Analogue recorders should comply with the display requirements of BS 3693. Recorders using a potentiometric system should comply with BS 5164.

8.12 Digital recorders (data loggers) have many advantages over traditional pen recorders. Data may be presented graphically or as a listing of numerical values or as a combination of both. In many cases parts of the operating cycle can be expanded and replotted for closer examination.

8.13 Digital recorders should have the facility to copy data onto tape or disk which can then be removed for secure storage. Software used with digital recorders should be developed under a quality system (such as BS EN ISO 9001).

8.14 The accuracies quoted by recorder manufacturers are measured under controlled reference conditions and do not include the errors from connected sensors. Temperature measurement errors due to ambient temperature changes should not exceed 0.04°C per °C rise.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Temperature measurement

Temperature sensors

8.15 Temperature sensors should be used to sense the temperature in locations specified in the tests described in this SHTM. The sensors should be either platinum resistance elements complying with BS EN 60751 or thermocouples complying with BS EN 60584.

8.16 The performance characteristics of the temperature sensor should not be adversely affected by the environment in which it is placed, e.g. pressure, hot detergent solution etc.

8.17 In order to avoid undue disturbance of the system being measured, the major diameter of the temperature sensors and their connecting leads which will be located within the WD should not exceed 2 mm.

Thermometric recording instrument(s)

8.18 One or more thermometric recording instruments should be used in conjunction with the temperature sensors to record the temperatures measured in the locations specified in the tests described in this SHTM. They may also be used to verify the readings obtained from instruments fitted to the WD.

8.19 The recording instrument(s) should record the temperature from a minimum of eight temperature sensors. The channels may be multiplexed or independent of one another. The data recording rate for each channel should not exceed 1.0 s. All data sampled should be used for the interpretation of results.

8.20 The scale range should include the expected maximum and minimum values of the cycle variables throughout the operating cycle with sufficient allowance for any deviations resulting from a malfunctioning WD. This should normally include at least the range 10°C to 110°C. Instruments determined as suitable for testing sterilizers according to SHTM 2010 will normally be suitable for most systems except tunnel washers.

8.21 In some WDs the air temperature close to the heater bank during the drying stage may considerably exceed the upper limit of the air drying temperature.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.22 The most critical stage of the WD operating cycle is the disinfection stage. It is during this period that the values of the cycle variables are at their most critical and the recorder should be capable of measuring them to sufficient accuracy to confirm that the disinfection conditions have been attained. The criteria are as follows:

a. For digital recorders, the sampling interval should be short enough for the holding time to contain at least five independent measurements in each recording channel;

b. The response time of the recorder should be short enough to enable the output to follow significant fluctuations in the cycle variables and to ensure that successive measurements are independent of each other. It should not be longer than the sampling interval;

c. The recorder must be accurate enough to show clearly whether the measured temperatures are within the disinfection temperature band. The intrinsic repeatability of the recorder should be ± 0.25°C or better and the uncertainty of measurement of the complete measurement system including sensors should be no more than ± 0.5°C taking all component errors into consideration. The additional error due to changes in environmental temperature should not exceed 0.04°C per °C;

d. For analogue instruments the minor mark interval should not exceed 0.5°C and the chart speed should be not less than 10 mm per minute/600 mm per hour. The resolution should be not less than 0.5°C. Digital instruments should register and record in increments of not more than 0.1°C.

NOTE: For the shortest holding time recommended (1 second at 90°C) this would correspond to a sampling interval of 0.2 second. However it is suggested that the minimum exposure time set should be not less than 12 seconds for which a sampling interval of 1 second is then appropriate. For pen recorders the chart speed should be fast enough to allow fluctuations on that scale to be clearly resolved. The duration of the holding time should be measurable to within ± 10%.

Use of sensors

8.23 WDs conforming to BS 2745 are equipped with thermocouple entry glands.

8.24 In older machines, having no dedicated entry port, sensors can be introduced through a door seal, with care. If possible, sensors should be distributed across the point of entry so that the integrity of the seal is not compromised, i.e. it is not good practice to introduce 8 thermocouples into a chamber via a door seal all at the one point since this will invariably compromise the seal.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

8.25 Many of the tests require a sensor to be placed at the reference point specified by the manufacturer as representative of the conditions prevailing throughout the chamber and load. This will usually be in the drain or sump of the chamber and will often be adjacent to the sensor used for the automatic controller.

8.26 The sensors may often be placed in positions where they are submerged for most of the cycle. Under these conditions water may migrate along the wire between the cores and the outer insulation sheath. To prevent damage to the recorder the outer sheath should either be punctured or stripped back a few centimetres from the end connected to the recorder to allow droplets of water to fall clear of the recorder.

8.27 Sensors used to monitor the temperature of load items and the chamber walls should be held securely in good thermal contact with the region to be monitored using high temperature masking tape or autoclave indicator tape.

Calibration

8.28 Calibration should be carried out in accordance with the instrument manufacturer's instructions by a validated method using a working or reference standard which is traceable to a UKAS/NAMAS laboratory reference.

8.29 It is normal practice to use a recorder which is routinely calibrated against an independent thermometer prior to measurement work on the WD being carried out. The independent thermometer is usually placed in a heat source or bath as are the recorder sensors. A comparison calibration is then carried out. The heat source should be of a design that meets the recommendation of publication EA-10.13 Feb 2000 'Guidelines on the calibration of temperature block calibrators'. Procedures used when applying comparison calibrations should also be in accordance with these guidelines. Comparison calibration is carried out before and after each series of tests on a WD. The heat source should be of a design that meets the recommendation of publication EA-10.13 Feb 2000 'Guidelines on the calibration of temperature block calibrators'. Procedures used when applying comparison calibrations should also be in accordance with these guidelines, and at a temperature within the disinfection temperature band.

8.30 Adjustment may be carried out to the recorder prior to testing to ensure the best results are obtainable. Following any adjustment, the temperature measured by all temperature sensors when immersed in a temperature source at a temperature within the disinfection temperature band should not differ by more than ±0.25 Deg ºC.

8.31 The temperature measured by all temperature sensors when immersed in a temperature source at a temperature known within ± 0.1°C and within the disinfection temperature band should not differ by more than 0.5°C after calibration and adjustment.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Self contained systems

8.32 Temperature measuring systems involving the use of leads from the sensing point within the load to an external measuring instrument are difficult or impractical to use within several designs of WD, for example continuous process machines consisting of several interconnecting cabins which are separated by intermediate doors during processing.

8.33 Single channel data loggers should only be used as a complementary test and trend of the full process. Full temperature mapping by traditional means remains the standard.

8.34 A number of different designs of small self-contained single channel data loggers for the measurement of temperature are commercially available. They are independently powered, may be programmed to take readings at the required rate for the required duration and are downloaded onto a personal computer on completion of the data logging period. Those housed in protective cases rated at IP68 are suitable for inclusion in washing machines.

8.35 Care needs to be taken in selecting units which are capable of withstanding the high temperature which may be found during the thermal disinfection stage (90°C) and drying stage (105°C) of the cycle since many of these devices are powered by batteries which will not withstand temperatures above approximately 75°C.

8.36 Data loggers with an external probe may be housed in an insulated waterproof container through which the lead to the sensor passes by means of a leak tight gland. A 25 mm thick layer of mineral wool insulation on all surfaces of a data logger contained within a 1000 ml screw top polypropylene jar has proved suitable. The waterproof container should protect the device from elevated temperatures.

8.37 The accuracy obtainable from these units is rarely to the standard specified for conventional temperature recorders but the limit of error should not exceed ± 0.8°C when tested over the range 0°C to 100°C at an ambient temperature of 20°C ± 3°C. Rapidly changing environmental temperatures, which can cause thermoelectric currents to alter measurement stability, are the most likely reasons for the greatest errors. The additional error due to changes in environmental temperature should not exceed 0.04°C per minute. Instruments should register and record in increments of not more than 1°C.

8.38 The device should be capable of recording the sensed temperature at least every 1 second and should be capable of storing not less than 1800 records.

8.39 For continuous process WDs, not less than three such devices will be needed together with a conventional temperature recorder.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Pressure measurement

8.40 Pressure may be required to be measured over the range from atmospheric to 10 bar (for example for the water supply pressure). Differential pressure of 1 –100 hectoPascals may be required to be measured (for example for the determination of the pressure drop across filters).

Transducers

8.41 Transducers for use with pressure recorders should conform with BS 6447, be suitable for the purpose and be of an accuracy equal to, or better than, the gauges specified below. The natural frequency of the sensor and connected tubing should be not less than 10Hz and the time constant for rising pressure (0–63%) should be not greater than 0.04 seconds.

Gauges

8.42 Pressure gauges are required when the pressure recorder is unsuitable or for verifying the calibration of pressure instruments fitted to the WD.

8.43 Three pressure gauge ranges will normally cover the whole pressure range for all WDs.

8.44 Pressure gauges should be temperature compensated and except for the differential pressure gauge be Bourdon-tube gauges conforming to BS EN 837 of nominal size 150 mm and accuracy class 0.25 (that is, the air should not exceed 0.25% FSD).

8.45 Gauges should be tested yearly by a recognised testing laboratory as described in BS EN 837-1, 1998.

8.46 The measurement of differential pressure across air filters may be made with an inclined water manometer.

8.47 The recorder for pressure measurement should have an overall limit of error no more than 1% of the maximum specified operating pressure.

Flow measurement

Water

8.48 The volume of water used for each stage of the operating cycle may be measured using a water meter complying with BS 5728.

8.49 The meter should be designed to operate at temperatures up to 90°C with a supply pressure up to 16 bar.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: When the meter is connected in the pipe there will be a noticeable pressure drop across the meter. Although this should be less than 1 bar it may interfere with the normal operation of the WD and therefore should not be used during tests for other characteristics than the volume of water used.

8.50 The meter should have a minimum scale division of 0.1 litres or less and be designed to measure flow rates over the range 1 litre per minute to 25 litres per minute.

8.51 A single jet turbine system is sufficiently accurate for the purpose. Other systems such as multi-jet turbine or semi-positive displacement systems complying with BS 5728 Class D, may also be used.

Chemical additives

8.52 The volume of chemical additive used for each stage of the operating cycle may be measured using a flow meter. There are a number of commercially available flow sensors designed to monitor flows in the range 0 to 2 litres/minute which are suitable for interfacing to a recorder or datalogger.

8.53 The sensor should be designed to operate at temperatures up to 70°C with a supply pressure up to 10 bar.

8.54 The system should have an accuracy of ± 2.5% of full scale deflections or better.

8.55 The calibration of the meter should be verified by determining the indicated volume flowing, using a graduated measuring cylinder.

Gas monitoring equipment

8.56 A gas monitoring instrument is required for tests on WDs using chemical additives which have a significant vapour pressure and are a potential risk.

8.57 The nature of the instrument will depend on the substance to be monitored. In case of doubt, advice should be sought from the manufacturer of the chemical additive or the Independent advisor.

8.58 The scale range of the measuring instrument should include the appropriate short term exposure limit or occupational exposure limit and extend to at least ten times that exposure limit.

Aerosol generator

8.59 An aerosol generator is required for tests on WDs incorporating air filters intended to deliver air free from micro-organisms.

8.60 The device should be capable of generating a polydisperse aerosol with

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

particles having the size distribution shown in Table 6.

Particle counting photometer

8.61 A particle counter is required for tests on WDs incorporating air filters intended to deliver air free from micro-organisms. The device should be suitable for estimation for comparison of mass concentration of airborne particles as defined in Table 6.

8.62 It should have an accuracy of better than ± 5% over the range of a five-expandable, six-decade resolution (that is 0.01% to 100% of the test cloud) as specified in Appendix C of BS 5295: Part 1.

8.63 The photometer should have a minimum threshold sensitivity of 0.0001 μgl^{-1} and should be capable of measuring aerosol concentration in the range 80-120 μgl^{-1}.

8.64 The sampling flow rate should be 0.40 ± 0.05 ls^{-1} and sampling should be via a suitable probe.

Table 6: Particle size distribution for aerosol generator

Particle size µm	Fraction % by mass
<0.5	>20
<0.7	>50
<1.0	>75

9. Testing methods

Introduction

9.1 This chapter discusses general principles and methods that are used in the tests described in this SHTM.

Terminology

9.2 For the purposes of this SHTM the following definitions have been adopted.

Cycle variables

9.3 The **cycle variables** are the physical and chemical properties such as time, temperature, pressure, flow rate, concentration and chemical composition that influence the efficacy of the cleaning and disinfection processes. Many of the tests described in this SHTM require the values of cycle variables to be determined experimentally and then compared with specified or standard values.

9.4 An **indicated value** is that shown by a visual display fitted to the WD.

9.5 A **recorded value** is that shown on the output of a recording instrument fitted permanently to the WD.

9.6 A **measured value** is that shown on a test instrument, for example a temperature recorder attached to the WD for test purposes.

9.7 A **noted value** is that written down following personal observation of an indicated, recorded or measured value.

Disinfection conditions

9.8 Most operating cycles have a stage in which the load is exposed to the disinfection conditions for a specified length of time. This period is known as the **holding time**.

9.9 The **disinfection conditions** are the ranges of the cycle variables which may prevail throughout the chamber and load during the holding time.

9.10 The holding time is preceded by a period in which the disinfection conditions are present in the chamber but have yet to be attained throughout the load. This is known as the **equilibration time**.

9.11 Together the equilibration time and the holding time constitute the **plateau period**. The plateau period can always be determined from the indicated or recorded temperature in the chamber during each cycle. The equilibration

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

and holding times cannot be ascertained unless the temperature in that part of the load which is slowest to reach temperature is also being measured.

9.12 For thermal (moist heat) disinfection, the disinfection conditions are specified by a **disinfection temperature band**, defined by a minimum acceptable temperature, known as the **disinfection temperature**, and a **maximum allowable temperature**.

9.13 The higher the disinfection temperature the shorter the holding time which will be required to achieve the same level of disinfection (see Table 3).

9.14 For liquid chemical disinfection, the disinfection conditions are specified by a **disinfection temperature band** and a **disinfectant contact concentration range**. The disinfection temperature band is defined by a minimum acceptable temperature, known as the disinfection temperature and a maximum allowable temperature. The disinfectant contact concentration is specified by the minimum acceptable concentration in contact with the load to be disinfected and the maximum allowable concentration.

9.15 For those WDs in which the chemical disinfection stage is thermostatically controlled at elevated temperature, the duration of the exposure to chemical germicide may be determined thermometrically. In most cases, investigation of the performance of chemical disinfection processes can only be carried out successfully using microbiological test methods in conjunction with physical testing.

9.16 The disinfection temperature band may also be quoted for liquid chemical disinfection/sterilization processes but is not a complete specification of the disinfection conditions since the efficacy of such processes depends also on the concentration of the chemical agent.

Blocked drain protection (Commissioning Test)

Introduction

9.17 In the event that the drain from the chamber of the WD become blocked, continued operation of the WD must not allow water and suspended soil to be discharged either during the operating cycle or, for cabinet type WDs with sealed door(s), by sudden discharge when the door is opened at the end of the cycle.

9.18 The purpose of blocked drain protection is to prevent spillage and minimise the risk of cross-infection.

9.19 In the test, the drain is deliberately blocked and successive operating cycles are run until the water level is above the level of the door seal. The test is intended for use both as a type test (and as such is a requirement of BS 2745: Part 2 1993) and as an installation test.

9.20 The manufacturer should be consulted to detail a suitable test method.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Estimation of dead volume of pipework (Manufacturers Type Test)

Introduction

9.21 Residual water that does not drain from the internal pipework of the WD may provide an environment for microbial growth; these micro-organisms may then be available to re-contaminate the disinfected load.

9.22 The test is intended primarily as a Type test but may also be of value as an operational test or when investigating microbial contamination occurring in a WD.

Equipment

9.23 Volumetric measuring vessels of appropriate size are necessary.

Method

9.24 The pipework of the WD which is known to be dry (either following dismantling and re-assembly or purging with dry compressed air for not less than 30 minutes) is flushed with a known volume of water (simulating the flow that would occur in normal use).

9.25 The volume of water flushed through the system should be twice that determined as the volume used per operating cycle. The volume of water discharged is measured and the dead volume, estimated as the volume retained, calculated from the difference between the two values.

9.26 When the WD has two or more pipework systems which are entirely separate (for example for flushing water, wash water, rinse water, chemical disinfectant solution) each system may be tested separately.

Results

9.27 The volume of retained water should be less than 1% of the volume of water used.

For WDs with chemical disinfection systems, the retained volume in the pipework providing the final rinse volume should be, as nearly as possible, zero.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Water system

Introduction

9.28 A continuous supply of water of the specified chemical and microbiological quality is essential to the correct functioning of all WDs. Water which is too hard or has too high a concentration of dissolved solids may impair the activity of detergents (or require the use of increased quantities of chemical additives) and cause deposits, scaling or corrosion of items being processed.

9.29 Water containing high numbers of micro-organisms may recontaminate disinfected items. For all these tests the water should be sampled from the water supply pipe to each WD. Additional samples may need to be taken from any water treatment plant when trying to identify the cause of a non-conformity.

9.30 Testing of water should be carried out by the microbiologist. The following is a typical example of sampling and testing method.

Water samples

9.31 Water samples should be obtained from draw-off points installed at convenient locations within the system.

9.32 The sampling procedure should be suitable for all the physical, chemical, and biological determinands of interest. It may be used for water samples throughout the water distribution system.

9.33 The sampling containers used should be specific for the determinants of interest. This should include, as appropriate:

a. 330 ml sterile single use plastic containers containing sodium thiosulphate for testing of microbiological quality of water (total coliform, faecal coliforms, and total viable count at 37^{o}C);

b. 250 ml sterile, pyrogen free, single use containers (for determination of bacterial endotoxin levels and/or total viable count);

c. 1 litre acid washed, borosilicate bottles, (for determination of cations);

d. 1 litre polypropylene bottles, (for determination of anions, total dissolved solids);

e. 100 ml high density polyethylene bottles (for determination of pH, conductivity).

9.34 The first 50 ml of sample taken at each sampling point should be run to waste.

9.35 All samples should be taken in duplicate.

9.36 Samples should be tested within four hours of collection or stored at 2°C to

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

5°C and tested within 48 hours of collection.

Water quality tests

9.37 The following sections describe analytical methods which may be used to determine the various biological, physical and chemical properties of water samples for the various qualities of feedwater to the WD.

9.38 The methods of analysis required to detect chemical contaminants at low concentrations with a high level of accuracy require the use of a laboratory with appropriate expertise, facilities and experience. Other tests can be carried out on-site or with very simple laboratory facilities; these lack the precision and sensitivity of the laboratory tests but are sufficient for most purposes.

NOTE: Advice on the testing of sterile water for final rinsing, should be sought from the microbiologist.

9.39 This SHTM contains detailed procedures for tests which may be carried out on-site or with very simple laboratory equipment at, or shortly after, the time of sampling.

9.40 The precision, accuracy, sensitivity and limits of detection of these methods are usually inferior to those of laboratory methods. They are useful, however, in that they provide evidence of any gross failure and the results are available straightaway making them of diagnostic value during a fault finding exercise. They are generally economical compared with more sophisticated laboratory analysis and can be carried out by non-specialist personnel after thorough, but limited, training. The results should not however be used as evidence in cases of dispute.

Choice of method

9.41 For any given determinant there will usually be several methods which are suitable and cover the range of concentrations of interest. The methods given below are intended to be representative of those which may be suitable. They are chosen as examples of tests which may conveniently be carried out on site.

9.42 A number of test systems are available commercially. Before adopting one of these methods care should be taken to ensure that the test(s) provides results of sufficient accuracy and sensitivity.

9.43 It is not necessary to use experienced chemical analysts to undertake the on-site analysis of water samples described. It is, however, essential that personnel receive appropriate training before attempting to carry out this work.

9.44 It is apparent that many contaminants will be detected by two or more of the determinations normally carried out for laboratory analysis. For example, an

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

increase in one or other of the ionic species present will cause an increase in electrical conductivity and an increase in the evaporative residue as well as showing an increase in the concentration of that particular ion.

9.45 Further guidance on appropriate test methods may be obtained from BS 1427: 1993.

9.46 Tests suitable for use on-site fall into three main categories:

a. **instrumental tests** using portable instruments designed for on-site use for example portable pH meters, ion selective electrodes etc.;

b. **spectrophotometric tests** based on measurement of the absorbance of a coloured reaction product; measurement may be visual or photometric and may be against a precalibrated coloured disc or against standard reference solutions;

c. **titrimetric tests** these may be carried out using standard laboratory equipment or with commercially available apparatus designed for field use; the latter is usually much simpler to use.

9.47 For all the instrumental methods described there is commercially available equipment specifically intended for field use. All the variables for which instrumental methods are described are temperature dependent. The equipment used should be temperature compensated. Also the equipment should be allowed sufficient time on site, before it is put into use, to equilibrate to the local ambient temperature.

9.48 Commercially available test kits based on visual or photometric comparison with coloured discs have become an accepted standard for on site analysis. Manufacturers usually supply a complete test system, including kits of reagents. To ensure compatibility, and maintenance of the manufacturers claimed sensitivity and accuracy for the method, the kit specified by the manufacturer should not be substituted.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Water supply temperature

Introduction

9.49 The water supplied to the various stages of the WD operating cycle should be at an appropriate temperature. If the temperature of the water supplied to the flushing stage is too high (> 45°C) there is a risk of coagulating proteinaceous soiling and inhibiting the cleaning process. If the temperature of water supplied to the washing, rinsing and disinfection stages is too low the WD cycle may be greatly extended, with a significant reduction in throughput, while the water is heated to the required temperature within the WD. Water supplied in the temperature range 25°C to 40°C presents a serious risk of microbial contamination of the system.

Equipment

9.50 An indicating or recording thermometer is necessary.

Method

9.51 The temperature of the water supply should be measured from a sampling point as close to the WD as possible. Place the temperature sensor in the middle of the flowing stream as close as practicable to the sampling point. Allow the water to flow for at least a minute before the temperature is read.

Alternative method (for periodic testing)

9.52 When it is not convenient, or practicable, to run the water to waste from a sampling point close to the WD the water temperature may be estimated by measurement of the temperature of the outer surface of the supply pipe. When it is intended to use this method the correlation between the temperature of the water flowing out of the pipe and the surface temperature of the pipe at a particular point should be established during installation testing. The surface temperature should be measured using a sensor designed for the purpose and the manufacturer's instructions for ensuring good thermal contact with the surface should be followed. The temperature should be noted or recorded during a normal operating cycle not less than 30 seconds after the start of water flow through the pipe to the WD.

Results

9.53 The noted value should be within the temperature range specified for the installation.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Water supply pressure

Introduction

9.54 If the pressure of the water supply to the WD is below the minimum pressure specified by the manufacturer, the performance and productivity of the WD will be affected adversely.

9.55 If the pressure of the water supply to the WD is above the maximum pressure specified by the manufacturer, the capacity of overflow devices may be inadequate, the designed performance characteristics of valves etc. may be exceeded and in extreme cases there may be the risk of damage to components of the WD or to products being processed. (For example many flexible endoscopes are likely to be damaged if subjected to internal pressures greater than 35 kPa.)

9.56 The test should be carried out as an installation and/or operational test. The test should be repeated when any change is made to the water services supplying the WD (including the connection or removal of other machines).

Equipment

9.57 Pressure indicator or recorder 0–10 bar is necessary.

Method

9.58 The pressure sensor should be connected to each of the water supply pipes to the WD, as close to the WD as may be practicable, on the supply side of the WD isolating valve for that supply. The static pressure when the valve is closed and the pressure indicated throughout a normal operating cycle should be recorded or observed and noted. When the water service also supplies other equipment on the same supply line, the test should be run both with the other equipment operating throughout the test (or their operation simulated by an appropriate discharge to waste) and with no other equipment operating.

Results

9.59 The water pressure should remain within the supply pressure limits specified by the WD manufacturer.

Overflow test

Introduction

9.60 For WDs which incorporate one or more water storage tanks within the WD the capacity of the overflow(s) to discharge all excess water, as intended, without spillage into the WD or working area should be verified.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Method a: Type test or Works test

9.61 The WD should be connected to all necessary services and the water supply pressure adjusted to not less than 6 bar under the conditions of flow which prevail with the supply valve(s) fully open.

9.62 Fully open the supply valve(s).

9.63 Observe the level of water in each tank or cistern until this has been unchanged for not less than 2 minutes.

Method b: Installation test

9.64 The WD should be connected to all necessary services.

9.65 Fully open the supply valve(s).

9.66 Observe the level of water in each tank or cistern until this has been unchanged for not less than 2 minutes.

Results

9.67 The WD and installation should be regarded as satisfactory when equilibrium conditions have been attained within the tank(s) without discharge of water other than by the intended (piped) overflow.

Volume of water used per stage

9.68 During type testing, the manufacturer should be required to determine the volume of water used during each stage of the cycle. These data are used in calculations of the service requirement (see SHTM 2030 Part 1; 'Design considerations'). The volume of water used for each stage of the cycle should be within ± 5% of the volume specified by the manufacturer.

Doors and door interlocks

Cycle start interlock

Introduction

9.69 The interlock should prevent a cycle being started with the door open.

Method

9.70 Testing should be carried out as follows. The doors should be left open and unlocked. All services should be connected. An attempt should be made to initiate an operating cycle.

9.71 The doors should then be closed and locked and a further attempt made to initiate an operating cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Results

9.72 It should not be possible to initiate a cycle with the door(s) left open. With the door(s) closed it should be possible to initiate an operating cycle.

In-cycle interlock

Introduction

9.73 An interlock is required to ensure that the door(s) cannot be deliberately or inadvertently opened while the WD is in operation.

NOTE: When practicable, the interlocks should be visually inspected to verify engagement before attempting to open the door.

Method

9.74 The door(s) should be closed and locked and the operating cycle started. While the operating cycle is in progress an attempt should be made to unlock each of the doors.

Results

9.75 In these circumstances it should not be possible to unlock any of the doors.

Double-ended WDs

Method

9.76 Both during and between cycles, attempts should be made to open either or both the loading door and unloading door of the double ended WD.

Results

9.77 It should not be possible to open the unloading door after initiation of a cycle until a cycle has been completed satisfactorily.

9.78 It should not be possible for both doors to be opened at the same time.

9.79 It should not be possible to open the loading door until a cycle has been satisfactorily completed and the unloading door has been opened and closed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Failed cycle interlock

Introduction

9.80 The interlock should prevent an operator from removing a load in the normal manner at the end of a cycle which failed.

Method

9.81 During an operating cycle one, or more, of the services to the WD should be interrupted sufficiently to cause a cycle failure.

Results

9.82 A ‘fault’ should be indicated. It should not be possible to open the unloading door (if fitted); it should only be possible to open the loading and/or unloading door by means of a special key, code or tool.

Fault indication on sensor failure

Introduction

9.83 A failure of any sensor used as part of the control system of the WD should cause a fault to be indicated by the automatic controller.

Method

9.84 Each sensor providing information to the automatic controller is disabled in turn to establish that a fault is indicated.

9.85 Testing of each sensor should be carried out as follows. An operating cycle should be started. During, or before, the stage of the cycle at which the sensor is intended to provide data used to determine the control of the cycle the sensor should be disabled.

9.86 Each sensor should be tested in both ‘open circuit’ and ‘short circuit’ failure modes.

Result

9.87 A fault should be indicated during or at the end of the cycle. It should not be possible to open the door on a single-ended WD or the unloading door of a double-ended WD.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chemical dosing

Reproducibility of volume admitted

Introduction

9.88 The test is intended to verify the setting for the dispensed volume of chemical additive(s) and to ensure that it is reproducible within defined limits. The test should be carried out for each chemical dosing system on the WD.

Equipment

9.89 A flow meter of appropriate range may be used.

A measuring cylinder to BS 604: 1982 (1993) is necessary [or BS 5404: Part 2: 1977 (1994) when compatibility with the chemical additive to be measured has been established].The size of measuring cylinder should be appropriate to the volume of chemical additive to be dispensed.

Method

9.90 Testing should be carried out as follows:

a. Disconnect the supply line to the chamber as close as possible to its discharge point into the chamber or water circulation system;

b. Actuate the dosing system and collect the discharged volume of the chemical solution in the measuring cylinder;

c. Repeat the test three more times. Record the volume dispensed on each test.

Results

9.91 The mean collected volume from the final three tests should be within ± 10% of the nominal dispensed volume.

Care is required since many of the concentrates used are irritant or corrosive. Water may not be an acceptable substitute because, for many dosing systems, differences in viscosity can affect the dispensed volume.

Indication of insufficient chemical additives

Introduction

9.92 The use of the correct volume of chemical additive(s) is necessary for the correct functioning of the WD. The WD should be equipped with means to ensure that a cycle is not initiated when there is insufficient chemical additive remaining in the reservoir to complete a cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9.93 The test should be carried out for each chemical dosing system on the WD.

Method

9.94 A low level of additives is placed in the dispenser reservoir and repeated cycles are run. Care is required since many of the concentrates used are irritant or corrosive. Water may not be an acceptable substitute because, for many dosing systems, differences in viscosity can affect the dispensed volume.

9.95 Fill an otherwise empty container with sufficient chemical for more than 2 but less than 4 operational cycles. Run the WD on 3 consecutive cycles. Estimate the volume remaining at the end of each cycle (pre-marked container, dipstick, or weight).

Results

9.96 The WD should indicate at the beginning of the third or fourth cycle that there is insufficient chemical remaining to complete a cycle.

Instrumentation fitted to WD

Verification of calibration

9.97 Specifications for instruments fitted permanently to WDs are given in the relevant British Standards and will be included in the forthcoming European Standards; they are discussed in SHTM 2030 Part 2; ‘Design Considerations’.

9.98 The calibration of instrumentation fitted to the WD should be verified by comparison with calibrated test instruments during steady state conditions e.g. the temperature during the disinfection hold period. A reference channel should be identified on the recording equipment and placed in the same position as the indicating sensor to ensure that the measurement probe is in the same position as the indicating probe.

9.99 This may be carried out concurrently with other testing, for example during the automatic control test during quarterly periodic testing.

Load carriers

Introduction

9.100 Load carriers come in a variety of forms including trolleys, carriages and baskets. Their correct functioning is essential to the successful outcome of a WD operating cycle. It is important that they cannot easily be misaligned, that they function correctly and that, when applicable, they make good connection with service supply points in the chamber and with load items (when necessary).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Method

9.101 The alignment of load carriers, their connection to water, air or chemical additive supply in the chamber (when applicable) and their connection to load items e.g. cannulated instruments (when applicable) should be verified by visual observation.

9.102 Load carriers with rotary spray arms should be checked to ensure that the spray arms are free to rotate, both when the load carrier is empty and when fully loaded.

Thermometric tests

9.103 Thermometric tests are carried out to verify the attainment of the specified conditions throughout the chamber and load during the operating cycle. Continuous process WDs and multi-chamber WDs in which the use of recorders with fixed sensors is impractical should be tested using single channel data loggers that can be processed through the WD. The use of biological indicators as a substitute for thermometric testing is not acceptable.

Load carrier temperature (Validation Tests, Yearly Tests & Re-validation)

Equipment and materials

9.104 A temperature recorder complying with the requirements specified in Chapter 8 and having not fewer than six sensors is necessary.

NOTE: Three independent data loggers and a temperature recorder having at least one sensor may be used as an alternative.

Method

9.105 Temperature sensors should be located at two diagonally opposite corners of the load carrier, in the approximate geometric centre of the load carrier and adjacent to the temperature sensor used as the reference sensor for chamber temperature and one on each door of cabinet washer.

9.106 The temperature attained should be measured throughout three operating cycles (3 tests for validation, 1 test for yearly), the first of which should be at least 60 minutes since the machine was last used (a ‘cold start’) and the final three with not more than a 15 minute interval between cycles (a ‘hot start’). The WD should be operated empty except for chamber furniture (for example load carriers).

9.107 The load carrier should be replaced between cycles with a load carrier at ambient temperature.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9.108 Multi-chamber WDs may be tested with each chamber tested consecutively using independent data loggers to record the temperature of the load carrier. A temperature recorder with fixed sensors may be used to record the temperature adjacent to the reference sensor.

9.109 This test may be run simultaneously with the chamber wall temperature test.

NOTE: When the length of cycle and/or the number of data-loggers available precludes re-use of the data-loggers with not more than 15 minutes between cycles the WD should be kept in continuous operation so that when the second and subsequent tests are initiated not more than 15 minutes has elapsed since the first chamber completed a cycle.

Results

9.110 The results should be the following:

a. The temperatures recorded on the surface of the load carrier should be within the range 0°C to 5°C of the disinfection temperature throughout the holding period for the disinfection stage;

b. The temperatures recorded on the surface of the load carrier should be within ± 5°C of the set temperature for the relevant stage throughout the holding period for each of the other stages;

c. The temperature indicated/recorded by the WD instruments should be within ± 2°C of that recorded by the test instrument from the sensor adjacent to the reference sensor throughout the holding period for the disinfection stage;

d. The temperature profile obtained for the operating cycle should be consistent within ± 2°C for the last three test cycles.

Over-temperature protection

Introduction

9.111 The WD is fitted with over-temperature protection (i.e. 5°C above the operating temperature) to ensure that, in the event of the automatic control failing to control the temperature in the WD, the temperature will not rise to a level which would damage the load in the WD.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Equipment and materials

9.112 A temperature recorder complying with the requirements specified in Chapter 8 and having not less than 4 sensors is necessary.

Method

9.113 Temperature sensors should be located at two diagonally opposite corners of the load carrier, in the approximate geometric centre of the load carrier and adjacent to the temperature sensor used as the reference sensor for chamber temperature.

9.114 The WD, empty except for the load carrier, should be operated on a normal operating cycle. For multi-cycle machines the two cycles that have the highest and lowest operating temperatures should be tested.

Results

9.115 The over-temperature protection should operate at a temperature not more than 5°C higher than that provided by any temperature control or temperature limiting device.

Load dryness

Introduction

9.116 The presence of residual water on cleaned and disinfected items may interfere with the correct functioning of the item, promote re-contamination and microbial growth or prevent attainment of sterilizing conditions.

9.117 The dryness of most items may be evaluated visually. The dryness of the internal surface of lengths of tubing may be tested by blowing through with dry compressed air onto a mirror; misting of the mirror will indicate residual internal moisture.

Air quality

Introduction

9.118 Many WDs are fitted with air filters to remove particulate material from the air supplied to the drying stage. These filters are often HEPA filters (for example EU 12/13) of the type used to remove bacterial contamination from the air supply. When they are used as general particulate filters, performance tests will not normally be required for the filter or the filter housing. The filter and filter housing should be tested when the intention is to provide air free from bacterial contamination when the load is intended for use without further processing (for example sterilization).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9.119 Microbial sampling will not normally be required for either system unless otherwise specified.

Method

9.120 The complete installation should be tested using the method described in BS 5295: Part 1 Appendix C: ‘Method of testing for the determination of filter installation leaks’. A challenge aerosol of inert particles of the type produced by a dispersed oil particle generator should be introduced into the air upstream of the filter. The downstream face of the filter and its housing should then be scanned for leakage using a photometer.

Results

9.121 The reading on the photometer should be steady and repeatable and should not exceed 0.01% of the upstream reading.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10. Disinfection efficacy tests

Introduction

10.1 Thermometric tests are required for both thermal disinfection processes and chemical disinfection processes. For thermal disinfection processes, the time temperature relationships which are generally regarded as acceptable are shown in Table 2. Microbiological testing is only required for chemical disinfection processes.

10.2 Temperature monitoring of the load should be used to determine the attainment of the required time-temperature conditions.

Thermometric test for disinfection

10.3 This test is suitable for all WDs and should be used to establish the adequacy of temperature control during chemical disinfection as well as for verifying attainment of thermal disinfection conditions.

10.4 The load under test will consist of a reference load (see Chapters 12 to 18) or a performance qualification load of discrete items of the type which the WD under test is intended to process, or of surrogate devices used to simulate such load items.

Equipment

10.5 The following equipment is necessary.

10.6 A temperature chart recorder calibrated 0°C–120°C in accordance with UKAS/NAMAS traceability.

NOTE: For type 1 machines and type 2 machines without physical separation of compartments (Conveyor WDs) sensors may be passed into the chamber through the thermocouple entry port into the chamber.

10.7 **Method**

Temperature sensors should be placed in the following positions:

a. sensors on product items at each level in the load carrier;

b. one on an item in the region known to be slowest to attain the disinfection temperature;*

c. one on an item in the region known to be fastest to attain the disinfection temperature;*

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. one adjacent to the automatic control temperature sensor;

e. one adjacent to the process recorder sensor (if fitted) in each chamber or compartment;

f. one on each door of double door cabinet WD.

NOTE: *These positions should be specified by the manufacturer and supported by data type tests. If these data are not available from the manufacturer, preliminary tests to map the temperature throughout the load will be necessary.

10.8 The sensors should be in good thermal contact with the item or installed sensor which they are monitoring and placed, if possible, in or on the part of the item which will be slowest to heat up.

10.9 The test should be performed in triplicate.

Results

10.10 The test should be considered satisfactory if the following requirements are met:

a. the requirements of the automatic control test;

b. the holding time, as determined from the measured temperatures on the surface of the load items, is not less than that specified for the appropriate disinfection temperature band in Table 3;

c. during the holding time the measured temperatures are within the disinfection temperature band specified for the operating cycle; the indicated and recorded chamber temperatures are within 2°C of the temperature measured at the automatic control sensor; the temperature measured on the surface of each load item does not fluctuate by more than ± 2°C and does not differ from that in other load items by more than 4°C;

d. at the end of the cycle: the temperature sensors have remained in position.

10.11 If having completed the commissioning tests based on a reference load the WD fails to meet the above requirements for the specific performance qualification load then it is possible that the WD is not capable of processing loads of the type intended. Advice should be sought from the Independent advisor.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11. Automatic control test

Introduction

11.1 The automatic control test is designed to show that the operating cycle functions correctly as shown by the values of the cycle variables indicated and recorded by the instruments fitted to the WD.

11.2 It is carried out once a week on most WDs and is the main test for ensuring that the WD continues to function correctly.

11.3 During the commissioning, yearly and quarterly test programmes the temperature sensors for subsequent thermometric tests will be connected to the chamber during this test. If a sensor is placed adjacent to each of the sensors connected to the installed temperature measuring instruments the calibration of these instruments may be checked during periods of stable temperature in the automatic control test.

Test procedure

11.4 Place the test load appropriate to the type of WD, contained within any load furniture normally used, in the chamber.

11.5 For WDs equipped with multiple cycle capability select the operating cycle to be tested. Start the cycle.

11.6 Ensure that a batch process record is made by the recording instrument fitted to the WD. If the WD does not have a recorder, observe and note the elapsed time indicated chamber temperatures and pressures at all significant points of the operating cycle, for example the beginning and ending of each stage or sub-stage, and the maximum values during the holding time.

11.7 At the approximate mid-point of the disinfection hold time, note the elapsed time and the indicated chamber temperature.

11.8 The test should be considered satisfactory if the following requirements are met:

a. a visual display indicating ‘cycle complete’ occurs;

b. during the whole of the operational cycle the values of the cycle variables as indicated by the instruments on the WD or shown on the batch process record are within the limits established as giving satisfactory results either by the manufacturer or during performance qualification;

c. during the disinfection hold period determined from the indicated and/or recorded chamber temperature:

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

(i) the indicated and recorded chamber temperatures are within the appropriate disinfection temperature band specified in Table 2;

(ii) the time for which the disinfection temperature is maintained is not less than that previously established, by either the manufacturer or performance qualification tests, as necessary to ensure that the load is maintained at temperatures within the disinfection temperature band for the time specified in Table 3;

d. the door cannot be opened until the cycle is complete;

e. the person conducting the test does not observe any mechanical or other anomaly.

12. Specific tests for WDs for human-waste containers

Introduction

12.1 WDs for human-waste containers are used to process bedpans, commode bowls, vomitus bowls, urine bottles, suction bottles, kidney dishes and sputum cups etc. The WD is usually a dedicated machine intended solely for human-waste containers.

12.2 WDs for human-waste containers (Bedpan WDs) are Type 1 (single or double door) machines only. The following tests are specific to WDs for human-waste containers.

12.3 Thermal disinfection should be verified by thermometric measurement; the use of biological indicators for assessment of thermal disinfection is not a satisfactory alternative.

Test for safety of loading and/or emptying of containers

Introduction

12.4 The test is intended to ensure that containers can be emptied without spillage or splashing which would cause a hazard to the operator. The WD should be tested for either manual or automatic emptying.

Equipment and materials

12.5 A full load of each type of container which the WD is intended to process is necessary.

Method: manual emptying

12.6 Each type of container which the WD is designed to process should be tested. Fill each container to not less than 75% of its brim full capacity and empty it and locate it in the load carrier in accordance with the manufacturer's instructions. Load the chamber to the maximum recommended capacity. Close the door. Observe whether any liquid is spilled or splashed. Carry out the test in triplicate on each type of container.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Method: automatic emptying

12.7 Each type of container which the WD is designed to process should be tested. Fill each container to 75% ± 5% of its brim full capacity and locate it in the load carrier in accordance with the manufacturer's instructions. Load the chamber to the maximum recommended capacity. Close the door. Observe whether any liquid is spilled or splashed. Carry out the test in triplicate on each type of container.

Results

12.8 There should be no spillage or splashing of the contents of the containers during the emptying process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13. Specific tests for WDs for surgical instruments

Introduction

13.1 WDs for surgical instruments may be Type 1 (double or single door) or Type 2 (multiple cabinet or conveyor).

13.2 'WDs for surgical instruments' is a description often given to a WD for general purposes which is used for other specific applications by using suitable load carriers (for example hollowware, anaesthetic accessories, laboratory ware). The tests described for WDs for each of these specific purposes (see Chapters 14, 15 and 16) should be carried out in addition to the test described in this Chapter, when relevant.

13.3 WDs for surgical instruments are used also to process those rigid endoscopes which are able to withstand thermal disinfection. Specific tests for WDs used for this purpose are considered in this category.

13.4 Thermal disinfection should be verified by thermometric measurement; the use of biological indicators for assessment of thermal disinfection is not a satisfactory alternative.

Water quality

13.5 Precautions must be taken to ensure that the microbiological quality of the final rinse water will not compromise in any way the efficacy of the process. The final rinse water will require to be of high quality and shown to be free of mycobacteria. The microbiological quality of the final rinse water should be monitored weekly to ensure compliance.

13.6 Water which is too hard or has too high a concentration of dissolved solids may impair the activity of detergents (or require the use of increased quantities of chemical additives) and cause deposits, scaling or corrosion of items being processed. Water for washing and subsequent stages of the process should be tested to ensure that it is not.

13.7 Trace elements in the water supply may cause corrosion of surgical instruments. The water supplied for the final rinse stage should be of high purity and this should be confirmed by testing.

13.8 It is necessary for the user and microbiologist to establish microbiological quality of the water, particularly final rinse water, and ensure that the quality is maintained. This should include discussions on microbiological testing, including the advisability of monitoring bacterial endotoxin levels.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Reference test loads

13.9 The following general equipment is suggested:

a. 3 cuscoe speculae;

b. 3 artery forceps (Crile, Kelly or Spencer Wells) with box joints;

c. 3 No 3 scalpel handles;

d. 3 Yankauers or Pooles suction tubes;

e. sufficient additional instruments to make up a full load;

f. dissecting forceps;

And where appropriate the following endoscope/MAT instruments are required:

g. 2 Trochar and Cannulae;

h. 2 MAT forceps;

i. 2 surrogate endoscopes (see below);

j. sufficient additional instruments to make up a full load.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14. Specific tests for WDs for hollowware

Introduction

14.1 Precautions must be taken to ensure that the microbiological quality of the final rinse water will not compromise in any way the efficacy of the process. The final rinse water will require to be of high quality and shown to be free of mycobacteria. The microbiological quality of the final rinse water should be monitored weekly to ensure compliance.

14.2 WDs for hollowware are used to process bowls, receivers, instrument trays, containers and lids etc. The WD may be a dedicated machine intended solely for hollowware or a WD for surgical instruments with an appropriate load carrier and operating cycle. In the latter case, the tests and reference loads described in this Chapter should also be applied to the WD for surgical instruments (see Chapter 13).

14.3 WDs for hollowware may be Type 1 (single or double door) or Type 2 (multiple chamber or conveyor).

14.4 Thermal disinfection should be verified by thermometric measurement; the use of biological indicators for assessment of thermal disinfection is not a satisfactory alternative.

Reference test loads

14.5 Metal and plastic hollowware has significantly different drying characteristics and may also have different carrier requirements since plastic containers are easily ‘flipped over’ and may then become filled with water. When this happens, not only are the containers impossible to dry but also, there may be a serious risk of scalding when unloading the WD. Plastic items are usually more difficult to dry and are therefore chosen for the standard test load.

14.6 The suggested standard test load for hollowware should consist of items conforming to BS 5452: 1977 (1989) as follows:

a. instrument tray 200 mm x 150 mm;

b. instrument tray 300 mm x 250 mm;

c. compartmented instrument tray 270 mm x 180 mm;

d. kidney dish of 150 mm x 300 mm;

e. wash bowl of 350 mm x 135 mm;

f. lotion bowl of 100 mm x 45 mm;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

g. lotion bowl of 250 mm x 110 mm;

h. gallipot of 40 mm (30 ml to 60 ml);

i. gallipot of 80 mm (250 ml to 280 ml);

j. sufficient additional items of the same type to form a full load.

Performance qualification tests

14.7 Additional tests are unlikely to be required for particular load items other than for WDs which are used to clean and disinfect re-usable containers for sterile products (see EN 868 Part 8 – Yet to be formally published).

14.8 A test load consisting of the following should be used:

- full size container (600 mm x 300 mm x 300 mm);
- 1 half height container (600 mm x 300 mm x 150 mm);
- 2 half-size half-height containers (300 mm x 300 mm x 150 mm).

14.9 Further tests may be necessary also for particular loading configurations. When load carriers are heavily loaded there may be ‘shadowing’ of some parts of the load causing inefficient cleaning and/or failure to achieve disinfection conditions throughout the load.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

15. Specific tests for WDs for anaesthetic accessories

Introduction

15.1 Precautions must be taken to ensure that the microbiological quality of the final rinse water will not compromise in any way the efficacy of the process. The final rinse water will require to be of high quality and shown to be free of mycobacteria. The microbiological quality of the final rinse water should be monitored weekly to ensure compliance.

15.2 WDs for anaesthetic accessories are used to process breathing tubes, reservoir bags, connectors, endotracheal tubes, tracheostomy tubes, face masks and similar items. The WD may be a dedicated machine intended solely for anaesthetic accessories or a WD for surgical instruments with an appropriate load carrier and operating cycle. In the latter case the tests and reference loads described in this chapter should be applied also to the WD for surgical instruments (see Chapter 13).

15.3 WDs for anaesthetic accessories may be Type 1 (single or double door) or Type 2 (multiple chamber or conveyor).

15.4 Long lengths of tubing are difficult to clean internally and the attainment of cleanliness is difficult to verify. Anaesthetic tubing is also difficult to dry; this is particularly the case for plastic tubing which cannot withstand high (100°C+) drying temperatures.

15.5 Thermal disinfection should be verified by thermometric measurement; the use of biological indicators for assessment of thermal disinfection is not a satisfactory alternative.

Reference test loads

15.6 A suggested test load consisting of the following should be used:

a. Breathing tubes > 600 mm in length (conforming to BS EN 12342: 1998) (transparent/translucent tubing should be used);

b. anaesthetic reservoir bag of 15 mm, 1.5 litre capacity (conforming to BS 1820:1970);

c. anaesthetic reservoir bag of 22 mm, 1.5 litre capacity (conforming to BS 1820:1970);

d. dis-assembled conical connectors of 15 mm, screw threaded with cone and socket joints (conforming to BS 3849-4);

e. dis-assembled conical connectors of 22 mm, screw threaded with cone

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

and socket joints (conforming to BS 3849-4);

f. tracheostomy tube and connector of 11mm size (conforming to BS EN 1282-1:1997);

g. endotracheal tube connector of 11 mm size (conforming to BS EN 1782:1998); face masks.

Performance qualification tests

Cleaning and disinfection

15.7 The inner surfaces of anaesthetic accessories are often those for which successful cleaning and disinfection are most critical. Some items may be used after disinfection without further decontamination (for example sterilization). Performance qualification tests, in addition to the operational tests specified may be required for all aspects of the process. The use of surrogate devices may be advantageous.

Drying

15.8 Items which are left warm and damp after an ineffective drying stage will rapidly become recontaminated with micro-organisms.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

16. Specific tests for WDs for laboratory glassware

Introduction

16.1 WDs for laboratory use are generally of Type 1 (single or double door) only. Their major use is for cleaning laboratory glassware and this is reflected in the reference load specified. However, there is a wide range of possible loads and load carriers adapted for particular purposes and specific performance qualification tests may therefore be required.

16.2 The disinfection stage may not be required for many laboratory applications.

Reference test loads

16.3 The suggested reference test load to be used in tests for cleaning efficacy, thermal disinfection efficacy and (when applicable) load dryness consists of a full load of glassware. This should contain:

a. rimless test tubes of 16 mm x 150 mm with 1.2 mm wall thickness(conforming to BS 3218: 1982);

b. low form beakers, 1000 ml volume, 106 mm diameter by 145 mm high (conforming to BS 6523: 1984);

c. additional items as may be required to fully load the chamber of the WD.

Performance qualification tests

Load items

16.4 For laboratory items other than general purpose glassware of the type included in the reference load, or of other items (for example hollowware) for which standard reference loads have been defined, it will be necessary to review how well they are represented by the items of which the reference loads are composed. If the reference loads do not adequately represent the loads which will be used further tests should be carried out using loads composed of items which will be in normal production loads.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Nature of soiling

16.5 Laboratory items may be subjected to soiling of a variety of types many of which are very difficult to remove. The test soil for operational testing is chosen to represent biological fluids which may be present. If other types of soiling will be encountered, tests should be conducted using items soiled in the manner which will occur for normal production loads.

Process residue tests

16.6 In many cases there will be a need for laboratory items to be free from residues of chemical additives used during the cycle since these may interfere with the subsequent use of the load items. The manufacturer(s) of the chemical additives which it is intended to use should be asked to provide appropriate test methods for the determination of residual levels.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

17. Specific tests for ultrasonic cleaners

Introduction

17.1 Precautions must be taken to ensure that the microbiological quality of the final rinse water will not compromise in any way the efficacy of the process. The final rinse water will require to be of high quality and shown to be free of mycobacteria. The microbiological quality of the final rinse water should be monitored weekly to ensure compliance.

17.2 Ultrasonic cleaners may be of the 'stand-alone' ultrasonic bath type or may be WDs of Type 1 or Type 2 (multiple chamber or conveyor) or they may be one stage of a Type 2 WD. Many Type 1 ultrasonic cleaners do not incorporate a disinfection stage and are intended for use as a pre-cleaning process before final cleaning and disinfection in a WD for surgical instruments (see Chapter 13).

17.3 Some ultrasonic cleaners are equipped with means to irrigate hollow instruments such as endoscopes. These WDs should be tested both with the general reference load and the endoscope/MAT reference load (see below).

Test for ultrasonic activity

Introduction

17.4 The activity of an ultrasonic cleaner may be investigated by the erosion pattern which is created on aluminium foil exposed in the bath for a short period. The activity will not be uniform throughout the ultrasonic bath. Tests carried out during commissioning are intended to establish the variation in activity at different positions and levels within the bath and the time required to obtain a characteristic erosion pattern.

17.5 The exposure time will depend on the thickness of the foil, the hardness of the foil, the operating frequency, the watt density and the temperature of the ultrasonic bath.

Equipment and materials

17.6 The following equipment and materials are necessary:

a. aluminium foil of nominal thickness 0.015 mm to 0.025 mm (sold as an aluminium foil wrap for cooking);

b. autoclave indicator tape;

c. stopwatch, graduated in 0.2 s and with an accuracy over a period of 15

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

min of ± 0.5 s, or better;

d. ruler/tape measure graduated in mm.

Method

17.7 Measure the depth of the bath from the level of the lid to the bottom of the bath. Let the depth be D mm.

17.8 Cut strips of aluminium foil 15 mm to 20 mm wide and {D + 120} mm.

17.9 Carry out the manufacturer's recommended start-up procedure; this will normally include a period of operation to eliminate dissolved gases from the solution in the bath (the de-gassing procedure).

17.10 Ensure that the water in the tank is at the required level, that the required amount of any chemical additive specified by the manufacturer has been added and that the water in the tank is at the specified operating temperature.

17.11 Using strips of autoclave indicator tape across the top of the bath suspend nine strips of the prepared foil in the bath in a 3 x 3 grid.

17.12 The rolled end of each foil strip acts as a sinker weight to maintain the foil in an approximately vertical position. The sinker weight should be not more than 10 mm above, but not touching, the bottom of the bath.

17.13 Operate the bath for the predetermined exposure time. This may vary typically between 30 seconds for a watt density of 20 Wdm^{-3} and 10 minutes for a watt density of 5 Wdm^{-3}.

17.14 Remove the strips from the bath, blot dry and examine.

17.15 The strips may be filed conveniently by sticking them to an A4 sheet of plain paper using a transparent adhesive tape.

17.16 Drain the bath and clean to remove debris of eroded aluminium foil.

Results

17.17 The zones of maximum erosion should be at similar positions on all nine foils and each should be eroded to a similar extent (by visual inspection).

17.18 On re-testing the extent of erosion and the erosion pattern should have remained consistent with those originally determined during commissioning.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: For precise evaluation the foils should be weighed before and after exposure to ultrasonication and the loss in weight recorded. The variation in loss of weight should be such that the weight of any one foil is within ± 20% of the mean loss of weight.

Reference test loads

17.19 The suggested test load should contain the following general equipment:

a. cuscoe speculae;

b. artery forceps (Crile, Kelly or Spencer Wells) with box joints;

c. no. 3 Scalpel handles;

d. Yankauers or Pooles suction tubes;

e. sufficient additional instruments to make up a full load.

17.20 The test load should contain the following endoscope/MAT instruments:

a. Trochar and Cannulae;

b. MAT forceps;

c. surrogate endoscopes (see below).

17.21 Sufficient additional instruments to make up a full load.

17.22 The surrogate endoscope should be constructed from 6 mm o.d./4 mm id stainless steel tubing. The overall length should be 450 mm. At the midpoint of the tube should be a 50 mm length of tubing connected to the tubing on either side with compression fittings.

17.23 The 50 mm demountable length may be used to provide a more readily visible section for determination of cleaning efficacy.

Performance qualification tests

Load items

17.24 For ‘difficult to clean’ laboratory items other than those of the type included in the reference load, or of other items (for example hollowware) for which standard reference loads have been defined, it will be necessary to review how well they are represented by the items of which the reference loads are composed. If the reference loads do not adequately represent the loads which will be used further tests should be carried out using loads composed

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

of items which will be in normal production loads.

Nature of soiling

17.25 Ultrasonic cleaners are often used for items which are contaminated with soiling which is difficult to remove by other cleaning processes.

17.26 The test soil for operational testing is chosen to represent biological fluids which may be present. If other types of soiling will be encountered (for example orthopaedic bone cement) tests should be conducted using items soiled in the manner which will occur for normal production loads.

18. Specific tests for WDs for endoscopes

Introduction

18.1 WDs for flexible thermolabile endoscopes are machines of Type 1 (single and double door) only. (Rigid endoscopes able to tolerate terminal steam sterilization are considered under WDs for surgical instruments).

18.2 These WDs are characterised by a chemical disinfection stage because the products which are intended to be processed will not withstand the high temperatures required for thermal disinfection. It is necessary to ensure that the disinfectant is removed from the endoscope before it is used on a patient; this is achieved by a post-disinfection rinsing stage. It is apparent that the microbiological control of this stage is of critical importance to the microbial status of the processed item. A number of additional tests are required to ensure that this aspect of the process is properly controlled.

WD self-disinfection test

Introduction

18.3 It is necessary to verify that the WD 'machine disinfection' mode will disinfect those parts of the WD which come into contact with fluids which are intended to, or may, contact the load.

18.4 The WD may be equipped with an auto or manually selected 'self-disinfect' mode; it may be thermal or chemical and in the latter case may be the same or a different germicide from that used for chemical disinfection of the load. The preferred method is thermal disinfection or, if this is not possible, the use of a different germicide. The use of the same germicide carries the risk of allowing organisms resistant to that particular germicide to proliferate.

18.5 The process is intended to deal with the situation where the WD has become contaminated. The piping used to convey rinse water to the endoscope, if contaminated, may easily develop a layer of biofilm containing many micro-organisms in a state which is highly resistant to chemical disinfection. This tubing should normally be replaced at the interval specified by the manufacturer. Normally this should not exceed 500 operating cycles or 3 months.

18.6 Thermal disinfection systems should be evaluated by thermometric monitoring of the system with sensors placed at the parts of the system most remote from the heat source. The entire system should attain the required disinfection temperature (see Table 3).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

NOTE: Advice on microbiological testing should be sought from the microbiologist.

Final rinse decontamination test

18.7 Precautions must be taken to ensure that the microbiological quality of the final rinse water will not compromise in any way the efficacy of the process. The final rinse water will require to be of high quality and shown to be free of mycobacteria. The microbiological quality of the final rinse water should be monitored weekly to ensure compliance.

18.8 Various methods are used to ensure that the final rinse water is decontaminated before use. The test should verify the performance of the particular system by the method specified by the manufacturer.

18.9 This may include:

a. verification of filter performance by a bubble point test or by measuring the differential pressure drop across the filter;

b. verification of thermal disinfection by thermometric testing;

c. verification of UV activity by confirmation that the illumination is at the wavelength and intensity specified by the manufacturer and that the residence time is also as specified.

NOTE: Advice should be sought from the microbiologist.

Channel patency detection test

18.10 WDs for endoscopes should be fitted with means to ensure that each of the channels is patent so that germicidal and rinse solutions will flow through each channel.

18.11 A surrogate device should be used to demonstrate that the system for determining the patency of each channel is functioning correctly. The surrogate device may be constructed by using a 1.5 metre length of 1mm ID PTFE tubing.

18.12 For each channel (air/water, biopsy, elevator as relevant) connect a 1.5 metre length of tubing of the appropriate diameter and run a operating cycle. On completion of the cycle replace one of the tubes with a similar tube which has a 100 mm long 1.1 mm OD 0.5 mm ID melting point tube (Borosilicate glass) inserted and secured in the distal end and run another operating cycle. Repeat the test changing the position of the partially obstructed tube on each test.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

18.13 The WD should indicate a fault for any channel to which the partially obstructed surrogate device is fitted.

Disinfectant concentration test

18.14 WDs employing a chemical disinfection stage may re-use the chemical germicide a number of times.

18.15 When such a system is employed the WD should be equipped with means to establish that the concentration of the active ingredient(s) in the germicide is above the concentration specified as the minimum acceptable. This may be in the form of a test kit to be employed by the user.

18.16 The disinfectant concentration test is carried out to establish that the means provided is effective.

18.17 The full strength solution, unused (and if necessary freshly prepared or activated), should be prepared according to the manufacturer's instructions. When this requires the addition of water, only distilled or purified water should be used.

18.18 A dilution series should be prepared using distilled or purified water.

NOTE: Handling of disinfectant solutions may need to be carried out in a laboratory with appropriate safety precautions. Seek advice from the Microbiologist or Independent Advisor.

Reference test loads and soil tests

18.19 For advice on reference test loads and test soil, consult the microbiologist/ Independent Advisor.

Microbiological tests for disinfection efficacy and performance qualification test

18.20 For advice on the above tests, consult the Microbiologist/Independent Advisor.

Appendix 1: Glossary

Automatic controller: device that, in response to pre-determined cycle variables, operates the WD sequentially through the required stages of the cycle(s)/process.

Calibration: the set of operations that establish, under specified conditions, the relationship between values of a quantity indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material, and the corresponding values realised by standards.

Chamber: that part of the WD in which the load is processed.

Chemical additive: one or more chemicals added to the chamber and load of a WD during one or more stages of the process.

NOTE: The chamber does not include steam generators, pipework and fittings from which it can be isolated.

Chemical disinfection: disinfection achieved by the action of one or more chemicals the primary purpose of which is to be microbiocidal.

Commissioning: obtaining and documenting evidence that equipment has been provided and installed in accordance with its specifications and that it functions within pre-determined limits when operated in accordance with operational instructions.

Cycle variables: the physical and chemical properties (e.g. times, temperatures, disinfectant concentration, pressures and flows) that influence the efficacy of the washing and processes.

D value: for a microbiological process the extent of exposure under defined conditions which cause a 90% decrease in the viable population of a specified micro-organism.

Decontamination: the combination of processes, including cleaning and disinfection and/or sterilization, used to render a re-usable item safe for further use.

Disinfection: the reduction of the number of viable micro-organisms on a product to a level previously specified as appropriate for its intended further handling or use.

Door: device provided as a means of closing and sealing the chamber.

Fail safe: attribute of WD design, component or its associated services that minimises a possible safety hazard.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Fault: recognition by the automatic controller that the pre-set cycle variables for the WD cycle have not been attained.

Installation qualification: see commissioning.

Installation test: series of checks and tests performed after installation of the WD in the place of use.

Load: a collective term used to describe all the goods equipment and materials that are put into a WD at any one time for the purpose of processing it by an operating cycle.

Medical device: see BS EN 46001: 1997 'Specification for application of EN ISO 9001 to the manufacture of medical devices'.

Monitoring: the measurement of physical variables, such as the function of the automatic controller to check the attainment, or otherwise, of the pre-set cycle variables essential to the efficacy of the operating cycle.

Operating cycle: the complete set of stages of the process that is carried out in the sequence as regulated by the automatic controller.

Performance qualification: obtaining and documenting evidence that the equipment as commissioned will produce acceptable product when operated in accordance with the process specification.

Product compatibility: ability of the WD operational cycle to achieve the intended results without detrimental effect on the product or its intended use.

Reference load: specified load made up to represent the most difficult combination of items to be processed in a particular WD operational cycle.

Routine test: series of tests intended to be performed by the user, or their representative, at various pre-determined intervals to demonstrate that the performance of the WD remains within the limits established during type/works/installation and validation testing.

Steam generator: vessel designed to contain water and a heating system (e.g. a steam coil or a fully immersed electric element) which is used to heat water to its vapour state.

Sterile: see BS EN 556, 'Sterilization of medical devices. Requirements for terminally sterilized devices to be labelled 'Sterile''.

Sterilization: the killing or removal of all micro-organisms including bacterial spores.

Surrogate device: a test piece designed and constructed to emulate those characteristics of a device which influence the facility with which it may be cleaned and disinfected.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Tank: a process vessel, integral to the WD, designed to hold solutions during processing.

Test soil: substance used to test the washing efficacy of WDs.

Thermal disinfection: disinfection achieved by the action of moist or dry heat.

Type test: series of tests to establish the working data for a WD type.

Validation: documented procedure for obtaining, recording and interpreting data to show that a process will consistently produce product complying with pre-determined specifications.

Viable micro-organism: micro-organisms, including viruses, which are capable of multiplication under specified culture conditions.

Washer-disinfector (WD): machine intended to clean and disinfect medical devices and other articles used in the context of medical, dental, pharmaceutical and veterinary practice.

NOTE: This type of machine does not include those deigned specifically to wash linen or clothing.

Works test: series of tests performed at the manufacturer's works to demonstrate compliance of each WD with its specification.

Z value: for a thermal microbicidal process the change in temperature required to cause a tenfold change in D value.

Status Note v2 amended 24th March 2017

Health Building Note 00-02 – Sanitary spaces

This document must be read in conjunction with current Scottish Government Policy and NHSScotland Guidance, which take precedence. These include publications in both: www.sehd.scot.nhs.uk/ and www.hfs.scot.nhs.uk/publications-/ .

Specific updates for NHSScotand use:

This guidance must be read in conjunction with the public sector equality duty in the Equality Act 2010 and the Specific Duties (Scotland) Regulations 2012. These state named Scottish public authorities, including NHSScotland, must have 'due regard' to the need to eliminate unlawful discrimination, advance equality of opportunity and foster good relations. This requires an integrated response across services, facilities, training and communications to ensure the characteristics protected by the Act are appropriately served. An Equality Impact Assessment (EIA) is required for all proposed investments. Scottish Capital Investment Manual's NHSScotland Design Assessment Process will also support the implementation of this public sector equality duty at key business case stages of the facility design process.

Update since last issue: new section 5.74 Changing Places facility, and reference to detailed design and registration requirements, which are available from www.changing-places.org.

Changing Places facilities are primarily for public not clinical use, as are general accessible toilets, their functions should not normally be combined. The quantity and location for both should be considered for all new public investment under an Equality Impact Assessment (EIA). It is anticipated that the population of Scotland served by majority of NHSScotland campuses, would require a Changing Places facility, as well as general accessible toilets, baby changing, gender neutral facilities, together with inclusive, dementia and age appropriate design inside and out.

Preface

About Health Building Notes

Health Building Notes give "best practice" guidance on the design and planning of new healthcare buildings and on the adaptation/ extension of existing facilities.

They provide information to support the briefing and design processes for individual projects in the NHS building programme.

The Health Building Note suite

Healthcare delivery is constantly changing, and so too are the boundaries between primary, secondary and tertiary care. The focus now is on delivering healthcare closer to people's homes.

The Health Building Note framework (shown below) is based on the patient's experience across the spectrum of care from home to healthcare setting and back, using the national service frameworks (NSFs) as a model.

Health Building Note structure

The Health Building Notes have been organised into a suite of 17 core subjects.

Care-group-based Health Building Notes provide information about a specific care group or pathway but cross-refer to Health Building Notes on **generic (clinical) activities** or **support systems** as appropriate.

Core subjects are subdivided into specific topics and classified by a two-digit suffix (-01, -02 etc), and may be further subdivided into Supplements A, B etc.

All Health Building Notes are supported by the overarching Health Building Note 00 in which the key areas of design and building are dealt with.

Example

The Health Building Note on accommodation for adult in-patients is represented as follows:

> "Health Building Note 04-01: Adult in-patient facilities"

The supplement to Health Building Note 04-01 on isolation facilities is represented as follows:

> "Health Building Note 04-01: Supplement 1 – Isolation facilities for infectious patients in acute settings"

Health Building Note number and series title	Type of Health Building Note
Health Building Note 00 – Core elements	Support-system-based
Health Building Note 01 – Cardiac care	Care-group-based
Health Building Note 02 – Cancer care	Care-group-based
Health Building Note 03 – Mental health	Care-group-based
Health Building Note 04 – In-patient care	Generic-activity-based
Health Building Note 05 – Older people	Care-group-based
Health Building Note 06 – Diagnostics	Generic-activity-based
Health Building Note 07 – Renal care	Care-group-based
Health Building Note 08 – Long-term conditions/long-stay care	Care-group-based
Health Building Note 09 – Children, young people and maternity services	Care-group-based
Health Building Note 10 – Surgery	Generic-activity-based
Health Building Note 11 – Community care	Generic-activity-based
Health Building Note 12 – Out-patient care	Generic-activity-based
Health Building Note 13 – Decontamination	Support-system-based
Health Building Note 14 – Medicines management	Support-system-based
Health Building Note 15 – Emergency care	Care-group-based
Health Building Note 16 – Pathology	Support-system-based

Other resources in the DH Estates and Facilities knowledge series

Health Technical Memoranda

Health Technical Memoranda give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare (for example medical gas pipeline systems, and ventilation systems).

They are applicable to new and existing sites, and are for use at various stages during the inception, design, construction, refurbishment and maintenance of a building.

All Health Building Notes should be read in conjunction with the relevant parts of the Health Technical Memorandum series.

Activity DataBase (ADB)

The Activity DataBase (ADB) data and software assists project teams with the briefing and design of the healthcare environment. Data is based on guidance given in the Health Building Notes, Health Technical Memoranda and Health Technical Memorandum Building Component series.

1. Room data sheets provide an activity-based approach to building design and include data on personnel, planning relationships, environmental considerations, design character, space requirements and graphical layouts.

2. Schedules of equipment/components are included for each room, which may be grouped into ergonomically arranged assemblies.

3. Schedules of equipment can also be obtained at department and project level.

4. Fully loaded drawings may be produced from the database.

5. Reference data is supplied with ADB that may be adapted and modified to suit the users' project-specific needs.

How to obtain publications

Health Building Notes are available from the UK Goverment's website at: https://www.gov.uk/government/collections/ health-building-notes-core-elements

Health Technical Memoranda are available from the same site at: https://www.gov.uk/government/collections/ health-technical-memorandum-disinfection-and-sterilization.

Executive Summary

Health Building Note 00-02 – 'Sanitary spaces' provides evidence-based best practice guidance on the design and layout of sanitary spaces for use in healthcare settings.

Room sizes have been standardised wherever possible. For areas where a standard room size is not appropriate, this document provides a sizing methodology suitable for briefing purposes. Most of the indicative room layouts are informed by one or more ergonomic drawings.

In places, the guidance differs from that provided in Approved Document M (2010) and BS 8300:2001 (2009 edition). Where this is the case, the reasons for the variations are discussed.

Contents

1 Introduction

1.1 Health Building Note 00-02 provides design guidance and indicative room layouts of sanitary spaces in healthcare buildings.

Purpose and scope of this document

1.2 Most of the layouts are informed by one or more ergonomic drawings (the colour-coding on the room layouts relates to ergonomic information). Both the ergonomic drawings and indicative room layouts aim to enable spaces to be designed that are fit for purpose, accessible, safe and secure.

1.3 The indicative room layouts represent example design solutions, not specific recommendations. Actual requirements should be determined on an individual project basis.

1.4 Although primarily applicable to new buildings, the recommendations contained within this guidance should also be applied, where practical, when existing facilities are being upgraded.

Principle of using generic rooms wherever possible

1.5 Generic rooms are designed to accommodate a range of activities rather than being tailored for a single function/specialty or narrow range of functions.

1.6 Sanitary spaces should be generic wherever possible to maximise flexibility in use. Generic rooms make up a high proportion of the sanitary spaces within healthcare buildings.

Standardised room sizes

1.7 The size (and dimensions) of the indicative room layouts have been standardised wherever possible. This may mean sizing up to some extent, but results in rooms that can be adapted (for alternative use) much more easily.

1.8 For areas where a standard room size is not appropriate, this document provides a sizing methodology suitable for briefing purposes.

1.9 Where special departmental requirements warrant a variation from the spaces described in this document, information is provided in the relevant guidance.

Evidence base

1.10 This document is based on the professional opinion of healthcare planning and design experts and ergonomic research (published and unpublished).

Grab rails

1.11 Grabrails are referenced extensively throughout this guidance. They are used to provide support and stability when transferring horizontally, sitting down and standing up, and while adjusting clothing. They should allow for a firm grip whether wet or dry.

1.12 Horizontal, vertical and hinged grabrails should be installed to allow users to choose the rail most appropriate for their needs. The grabrail positions on the drawings provided are generally in accordance with Approved Document M unless stated otherwise.

1.13 Hinged grabrails should lock in the vertical position, but be easy to unlock with one hand. Hinged grabrails should be capable of use with:

- vertical weight of 88 kg+50% = 132 kg; and
- a horizontal force of 155 Newtons (N) +50% = 233 N

1.14 Where appropriate grabrails may be used in place of (and to act as) towel rails.

Use of colour

1.15 Adequate colour contrast can help a visually impaired person identify features and appliances in toilets. The colour of the appliances themselves is unimportant, white being perfectly acceptable, providing they are set against a background which contrasts adequately.

1.16 When using toilets there is often a need to identify features more quickly than would be the case if undertaking a simple navigation task to get around. As such the differences in colour and tones used to contrast appliances with their backgrounds should be greater than for other circumstances.

1.17 Wherever possible the lighting to toilet areas should offer good overall illuminance and the use of highly reflective glazed tiles should be avoided.

1.18 Smaller items such as grabrails, soap dispensers and dryers should be provided against a background which affords them adequate contrast.

1.19 Wall mirrors which are placed inside the toilet, directly opposite the entrance door, can cause confusion for visually impaired people when understanding the space they have just entered or when trying to determine the layout and location of facilities. Therefore, they should be avoided.

2 Bathrooms

Bathroom with bidet: semi-ambulant

Room description and layout

2.1 See Figure 1. The following activities take place in semi-ambulant bathrooms with bidets:

- undressing and dressing;
- hanging/holding clothes;
- use of the toilet;
- use of the bidet;
- personal washing;
- use of the bath.

2.2 Semi-ambulant bathrooms should contain a bath, semi-ambulant toilet, bidet and ambulant wash-hand basin.

2.3 Bidets should be fitted with a sensor-operated over-rim supply.

2.4 Bidets are not considered appropriate for independent wheelchair users because of the difficulty in transferring between the wheelchair, toilet and bidet.

2.5 Semi-ambulant bathrooms with bidets are also suitable for ambulant users.

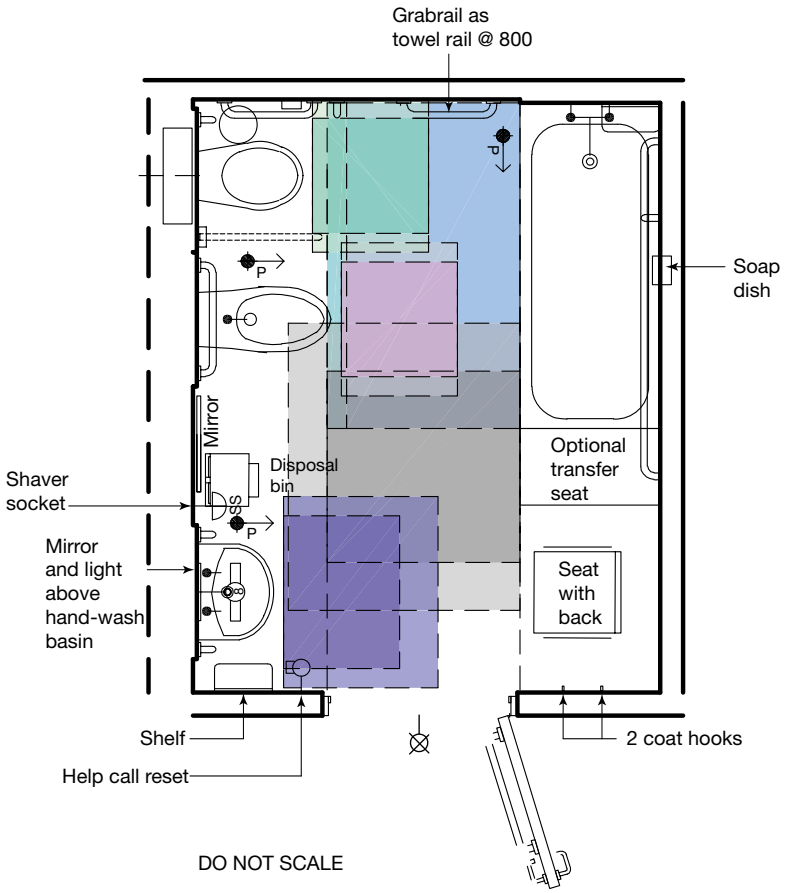

Figure 1 Space requirements for bidet: semi-ambulant

Ergonomic drawings

Bidet

2.6 This ergonomic drawing (see Figure 2) shows the space requirements for a bidet.

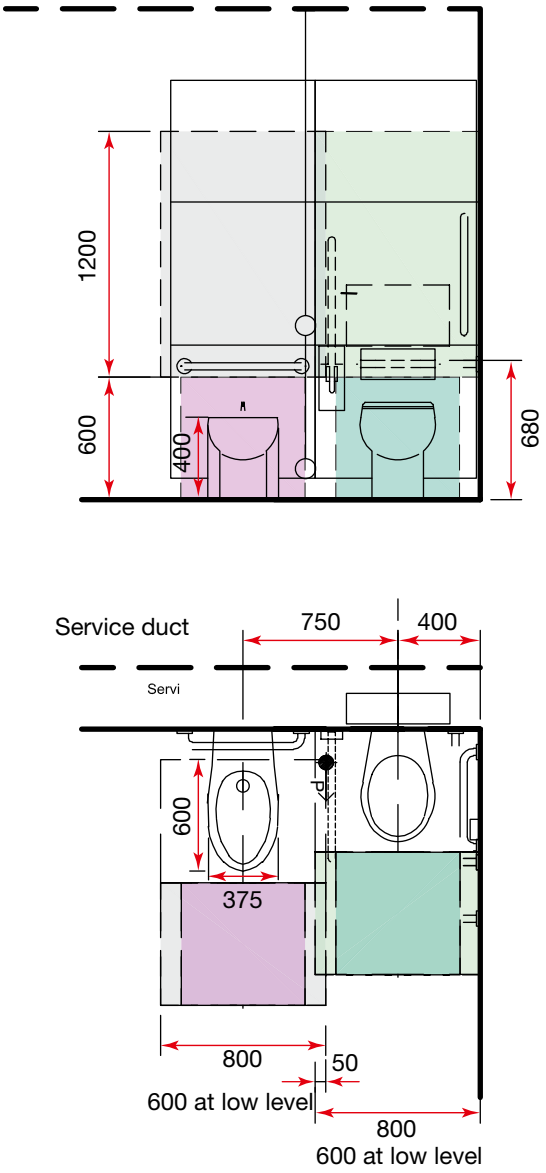

Figure 2 Space requirements for access to a bidet

Dressing and undressing: ambulant

2.7 These ergonomic drawings (see Figure 3) show the space requirements for ambulant dressing and undressing.

2.8 An identical space provision is suitable for semi-ambulant users though it should be located adjacent to a seating area.

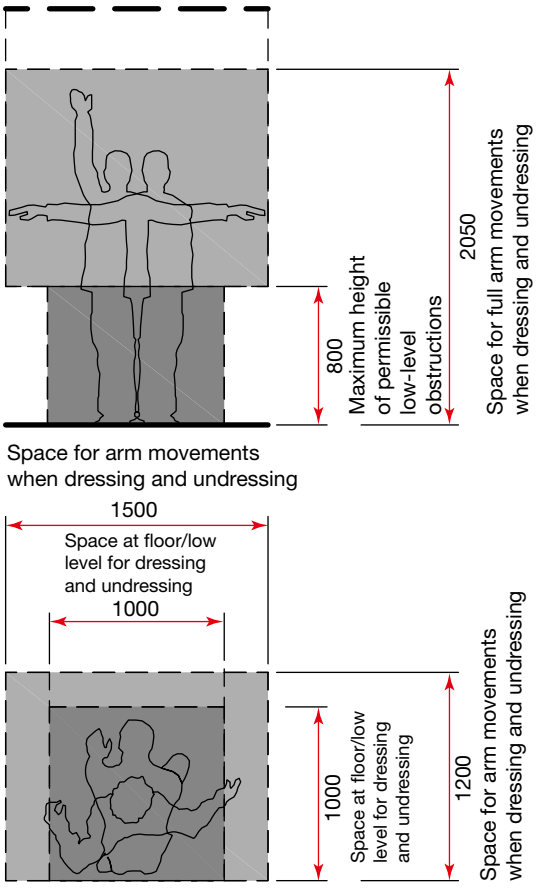

Figure 3 Space requirements for ambulant dressing and undressing

Toilet: semi-ambulant

2.9 This ergonomic drawing (see Figure 4) shows the space requirements for a semi-ambulant toilet.

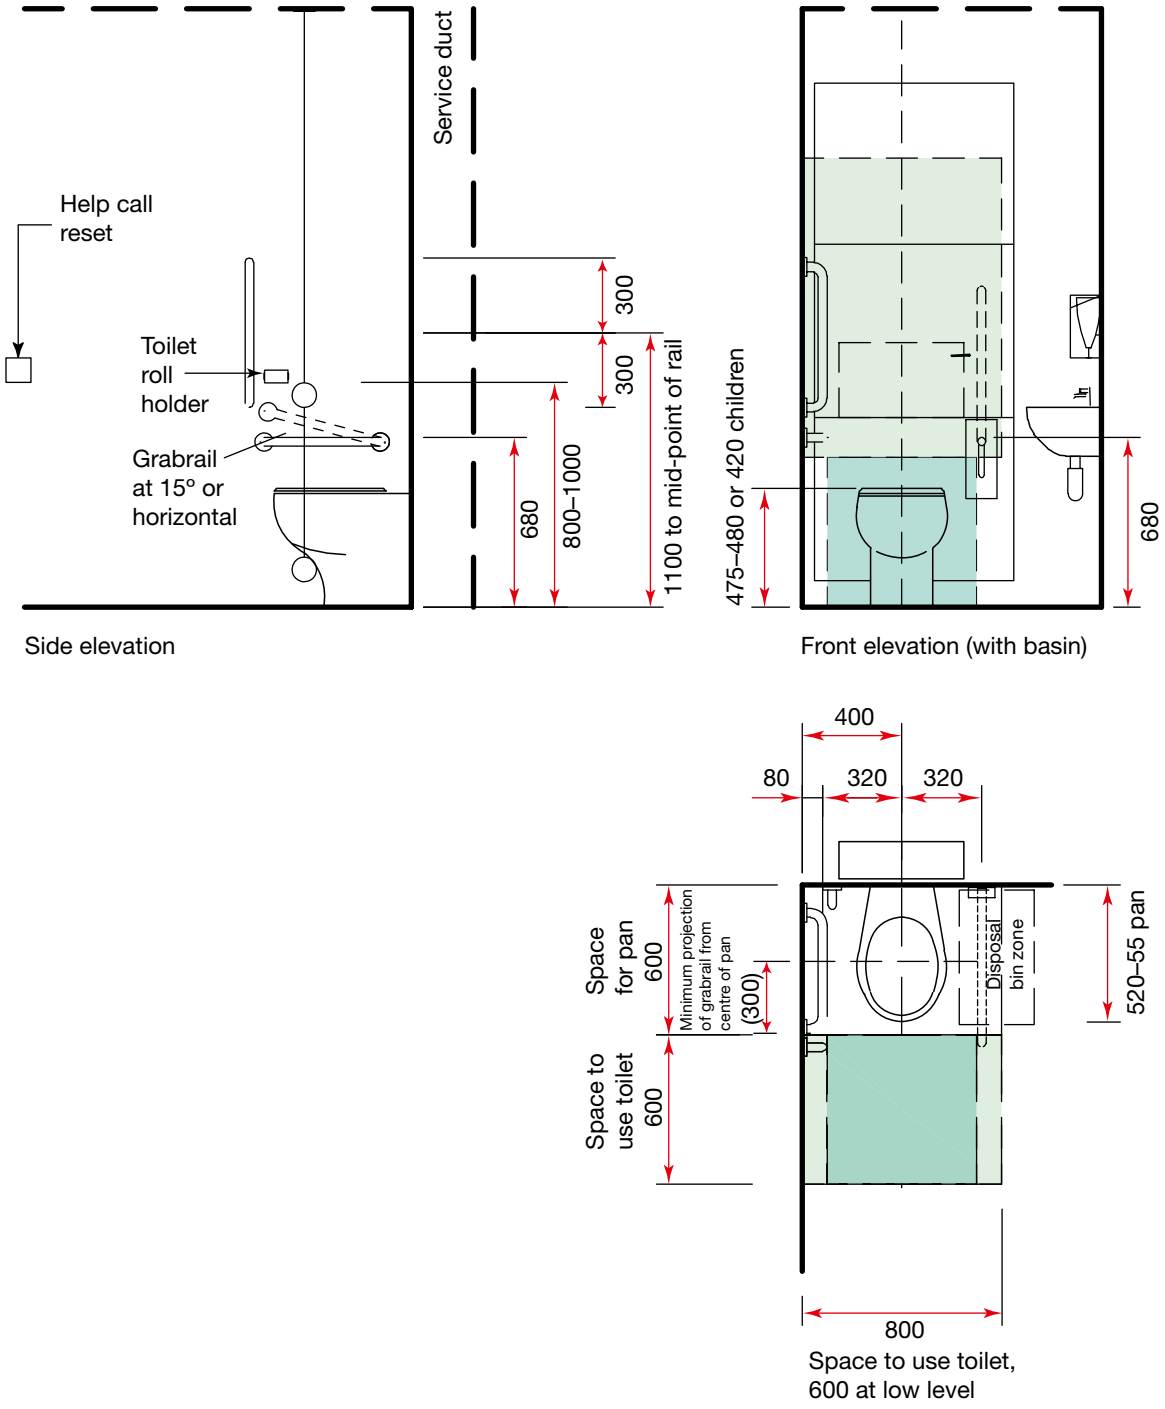

Figure 4 Space requirements to access a semi-ambulant toilet

Wash-hand basin: ambulant

2.10 Wash-hand basins may be used for personal washing activities.

2.11 This ergonomic drawing (see Figure 5) shows the space requirements for ambulant/ semi-ambulant use of a 400 mm deep × 500 mm wide wash-hand basin.

2.12 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

2.13 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

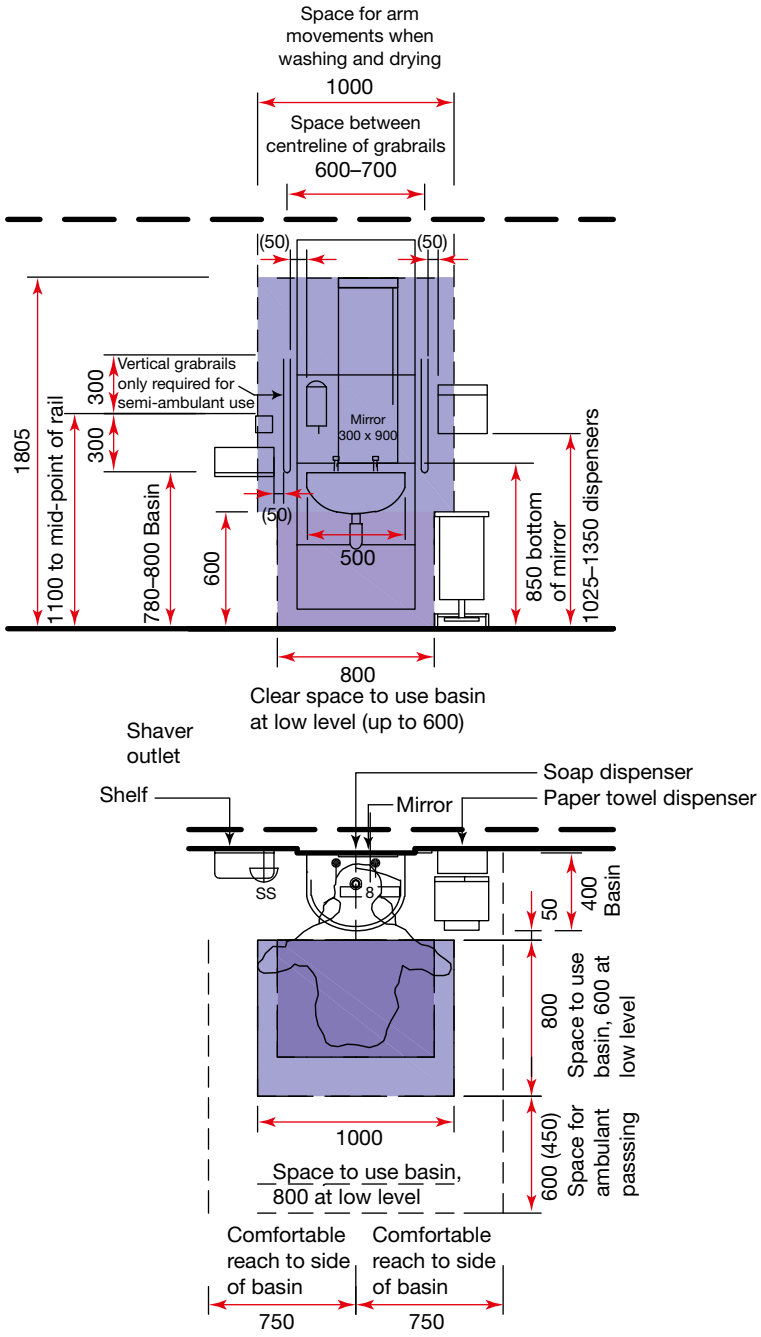

Figure 5 Space requirements for ambulant/semi-ambulant use of a 400 mm deep x 500 mm wide wash-hand basin

Full-length mirror: standing or seated users

2.14 This ergonomic drawing (see Figure 6) shows the space requirements for a full-length mirror for standing or seated users.

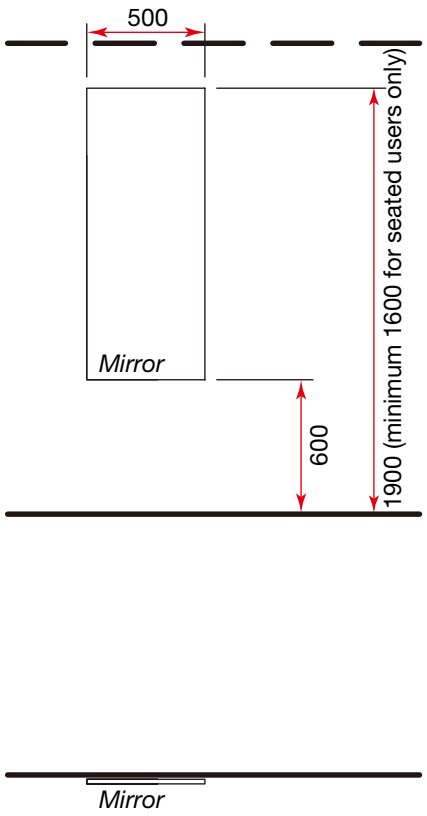

Figure 6 Space requirements to full-length mirror for standing or seated users

Bath: semi-ambulant

2.15 This ergonomic drawing (see Figure 7) shows the space requirements for a semi-ambulant bath.

2.16 Where a fixed transfer seat is not provided at the foot of the bath, an independent use bath hoist (chair) should be available, of the type that can be securely fixed to the bath rim when required. Manufacturers' advice should be sought regarding space requirements for such bath hoists.

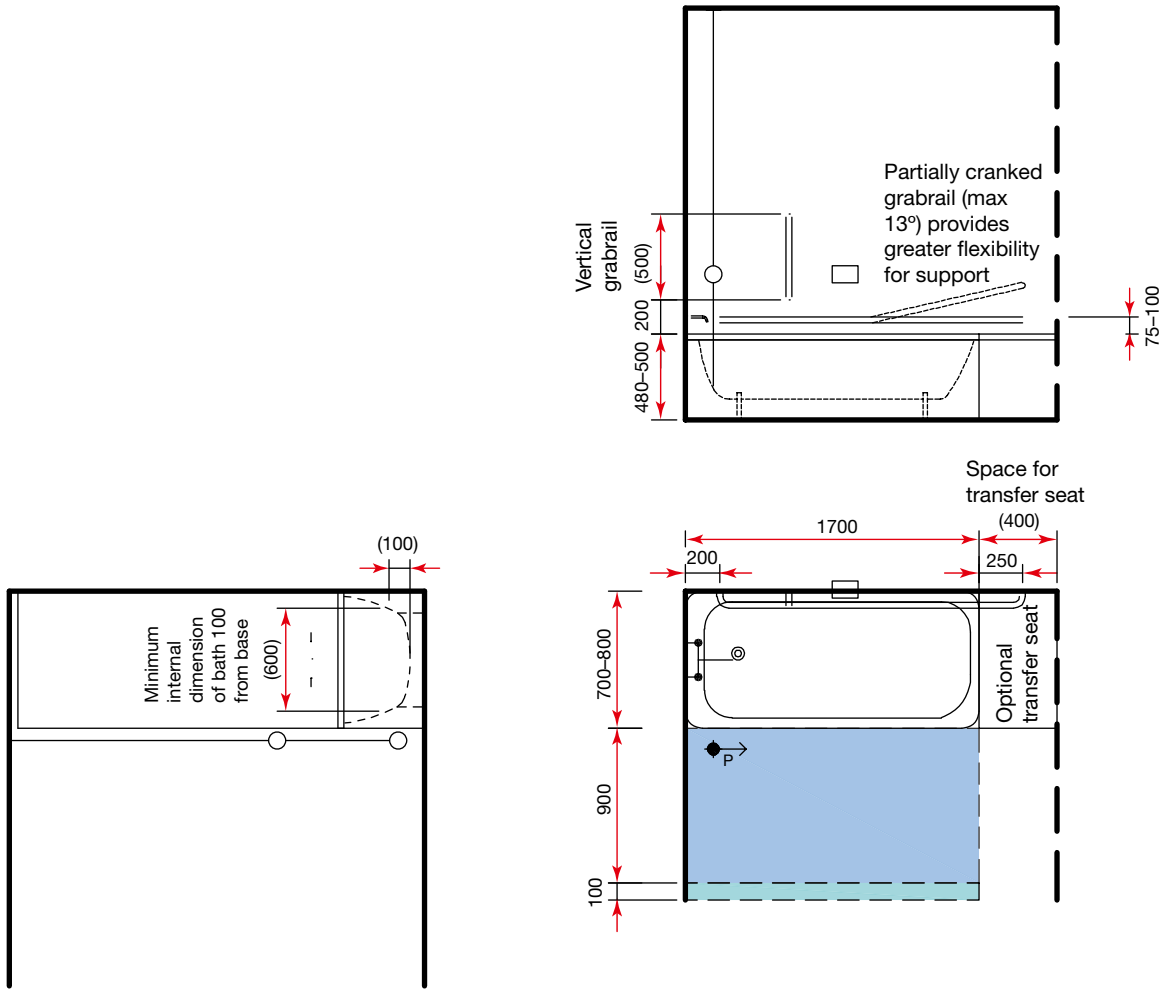

Figure 7 Space requirements to access a semi-ambulant bath

Bathroom: assisted

Bathroom: assisted

2.17 The following assisted activities take place in assisted bathrooms (end access to bath):

- undressing and dressing;
- hanging/holding clothes;
- wheelchair and sanitary chair access to the toilet and wash-hand basin;
- mobile hoist access to transfer a patient to the toilet or bath or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet (supervised only);
- use of the toilet;
- personal washing (whilst seated);
- use of the bath.

2.18 An assisted bathroom should contain an adjustable-height bath, assisted toilet and wheelchair wash-hand basin.

2.19 Assisted variable-height baths are available in a large variety of sizes and are not covered by 'Element 4: Sanitary assemblies'. The room layout provided is based on a variable height bath measuring 800 mm wide and 2400 mm long.

2.20 The bath should be positioned in the centre of the room to provide increased access for users and staff.

2.21 Assisted bathrooms are not suitable for independent wheelchair users, and are of limited use for ambulant and semi-ambulant use without due consideration of bath access requirements and the use of an adjustable-height wash-hand basin for standing users.

2.22 The room layout (see Figure 8) utilises the minimum clear space requirement to the side of the toilet for mobile hoist transfer (that is, 1150 mm from the centreline of the toilet to the nearest obstruction), on the bath side of the toilet only.

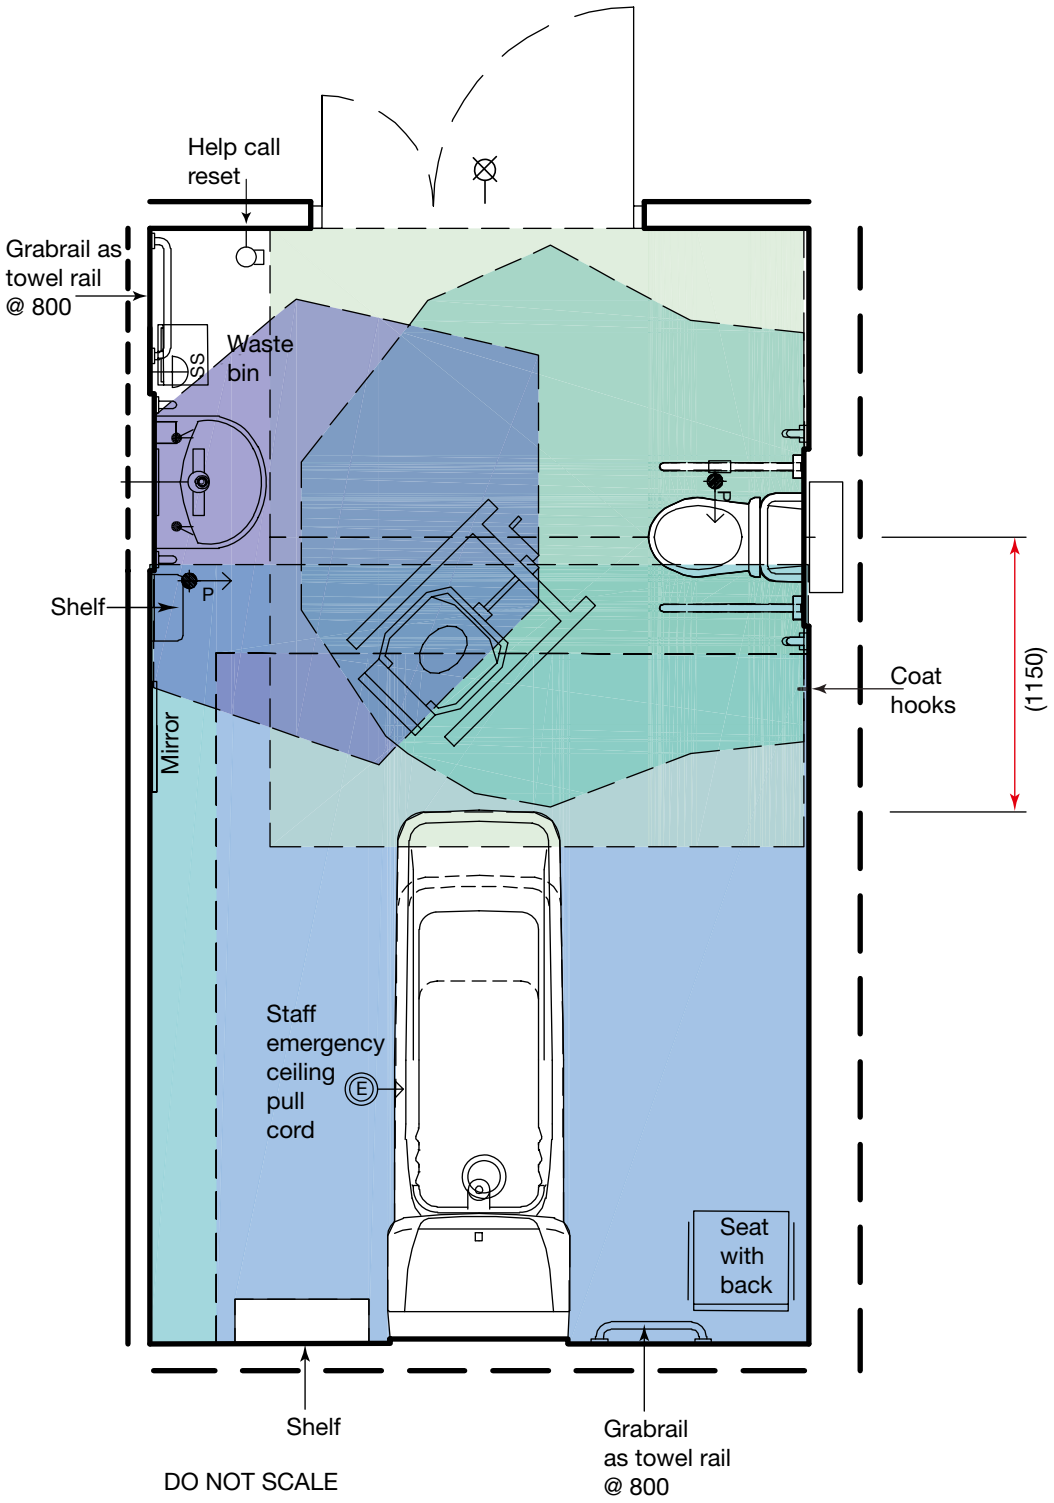

Figure 8 Space requirements for bathroom: assisted

Ergonomic drawings

Assisted bath

2.23 This ergonomic drawing (see Figure 9) shows the space requirements for an assisted bath.

2.24 Variable-height baths vary considerably in size and service requirements depending on the model and manufacturer. Specialist/ manufacturer advice should be sought at the earliest possible stage to clarify requirements.

2.25 Where used as a treatment bathroom, medical gases should be provided at the head of the bath, and the model of bath should allow for the use of a stretcher hoist.

2.26 This is generic briefing information, and manufacturers' advice should be sought on the specific requirements of baths and associated lifting aids.

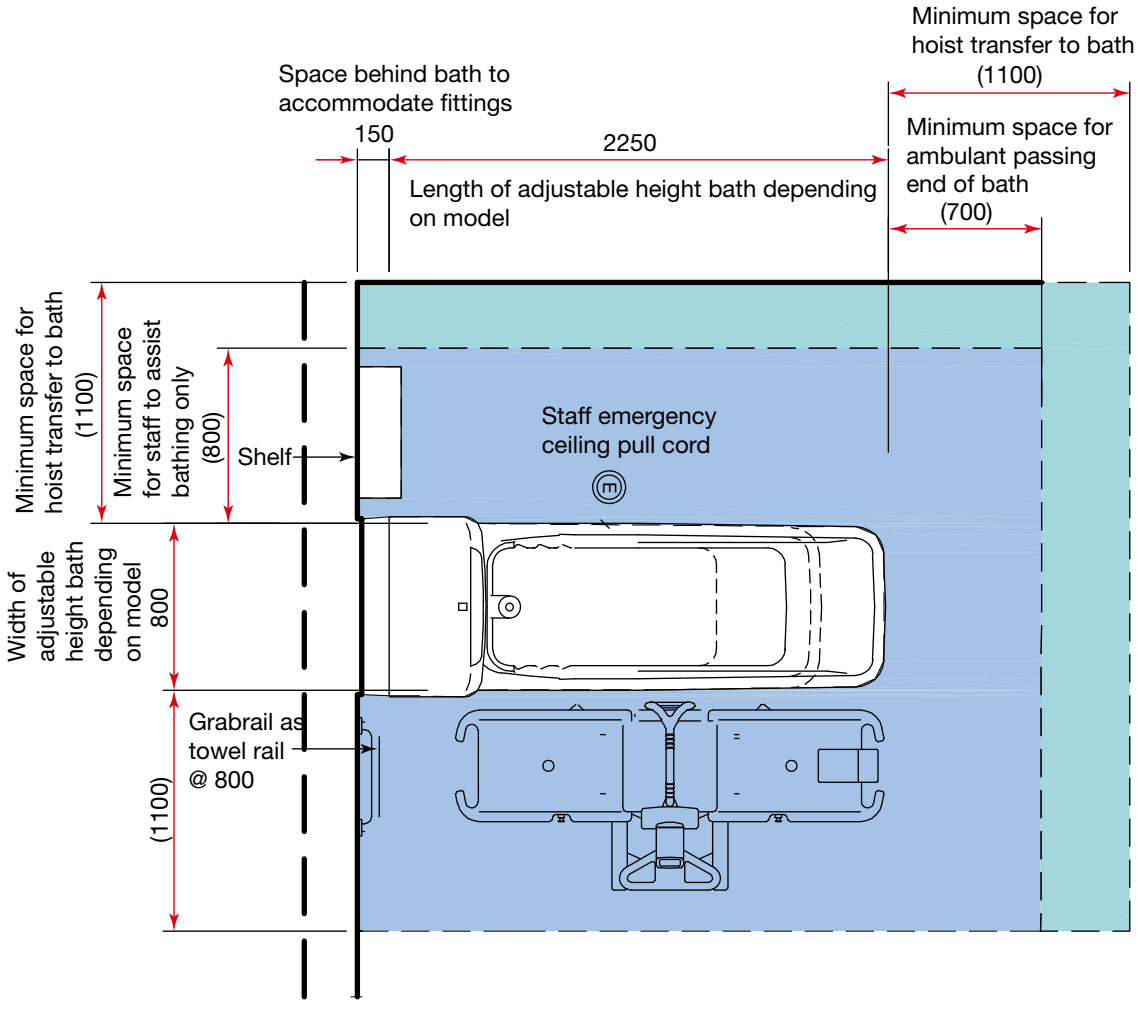

Figure 9 Space requirements to access an assisted bath

Toilet: assisted

2.27 This ergonomic drawing (see Figure 10) shows the space requirements for an assisted toilet.

2.28 The clear space on either side of the toilet for mobile hoist transfer is greater than that recommended in BS 8300 (Figure 55).

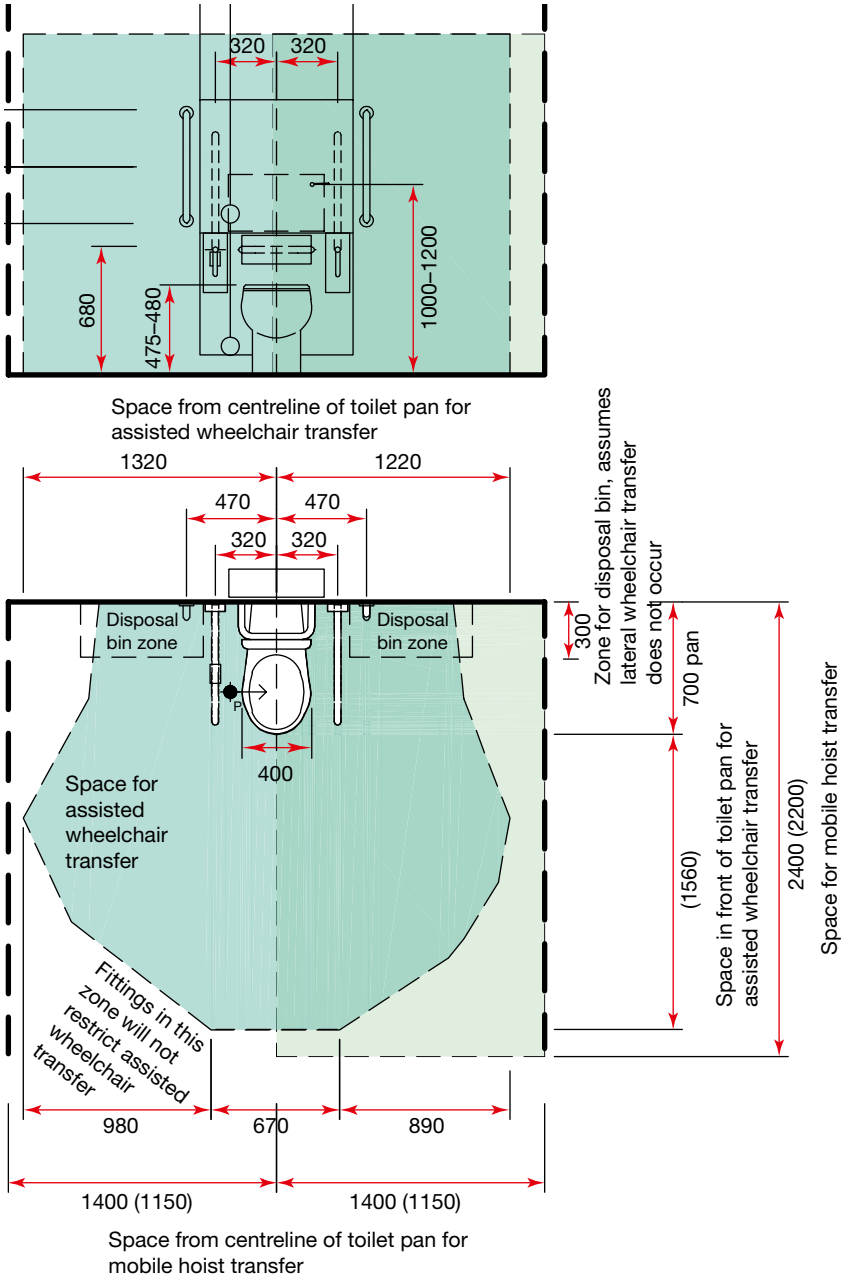

Figure 10 Space requirements to access an assisted toilet

Full-length mirror: standing or seated users

2.29 This ergonomic drawing (see Figure 11) shows the space requirements for a full-length mirror for standing or seated users.

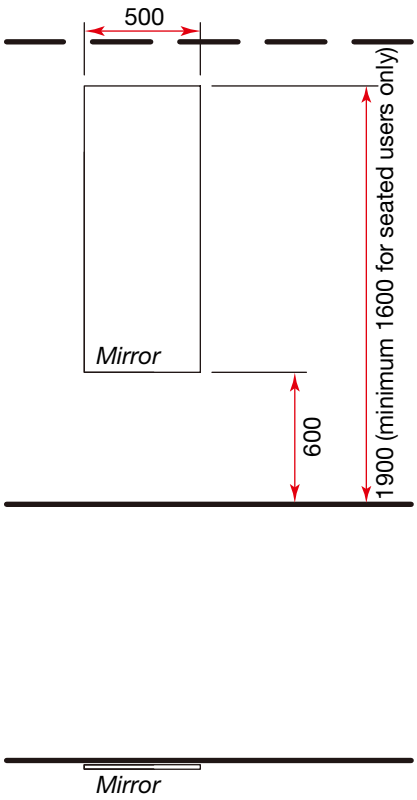

Figure 11 Space requirements for a full-length mirror for standing or seated users

Wash-hand basin: wheelchair

2.30 Wash-hand basins may be used for personal washing activities.

2.31 This ergonomic drawing (see Figure 12) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

2.32 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

2.33 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

2.34 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

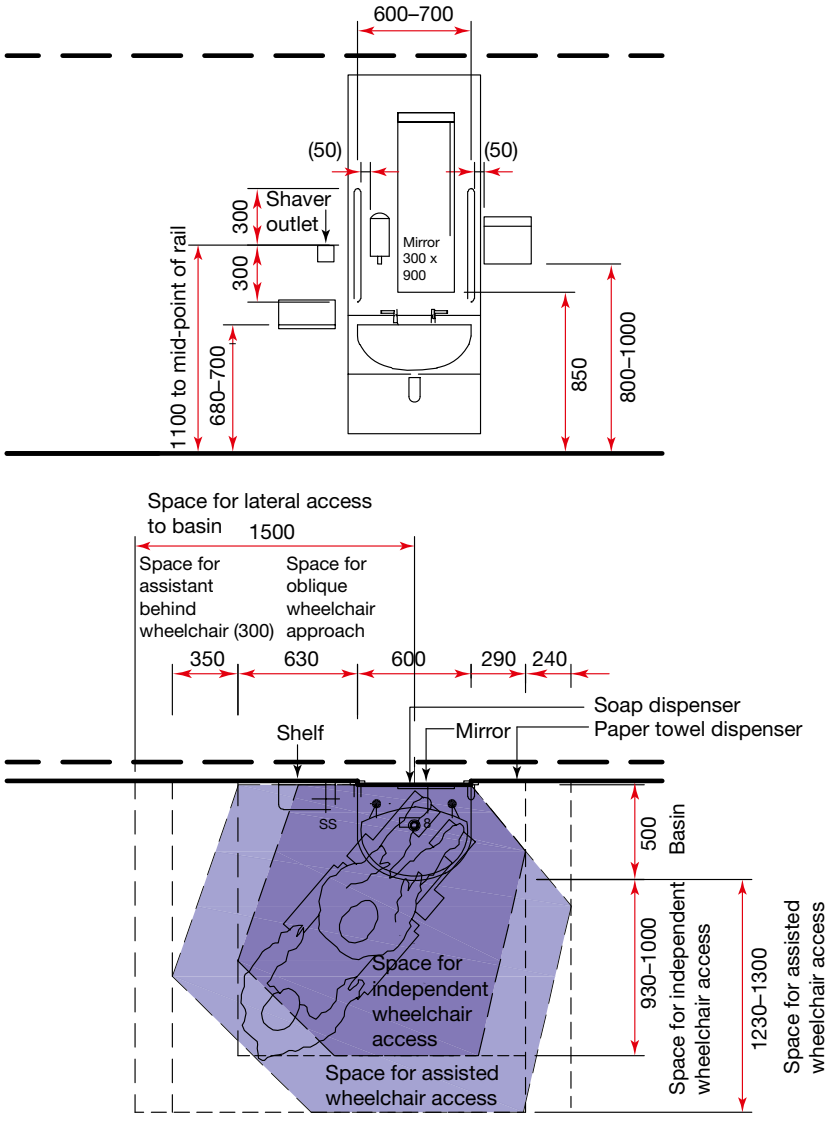

Figure 12 Space requirements for a wheelchair accessible wash-hand basin

Bathroom: independent wheelchair

Room description and layout

2.35 The following activities take place in independent wheelchair bathrooms:

- undressing and dressing;
- hanging/holding clothes;
- wheelchair access to the toilet, hand-rinse basin, wash-hand basin and bath;
- independent transfer from a wheelchair to the toilet or bath;
- use of the toilet;
- disposal of sanitary towels (optional);
- emptying of urine bottles and colostomy bags;
- hand-rinsing (whilst in a wheelchair facing the hand-rinse basin or seated on the toilet);
- personal washing (whilst seated);
- use of the bath.

2.36 Bathrooms for independent wheelchair use should contain an independent wheelchair toilet and adjacent hand-rinse basin, separate wheelchair wash-hand basin for personal washing and an independent wheelchair bath.

2.37 The example layout provided (see Figure 13) conflicts with the equivalent space in Approved Document M and BS 8300.

2.38 The layouts of independent wheelchair bathrooms in Approved Document M (Diagrams 24 and 25) and BS 8300 (Figure 45) show a wash-hand basin adjacent to the toilet. This is based on the assumption that users will fill the basin before sitting at the toilet (since the taps may be out of reach) to be able to wash their hands from a seated position on the toilet. This is not considered acceptable in healthcare premises, and hence a separate wash-hand basin has been included within the room (in addition to the hand-rinse basin adjacent to the toilet).

2.39 The example layout allows for right-hand independent wheelchair transfer to the toilet and bath.

2.40 To enable this space to be suitable for all unassisted use, an adjustable-height wash-hand basin may be provided in place of the wheelchair wash-hand basin.

2.41 Additional space may be required for special baths.

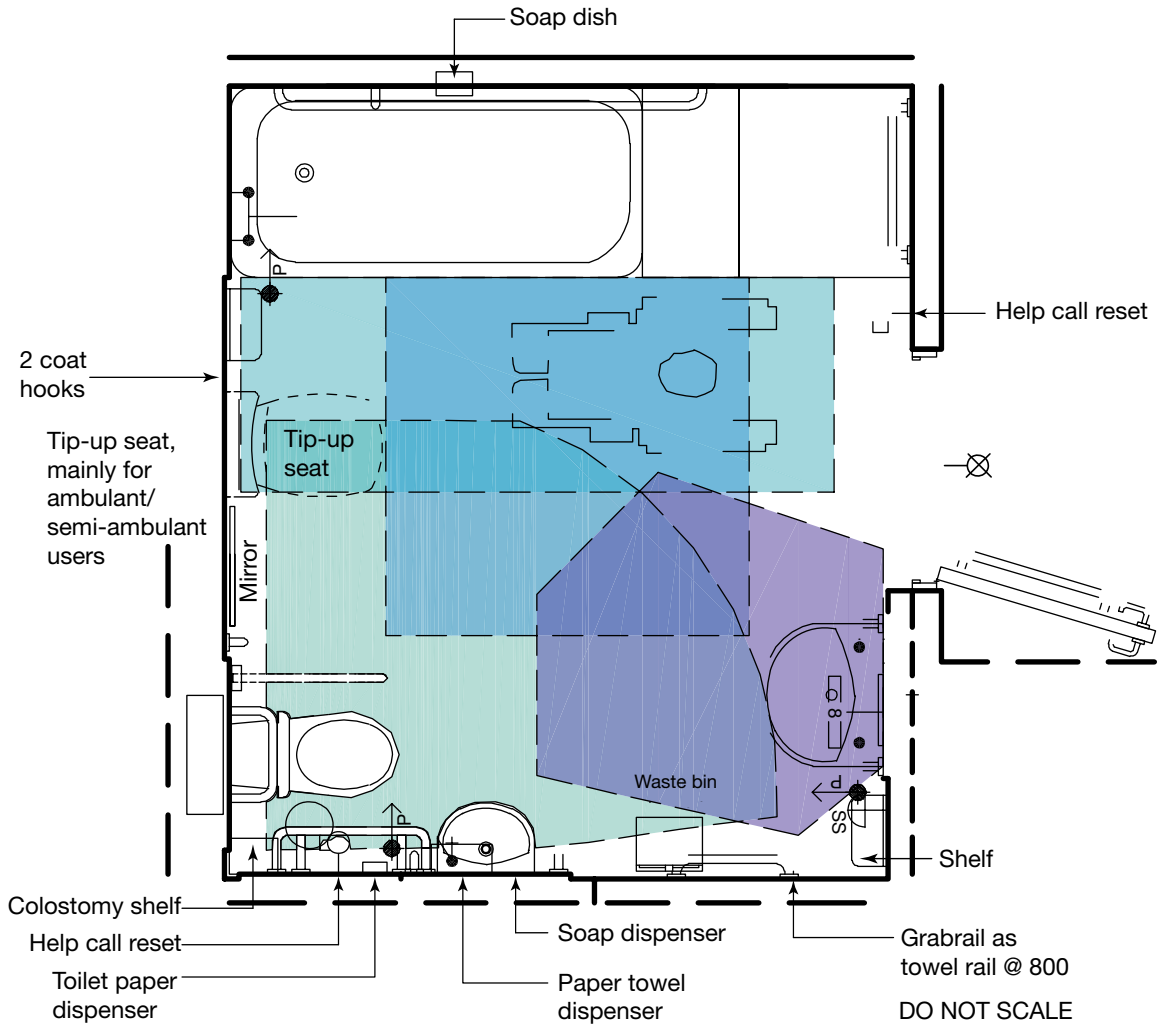

Figure 13 Space requirements to access bathroom: independent wheelchair

Ergonomic drawings

Bath: independent wheelchair

2.42 This ergonomic drawing (see Figure 14) shows the space requirements for an independent wheelchair bath.

2.43 Note the bath and fixings are similar to the bath for semi-ambulant use except for the tap location.

2.44 Wall-mounted taps (compliant with 'Health Building Note 00-10 Part C – Sanitary assemblies') should be provided for reasons of infection control (rather than the corner deck-mounted taps shown in BS 8300). The taps should be located close to the edge of the bath to allow access to the taps for a wheelchair user.

2.45 Where a fixed transfer seat is not provided at the foot of the bath, an independent use bath hoist (chair) should be available, of the type that can be securely fixed to the bath rim when required. Manufacturers' advice should be sought regarding space requirements for such bath hoists.

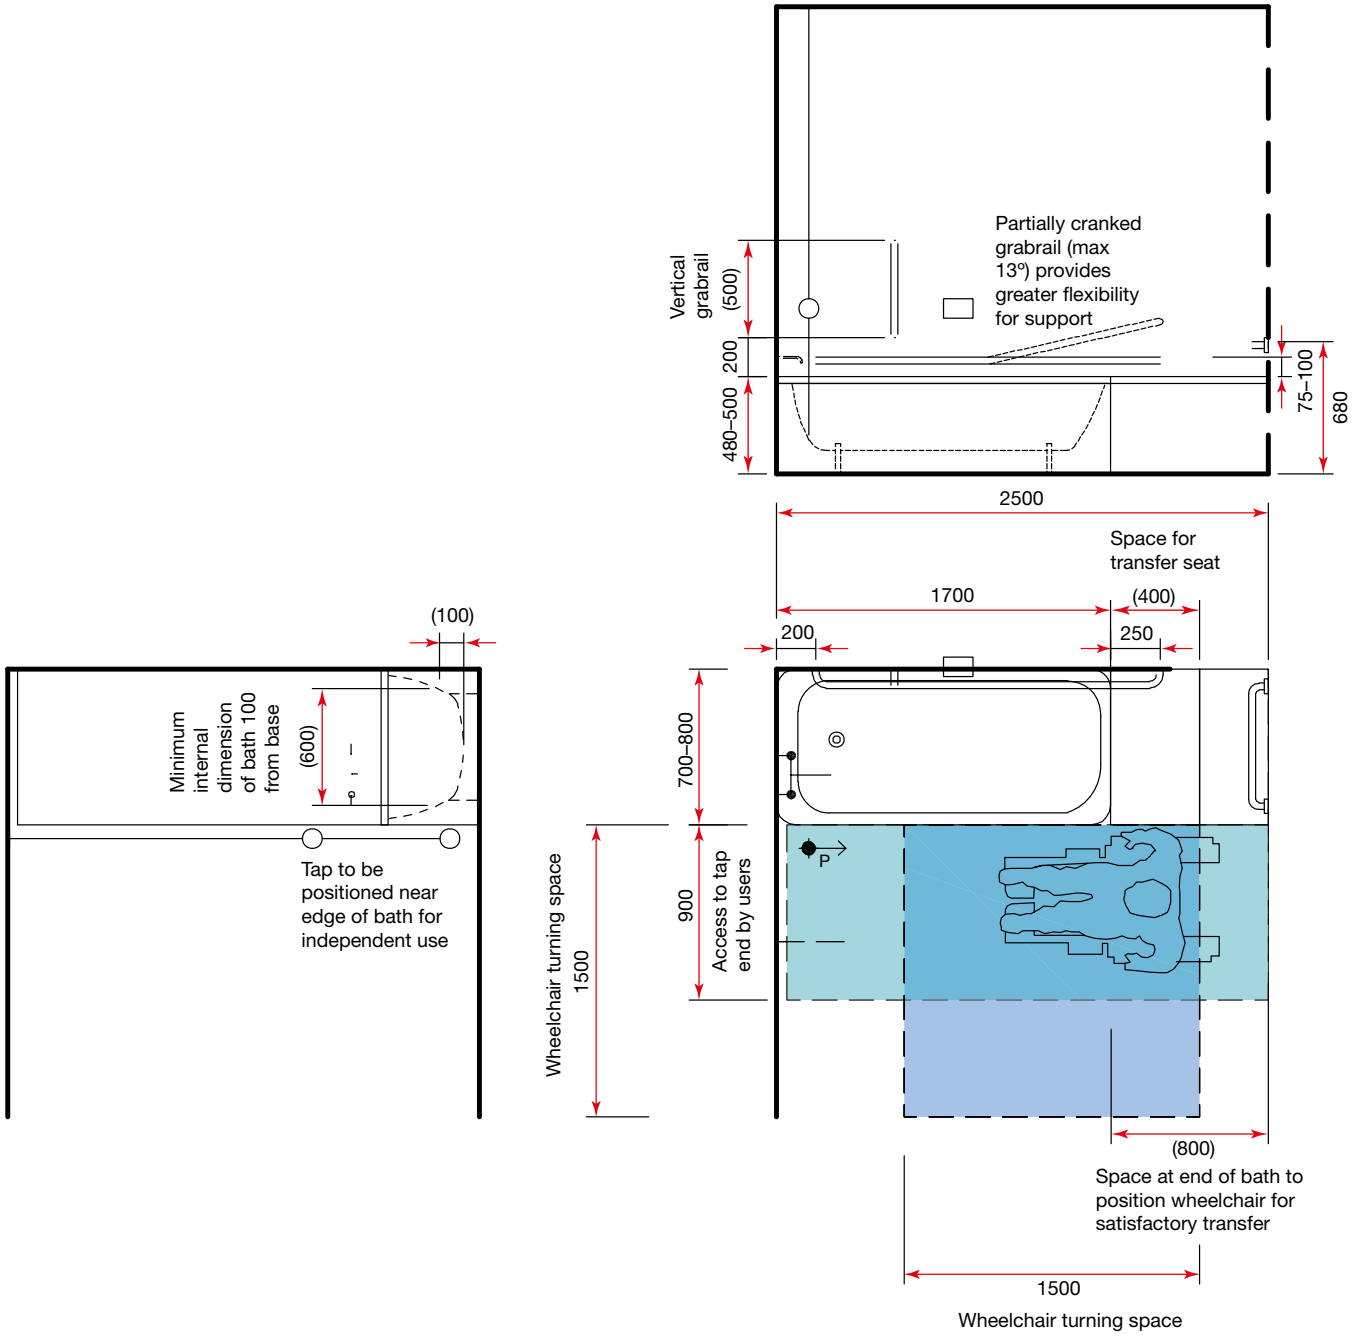

Figure 14 Space requirements for an independent wheelchair bath

Toilet and adjacent hand-rinse basin: independent wheelchair: grabrail options

2.46 These ergonomic drawings (see Figure 15) show the fixing position of grabrails for an independent wheelchair toilet and adjacent hand-rinse basin.

2.47 Grabrails should be provided symmetrically on either side of the toilet at 320 mm from the centreline of the toilet pan. This conflicts with the recommendations in Approved Document M and BS 8300.

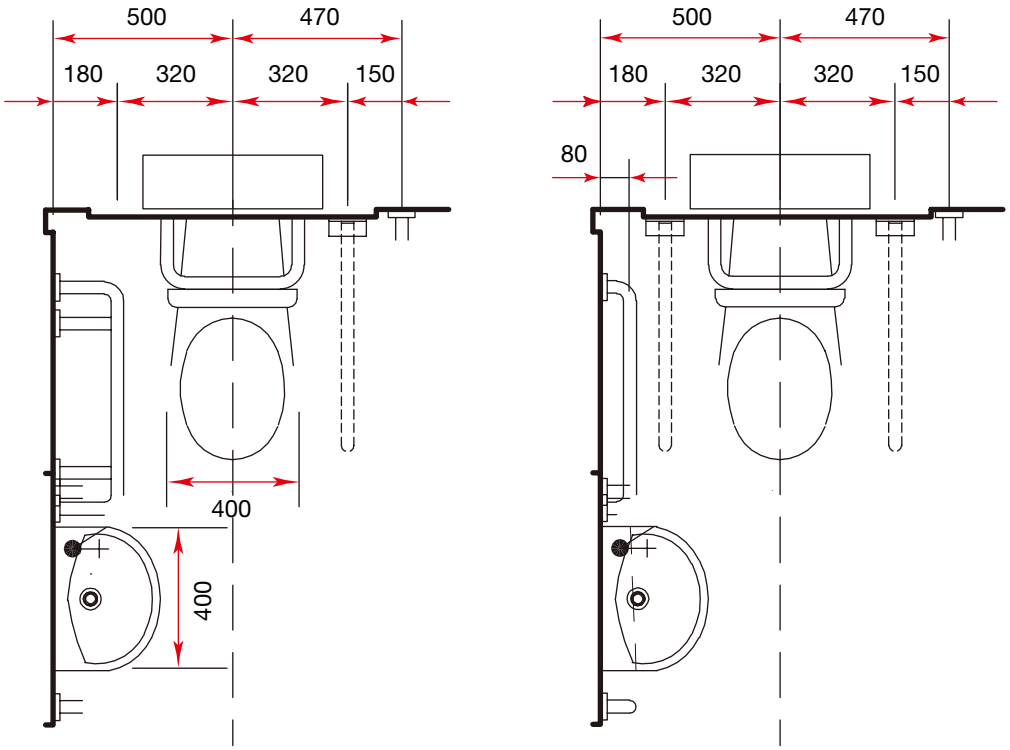
2.48 Approved Document M (paragraph 5.10j) states: "where the horizontal support rail on the wall adjacent to the toilet is set with the minimum spacing from the wall, an additional dropdown rail should be provided on the wall side at a distance of 320 mm from the centreline of the toilet."

Note

Where the maximum spacing defined in Approved Document M, 85 mm, is used, this positions the grabrail approximately 390 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

2.49 BS 8300 (paragraph 12.6.3.5 b) states: "A fixed horizontal rail should be located on the side wall with a 50 mm to 60 mm clearance between the rail and the wall." This places the rail approximately 420 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

2.50 The ergonomic drawings provided illustrate two options for the provision of grabrails. The room layouts on this website are based on option one.



Fixed grabrail between toilet and wall

Alternative fixed and hinged grabrail between toilet and wall

Figure 15 Space requirements showing the fixing position of grabrails for an independent wheelchair toilet and adjacent hand-rinse basin

Toilet and adjacent hand-rinse basin: independent wheelchair

2.51 This ergonomic drawing (see Figure 16) shows the space requirements for an independent wheelchair toilet and adjacent hand-rinse basin.

2.52 The recommended clear space in front and to the open side of the toilet (for independent wheelchair transfer) is greater than the recommendations in Approved Document M and BS 8300.

2.53 Approved Document M and BS 8300 recommend a minimum clear distance of 1000 mm to the open side of the centreline of the toilet for independent wheelchair transfer. Robert Feeney Associates (RFA) research for BS 8300 indicates that this will allow just over 60% of wheelchair users to comfortably transfer onto the toilet. The same research indicates that a clear space of 1400 mm accommodates 90% of wheelchair users and this is, therefore, recommended.

2.54 Approved Document M and BS 8300 recommend a 750 mm long toilet pan for independent wheelchair transfer. However, RFA research indicated that a 700 mm long toilet pan allows independent wheelchair transfer. For maximum space efficiency a 700 mm pan is recommended.

2.55 As a consequence of the reduction in pan length, the hand-rinse basin is located closer to the corner of the room than the position given in Approved Document M and BS 8300, to allow hand-rinsing from a seated position on the toilet.

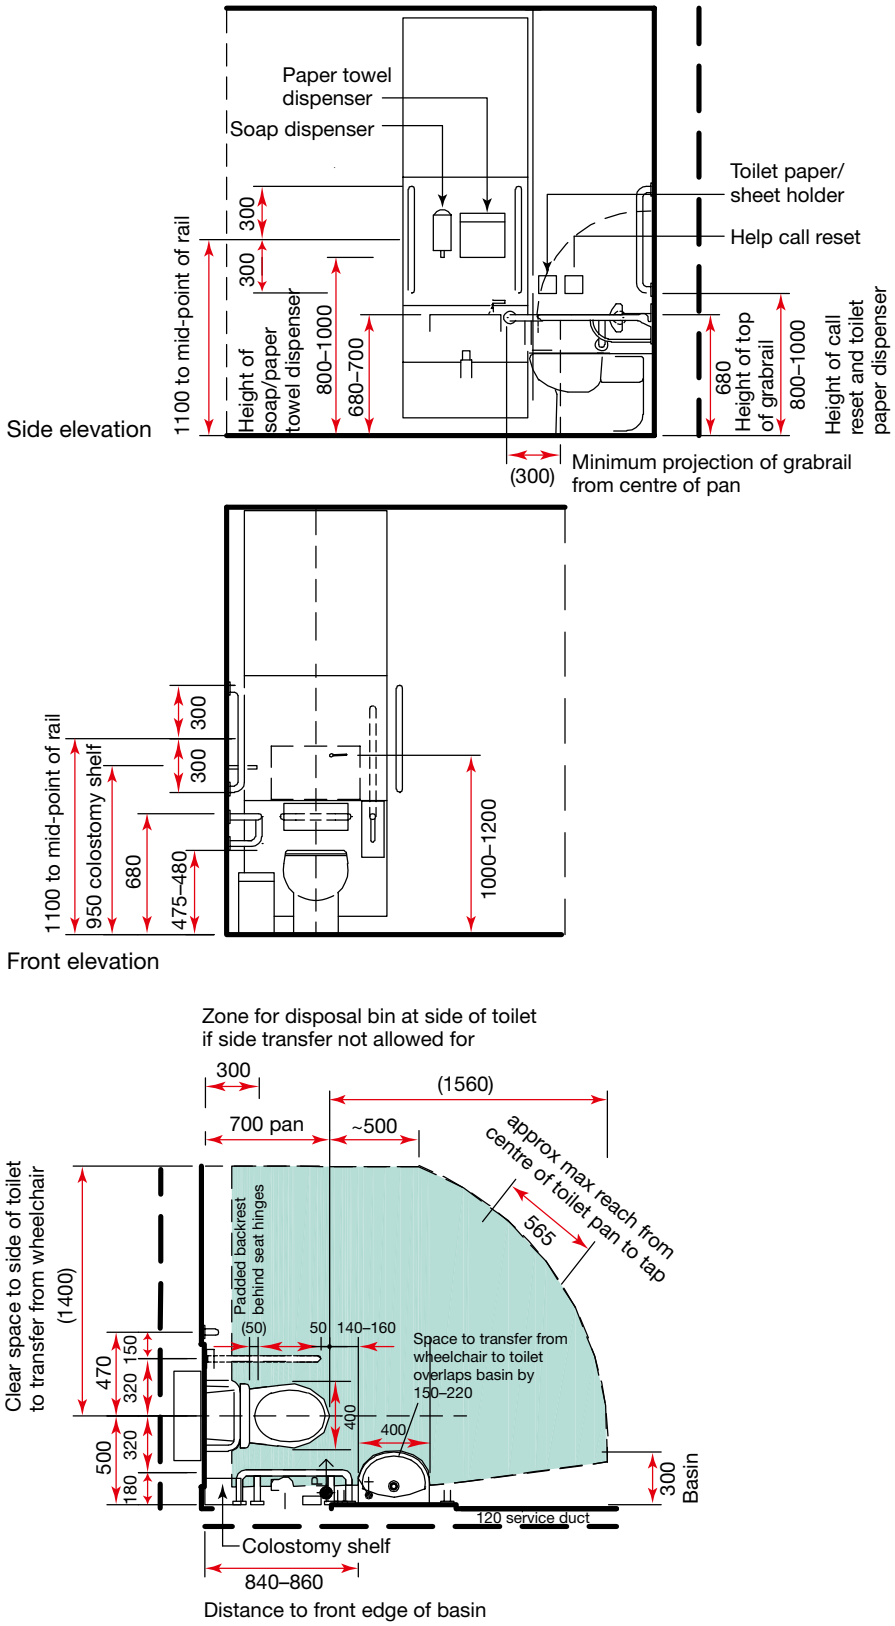


Figure 16 Space requirements for an independent wheelchair toilet and adjacent hand-rinse basin

Wash-hand basin: wheelchair

2.56 Wash-hand basins may be used for personal washing activities.

2.57 This ergonomic drawing (see Figure 17) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

2.58 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

2.59 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

2.60 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

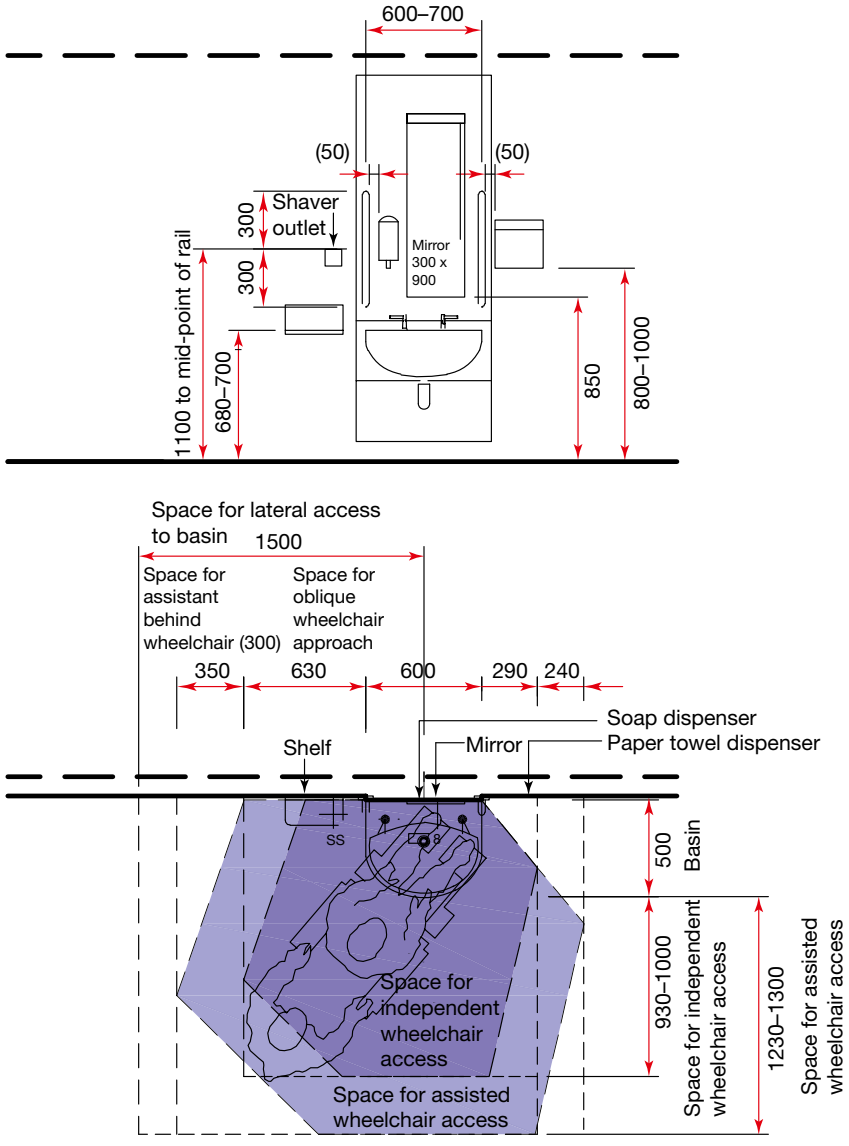

Figure 17 Space requirements for a wheelchair accessible wash-hand basin

Full-length mirror: standing or seated users

2.61 This ergonomic drawing (see Figure 18) shows the space requirements for a full-length mirror for standing or seated users.

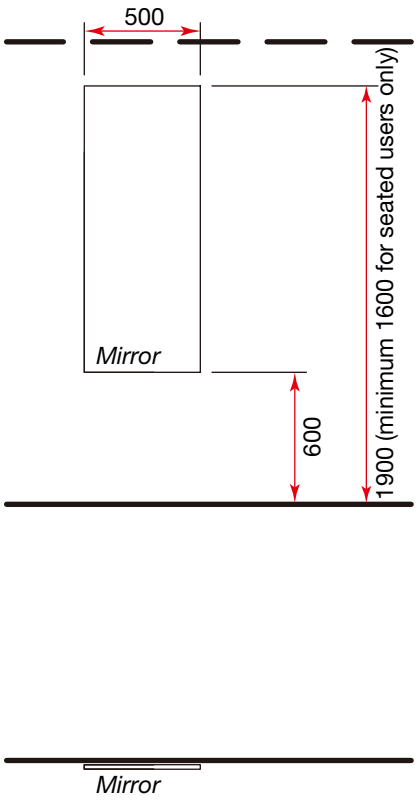

Figure 18 Space requirements for a full-length mirror for standing or seated users

Bathroom: semi-ambulant

Room description and layout

2.62 See Figure 19. The following activities take place in semi-ambulant bathrooms:

- undressing and dressing;
- hanging/holding clothes;
- use of the toilet;
- personal washing;
- use of the bath.

2.63 Semi-ambulant bathrooms should contain a semi-ambulant bath, semi-ambulant toilet and ambulant wash-hand basin.

2.64 Semi-ambulant bathrooms are also suitable for ambulant users.

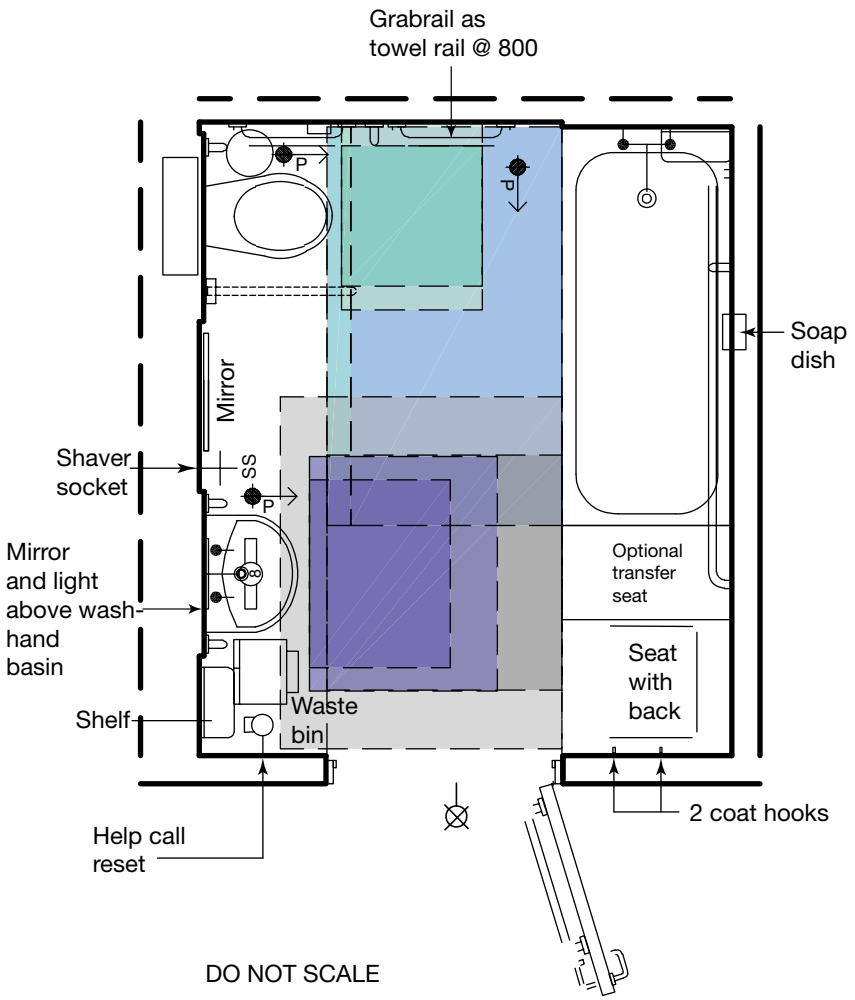

Figure 19 Space requirements for a bathroom: semi-ambulant

Ergonomic drawings

Dressing and undressing: ambulant

2.65 These ergonomic drawings (see Figure 20) show the space requirements for ambulant dressing and undressing.

2.66 An identical space provision is suitable for semi-ambulant users though it should be located adjacent to a seating area.

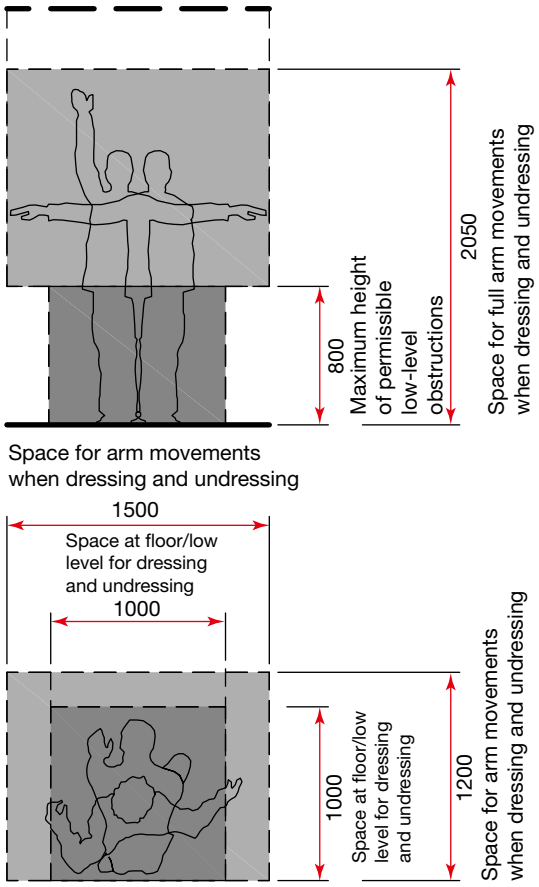

Figure 20 Space requirements for ambulant dressing and undressing

Toilet: semi-ambulant

2.67 This ergonomic drawing (see Figure 21) shows the space requirements for a semi-ambulant toilet.

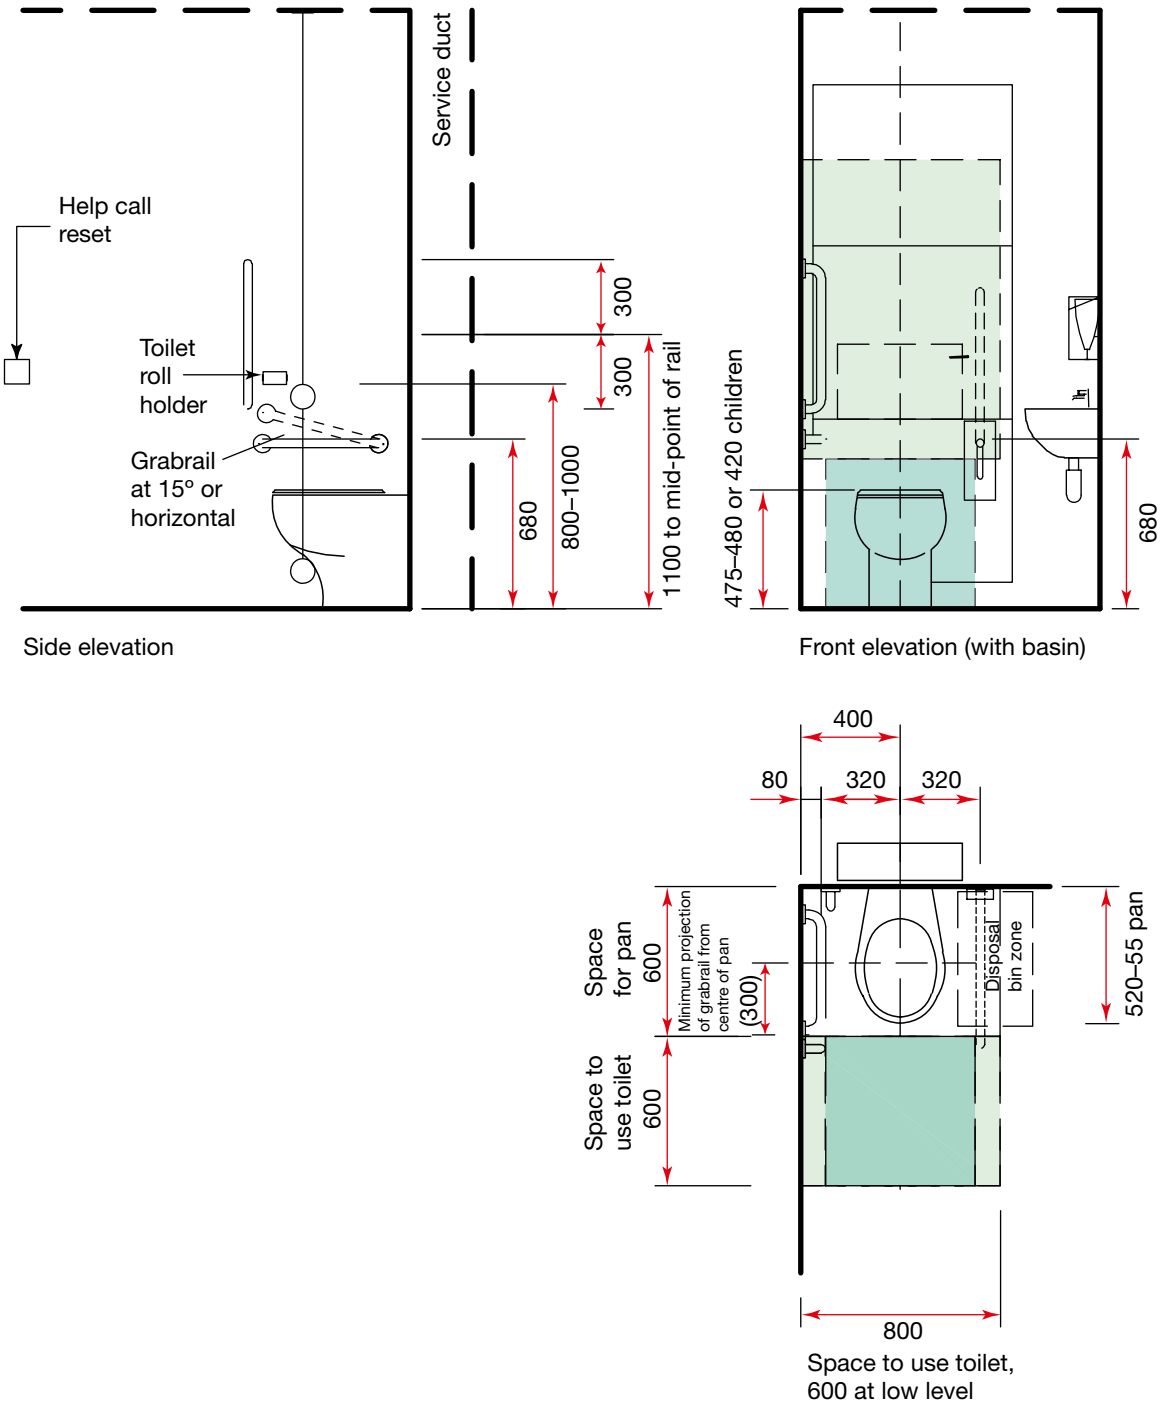

Figure 21 Space requirements for a semi-ambulant toilet

Wash-hand basin: ambulant

2.68 Wash-hand basins may be used for personal washing activities.

2.69 This ergonomic drawing (see Figure 22) shows the space requirements for ambulant/ semi-ambulant use of a 400 mm deep × 500 mm wide wash-hand basin.

2.70 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

2.71 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

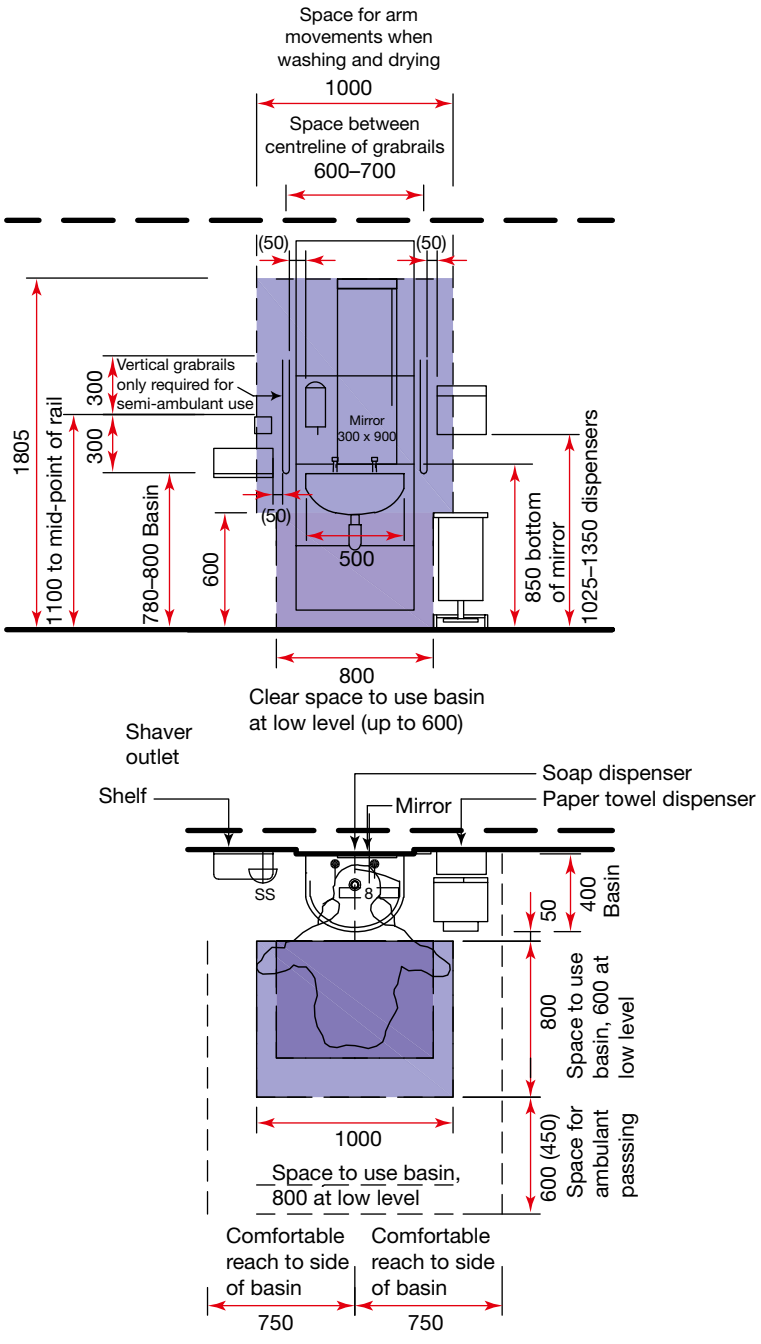

Figure 22 Space requirements for ambulant/semi-ambulant use of a 400 deep x 500 mm wide wash-hand basin

Full-length mirror: standing or seated users

2.72 This ergonomic drawing (see Figure 23) shows the space requirements for a full-length mirror for standing or seated users.

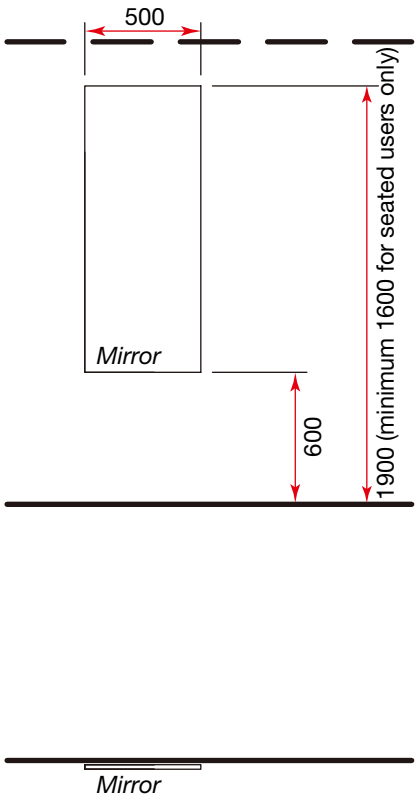

Figure 23 Space requirements for a full-length mirror for standing or seated users

Bath: semi-ambulant

2.73 This ergonomic drawing (see Figure 24) shows the space requirements for a semi-ambulant bath.

2.74 Where a fixed transfer seat is not provided at the foot of the bath, an independent use bath hoist (chair) should be available, of the type that can be securely fixed to the bath rim when required. Manufacturers' advice should be sought regarding space requirements for such bath hoists.

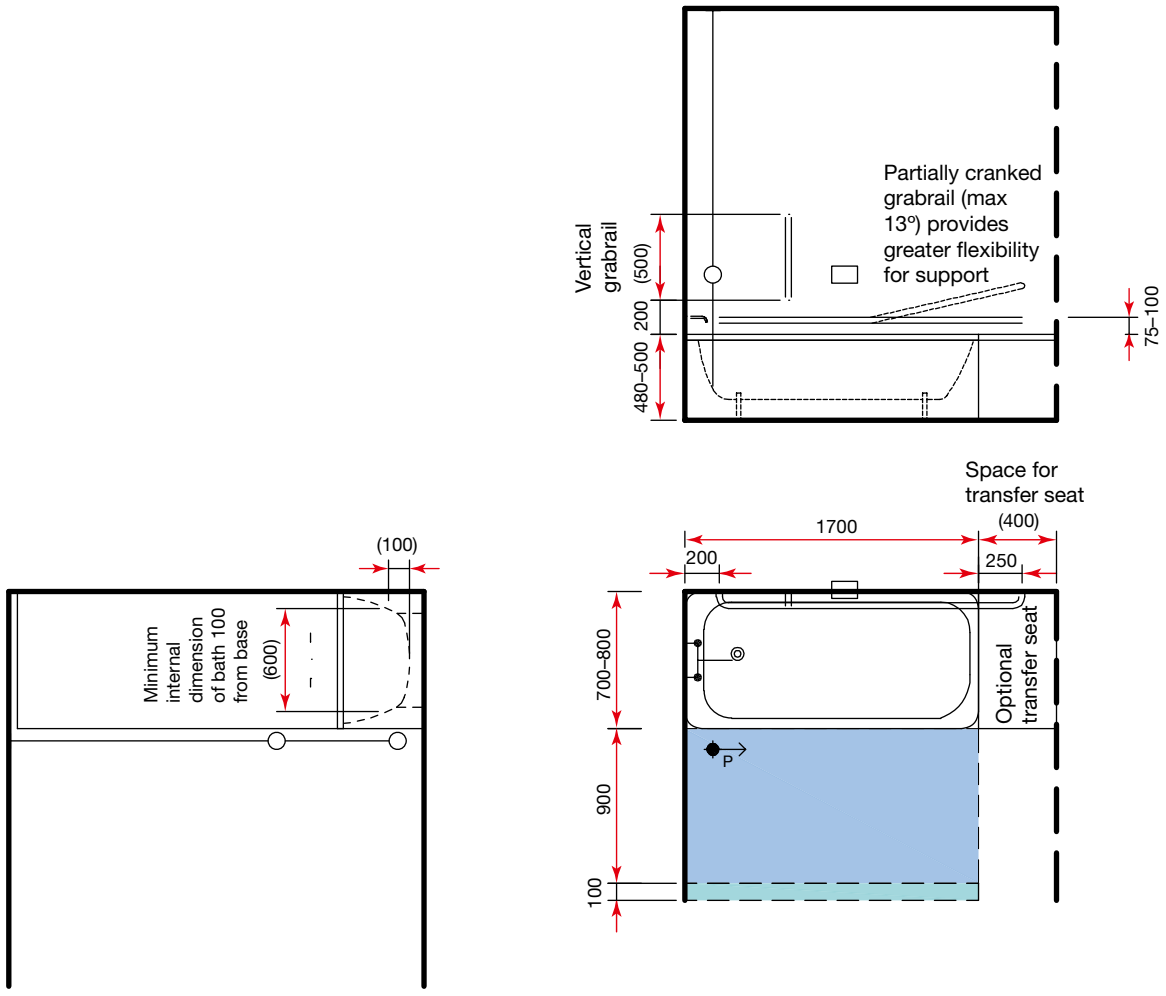

Figure 24 Space requirements for a semi-ambulant bath

3 Changing facilities

Changing area: staff

Room description and layout

3.1 The following activities take place in staff changing areas:

- undressing and dressing;
- changing into clean uniforms, blues or greens (including clean footwear);
- hanging/holding coats and wet clothes;
- storage of clothing and personal belongings;
- storage of clean footwear;
- depositing of dirty uniforms (optional).

3.2 Staff changing areas should include:

- full-length (lockable) lockers for clothing and personal belongings;
- open changing area and/or individual changing rooms;
- changing rails for secure storage of coats and wet clothes;
- storage space for clean footwear (required in theatres etc).

3.3 Separate changing facilities are required for male and female staff.

3.4 Access to the area should be controlled by a keypad lock, close proximity card or similar security system.

3.5 It is assumed that the following facilities will be provided separately but nearby:

- showers;
- wash-hand basins, with soap and paper towel dispensers;
- toilets;
- shaving points (optional);
- power points for hairdryers;
- well-illuminated mirrors with shelves;
- uniform exchange area.

3.6 Consideration should be given to the provision of independent wheelchair showers and WCs in accordance with the requirements of Approved Document M.

3.7 As a minimum, the number of WCs and showers should be provided in accordance with the requirements of the Workplace (Health, Safety & Welfare) Regulations 1992, or current legislation.

3.8 Hand-rinse or personal washing facilities should be provided either within the associated WCs or immediately outside them, accessible from the changing area.

3.9 The room layout provided generally assumes ambulant or semi-ambulant use. Where independent wheelchair access is required, an independent wheelchair changing room(s) should be included and the minimum distance between lockers should be increased to 1500 mm. The area allocation, per locker, should therefore be increased accordingly.

3.10 Locker numbers should be provided on the following basis:

- for a shift system: twice the number of lockers as the maximum number of staff on duty at any one time (to allow for staff changeover), plus an allowance for visiting staff;

- for a non-shift system: the same number of lockers as the maximum number of staff on duty at any one time, plus an allowance for visiting staff.

3.11 The changing area provided should allow at least half the maximum number of staff on duty at any one time to change simultaneously. It is generally assumed that this will be in an open-plan space between lockers. At least one individual changing room should be provided.

3.12 The room layout (see Figure 25) includes 20 lockers and space for six people to change (suitable for a maximum of 10 staff on duty at any one time, including visiting staff).

3.13 The room layout includes the recommended minimum of one semi-ambulant changing room. Consideration should be given to:

- the number of individual changing rooms required. This will depend on local policy;
- the provision of independent wheelchair changing rooms in accordance with the requirements of Approved Document M.

3.14 The actual space requirements for lockers and changing will depend upon the size and quantity of lockers and whether changing space is provided in open-plan space between the lockers or in individual changing rooms. However, as a general guide the following space allocations should be allowed:

a. Where changing space is generally provided in the open space between lockers, 1.1 m² per full-height locker for up to 30 lockers and 0.75 m² per full-height locker for greater than 30 lockers;

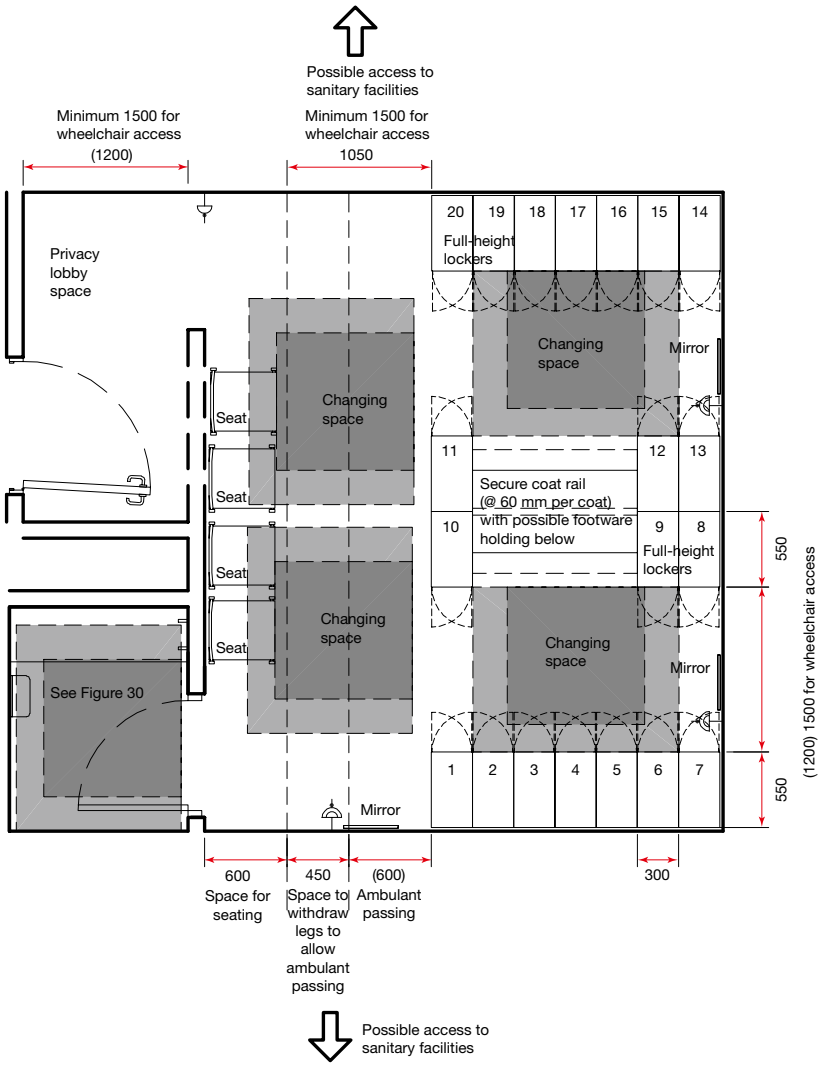

Figure 25 Space requirements for changing area: staff, 20 lockers

b. Where changing space is provided within separate changing cubicles, 0.75 m² per full-height locker for up to 50 lockers.

3.15 For the purposes of creating a briefing schedule, staff changing areas may be sized at 1.4 m² per locker. This allows for full height lockers, communal changing space for approx 25% of the lockers, an allowance for local uniform exchange, one individual semi-ambulant changing room and one ambulant shower room for every 20 lockers. It assumes cube lockers for personal belongings, if provided, are located elsewhere. See the table below.

3.16 The allowance does not include WCs, which need to be calculated separately based on the total number of staff.

3.17 When dividing changing areas into separate male and female allowance each space should be overprovided by, say, 10% to allow for flexibility in the percentage split between male and female users.

3.18 The staff multiplier for uniform exchange assumes that not everybody works full-time. In critical care areas, the multiplier may be as big as 5 but generally:

- 3.5 is considered reasonable for a facility with a shift system;
- 1.2 is considered acceptable for a facility without a shift system.

Table 1 Changing areas: staff

Shift system 40 lockers = 20 staff on duty						
	Staff multiplier for uniform exchange	**Qty**	**Area (m²)**	**Total**		
Changing area: 20 lockers		2	20	40		
Semi-ambulant changing room		2	2	4		
Ambulant shower room		2	2	4		
Uniform exchange lockers	5	100	0.1	10		
				58	**or**	**1.45 sq m per locker**
Shift system 40 lockers = 20 staff on duty						
	Staff multiplier for uniform exchange	**Qty**	**Area (m²)**	**Total**		
Changing area: 20 lockers		2	20	40		
Semi-ambulant changing room		2	2	4		
Ambulant shower room		2	2	4		
Uniform exchange lockers: 70	3.5	70	0.1	7		
				55	**or**	**1.38 sq m per locker**
Non-shift system 40 lockers = 40 staff on duty						
	Staff multiplier for uniform exchange	**Qty**	**Area (m²)**	**Total**		
Changing area: 20 lockers		2	20	40		
Semi-ambulant changing room		2	2	4		
Ambulant shower room		2	2	4		
Uniform exchange lockers: 80	1.2	48	0.1	4.8		
				52.8	**or**	**1.32 sq m per locker**
			AVERAGE			**1.4 sq m per locker**

Ergonomic drawings

Dressing and undressing: ambulant

3.19 These ergonomic drawings (see Figure 26) show the space requirements for ambulant dressing and undressing.

3.20 An identical space provision is suitable for semi-ambulant users though it should be located adjacent to a seating area.

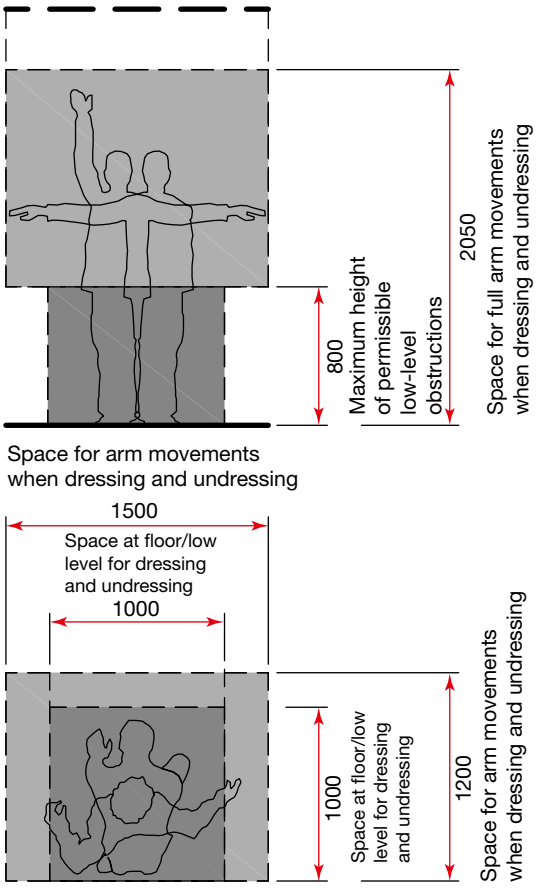

Figure 26 Space requirements for ambulant dressing and undressing

Full-length mirror: standing or seated users

3.21 This ergonomic drawing (see Figure 27) shows the space requirements for a full-length mirror for standing or seated users.

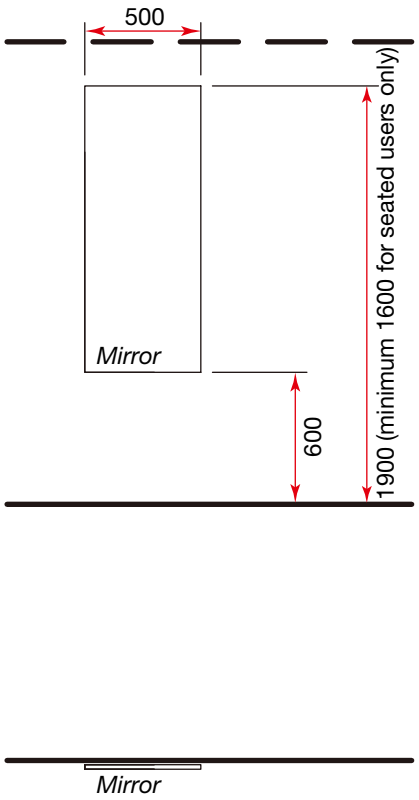

Figure 27 Space requirements for a full-length mirror for standing or seated users

Changing room: independent wheelchair

Room description and layout

3.22 See Figures 28 and 29. The following activities take place in independent wheelchair changing rooms:

- undressing and dressing;
- hanging/holding clothes;
- wheelchair transfer to the bench or tip-up seat.

3.23 Independent wheelchair changing rooms should contain a full-length mirror, a shelf for holding personal belongings, a bench or tip-up seat and two coat hooks for hanging garments.

3.24 Help call should be provided if the room is for staff or patient use.

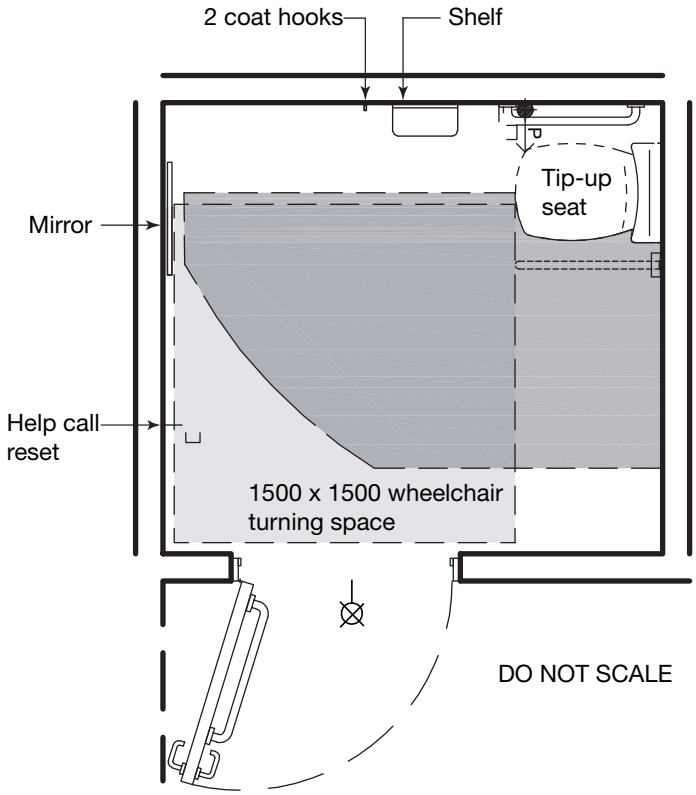

Figure 28 Space requirements for independent wheelchair changing room

Ergonomic drawings

Independent wheelchair changing

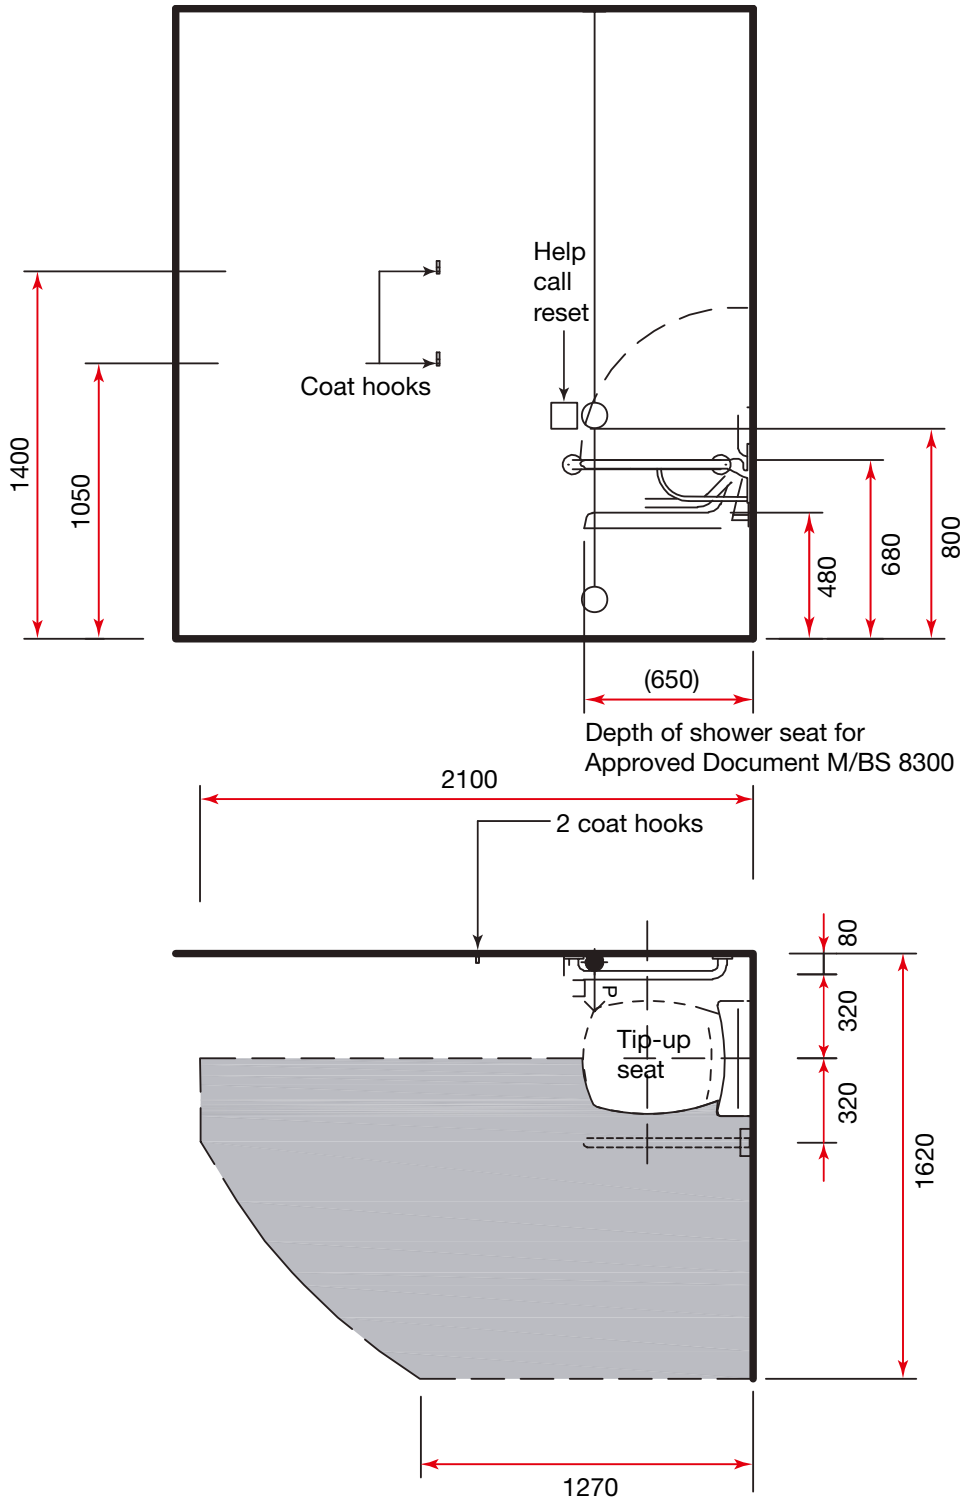

Figure 29 Independent wheelchair changing room

Changing room: semi-ambulant

Room description and layout

3.25 See Figure 30. The following activities take place in semi-ambulant changing rooms:

- undressing and dressing;
- hanging/holding clothes.

3.26 Semi-ambulant changing rooms should contain a full-length mirror, a shelf for holding personal belongings, a bench or tip-up seat and two coat hooks for hanging garments.

3.27 They are also suitable for ambulant use.

3.28 Help call should be provided if the room is for patient use.

3.29 The room should be lockable. Clothes/belongings may either be locked in the room or in a separate locker, or kept with the patient.

3.30 Access arrangements to and from the room and its relationship with changed waiting areas (where provided) should ensure patient privacy and dignity.

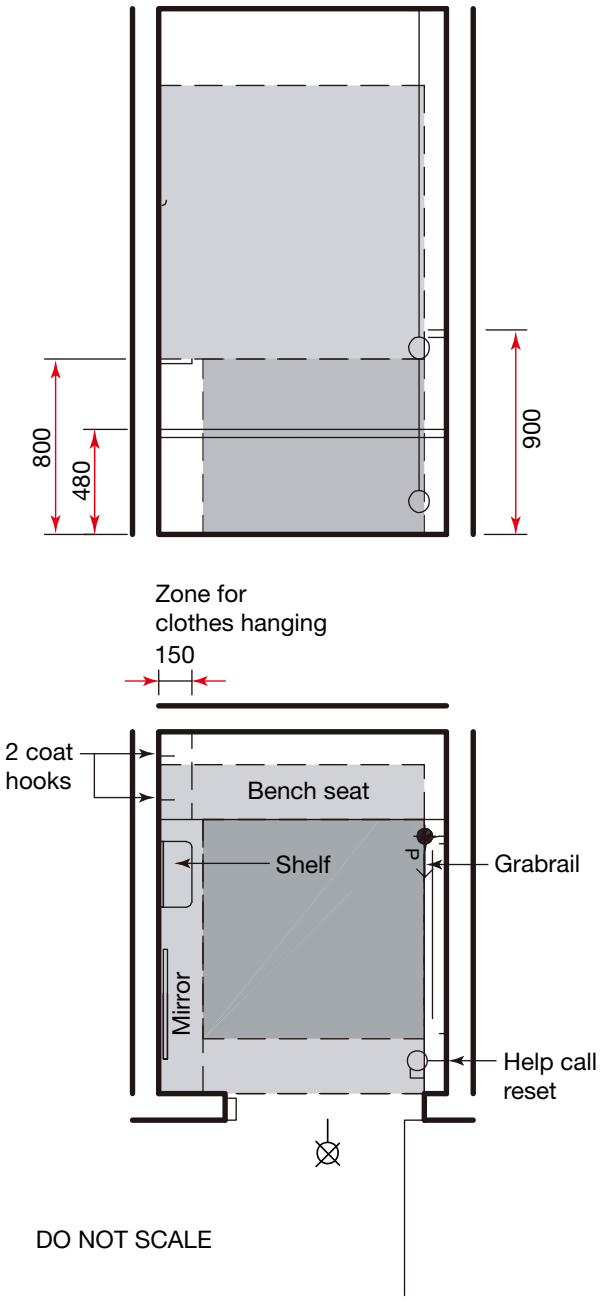

Figure 30 Space requirements for changing room: semi-ambulant

Ergonomic drawings

Dressing and undressing: ambulant

3.31 These ergonomic drawings (see Figure 31) show the space requirements for ambulant dressing and undressing.

3.32 An identical space provision is suitable for semi-ambulant users though it should be located adjacent to a seating area.

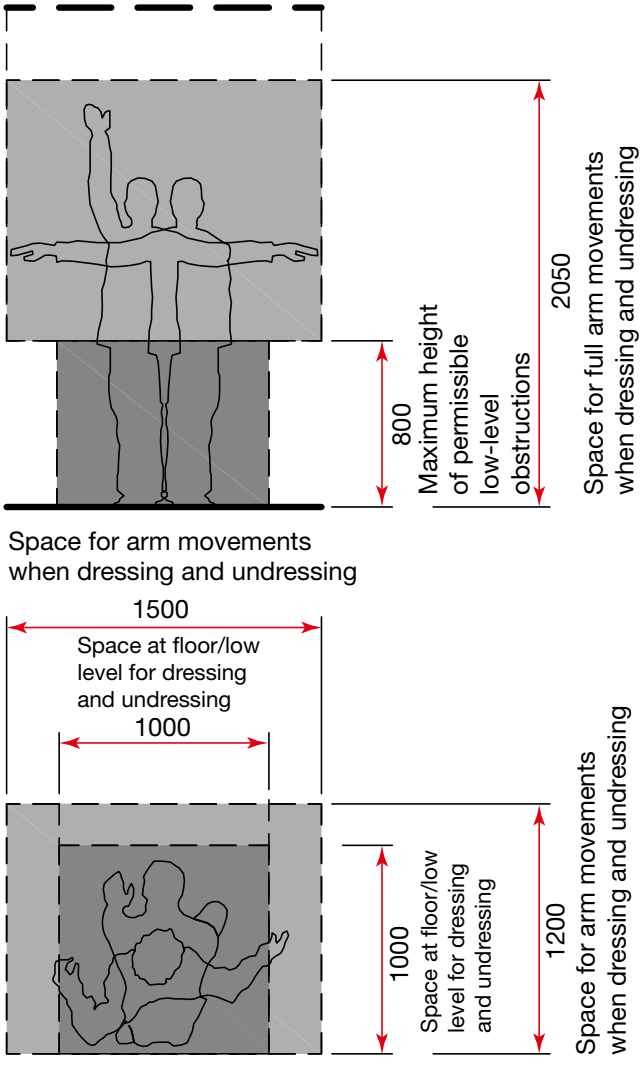

Figure 31 Space requirements for ambulant dressing and undressing

Full-length mirror: standing or seated users

3.33 This ergonomic drawing (see Figure 32) shows the space requirements for a full-length mirror for standing or seated users.

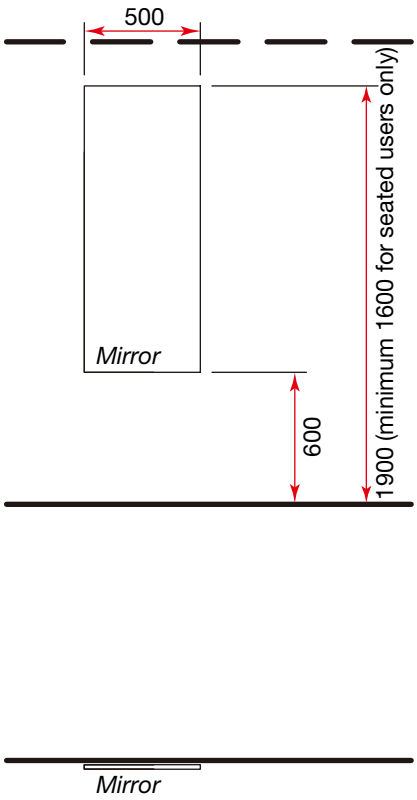

Figure 32 Space requirements for a full-length mirror for standing or seated users

Nappy changing room

Room description and layout

3.34 The following activities take place in nappy changing rooms:

- changing infants' nappies;
- disposal of soiled nappies;
- personal washing.

3.35 Nappy changing rooms are suitable for use by a single ambulant adult with a baby or infant.

3.36 Nappy changing rooms should contain the following:

- changing table;
- shelf, at worktop height, at the end of the table for placing packs of wipes etc (not above the table, as the parent/carer may hit their head when rising);
- seat for a parent/carer;
- wash-hand basin with sensor-operated taps;
- disposal bin for soiled nappies and other clinical waste;
- soap dispenser and paper towel dispenser;
- waste bin for used paper towels.

3.37 Sensor-operated taps are recommended for infection control; users may have heavily soiled hands and, as this is a public space, the room may not be fully cleaned between usages.

3.38 The folding nappy changing table recommended in Approved Document M (paragraph 5.14d) for use in larger semi-ambulant WCs is not recommended in healthcare premises. In healthcare premises, it is recommended that nappy changing facilities should be provided separately from WC provision.

3.39 The room layout provided (see Figure 33) illustrates two options for the changing table within the same overall space: a fold-down table with primary access from the end and a fixed or adjustable-height changing table with access from one end.

3.40 Sound attenuation of doors, ceilings and partitions should be considered to prevent the sound of crying children travelling into adjacent spaces.

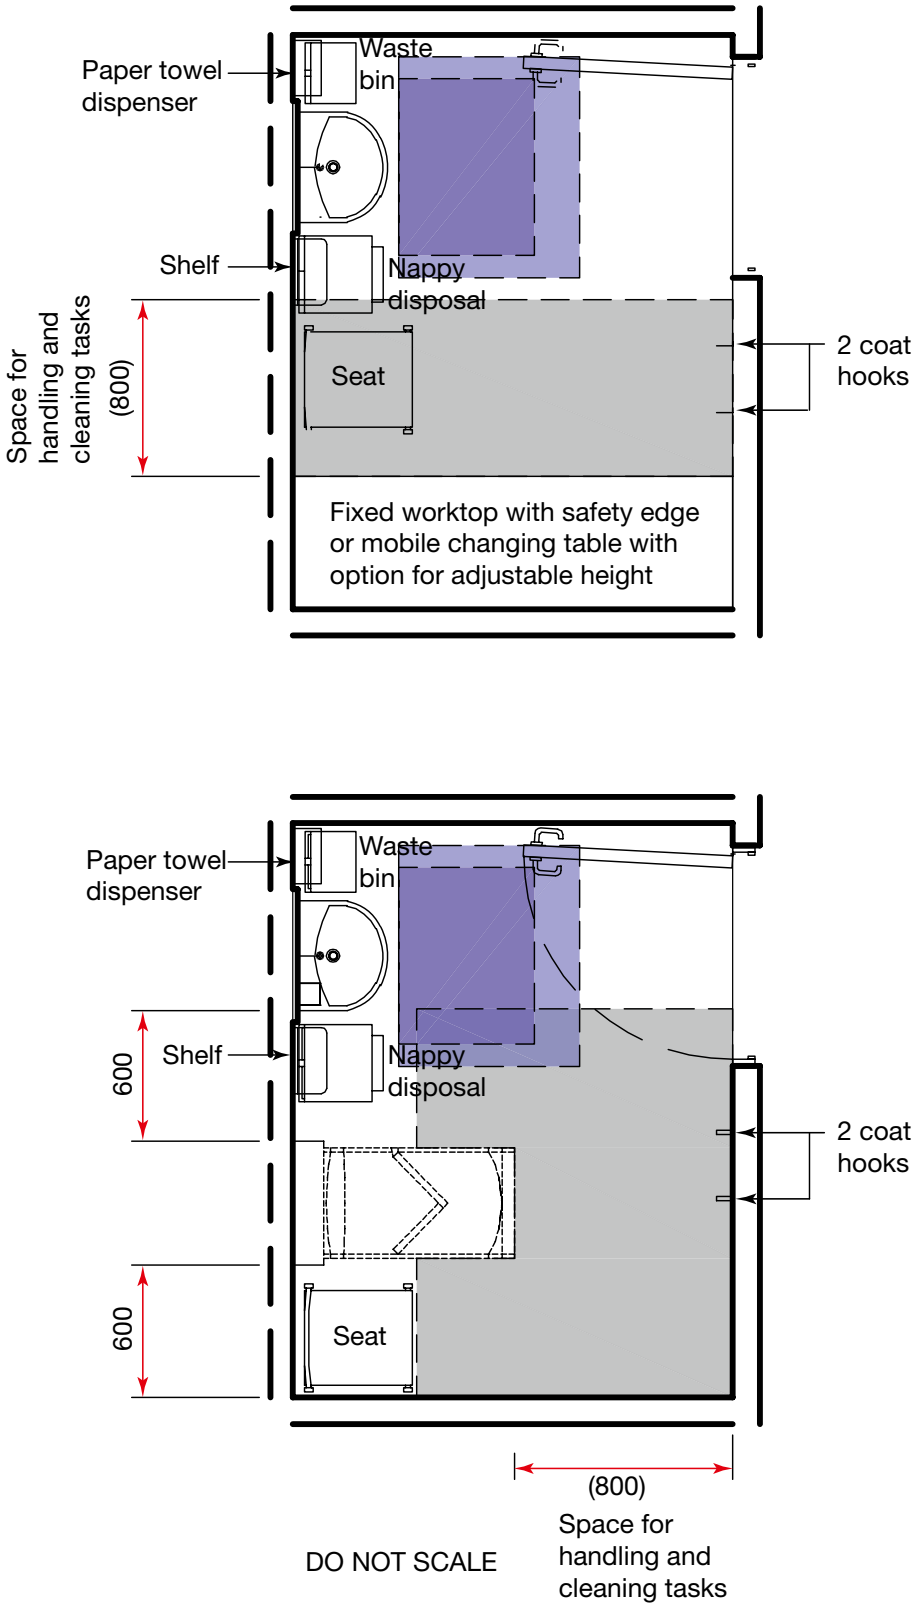

Figure 33 Space requirements for nappy changing room

Ergonomic drawings

Wash-hand basin: ambulant

3.41 Wash-hand basins may be used for personal washing activities.

3.42 This ergonomic drawing (see Figure 34) shows the space requirements for ambulant/ semi-ambulant use of a 400 mm deep × 500 mm wide wash-hand basin.

3.43 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

3.44 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

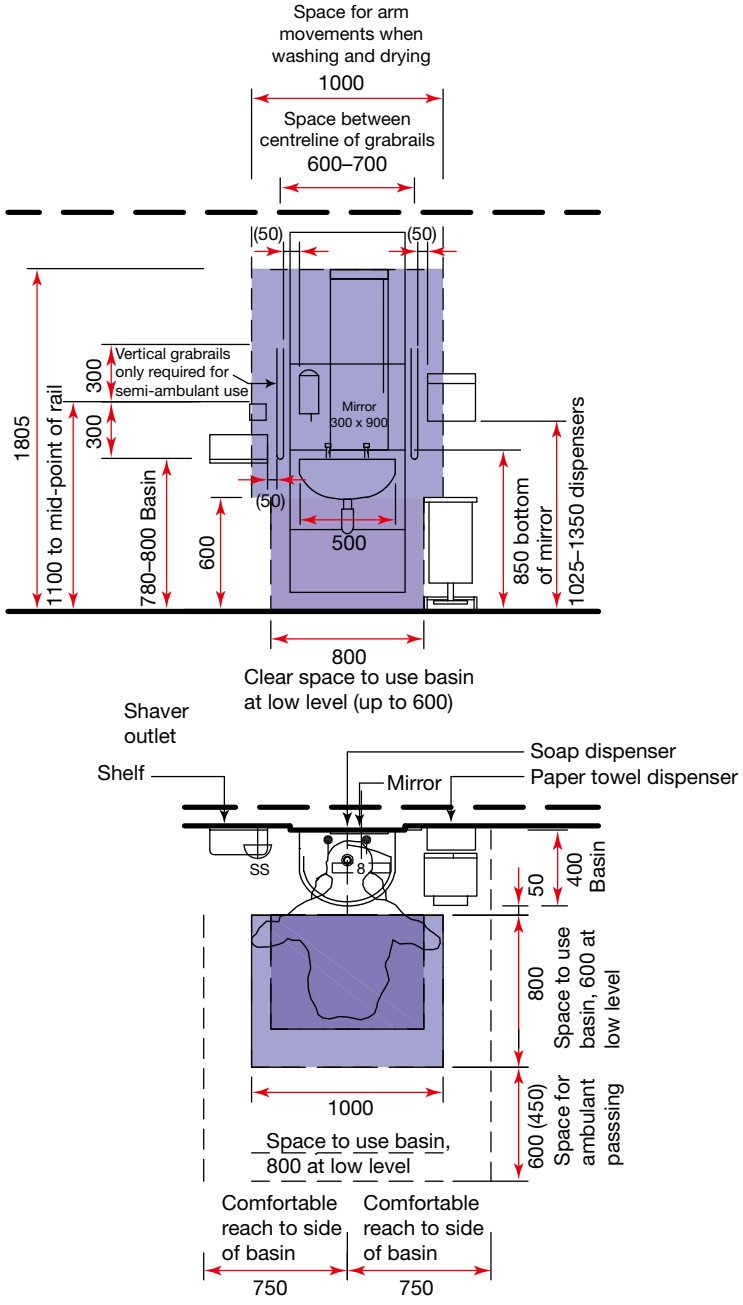

Figure 34 Space requirements for ambulant/semi-ambulant use of a 400 mm deep x 500 mm wide wash-hand basin

Uniform exchange area

Room description and layout

3.45 It is assumed that separate lockers will be provided for uniform exchange (for personalised uniforms only). Non-personalised uniforms may be provided in the changing areas or adjacent lobby.

3.46 The layout provided (see Figure 35) shows 70 lockers, 10 high in each bank, with a built-in dirty uniform collection point.

3.47 The actual number of uniform exchange lockers required will depend upon the number of staff working in any given area. An allowance of 0.1 m² per uniform locker has been allowed.

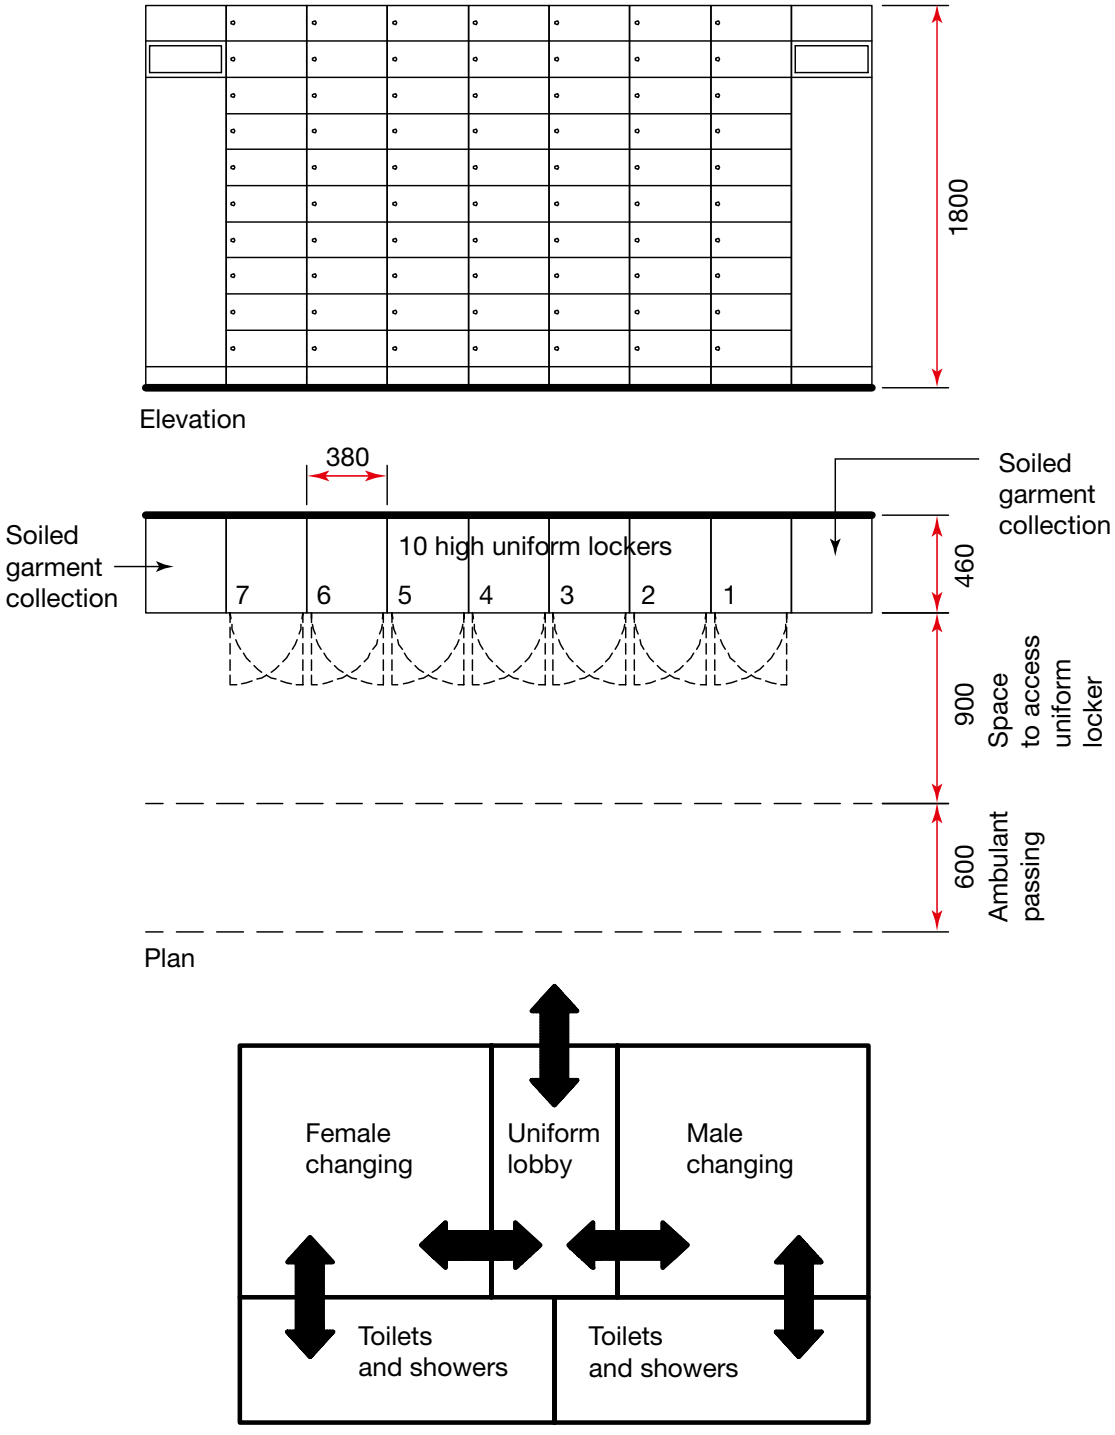

Figure 35 Space requirements for 70 lockers, 10 high in each bank, built-in dirty uniform collection point

4 Shower rooms

Shower room: ambulant

Room description and layout

4.1 See Figure 36. The following activities take place in ambulant shower rooms:

- undressing and dressing;
- hanging/holding clothes;
- showering.

4.2 Ambulant shower rooms (without toilets or tip-up shower seats) are only suitable for fully ambulant staff or visitors.

4.3 The use of shower trays is acceptable in ambulant shower rooms. They should not be used in any patient areas as they present a tripping hazard.

4.4 An inward-opening door may be used without increasing the space requirements within the room.

4.5 The room layout provided shows a small mirror. Alternatively, a full-length mirror may be provided.

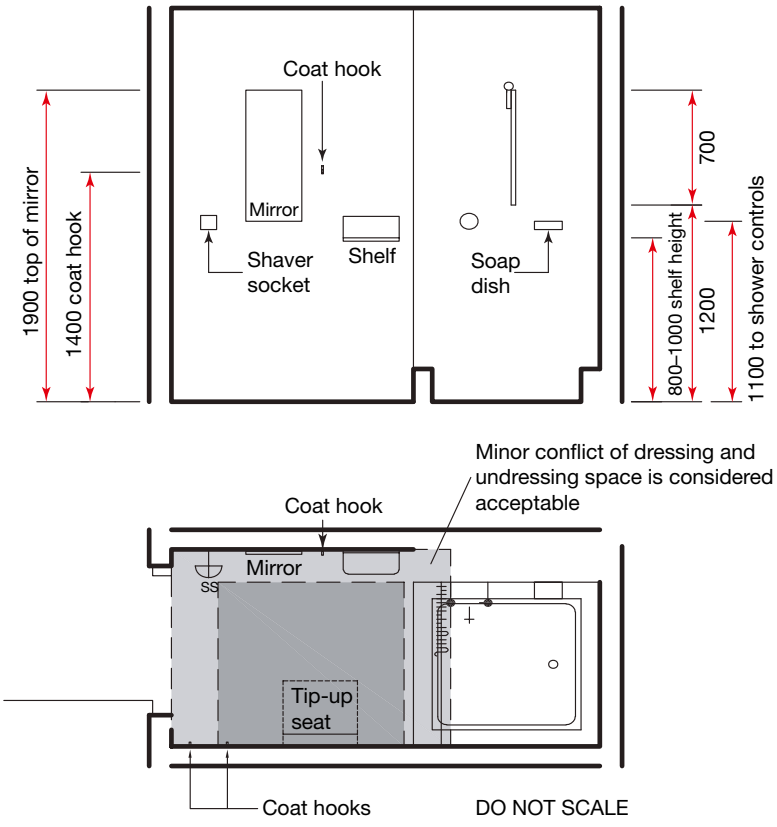

Figure 36 Space requirements for ambulant shower room

Ergonomic drawings

Dressing and undressing: ambulant

4.6 These ergonomic drawings (see Figure 37) show the space requirements for ambulant dressing and undressing.

4.7 An identical space provision is suitable for semi-ambulant users though it should be located adjacent to a seating area.

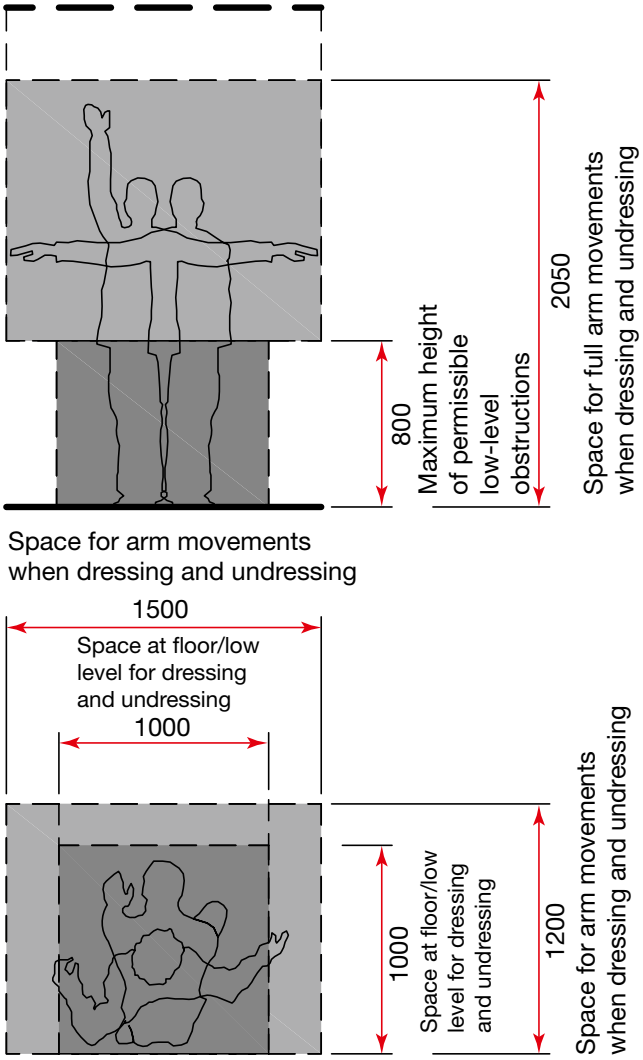

Figure 37 Space requirements for ambulant dressing and undressing

Shower room: assisted

Room description and layout

4.8 The following assisted activities take place in assisted shower rooms:

- undressing and dressing;
- hanging/holding clothes;
- wheelchair, sanitary chair and shower chair access to the toilet, wash-hand basin and shower;
- mobile hoist access to transfer a patient to the toilet or shower seat or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet or shower seat (supervised only);
- use of the toilet;
- personal washing (whilst seated);
- showering (whilst seated).

4.9 An assisted shower room should contain an assisted shower with tip-up shower seat, assisted toilet and wheelchair wash-hand basin.

4.10 The assisted shower should provide staff access from both sides and from the front of the shower and to the shower controls.

4.11 Staff should be able to remain dry whilst assisting in showering.

4.12 Mobile hoist access will be required if a patient collapses on the floor, even if it is not used for transferring patients to the toilet.

4.13 The room layout provided (see Figure 38) includes a fixed tip-up shower seat. A mobile shower chair may be used instead of the tip-up shower seat.

4.14 Assisted wheelchair and hoist transfer to the shower seat is only possible from the right-hand side of the shower (if facing the shower). Consideration should be given to providing both left- and right-hand versions of this layout to allow for all users.

4.15 Where assisted shower rooms are provided en-suite to bedrooms and additional assisted shower rooms or bathrooms are provided nearby, consideration may be given to reducing the clear space in front and to the side of the toilet in accordance with the en-suite shower room layouts.

4.16 To enable this space to be suitable for ambulant and semi-ambulant use as well as assisted use, an adjustable-height wash-hand basin may be provided in place of the wheelchair wash-hand basin.

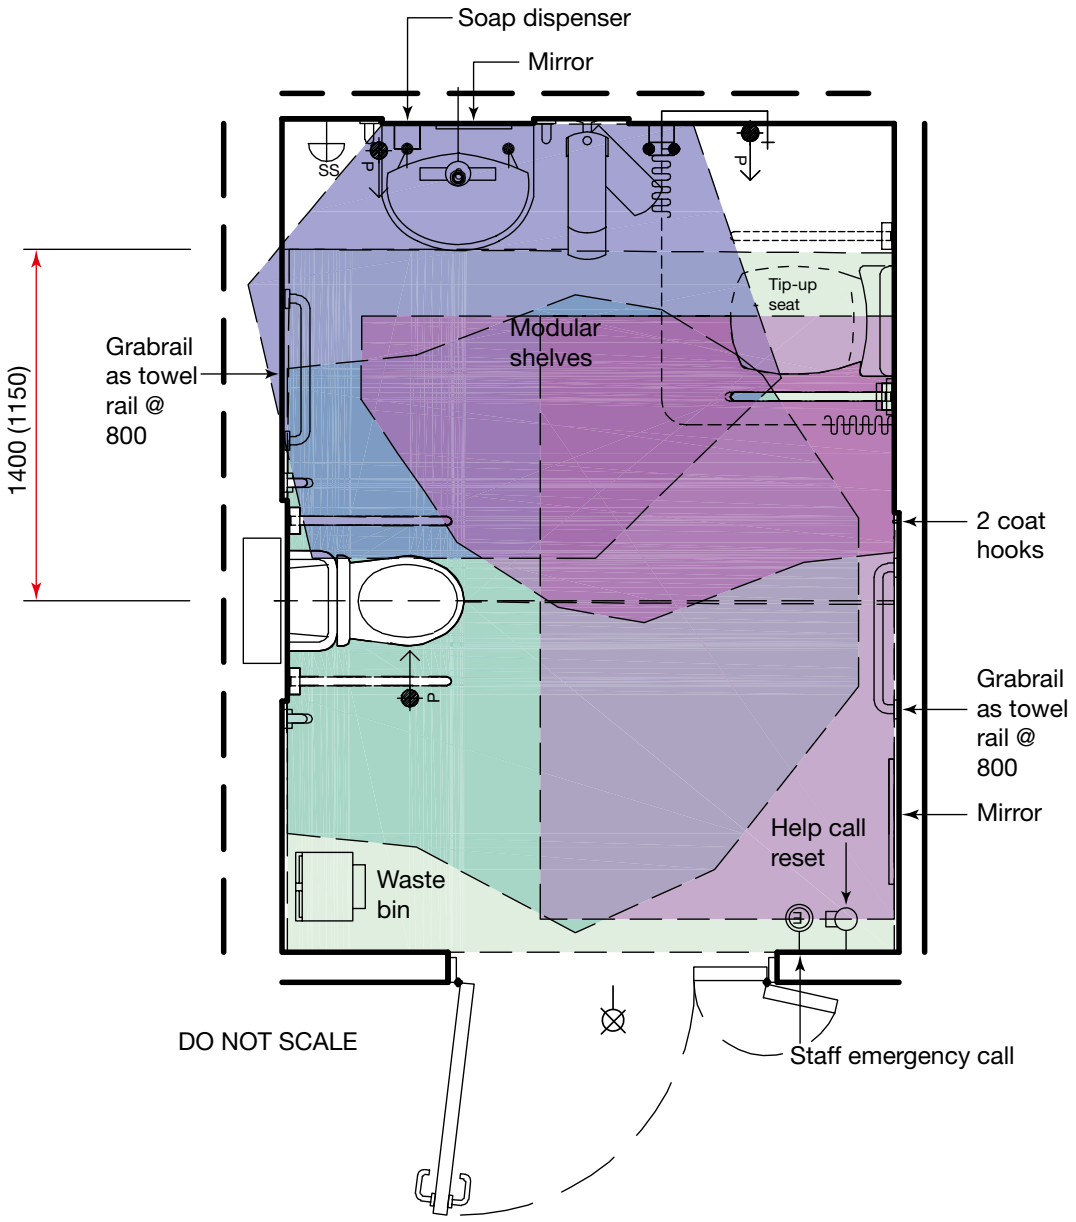

Figure 38 Space requirements for shower room: assisted

Ergonomic drawings

Assisted shower with fixed tip-up shower seat

4.17 This ergonomic drawing (see Figure 39) shows the space requirements for an assisted shower with a fixed tip-up shower seat.

4.18 Fixed-position shower controls should be sited close to the shower curtain and at a height of 900–1000 mm to satisfy both staff and seated users.

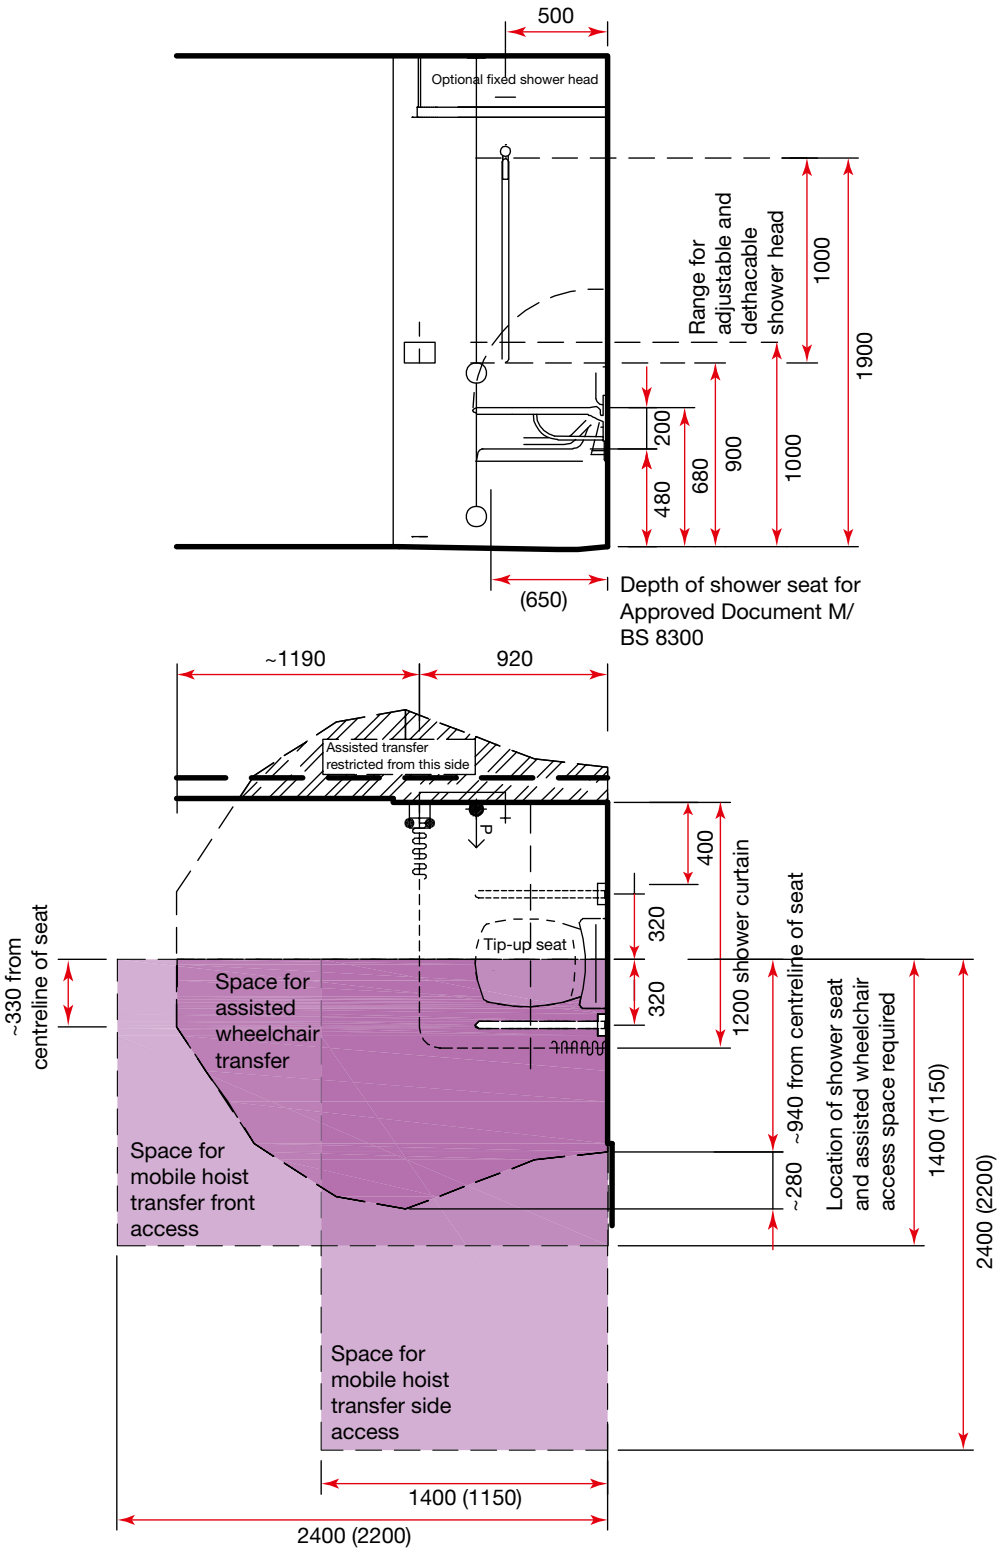

Figure 39 Space requirements for assisted shower with fixed tip-up shower seat

Toilet: assisted

4.19 This ergonomic drawing (see Figure 40) shows the space requirements for an assisted toilet.

4.20 The clear space on either side of the toilet for mobile hoist transfer is greater than that recommended in BS 8300 (Figure 55).

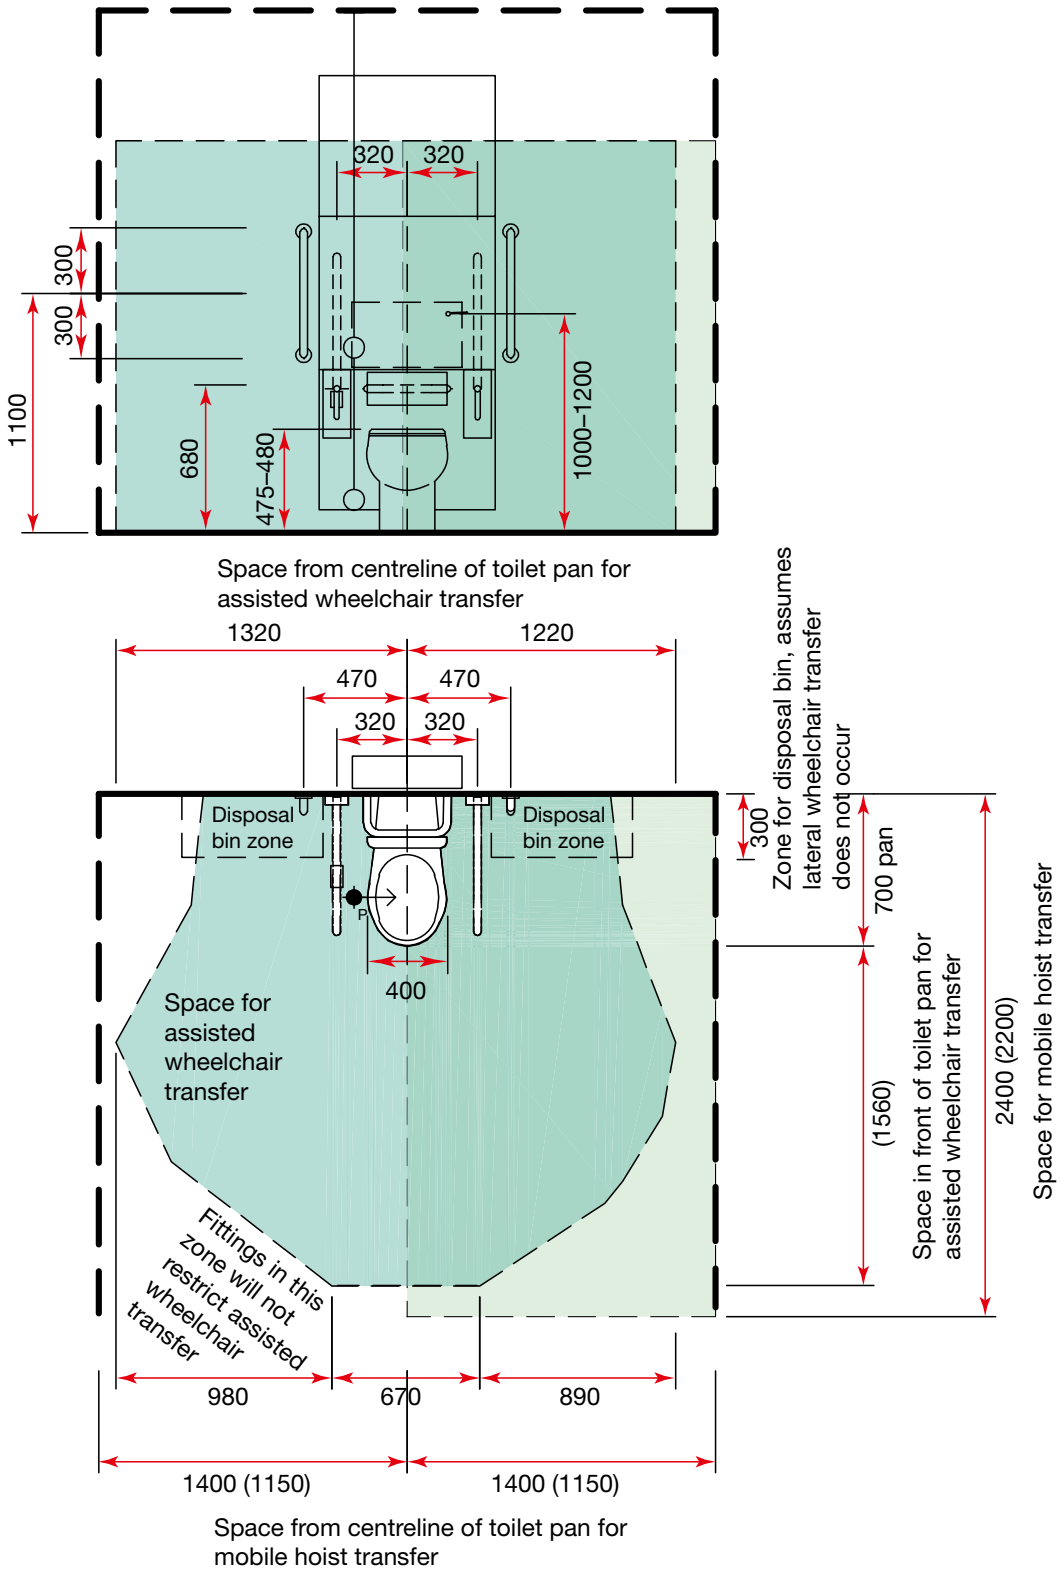

Figure 40 Space requirements for assisted toilet

Wash-hand basin: wheelchair

4.21 Wash-hand basins may be used for personal washing activities.

4.22 This ergonomic drawing (see Figure 41) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

4.23 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

4.24 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

4.25 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

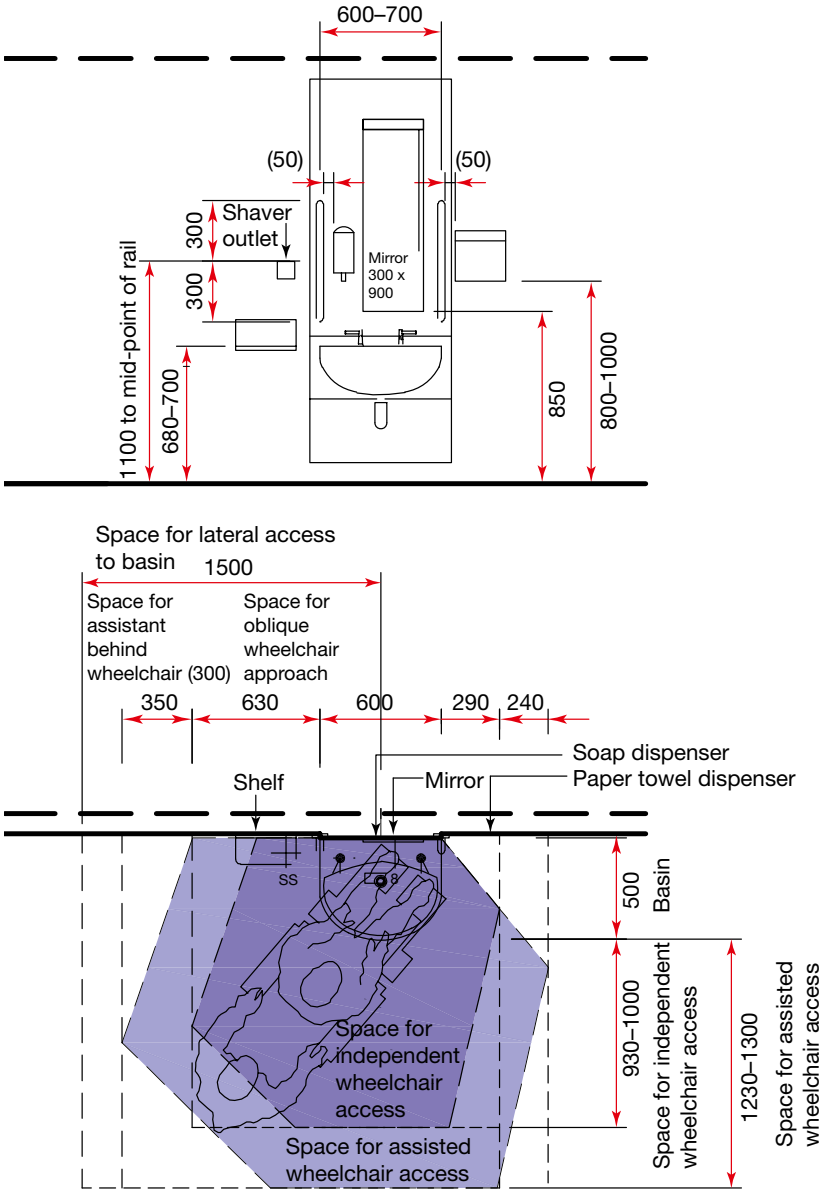

Figure 41 Space requirements for wheelchair accessible wash-hand basin, suitable for seated use

Full-length mirror: standing or seated users

4.26 This ergonomic drawing (see Figure 42) shows the space requirements for a full-length mirror for standing or seated users.

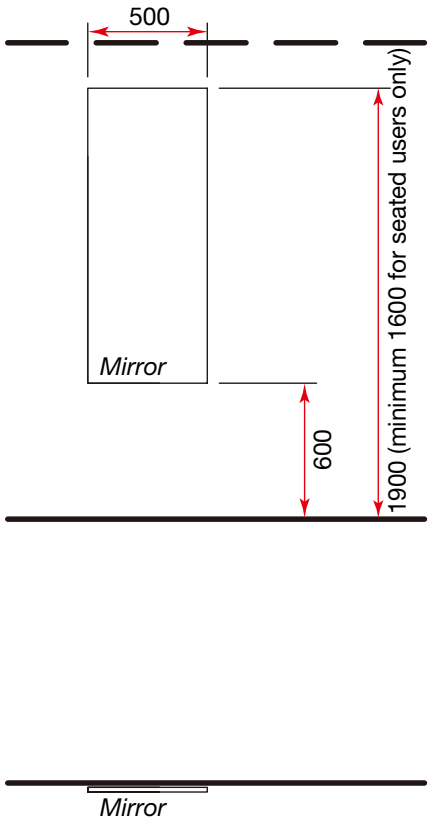

Figure 42 Space requirements for wheelchair accessible wash-hand basin, suitable for seated use

Shower room: en-suite: chamfered

Room description and layout

4.27 The following activities take place in chamfered en-suite shower rooms:

- assisted wheelchair, sanitary chair and shower chair access to the toilet, wash-hand basin and shower;
- mobile hoist access to transfer a patient to the toilet or shower seat or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet or shower seat (supervised only);
- independent transfer from a wheelchair to the toilet or shower seat;
- use of the toilet;
- personal washing;
- showering (whilst seated).

4.28 The room layout provided (see Figures 43 and 44–45) is a variation on the en-suite shower room with a reduction in the shower room area but no saving on overall area when combined with a single-bed room.

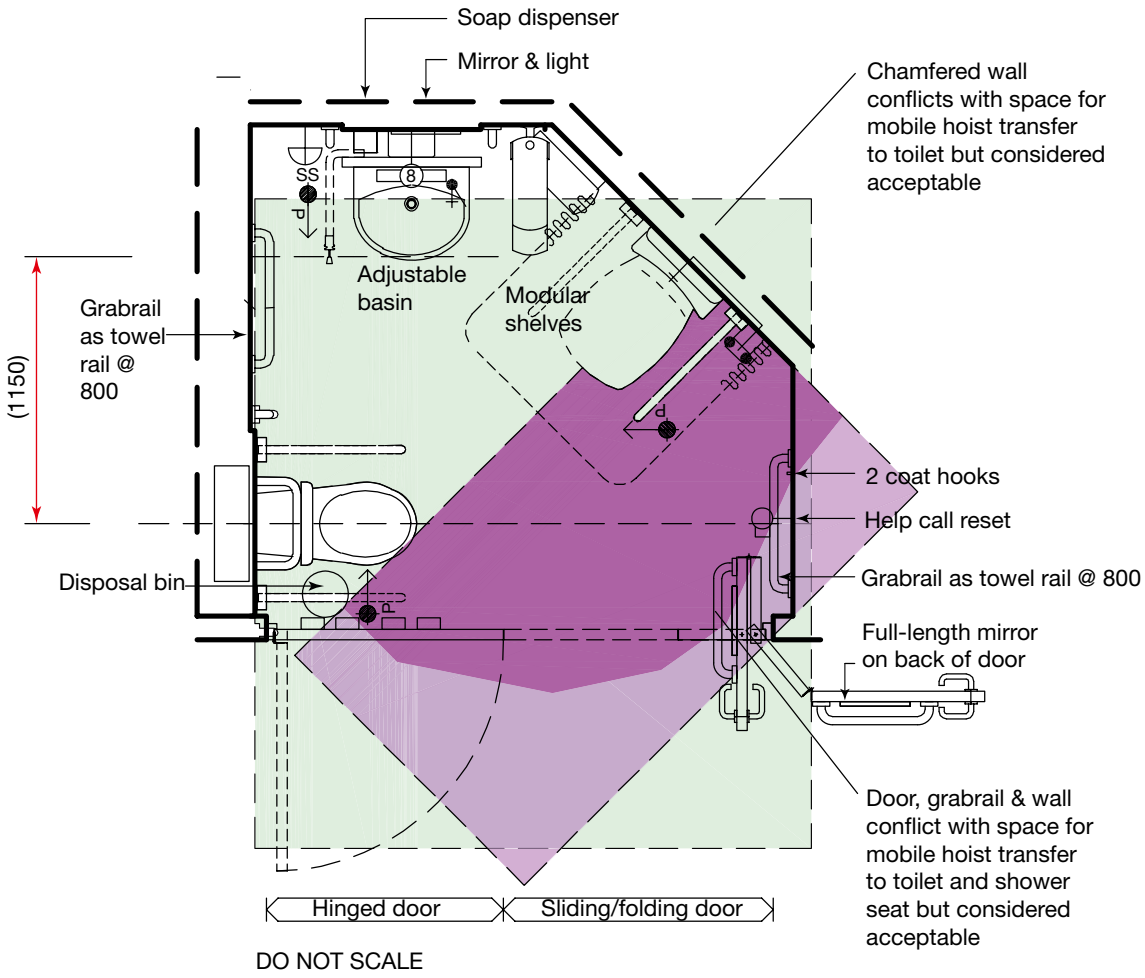

Figure 43 Shower room: en-suite: chamfered: mobile hoist access

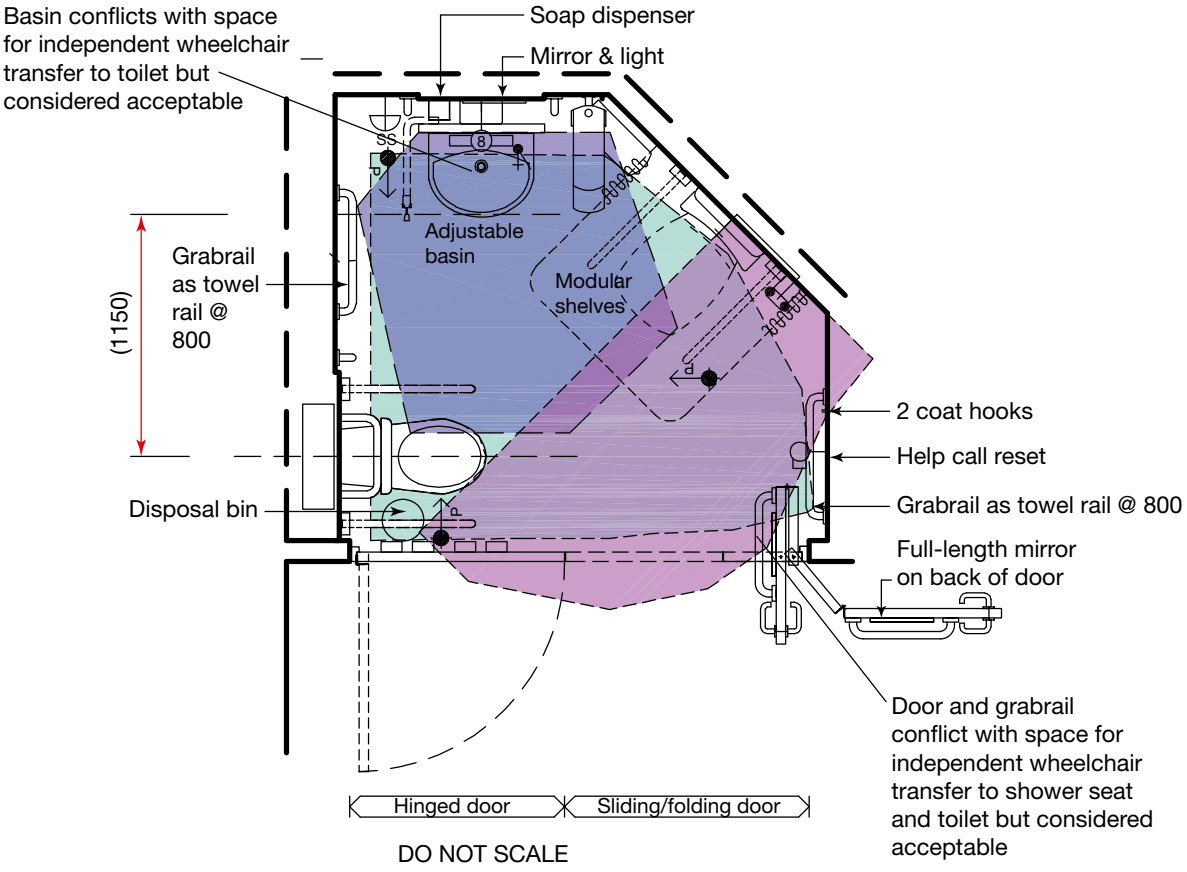

Figure 44 Shower room: en-suite: chamfered: assisted wheelchair access

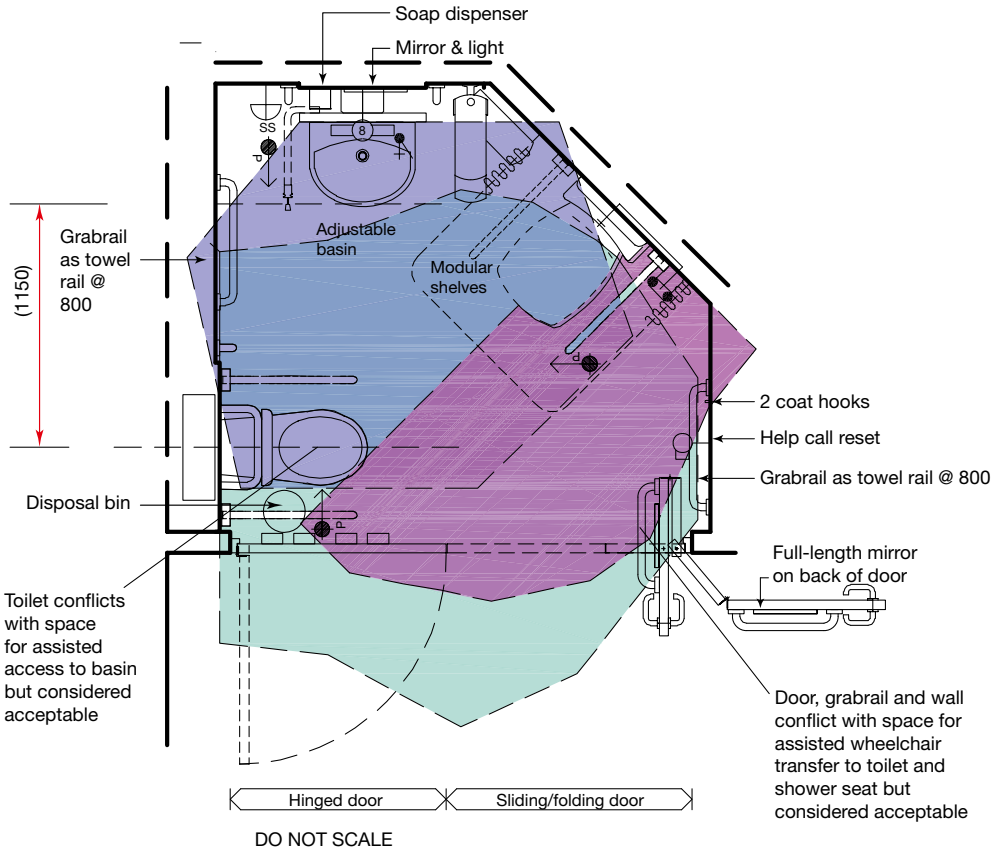

Figure 45 Shower room: en-suite: chamfered: independent wheelchair access

Ergonomic drawings

En-suite toilet

4.29 This ergonomic drawing (see Figure 46) shows the space requirements for an en-suite toilet (as used in the en-suite shower rooms).

4.30 The dispensers mounted on the back of the hinged door should not project more than approximately 50 mm (depending on the door design) to ensure they do not conflict with the use of the hinged grabrail between the door and the toilet pan.

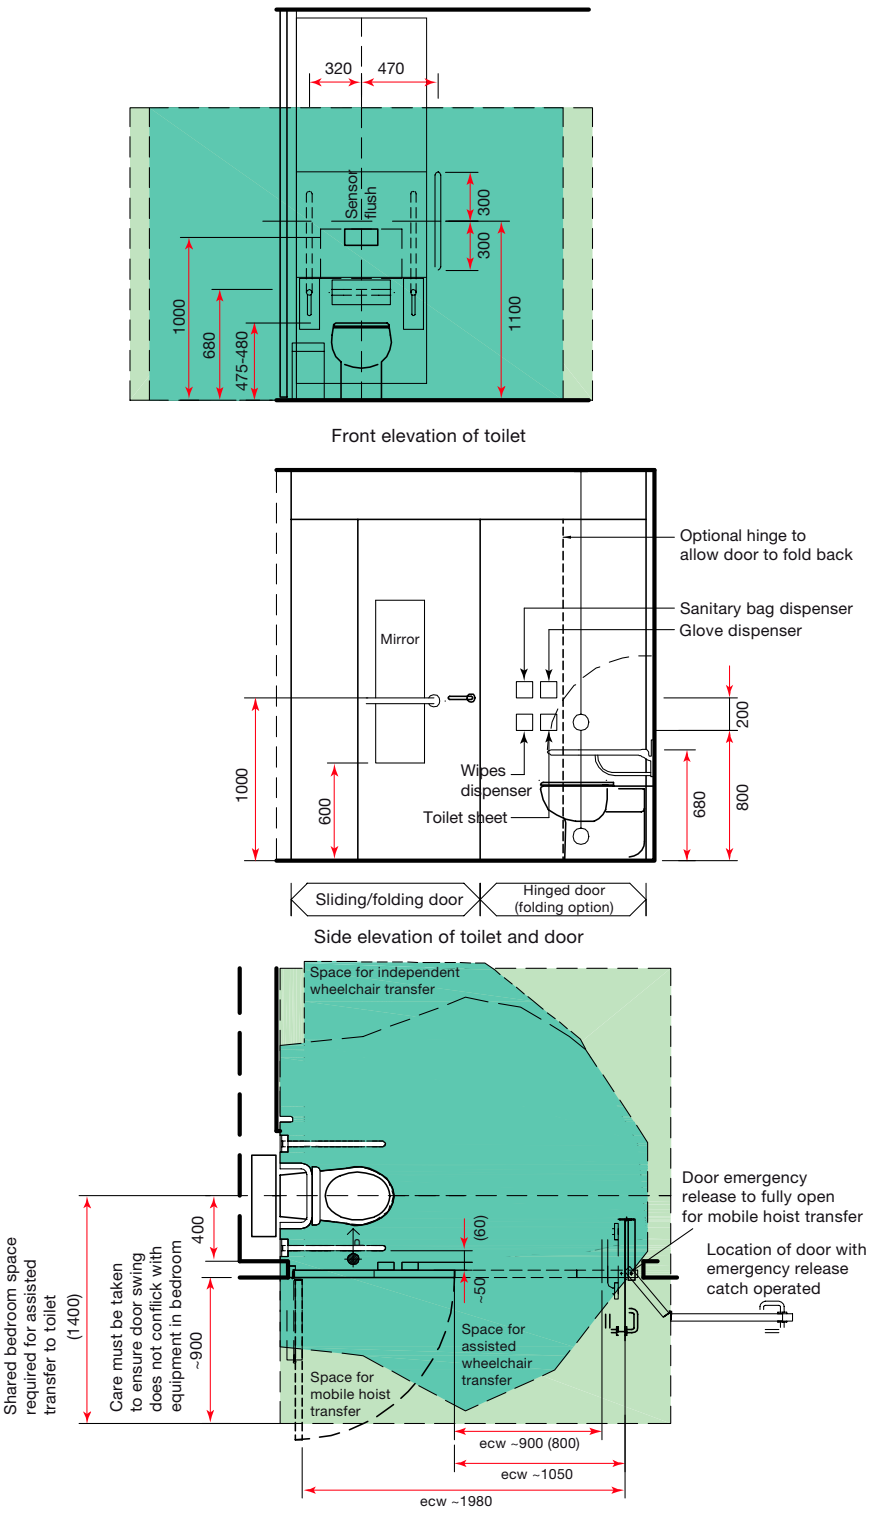

Figure 46 Space requirements for en-suite toilet

Adjustable-height wash-hand basin

4.31 This ergonomic drawing (see Figure 47) shows the space requirements for an adjustable-height wash-hand basin.

4.32 The position of the grabrails and fixtures should not conflict with the height-adjustment mechanism of the basin.

4.33 The general recommended lowest height of a mirror above a basin is 800 mm. However, 900 mm is acceptable where a lower height would conflict with the height-adjustment mechanism.

4.34 Consideration should be given to the choice of height-adjustment mechanism for ease of use; the controls should be accessible without interfering with normal access to the basin.

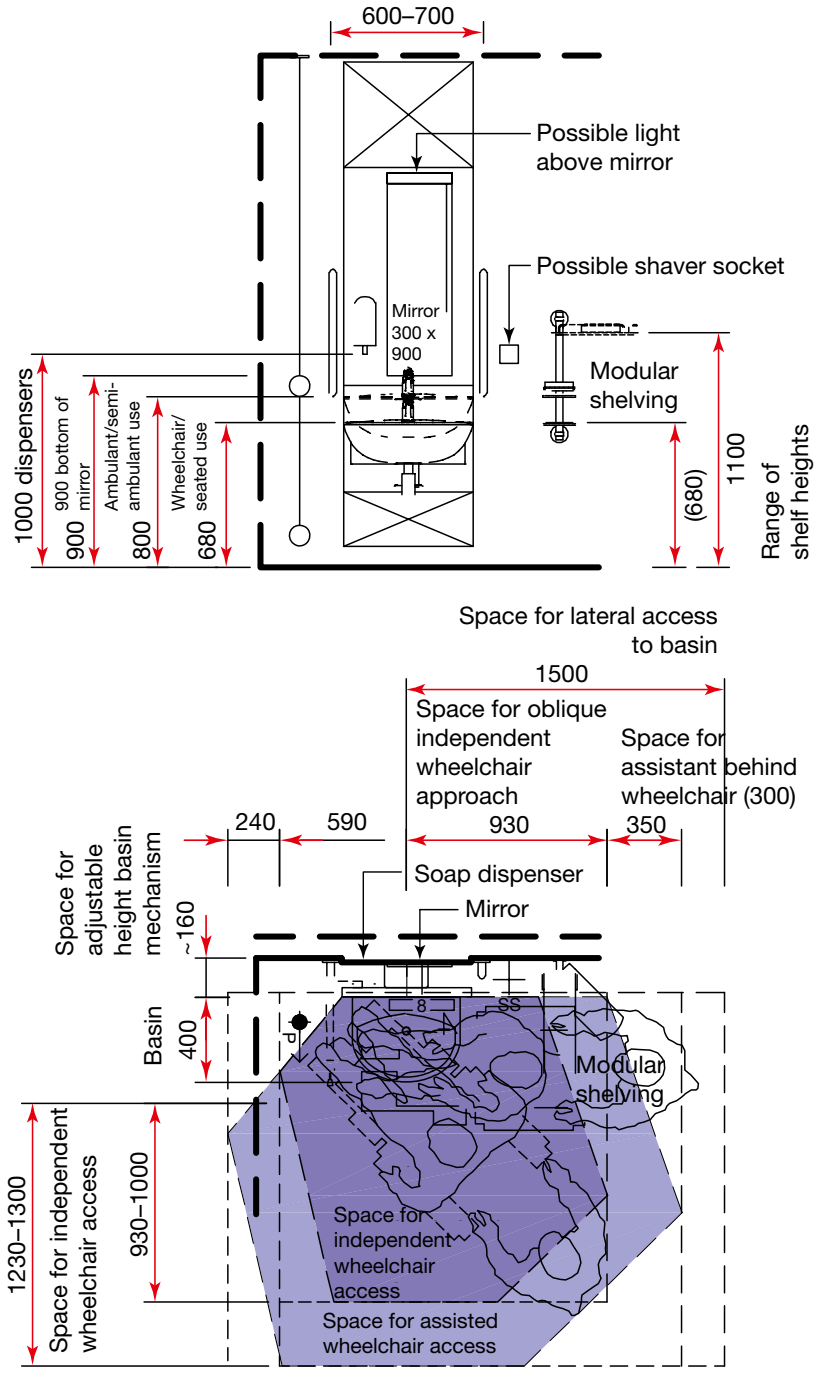

Figure 47 Space requirements for adjustable-height wash-hand basin

Shower for chamfered en-suite shower room

4.35 This ergonomic drawing (see Figure 48) shows the space requirements for the shower for use in the chamfered en-suite shower room.

4.36 Unassisted use of the shower may be limited because of the position of fixed shower controls on the back wall.

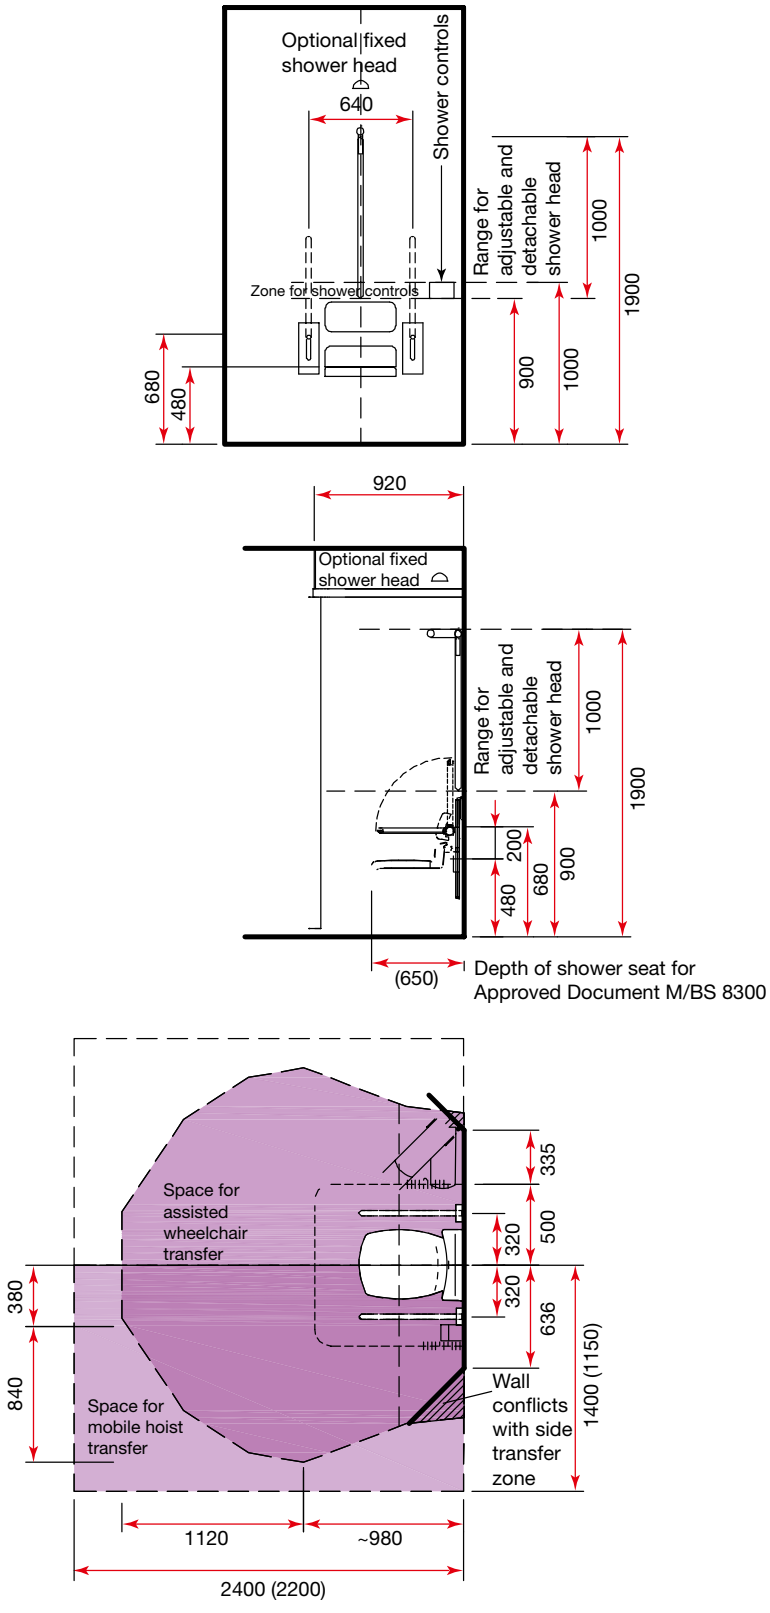

Figure 48 Space requirements for shower for use in chamfered en-suite shower room

Full-length mirror: standing or seated users

4.37 This ergonomic drawing (see Figure 49) shows the space requirements for a full-length mirror for standing or seated users.

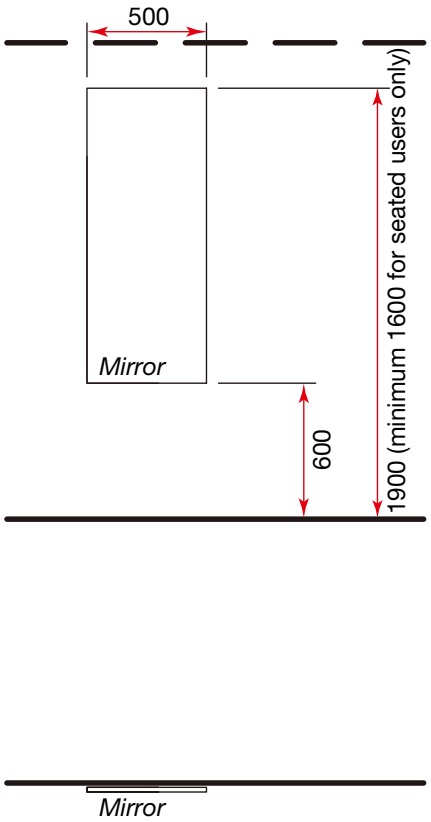

Figure 49 Space requirements for full-length mirror for standing or seated users

Shower room: en-suite

Room description and layout

4.38 The following activities take place in en-suite shower rooms:

- assisted wheelchair, sanitary chair and shower chair access to the toilet, wash-hand basin and shower;
- mobile hoist access to transfer a patient to the toilet or shower seat or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet or shower seat (independent or supervised);
- use of the toilet;
- personal washing;
- showering (whilst seated).

4.39 The room layout provided (see Figure 60) shows a shower room and part of the adjoining single-bed room. The adjoining room is required to provide the necessary space for assistance and to maintain patient privacy.

4.40 The double door to the shower room consists of a sliding/folding door and a hinged door. The sliding/folding door provides staff and unassisted patient access. Both doors need to be fully open for assisted use of the facilities.

4.41 The sliding/folding door is designed to release from the overhead track in order to provide mobile hoist access to the room and transfer to one side of the toilet.

4.42 A roller catch may be provided on the sliding/ folding door rather than the lever handle indicated.

4.43 The hinged door should be able to open unhindered. To maximise the free space in the bedroom, consideration should be given to making this a folding door.

4.44 Assisted wheelchair and hoist transfer to the shower seat is only possible from the right-hand side of the shower (if facing the shower).

4.45 The room layout (see Figure 50) utilises the minimum clear space requirement to the side of the toilet for mobile hoist transfer (that is, 1150 mm from the centreline of the toilet to the nearest obstruction), on the basin side of the toilet only.

4.46 This is less than that generally recommended for right-hand independent wheelchair transfer to the toilet but was considered acceptable in the mock-up trials and complies with Approved Document M.

4.47 The clear space in front of the toilet is less than that generally recommended for mobile hoist transfer but was considered acceptable in the mock-up trials.

4.48 The room layout includes an adjustable tip-up shower seat. This is to allow for both non-assisted and assisted showering. The position of the shower seat should be adjusted between uses as required.

4.49 A depth of approximately 160 mm has been allowed for the height-adjustment mechanism on the basin. Where a greater depth is required, the internal room dimensions may need to increase or the room layout may need to be altered to maintain the required activity space.

4.50 The shower rooms are assumed to be wet rooms. The slope of the floor and location of the floor gully should ensure that water does not escape into the adjoining bedroom.

4.51 Where the en-suite is intended for independent wheelchair use, call reset buttons should be located near to the toilet (on the back of the door).

4.52 The disposal bin, adjacent to the toilet, should be a maximum of 200 mm wide and 480 mm high and capable of being operated with one hand.

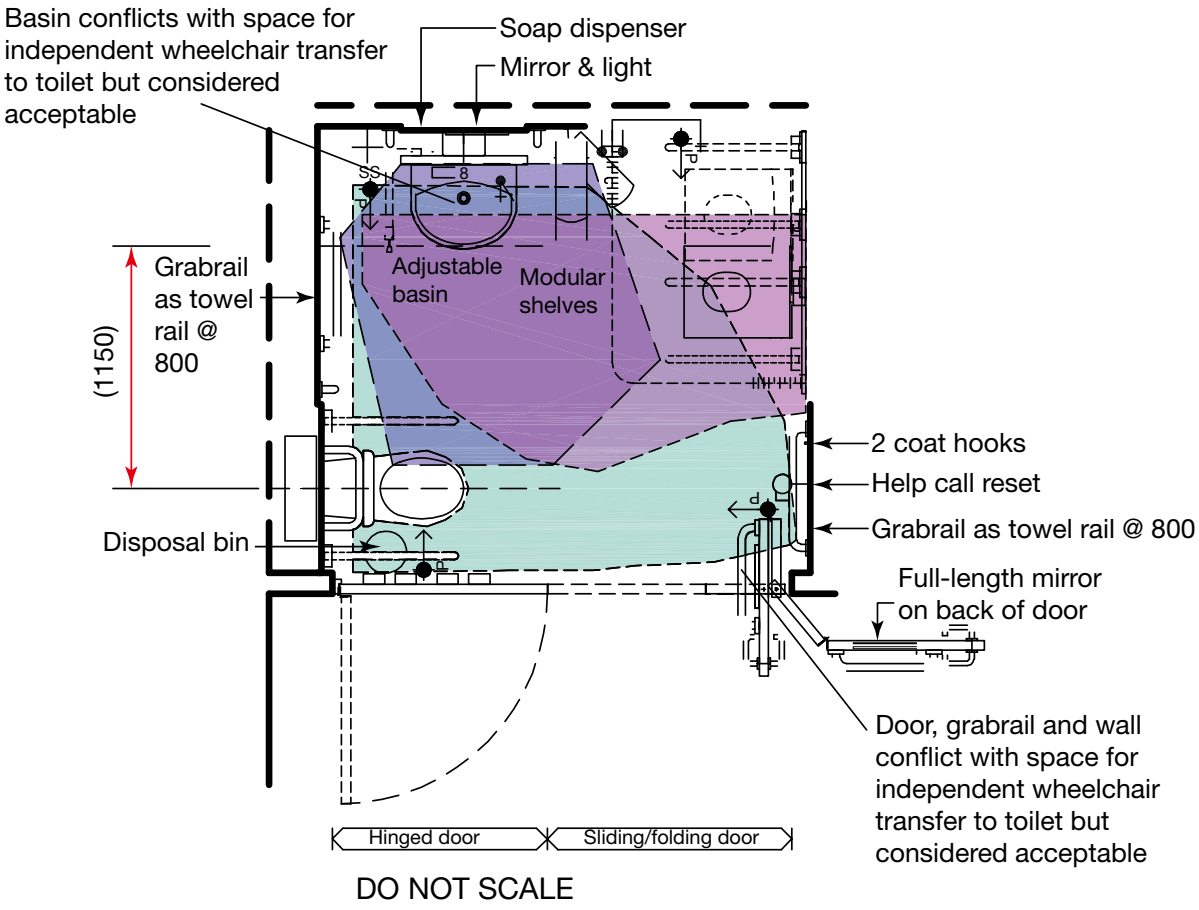

Figure 50 Space requirements for shower room: en-suite

Ergonomic drawings

En-suite toilet

4.53 This ergonomic drawing (see Figure 51) shows the space requirements for an en-suite toilet (as used in the en-suite shower rooms).

4.54 The dispensers mounted on the back of the hinged door should not project more than approximately 50 mm (depending on the door design) to ensure they do not conflict with the use of the hinged grabrail between the door and the toilet pan.

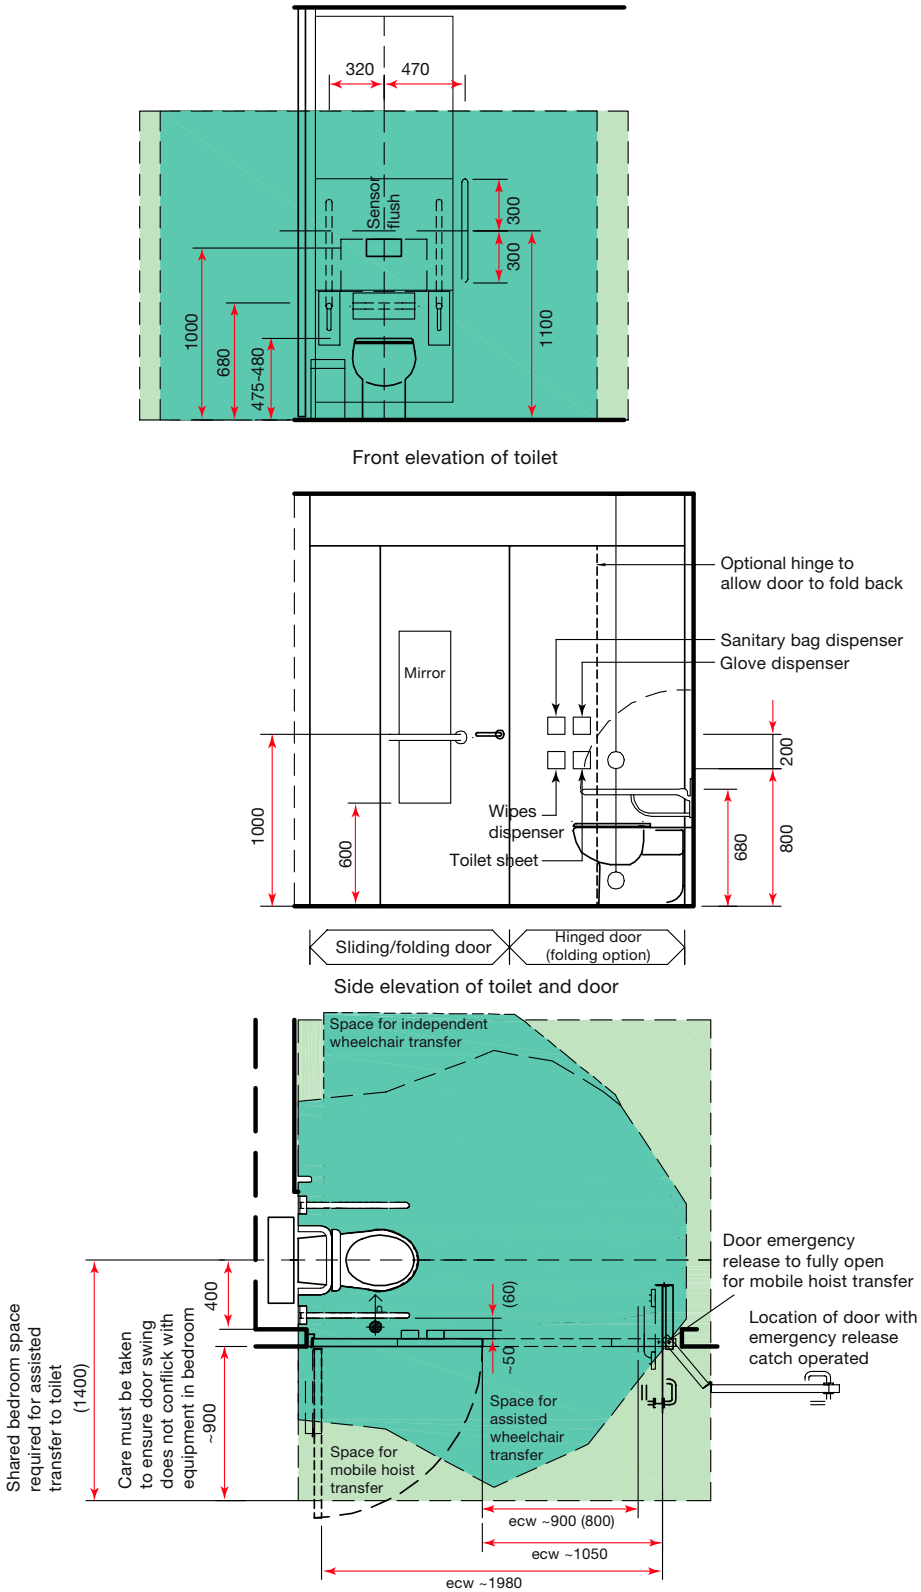

Figure 51 Space requirements for adjustable-height wash-hand basin

Adjustable-height wash-hand basin

4.55 This ergonomic drawing (see Figure 52) shows the space requirements for an adjustable-height wash-hand basin.

4.56 The position of the grabrails and fixtures should not conflict with the height-adjustment mechanism of the basin.

4.57 The general recommended lowest height of a mirror above a basin is 800 mm. However, 900 mm is acceptable where a lower height would conflict with the height-adjustment mechanism.

4.58 Consideration should be given to the choice of height-adjustment mechanism for ease of use; the controls should be accessible without interfering with normal access to the basin.

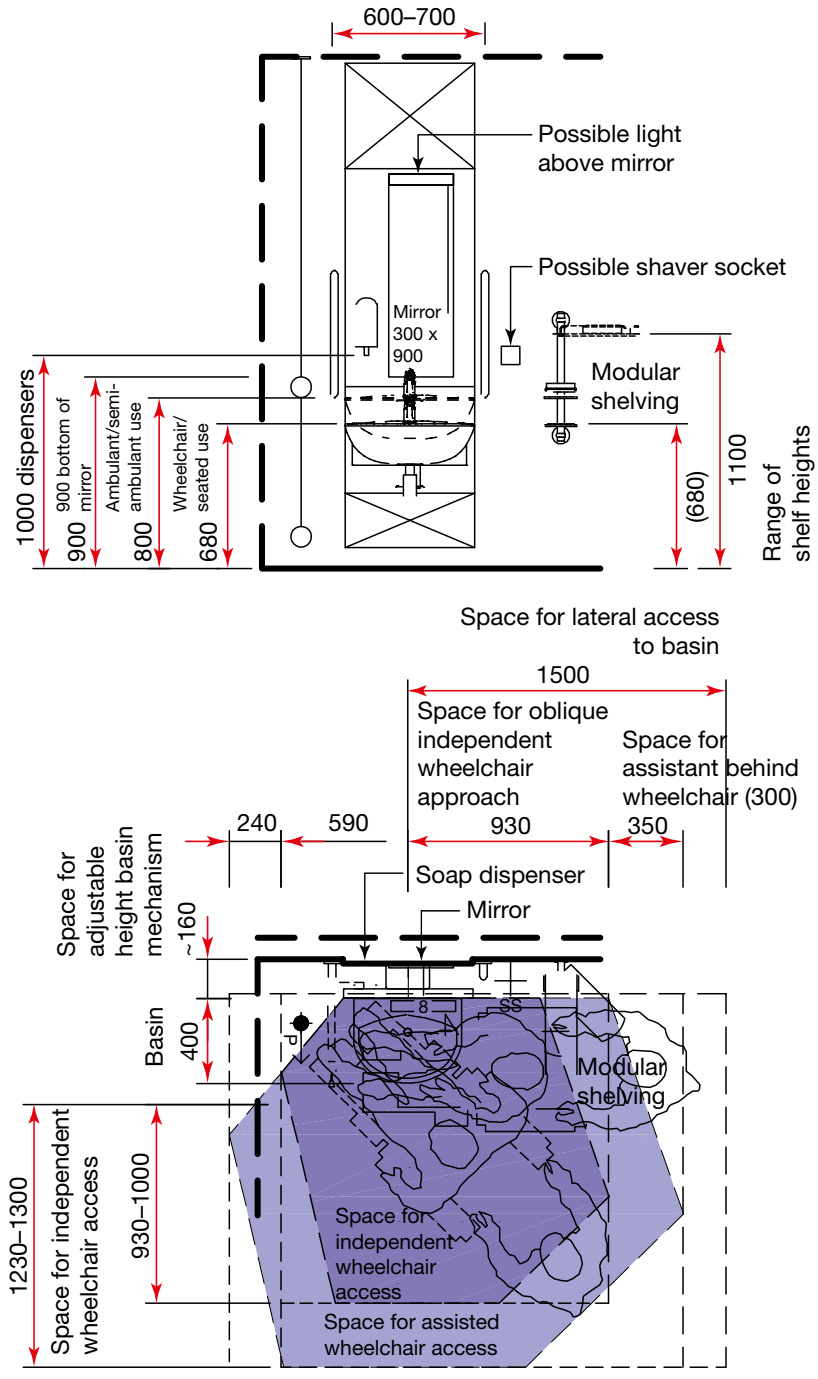

Figure 52 Space requirements for adjustable-height wash-hand basin

Shower with adjustable tip-up shower seat

4.59 This ergonomic drawing (see Figure 53) shows the space requirements for a shower with an adjustable tip-up shower seat.

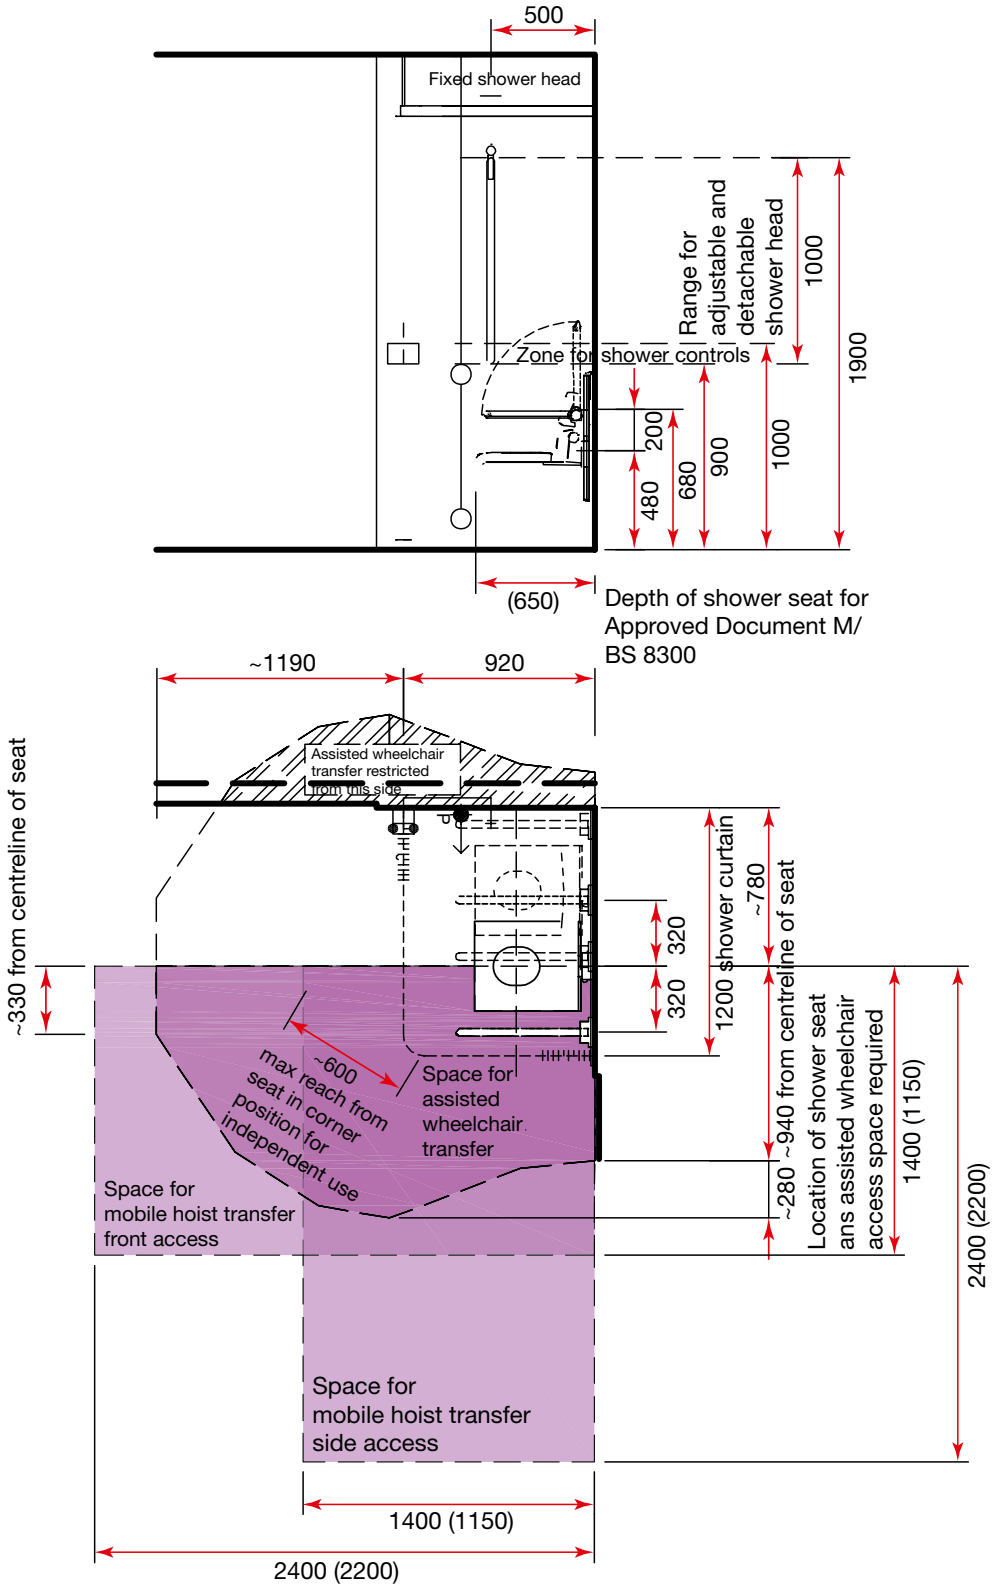

Figure 53 Space requirements for shower with adjustable tip-up shower seat

Full-length mirror: standing or seated users

4.60 This ergonomic drawing (see Figure 54) shows the space requirements for a full-length mirror for standing or seated users.

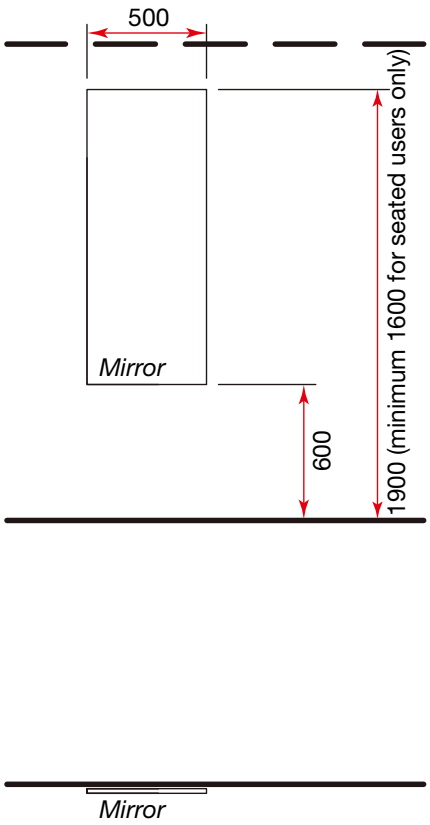

Figure 54 Space requirements for full-length mirror for standing or seated users

Shower room: independent wheelchair

Room description and layout

4.61 The following activities take place in independent shower rooms:

- undressing and dressing;
- hanging/holding clothes;
- wheelchair access to the toilet, hand-rinse basin, wash-hand basin and shower seat;
- independent transfer from a wheelchair to the toilet or shower seat;
- use of the toilet;
- disposal of sanitary towels and wipes;
- emptying of urine bottles and colostomy bags;
- hand-rinsing (whilst in a wheelchair facing the hand-rinse basin or seated on the toilet);
- personal washing (whilst seated);
- showering (whilst seated).

4.62 Independent shower rooms should contain an independent wheelchair toilet with adjacent hand-rinse basin, and separate wheelchair wash-hand basin for personal washing.

4.63 This facility is also suitable for semi-ambulant users with, or without, "hands-off assistance" who may wish to sit down to wash their hands when using the toilet or whilst showering.

4.64 In healthcare premises, for the privacy and dignity of patients, it is generally considered preferable for shower rooms to include a toilet. It may be acceptable to provide an independent wheelchair shower room without toilet facilities in staff-only areas.

4.65 The room layout provided (see Figure 55) allows for right-hand independent wheelchair transfer to the toilet and shower seat. Where more than one independent wheelchair shower room is provided, both left-hand and right-hand transfer options should be available.

4.66 To enable this space to be suitable for all unassisted use, an adjustable-height wash-hand basin may be provided in place of the wheelchair wash-hand basin.

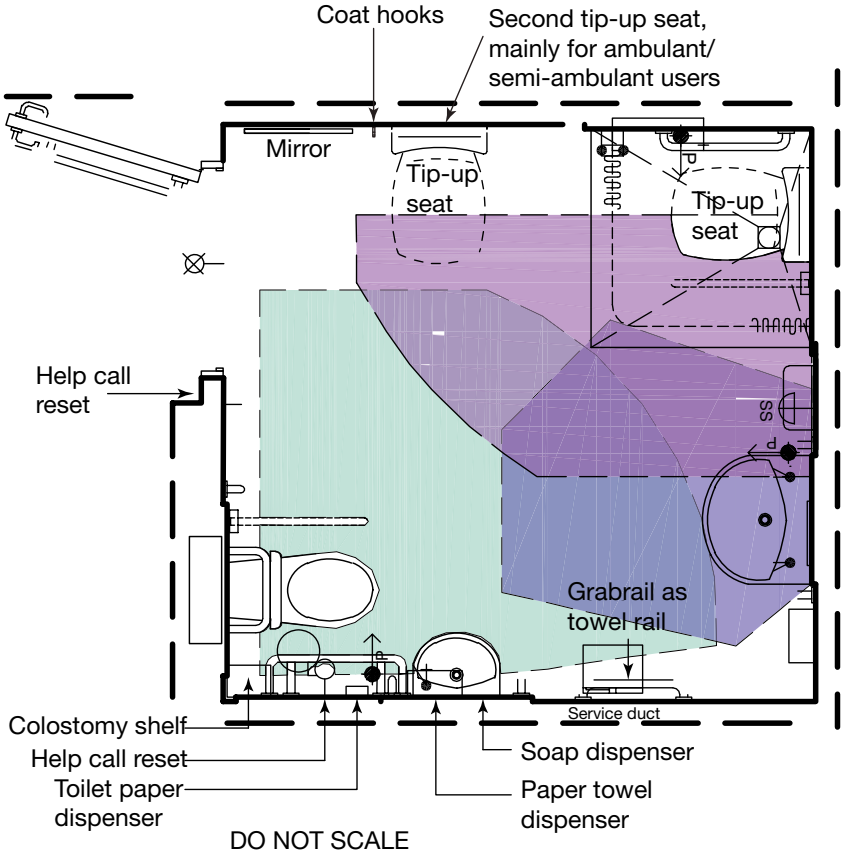

Figure 55 Space requirements for shower room: independent wheelchair

Independent wheelchair shower

4.67 This ergonomic drawing (see Figure 56) shows the space requirements for an independent wheelchair shower.

4.68 BS 8300 recommends a hinged grabrail at right-angles in front of shower seats for independent wheelchair transfer. This grabrail is to help prevent users falling forward. This rail is not considered necessary in healthcare premises. However, a risk assessment is recommended to confirm requirements.

4.69 The shower curtain consists of two parts to assist seated users to close the curtain, that is, to draw one half of the curtain from either side. The locations of the shower curtains and shower controls conflict with the recommendations in Approved Document M and BS 8300, and were informed by ergonomic studies and the mock-up trials for the en-suite shower rooms.

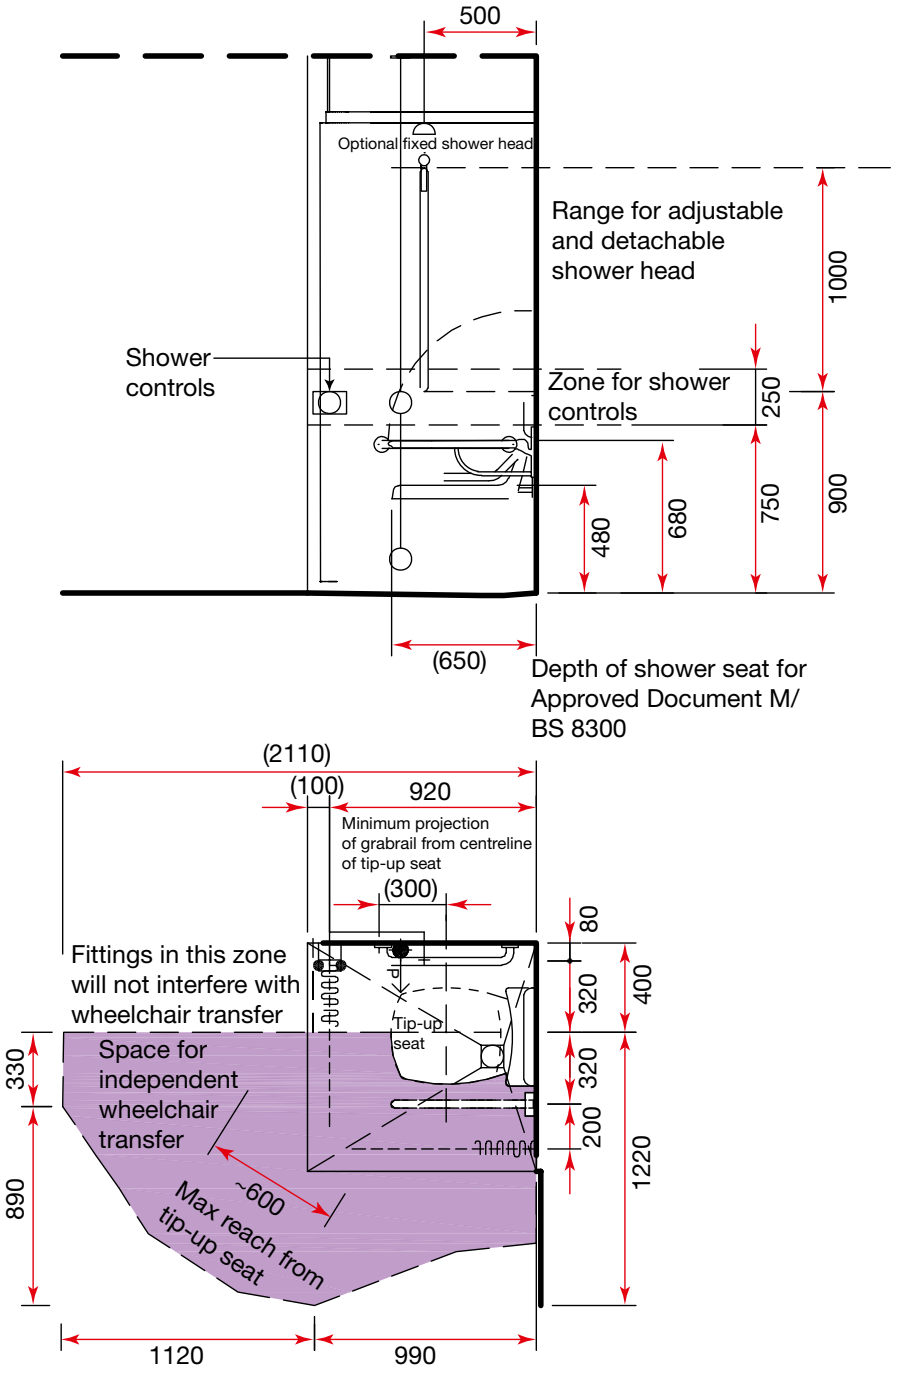

Figure 56 Space requirements for an independent wheelchair shower

Toilet and adjacent hand-rinse basin: independent wheelchair: grabrail options

4.70 These ergonomic drawings (see Figure 57) show the fixing position of grabrails for an independent wheelchair toilet and adjacent hand-rinse basin.

4.71 Grabrails should be provided symmetrically on either side of the toilet at 320 mm from the centreline of the toilet pan. This conflicts with the recommendations in Approved Document M and BS 8300.

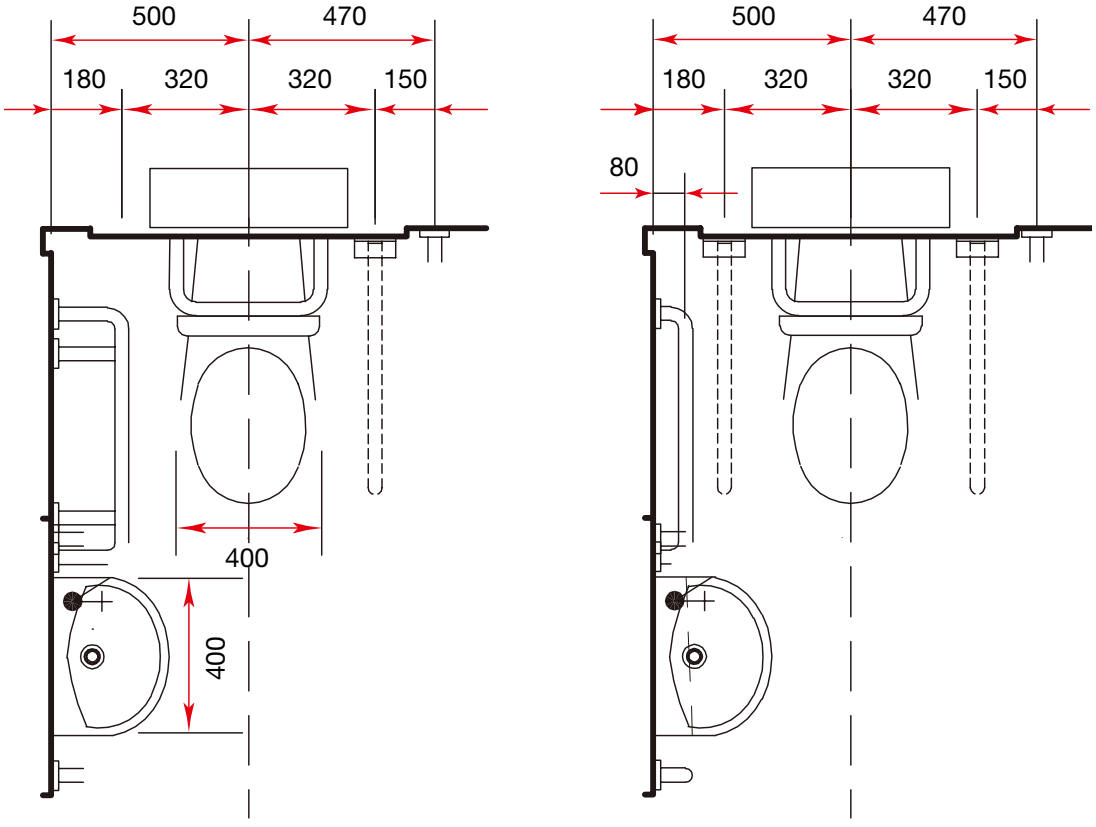
4.72 Approved Document M (paragraph 5.10j) states: "where the horizontal support rail on the wall adjacent to the toilet is set with the minimum spacing from the wall, an additional dropdown rail should be provided on the wall side at a distance of 320 mm from the centreline of the toilet."

Note

Where the maximum spacing defined in Approved Document M, 85 mm, is used, this positions the grabrail approximately 390 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

4.73 BS 8300 (paragraph 12.6.3.5 b) states: "A fixed horizontal rail should be located on the side wall with a 50 mm to 60 mm clearance between the rail and the wall." This places the rail approximately 420 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

4.74 The ergonomic drawings provided illustrate two options for the provision of grabrails. The room layouts on this website are based on option one.



Fixed grabrail between toilet and wall

Alternative fixed and hinged grabrail between toilet and wall

Figure 57 Space requirements showing fixing positions of grabrails for an independent wheelchair toilet and adjacent hand-rinse basin

Toilet and adjacent hand-rinse basin: independent wheelchair

4.75 This ergonomic drawing (see Figure 58) shows the space requirements for an independent wheelchair toilet and adjacent hand-rinse basin.

4.76 The recommended clear space in front and to the open side of the toilet (for independent wheelchair transfer) is greater than the recommendations in Approved Document M and BS 8300.

4.77 Approved Document M and BS 8300 recommend a minimum clear distance of 1000 mm to the open side of the centreline of the toilet for independent wheelchair transfer. Robert Feeney Associates (RFA) research for BS 8300 indicates that this will allow just over 60% of wheelchair users to comfortably transfer onto the toilet. The same research indicates that a clear space of 1400 mm accommodates 90% of wheelchair users and this is, therefore, recommended.

4.78 Approved Document M and BS 8300 recommend a 750 mm long toilet pan for independent wheelchair transfer. However, RFA research indicated that a 700 mm long toilet pan allows independent wheelchair transfer. For maximum space efficiency a 700 mm pan is recommended.

4.79 As a consequence of the reduction in pan length, the hand-rinse basin is located closer to the corner of the room than the position given in Approved Document M and BS 8300, to allow hand-rinsing from a seated position on the toilet.

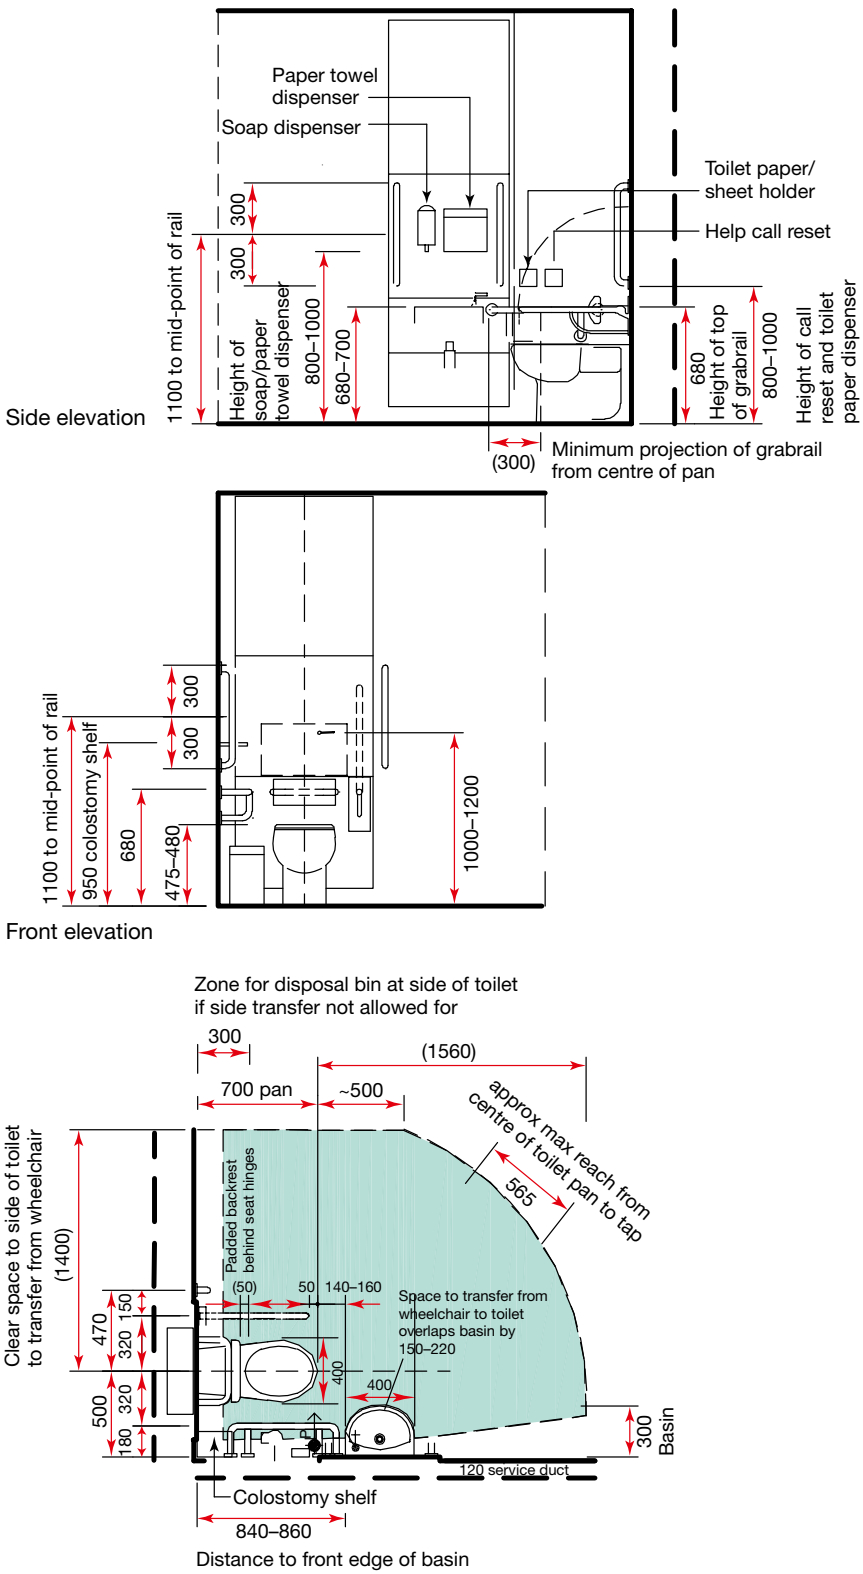


Figure 58 Space requirements for an independent wheelchair toilet and adjacent hand-rinse basin

Wash-hand basin: wheelchair

4.80 Wash-hand basins may be used for personal washing activities.

4.81 This ergonomic drawing (see Figure 59) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

4.82 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

4.83 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

4.84 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

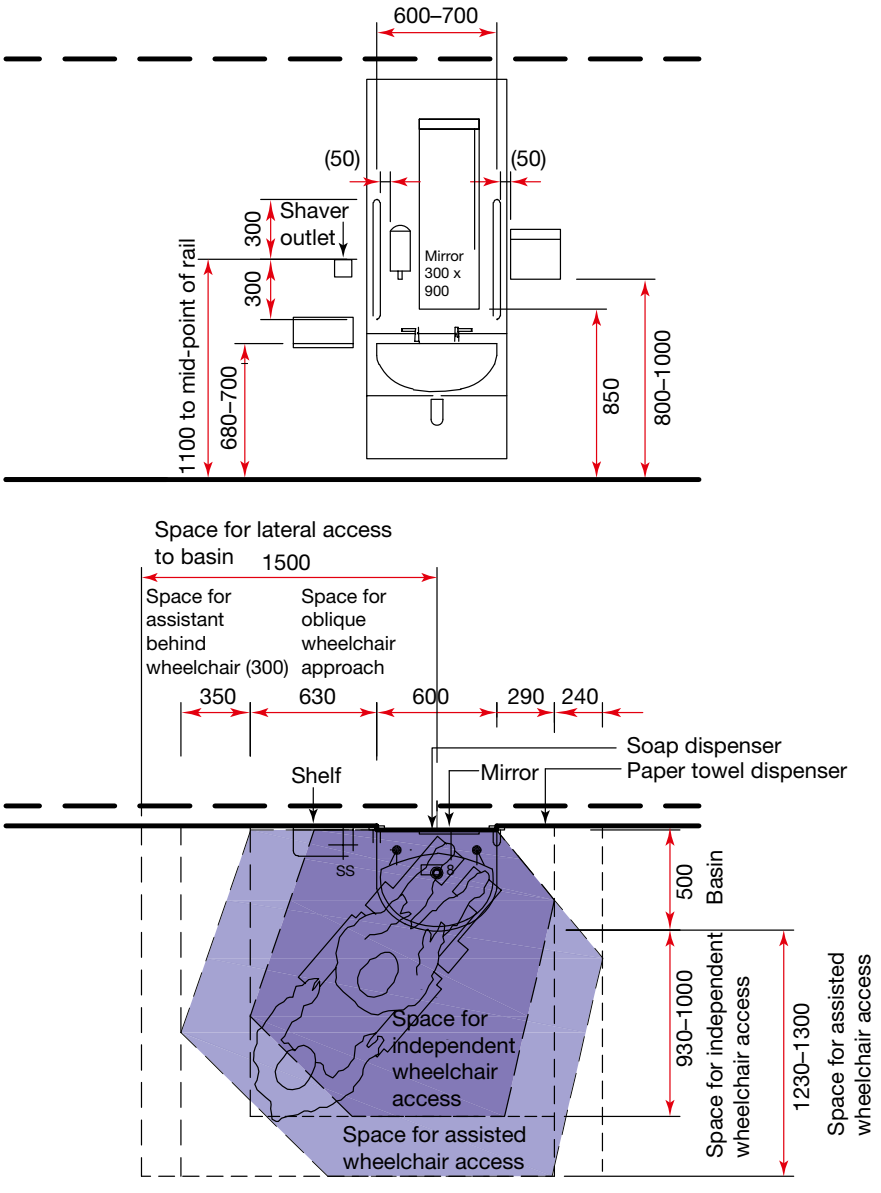

Figure 59 Space requirements for wheelchair accessible wash-hand basin

Full-length mirror: standing or seated users

4.85 This ergonomic drawing (see Figure 60) shows the space requirements for a full-length mirror for standing or seated users.

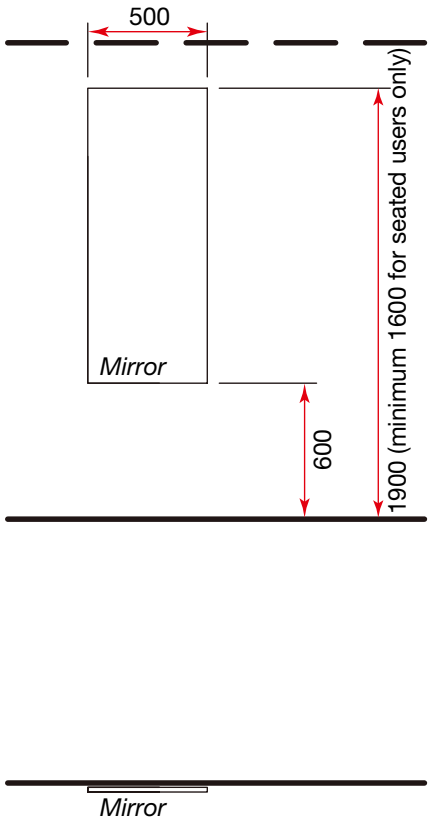

Figure 60 Space requirements for full-length mirror for standing or seated users

Shower room: semi-ambulant: standing use

Room description and layout

4.86 See Figure 61. The following activities take place in semi-ambulant shower rooms:

- undressing and dressing;
- hanging/holding clothes;
- use of the toilet;
- personal washing;
- showering (whilst standing).

4.87 Shower rooms for semi-ambulant use should contain a semi-ambulant toilet, ambulant wash-hand basin and a wet floor shower area (not a shower tray).

4.88 Semi-ambulant shower rooms are also suitable for ambulant users.

4.89 A continuous horizontal grabrail should be provided within the shower area. Users should be able to touch two sides of the shower area/two grabrails, opposite or at right angles, in order to keep their balance.

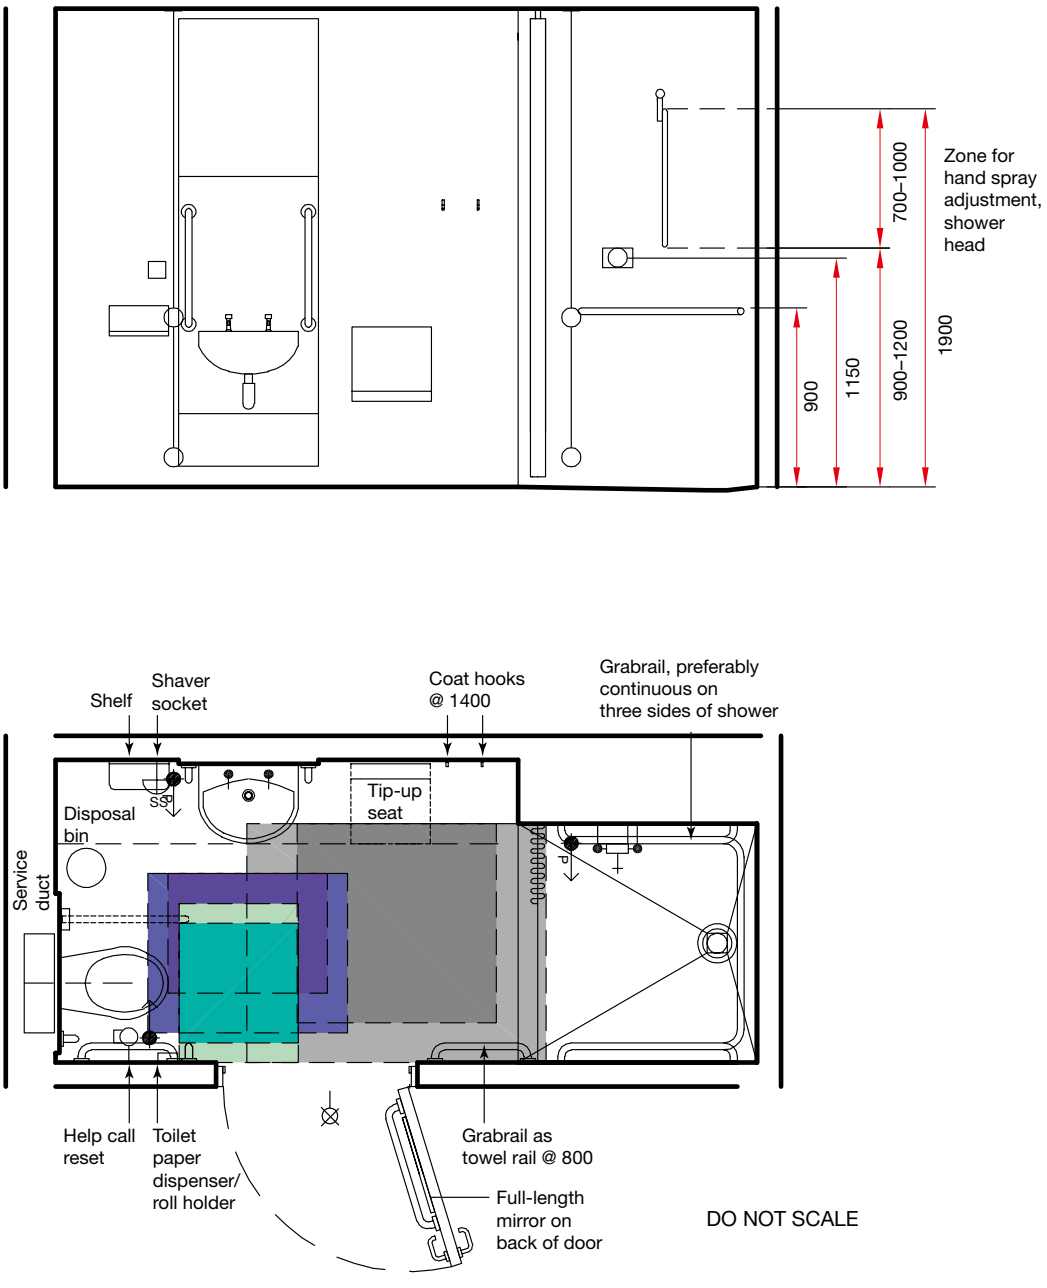

Figure 61 Space requirements for shower room: semi-ambulant: standing use

Ergonomic drawings

Toilet: semi-ambulant

4.90 This ergonomic drawing (see Figure 62) shows the space requirements for a semi-ambulant toilet.

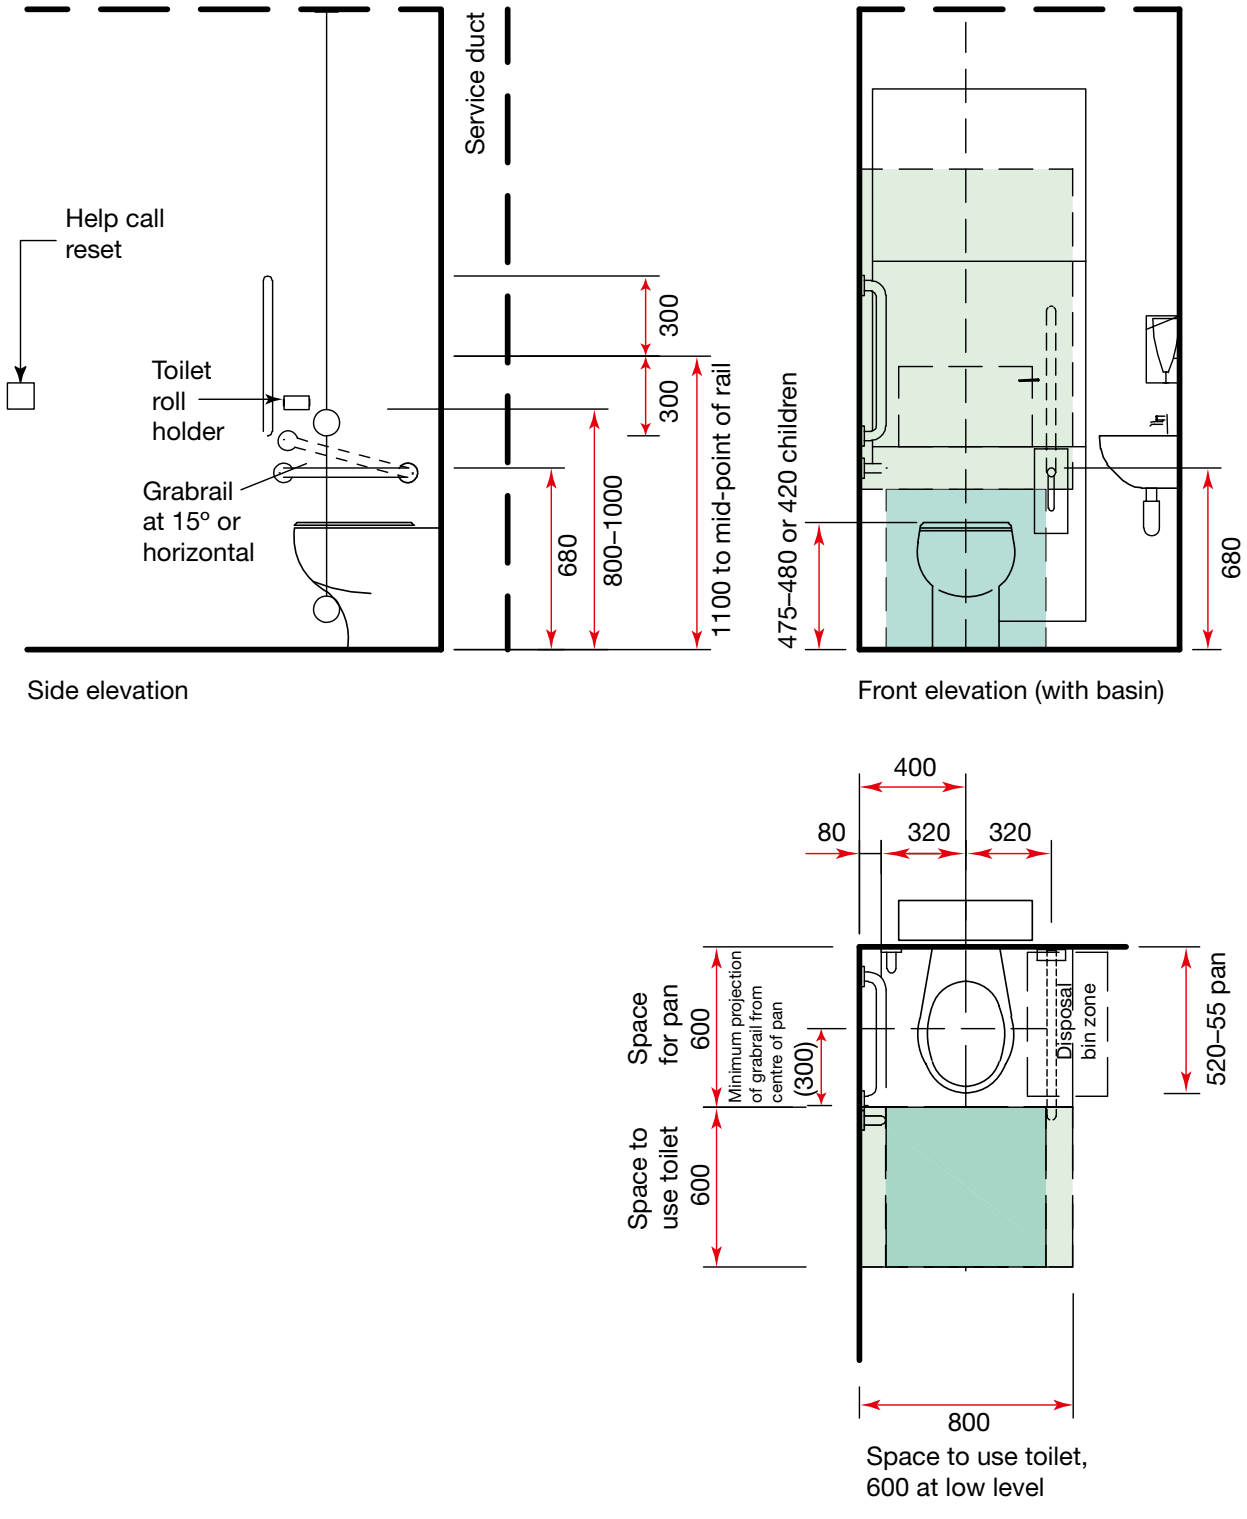

Figure 62 Space requirements for semi-ambulant toilet

Wash-hand basin: ambulant

4.91 Wash-hand basins may be used for personal washing activities.

4.92 This ergonomic drawing (see Figure 63) shows the space requirements for ambulant/ semi-ambulant use of a 400 mm deep × 500 mm wide wash-hand basin.

4.93 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

4.94 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

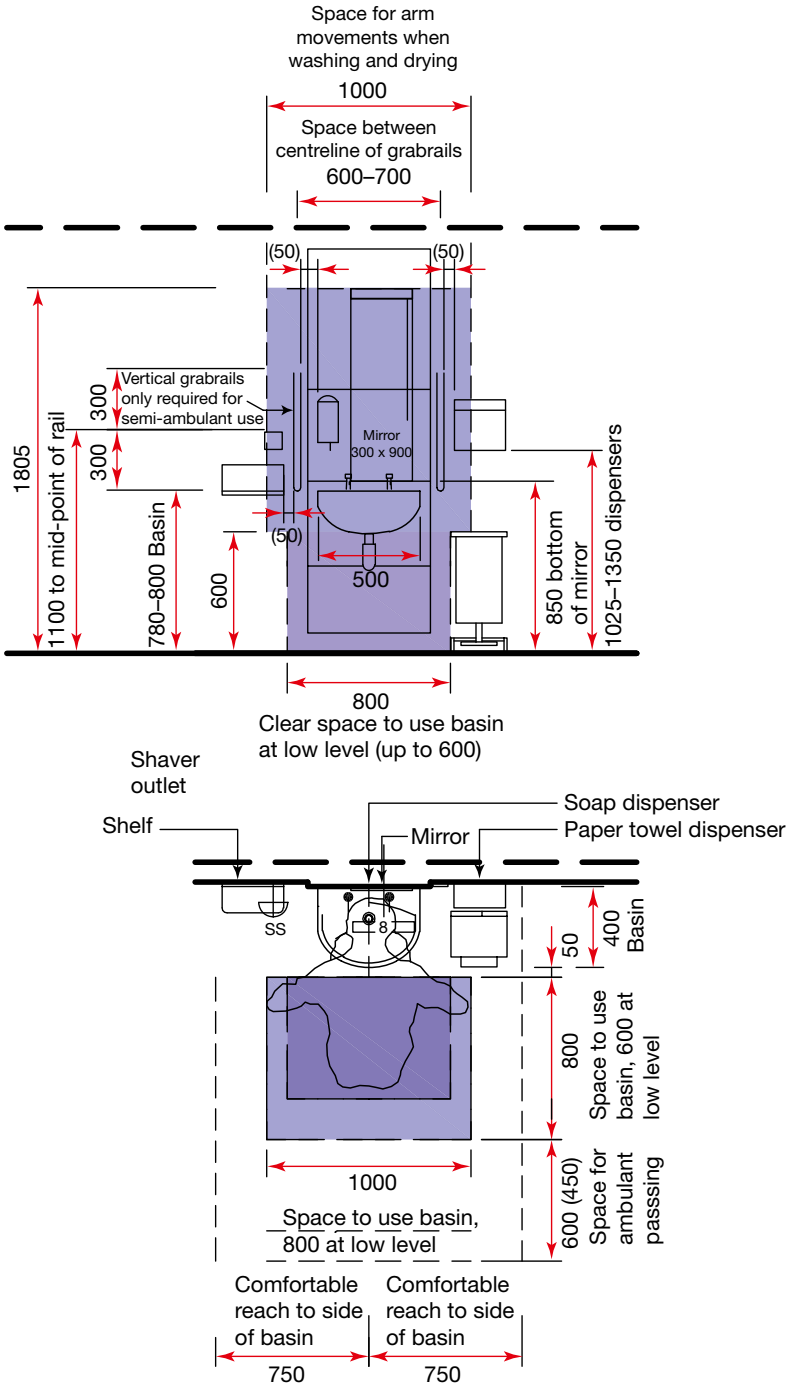

Figure 63 Space requirements for ambulant/semi-ambulant use of a 400 mm deep x 500 mm wide wash-hand basin

Full-length mirror: standing or seated users

4.95 This ergonomic drawing (see Figure 64) shows the space requirements for a full-length mirror for standing or seated users.

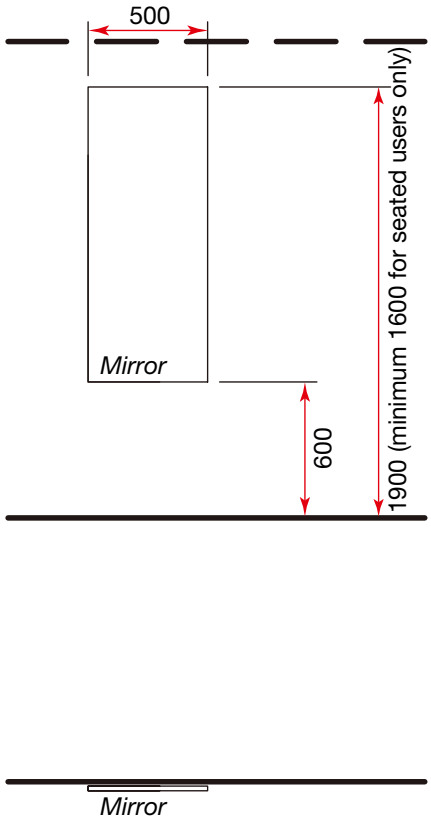

Figure 64 Space requirements for full-length mirror for standing or seated users

Dressing and undressing: ambulant

4.96 These ergonomic drawings (see Figure 65) show the space requirements for ambulant dressing and undressing.

4.97 An identical space provision is suitable for semi-ambulant users though it should be located adjacent to a seating area.

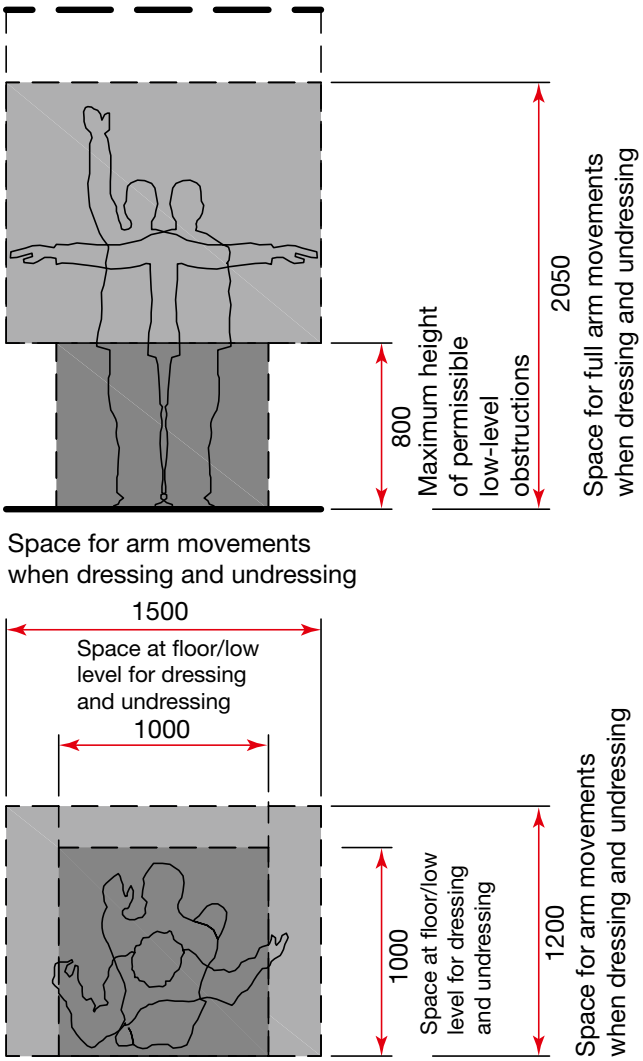

Figure 65 Space requirements for ambulant dressing and undressing

Shower room: trolley access

Room description and layout

4.98 The following assisted activities take place in trolley access shower rooms:

- wheelchair and sanitary chair access to the toilet and wash-hand basin;
- mobile hoist access to transfer a patient to the toilet or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet (supervised only);
- use of the toilet;
- personal washing (whilst the patient is seated);
- shower trolley access to the shower;
- showering (whilst the patient is lying on the shower trolley).

4.99 Trolley access showers are suitable for patients who are reliant on assisted movement. The room layout provided (see Figure 66) utilises the minimum clear space requirement to the side of the toilet for mobile hoist transfer (that is, 1150 mm from the centreline of the toilet to the nearest obstruction), on the basin side of the toilet only.

4.100 It features two toilets: one in the wet area and the other in the dry area. The drainpipe at the foot of the shower trolley should be positioned over the toilet in the wet area to deal with incontinence episodes during showering.

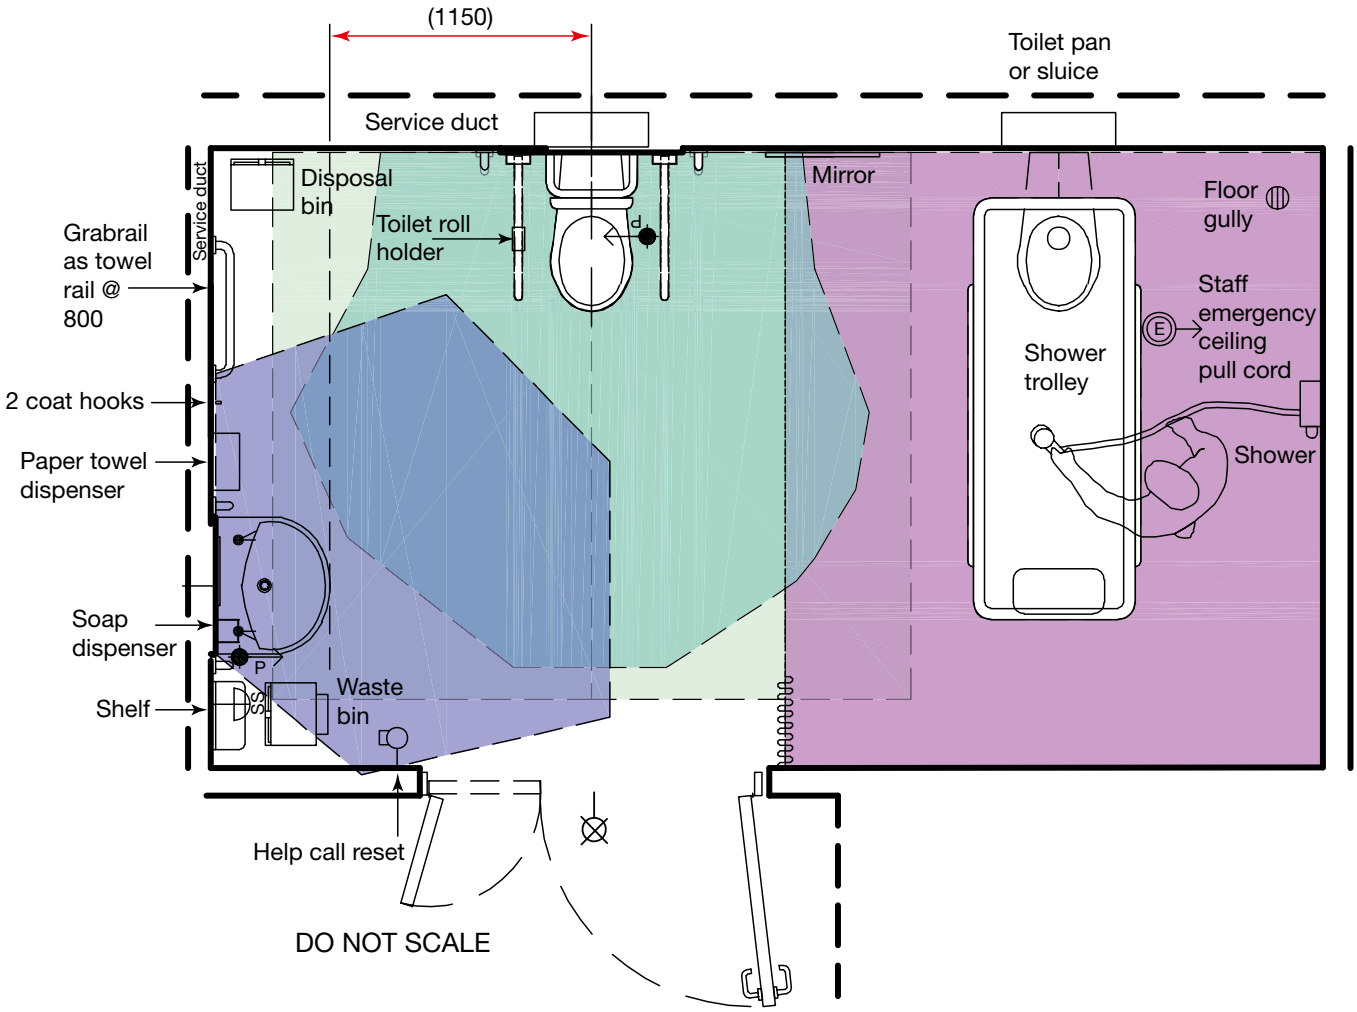

Figure 66 Space requirements for shower room: trolley access minimum space requirement

Ergonomic drawings

Trolley access shower

4.101 This ergonomic drawing (see Figure 67) shows the space requirements for a trolley access shower.

4.102 A minimum of 800 mm clear space at the head of the trolley is required if staff need to stand in this position during showering.

4.103 The shower panel should have a pressure and temperature control thermostatic mixer. The shower hose should be long enough to allow staff to shower the full length of the patient from either side with a trigger handle. This shower fitting is not specifically covered in Health Building Note 00-10 Part C – 'Sanitary assemblies'.

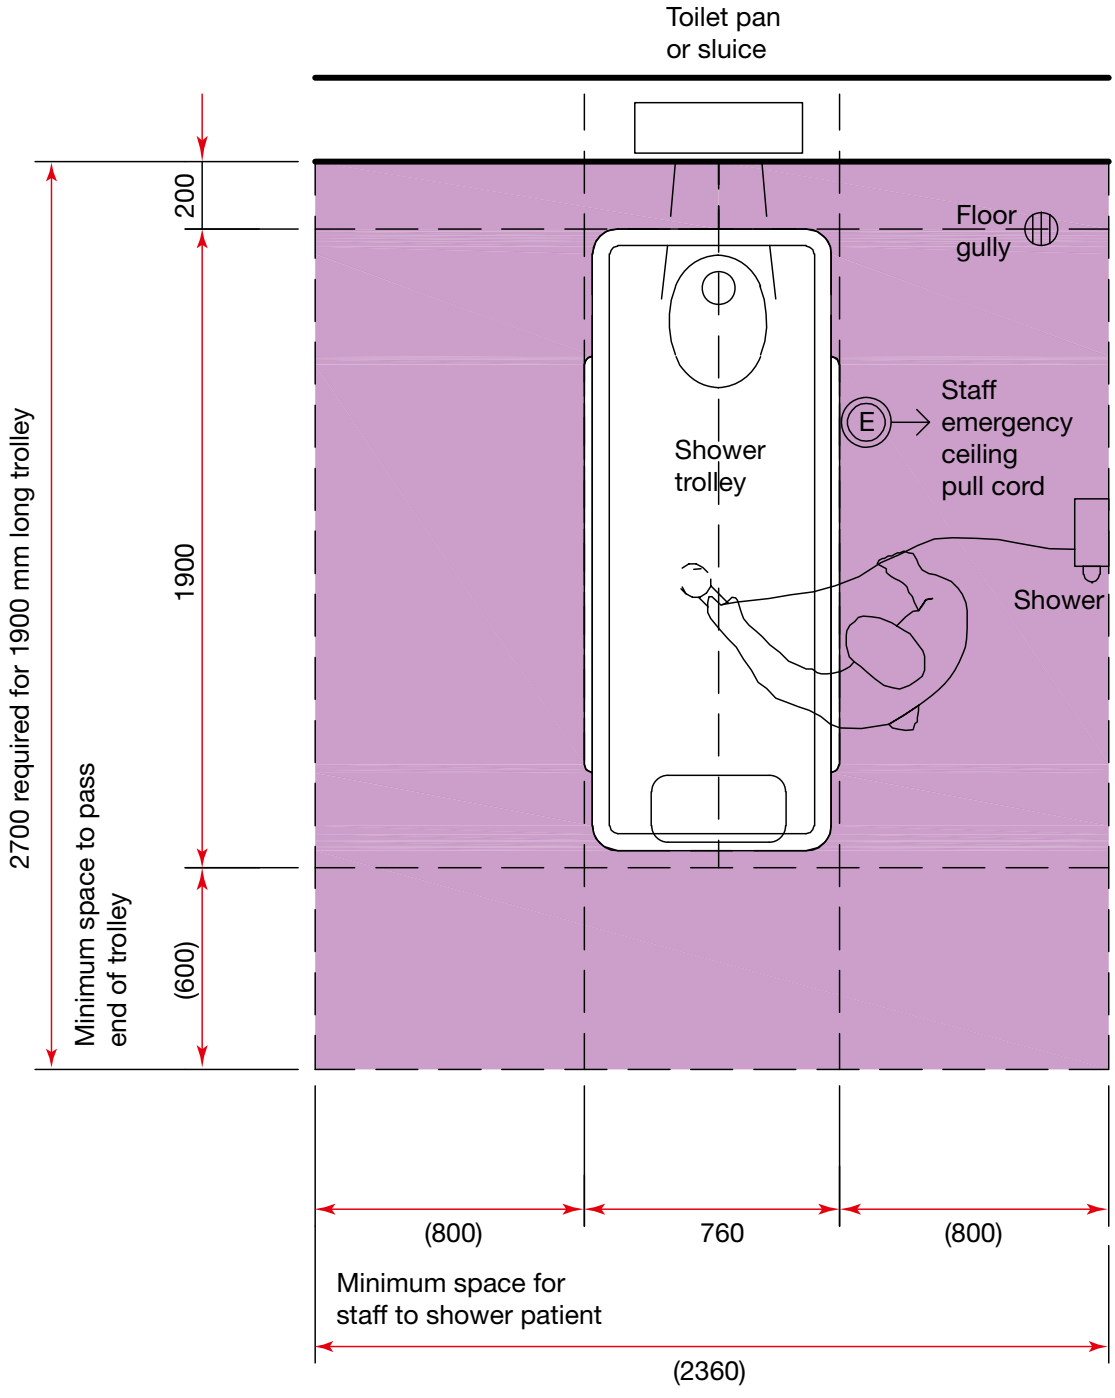

Figure 67 Space requirements for trolley access shower

Toilet: assisted

4.104 This ergonomic drawing (see Figure 68) shows the space requirements for an assisted toilet.

4.105 The clear space on either side of the toilet for mobile hoist transfer is greater than that recommended in BS 8300 (Figure 55).

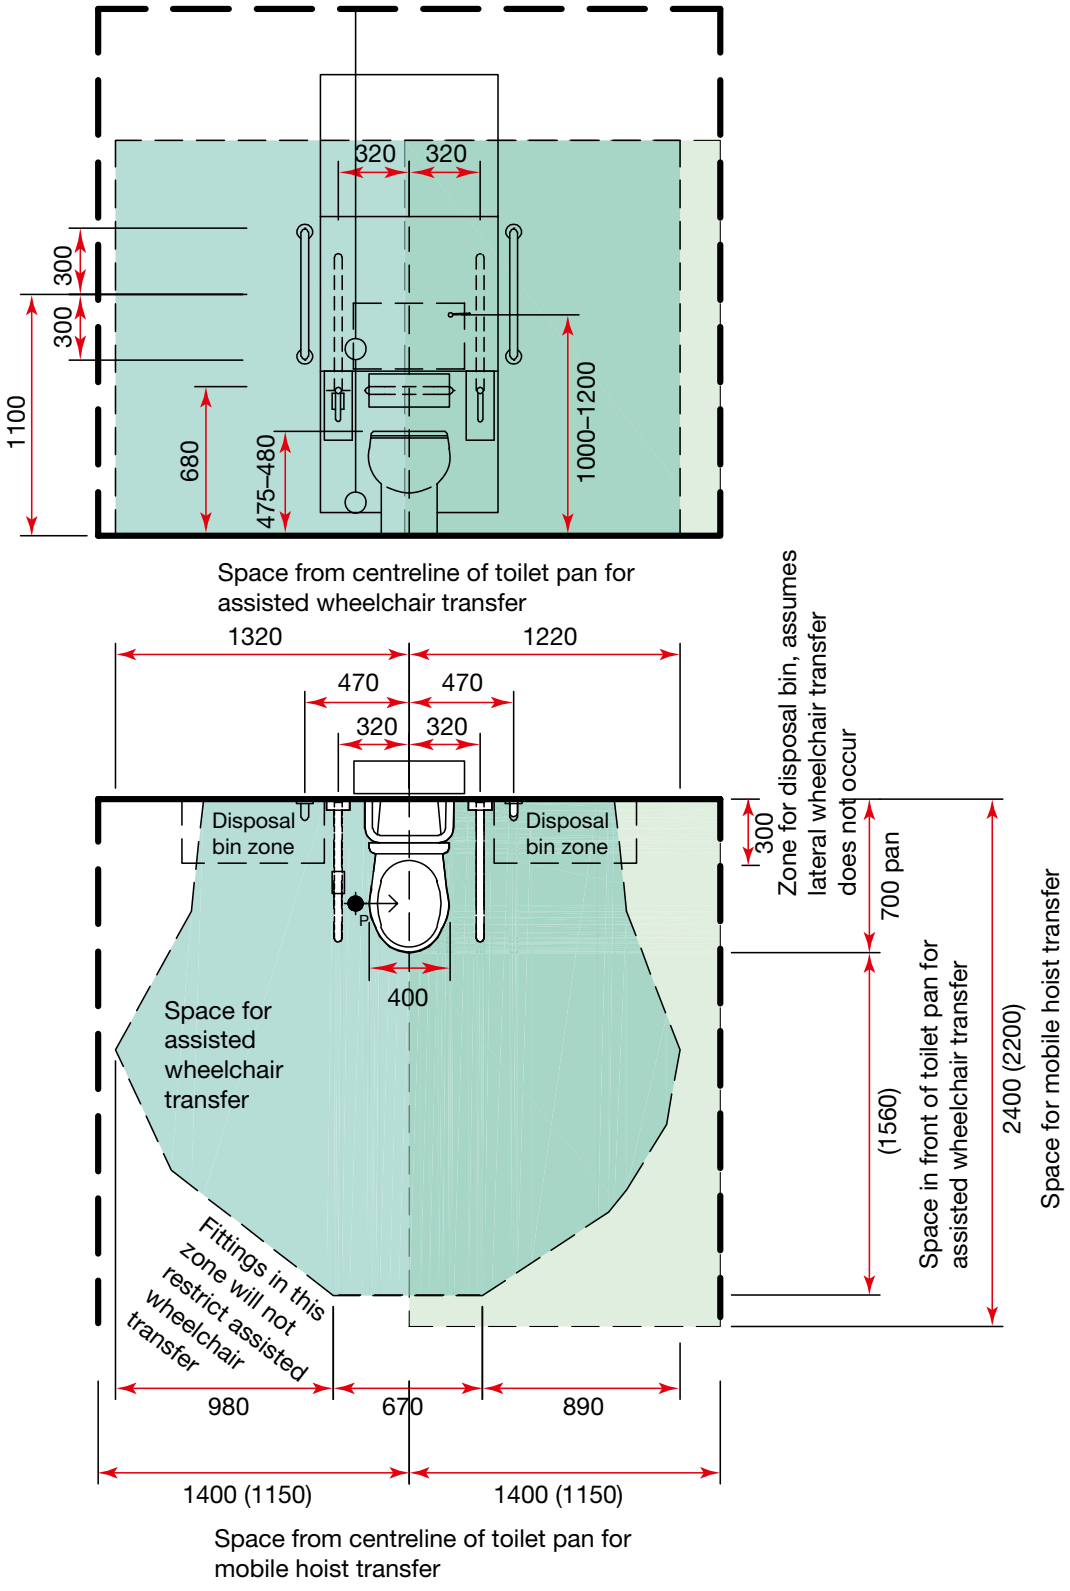

Figure 68 Space requirements for assisted toilet

Wash-hand basin: wheelchair

4.106 Wash-hand basins may be used for personal washing activities.

4.107 This ergonomic drawing (see Figure 69) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

4.108 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

4.109 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

4.110 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

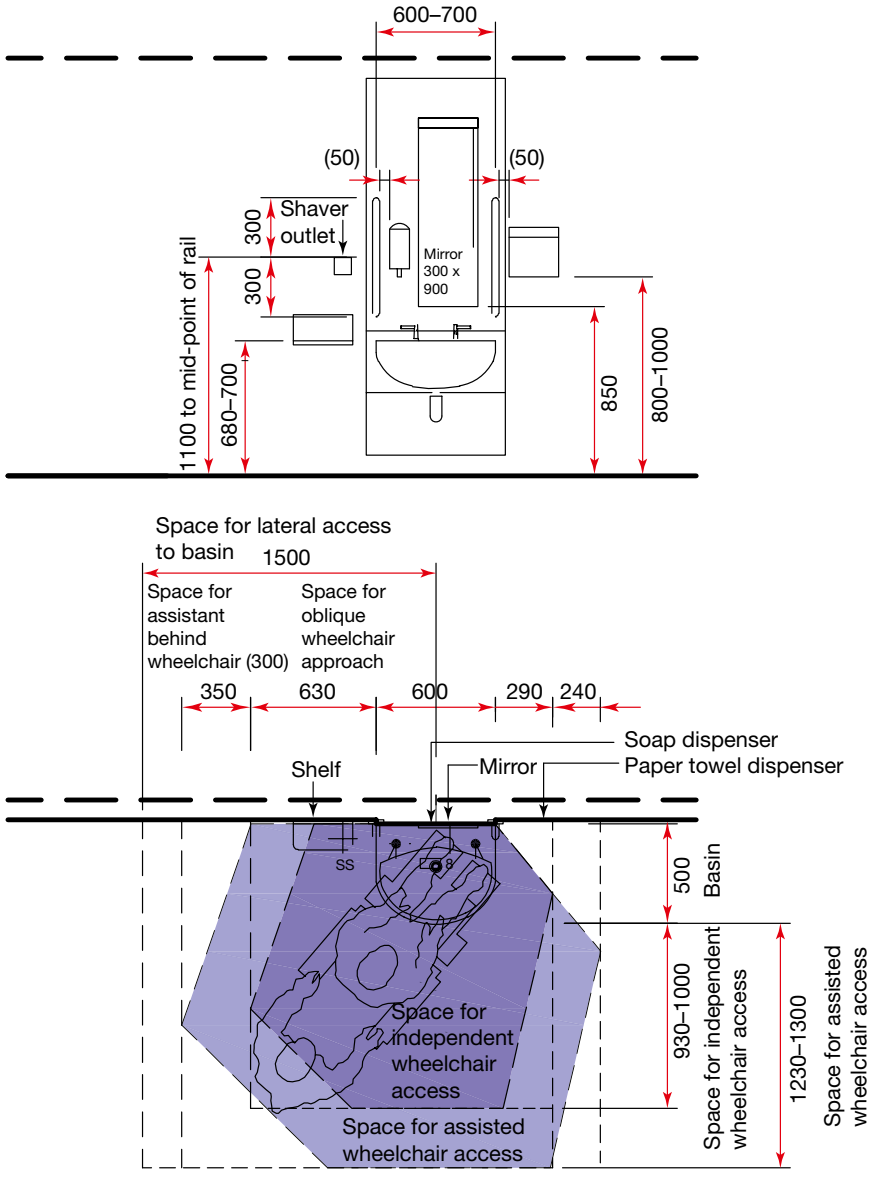

Figure 69 Space requirements for wheelchair accessible wash-hand basin

Full-length mirror: standing or seated users

4.111 This ergonomic drawing (see Figure 70) shows the space requirements for a full-length mirror for standing or seated users.

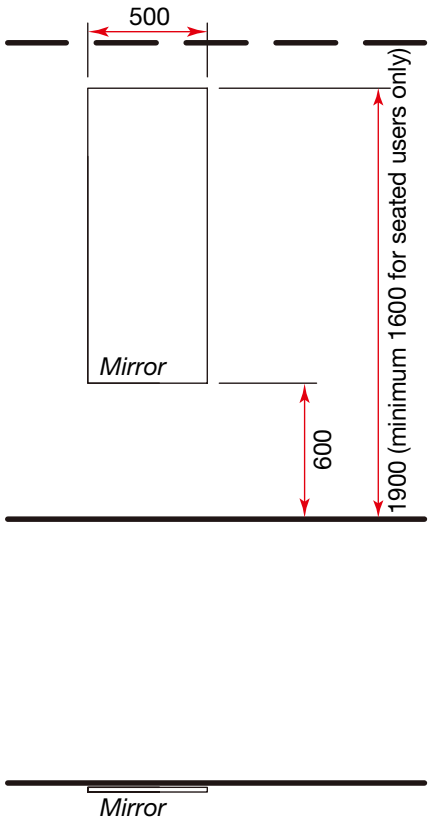

Figure 70 Space requirements for full-length mirror for standing or seated users

Shower room: trolley access: private use

Room description and layout

4.112 The following assisted activities take place in trolley access shower rooms:

- wheelchair and sanitary chair access to the toilet and wash-hand basin;
- mobile hoist access to transfer a patient to the toilet or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet (supervised only);
- use of the toilet;
- personal washing (whilst the patient is seated);
- shower trolley access to the shower;
- showering (whilst the patient is lying on the shower trolley).

4.113 Trolley access showers are suitable for patients who are reliant on assisted movement. The room layout provided (see Figure 71) utilises the minimum clear space requirement to the side of the toilet for mobile hoist transfer (that is, 1150 mm from the centreline of the toilet to the nearest obstruction), on the basin side of the toilet only.

4.114 The drainpipe at the foot of the shower trolley should be positioned over the toilet to deal with incontinence episodes during showering.

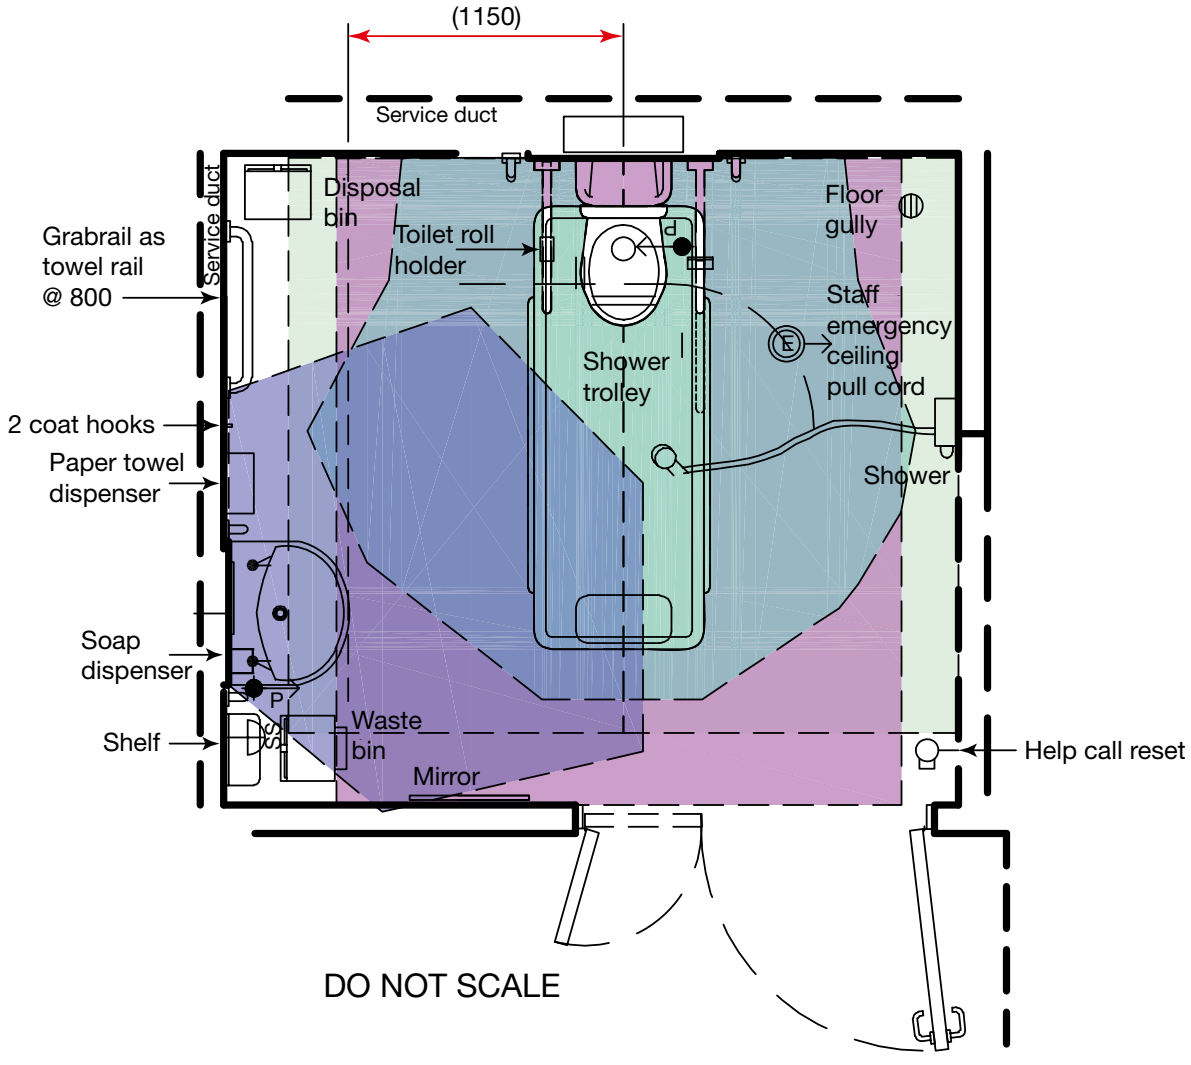

Figure 71 Space requirements for shower room: trolley access: private use, minimum clear space requirement for mobile hoist transfer

Ergonomic drawings

Trolley access shower

4.115 This ergonomic drawing (see Figure 72) shows the space requirements for a trolley access shower.

4.116 A minimum of 800 mm clear space at the head of the trolley is required if staff need to stand in this position during showering.

4.117 The shower panel should have a pressure and temperature control thermostatic mixer. The shower hose should be long enough to allow staff to shower the full length of the patient from either side with a trigger handle. This shower fitting is not specifically covered in Health Building Note 00-10 Part C – 'Sanitary assemblies'.

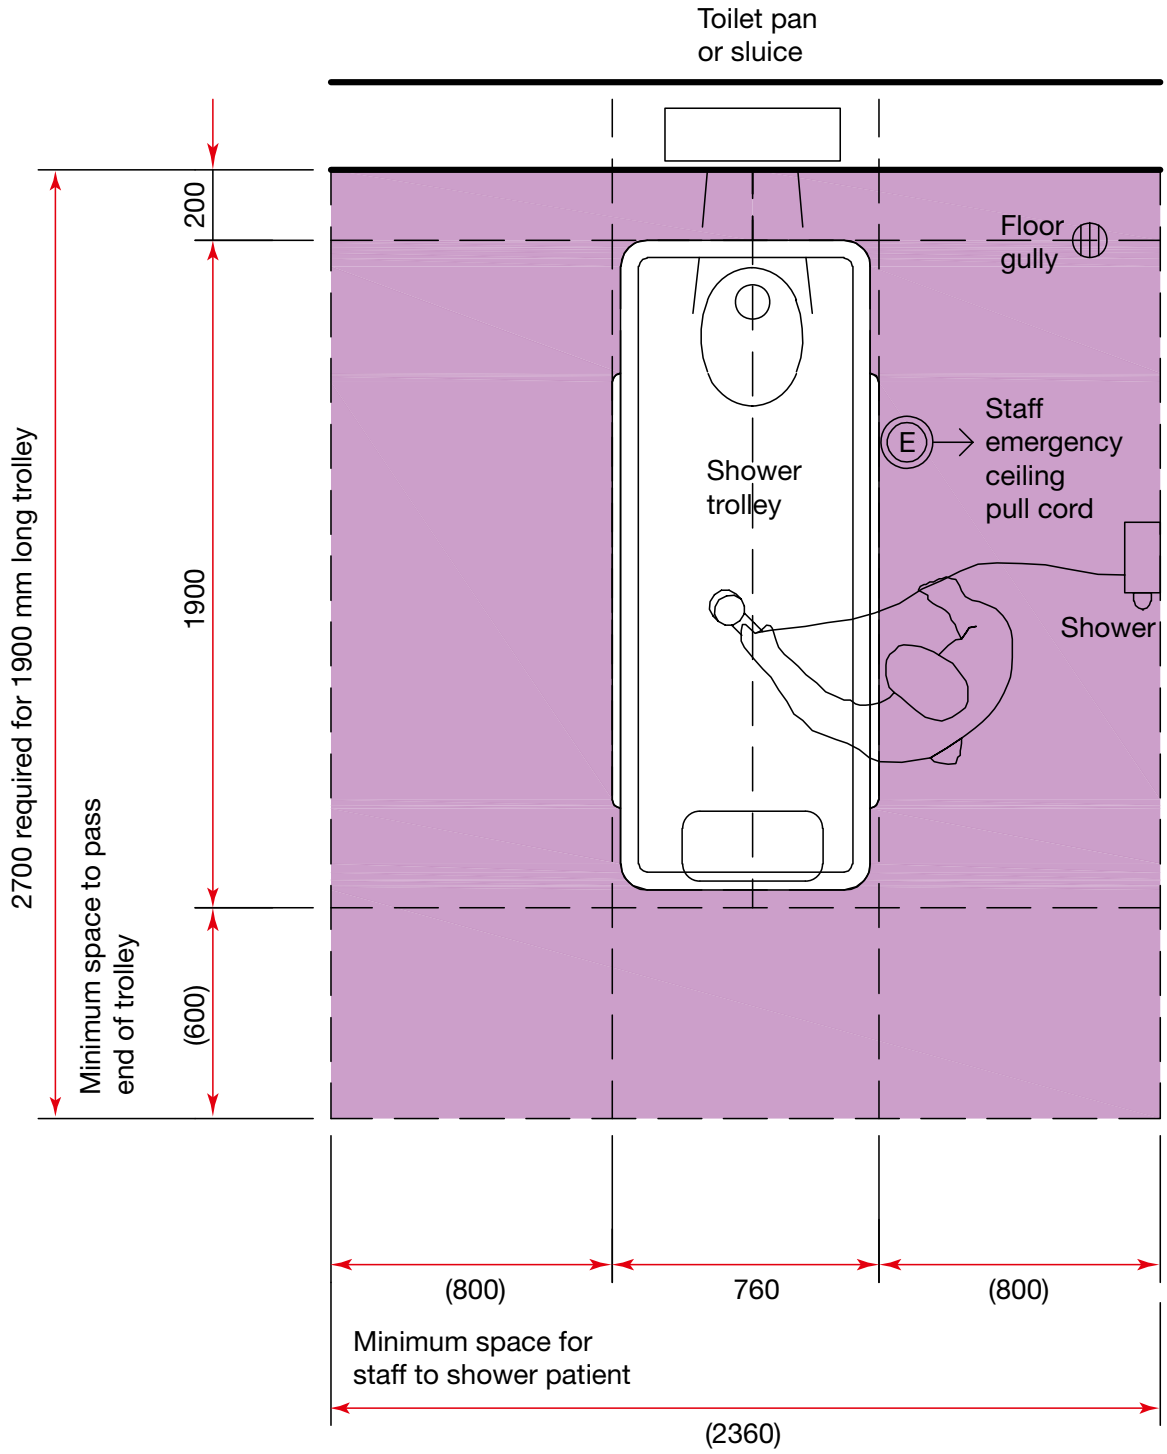

Figure 72 Space requirements for trolley access shower

Toilet: assisted

4.118 This ergonomic drawing (see Figure 73) shows the space requirements for an assisted toilet.

4.119 The clear space on either side of the toilet for mobile hoist transfer is greater than that recommended in BS 8300 (Figure 55).

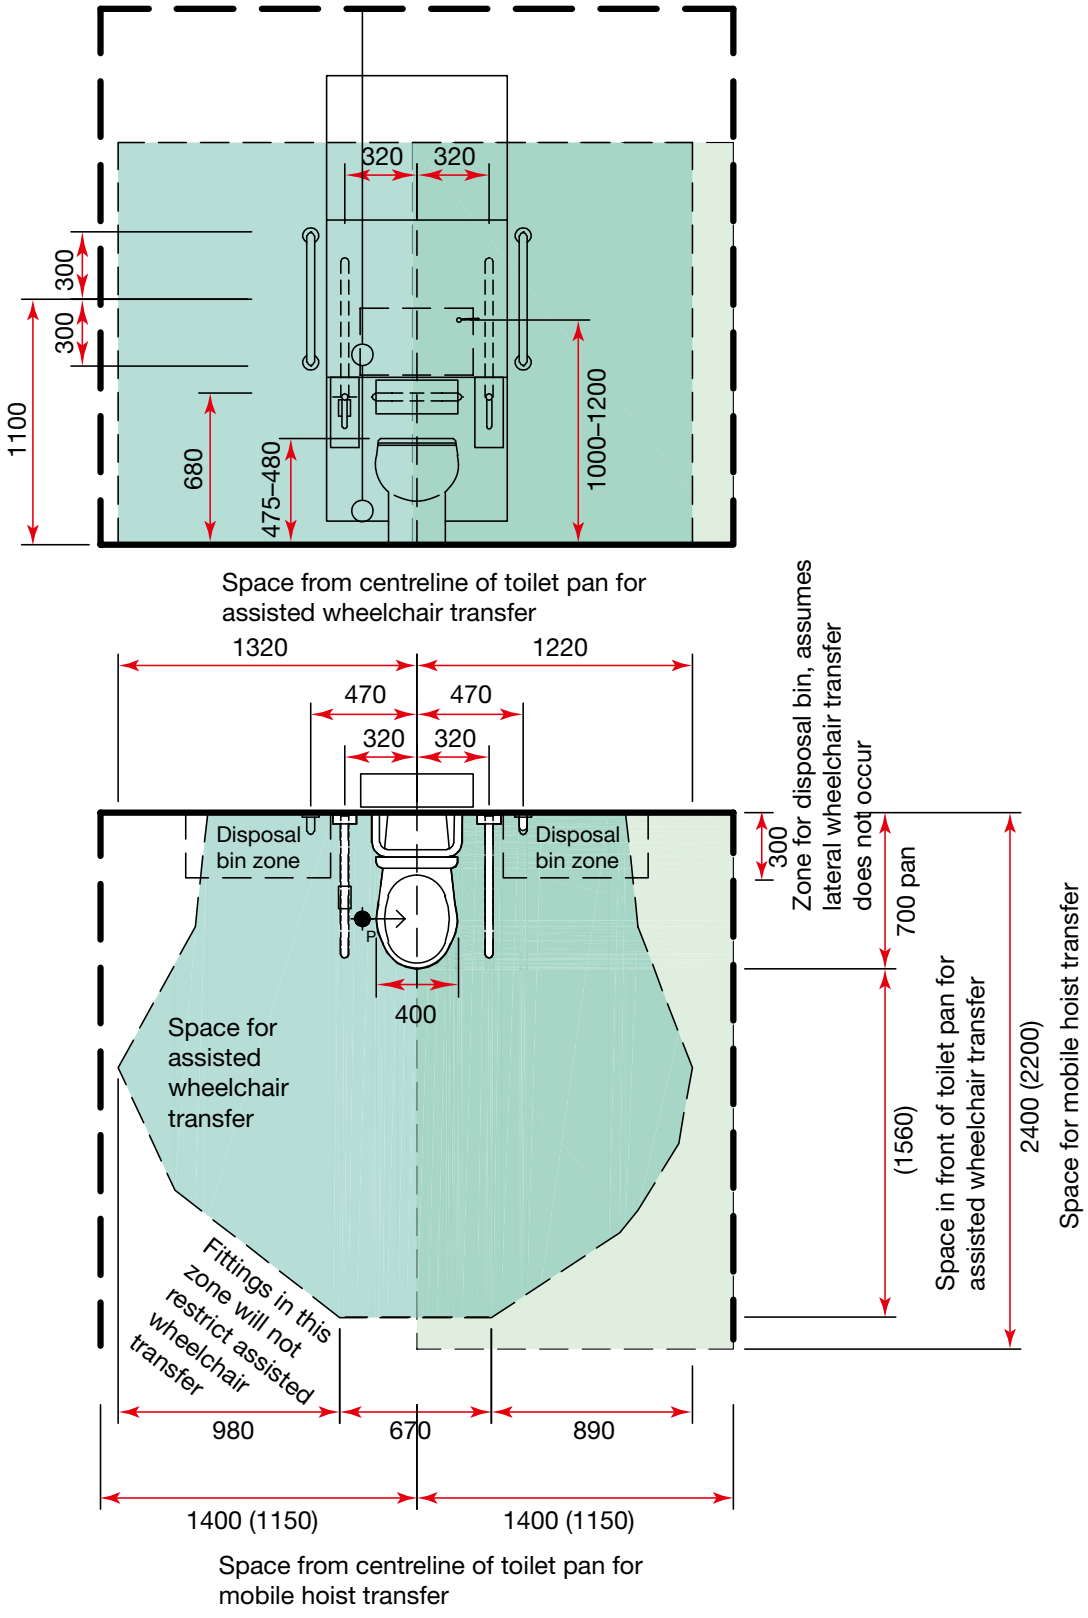

Figure 73 Space requirements for assisted toilet

Wash-hand basin: wheelchair

4.120 Wash-hand basins may be used for personal washing activities.

4.121 This ergonomic drawing (see Figure 74) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

4.122 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

4.123 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

4.124 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

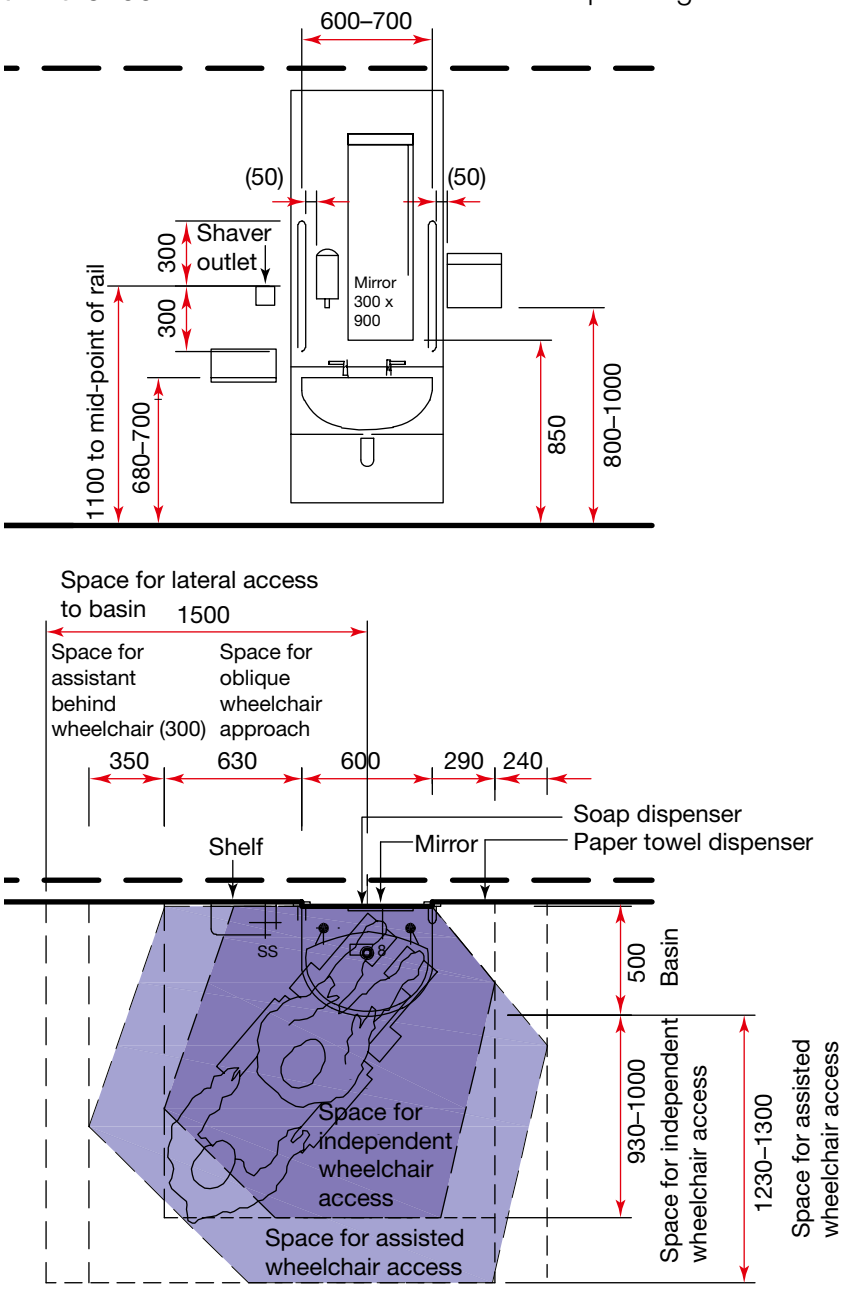

Figure 74 Space requirements for wheelchair accessible wash-hand basin

Full-length mirror: standing or seated users

4.125 This ergonomic drawing (see Figure 75) shows the space requirements for a full-length mirror for standing or seated users.

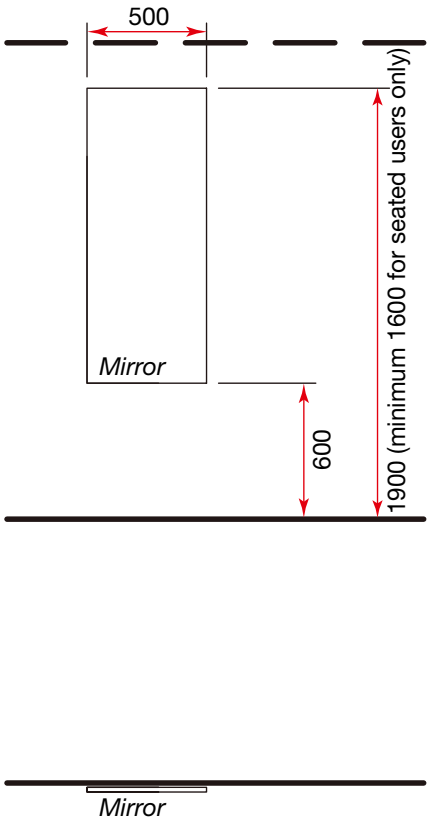

Figure 75 Space requirements for full-length mirror for standing or seated users

5 WCs

WC: ambulant

Room description and layout

5.1 The following activities take place in ambulant WCs:

- use of the toilet:
- disposal of sanitary towels (optional);
- hand-rinsing.

5.2 Ambulant WCs are only suitable for fully ambulant users and should not be used in patient spaces.

5.3 Toilet seats should be provided in ambulant WCs.

5.4 The room layout provided (see Figure 76) includes a 300 mm deep hand-rinse basin. Where a larger hand-rinse basin (up to 350 mm deep) is used, minimum internal room dimensions may need to increase to maintain the required activity space.

5.5 A space allocation for luggage has been included to allow belongings/bags to be comfortably taken into the WC for security.

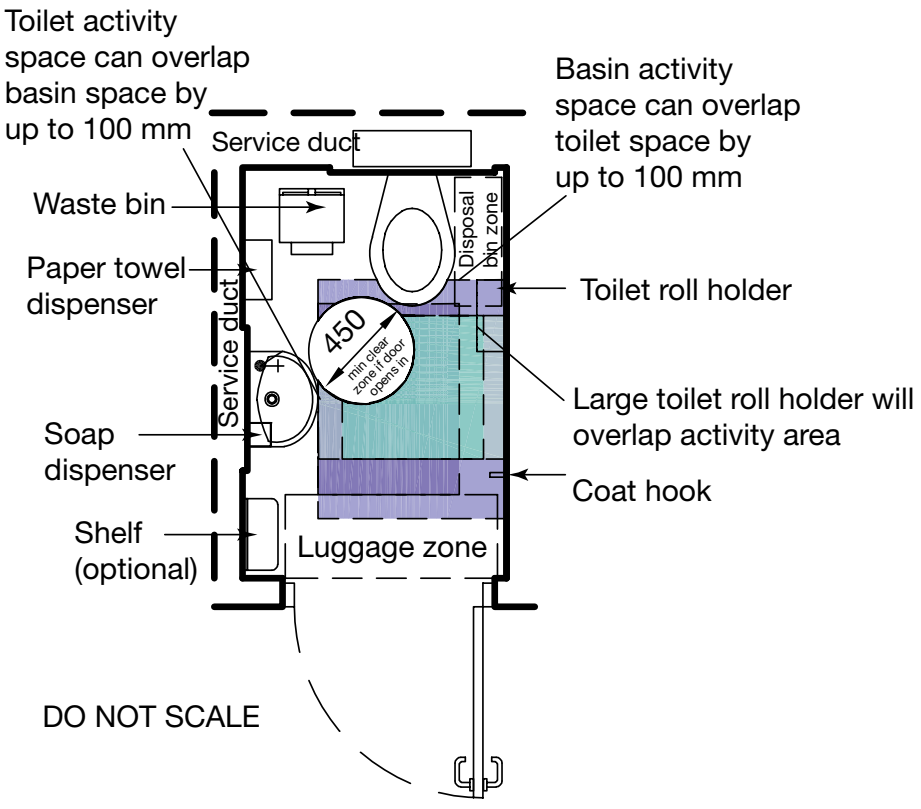

Figure 76 Space requirements for WC: ambulant, 300 mm deep hand-rinse basin

Ergonomic drawings

Toilet: ambulant

5.6 This ergonomic drawing (see Figure 77) shows the space requirements for an ambulant toilet.

5.7 A large toilet roll holder would overlap the activity area.

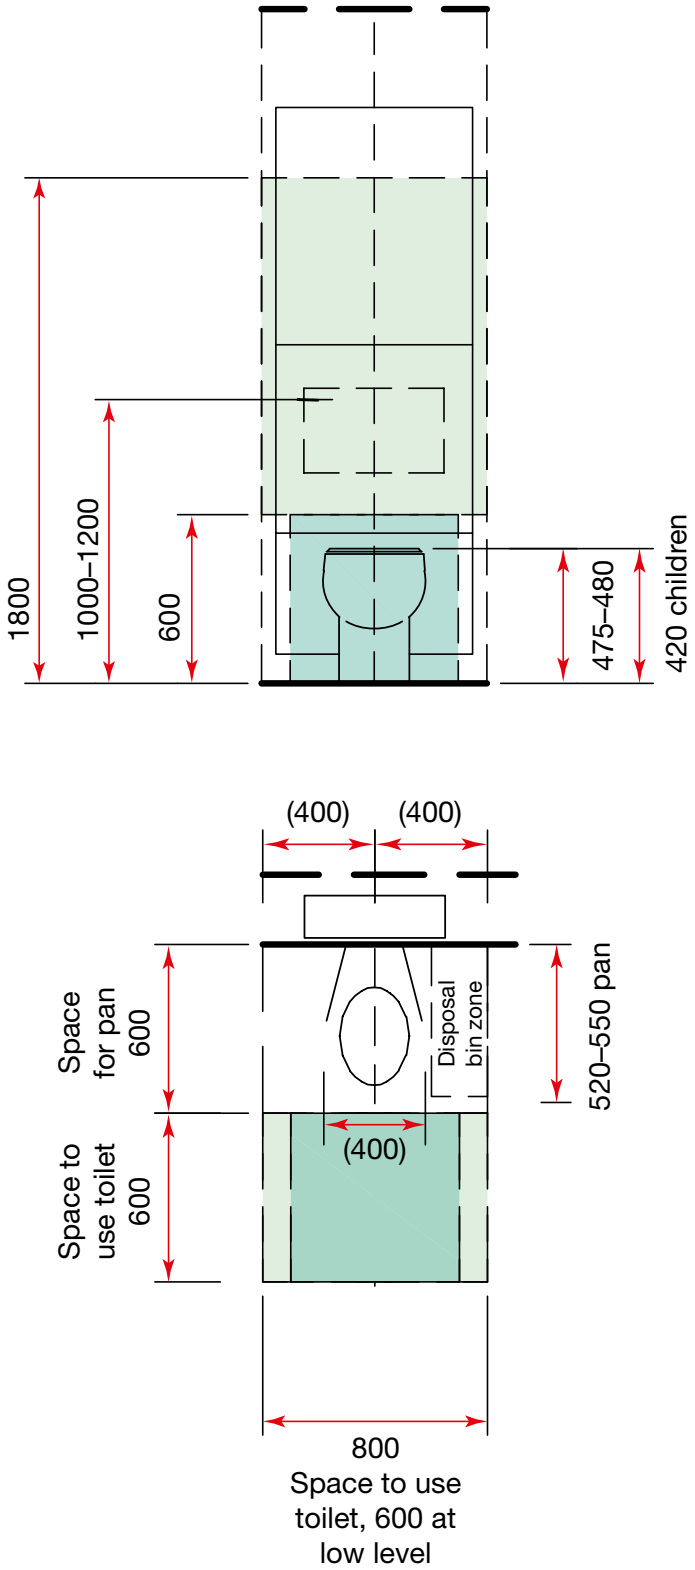

Figure 77 Space requirements for ambulant toilet

Hand-rinse basin: ambulant

5.8 This ergonomic drawing (see Figure 78) shows the space requirements for a 300 mm deep hand-rinse basin. It is suitable for ambulant and semi-ambulant use.

5.9 Hand-rinse basins are generally only suitable for rinsing hands under running water. They should have a single mixer tap.

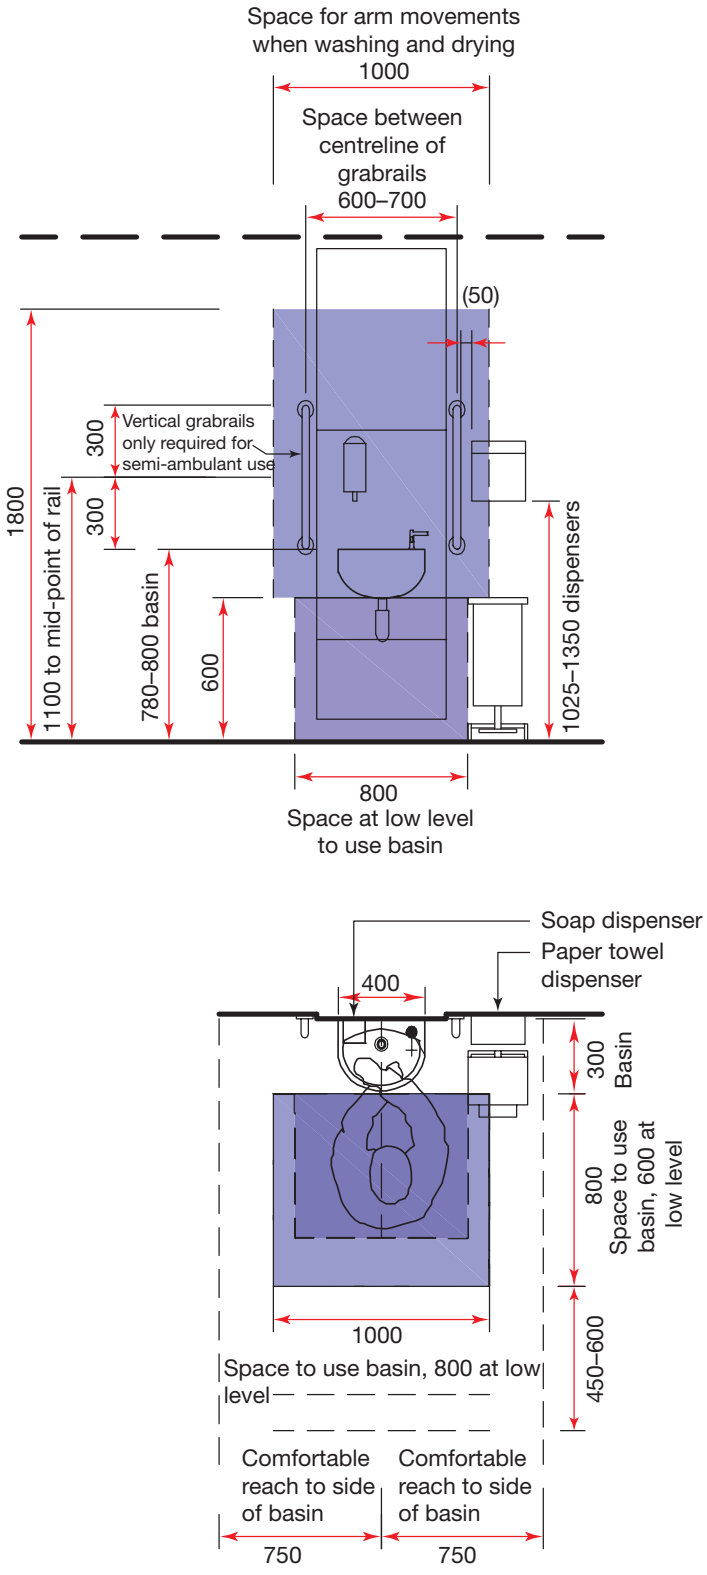

Figure 78 Space requirements for 300 mm deep hand-rinse basin suitable for ambulant and semi-ambulant use

WC: assisted

Room description and layout

5.10 The following assisted activities take place in assisted WCs:

- wheelchair and sanitary chair access to the toilet and wash-hand basin;
- mobile hoist access to transfer a patient to the toilet or to attend to a patient collapsed on the floor;
- patient transfer from a wheelchair to the toilet (supervised only);
- use of the toilet;
- personal washing (whilst the patient is seated).

5.11 Peninsular (also known as island) toilets are required to allow space on either side of the toilet pan for assistance. With the absence of an adjacent wall, this layout may not provide the same feeling of security as a corner toilet layout and is not considered suitable for independent wheelchair users.

5.12 An assisted WC should contain a wheelchair wash-hand basin. A hand-rinse basin, accessible from the toilet, is not acceptable since this would conflict with the space requirements for assistance.

5.13 Assisted WCs should only be used where appropriate assistance is available.

5.14 Mobile hoist access will be required if a patient collapses on the floor even if it is not used for transferring patients to the toilet.

5.15 The room layout provided (see Figure 79) utilises the minimum clear space requirement to the side of the toilet for mobile hoist transfer (that is, 1150 mm from the centreline of the toilet to the nearest obstruction), on the basin side of the toilet only.

5.16 To enable this space to be suitable for ambulant and semi-ambulant use as well as assisted use, an adjustable-height wash-hand basin may be provided in place of the wheelchair wash-hand basin.

5.17 The disposal bin is shown located away from the toilet to maximise the space for transfer and because it is assumed that the assistant will transfer waste to the bin or move the bin closer to the toilet when required.

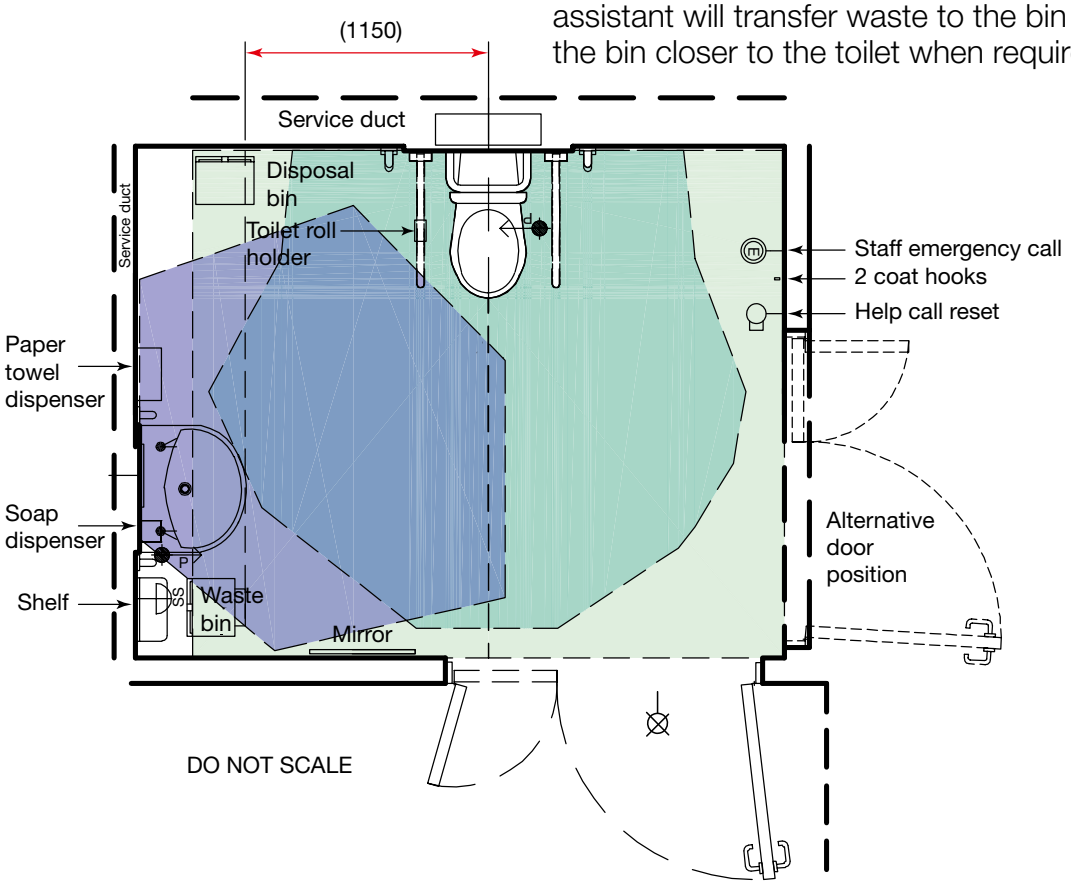

Figure 79 Space requirements for WC: assisted with minimum clear space requirement for mobile hoist transfer

Ergonomic drawings

Toilet: assisted

5.18 This ergonomic drawing (see Figure 80) shows the space requirements for an assisted toilet.

5.19 The clear space on either side of the toilet for mobile hoist transfer is greater than that recommended in BS 8300 (Figure 55).

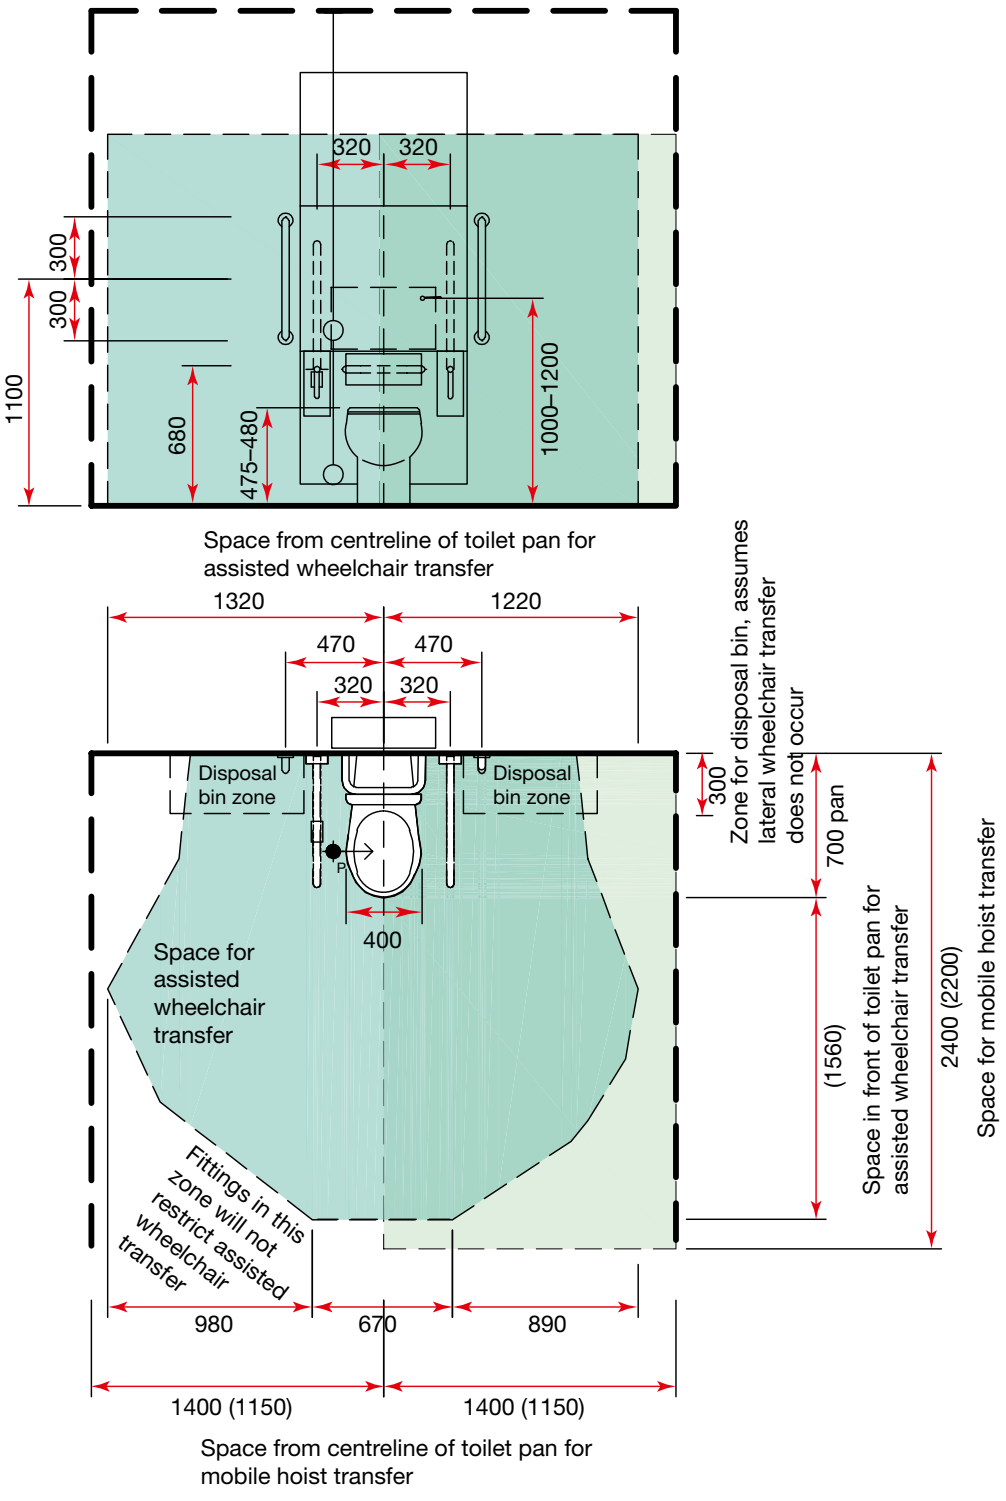

Figure 80 Space requirements for assisted toilet

Wash-hand basin: wheelchair

5.20 Wash-hand basins may be used for personal washing activities.

5.21 This ergonomic drawing (see Figure 81) shows the space requirements for a wheelchair accessible wash-hand basin. It is also suitable for seated use.

5.22 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

5.23 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

5.24 Wheelchair-accessible wash-hand basins should have a size and profile that maximises access and reduces obstructions. They should:

- be as shallow as possible, that is, tapered from the rim to a depth not exceeding 250 mm at the outlet, which in turn should be positioned as near the supporting wall as possible;
- preferably project 500 mm in order to provide adequate leg room underneath the basin.

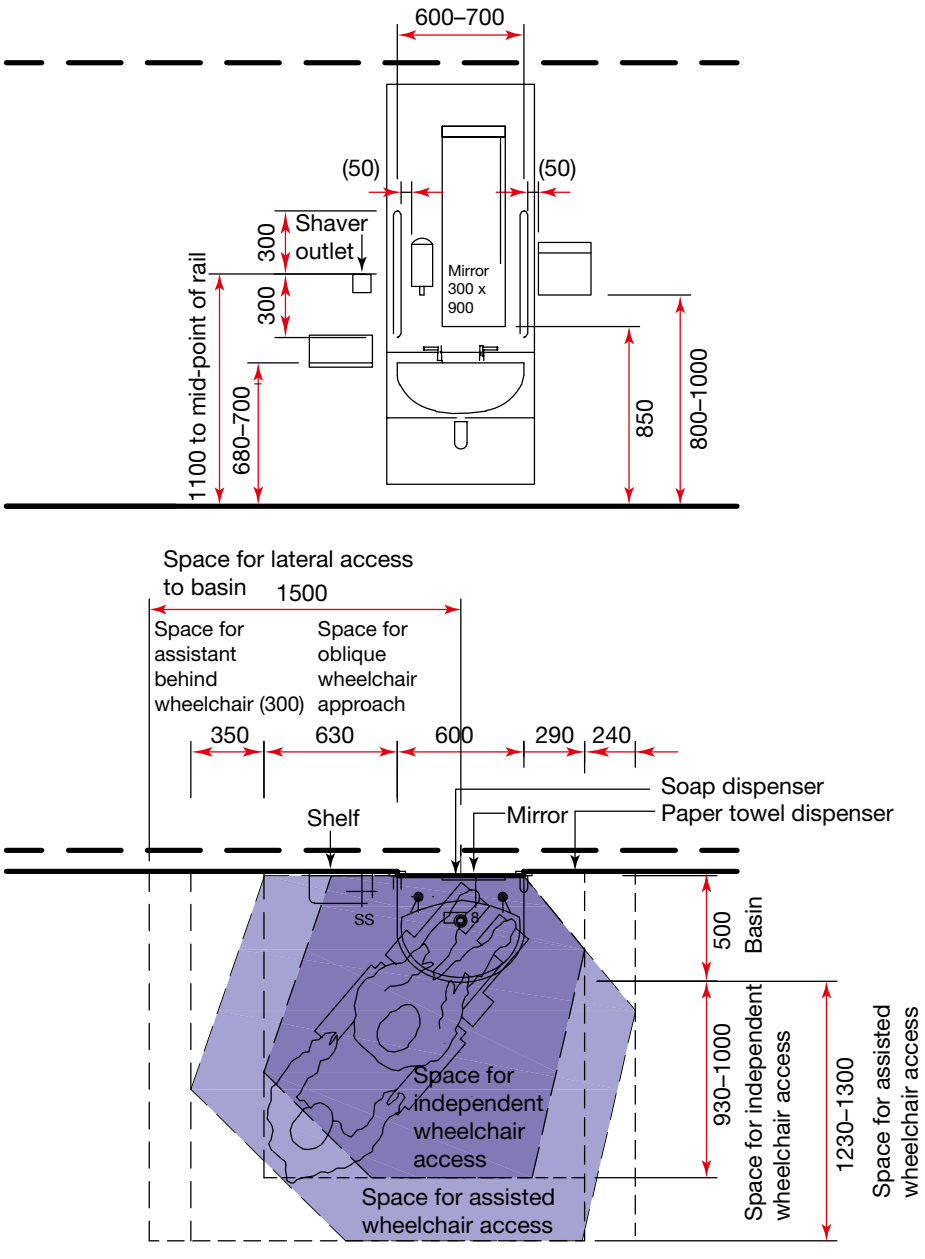

Figure 81 Space requirements for wheelchair accessible wash-hand basin

Full-length mirror: standing or seated users

5.25 This ergonomic drawing (see Figure 82) shows the space requirements for a full-length mirror for standing or seated users.

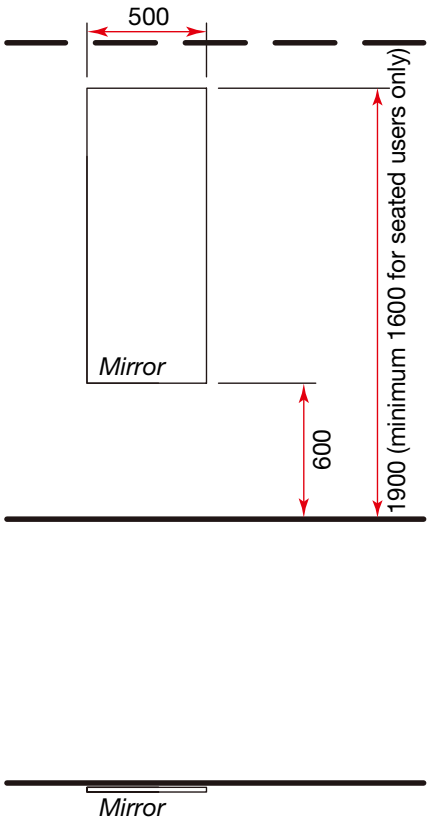

Figure 82 Space requirements for full-length mirror standing or seated users

WC: independent wheelchair/semi-ambulant

Room description and layout

5.26 The following activities take place in independent wheelchair/semi-ambulant WCs:

- wheelchair access to the toilet and hand-rinse basin;
- independent transfer from a wheelchair to the toilet;
- use of the toilet;
- disposal of sanitary towels and wipes;
- emptying of urine bottles/colostomy bags;
- hand-rinsing (whilst in a wheelchair facing the hand-rinse basin or seated on the toilet);
- personal washing (for semi-ambulant users).

5.27 An independent wheelchair/semi-ambulant WC should be provided where it is the only WC within an area. See BS 8300 (paragraph 12.6.1) and Approved Document M (paragraph 5.10e).

5.28 Wheelchair users need to be able to rinse and dry their hands from a seated position on the toilet before transferring back onto their wheelchairs (to avoid the possibility of staining clothes or wheelchairs and to assist with infection control). This is only possible with a corner toilet with an adjacent hand-rinse basin.

5.29 To facilitate good access to the hand-rinse basin from the toilet, the mixer tap should be positioned on the side of the hand-rinse basin nearest to the toilet. Left or right-handed tap hole hand-rinse basins may be required depending on the layout of facilities.

5.30 The flush system should be located on the open (transfer) side of the toilet to ensure it is easily reachable by a wheelchair user facing the toilet.

5.31 The layout (see Figure 83) allows for right-hand independent wheelchair transfer to the toilet.

5.32 It includes a separate ambulant wash-hand basin for semi-ambulant users.

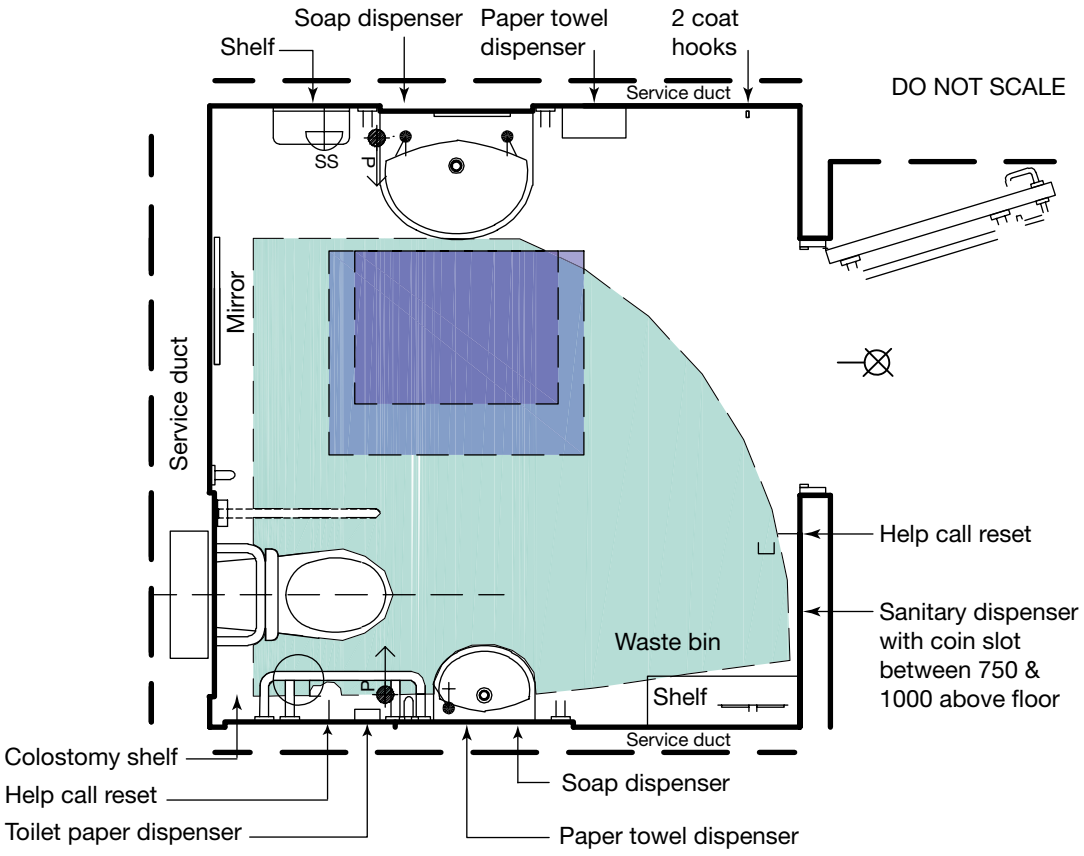

Figure 83 Space requirements for WC: independent wheelchair/semi-ambulant use with right-hand independent wheelchair transfer

Ergonomic drawings

Toilet and adjacent hand-rinse basin: independent wheelchair

5.33 This ergonomic drawing (see Figure 84) shows the space requirements for an independent wheelchair toilet and adjacent hand-rinse basin.

5.34 The recommended clear space in front and to the open side of the toilet (for independent wheelchair transfer) is greater than the recommendations in Approved Document M and BS 8300.

5.35 Approved Document M and BS 8300 recommend a minimum clear distance of 1000 mm to the open side of the centreline of the toilet for independent wheelchair transfer. Robert Feeney Associates (RFA) research for BS 8300 indicates that this will allow just over 60% of wheelchair users to comfortably transfer onto the toilet. The same research indicates that a clear space of 1400 mm accommodates 90% of wheelchair users and this is, therefore, recommended.

5.36 Approved Document M and BS 8300 recommend a 750 mm long toilet pan for independent wheelchair transfer. However, RFA research indicated that a 700 mm long toilet pan allows independent wheelchair transfer. For maximum space efficiency a 700 mm pan is recommended.

5.37 As a consequence of the reduction in pan length, the hand-rinse basin is located closer to the corner of the room than the position given in Approved Document M and BS 8300, to allow hand-rinsing from a seated position on the toilet.

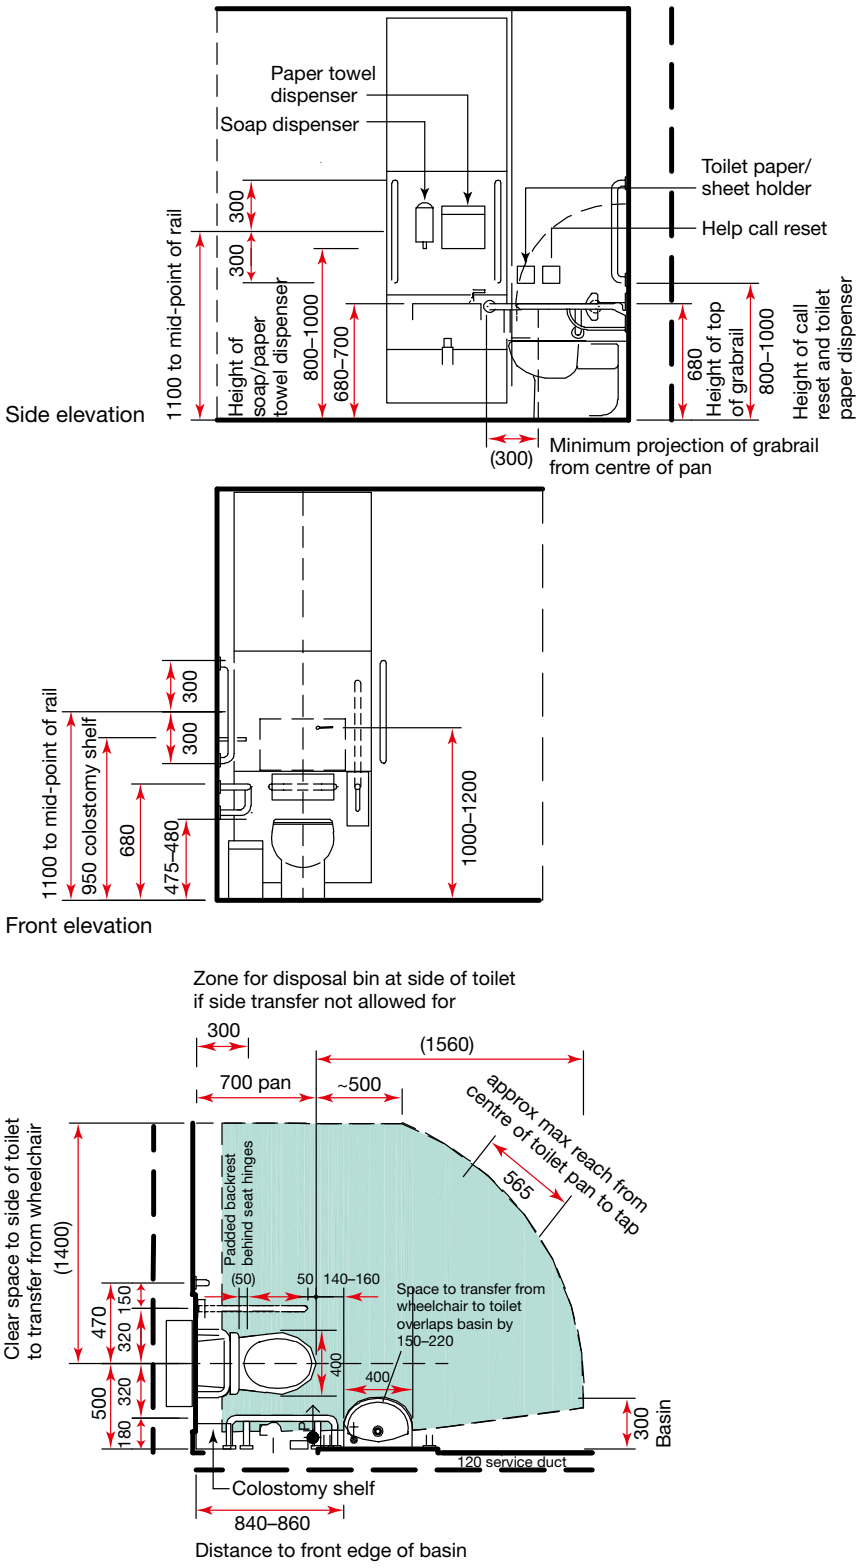

Figure 84 Space requirements for an independent wheelchair toilet and adjacent hand-rinse basin

Toilet and adjacent hand-rinse basin: independent wheelchair: grabrail options

5.38 These ergonomic drawings (see Figure 85) show the fixing position of grabrails for an independent wheelchair toilet and adjacent hand-rinse basin.

5.39 Grabrails should be provided symmetrically on either side of the toilet at 320 mm from the centreline of the toilet pan. This conflicts with the recommendations in Approved Document M and BS 8300.

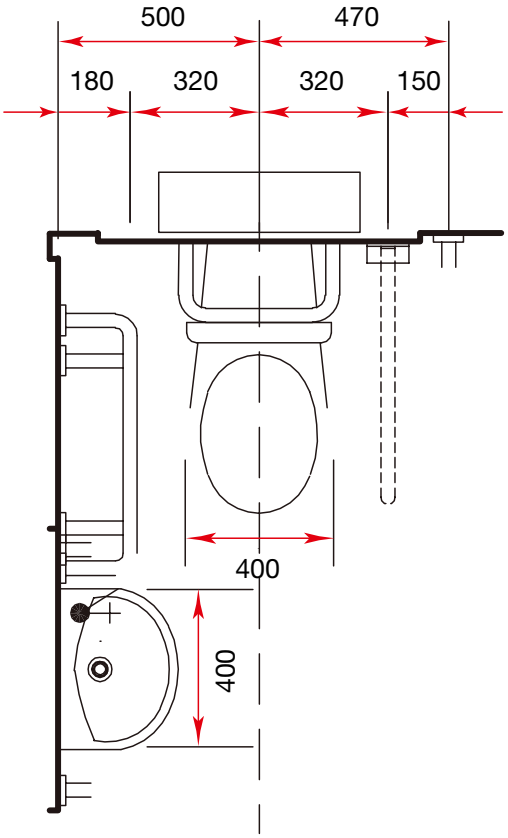
5.40 Approved Document M (paragraph 5.10j) states: "where the horizontal support rail on the wall adjacent to the toilet is set with the minimum spacing from the wall, an additional dropdown rail should be provided on the wall side at a distance of 320 mm from the centreline of the toilet."

Note

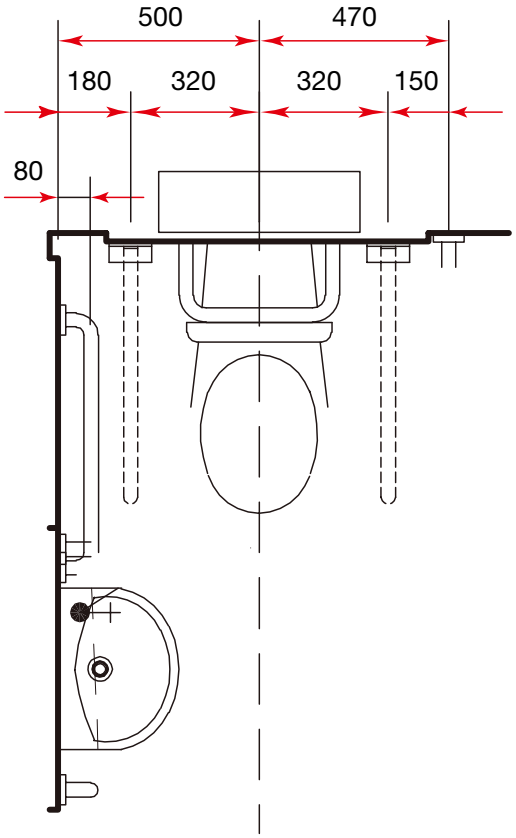
Where the maximum spacing defined in Approved Document M, 85 mm, is used, this positions the grabrail approximately 390 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

5.41 BS 8300 (paragraph 12.6.3.5 b) states: "A fixed horizontal rail should be located on the side wall with a 50 mm to 60 mm clearance between the rail and the wall." This places the rail approximately 420 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

5.42 The ergonomic drawings provided illustrate two options for the provision of grabrails. The room layouts on this website are based on option one.



Fixed grabrail between toilet and wall



Alternative fixed and hinged grabrail between toilet and wall

Figure 85 Space requirements showing fixing position of grabrails for independent wheelchair toilet and adjacent hand-rinse basin

Wash-hand basin: ambulant

5.43 Wash-hand basins may be used for personal washing activities.

5.44 This ergonomic drawing (see Figure 86) shows the space requirements for ambulant/ semi-ambulant use of a 400 mm deep × 500 mm wide wash-hand basin.

5.45 It includes a shaver socket adjacent to the wash-hand basin and a light above the mirror; these are optional. The inclusion of a shaver socket depends on project requirements. The need for a local light depends on the overall lighting scheme within the room.

5.46 The drawing also shows two short lever taps. Alternatively a single mixer tap or sensor-operated taps may be used. See Health Building Note 00-10 Part C – 'Sanitary assemblies' for details.

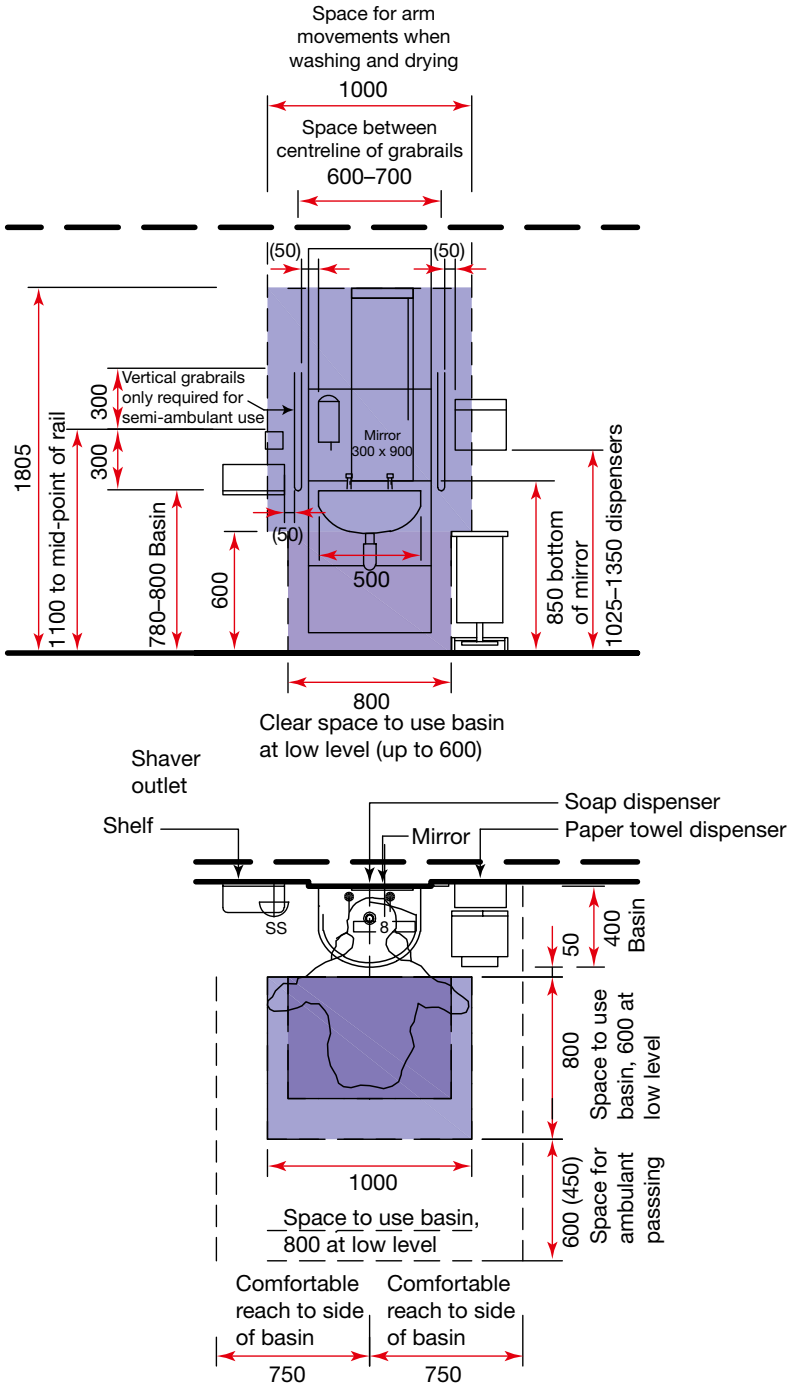


Figure 86 Space requirements for ambulant/semi-ambulant use of 400 mm deep x 500 mm wide wash-hand basin

Full-length mirror: standing or seated users

5.47 This ergonomic drawing (see Figure 87) shows the space requirements for a full-length mirror for standing or seated users.

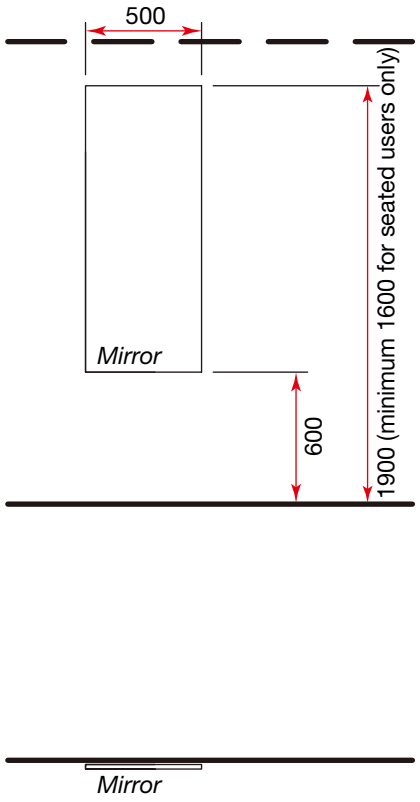

Figure 87 Space requirements for full-length mirror for standing or seated users

WC: Semi-ambulant

Room description and layout

5.48 The following activities take place in a semi-ambulant WC (see Figure 88):

- use of the toilet;
- disposal of sanitary towels (optional);
- hand-rinsing.

5.49 Semi-ambulant WCs are also suitable for fully ambulant users.

5.50 The semi-ambulant WC layout includes a hand-rinse basin.

5.51 A space allocation for luggage has been included to provide room for belongings/ bags to be comfortably taken into the WC for security.

5.52 The minimum clear width is 900 mm. While 1000 mm is preferred for movement with walking aids, 900 mm is considered acceptable since there is additional space above and below the basin for movement.

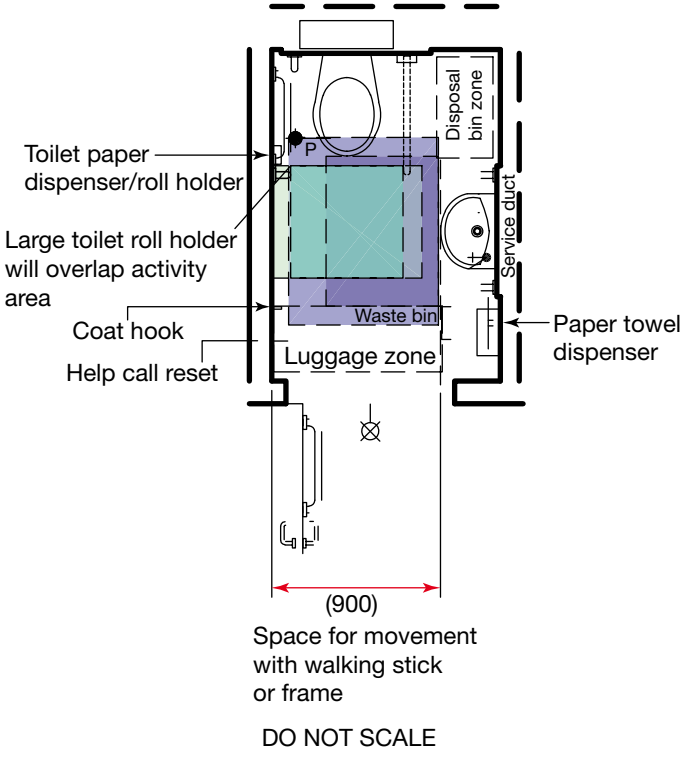

Figure 88 WC: semi-ambulant

Ergonomic drawings

5.53 The ergonomic drawings (see Figure 89) show the space requirements for a semi-ambulant WC and hand-rinse basin.

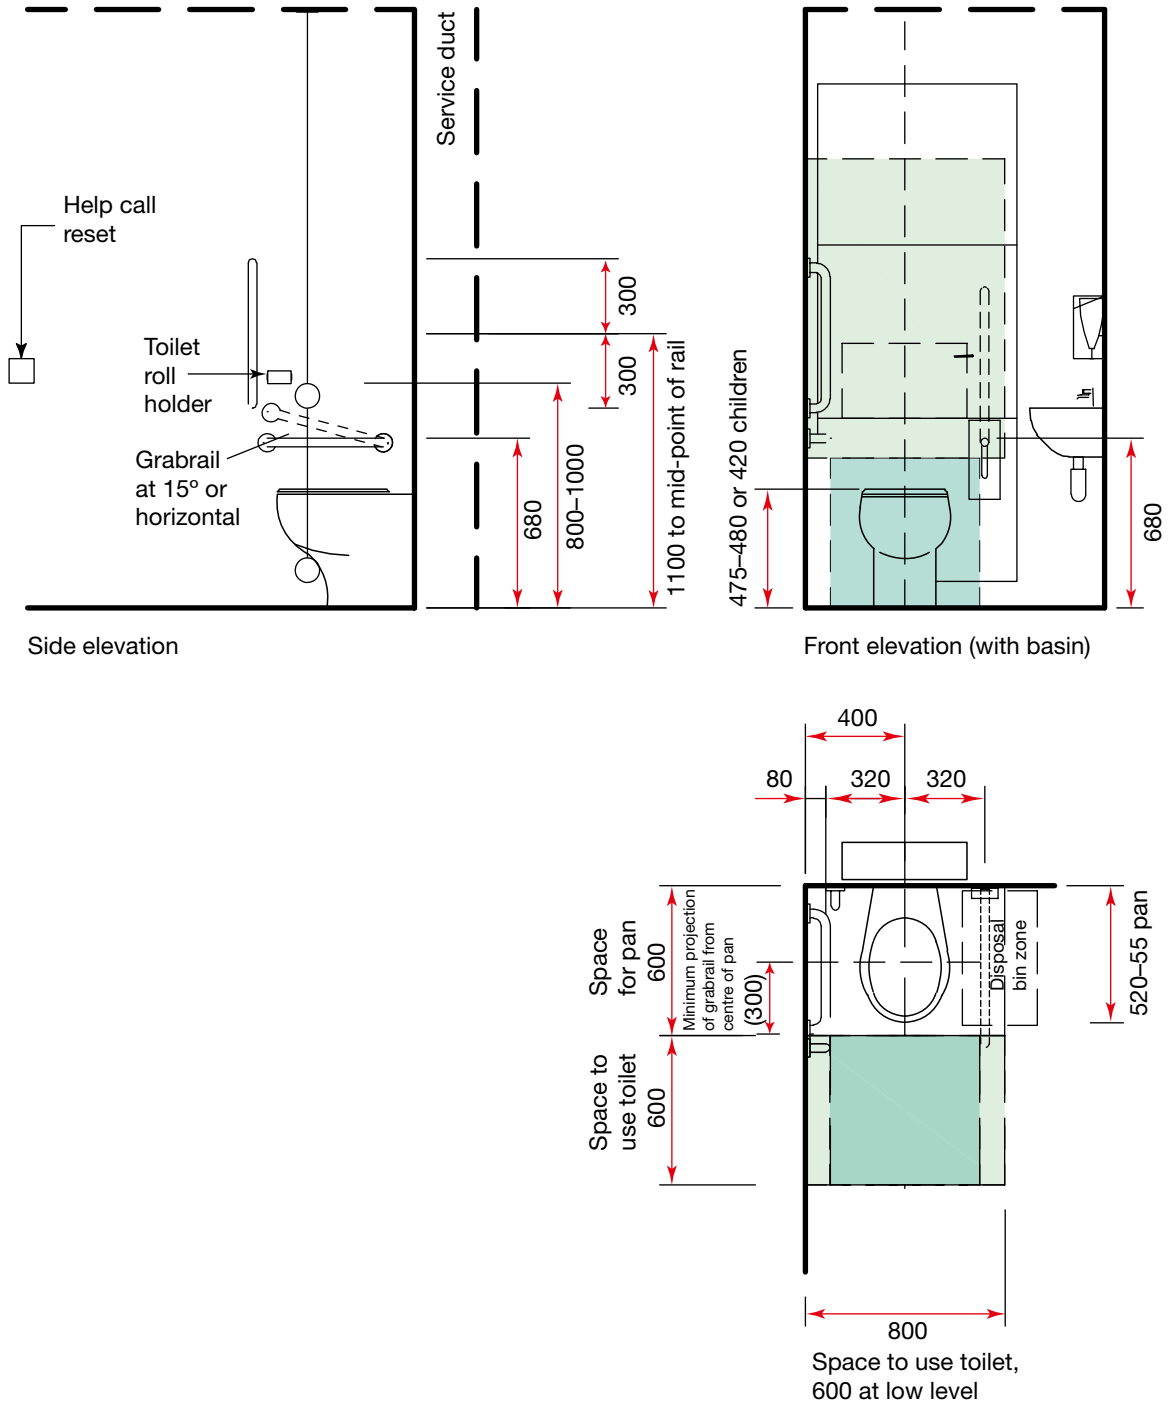

Figure 89 Space requirements for semi-ambulant toilet and adjacent hand-rinse basin

WC: independent wheelchair

Room description and layout

5.54 The following activities take place in independent wheelchair WCs:

- wheelchair access to the toilet and hand-rinse basin;
- independent transfer from a wheelchair to the toilet;
- use of the toilet;
- disposal of sanitary towels and wipes;
- emptying of urine bottles/colostomy bags;
- hand-rinsing (whilst in a wheelchair facing the hand-rinse basin or seated on the toilet).

5.55 Users need to be able to rinse and dry their hands from a seated position on the toilet before transferring back onto their wheelchairs (to avoid the possibility of staining clothes or wheelchairs and to assist with infection control). This is only possible with a corner toilet with an adjacent hand-rinse basin.

5.56 To facilitate good access to the hand-rinse basin from the toilet, the mixer tap should be positioned on the side of the hand-rinse basin nearest to the toilet. Left or right-handed tap hole hand-rinse basins may be required depending on the layout of facilities.

5.57 The flush system should be located on the open (transfer) side of the toilet to ensure it is easily reachable by a wheelchair user facing the toilet.

5.58 Independent wheelchair WCs are also suitable for semi-ambulant users with, or without, “hands-off assistance” who may wish to sit down to wash their hands.

5.59 The room layout provided is larger than the equivalent space in Approved Document M and BS 8300.

5.60 Approved Document M and BS 8300 recommend a minimum room length of 2200 mm for independent wheelchair WCs. Robert Feeney Associates research for BS 8300 indicates that a clear space of 1600 (1560) mm in front of the toilet is required for transfer. This equates to a minimum room length of 2300 (2260) mm (using a 700 mm long toilet pan) and is recommended.

5.61 The room layout (see Figure 90) allows right-hand transfer to the toilet. Where more than one independent wheelchair WC is provided within a facility, left-hand and right-hand options should be available. See Approved Document M, paragraph 5.10d.

5.62 The disposal bin adjacent to the toilet should be a maximum of 200 mm wide and 480 mm high and capable of being operated with one hand.

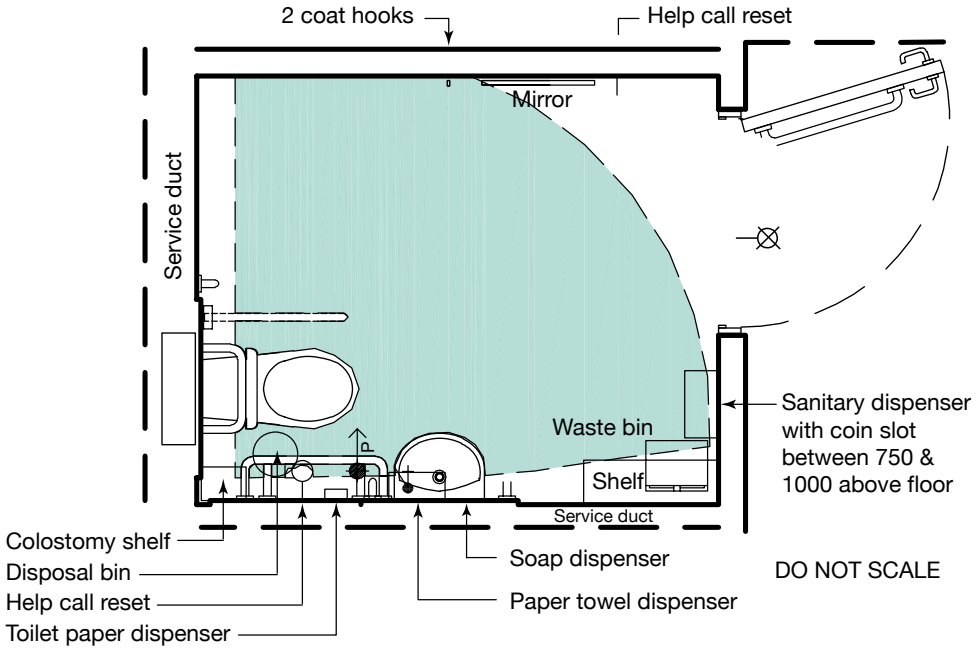

Figure 90 Space requirement for WC: independent wheelchair with right-hand transfer to toilet

Ergonomic drawings

Toilet and adjacent hand-rinse basin: independent wheelchair

5.63 This ergonomic drawing (see Figure 91) shows the space requirements for an independent wheelchair toilet and adjacent hand-rinse basin.

5.64 The recommended clear space in front and to the open side of the toilet (for independent wheelchair transfer) is greater than the recommendations in Approved Document M and BS 8300.

5.65 Approved Document M and BS 8300 recommend a minimum clear distance of 1000 mm to the open side of the centreline of the toilet for independent wheelchair transfer. Robert Feeney Associates (RFA) research for BS 8300 indicates that this will allow just over 60% of wheelchair users to comfortably transfer onto the toilet. The same research indicates that a clear space of 1400 mm accommodates 90% of wheelchair users and this is, therefore, recommended.

5.66 Approved Document M and BS 8300 recommend a 750 mm long toilet pan for independent wheelchair transfer. However, RFA research indicated that a 700 mm long toilet pan allows independent wheelchair transfer. For maximum space efficiency a 700 mm pan is recommended.

5.67 As a consequence of the reduction in pan length, the hand-rinse basin is located closer to the corner of the room than the position given in Approved Document M and BS 8300, to allow hand-rinsing from a seated position on the toilet.

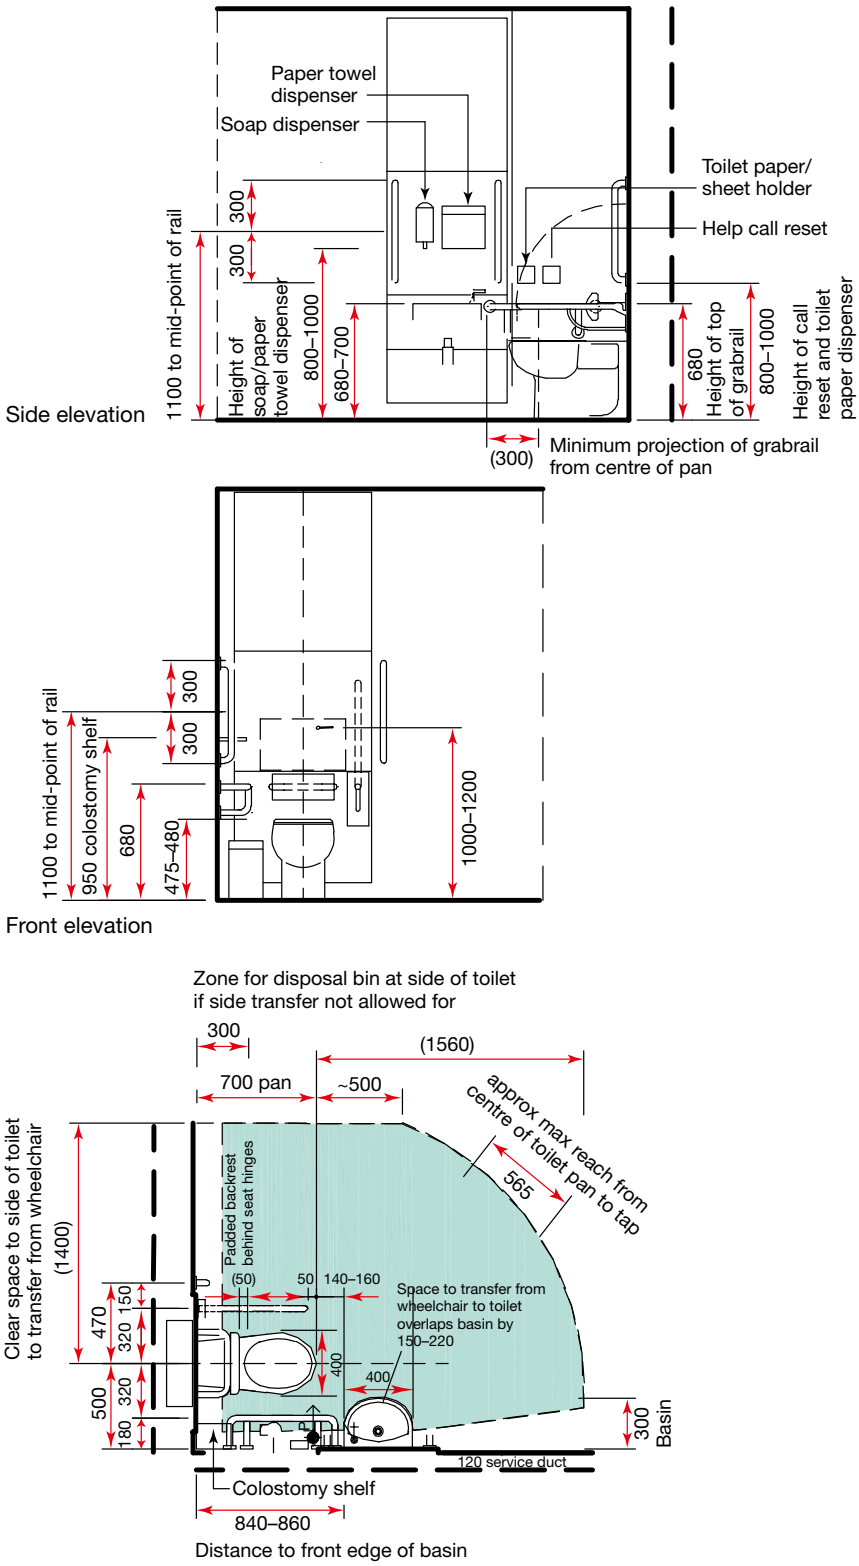

Figure 91 Space requirements for independent wheelchair toilet and adjacent hand-rinse basin

Toilet and adjacent hand-rinse basin: independent wheelchair: grabrail options

5.68 These ergonomic drawings (see Figure 92) show the fixing position of grabrails for an independent wheelchair toilet and adjacent hand-rinse basin.

5.69 Grabrails should be provided symmetrically on either side of the toilet at 320 mm from the centreline of the toilet pan. This conflicts with the recommendations in Approved Document M and BS 8300.

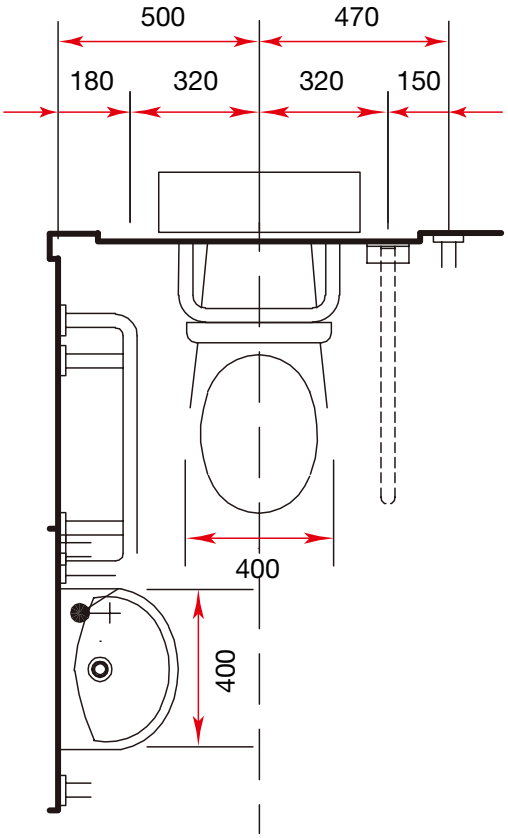
5.70 Approved Document M (paragraph 5.10j) states: "where the horizontal support rail on the wall adjacent to the toilet is set with the minimum spacing from the wall, an additional dropdown rail should be provided on the wall side at a distance of 320 mm from the centreline of the toilet."

Note

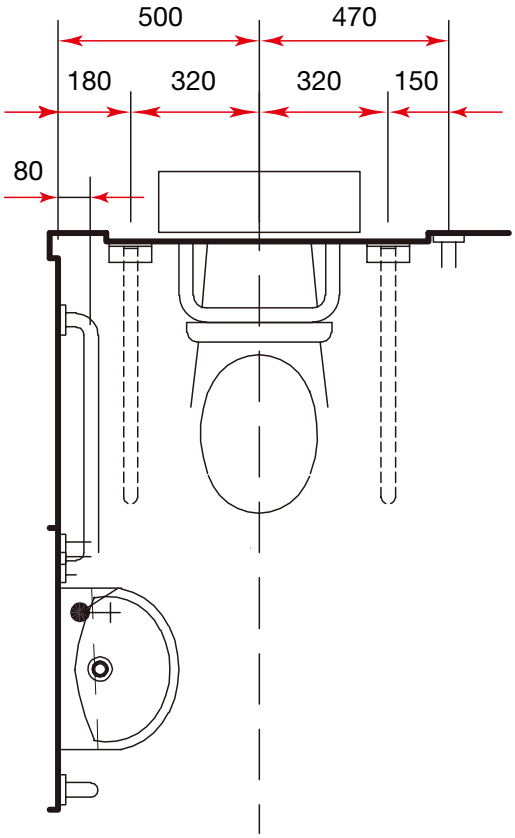
Where the maximum spacing defined in Approved Document M, 85 mm, is used, this positions the grabrail approximately 390 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

5.71 BS 8300 (paragraph 12.6.3.5 b) states: "A fixed horizontal rail should be located on the side wall with a 50 mm to 60 mm clearance between the rail and the wall." This places the rail approximately 420 mm from the centreline of the toilet, which is not symmetrical with the hinged grabrail on the other side.

5.72 The ergonomic drawings provided illustrate two options for the provision of grabrails. The room layouts on this website are based on option one.



Fixed grabrail between toilet and wall



Alternative fixed and hinged grabrail between toilet and wall

Figure 92 Space requirements showing fixing position of grabrails for independent wheelchair toilet and adjacent hand-rinse basin

Full-length mirror: standing or seated users

5.73 This ergonomic drawing (see Figure 93) shows the space requirements for a full-length mirror for standing or seated users.

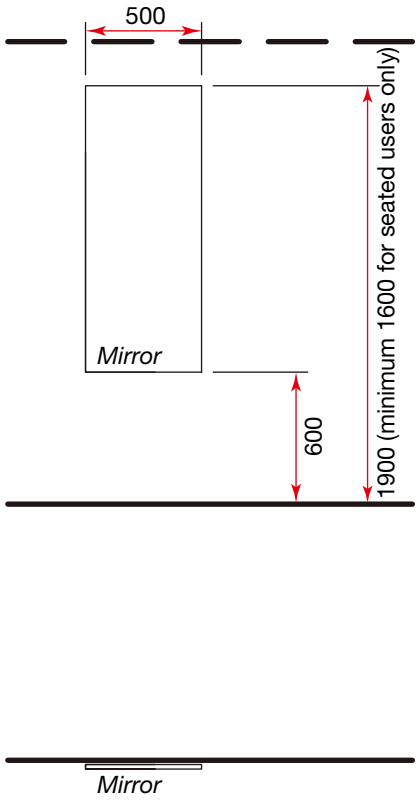


Figure 93 Space requirements for full-length mirror for standing or seated users

WC: 'Changing Places'[1]

Room description and layout

5.74 The following activities take place in a 'Changing Places' toilet:

- wheelchair access to the changing table, toilet and hand-rinse basin;
- transfer from a wheelchair to the toilet or changing table;
- use of the toilet;
- use of a hoist;
- changing older children/adults with continence problems;
- disposal of soiled nappies/continence pads;
- hand rinsing;
- personal washing.

5.75 'Changing Places' toilets provide the right equipment, including a changing bench and hoist, to support disabled people who cannot use standard accessible toilets. The range of people who might use a 'Changing Places' toilet includes:

- people with profound and multiple learning disabilities;
- people with conditions that may affect their movement, including cerebral palsy, multiple sclerosis, motor neurone disease;
- people with head injuries or severe spinal injuries;
- people living with stroke;
- older people who require assistance.

5.76 Where provided, they should be in public areas for ease of access to everyone who needs to use them.

5.77 Comprehensive guidance on the design and equipment which should be provided in these toilets together with advice on health and safety and day-to-day operational management is available in:

- 'Changing Places: the practical guide', published by the Changes Places Consortium and available as a download from http://changing-places.org/; and
- BS 8300:2009, Design of buildings and their approaches to meet the needs of disabled people – Code of practice.

[1] The Changing Places Consortium launched its campaign in 2006 on behalf of people who cannot use standard accessible toilets. To use the toilet in safety and comfort, many people need to be able to access a 'Changing Places' toilet. See http://www.changing-places.org/ for details.

1. Sterilization and the role of management

Introduction

"The fundamental cause of this disaster is to be found in human failings ranging from simple carelessness to poor management of men and plant. The Committee heard of no imminent technological advance in the field of production of intravenous fluids which will eliminate the need for skilful men devoted to their work ... Too many people believe that sterilization of fluids is easily achieved with simple plant operated by men of little skill under a minimum of supervision ... Public safety in this, as in many other technological fields, depends ultimately on untiring vigilance ... "

1.1 The quotation above comes from the principal conclusions of the committee chaired by Sir Cecil Clothier and appointed to investigate an incident in which five patients died as a result of a faulty sterilizer. The tragedy led to a thorough overhaul of the methods of managing sterilizers, among which was the revision of Health Technical Memorandum 2010 (then HTM 10), the last edition of which was published in 1980.

1.2 No disaster on a comparable scale has been reported since. Nonetheless, both the law and public opinion are now less forgiving of lapses than they were two decades ago. Tighter statutory control, resulting from new European Union (EU) Directives, will soon extend to almost every aspect of sterilization, and practices which were common a few years ago will no longer be acceptable or even lawful.

1.3 The science and art of sterilization are complex and subtle. The testing, maintenance and reporting procedures described in this SHTM may seem excessive to some, but they are based upon good practice in both the UK and Europe, as formalised in European Standards designed to support the new EU Directives.

The European Union Directives on medical devices

1.4 Until now, statutory controls on the practice of sterilization, other than in the manufacture of medical products, have been few. The major Acts and Regulations which are likely to affect the management of a sterilizer are described in Chapter 3, but specific references to sterilization in the legislation were rare. This has changed as a series of three EU Directives came into effect regulating the safety, quality and effectiveness of medical devices.

1.5 This section summarises basic information about the Directives. Further details are available from the Medical Devices Agency of the Department of Health, England, which has a UK remit.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Definition of medical device

1.6 The Directives define a medical device as any instrument, apparatus, appliance, material or other article, whether used alone or in combination, including the software necessary for its proper application intended by the manufacturer to be used on human beings for the purpose of:

a. diagnosis, prevention, monitoring, treatment or alleviation of disease;

b. diagnosis, monitoring, treatment, alleviation or compensation of an injury or handicap;

c. investigation, replacement or modification of the anatomy or of a physiological process;

d. control of conception;

and which does not achieve its principal intended action in or on the human body by pharmacological, immunological or metabolic means, but which may be assisted in its function by such means (Council Directive 93/42/EEC).

1.7 The Directives apply equally to “accessories”. An accessory is defined as “an article which, whilst not being a device, is intended specifically by its manufacturers to be used together with a device to enable it to be used in accordance with the use of the device intended by the manufacturer of the device”.

The three Directives

1.8 The three EU directives are as follows:

a. the Active Implantable Medical Devices Directive (Council Directive 90/385/EEC) covers all powered implants or partial implants that are left in the human body. (Heart pacemakers are the most common example of powered implants.) The directive was adopted by the EU council on 20 June 1990 and came into effect in the UK on 1 January 1993 as the Active Implantable Devices Regulations 1992 (see paragraph 3.32);

b. the Medical Devices Directive (Council Directive 93/42/EEC) covers most other medical devices ranging from first aid bandages and tongue depressors through to hip prostheses and will therefore have a wide impact on sterilization. The directive was adopted by the EU council on 14 June 1993. It came into effect on 1 January 1995;

c. the In Vitro Diagnostic Medical Devices Regulations 2000 (SI 1315) implements the council directive 98/79/EC and covers any medical device, reagent product, kit, instrument, apparatus or system which is intended to be used in vitro for the examination of substances derived from the human body. Some examples of in-vitro diagnostic devices are blood group reagents, pregnancy test kits, and hepatitis B test kits.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

The regulatory framework

1.9 The Directives set out the essential requirements that devices must not compromise the health or safety of the patient, user or any other person and that any risks associated with the device are compatible with patient health and protection. Any side-effects must be acceptable when weighed against the intended performance.

1.10 Devices meeting these requirements will be entitled to carry the “CE” marking, signifying that the device satisfies the requirements essential for it to be fit for its intended purpose. All devices except custom-made devices and devices intended for clinical trials, (“investigations” in the directive), whether used in public-sector or private-sector hospitals and nursing homes, or sold in retail outlets, will have to carry the “CE” marking.

1.11 Adoption of the Directives has meant that the UK’s voluntary system of manufacturer registration and product approval for controlling certain medical devices used by the NHS has been replaced by a more comprehensive statutory system covering all devices used in the UK. The Medical Devices Agency (MDA) of the Department of Health, is the competent authority to carry out the requirements of the Directives in the UK. The main role of the MDA is to ensure compliance with the UK regulations, evaluate vigilance reports received from manufacturers, and carry out a preclinical assessment of devices intended for clinical investigation. The MDA is also responsible for approving the independent certification organisations (the notified bodies) that will check and prove that defined classes of medical devices meet the essential requirements and thus enable manufacturers to apply the “CE” marking to their products.

1.12 The Medical Devices Directive includes a classification system whereby the level of regulatory control applied to devices is proportional to the degree of risk inherent in the device. The strictest controls will therefore only apply to the limited number of high-risk products.

Impact on sterilization

1.13 Managers who ensure that their machines and procedures comply with the guidance in this SHTM should have no difficulty in complying with the Medical Devices Directive.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Summary of management responsibilities

1.14 SHTM 2010 will assist managers and other personnel to ensure that sterilizers are operated safely and effectively and in compliance with existing and anticipated legislation and standards. To this end, the major responsibilities of management can be summarised as follows:

a. to ensure that sterilization is carried out in compliance with the law and policy of the Scottish Executive Health Department;

b. to ensure that all personnel connected with sterilization, whether NHS employees or contract personnel, are suitably qualified and trained for their responsibilities;

c. to ensure that purchased sterilizers conform to legal requirements, the minimum specifications set out in British and European standards, and any additional requirements of the Scottish Executive Health Department

d. to ensure that sterilizers are installed correctly and safely with regard to proper functioning, safety of personnel and environmental protection;

e. to ensure that newly installed sterilizers are subject to a documented scheme of validation comprising installation checks and tests, commissioning tests and performance qualification tests before they are put into service;

f. to ensure that sterilizers are subject to a documented scheme of periodic tests at yearly, quarterly, weekly and (in some cases) daily intervals;

g. to ensure that sterilizers are subject to a documented scheme of preventative maintenance;

h. to ensure that procedures for production, quality control and safe working are documented and adhered to in the light of statutory requirements and accepted best practice;

i. to ensure that procedures for dealing with malfunctions, accidents and dangerous occurrences are documented and adhered to.

NHSScotland Property and Environmental Forum

2. Sterilizers – an overview

Introduction

2.1 This Scottish Health Technical Memorandum groups sterilizers into two broad categories according to their use:

a. **clinical sterilizers** are designed to process medical devices, medicinal products and other goods and materials that are used in the clinical care of patients;

b. **laboratory sterilizers** are designed to process goods and materials and are not directly used in the clinical care of patients.

2.2 Their operation should be kept strictly separate. Loads intended for processing in a clinical sterilizer should not be put into a laboratory sterilizer, and vice-versa.

2.3 Sterilizers can also be classified according to the sterilizing agent (the sterilant) used:

a. high-temperature steam;

b. low-temperature steam and formaldehyde;

c. ethylene oxide.

2.4 High-temperature steam is the sterilant of choice because of its superior performance. Machines using other sterilants should be reserved either for loads which would be damaged by exposure to high-temperature steam (such as certain surgical devices) or for loads that would not be sterilized by exposure to high-temperature steam (such as certain non-aqueous fluids).

2.5 Clinical sterilizers are available employing any one of the four sterilants. The laboratory sterilizers described in this SHTM use only high-temperature steam.

2.6 Guidance on selection and specification, operational management, validation and verification is given in the other parts of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Clinical sterilizers using high-temperature steam

2.7 These are by far the most common sterilizers used in the NHS, and are manufactured in three basic types according to the nature of load they are designed to process: porous loads, fluids, or unwrapped instruments and utensils. The operating cycles are designed to cope with the differing properties of the various types of load. It is essential that a sterilizer is used only for the type of load for which it is designed.

2.8 High-temperature steam inactivates pathogens by a combination of moisture and heat. The process is well understood and the attainment of sterilization conditions can normally be confirmed by simple physical measurements. (This is not so for sterilizers using chemical sterilants, where microbiological test procedures are necessary.)

2.9 High-temperature steam sterilizers are large machines requiring permanently installed engineering services (including good-quality steam) and purpose-built accommodation. Some smaller models are transportable and generate steam from an internal reservoir.

Porous loads

2.10 Clinical sterilizers using high-temperature steam to process porous loads are commonly known as “porous load sterilizers”. They are intended to deal with porous items such as towels, gowns and dressings; and medical and surgical equipment, instruments and utensils packaged or wrapped in porous materials such as paper or fabrics.

2.11 Sterilization is achieved by direct contact of the load items with good-quality saturated steam at a preferred sterilization temperature of 134°C.

2.12 As porous loads trap both air and moisture, an efficient and reliable air removal system is essential. An air detector is fitted to ensure that the operating cycle does not proceed until sufficient air and other non-condensable gases have been removed from the chamber and load. The correct functioning of the air detector is crucial to the performance of the sterilizer.

Fluids

2.13 Clinical sterilizers using high-temperature steam to process aqueous fluids are commonly known as “fluids sterilizers”. They are used to sterilize fluids in sealed containers (normally bottles) of either glass or plastic. They operated at a preferred sterilization temperature of 121°C.

2.14 Fluids in glass containers can be hazardous. At a temperature of 121°C the pressure inside a one-litre bottle having a normal fill of fluid is approximately 4 bar. If the door were to be opened at this temperature, and the load

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

exposed to ambient air, the thermal stresses arising in the glass would be sufficient to crack the bottle and cause an explosion. A temperature of 80°C is regarded as a safe maximum at which the door can be opened (even at this temperature the pressure inside a one-litre bottle is still 1.8 bar). Fluid sterilizers are fitted with a thermal door-lock to ensure that when glass containers are being processed the door cannot be opened until the temperature inside all the containers has fallen below 80°C. Failure to observe this requirement has led to serious accidents resulting from the explosion of glass containers.

2.15 Fluids in plastic containers present less of a hazard. Operating cycles for plastic containers allow the door to be opened when the temperature inside the containers falls below 90°C.

Unwrapped instruments and utensils

2.16 This type of sterilizer is used to process unwrapped surgical components intended for immediate use. Sterilization is achieved by the direct contact of the component with saturated steam at a preferred sterilization temperature of 134°C.

2.17 These sterilizers should not be used to process wrapped instruments and utensils, where the wrapping could inhibit the removal of air and the penetration of steam. Neither should they be used for unwrapped instruments and utensils with narrow lumens, where air removal and steam penetration would similarly be impaired.

2.18 Since the sterilized instruments and utensils are exposed to the air on being removed from the chamber, they are susceptible to immediate recontamination. These sterilizers are therefore suitable for clinical use only within the immediate environment in which the instruments are to be used. Wherever possible, instruments and utensils should be wrapped and processed in a porous load sterilizer.

2.19 Transportable (bench-top) models are electrically heated, requiring only a 13 Amp socket-outlet and no piped services. They are commonly used in theatre suites where there is no central supply service and in primary healthcare units such as general practitioners' and dentists' surgeries.

Clinical sterilizers using hot air

2.20 Clinical sterilizers using hot air as a sterilant are correctly known as "dry-heat sterilizers", and sometimes as "hot-air sterilizers" or "sterilizing ovens". They are intended to process materials such as oils, powders and some ophthalmic instruments, which can withstand high temperatures but are likely to be damaged or not sterilized by contact with steam. They operate at a preferred sterilization temperature of 160°C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

2.21 They are not suitable for use as drying cabinets (see BS 2648 for specifications for drying cabinets).

2.22 Dry-heat sterilizers are essentially electric ovens and are therefore simpler than the other pressure sterilizers described in this SHTM. A filter and fan are used to maintain the chamber slightly above atmospheric pressure to ensure that the sterility of the product and the integrity of the clean-room environment are not compromised. Although the cycle is under automatic control, the operator is allowed considerable freedom in selecting the required combination of sterilization temperature and time. Recommended combinations are shown in Table 2.1 and advice on their selection is given in Part 4 of this SHTM.

2.23 Dry-heat sterilizers are not efficient. It is difficult to obtain an even temperature distribution within the chamber, air circulation is inhibited when the chamber is full (even with a circulating fan), and heat transfer from the air to the load can be very slow. A complete cycle, including cooling to 80°C, takes approximately eight hours for a full test load as described in Part 3 of this SHTM. If this time is unacceptable, a sterilizer fitted with assisted cooling is recommended, reducing the cycle time for the same load to approximately five hours.

Clinical sterilizers using low-temperature steam and formaldehyde

2.24 Heat-sensitive materials (wrapped or unwrapped) which will withstand saturated steam at temperatures up to 80°C are normally processed in either low-temperature steam disinfectors (“LTS disinfectors”) or low-temperature steam and formaldehyde sterilizers (“LTSF sterilizers”). Sterilizers designed for LTSF will normally incorporate an LTS disinfection cycle.

2.25 Disinfection is achieved by the direct contact of the load with saturated steam at a minimum temperature of 71°C at sub-atmospheric pressure. Sterilization is achieved by contact with both saturated steam and formaldehyde gas. Either process may also be used to decontaminate soiled surgical components before they are washed and reprocessed.

2.26 Formaldehyde is a toxic gas. Part 5 of this SHTM contains safety information.

2.27 Since the sterilization process is ultimately dependent on chemical action, microbiological test methods are required to confirm that sterilization conditions have been attained.

NOTE: Despite their name, LTSF sterilizers are disinfectors.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Clinical sterilizers using ethylene oxide

2.28 Clinical sterilizers using ethylene oxide gas as a sterilant are commonly known as “ethylene oxide sterilizers” or “EO sterilizers”.

2.29 EO sterilizers are used to process heat-sensitive materials and devices which cannot withstand low-temperature steam. They should not be used to process items which can be sterilized by alternative methods, that is, by high-temperature steam, dry heat or LTSF. They should not be used to re-sterilize items which have been sterilized by irradiation.

2.30 EO sterilizers are used extensively in industrial manufacture of sterile medical devices but are relatively uncommon in hospitals. Two classes of EO sterilizers are suitable for NHS use:

a. small sterilizers, of chamber volumes around 150 litres, where the sterilant is pure EO at sub-atmospheric pressure supplied from a disposable cartridge contained within the chamber;

b. large sterilizers, of chamber volume up to 500 litres, where the sterilant is either pure EO or EO diluted with another gas, supplied from cylinders. EO sterilizers have the potential to cause serious environmental pollution. Sterilizers using chlorofluorocarbon (CFC) gases as diluents should no longer be installed.

2.31 EO is a highly reactive liquid and gas which is toxic, flammable and explosive. The safe operation of EO sterilizers requires careful consideration of all aspects of the installation and operation of equipment.

2.32 The entire EO process is complex and requires specialised facilities for washing, packaging and preconditioning loads before processing and degassing before use. Large sterilizers will also require additional plant to dispose safely of exhaust products.

2.33 The efficacy of the process is affected by the packaging used to wrap goods for sterilization. Since the sterilization process is ultimately dependent upon chemical action, microbiological test methods are required to confirm that sterilization conditions have been attained.

2.34 Managers considering installing EO sterilizers should be aware of the following points:

a. the difficulty in validating and monitoring suitable cleaning processes for loads before they are sterilized;

b. the difficulty in carrying out representative performance qualification tests for the wide variety of loading conditions that may be used;

c. the difficulty in carrying out meaningful bioburden studies on small numbers of widely differing devices to be sterilized;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

d. the problems associated with determining the levels of residual EO and its reaction products when small numbers of widely differing devices are processed.

Laboratory sterilizers/autoclaves

2.35 Laboratory sterilizers, also known as autoclaves, are used for making-safe discard material and processing apparatus and materials to be used within clinical laboratories. They are not intended for the sterilization of medical devices or medicinal products intended for the clinical care of patients.

2.36 Unlike clinical sterilizers, the laboratory sterilizers covered in this SHTM are designed for use only with high-temperature steam. No chemical sterilants are used.

2.37 Certain common laboratory operations may be carried out more economically with specialised machines designed for the purpose, and these are described below.

Operating cycles

2.38 Laboratory sterilizers are often required to process a wide range of materials and objects, and they are equipped with one or more operating cycles each designed for a particular application. Different types of load generally require different operating cycles. Cycles are normally preset, and proceed automatically once selected and started.

2.39 The range of cycles that a sterilizer can provide will depend on details of its construction. For example, the methods used to remove air from the chamber, the means employed to cool and dry the load, and the provision of safety features.

2.40 Laboratory sterilizers may be equipped with one or more of the following operating cycles:

a. make-safe of small plastic discard;
b. make-safe of contained fluid discard;
c. sterilization of culture media;
d. disinfection of fabrics;
e. sterilization of glassware and equipment;
f. free steaming.

2.41 Guidance on the specification of operating cycles is given in Part 2 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Culture media preparator

2.42 Many of the problems which relate to sterilizing culture media can be solved by the use of small sterilizers in which the media constituents are placed directly into the chamber, thus avoiding the use of glass containers and their attendant hazards.

2.43 The machine consists of two or three modules incorporated into a system designed to provide controlled preparation, sterilization, cooling and dispensing of culture media with a minimum of attention by the operator. The system may also include a module which automatically stacks the completed culture plates.

2.44 The sterilizer module is essentially a pressure-cooker in which water and dehydrated culture media are mixed, sterilized and then cooled to below 80°C. This type of sterilizer is particularly suitable for manufacturing batches of culture media in volumes between 1 and 20 litres.

Köch steamer

2.45 A Köch steamer is designed to expose a load to steam at near-atmospheric pressure and is commonly used for melting solidified agar. Steamers are not sterilizers and the product cannot be regarded as sterile. No further information specific to Köch steamers is given in this SHTM.

Animal house sterilizer

2.46 The very wide range of materials and implements used in the care of laboratory animals is often catered for by specialised sterilizers with capacities as high as 10 m^3, which run several operating cycles. Examples of loads include bedding for discard, fresh bedding, feed bottles, food and water, cages, and tools and implements for use by personnel in the animal house. In view of the specialised nature of these machines, no further information specific to animal house sterilizers is given in this SHTM. Users are advised to adapt the guidance on laboratory sterilizers to their circumstances in consultation with the authorised person.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Table 2.1 Sterilization temperature bands

	High-temperature steam				Dry heat			LTS	LTSF	Ethylene oxide
Sterilization temperature (°C)[a]	115	121	126	134	160	170	180	71[b]	71	30-56
Maximum allowable temperature (°C)	118	124	129	137[c]	170	180	190	80	80	[d]
Minimum holding time (min)	30	15	10	3	120	60	30	10	180[e]	[f]

Notes:

a. The temperature setting on the automatic controller will not generally be the sterilization temperature, but a higher temperature within the sterilization temperature band.

b. Disinfection temperature.

c. British Standards permit 138°C.

d. For EO, the maximum allowable temperature will normally be 4°C above the sterilization temperature.

e. For LTSF, the sterilization conditions may specify either a continuous holding time or the number of pulses for formaldehyde required to achieve sterilization.

f. For EO, the “gas exposure time” is determined for each sterilizer by microbiological methods during commissioning but is typically 2-7 hours depending upon sterilization temperature and gas concentration.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

3. Statutory requirements

Introduction

3.1 So far as sterilization is concerned, the chief areas of legislation with which managers should be familiar are health and safety, medicinal products and consumer protection.

Health and safety

3.2 The largest body of law with which managers need to be familiar concerns health and safety, in particular the Health and Safety at Work etc Act 1974 (the HSW Act) and its various regulations.

3.3 The HSW Act and its regulations require employers to assess the risk to their employees. Attention is drawn to the following hazards which are implicit in the practice of sterilization:

a. the hazard of scalding from escaping steam;

b. the high temperatures (up to 200°C) at which sterilizers are operated;

c. the stored energy hazards associated with the operation of pressure vessels contained within all steam and some EO sterilizers;

d. the stored energy hazards associated with the pressurised containers in which EO gas is transported;

e. the explosive hazards associated with the sterilization of fluids in sealed glass bottles;

f. the toxic properties of formaldehyde gas used in low-temperature steam and formaldehyde (LTSF) sterilizers;

g. the toxic and explosive properties of ethylene oxide gas used in ethylene oxide (EO) sterilizers;

h. the infection hazard associated with the microbial pathogens that may be handled by personnel using certain laboratory sterilizers;

i. the hazard of infection to patients and staff by the inadvertent release of an unsterile load due to the failure of a sterilization and quality control process;

j. the hazards associated with the handling of heavy and hot loads while loading and unloading sterilizers.

3.4 The guidance given throughout this SHTM is designed to ensure that these hazards are minimised and that sterilization procedures comply with the relevant legislation and established good practice.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

Health and Safety at Work etc Act 1974

3.5 The HSW Act sets out the basic legal responsibilities of employers and employees with regard to health and safety at work.

Management of Health and Safety at Work Regulations 1999

3.6 The Management of Health and Safety at Work Regulations 1999 (SI 3242) expand upon the principles of the HSW Act.

3.7 The core of the regulations is a requirement of employers to make a systematic assessment of the risks to health and safety of their employees and others, arising from work activities.

Workplace (Health, Safety and Welfare) Regulations 1992

3.8 The Workplace (Health, Safety and Welfare) Regulations 1992 (SI 1992/3004) aim to ensure that workplaces meet the health, safety and welfare needs of each member of the workforce, including people with disabilities.

3.9 Most of the regulations deal with the physical requirements of the workplace. Managers concerned with the operation of sterilizers should pay particular attention to the regulations and maintenance, ventilation, temperature, lighting, cleanliness, room dimensions and space, floors, doors and traffic routes.

Provision and Use of Work Equipment Regulations 1998

3.10 The Provision and Use of Work Equipment Regulations 1998 (PUWER) aim to ensure the provision of safe work equipment and its safe use.

3.11 PUWER 98 replaces the existing Provision and Use of Work Equipment Regulations 1992 and applies to all equipment (including lifting equipment) used at work in the health care sector. PUWER 92's requirements are carried forward in full but there are important new additions, including a requirement to inspect work equipment where significant risk could result from incorrect installation or relocation; deterioration; or as a result of exceptional circumstances; and to record the results those inspections (Regulation 6).

Pressure Systems Safety Regulations 2000

3.12 The regulations on pressure systems apply to all steam sterilizers, to EO sterilizers operating above 0.5 bar, and to the steam and compressed air services. They replace the Pressure Systems and Transportable Gas Containers Regulations 1989, which had earlier replaced the sections of the Factories Act 1961 that were relevant to steam sterilizers. Transportable gas containers were also removed from the scope of the 1989 Regulations and are now covered by the Carriage of Dangerous Goods (Classification,

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Packaging and Labelling) and Use of Transportable Pressure Receptacles Regulations 1996. This would apply to cartridges and cylinders used to supply sterilant or purging gas to EO sterilizers.

3.13 The regulations also define the duties of the competent person: a competent individual person (other than an employee) or a competent body of persons corporate or unincorporate.

Control of Substances Hazardous to Health Regulations 1999

3.14 Schedule 1 of the Control of Substances Hazardous to Health (COSHH) Regulations lists ethylene oxide and formaldehyde as two substances hazardous to health which are subject to a maximum exposure limit for inhalation. These limits are reviewed annually and updated by amendments to the regulations. The current limits (1999) are given in Table 3.1. These limits must not be regarded as safe work exposures.

3.15 The Health and Safety Executive (HSE) publishes an annually updated guidance note on current exposure limits, *Occupational exposure limits (EH 40)*.

3.16 Users of laboratory sterilizers should note that a “substance hazardous to health” may include a micro-organism which creates a hazard to the health of any person. Guidance on the precautions to be taken when handling micro-organisms may be found in the Health and Safety Committee (HSC) documents, *Categorisation of pathogens according to hazard and categories of containment*, (second edition 1990) complied by the Advisory Committee on Dangerous Pathogens, and *Safe working and the prevention of infection in clinical laboratories*, compiled by the Health Services Advisory Committee.

Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1995

3.17 Commonly known as RIDDOR, these regulations impose duties on persons responsible for the activities of persons at work, and on self-employed persons, to report accidents resulting in death or major injury arising out of or in connection with work, and to report specified dangerous occurrences. They also require certain particulars of accidents at work to be reported both to the Department of Health and also to the Health and Safety Executive, and require records to be kept.

3.18 Steam and certain EO sterilizers contain pressure vessels as defined under Part 1 of Schedule 1.

3.19 Poisoning by ethylene oxide is a reportable disease listed under Schedule 2.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Manual Handling Operations Regulations 1992

3.20 The regulations require employers to make an ergonomic assessment of all manual handling operations which involve a risk injury, and to reduce the risk as far as is reasonably practicable. Factors to be assessed include the nature of the task, the load, the working environment and individual capability.

3.21 Managers should assess the risks associated with loading and unloading sterilizers, whether by loading trolleys or by hand. Top-loading sterilizers can be especially hazardous if lifting equipment is not available. The mass of the load is not the only source of risk; the temperature and other factors should be taken into account. Risks associated with maintenance and overhauling should also be assessed. Reference should also be made to the Lifting Operations and Lifting Equipment Regulations 1998 (LOLER).

Personal Protective Equipment at Work Regulations 1992

3.22 Managers should assess whether the risks associated with sterilization require the use of personal protective equipment (PPE). Some examples include heat-resistant gloves for use when hot loads are removed from sterilizers, protective gloves for use when handling discard material in laboratories, eye or face protection when testing sterilizers containing fluids in glass bottles, and foot protection of operators loading and unloading sterilizers.

Medicinal products

Medicines Act 1968

3.23 Where a sterilizer is to be used to sterilize medicinal products, the licensing provisions of the Medicines Act 1968 apply. Further information may be found in, *Guidance to the NHS on the licensing requirements of the Medicines Act 1968*, published by the Medicines Control Agency.

Medicines (Standard Provisions of Licences and Certificates) Amendment (No 3) Regulations 1977

3.24 The Medicines (Standard Provisions of Licences and Certificates) Amendments (No 3) Regulations 1977 introduced a qualified person who, in certain circumstances, has statutory responsibility for quality control in the manufacture of medicinal products (see Chapter 5). This will include decisions on release of a sterilized product.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Medicines (Standard Provision of Licences and Certificates) Amendment Regulations 1992

3.25 The Medicines (Standard Provisions of Licences and Certificates) Amendment Regulations 1992 (SI 1992/2846) give statutory force to the commission document, *The rules governing medicinal products in the European Community Volume IV: Guide to good manufacturing practice for medicinal products*. All provisions in the guide came into force on or before 1 January 1993. The annex on sterilization contains requirements that are implemented by the guidance in this SHTM.

Consumer protection

3.26 In recent years, new legislation has been introduced affording protection to persons who may be harmed by unsafe goods supplied to them. In certain circumstances this may include products from sterilizers.

Consumer Protection Act 1987

3.27 Part 1 implements EU Council Directive 85/374/EEC (the Product Liability Directive) providing for compensation to be paid to persons injured by a defective product. Under the Act a product is defective "if the safety of the product is not such as persons generally are entitled to expect", taking the circumstances into account. It is likely that civil action for damages could be taken against a hospital for supplying, for example, "sterile" products that were not in fact sterile and caused the infection of a patient.

3.28 Part 2 introduces a "general safety requirement" on the suppliers of "consumer goods" only. It is a criminal offence to supply unsafe consumer goods, whether or not actual harm has been caused. Consumer goods are defined as "any goods which are ordinarily intended for private use or consumption", and are regarded as unsafe when "they are not reasonably safe having regard to all the circumstances". It is not clear whether products from hospital sterilizers are to be regarded as consumer goods. (Controlled drugs and licensed medicinal products are exempt from Part 2 since they are governed by other legislation.)

Electromagnetic Compatibility Regulations 1992

3.29 The Electromagnetic Compatibility Regulations (SI 2372) (the EMC Regulations), impose requirements concerning the electromagnetic compatibility of most types of electrical and electronic apparatus which must be complied with, before such apparatus is to be supplied or taken into service.

3.30 A sterilizer (and any ancillary equipment) is a "relevant apparatus" within the terms of the regulations, and will have to meet standards of emission of an immunity to electromagnetic disturbance. Note that it is an offence not only

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

to supply but also to “take into service” a sterilizer that does not conform to the regulations.

3.31 The regulations do not apply to any sterilizer supplied to be taken into service in the EU before 28 October 1992. A sterilizer supplied or taken into service in the UK on or before 31 December 1995 is not required to comply with the regulations provided it complies with the requirements of the Wireless Telegraphy Acts listed in Schedule 1 of the regulations.

NOTE: Detailed guidance on the application of the EMC regulations in healthcare premises may be found in SHTM 2014; *Abatement of electrical interference*.

Active Implantable Medical Devices Regulations 1992

3.32 The Active Implantable Medical Devices Regulations 1992 (SI 3146) set out the essential requirements which active implantable medical devices (such as heart pacemakers) must satisfy before they can be placed on the market or put into service.

3.33 Schedule 2, paragraph 7 requires such devices to be designed, manufactured and packed in a non-reusable packaging according to procedures which are sufficient to ensure that:

a. the device is sterile when placed on the market; and

b. if handled in accordance with conditions as to storage and transport laid down by the manufacturer, the device remains sterile until the packaging is removed and the device is implanted.

3.34 Schedule 2, paragraph 14 sets out requirements for the labelling of sterile packs.

Table 3.1 Maximum exposure limits at atmospheric formaldehyde and ethylene oxide

Gas	Short-term exposure limits		Long-term exposure limits	
	[ppm]	[mg m^{-3}]	[ppm]	[mg m^{-3}]
Formaldehyde	2	2.5	2	2.5
Ethylene oxide	–	–	5	9.2

Notes:

The short-term exposure limit (STEL) is the average exposure over any 15-minute period.

The long-term exposure limit (STEL) is the exposure over any 24-hour period expressed as a single uniform exposure over an 8-hour period.

COSHH does not specify a STEL for EO. In such cases the STEL is deemed to be three times the LTEL in accordance with the recommendations of the Health and Safety Executive.

4. British and European standards

Introduction

4.1 Industry standards for sterilization have developed rapidly since the publication of HTM 10 in 1980. British standards which existed at that time have been thoroughly revised and extended. European standards now cover not only design, construction, performance and safety, but also validation, routine testing and operation.

4.2 British and European standards, supplemented by specific requirements for the NHS, form the basis of the guidance given in the 'Design considerations' part of this SHTM.

4.3 The main standards for sterilizers are BS 3970 for clinical sterilizers and BS 2646 for laboratory sterilizers.

European standards

4.4 European standards on sterilization are generally more extensive than British standards in specifying not only design, construction, performance and safety requirements of sterilizers, but also that persons responsible for sterilization operate a quality system and that part of that system is validation and routine testing of the process.

4.5 While the guidance given here is designed to conform broadly with European standards, SHTM 2010 must not be regarded as a substitute for the standards themselves.

5. Personnel

Introduction

5.1 This chapter introduces the personnel who may share the responsibility for the safe and efficient operation of sterilizers. It gives guidance on qualifications and training and summarises areas of responsibility.

Training

5.2 It is essential that personnel at all levels have a sound general knowledge of the principles, design and functions of sterilizers. They should be trained on those types and models of sterilizers with which they are concerned. They should have some knowledge of the basic elements of microbiology in order to ensure personal safety, safety of others and general safety. Training given to individuals should be recorded and reviewed regularly.

5.3 Accredited courses on sterilization, suitable for personnel at all levels, are run by various training providers. Further information is available from the NHS in Scotland Property and Environment Forum Executive and the authorised persons (sterilizers).

5.4 Detailed training on particular models of sterilizer is usually available from the manufacturer, either on-site (such as during validation) or by courses at their premises.

Functional responsibility

5.5 There have been profound changes in the management philosophy of the NHS over recent years, and there is a trend towards deregulation and contracting-out of services. It is not possible to prescribe a management structure for sterilization that is universally applicable given the wide range of circumstances in which a sterilizer may be employed, from a busy sterile services department in a major general hospital to a small rural dental practice.

5.6 The approach chosen for this SHTM is to identify the distinct functions that need to be exercised and the responsibilities that go with them. The titles given are therefore generic; they describe the individual's role in connection with sterilization, but are not intended to be prescriptive job titles for terms of employment, indeed, many of the personnel referred to may not be resident staff but employed by outside bodies and working on contract. Some of them will have other responsibilities unconnected with sterilization and in some cases the same individual may take on more than one role.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environmental Forum

5.7 In every case, however, it is possible to identify a **user** who is responsible for the day-to-day management of the sterilizer. The philosophy of this SHTM is to invest the user with the responsibility for seeing that the sterilizer is operated safely and efficiently.

5.8 The law requires that a **competent person (pressure vessels)** who is not the **user** is designated to exercise certain responsibilities of inspection for all steam sterilizers and other sterilizers containing pressure vessels.

5.9 For small installations where the user is qualified to perform all required test and maintenance functions, no other personnel may be necessary. This may be satisfactory for small sterilizers run by dentists or general practitioners. However, it is strongly recommended that in all cases the user receive professional advice from an **authorised person (sterilizers)**, and that testing and maintenance be carried out by a suitably qualified **test person (sterilizers)** and a **maintenance person (sterilizers)** with assistance from a **microbiologist (sterilizers)** where microbiological testing is required.

5.10 Where the sterilizer is used to manufacture medicinal products, the functions of the user are exercised by a **production manager** and a **quality controller**.

Key personnel

5.11 For the purposes of SHTM 2010, the following are the key roles in the management of sterilization.

Management

5.12 Management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the sole operation of its premises.

User

5.13 The user is defined as the person designated by management to be responsible for the sterilizer.

5.14 In a hospital, the user could be a sterile services department manager, laboratory manager or theatre manager; in primary care he or she could be a general practitioner, dentist, or other health professional. Where a sterilizer is used to process medicinal products, the user is normally the production manager in charge of the entire manufacturing process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

5.15 The principal responsibilities of the user are as follows:

a. to certify that the sterilizer is fit for use;

b. to hold all documentation relating to the sterilizer, including the names of other key personnel;

c. to ensure that the sterilizer is subject to periodic testing and maintenance;

d. to appoint operators where required and ensure that they are adequately trained;

e. to maintain production records;

f. to establish procedures for product release (for medical products, in cooperation with the quality controller).

Competent person (pressure vessels)

5.16 The competent person (pressure vessels) is defined as a person or organisation designated by the management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a sterilizer described in the Pressure Systems Safety Regulations 2000. The shorter term “competent person” is used in this SHTM.

5.17 The competent person should not be the user, nor any of the other key personnel associated with the sterilizer in question.

5.18 The HSC Approved Code of Practice, ‘Safety of pressure systems’ requires the competent person to have the necessary expertise, knowledge and experience for the system in question.

5.19 The principal duties of the competent person under the regulations are as follows (they need not all be exercised by the same individual):

a. advising on the scope of the written scheme of examination;

b. drawing up the written scheme of examination or certifying the scheme as being suitable;

c. carrying out examinations in accordance with the written scheme, assessing the results and reviewing the written scheme for its suitability.

5.20 Most insurance companies maintain a technical division able to advise on appointing a competent person. The authorised person (sterilizers) will also be able to provide advice.

5.21 Further information about the written scheme of examination will be found in Part 4 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Authorised person (sterilizers)

5.22 The authorised person (sterilizers) is defined as a person designated by management to provide independent auditing and advice on sterilizers and sterilization and to review and witness documentation on validation. The shorter term “authorised person” is used in this SHTM.

5.23 The authorised person should:

a. have a minimum of two years recent experience in the validation of sterilization processes to modern standards;

b. have a degree in a relevant science subject or corporate membership of a relevant professional institution;

c. have completed an accredited course for authorised persons (sterilizers) and successfully passed the examination;

or alternatively, should:

d. have applied for registration as an authorised person (sterilizers) no later than 31 December 1994;

e. have at least ten years experience in the validation of porous load and laboratory sterilization processes;

f. have two years experience in a responsible position;

g. successfully pass an accredited examination for authorised persons (sterilizers) within five years of registration.

5.24 The authorised person is required to liaise closely with other professionals in various disciplines and consequently, the appointment should be made known in writing to all interested parties. He or she should have direct contact with the user and other key personnel.

5.25 The principal responsibilities of the authorised person are as follows:

a. to provide general and impartial advice on all matters concerned with sterilization;

b. to advise on programmes of validation;

c. to audit reports on validation, revalidation and yearly tests prepared by the test person;

d. to advise on programmes of periodic tests and periodic maintenance;

e. to advise on operational procedures for routine production.

5.26 A register of suitably qualified authorised persons is maintained by the Institute of Healthcare Engineering and Estate Management (IHEEM).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

Test person (sterilizers)

5.27 The test person (sterilizers) is defined as a person designated by management to carry out validation and periodic testing of sterilizers. The shorter term “test person” is used in this SHTM.

5.28 The test person should:

a. be qualified to at least HNC in engineering or microbiological sciences;

b. have completed an accredited course for test persons (sterilizers) and successfully passed the examination;

c. have been recently employed in an NHS hospital with responsibility for validation and periodic testing for one or more sterilization processes;

or alternatively:

d. have a certificate demonstrating satisfactory completion of an accredited course (City and Guilds or equivalent) in the validation and periodic testing of at least two sterilization processes;

e. have at least three years experience in the validation and periodic testing of porous load sterilizers and at least one other sterilization process.

5.29 The principal responsibilities of the test person are as follows:

a. to conduct the validation tests specified in Part 3 of this SHTM and to prepare the validation report;

b. to conduct the periodic tests specified in Part 3 and to prepare reports as required by the user;

c. to conduct any additional tests at the request of the user.

Maintenance person (sterilizers)

5.30 The maintenance person (sterilizers) is defined as a person designated by management to carry out maintenance duties on sterilizers. The shorter term “maintenance person” is used in this SHTM.

5.31 The maintenance person should be a fitter or an electrician with documentary evidence to demonstrate competence in the maintenance of one or more types of sterilizer. He or she should be in a position to deal with any breakdown in an emergency and have the ability to diagnose faults and carry out repairs or to arrange for repairs to be carried out by others.

5.32 The principal responsibilities of the maintenance person are as follows:

a. to carry out the maintenance tasks outlined in Part 4;

b. to carry out additional maintenance and repair work at the request of the user.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

5.33 A maintenance person who has a minimum of two years experience in the maintenance of sterilizers and who has obtained a recognised qualification in the testing of sterilizers may perform the duties of the test person for the daily, weekly and quarterly tests described in Part 3.

Microbiologist (sterilizers)

5.34 The microbiologist (sterilizers) is defined as a person designated by management to be responsible for advising the user on microbiological aspects of the sterilization of non-medical products. The shorter term “microbiologist” is used in this SHTM.

5.35 The microbiologist should have a relevant degree (for example microbiology or medicine) and will normally be a member of the hospital staff.

5.36 The principal responsibilities of the microbiologist are as follows:

a. to advise the user on the microbiological aspects of sterilization procedures for non-medicinal products;

b. to arrange for the culturing of biological indicators used in microbiological tests (normally low-temperature steam and formaldehyde (LTSF) and ethylene oxide (EO) sterilizers);

c. to audit the documentation from all sterilizers which have been tested by microbiological methods.

Personnel for medicinal products

5.37 Where a sterilizer is to be used in the productron of medicinal products, the provisions of the Medicines Act 1968 apply. The responsibilities that would otherwise be exercised by the user are divided between the production manager and the quality controller. Guidance on the duties of each can be found in the EU commission document, *Guide to good manufacturing practice for medicinal products*.

Production manager

5.38 The production manager is defined as a person designated by management to be responsible for the production of medicinal products.

Quality controller

5.39 The quality controller is defined as a person designated by management to be responsible for quality control and medicinal products with authority to establish, verify and implement all quality control and quality assurance procedures.

5.40 He or she should have the authority, independent of the production manager, to approve materials and products and to reject, as seen fit, raw materials, packaging materials, and intermediate, bulk and finished products

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environmental Forum

not complying with the relevant specification or not manufactured in accordance with approved procedures.

5.41 The quality controller should be professionally qualified (for example in pharmacy). Any additional qualifications will depend on the type of licence which is held, for example:

a. where a product licence is held, the quality controller should satisfy the requirements of the qualified person as defined in the Medicines (Standard Provisions of Licences and Certificates) Amendment (No. 3) Regulations 1977. If the quality controller does not meet these requirements, a qualified person should be designated to exercise the functions specified in the regulations;

b. where the manufacturer's licence "specials" is held, as is generally the case in hospitals, the quality controller need not satisfy the requirements of a qualified person.

5.42 Further information about qualified person can be found in MAL 45 Medicines Acts 1968, 1971.

Other personnel

5.43 The following personnel are also mentioned in this SHTM.

5.44 The **laboratory safety officer** is defined as a person designated by management to be responsible for all aspects of laboratory safety including equipment, personnel and training relating to safety issues, and ensuring compliance with safety legislation and guidelines.

5.45 An **operator** is defined as any person with the authority to operate a sterilizer, including the noting of sterilizer instrument readings and simple housekeeping duties.

5.46 The **manufacturer** is defined as a person or organisation responsible for the manufacturer of a sterilizer.

5.47 The **contractor** is defined as a person or organisation designated by management to be responsible for the supply and installation of the sterilizer, and for the conduct of the installation checks and tests. The contractor is commonly the manufacturer of the sterilizer.

NHSScotland, P&EFEx, June 2001

Preface

SHTM 2010 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of the following types of sterilizer in use in the National Health Service:

a. clinical sterilizers:
   (i) high-temperature steam sterilizers used for processing porous loads (including instruments and utensils wrapped in porous materials);
   (ii) high-temperature steam sterilizers used for processing aqueous fluids in sealed containers;
   (iii) high-temperature steam sterilizers used for processing unwrapped solid instruments and utensils;
   (iv) dry-heat sterilizers (hot-air sterilizers);
   (v) low-temperature steam (LTS) disinfectors and low-temperature steam and formaldehyde (LTSF) sterilizers;

> **NOTE:** Despite their name LTSF sterilizers are disinfectors.

   (vi) ethylene oxide (EO) sterilizers;
b. laboratory sterilizers:
   (i) high-temperature steam sterilizers used with one or more specialised operating cycles;
   (ii) culture media preparators.

No guidance is given on sterilization by irradiation, hydrogen peroxide, gas plasma or filtration. Users who wish to employ these processes bear the responsibility of ensuring that the validation procedures comply with the principles outlined in Part 3 of this SHTM, 'Validation and Verification', and that the intended operating procedures will ensure an efficacious process for the different types of load.

This SHTM is intended primarily as a guide for technical personnel, whether specialists in sterilizers and sterilization procedures or those responsible for maintenance and testing. It is also intended for those responsible for the day-to-day running of sterilizers, and will also be of interest to supplies officers, architects, estates managers and others in both the public and private sectors.

Detailed information on the planning and design of a sterile services department, including the level of provision of sterilizers, is given in Scottish Hospital Planning Note 13, *Sterile services department*. Guidance for

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

laboratory installations can be found in Scottish Hospital Planning Note 15, *Accommodation for pathology services*.

Although this edition of SHTM 2010 reflects established sterilizer technology, it is recognised that considerable scope exists for the utilisation of emerging technology in the management of sterilizers. This will be kept under review with the aim of introducing recommendations for such technology at the earliest opportunity so that the procedures essential for the efficient, safe and effective operation of sterilizers can be optimised.

The sterilizers described in this SHTM may not be suitable, without modification, for safely processing articles infected either with Hazard Group 4 pathogens or with agents, such as those associated with transmissible spongiform encephalopathies, which are unusually resistant to sterilization. Design considerations for sterilizers intended to process articles infected with such organisms are discussed in Chapter 14.

NOTE: Information about Hazard Groups may be found in the HSC document, *Categorisation of pathogens according to hazard and categories of containment* (4th edition 1995) compiled by the Advisory Committee on Dangerous Pathogens.

1. General

Introduction

1.1 This Part of SHTM 2010 covers the specification, purchase and installation of the various types of sterilizer used in hospitals, laboratories and other healthcare facilities.

1.2 Terminology used in sterilization has long been inconsistent and occasionally ambiguous. This SHTM introduces a set of terms consistent with European Standards (see paragraph 1.14) which, it is hoped, will in time be adopted by sterilization workers in the NHS. The Glossary contains definitions referred to in this Part.

1.3 The References contains full references for all the documents referred to in this Part and for selected documents of which the reader should be aware.

Legal frameworks for sterilization

1.4 There are now two legal frameworks applying to products from sterilizers. The long-standing legislation on medicinal products has now been joined by EU Directives on medical devices.

1.5 Purchasers must be clear as to whether the load items they intend to process in a sterilizer are classified as medicinal products or medical devices. While the practical requirements have much in common, their implementation is very different.

1.6 For the guidance given in this SHTM, the various types of sterilizer are presumed to be used primarily as follows:

a. for **medicinal products**: fluid sterilizers, dry-heat sterilizers;

b. for **medical devices**: porous load sterilizers, sterilizers for unwrapped instruments and utensils, dry-heat sterilizers, low-temperature steam (LTS) disinfectors, low-temperature steam and formaldehyde (LTSF) sterilizers, ethylene oxide (EO) sterilizers.

1.7 Where a sterilizer is purchased with the intention of processing both medicinal products and medical devices, purchasers should ensure that the requirements for both types of load are met.

Medicinal products

1.8 The manufacture and supply of medicinal products are controlled by a large body of legislation stemming from the EU Directives on medicinal products and enacted by the UK Medicines Acts and numerous Regulations. Further

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

details can be found in Part 1 of this SHTM, 'Overview and management responsibilities'.

1.9 The requirements for the manufacture of medicinal products are set out in the *Guide to good manufacturing practice for medicinal products* published in Volume IV of *The rules governing medicinal products in the European Community* (see References). This document is referred to as the 'GGMP' in this SHTM.

1.10 The GGMP contains an Annex on the *Manufacture of sterile medicinal products* which has considerable implications for the design of sterilizers and the premises in which they are used. Where purchasers are considering installing a sterilizer for the processing of medicinal products, the GGMP should be consulted at an early stage. Attention is drawn to these requirements in the relevant chapters of this SHTM.

1.11 Guidance on the application of medicines legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medicines Control Agency (MCA).

Medical devices

1.12 Part 1 of this SHTM discusses the three EU Directives on the manufacture and supply of medical devices, active implantable medical devices and in-vitro diagnostic medical devices, which are being implemented by UK Regulations in stages from 1993 onwards. While the full implications of the legislation for the NHS are not yet clear, it is likely that all or most products for clinical use that are not classified as medicinal products will be classified as medical devices. Whether such medical devices will be subject to the Regulations is a complex issue turning on the relationship between the producer and the user of the devices and is beyond the scope of this SHTM.

1.13 One of the essential requirements of the directives is that "devices delivered in a sterile state must have been manufactured and sterilized by an appropriate, validated method". There is no equivalent of the GGMP for medical devices. Instead, the European Committee for Standardisation (Comité Européen de Normalisation, CEN) has prepared a number of draft European Standards on the manufacture of medical devices. These are known as "mandated" standards. Compliance with a mandated standard is considered to be a legal presumption of compliance with the essential requirements of the Directive it supports. Official notification of mandated European Standards supporting EU Directives is published in the Official Journal of the European Communities and in the London, Edinburgh and Belfast Gazettes.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.14 Although compliance with a mandated standard is not the only way of complying with the directives, it is the simplest. Purchasers intending to process sterile medical devices in compliance with the directives should therefore ensure that their processes conform with one of the mandated standards. The following British Standards on the validation and control of sterilization processes have been mandated and are discussed in Part 3, 'Validation and verification', and Part 4, 'Operational management', of this SHTM:

a. BS EN 556 covering the requirements for a device to be labelled "STERILE";

b. BS EN 554 covering sterilization by "moist heat" (that is, steam);

c. BS EN 550 covering sterilization by ethylene oxide.

1.15 These standards are themselves supported by the following standards for the specification of sterilizers which are discussed in this Part of this SHTM:

a. BS EN 285 covering "large" porous load sterilizers;

b. BS EN 1422 covering EO sterilizers.

1.16 While the guidance given here is designed to be broadly consistent with the standards, SHTM 2010 should not be regarded as a substitute for the standards themselves when ascertaining compliance with EU Directives and the UK Regulations that implement them.

1.17 Guidance on the application of medical devices legislation to particular cases is beyond the scope of this SHTM and advice should be sought from the Medical Devices Agency (MDA).

Personnel

1.18 The following personnel are referred to in this Part of SHTM 2010. Further information, including qualifications and areas of responsibility, can be found in Part 1.

1.19 **Management** is defined as the owner, occupier, employer, general manager, chief executive or other person of similar authority who is ultimately accountable for the sole operation of the premises.

1.20 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of similar authority. In small, autonomous installations the user may take on this function.

1.21 The **User** is defined as the person designated by management to be responsible for the management of the sterilizer.

1.22 In a hospital the user could be a sterile services department manager, laboratory manager or theatre manager; in primary care he or she could be

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

a general practitioner, dentist, or other health professional. Where a sterilizer is used to process medicinal products, the user is normally the production manager (see paragraph 1.30) in charge of the entire manufacturing process.

1.23 The **Competent Person (Pressure Vessels)** is defined as a person or organisation designated by management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a sterilizer described in the Pressure Systems Safety Regulations 2000. The shorter term “competent person” is used in this SHTM.

1.24 The **Authorised Person (Sterilizers)** is defined as a person designated by management to provide independent auditing and advice on sterilizers and sterilization and to review and witness documentation on validation. The shorter term “authorised person” is used in this SHTM.

1.25 A list of suitably qualified authorised persons is maintained by the Institute of Healthcare Engineering and Estate Management (see Appendix 1).

1.26 The **Test Person (Sterilizers)** is defined as a person designated by management to carry out validation and periodic testing of sterilizers. The shorter term “test person” is used in this SHTM.

1.27 The **Maintenance Person (Sterilizers)** is defined as a person designated by management to carry out maintenance duties on sterilizers. The shorter term “maintenance person” is used in this SHTM.

1.28 The **Microbiologist (Sterilizers)** is defined as a person designated by management to be responsible for advising the user on microbiological aspects of the sterilization of non-medicinal products. The shorter term “microbiologist” is used in this SHTM.

1.29 The **Production Manager** is defined as a person designated by management to be responsible for the production of medicinal products.

1.30 The **Quality Controller** is defined as a person designated by management to be responsible for quality control of medicinal products with authority to establish, verify and implement all quality control and quality assurance procedures.

1.31 The **Laboratory Safety Officer** is defined as a person designated by management to be responsible for all aspects of laboratory safety including equipment, personnel and training relating to safety issues, and ensuring compliance with safety legislation and guidelines.

1.32 An **Operator** is defined as any person with the authority to operate a sterilizer, including the noting of sterilizer instrument readings and simple housekeeping duties.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1.33 The **Manufacturer** is defined as a person or organisation responsible for the manufacture of a sterilizer.

1.34 The **Contractor** is defined as a person or organisation designated by Management to be responsible for the supply and installation of the sterilizer, and for the conduct of the installation checks and tests. The contractor is commonly the manufacturer of the sterilizer.

1.35 The **Purchaser** is defined as the person or organisation who orders the sterilizer and is responsible for paying for it.

Safety

1.36 Extensive guidance on the safe operation of the various types of sterilizer is given in Part 4 of this SHTM. Guidance on safe practices in the testing of sterilizers is given in Part 3.

1.37 LTSF sterilizers and EO sterilizers both use toxic gases in the sterilization process. Occupational exposure to formaldehyde and EO is controlled by the Control of Substances Hazardous to Health Regulations 1999. Maximum exposure limits are set out in the annual Guidance Note EH40, *Occupational exposure limits*, published by the Health and Safety Executive. The limits shown in Table 1 (are as at 2001). These limits are statutory maxima but should not be regarded as representing a safe working exposure; employers have a legal obligation to ensure that the level of exposure is reduced so far as is reasonably practicable and in any case below the maximum exposure limit.

1.38 The COSHH Regulations 1999 also introduce new controls on biological agents which are of relevance to purchasers of laboratory sterilizers.

Table 1: Maximum exposure limits for atmospheric formaldehyde and ethylene oxide

	Short-term maximum exposure limit		Long-term maximum exposure limit	
Gas	[ppm]	[mg m^{-3}]	[ppm]	[mg m^{-3}]
Formaldehyde	2	2.5	2	2.5
Ethylene oxide	_	_	5	9.2

Note:

The short-term maximum exposure limit (STMEL) is the average exposure over any 15 min period.

The long-term maximum exposure limit (LTMEL) is the exposure over any 24 h period expressed as a single uniform exposure over an 8 h period.

COSHH does not specify a STMEL for EO. In the above table the STMEL is deemed to be three times the LTMEL in accordance with the recommendations of the Health and Safety Executive.

Source: COSHH Regulations 1999, HSE Guidance Note EH40 (2001).

2. Procurement of a sterilizer – an overview

Introduction

2.1 This chapter gives a short overview of the process of purchasing a sterilizer. It refers to more detailed information in subsequent chapters, including information specific to each type of sterilizer given in Chapters 8 to 14.

Purchasing a sterilizer

2.2 The purchase of a sterilizer can be broken down into the following sequence of steps.

What type of load needs to be processed?

2.3 Knowing the load is the first step in making the correct decision about which sterilizer to purchase. Different loads require different processes. Some loads are degraded by prolonged exposure to heat, others cannot withstand moisture or chemical sterilants, while others, owing to their materials or construction, cannot reliably be sterilized by conventional techniques.

What type of sterilizer is required?

2.4 In this SHTM sterilizers are classified as either clinical or laboratory sterilizers. Clinical sterilizers can use one of four different sterilizing agents ("sterilants"): high-temperature steam, hot air (dry heat), low-temperature steam and formaldehyde (LTSF) or ethylene oxide (EO). High-temperature steam sterilizers are specialised for processing porous loads, fluids or unwrapped instruments and utensils. They are also used in laboratory applications. Guidance on the selection of a sterilizer is given in Chapter 3.

What models are available?

2.5 Once the type of sterilizer has been settled, brochures and data sheets should be obtained from a number of manufacturers. The internal market in the European Union, supported by European Standards on sterilization, has considerably widened the choice open to purchasers. Guidance on what information to look for is given in Chapter 4.

Where will the sterilizer be sited?

2.6 Decide on the location of the sterilizer. Some sterilizers will require considerable building work. Guidance on siting is given in Chapter 5.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

What services are available?

2.7 A sterilizer will require one or more of the following services: steam, electricity, water, compressed air, drainage, ventilation and sterilant gas supply. The manufacturers' data will show which services are required for each model. Determine which of these are available at the proposed site and the capacities of each service. It may be necessary to plan for a new service which would add greatly to the cost of the installation. Further information about services may be found in Chapter 6. Steam supply is crucial and is discussed in detail in Chapter 7.

How big and how many?

2.8 Establish the likely weekly workload that the sterilizer will have to process. Calculate the size and number of sterilizers required to process the workload. A judgement has to be made on the trade-off between size and number. Guidance on how to do this is given in Chapter 3.

What other equipment will be needed?

2.9 A sterilizer installation may require auxiliary equipment such as steam generators, air compressors, preconditioning facilities, degassing facilities and gas disposal plants. If required, these are discussed in Chapters 8 to 14.

What specification?

2.10 Most sterilizers will be constructed to either a European Standard or a British Standard. In some cases additional specifications will be required and these are detailed in Chapters 8 to 14. Advice on preparing a detailed specification for the sterilizer is given in Chapter 4.

What sort of contract?

2.11 Once the specification has been completed, a contract should be drawn up for the supply and installation of the sterilizer. Guidance on suitable forms of contract is given in Chapter 4.

Which manufacturer?

3.12 Invite a number of manufacturers to tender for the supply of the sterilizer. Guidance on tendering is given in Chapter 4.

What happens after delivery?

2.13 Chapter 4 contains advice on the documentation that the manufacturer should include with the sterilizer. After delivery the sterilizer is subject to a programme of validation. This is discussed in detail in Part 3 of this SHTM.

3. Choice of sterilizer

Introduction

3.1 This chapter contains information relevant to the choice of a new sterilizer. It discusses the types of sterilizer and the loads for which they are suitable, and gives guidance on selecting the size and number of sterilizers required for a given application.

Types of sterilizer

3.2 This SHTM groups sterilizers into two broad categories according to the use to which they are put:

a. **clinical sterilizers** are designed to process medical devices or medicinal products;

b. **laboratory sterilizers** are designed to process laboratory goods and materials that are neither medical devices nor medicinal products and are not intended for use in the clinical care of patients.

3.3 The operation of sterilizers in the two categories should be kept strictly separate. Loads intended for processing in a clinical sterilizer should not be put into a laboratory sterilizer and vice versa.

Sterilants

3.4 Sterilizers can also be classified according to the agent (the sterilant) used to effect sterilization. The following sterilants are in common use in the NHS:

a. high-temperature steam;

b. dry heat (hot air);

c. low-temperature steam and formaldehyde (LTSF);

d. ethylene oxide (EO).

3.5 Because of its superior sterilizing qualities, high-temperature steam is the sterilant of choice. Machines using other sterilants should be reserved either for loads which would be damaged by exposure to high-temperature steam (such as certain surgical devices) or for loads that would not be sterilized by exposure to high-temperature steam (such as non-aqueous fluids).

3.6 Low-temperature steam used without formaldehyde is not considered to be a sterilant but is commonly used for disinfection.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.7 Clinical sterilizers may employ any one of the four sterilants. The laboratory sterilizers described in this SHTM use only high-temperature steam.

3.8 High-temperature steam sterilizers are by far the most common sterilizers used in the NHS, and are manufactured in three basic types according to the nature of load they are designed to process: porous loads, fluids, or unwrapped instruments and utensils. The operating cycles are designed to cope with the differing properties of the various types of load, and it is essential that a sterilizer is used only for the type of load for which it is designed.

3.9 High-temperature steam inactivates pathogens by a combination of moisture and heat; water molecules combine with proteins and genetic material, which are then susceptible to thermal disruption. The process is well understood and the attainment of sterilization conditions can normally be confirmed by simple physical measurements. (This is not so for sterilizers using gaseous sterilants, where microbiological test procedures are necessary.)

3.10 Many high-temperature steam sterilizers are large machines requiring permanently installed engineering services (including good-quality steam) and purpose-built accommodation. Smaller models are transportable and generate steam from an internal water reservoir.

Choice of sterilizer

3.11 The choice of sterilizer will be governed by the nature of the loads required to be sterilized. Table 2 summarizes the type of load that can and cannot be processed in each type of machine. More detailed guidance on appropriate processes for different load items can be found in *Sterilization, disinfection and cleaning of medical equipment: Part 1: Principles*, published by the Medical Devices Agency, *Sterilization and disinfection of heat-labile equipment* published by the Central Sterilising Club, and in Part 4 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 2: Suitable and unsuitable loads for different types of sterilizer

Type of sterilizer	Suitable loads	Unsuitable loads
Porous load (high-temperature steam)	Porous items; items with narrow lumens that may trap air and inhibit the penetration of steam. *Examples*: any item with porous wrapping, dressings, clothing, towels	Items which would be damaged by exposure to steam at 121 - 137°C
Fluid (high-temperature steam)	Aqueous fluids in sealed glass or plastic containers. *Examples*: intravenous fluids	Non-aqueous fluids
Unwrapped instruments and utensils (high-temperature steam)	Solid metal items. *Examples*: surgical or dental instruments, bowls	Items with narrow lumens that may trap air and inhibit the penetration of steam. *Examples*: ENT suction tubes, laparoscopic instruments, orthopaedic reamers
Dry heat	Items which would not be sterilized by high-temperature steam, or would be damaged by doing so. *Examples*: solids, powders, non-aqueous fluids, ointments, ophthalmic instruments, items in closed containers	Aqueous fluids and items which would be damaged by prolonged exposure to dry heat at 160-200°C. *Examples*: fibre optics, rubber, plastics
Low-temperature steam and formaldehyde (LTSF)	Wrapped or unwrapped items which would be damaged or not sterilized by high-temperature steam or dry heat. *Examples*: certain items containing plastic components, electromedical equipment	Items which would be damaged by exposure to steam or formaldehyde gas at 71-80°C; sealed, oily or greasy items; items contaminated with body fluids
Ethylene oxide (EO)	Wrapped or unwrapped items which would not be sterilized by steam or dry heat or would be damaged by doing so. *Examples*: heat-labile plastic items, heart valves, electromedical equipment	Items which can be sterilized by other means; soiled items; items previously sterilized by irradiation. *Examples*: ventilatory and respiratory equipment
Laboratory (high-temperature steam)	Laboratory materials and equipment. *Examples*: infected materials to be made safe, culture media, glassware and other equipment	Medical devices, medicinal products and other items to be used in the clinical care of patients

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.12 Purchasers should be aware that items suitable for a particular type of sterilizer may still require different operating cycles, which need to be specified before purchase. For example, a porous-load sterilizer is required for wrapped instruments and microbiological filters. However, a cycle suitable for instruments may be harmful to the filters unless the rate of change of pressure is reduced to prevent rupture of the membrane. Similarly, a container with a small orifice will also require a porous-load sterilizer but the duration of each air removal pulse will need to be extended to allow for pressure equilibration; otherwise the air will remain in the container and sterilization will not be achieved. Guidance on the modification of operating cycles to suit particular loads (process development) is given in Part 4 of this SHTM.

3.13 More information about the different types of sterilizer is given in Chapters 8 to 14.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

Table 3: Suggested information to be obtained from manufacturers before inviting tenders

Information required	Objective
The **standards** (BS or EN) to which the sterilizer is designed and constructed and a statement of compliance	To confirm that the sterilizer meets recognised specifications for design, construction, performance and safety
Installation data, including the overall dimensions and mass of the sterilizer; the number of supports and the maximum floor loading at each support; the clearance required for access and the masses of the principal heavy components	To enable the user to establish whether the proposed location is suitable for the sterilizer and the extent of any building work required (see Chapter 5)
The volume of the **usable chamber space** expressed both in litres and an integral number of sterilization modules, and its principal dimensions in metres	To enable the user to determine the capacity of the sterilizer and hence the number of sterilizers required to process the workload
Specifications for each of the **engineering services** required by the sterilizer	To enable the user to establish that the demands of the sterilrzer are within the capacity of the services in the proposed location (see Chapters 6 and 7)
A description of the **operating cycles** offered with the sterilizer, including numerical and graphical representations of typical values of cycle variables throughout each cycle and the extent to which pre-set variables may be adjusted	To enable the user to confirm that the cycles are appropriate for the anticipated loads
For each operating cycle and sterilization temperature the cycle time and corresponding **performance class** for the relevant full load tests specified in Part 3 of this SHTM	To enable the user to determine the capacity of the sterilizer and hence the number of sterilizers required to process the workload
The mean and peak **sound power levels** generated by the sterilizer, expressed as an A-weighted sound power level measured as described in Appendix D of BS 3970: Part 1 or in Part 5 of this SHTM, 'Good practice guide'	To enable the contractor to confirm that the sound pressure level after installation, as measured by the method given in Part 3 of this SHTM, will not exceed that specified for the location (see Chapter 5)
The **fatigue life** of the pressure vessel	To enable the user to estimate the working life of the sterilizer (see Chapter 4)
The type of **doors** and information on the necessary space required for the movement of the doors (see Chapter 4)	To enable the user to make the necessary provisions in the design of the loading area (see Chapter 5)

3.14 Advice on individual cases should be sought from the authorised person before any decision is made. Where an LTSF or EO sterilizer is being considered the microbiologist should also be consulted.

3.15 Once the type of sterilizer has been decided, preliminary enquires should be made with a number of manufacturers to obtain specifications and price lists. Table 3 indicates some of the information that will be useful for planning purposes and which should be obtained at this stage.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Sterilization conditions

3.16 For the purposes of this SHTM the following definitions have been adopted.

3.17 The **cycle variables** are the physical properties, such as time, temperature, pressure, humidity and sterilant gas concentration, that influence the efficacy of the sterilization process.

3.18 Most operating cycles have a stage in which the load is exposed to the sterilization (or disinfection) conditions for a specified length of time. This period is known as the **holding time**.

3.19 The **sterilization conditions** are the ranges of the cycle variables which may prevail throughout the chamber and load during the holding time.

3.20 The holding time is preceded by a period in which the sterilization conditions are present in the chamber but not yet present throughout the load. This is known as the **equilibration time**.

3.21 Together, the equilibration time and the holding time constitute the **plateau period**. While the plateau period can always be determined from the recorded chamber temperature, the equilibration and holding times cannot be distinguished unless the temperature in the part of the load that is slowest to reach the sterilization temperature is also being recorded or measured.

3.22 Certain LTSF sterilizers may achieve sterilization by exposing the load to a series of pulses of formaldehyde rather than a single holding time.

3.23 For EO sterilizers the plateau period is equivalent to the **gas exposure time**. The holding time cannot be determined by thermometry and is therefore of no practical interest.

3.24 For steam and dry heat sterilizers, the sterilization conditions are specified by a **sterilization temperature band**, defined by a minimum acceptable temperature, known as the **sterilization temperature**, and a maximum allowable temperature. The higher the sterilization temperature, the shorter the holding time and the more rapidly the cycle is completed. A sterilization temperature band can also be quoted for LTSF and EO sterilizers, but since these processes depend primarily upon chemical action such a band is not a complete specification of the sterilization conditions. Bands for the different types of sterilizer are listed in Table 4.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 4: Sterilization temperature bands

	High-temperature steam				Dry heat			LTS	LTSF	EO
Sterilization temperature (°C)[a]	115	121	126	134	160	170	180	71[b]	71	30-56
Maximum allowable temperature (°C)	118	124	129	137[c]	170	180	190	80	80	[d]
Minimum holding time (min)	30	15	10	3	120	60	30	10	180[e]	[f]

Note:

a. The temperature setting on the automatic controller will not generally be the sterilization temperature, but a higher temperature within the sterilization temperature band.

b. Disinfection temperature.

c. British Standards permit 138°C.

d. For EO, the maximum allowable temperature will normally be 4°C above the sterilization temperature.

e. For LTSF, the sterilization conditions may specify either a continuous holding time or the number of pulses for formaldehyde required to achieve sterilization.

f. For EO, the "gas exposure time" is determined for each sterilizer by microbiological methods during commissioning but is typically 2-7 hours depending upon sterilization temperature and gas concentration.

Sizes and numbers

3.25 It is difficult to give precise information on the sizes and number of sterilizers required for particular installations since in practice there are significant variations in patterns of use. The following guidance is applicable to all types of sterilizer. More detailed advice and examples of how to calculate sizes and numbers of sterilizers in a Sterile Services Department (SSD) is given in Scottish Hospital Planning Note 13 for porous loads, and in Supplement 1 to Scottish Hospital Planning Note 13 for EO sterilizers.

3.26 The number of sterilizers required will depend on two critical properties of the machine: the cycle time (denoted by a performance class) and the chamber size (denoted by the volume of the usable chamber space).

Cycle time and performance class

3.27 The time required to complete an operating cycle depends both on the design of the sterilizer (especially the methods used to remove air from the chamber and to heat and cool the load) and on the type and size of load to be processed. An operating cycle is assigned a performance class which is related to the time required to process a standard full load, as specified in the tests described in Part 3 of this SHTM. A Class 1 cycle will be complete in less than 10 min, while a Class 20 cycle will take over 13 hr. The relation between cycle time and performance class is given in Table 5. If the cycle time is to be extended to dry difficult loads, this should be allowed for when calculating the number of sterilizers required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 5: Performance classes for sterilizers

Class	Full load cycle time [mins]	Class	Full load cycle time [mins]	Class	Full load cycle time [mins]	Class	Full load cycle time [mins]
1	0 – 10	6	61 – 90	11	241 – 300	16	541 – 600
2	11 – 15	7	91 – 120	12	301 – 360	17	601 – 660
3	16 – 30	8	121 – 150	13	361 – 420	18	661 – 720
4	31 – 45	9	151 – 180	14	421 – 480	19	721 – 780
5	46 – 60	10	181 – 240	15	481 – 540	20	over 780

3.28 Loading conditions that present a greater challenge to the cycle than the full loads specified in Part 3 of this SHTM will require further investigation and performance qualification to establish a cycle time. The authorised person will advise on this.

Chamber size

3.29 The size of a sterilizer is denoted by the volume of the usable chamber space, commonly expressed in litres. The usable chamber space is the space inside the chamber which is not restricted by chamber furniture and which is available to accept the load. It should be distinguished from the total chamber volume, which is equal to the volume of water required to fill the chamber and is therefore larger than the usable chamber space.

3.30 With the gradual introduction of European Standards on sterilization, the size of larger sterilizers will be denoted by an integer number of sterilization “modules” which can be accommodated within the usable chamber space. One module is a rectangular box measuring 300 x 300 x 600 mm, of volume 54 litres. In the European Standards a “large” sterilizer can accommodate one or more modules; a “small” sterilizer has a capacity of less than one module. Table 6 lists the recommended sizes for different types of sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 6: Recommended sizes for different types of sterilizer

	Usable chamber space [modules][a]						
Type	<1	1	2	4	6	9	12
Porous load	-	-	X[b]	-	X	X	X
Fluid	-	-	X	X	X	X	X
Unwrapped instrument	X	X[b]	X[b]	-	-	-	-
LTSF	-	-	-	-	X	X	-
Dry heat	-	-	-	X	-	-	-
EO	-	X	X	-	-	-	-
Laboratory	X	-	-	-	X	X	-

a. A module is a rectangular box measuring 300 x 300 x 600 mm, of volume 54 litres (see paragraph 3.30).

b. May be used in a surgical facility where supply from an SSD is impractible or not cost effective.

3.31 In the case of sterilizers for unwrapped instruments and utensils and laboratory sterilizers, small transportable units of capacity less than one module are available and may be the most economical solution where workloads are light.

Sizing calculation

3.32 Once the cycle time is known, the size and number of sterilizers to be purchased can be calculated. Size and number are complementary: in principle, the same workload can be processed by a single large sterilizer or a number of smaller sterilizers.

3.33 The first step in making this decision is to establish the workload which the sterilizer is intended to process, expressed in modules per week. (For some types of sterilizer it may be more appropriate to express the workload in other units; for example trays or discard boxes per week.) This is not simply the bulk volume of goods to be processed, but the volume they will occupy inside the sterilizer allowing for spacing within the chamber. Spacing is particularly important for sterilizers using mixtures of steam and air and for dry-heat sterilizers. An item which cannot be fitted into a single module should be allowed two or more modules as appropriate.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.34 Once the workload is established, the capacity for a sterilizer of given size can be calculated from

$$\text{capacity} = 60\ \frac{Vf_V\ x\ Tf_T}{t_C}\ \text{modules/week}$$

where

V = the volume of the usable chamber space (modules);

f_v = the loading factor, the average fraction of the usable chamber space occupied by a load (typically 0.5 for an SSD);

T = the "open hours", the number of hours each week for which the sterilizer unit will be operational;

f_T = the utilisation factor, the fraction of the open hours for which the sterilizer is available to process loads. This should allow for loading and unloading, periodic testing and maintenance, and warm-up cycles. It should be chosen so that a sterilizer may be withdrawn from service for planned maintenance and periodic testing without jeopardising production. For an SSD the utilisation factor is typically 0.55;

t_c = the cycle time for the selected operating cycle (minutes).

3.35 The minimum number of sterilizers required to process the workload can then be calculated from

$$\text{Number of sterilizers required x}\ \frac{workload}{capacity}$$

3.36 Purchasers should make the above calculation for a number of different sizes of sterilizer to establish the combinations of size and number that will satisfy the workload requirement.

3.37 In practice, the number of sterilizers of the same type in a single installation will be usually at least two and rarely more than four.

3.38 Where more than one sterilizer of the same type is installed, they should be of the same size and from the same manufacturer. This will allow common loading systems to be used.

3.39 If further sterilizers are likely to be purchased in the future, then consideration should be given to the extra space required both in the plantroom and in the loading area.

3.40 Special considerations for laboratory sterilizers are discussed in Chapter 14.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4. Specification and contract

Introduction

4.1 This chapter discusses general specifications for sterilizers and the steps to be taken in inviting tenders and issuing a contract. The validation procedure, which begins on installation of the sterilizer, is discussed in detail in Part 3 of this SHTM.

Preparing a specification

4.2 Purchasers are strongly recommended to seek assistance from the authorised person when preparing a specification for a sterilizer.

4.3 To keep abreast of changing requirements, purchasers should ensure that they consult the latest editions of any standards and other specification documents, including any amendments issued after publication. The authorised person will advise on this.

4.4 Most sterilizers are constructed either to a European Standard (EN) or a British Standard (BS). A summary of the current relevant standards is given in Table 7. As many British Standards will be replaced by European Standards in due course, purchasers should specify a European Standard where one exists. The relevant standards are discussed in the ‘Standard specifications’ section of each chapter.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

Table 7: British and European Standards on sterilizers

Topic	British Standard
Clinical sterilizers	
Porous load	BS 3970: Parts 1& 3, BS EN 285
Fluid	BS 3970: Parts 1 & 2
Unwrapped instruments	BS 3970: Parts 1 & 4
Dry heat	-
LTS	BS 3970: Parts 1 & 5
LTSF	BS 3970: Parts 1, 5 & 6
EO	BS EN 1422
Laboratory sterilizers	BS 2646 Parts 1-5
Electrical safety	BS EN 61010: Part 1
Steam	BS EN 61010: Part 2-041
Dry heat	BS EN 61010: Part 2-043
LTSF and EO	BS EN 61010: Part 2-042

Full references for these standards are given in the Reference section

4.5 In some cases the standard specifications may not be adequate for sterilizers to be used in the public service. In these cases, additional specifications are listed below for general design considerations (see paragraphs 4.9 onwards) and, if appropriate, in an 'Additional specifications' section of each chapter.

4.6 Purchasers are strongly advised to use the NHS Model Engineering Specification C14, *Sterilizers* and the *C14 User Guide*, both published by NHS Estates, when ordering sterilizers. C14 is an exhaustive, detailed statement of specifications, conforming both with current standards and with the recommendations of this SHTM. There should be no need for any further documentation, alterations or additions to be included in the tender documents.

4.7 Details of the proposed location for the sterilizer should be stated clearly in the specification.

4.8 Except when the manufacturer is responsible for the installation of the machine, the type and standard of packing for delivery of the sterilizer should be specified. Where site conditions are likely to be poor and damage could occur, a substantial dustproof transit case may be necessary.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

General design considerations

4.9 The following design considerations are applicable to all or most types of sterilizer, but are not necessarily required by the current standards. Where applicable they should be included in the specification for any sterilizer to be operated in the NHS.

4.10 All sterilizers and associated equipment are classed as “work equipment” and should comply with the Provision and Use of Work Equipment Regulations 1998 (PUWER 98), (see Part 1 of this SHTM). Purchasers are reminded that under the Regulations it is the responsibility of the employer, not the manufacturer, to provide a sterilizer that is “suitable for the purpose for which it is used or provided”.

4.11 All sterilizers made or sold in the UK from 1 January 1996 should conform to the emission and immunity requirements of the Electromagnetic Compatibility Regulations 1992. This may be achieved by compliance with BS EN 50081 (emission) and BS EN 50082 (immunity). The manufacturer should be informed of any local sources of electromagnetic disturbance which may affect the operation of the sterilizer (see Chapter 5).

4.12 For maintenance purposes, side, back and top panels for free-standing sterilizers should be easily removable and replaceable.

4.13 Special foundations are not normally required. The weight of the sterilizer, which can be as much as 2.5 tonnes when fully loaded, should be borne by at least four pads, each measuring at least 150 x 150 mm. Floor mountings should be designed to minimise vibration.

Safety features

4.14 Safety features should be designed in accordance with the British Standard code of practice for safety of machinery, PD 5304: 2000, and the British Standard for the safety of electrical equipment, BS EN 61010.

4.15 The design of the control system should ensure that the door cannot be opened except by a key code or tool until the cycle is either complete or returned to a safe condition and a fault is indicated.

4.16 The sterilizer should conform to the requirements listed under *Safeguards* and *Interlocking* in HSE Guidance Note PM73, *Safety at autoclaves*.

4.17 The manufacturer should provide a list of all safety devices together with their settings and methods of adjustment.

4.18 All safety devices should be designed to fail in a manner which does not cause a safety hazard to personnel.

4.19 A safety hazard should not be caused by an error in the control or indication system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Instrumentation

4.20 Whilst it is preferable that the recording system is wholly independent of control and indication, a system which combines both control and instrumentation may be used, providing that any fault which could cause a failure to attain specified parameters within all parts of the load is either indicated or recorded. If this requirement cannot be met, an independent recording system should be provided. (See also paragraph 4.30.)

4.21 Where an instrument has a facility for adjusting one or more preset variables (such as a thermostat) the adjustment should be by means of a key, code or tool not available to the operator.

4.22 Where more than one instrument is fitted in the same area, every effort should be made to obtain a uniform appearance. As an alternative to discrete instruments, any or all of the required displays may be provided by a single display unit.

4.23 Where a fault is indicated in the form of an error message shown on a visual display unit, it should be clearly distinguishable from normal messages, for example, by use of a different colour or larger size of text. The indication should remain displayed until acknowledged by the operator.

4.24 The sterilizer contractor should be required to carry out adjustments to the instruments on site so that the accuracies specified at the sterilization temperature can be met with the plant running and under the conditions normally prevailing on site.

4.25 An indicator should show which stage of the operating cycle is in progress and indicate “cycle complete” at the end of the cycle.

4.26 A five-digit counter should be provided to indicate the cumulative total of cycles started. The counter should be tamper-evident or sealed.

4.27 Provision should be made for the attachment of the test instruments required for the tests specified in Part 3 of this SHTM.

a. For temperature testing, a connection should be provided to permit the entry of sensors into the chamber, as described in BS EN 285. A suitable gland for attachment to the connection is illustrated in Part 3 of this SHTM.

b. For pressure or humidity testing, test tees and valve cocks with sealing plugs should be fitted to permit connection of test instruments for the verification and calibration of all pressure and humidity instruments permanently fitted to the sterilizer. The connection should be as described in BS EN 285.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Programmable electronic systems

4.28 Modern sterilizers frequently use programmable electronic systems (PES) for control and data recording. Where such systems are used, they should be designed in accordance with the principles set out in the two parts of the HSE document, *Programmable electronic systems in safety related applications*.

4.29 Where a PES is used for control or monitoring of the process, the values of cycle variables critical to process performance and determined during validation should be documented in the validation report regardless of whether or not they are held in the PES memory. The version number of the software should be available for display when required.

4.30 Combined control and instrumentation systems that are wholly operated by means of PESs should incorporate at least two timing systems, independent of each other, such that the timer used to control the holding time is verified by the other timer.

Overpressure protection

4.31 Overpressure safety valves should be fitted to protect components that may be damaged by inadvertent high pressures. These include the chamber, jacket, pressurised door-sealing system, heat exchanger system and ballast air system. The discharge from safety valves should be terminated in a safe position (see paragraph 7.15).

4.32 The steam pipework should include a pressure-reducing system with a separator on the high-pressure side. The system should be fitted with a strainer and trap to prevent condensate accumulating in the system.

Access to chamber drain

4.33 For steam sterilizers, the chamber drain should be positioned so that any debris caught on the strainer can be seen and removed by the operator without the need to dismantle any part of the sterilizer.

Doors

4.34 A single door is preferred. Sterilizers with a door at each end (“double-ended” sterilizers) create problems of maintenance and ventilation and should only be considered where alternatives have been discounted.

4.35 Power-operated doors are desirable on sterilizers of 300-litre capacity and over. The following designs are available:

a. sliding doors (vertical or horizontal);

b. side-hinged doors;

c. bell-shaped sterilizer, where the chamber is raised vertically from a fixed bedplate.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.36 The choice of design for any particular installation will depend on the workload, space restrictions, price and ease of maintenance. With side-hinged doors there is a risk of the operator touching the hot inside face as the door is opened. If hinged doors are required, the specification should state whether they are to be hinged on the left-hand or right-hand side of the opening. Bell-shaped sterilizers require special guards to ensure the safety of the operator when the chamber is being lowered.

4.37 It should be possible to clean the contact surfaces of the door seal without removing parts of the sterilizer.

Materials of construction

4.38 Table 8 summarises the materials to be used for clinical sterilizers and for laboratory sterilizers.

Table 8: Recommended materials of construction

	Clinical sterilizers	Laboratory sterilizers
Pressure vessel and steam generator	Group A	Group A, B or C
Pipework for circulating media coming into contact with load	Group E	Group G
Pipework for circulating media **not** coming into contact with load	Group J or K	Group H, J or K

Groups are defined in Annex 1 of BS EN 285.

4.39 The fatigue life of sterilizer vessels (see paragraph 4.40) constructed from dissimilar materials welded together can be considerably reduced by unpredictable high stresses caused by differential expansion and weld inconsistencies. For this reason the use of carbon-steel jackets or stiffeners should be avoided on stainless-steel chamber shells.

Fatigue life of pressure vessel

4.40 The fatigue life of a sterilizer vessel will depend on the level of alternating stresses caused by the following:

a. changes of pressure within the chamber;

b. differential temperature changes within the chamber and jacket (if fitted);

c. differential expansion;

d. stresses “locked” within the pressure-retaining parts of the vessel.

4.41 Vessels should be designed to withstand $25{,}000/t_C$ operating cycles, where t_C is the minimum cycle time (in hours) corresponding to the performance class quoted by the manufacturer.

4.42 The manufacturer should determine the fatigue life by the method given in Part 5 of this SHTM (reprinted from BS 3970: Part 1).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Integral air compressors

4.43 European and British Standards permit the use of built-in air compressors for sterilizers but do not give specifications, current experience indicates, however, that certain small compressors of the type fitted to domestic refrigerators are not suitable for use in sterilizers. Unless they are meticulously maintained, a small air leak can cause them to run continuously, causing rapid carbonisation of the oil and consequent failure of the sterilizer pneumatic system.

Integral steam generators

4.44 Where an integral steam generator is fitted to the sterilizer, it should be equipped with blow-down facilities to enable sludge to be expelled from the boiler.

Loading systems

4.45 Sterilizer loading systems should be designed with regard to the Manual Handling Operations Regulations 1992 and the Lifting Operation and Lifting Equipment Regulations 1998 (LOLER).

Invitation to tender

4.46 Once detailed specifications have been drawn up, manufacturers should be invited to tender for the supply and, if required, the installation of the sterilizer.

4.47 When inviting tenders, purchasers should follow the principles described in Scottish Capital Investment Manual and PROCODE.

4.48 The purchaser should specify that the sterilizer manufacturer operates a quality system in accordance with the principles described in BS 5750 and the EN 9000 series. If the manufacturer has both designed and manufactured the sterilizer, the quality system should conform with EN 9001. If the sterilizer has been manufactured to a design supplied by a third party, the manufacturer's quality system should conform to EN 9002. In either case the manufacturer should ensure that each supplier of accessories, fittings and other materials also operates an appropriate quality system.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

4.49 Prospective contractors should be given the following information:

a. that each sterilizer will be subject to a validation process as described in Part 3 of this SHTM;

b. unless otherwise specified, that the installation checks and tests specified in the validation process must be satisfactorily completed before the sterilizer can be accepted;

c. whether the installation checks and tests are to be witnessed by the purchaser's representative (normally the test person);

d. the date by which all services will be available;

e. the date by which the validation process is expected to be completed.

4.50 In assessing tenders, purchasers should not automatically opt for the lowest quoted price. An unusually low tender should not be chosen without further investigation into the financial circumstances of the prospective contractor.

Contract

4.51 For procurement of sterilizers Conditions of Contract as advised by PROCODE may be used. Modifications to suit local purchasing policy may be required.

4.52 Consideration may also be given to the use of alternative forms of contract, for example MF/1 (available from the Institution of Electrical Engineers, the Institution of Mechanical Engineers or the Association of Consulting Engineers) or the Joint Contracts Tribunal (JCT) suite of documents (available from RIBA Publications). Addresses are given in Appendix 1.

4.53 Purchasers using other forms of contract are strongly advised to seek legal advice, from the Central Legal Office (CLO) especially where a contract proposed by the prospective contractor is being considered.

4.54 Other contracts, notably for the authorised person, the test person, the maintenance person, the competent person and the microbiologist, may need to be considered at this time (see Part 1 of this SHTM). In awarding these contracts, purchasers should ensure that there is no conflict of interest that would compromise the validation process set out in Part 3 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Delivery

4.55 On or before delivery of the sterilizer, the manufacturer should provide the purchaser with the information specified in Appendix 2.

4.56 Sterilizers for a particular scheme should not be ordered and stored on site for long periods prior to installation and validation. Disregard of this recommendation could result in the installation of a technically obsolescent sterilizer. Where a long delay is unavoidable, conditions for storage should be agreed with the manufacturer.

NHSScotland Property and Environment Forum

5. Siting

Introduction

5.1 This chapter sets out some of the considerations to be taken into account when siting a sterilizer. A thorough discussion of the planning requirements for a sterile services department (SSD) is given in HBN 13. Additional guidance on the siting of ethylene oxide (EO) sterilizers may be found in Chapter 13 and in Scottish Hospital Planning Note 13, Supplement 1; *Ethylene oxide sterilization section*. Guidance on the siting of laboratory sterilizers is given in Chapter 14 and in BS 2646: Part 2. Guidance on accommodation for ethylene oxide gas cylinders, manifolds and canisters is given in Part 5 of this SHTM.

5.2 The room in which a sterilizer is installed should meet the requirements of the Workplace (Health, Safety and Welfare) Regulations 1992, which have far-reaching implications for the design of sterilizer accommodation.

5.3 Fire safety precautions should comply with the NHS in Scotland Firecode series published by the NHS in Scotland Property and Environment Forum Executive.

5.4 Where possible, sterilizers should be transported as a whole and not partially stripped.

Accommodation

5.5 Except where sterilizers are free-standing (paragraph 5.14) or transportable (paragraph 5.17), a sterilizer installation will normally be separated into two areas: a plantroom containing the sterilizer itself, services and ancillary equipment; and an adjacent loading area from which the sterilizer is loaded and unloaded. The areas are divided by a partition wall into which the front panel and door of the sterilizer are set.

5.6 The wall aperture should meet the tolerances quoted in BS EN 285. The contractor should be required to provide the trim to the wall or provide the panelling. Fascia panels should be adequately supported and insulated to minimise vibration and heat transmission from the plantroom to the loading area. Foamed plastic materials which are either combustible or subject to degradation at the operating temperatures should not be used, nor should asbestos products. Suitable specifications for such insulation may be found in NHS Model Engineering Specifications C02, *Thermal insulation*.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

5.7 Maintenance staff should be able to enter the plantroom without passing through the loading area. Direct access between the plantroom and loading area should be provided for use during testing. Operators will normally require access to the loading area only.

5.8 If a sterilizer with a door at each end is installed (a “double-ended” sterilizer), arrangements for maintenance should be from the “dirty” end. Except where the product would be jeopardised or a microbiological hazard created, maintenance access from the “clean” end should also be provided.

Plantroom

5.9 Wherever practicable the sterilizer should be located on the ground floor and the plantroom should have an outside wall. This arrangement will facilitate easy access for engineering staff and for plant replacement. It will also simplify safety requirements for ventilation and drainage, particularly for low-temperature steam and formaldehyde (LTSF), EO and laboratory sterilizers.

5.10 The plantroom floor should be non-slip and waterproofed to avoid damage to rooms and equipment which may be below the sterilizers. To facilitate cleaning, the floor should fall naturally to a drain.

5.11 Adequate clearance around the machines is essential for access and maintenance. The minimum clearance should be 1.0 m around all parts to which access for routine maintenance is necessary. The minimum ceiling height is 2.7 m above floor level. Spacing should be such that it is possible to replace any sterilizer without disturbing others in the same installation. Particular care should be taken to ensure that sufficient clearance is allowed for large items, such as vacuum pumps, to be withdrawn from the sterilizer frames.

5.12 Extra space should be allowed for installation and maintenance of free-standing equipment such as steam generators, air compressors and water conservation systems. Possible future expansion should be considered. For EO sterilizers, a separate but adjacent manifold room will be required for gas cylinders (see paragraph 6.74).

Loading area

5.13 Where carriage or trolley loading is used, the minimum clearance for access to the sterilizer should be 3.0 m or twice the length of the carriage loading system, whichever is the greater. Careful attention should be paid to height adjustment, so that all sterilizers in a group can be served wherever possible by a common loading system.

Free-standing sterilizers

5.14 Certain permanently installed sterilizers, such as smaller laboratory machines, may be “free standing”, that is, installed in a room with no separation into plantroom and loading area. Such installations may present problems of safety and access, and are not recommended where a more

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

conventional arrangement is possible. Where a free standing installation is unavoidable, the authorised person should be consulted at an early stage to ensure that adequate safety precautions are taken.

5.15 A free-standing sterilizer may not meet the environmental quality control standards required for the manufacture of medicinal products or medical devices (see Chapter 1). Advice may be obtained from the authorised person.

Transportable sterilizers

5.16 Benches on which transportable sterilizers are placed should comply with HTM 67, *Laboratory fitting-out system*.

5.17 The sterilizer should be placed within 2 m of a switched 13 A socket outlet. Extension flexes should not be used.

5.18 The pressure relief valve should be able to discharge freely and safely. Equipment which could be damaged by steam or moisture should not be placed near the sterilizer.

5.19 It has been known for the door of a transportable sterilizer to be blown off with considerable force; the sterilizer should therefore be sited so that a safety hazard is not created in the event of an accident. Sterilizers in dental practices should preferably be sited in a different room to that used for operating. If this is impossible, the sterilizer door should face in such a direction that there is no hazard to patients or staff.

5.20 Users should be aware of the heat and water vapour that may be emitted in normal operation by even a small sterilizer and make appropriate provision for ventilation (see Chapter 6). The authorised person will advise on suitable arrangements.

Noise and vibration

5.21 Sound pressure levels sensed in a room are a function of the sound power generated by the sterilizer and the acoustic design of the room in which the sterilizer is installed.

5.22 European and British Standards do not specify permitted sound power levels. The sterilizer manufacturer should state at the time of tendering the A-weighted sound power level determined in accordance with the method detailed in Part 5 of this SHTM. Purchasers should be aware that the uncertainty inherent in this method can amount to a standard deviation of 5 dB for sources containing discrete tones and 4 dB for wide-band noise sources. These uncertainties should be taken into account in the acoustic design of the room in which the sterilizer is installed. The design should ensure that sound pressure levels stated in the sound pressure test described in Part 3 are not exceeded.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

5.23 The sound pressure levels specified in Part 3 are for an area or space where the sterilizer is operating under normal working conditions. The levels include noise from all sources including the sterilizer.

5.24 The room in which the sterilizer is to be installed should be located and designed so that the noise transmitted from the room does not increase the sound pressure levels in adjacent rooms in excess of the levels specified in SHTM 2045; *Acoustics*. Account should be taken of all transmission paths, including open windows and building structures. A fascia panel should not be used to separate a noise-sensitive area from the operating parts of the sterilizer without additional insulation (this may double as thermal insulation – see paragraph 5.6).

5.25 If the sterilizer is in or adjacent to a main building or a noise-sensitive area, open louvres in internal doors and partitions should be avoided; doors should be solid, self-closing and a good fit in their frames, preferably with compressed rubber seals. If this affects natural ventilation, mechanical ventilation may be required (see Chapter 6). The need for such a solution can usually be avoided in the planning stage.

5.26 Vibration transmitted to the building structure is generally produced by pumps, motors and on/off valves connected to the services. If vibration is likely to be a problem the following measures are recommended:

a. transmission of vibration through service connections can be avoided by the use of flexible connections;

b. pumps and motors associated with sterilizers should be resiliently mounted, whether or not they are integral with the sterilizer;

c. the forcing frequency of the vibration generator should be taken into account when designing vibration isolators.

Lighting

5.27 Fluorescent lighting should be used. The stroboscopic effect of the lighting should be minimised in the plantroom by the use of two tube fittings suitably adapted for this purpose or by the use of two phases for the lighting circuits. The fittings should be sited longitudinally between the sterilizers. Further guidance on lighting may be found in *Lighting guide: hospitals and health care premises*, published by the Chartered Institution of Building Services Engineers (CIBSE).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Electromagnetic compatibility

5.28 Although a new sterilizer will be designed to comply with the Electromagnetic Compatibility Regulations 1992, purchasers should establish whether existing equipment on the premises is likely to give rise to electromagnetic disturbance at the intended location of the sterilizer. If so, the sterilizer manufacturer should be informed at an early stage. Further guidance may be found in SHTM 2014; *Abatement of electrical interference*.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6. Engineering services

Introduction

6.1 A sterilizer installation will require one or more external services including steam, electricity, water, compressed air, drainage, ventilation and ethylene oxide gas. The manufacturer should make clear at an early stage which services will be needed and the detailed requirements for each, as outlined in Table 9. Steam supply is the most critical of the services and is considered in detail in Chapter 7.

6.2 If the services are to be installed by a contractor other than the contractor installing the sterilizer, care must be taken to ensure that the size and location of terminations are agreed before the contracts are placed.

6.3 All services should be terminated within the plantroom by appropriate valves and isolators within 2.0 m of the sterilizer.

6.4 Care should be taken to ensure that pipework and cables used to connect the sterilizer to the service terminations are of adequate size to meet the demands of the sterilizer. Inadequate services may cause malfunctioning. Pipework and cables should be installed close to a wall and not over the top of a sterilizer.

Electricity

6.5 The electrical power requirements will depend on a number of factors, such as the type of sterilizer and the method used to generate steam. (Local or integral electrical steam generators will result in a high electrical load.) Some sterilizers will require a three-phase supply. The manufacturer should provide details of the type of supply (AC or DC), number of phases, frequency, and voltages with tolerances and loading.

6.6 Each sterilizer should be connected via an isolator. The type of isolator will depend on the nature of the supply:

a. isolators for transportable sterilizers with a maximum current demand of 13 A may be of the simple plug and socket-outlet type, with the plug correctly fused and the socket outlet switched;

b. where a three-phase-and-neutral supply is necessary, or where a maximum single-phase current demand is more than 13 A, the sterilizer should be wired directly to the isolator. The switch should isolate all poles simultaneously and each pole should be fused separately. The cable from isolator to sterilizer should be fixed and protected from the effects of heat, water and steam.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 9: Information on services to be obtained from the sterilizer manufacturer

Steam	a. the maximum flow and usage rate; b. the acceptable range of steam supply pressures; c. where steam is generated within the sterilizer, the maximum hardness value, the range of pH and the conductivity of the boiler feed water.
Electricity	a. type of supply, e.g. AC or DC; b. number of phases (normally one or three) and whether neutral is required for a 3-phase supply; c. supply voltage and frequency including acceptable minimum and maximum values; d. maximum continuous power in kW or kVA.
Water	a. the minimum and maximum supply pressure; b. the flow at minimum pressure; c. the volume used per cycle; d. the maximum temperature of the water; e. the maximum permissible chlorine and chloride content.
Compressed air	a. the minimum and maximum supply pressure; b. the flow at minimum pressure; c. the volume of air used for each cycle.
Sterilant gas	For EO sterilizers, details of the type of sterilant supply required and the quantity required for a single cycle.
Drainage	a. the maximum flow of effluent (water and condensed steam) to the hospital drain; b. the maximum temperature of the effluent on leaving the sterilizer; c. the sources of effluent contributing to the total outflow.
Ventilation	The following quantities should be given as peak values during the cycle and as average values over a complete cycle: a. the heat (in watts) transmitted to the environment when the sterilizer is operated in a nominal ambient temperature of 23 ± 2°C in still air with the doors closed; b. for a recessed sterilizer, the heat (in watts) transmitted to the loading area when the sterilizer is operated in a nominal ambient temperature of 23 ± 2°C in still air with the doors closed.

6.7 Within the loading area an additional switch should be provided so that the operator can electrically isolate the sterilizer or group of sterilizers in the event of an emergency. The switch should be placed between the normal operating position and the exit door.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.8 Sterilizers used to process heat-sensitive loads should be connected to the essential supplies circuit, if available, to avoid heat damage in the event of a power failure. Guidance on the supply of electricity in the event of a failure of the normal supply is given in SHTM 2011; *Emergency Electrical Services.*

6.9 All electrical installations should conform to the IEE Regulations contained in BS 7671. Further guidance is given in SHTM 2007; *Electrical services: supply and distribution* and SHTM 2020; *Electrical safety code for low voltage systems* (Escode - LV).

Water

6.10 A water supply of potable quality may be needed for equipment such as condensers, heat exchangers and water-sealed vacuum pumps (feed-water for steam generation is discussed in Chapter 7). Details of the water-quality requirements, the maximum pressure, minimum pressure and maximum flow rate should be obtained from the sterilizer manufacturer.

6.11 To prevent possible contamination of the water main, the supply should be connected to the sterilizer via a backflow protection device, such as a break tank.

6.12 The temperature of water used for sterilizers with vacuum systems should not normally exceed 15°C. Higher water temperatures will reduce the efficiency of vacuum pumps and compromise the specified vacuum levels.

6.13 Performance will also deteriorate if the water is very hard or contains large quantities of solids in suspension. The hardness of the water should be in the range 0.7-2.0 mmol litre^{-1}. Hardness values outside these limits may cause scaling and corrosion problems. This can be overcome by the installation of simple water-treatment plant at the sterilizer site.

6.14 Water economy devices, which sense the temperature of cooling water and adjust the flow rate accordingly, should be fitted to reduce water consumption.

6.15 Chlorine and chlorides may cause corrosion of stainless steel in the presence of heat. Advice on maximum permissible levels should be obtained from the sterilizer manufacturer.

6.16 A copious supply of piped water is required for emergency use in any area where a spillage of liquid EO may occur. The supply should be capable of delivering at least 18 litre min^{-1} at a minimum pressure of 1.5 bar.

6.17 Further guidance on water supply is given in SHTM 2027; *Hot and cold water supply, storage and mains services*.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Compressed air

6.18 A compressed-air supply may be required for the operation of controls and also for pressure ballasting in certain fluid and laboratory sterilizers. Where the sterilizer does not contain an integral air compressor (see paragraph 4.43), the air may be supplied from a mains supply or from a local compressor.

6.19 If pressure ballasting is required, additional reservoir capacity or compressors will be needed. The system should be capable of delivering at least 12 m^3h^{-1} at 8 bar.

Mains supply

6.20 If air is supplied by pipeline from a central air-compressor system, a pressure gauge, of the Bourdon type complying with BS EN 837, should be fitted inside the plantroom and terminated with an isolation valve.

6.21 A reducing valve or other automatic device should be fitted to reduce the pressure of the air delivered to the sterilizer to not more than the maximum working pressure of the sterilizer. A pressure relief valve will normally be required.

Local compressors

6.22 Where it is not practicable to obtain compressed air from a mains supply, a dedicated compressed-air facility should be installed to supply the sterilizers and other equipment. At least two compressors should be provided, with autochange between the two. The system should be sized to meet all the compressed air requirements of the unit and give priority to the sterilizers.

6.23 The compressors are likely to be too noisy to be installed in the sterilizer plantroom, and it is better to place them in a dedicated location away from any noise-sensitive areas.

6.24 Components which require servicing or maintenance, such as dryers and filters, should be installed in locations where they can be readily serviced or exchanged.

Air quality

6.25 Quality of air is critical and certain types of sterilizer will incorporate the appropriate filters. If the purchaser is to be responsible for supplying filtered air, note the following points:

a. air for controls should be free of liquid water, filtered to 25 µm (5 µm for precision controls) and lubricated with micro-fog oil particles of 2 µm or less;

b. air that could come into direct contact with the load, such as air for pressure ballasting or door seals, should be filtered to remove contaminating oil-mist and micro-organisms. It should have not more

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

than 0.5 mg of oil per cubic metre of free air (measured at 1013 mbar and 20°C; see IS0 554), be filtered to an efficiency of at least 95% when tested in accordance with BS 3928 and be free of bacteria.

Drainage

6.26 Condensate from the jacket, heat exchangers and steam traps is suitable for recovery and should be returned to the steam generating plant where there are means for recovery.

6.27 All other effluent from a sterilizer is potentially contaminated and should be disposed of to the main drain. Effluent may originate from one or more of the following sources:

a. air, condensate and steam from the chamber drain, which may contain chemicals and micro-organisms, especially those from a make-safe process;

b. discharge from a water-sealed vacuum pump, ejector or chamber vent, which may also contain micro-organisms;

c. water from a chamber cooling system;

d. water introduced to cool and dilute the discharge from the chamber.

6.28 Drainage requirements for different types of sterilizer are summarised in Table 10 and discussed below.

Non-hazardous effluents

6.29 Effluent from steam-only sterilizers should pass via an air break into a tun-dish or tank before being discharged to the drain. The air break should be preserved at all times so that the sterilizer and its associated piping cannot be contaminated by reverse flow from the drainage system. This can be achieved by ensuring that under all working conditions the discharge rate from the tun-dish is such that the maximum flow rate of effluent from the sterilizer will not cause the water level in the tun-dish to rise to the level of the outlet from the sterilizer. For clinical sterilizers the above equipment is normally provided by the manufacturer and contained within the sterilizer itself, but for certain laboratory sterilizers it is the responsibility of the purchaser to install it in the plantroom.

6.30 The drain system from the plantroom should be trapped and designed to pass the flow rate of water, air and condensed steam specified by the manufacturer, with account taken of peak demands during the operating cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 10: Discharge and ventilation requirements for different types of sterilizer

Type of sterilizer	Effluent discharge	Ventilation
LTSF sterilizers	Trapped and vented, sealed to main drain. No open gulleys	General room ventilation ten changes/hour, non-recirculating. Discharge to stack LEV on sterilizer door, Discharge to stack
EO sterilizers	Small - no drainage required Large - Trapped and vented, sealed to main drain. No open gulleys Very large sterilizers may require fan-assisted venting of drain	General room ventilation ten changes/hour, non-recirculating. Discharge to stack Small - chamber exhaust to stack LEV on sterilizer door, aeration facility door and manifold room. Discharge to stack
Laboratory sterilizers	Trapped and vented, sealed to main drain. No open gulleys	General room ventilation, non-recirculating. Filtered discharge for Category 3 and 4 laboratories
Other sterilizers	Direct to main drain	General room ventilation. No special requirements

6.31 Means should be provided to prevent, as far as possible, flash steam being liberated into the atmosphere or causing condensation on electrical equipment.

6.32 The discharge temperature from a steam sterilizer is unlikely to exceed 80°C, but in the event of failure of the diluting and cooling system it might reach 100°C. The materials used for the construction of the drainage system should be chosen to withstand this temperature. Attention is drawn to the legal requirement (Public Health (Scotland) Act 1897 as amended) that the maximum temperature of any liquid to be emptied into the public sewer or communicating drain is 43°C. This may be interpreted as relating to the main building connection to the sewer and not to the internal building drain.

6.33 Where a tank supplies water to a water-sealed vacuum pump or a water pump used for an ejector vacuum system, the overflow discharge from the tank should also include an air break.

Hazardous effluents

6.34 A sealed and vented drain is required for LTSF sterilizers, large EO sterilizers (supplied from cylinders), EO gas disposal units and laboratory sterilizers used to make-safe discard material. Small EO sterilizers (supplied from cartridges) discharge gas only (see paragraph 6.62).

6.35 Chamber drains and vents should have a sealed independent discharge which should be vented and trapped before it is connected to the drainage system. Open tun-dishes should not be used. The vent should be not less than 30 mm in diameter and terminated above roof level, clear of ventilation

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

air inlets or windows. Steam should not issue from the vent. A “Hazardous Discharge” warning notice should be fitted next to it. A similar arrangement should be provided for any safety valves.

6.36 EO is considerably denser than air. For sterilizers with chamber volumes greater than 300 litres there is a risk that the amount of gas discharged into the drainage system could result in pockets of explosive mixtures of EO and air accumulating at the bottom of the vent stack. Although there is no known case of such an explosion in the UK, consideration should be given to installing a fan-driven gas-capture system to draw gas from above the liquid effluent before the liquid is discharged to the main drain. The gas should either be disposed of chemically (see Chapter 13) or discharged at a high level. The vent should meet the requirements of the local exhaust ventilation system (see paragraph 6.61).

6.37 In certain circumstances, such as special research activities involving high concentrations or volumes of pathogens in Hazard Group 3, additional safeguards may be required for laboratory sterilizers. The advice of HSE should be sought in such cases.

6.38 Where a laboratory sterilizer is to be used to make-safe material contaminated with Hazard Group 4 pathogens, further containment, filtration or heat treatment will be necessary. Again, advice should be sought from HSE.

Ventilation

6.39 Ventilation of the area near the sterilizers is needed to remove both excessive heat and odours, and also sterilant gases such as formaldehyde and EO.

6.40 General room ventilation will be sufficient for most sterilizers, but chamber exhaust ventilation will be required for certain small EO sterilizers and local exhaust ventilation will be required to remove local concentrations of EO or formaldehyde. The requirements are summarized in Table 10 and discussed below.

6.41 Electrical systems used in ventilation systems should take account of the explosion risk associated with ethylene oxide and comply with the requirements of BS EN 61010: Part 2-042.

6.42 All ventilation systems should meet the ventilation requirements of the Workplace (Health, Safety and Welfare) Regulations 1992.

6.43 Further guidance on ventilation systems may be found in SHTM 2025; *Ventilation in healthcare premises*.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

General room ventilation

6.44 The air change rate should be related to the heat and vapour emission from the sterilizer and associated equipment and pipework so that working conditions remain acceptable and control equipment is not adversely affected. The ambient temperature in the plantroom with all plant running normally should not be allowed to exceed 35°C at any time.

6.45 Current experience indicates that a 400-litre high-temperature steam sterilizer with door closed will release by radiation and convection approximately 1.0 kW into the loading area and 4.0 kW into the plantroom. Sliding-door machines installed behind a fascia panel with a separate door will release almost all the heat into the plantroom. With the door open, additional heat into the loading area might typically be 3.5 kW for a side-hinged door and 3.0 kW for a sliding door. More specific figures should be obtained from the manufacturer of the sterilizer (see Table 9).

6.46 In designing a ventilation system, account should also be taken of the heat emitted from the sterilized load after it has been removed from the chamber.

6.47 Ventilation air to the plantroom may be taken in either at low level from the loading area or from an independent source and should be discharged to the outside.

6.48 Where the plantroom does not have an outside wall, heat emissions will need to be absorbed by a recirculating cooling unit with remote fan-cooled condensers. The rating of the units should have sufficient reserve capacity to reduce the temperature to 30°C in order to provide a safe and acceptable working environment for staff during maintenance of the plant. Additional plant space is required for the installation of the cooling units.

Room ventilation for LTSF and EO sterilizers

6.49 For LTSF, EO and laboratory sterilizers, the loading area should be maintained at a lower pressure than the main corridor and at a higher pressure than the plantroom. The discharge to the outside should not be sited where the extracted air will be drawn into the building via windows or ventilation inlets.

6.50 Areas containing LTSF or EO sterilizers and aerators should have a dedicated, non-recirculating room-ventilation system which ensures that air movement is from the operator towards the sterilizer both during normal operation and also when local exhaust ventilation (see paragraph 6.54) is operative. During normal operation, exposure to formaldehyde and EO should not be allowed to exceed the exposure limits given in Table 1.

6.51 Room ventilation for LTSF and EO sterilizers should be designed to permit the extraction of the maximum possible leakage of gas within a reasonable time. This requires at least ten air changes an hour. For example, Figure 1 shows the relationship between the volume of a room and the number of air

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

changes required to reduce the concentration of EO to 5 ppm when a standard 134 g cartridge is discharged into the room.

6.52 Sensing devices and interfaces should be provided to ensure that if the room ventilation fails to maintain a rate of flow sufficient to ensure ten air changes an hour:

a. a visual and audible alarm is given;

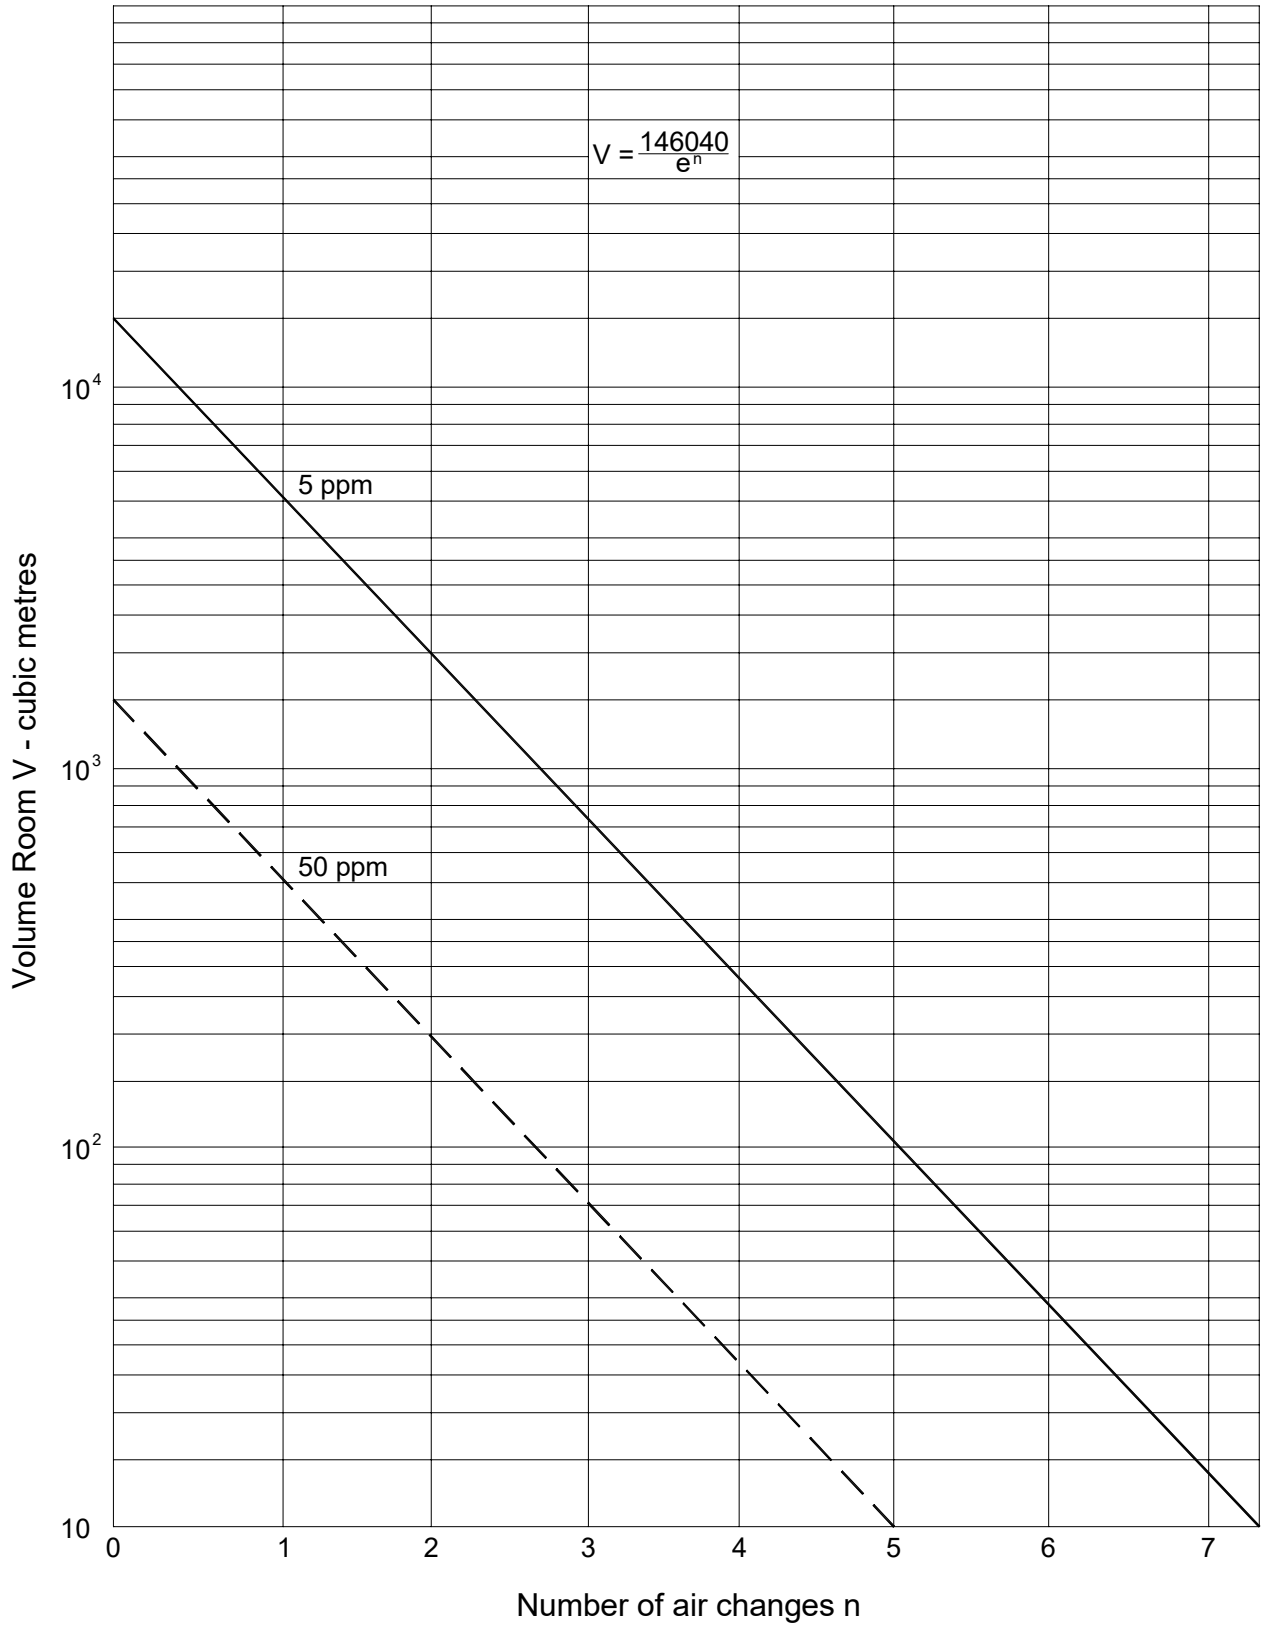
b. where the operating cycle has progressed beyond the point where sterilant has been admitted into the chamber, it is not possible to open the door at the end of the cycle until the room ventilation is restored to normal operation;

c. it is not possible to start a new cycle until the room ventilation is restored to normal operation.

Requirement 6.52(b) may be waived if the load can be transferred from the sterilizer to an aeration facility without gas escaping into the atmosphere. This would normally require a local exhaust ventilation system with a common extractor hood covering both the door of the sterilizer and the door of the aeration facility. If such a system is installed, it should be validated to demonstrate that the specified rates of flow (see paragraph 6.54) can be achieved when the room ventilation is not operating.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 1: Air changes required to reduce the concentration of ethylene oxide to 50 ppm and 5 ppm following the sudden release of 134g of the gas into the workroom



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Local exhaust ventilation

6.54 In addition to the room ventilation, LTSF sterilizers, EO sterilizers and EO aerating equipment should be fitted with an independent local exhaust ventilation (LEV) system having a minimum flow of 0.3 m^3s^{-1} at each extractor hood. The system should have hoods near any place where formaldehyde or EO could be released into the atmosphere; for example, around the doors of sterilizers and aeration cabinets and in the manifold room where cylinders are connected to the EO supply manifold (see paragraph 6.74).

6.55 When activated, the LEV should operate for a preset period of up to 30 min.

6.56 Sensing devices and interfaces should be provided to ensure that the LEV is activated on the following occasions:

a. when the door is ready to be released at the end of an operating cycle;
b. when sterilant cylinders are being changed;
c. on a pressurization failure of inflatable or pressure-activated door seals;
d. whenever the atmospheric concentration of sterilant gas exceeds a preset safe level not greater than the short-term maximum exposure limit given in Table 1.

6.57 Controls should be provided both within and outside the loading area to activate the LEV manually.

6.58 Sensing devices and interfaces should be provided to ensure that if the LEV, when activated, fails to attain or maintain a flow of at least 0.3 m^3s^{-1} :

a. an audible and visual alarm is given;
b. it is not possible to open the door at the end of the cycle until the LEV is restored to normal operation;
c. it is not possible to start a new cycle until the LEV is restored to normal operation.

6.59 Make-up air provision, preferably by indirect means, will be required.

6.60 Ducts designed to carry formaldehyde or EO gas should be maintained under negative pressure, for example by locating the extractor fan at the discharge end.

6.61 The discharge should be above roof level and away from windows, doors and air intakes. This may be the same vent used to discharge gas from the chamber. A “Hazardous Discharge” notice should be fitted next to the outlet. For EO sterilizers supplied from cylinders, the discharge stack should be fitted with a flame arrestor.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chamber exhaust ventilation

6.62 Small EO sterilizers (supplied from cartridges) and EO aerators will require a chamber exhaust ventilation (CEV) independent of the room and LEV systems.

6.63 The CEV for a sterilizer should extract gas from the sterilizer chamber during the gas removal stage and throughout any aeration stage.

6.64 The CEV for an aerator should operate whenever an aeration cycle is in operation. If an aeration room is used, the temperature and ventilation should be controlled within adjustable ranges from ambient temperature to 55°C and nominally zero to ten air changes an hour.

6.65 Interfaces should be provided so that in the event of a failure of the CEV:

a. an audible and visual alarm is given;

b. where the operating cycle has progressed beyond the point where EO has been admitted to the chamber, it is not possible to open the door at the end of the cycle until the CEV is restored to normal operation;

c. it is not possible to start a new cycle until the CEV is restored to normal operation.

6.66 The discharge should be above roof level and away from windows, doors, and air intakes. This may be the same vent used for the LEV. A “Hazardous Discharge” notice should be fitted next to the outlet.

6.67 The CEV alarm circuit should be independent of the mains electricity supply. It is recommended that the CEV system itself be connected to the essential supplies circuit in the event of a mains power failure.

Ethylene oxide gas

6.68 Ethylene oxide gas may be supplied either from disposable cartridges (pure EO) or from cylinders (pure EO or EO mixed with diluent gases). Both the containers and the delivery system are subject to the Pressure Systems Safety Regulations 2000.

Supply from cartridges

6.69 The number of cartridges kept within the plantroom should be limited to those actually in use and those required for immediate stand-by. Cartridges should be stored as described in Part 5 of this SHTM. Cartridges for immediate use may be held in the loading area.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Supply from cylinders

6.70 All pipework intended to carry EO should be in stainless steel. Flexible hoses should be of stainless steel, preferably lined with PTFE or nitrile rubber.

6.71 Cylinders should be stored as described in Part 5 of this SHTM.

6.72 Where EO is stored at a temperature below its normal boiling point (10.7°C) it is essential to exclude air by pressurising the cylinder with nitrogen or other diluent gas. Even when nominally empty of liquid EO, cylinders should be maintained at a minimum pressure of 2 bar. Nitrogen used for pressurising will stay in the gaseous state and will not mix with the liquid EO.

6.73 Fittings to the cylinder, such as valves and pressure gauges, should be protected against mechanical damage. Cylinders should be secured to prevent them falling over or colliding during storage and transport.

6.74 Cylinders should be connected to the sterilizer supply line in a dedicated manifold room separate from the plantroom. The room should not have direct access from the loading area. The manifold room should meet the requirements of SHTM 2022. Local exhaust ventilation should be installed as described in paragraph 6.54.

6.75 A duty and a reserve cylinder should each be connected to a common gas manifold via a manual stop valve, at least one automatic stop valve, and a vent with a stop valve (for use during cylinder change and inert gas purging). These are in addition to the valve on the cylinder itself. The system should be designed and constructed to allow only one cylinder at a time to supply gas to the sterilizer. An indicator should show which cylinder is being used.

6.76 Each cylinder should be located on weighing scales with sufficient tare capacity for the largest cylinder expected to be used. The scales should be accurate enough to determine the mass of gas admitted to an accuracy of ± 1% of the mass of gas required to fill the empty chamber to the preset operating pressure. Recording scales are preferable, since the data obtained may be used in the routine monitoring of the operating cycle.

6.77 An automatic change-over facility is recommended so that the reserve cylinder can be brought on-line without interruption of the supply. An electrical signal from the weighing scales may be used to determine when the duty cylinder is nearly empty and to initiate the change-over automatically.

6.78 The temperature of the cylinders should not be allowed to exceed the maximum stated by the supplier, and in any case not more than 45°C. The temperature of the manifold and supply line should be kept above 11°C to prevent EO condensing inside the pipework.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

6.79 The number of cylinders kept within the manifold room should be limited to those actually in use and those required for immediate stand-by.

6.80 Cylinders of an inert gas such as nitrogen should be available for purging the pipework before maintenance and testing.

NHSScotland Property and Environment Forum

7. Steam supply

Introduction

7.1 A continuous supply of saturated steam is required for steam sterilization, low-temperature steam and formaldehyde (LTSF) sterilization and for humidification in certain ethylene oxide (EO) sterilizers and EO preconditioning units.

7.2 The critical variables are the dryness of the steam (expressed as a dryness value) and the level of non-condensable gases (expressed as a fraction by volume). Before a newly installed or replaced sterilizer is handed over to the user, the steam supply should be examined and tested by the methods described in Part 3 of this SHTM to ensure that it is satisfactory.

7.3 Users should note that where the steam is supplied from the mains, quality can vary greatly during the course of a working day. In many hospitals, steam demand is greatest early in the morning when sterile service departments (SSDs), kitchens and laundries may start work at the same time. Care should be taken to sample the steam at times throughout a typical working day to gauge the likely range of steam quality.

7.4 Where a sterilizer is to be used in the aseptic production of medicinal products, the steam should also be free of pyrogens. Details on the supply of apyrogenic steam can be found in SHTM 2031; *Clean steam for sterilization.*

7.5 BS EN 554 and BS EN 285 provide guidance on the chemical quality of steam and quality of environment in contact with a medical device. Further guidance on steam quality can be found in SHTM 2031; *Clean steam for Sterilization*.

Engineering considerations

7.6 Except where the steam is generated within the chamber (such as in transportable sterilizers), steam is generally obtained from the hospital mains and the delivery of high-quality steam depends on careful engineering.

7.7 Occasionally, suitable steam may be available from the high-pressure hot-water systems used in some hospitals. Steam from this source is not recommended for porous-load sterilizers since the steam is generally too wet for reliable sterilization, even with a recommended minimum return temperature of 150°C.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Capacity

7.8 The steam service should be designed to meet the maximum steam demand of the sterilizer for short periods, while keeping the fall in pressure before the final pressure-reducing system to not more than 10%. Experience shows that a single porous-load sterilizer of up to 600 litres requires a boiler of at least 50 kW and storage to meet a peak demand of 125 kW for 15 min. The effect on the steam supply of the demands of other sterilizers and equipment should be carefully considered.

Pipework

7.9 Except for vertical rises between floors, steam pipework should be designed so that any condensate flows by gravity in the same direction as the steam. This general principle applies equally to steam mains, branch connections and pipework on the sterilizer itself. Air vents and steam traps should be fitted at each vertical rise. Care should be taken to trap, drain and return any condensate which may be collected in pockets in the pipework. Dead-legs should be avoided.

7.10 The accumulation of condensate in the periods when the sterilizer is not in operation should be avoided, particularly in any part of the pipework and fittings between the take-off from the manifold and the sterilizer chamber. This can be achieved by the correct declination of each portion of pipework and by adequate trapping throughout the steam distribution system.

7.11 Figure 2 shows a suggested layout for the steam service in the plantroom. The supply main should terminate in an adequately vented and trapped manifold, not less than 150 mm nominal bore, running the entire length of the room (this provides for future expansion). A vent, with a cooling pot, should be installed on the manifold upstream of the supply pipes to individual sterilizers. A pressure gauge should be fitted to the manifold.

7.12 Where the supply pressure at the inlet to the sterilizer would exceed the maximum value specified by the manufacturer, a pressure-reducing system and separator should be fitted to the supply pipe at least 3 m from the sterilizer. Heat loss from the section between the pressure-reducing system and the sterilizer will help prevent superheating (paragraph 7.24).

7.13 If the sterilizer manufacturer has not already fitted them, an appropriate and correctly installed separator and steam trap should be fitted upstream of the sterilizer reducing valve.

7.14 Three suitable test connections should be provided on the supply pipe to each sterilizer to permit the attachment of a needle valve, a pitot tube and a temperature sensor as shown in Figure 2. (Details of the use of these items can be found in Part 3 of this SHTM.)

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

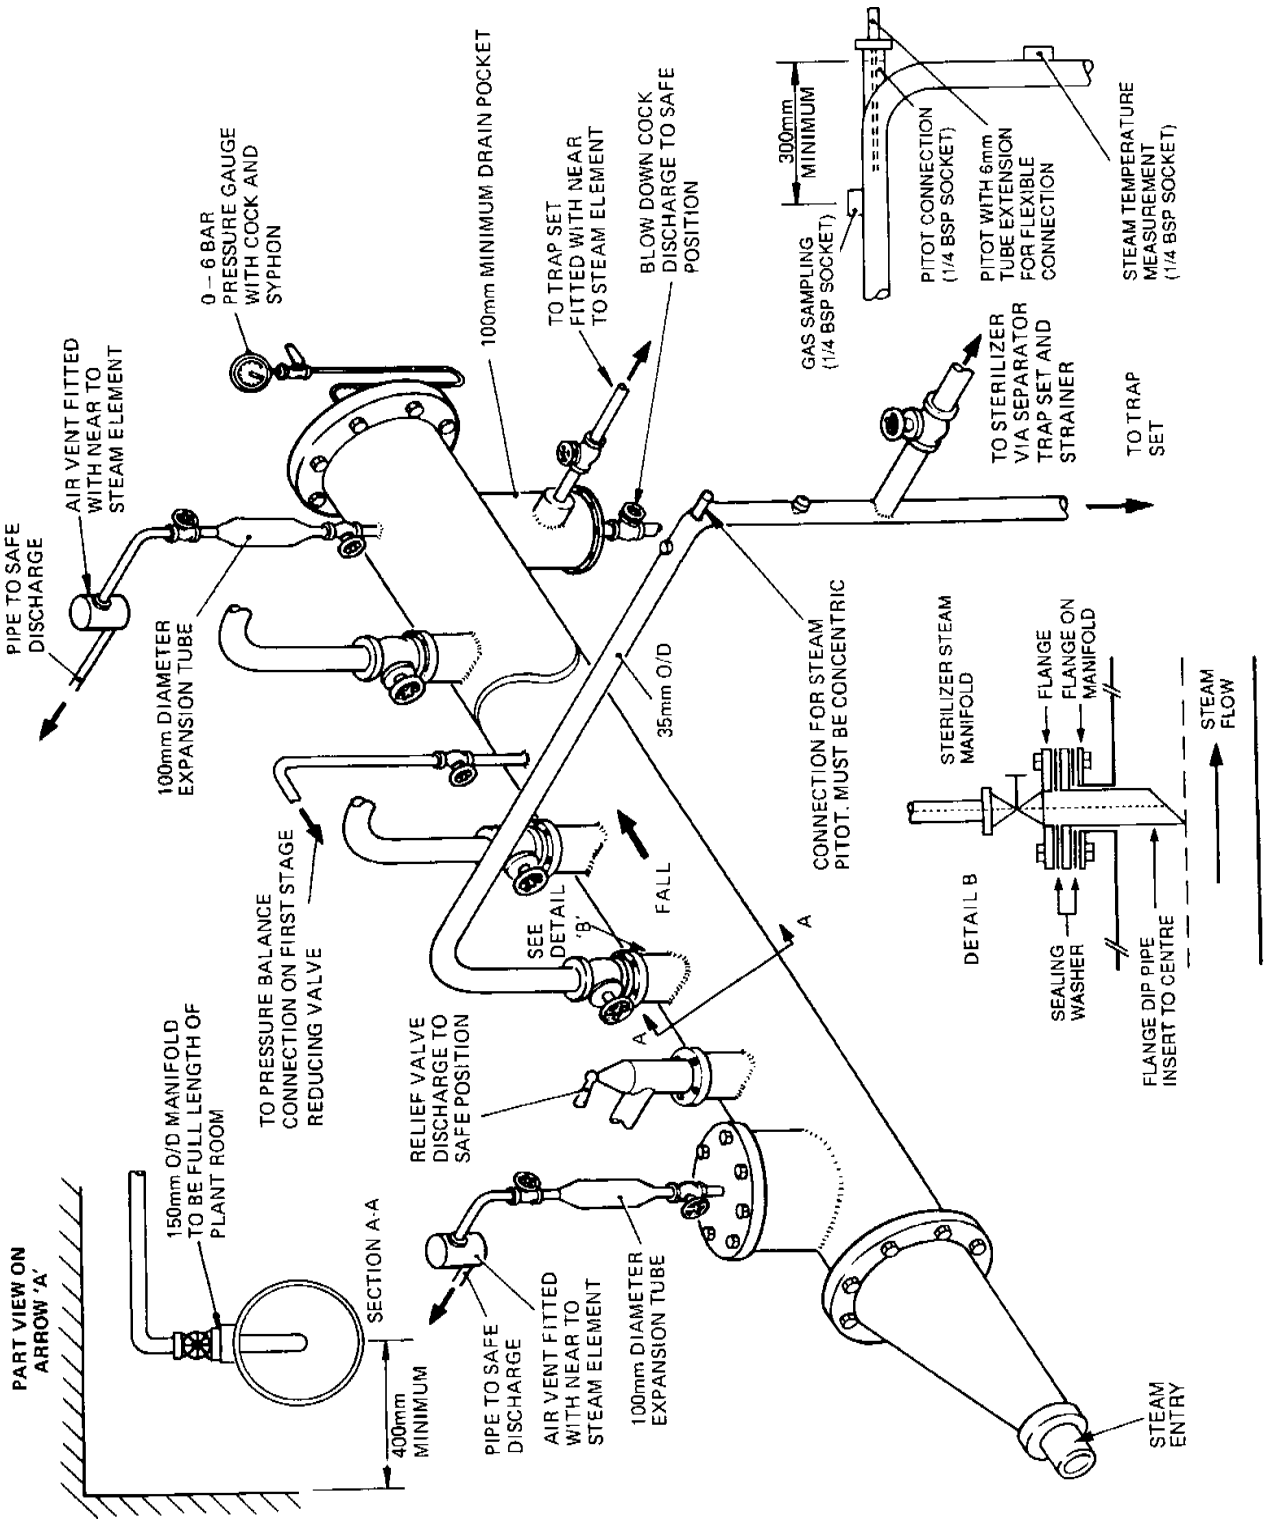
7.15 Careful attention should be paid to the location of all pressure relief valves to ensure that the sterilizer is properly protected. Relief valves and their discharge pipes should be large enough to prevent the pressure in the supply pipe rising to more than 10% above the design pressure for the sterilizer. The discharge pipe should terminate outside the building in a safe, visible position not affected by frost. Any rising discharge pipe should be fitted with a drain at the lowest point to prevent the accumulation of condensate. A tell-tale pipe of narrow bore should be connected to the drain point and terminate inside the plantroom.

Materials

7.16 Steel and copper piping have traditionally been used for steam supply, but these materials will not be acceptable if compliance with the EU Directives on medical devices is required. Suggested minimum standards for steam purity are given in BS EN 285 (analytical methods for testing for these impurities, including tests for pyrogens, is included in SHTM 2031), but these are unlikely to be achieved with plant currently installed in the UK. Moreover, steam of such purity would be severely corrosive to the steel and copper piping in the majority of sterilizers in use in the NHS.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 2: Layout of steam service in the plantroom



© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.17 To meet the suggested purity standard for clinical sterilizers it will be necessary for parts in contact with steam entering the chamber to be constructed from low-carbon or stabilised stainless steel. However, in designing a steam service purchasers should bear in mind that the steam service (and indeed the sterilizer itself) may need to be upgraded within the life of the sterilizer and that compliance for steam purity may be achieved at that stage. Until the detailed implications of the Directives are known, it is recommended that steel and copper piping continue to be used, but that space be reserved in the plantroom for a mains steam conditioning unit. A space approximately 1.5 m square by 2.0 m high will accommodate a unit capable of supplying two 600 litre porous-load sterilizers.

Dryness

7.18 The dryness of the steam is of vital importance to the performance of any steam sterilizer. Excess moisture may cause damp loads in porous materials and uneven temperature distributions in non-porous loads, particularly those containing a large number of small items such as ampoules. When steam is required to be in direct contact with the surface to be sterilized, such as in porous-load sterilizers, sterilising conditions may not be attained if the moisture contained in the steam supply is insufficient to prevent the steam from becoming superheated when expanding into the chamber.

7.19 Steam dryness is traditionally characterised by a “dryness fraction”, but this is not appropriate for sterilizers because the method of measurement is difficult and requires a constant flow of steam. The low-volume sampling technique described in the steam dryness test (Part 3 of this SHTM) cannot be regarded as measuring a true dryness fraction because the sample is taken from the centre of the steam supply pipe and condensate flowing along the pipe wall is not collected. Consequently the term “dryness value” is used, where 1.0 represents dry, saturated steam. This method is used to determine whether performance problems could occur during testing and routine production. It is suitable for sterilizer installations because control valves and pipe services fitted to the sterilizer considerably reduce the amount of condensate entering the sterilizer chamber such that the sample has a similar amount of free condensate to the steam in the chamber.

7.20 European Standards require that sterilizers be designed to operate with steam having a dryness value of not less than 0.9 when measured in accordance with the steam dryness test described in Part 3 of this SHTM. For metal loads, the dryness value should not be less than 0.95. In practice, problems are unlikely to occur if the dryness value lies between 0.9 and 1.0, if it is reasonably constant and if the pressure reduction through the final pressure-reducing system is of the order two to one.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

7.21 Although experience has shown that acceptable conditions are sometimes achieved when optimum conditions do not prevail, significant deviations are likely to cause the following problems:

a. wet loads, resulting from too low a dryness value;

b. superheating, resulting from either too high a dryness value before the pressure-reducing system, or excessive pressure reduction through the valve (superheating may be severe if both conditions are present simultaneously);

c. difficulties with operation of the pressure-reducing system, resulting from a low pressure-reduction ratio, water hammer, water logging, dirt and other carry-over.

Excessive moisture

7.22 Excessive moisture, where droplets of water are present at the same temperature as that of the steam, will cause wet loads in porous-load sterilizers, low-temperature steam (LTS) disinfectors and LTSF sterilizers. It will reduce formaldehyde concentration in LTSF sterilizers and impair the efficacy of the process. Humidification may be impaired in EO sterilizers. Some causes of wet loads are as follows:

a. steam pipes or manifolds may be incorrectly sloped and drained;

b. the sterilizer may be supplied from an inadequately drained and vented “dead-leg” rather than a live steam main;

c. the pipework between the boiler and the sterilizer may be insufficiently insulated, causing excessive condensation of the supply steam.

7.23 If wet steam continues to be a problem, “priming” may be occurring in the boiler, causing water droplets to be delivered in the steam. Modern compact and high rated boilers and steam generators are particularly sensitive to the quality of feed-water treatment and are much more likely to prime than boilers of traditional design. Priming or foaming (which results in carry-over of the boiler water) may be caused by any of the following:

a. incorrect feed-water treatment;

b. boiler water level being set too high;

c. forcing a boiler which needs internal cleaning;

d. violent boiling under fluctuating load conditions;

e. a high level (typically 2000 ppm) of total dissolved solids.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Superheating

7.24 Superheated steam is an unsuitable medium for moist heat sterilization and can cause failure to sterilise, scorching of textiles and paper and rapid deterioration of rubber. Superheat conditions within the load and chamber may result from adiabatic expansion, exothermic reaction or both.

7.25 European Standards require that the superheat in free steam at atmospheric pressure should not exceed 25°C when measured by the superheat test described in Part 3 of this SHTM.

7.26 Superheating caused by **adiabatic expansion** is usually the result of an excessive reduction in pressure through a throttling device, such as a pressure-reducing system or a partially closed main steam valve. It is unlikely to be of significance in the circumstances normally encountered in hospital steam distribution systems, but superheating may arise if the main steam supply is dry, or the pressure is unusually high before the throttling device. This superheat can sometimes be avoided by the measures described in paragraph 7.12, which will reduce the dryness value of the steam at the inlet to the sterilizer pressure-reducing system. The reduced pressure ratio will minimise the effect of the expansion through it.

7.27 Superheating arising from **exothermic reaction** may occur during sterilization as a result of rehydration of exceptionally dry hygroscopic material. Methods of avoiding this are described in Part 4 of this SHTM.

Non-condensable gases

7.28 Non-condensable gases (NCGs) are defined as gases which cannot be liquefied by compression under the range of conditions of temperature and pressure used during the sterilization process. Low levels of NCGs contained in steam supplied to sterilizers can markedly affect the performance of the sterilizer and the efficacy of the process, cause chamber overheat and lead to inconsistencies in the performance of air detectors and failure of the Bowie-Dick test (see Part 3). The major NCGs are air and carbon dioxide.

7.29 British and European Standards require that sterilizers be designed to operate with steam having a fraction of NCGs not exceeding 3.5% by volume when measured by the method described in the non-condensable gas test (see Part 3).

7.30 The main source of NCGs in the steam supply is the boiler feed-water and the level will be greatly influenced by the water treatment employed. In some cases a study by a water treatment specialist will be necessary. The study should cover analysis of the water, venting and the blow-down regime required in order to ensure protection of the boiler against corrosion whilst minimising the entrainment of NCGs in the steam supply.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.31 If anti-foaming agents and oxygen-scavenging agents (such as sodium sulphite) are used it is essential to ensure that the dosages are accurate.

7.32 Water-softening treatment is required to prevent the formation of scale. Except in hard water areas, a simple base-exchange system may be adequate in which bicarbonate ions are effectively converted into sludge-forming carbonates. This releases carbon dioxide into the water. A properly managed blow-down regime is essential to remove the accumulated sludge.

7.33 The most effective way of driving off dissolved air, carbon dioxide and other NCGs is by degassing the boiler feed-water before use by heating in a vented tank (a hot well). This will also break down bicarbonate ions, driving off further carbon dioxide. For the degassing to be effective, it is important that the temperature of the feed-water does not fall below 80°C at any time. The following measures should be adopted:

a. pipework returning condensate to the hot well should be well lagged to keep the condensate hot;

b. the amount of cold make-up water in the hot well should at no time exceed 15% (the rest being returned condensate) since new water will both lower the temperature and introduce further NCGs;

c. the water in the well should be kept well mixed; this may be achieved by locating the feed-water inlet on the opposite side of the tank from the outlet, and by arranging for the feed-water to be “sparged” from the inlet through a number of small openings.

7.34 In very hard water areas the level of NCGs may still be high despite these measures, and dealkalisation treatment of the feed-water may then be necessary. In such cases the maintenance of high temperatures in the hot well is even more critical. Treatment with filming amines should be avoided since this method requires careful control and monitoring.

7.35 Users should note that, even with a well-designed system, the level of NCGs can be affected by competing demands on the steam service. For example, where a central steam boiler supplies both a sterilizer unit and a laundry through the same distribution system, the level of NCGs in the steam at the sterilizer may rise when the laundry demand is high. This is the result of an influx of cold make-up water into the hot well. Paradoxically, in some installations the NCG level may also rise when steam demand is low. In this case NCGs which would normally be removed by the laundry are being carried through to the sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

7.36 Some other causes of the presence of NCGs in the steam are as follows:

a. the boiler may be priming (paragraph 7.23);

b. air may be being drawn into the system either through the boiler feed-pump glands or through a leak in the steam pipework between the boiler and the sterilizer;

c. steam pipework may be inadequately vented;

d. where NCGs are found in the sterilizer chamber during a production cycle:

   (i) there may be an air leak into the chamber;

   (ii) packaging materials, for example certain boxes, inks, adhesives, labels or trays, may be liberating gases. See Part 4 for guidance on packaging materials.

8. Porous-load sterilizers

Introduction

8.1 This chapter discusses specifications for clinical sterilizers designed to process porous items such as towels, gowns and dressings; and medical and surgical equipment, instruments and utensils that are packaged or wrapped in porous materials such as paper or fabrics. Clinical sterilizers using high-temperature steam to process porous loads are commonly known as “porous-load sterilizers”.

8.2 The guidance given here assumes that the sterilizer is to be used to process medical devices in compliance with the Standards discussed in Chapter 1.

8.3 Sterilization is achieved by direct contact of the load items with good-quality saturated steam at a preferred sterilization temperature of 134°C (see Table 4).

8.4 Porous-load sterilizers are distinguished from other high-temperature steam sterilizers by the following features:

a. as porous loads trap both air and moisture, the sterilizer has a vacuum system to ensure that sufficient air is removed from the chamber and load before steam is admitted to the chamber. It also ensures that the pressure during the drying stage is sufficiently reduced so that the load is sensibly dry on completion of the cycle;

b. an air detector is fitted to the chamber to ensure that the plateau period cannot start until sufficient air has been removed from the chamber and load (see paragraph 8.7);

c. a heated jacket is generally used to prevent condensate from forming on the chamber walls and to assist drying of the load.

Standard specifications

8.5 Porous-load sterilizers should conform to the specifications in BS EN 285 and the safety specifications in BS EN 61010: Part 2-041.

Additional specifications

8.6 The following specifications are additional to those in BS EN 285 and permitted as options.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Air detector

8.7 BS EN 285 requires means to be provided to ensure that the requirement for steam penetration throughout the chamber and load is achieved for each cycle. The most reliable way to do this is to specify an air detector to ensure that the plateau period cannot commence if sufficient air and other non-condensable gases have not been removed from the chamber. The correct functioning of the air detector is crucial to the performance of the sterilizer.

8.8 Although an air detector is not required by BS EN 285, there is no other proven means of assuring that air is not present during production cycles. (The quantity of air sufficient to cause a failure of a sterilization cycle is small and for this reason the comparison of pressure and temperature within the chamber is by itself an unacceptable alternative.) An air detector is the most cost-effective way of ensuring that the sterilization conditions established during validation continue to apply.

8.9 If an air detector is not fitted, microbiological testing as described in BS EN 285 will be required, along with more frequent periodic testing and more demanding performance qualification. This option is expensive.

Port for air-flow metering device

8.10 A quarter-inch BSP port should be fitted on the side of the sterilizer, preferably towards the lower front, for the attachment of an air-flow metering device used for testing air-detector performance and chamber integrity (see Part 3).

Absolute pressure indicator

8.11 For leak-testing purposes an absolute pressure indicator (0 to 160 mbar) should be fitted, conforming to clause 6.2.2.2 of BS EN 285.

Bowie-Dick test cycle

8.12 Sterilizers for use in the NHS should be provided with a Bowie-Dick test cycle.

Extended drying

8.13 An additional cycle with extended drying time should be provided to process loads which are difficult to dry.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9. Fluid sterilizers

Introduction

9.1 This chapter discusses specifications for clinical sterilizers designed to sterilise aqueous fluids in sealed containers (normally bottles) of either glass or plastic. Such sterilizers are commonly known as “fluid sterilizers”.

9.2 The guidance given here assumes that the sterilizer is to be used to process medicinal products in compliance with the GGMP and EU Directives discussed in Chapter 1.

9.3 Sterilization is achieved by direct contact of the load items with a heating medium, normally good-quality saturated steam, and then by heat transfer through the container to increase and maintain the product at a preferred sterilization temperature of 121°C (see Table 4).

9.4 Fluid sterilizers are distinguished from other high-temperature steam sterilizers by the following features:

a. a thermal door lock is fitted to ensure that when glass containers are being processed the door cannot be opened until the temperature inside all the containers has fallen below 80°C: this prevents the containers fracturing due to thermal stress;

b. operating cycles for plastic containers allow the door to be opened when the temperature inside the containers has fallen below 90°C: this prevents “blooming” of the containers;

c. cooling is usually by means of a water spray. The water may be either derived from steam condensate collected in the chamber or sterile water fed in from outside;

d. during all or parts of the cycle air may be introduced into the chamber to prevent large pressure differences arising between the inside and outside of containers; this is known as “pressure ballasting” (see paragraph 9.8).

Standard specifications

9.5 Fluid sterilizers intended for the sterilization of fluids in sealed rigid containers (glass bottles) should conform to the specifications in BS 3970: Parts 1 and 2 and the safety specifications in BS EN 61010: Part 2-041. See paragraph 9.8 for additional specifications for flexible (plastic) containers.

9.6 A European Standard for fluid sterilizers is being planned.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Additional specifications

9.7 The following specifications are in addition to those in BS 3970: Parts 1 and 2.

Cycle for plastic containers

9.8 Where the sterilizer is to be used to process plastic containers, a modified operating cycle may need to be specified. This is similar to the standard glass cycle but with the following modifications:

a. pressure ballasting should be used to prevent pressure differences arising between the inside and the outside of containers sufficient to burst or distort them;

b. the design pressure for the sterilizer chamber should be at least 10% higher than the allowable pressure; the operating pressure will typically be 3.3 bar gauge for a sterilization temperature of 121°C;

c. the thermal door lock (9.4a) should be set so that the door cannot be opened until the temperature of the fluid in all the containers has fallen below 90°C.

9.9 If loads consisting solely of plastic containers are to be processed infrequently, then it may be better to specify a single cycle suitable for both glass and plastics (rarely used cycles may not be reliable). In that case the thermal door lock should be set so that the door cannot be opened until the temperature of the fluid in all the containers has fallen below 80°C.

Heat exchanger

9.10 The design of the coolant system should be such that, whenever a single fault occurs in the coolant system, the quality of all water in contact with the load complies with the requirements of the full-load test described in Part 3 of this SHTM. One example is a system whereby during any part of each operating cycle the primary coolant pressure is known to be less than the pressure external to each load container.

9.11 Connections for a pressure test gauge should be provided so that measurements can be made of:

a. the pressure in the primary circuit;

b. the differential pressure between the primary and secondary circuits.

Monitoring and control by F_0

9.12 F_0 is a measure of the “lethality” delivered to a load throughout an operating cycle, including the heating and cooling stages. It is expressed as a time in minutes equivalent to a continuous period at 121°C. Guidance on the use of F_0 is given in Part 4 of this SHTM and an extensive discussion of the theory and applications of F_0 can be found in Part 5.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

9.13 F_0 may be used instead of the standard time - temperature relationships given in Table 4 to determine whether sterilization conditions have been achieved. When F_0 measured inside the load attains a certain value (normally 8 min or more) the load may be deemed to be sterile. It is particularly useful for heat-sensitive loads that can withstand the heat received during the prescribed holding time, but not the additional heat received during the heating and cooling stages, or for loads which would not survive a second operating cycle.

9.14 F_0 may be used either to monitor or to control an operating cycle:

a. where monitoring is required, a recorder displays the accumulated F_0 throughout the operating cycle. This facility may be useful in borderline cases where the batch process record falls just outside the permitted tolerances established during performance qualification. Quality control procedures may then permit heat-sensitive products which would not survive resterilization to be released provided that the required F_0 has been attained;

b. where control is required, the holding time continues until the required F_0 is attained.

9.15 Sterilizers monitored by F_0 should be equipped with a load temperature probe to be inserted into the container of the load known to receive the lowest F_0 The probe should be connected to a recorder displaying accumulated F_0 throughout the cycle.

9.16 Sterilizers controlled by F_0 should have at least two load-temperature probes to be inserted into two containers of the load known to receive the lowest F_0. The probe showing the lowest accumulated F_0 at any instant should be used to control the cycle.

9.17 The recorder should display accumulated F_0 computed from the following equation:

$$F_O = \Delta t \sum_i log^{-1}\left[\frac{T_i - 121}{10}\right]$$

where:

Δt = sampling interval;

T_i = temperature of sample *i*.

9.18 The sampling interval, Δt, should be not greater than two seconds.

9.19 The precision and accuracy of the measuring and computing equipment should be such that the performance requirements given in BS 3970: Part 2 can be met.

9.20 If an F_0 system is to be specified, then the responsibility is on the user to determine the nature of the bioburden in the load and also to determine that

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

the proposed cycle will ensure that the probability of survival of micro-organisms on any given load item does not exceed 10^{-6}. Guidance on how to do this is given in Part 4 of this SHTM.

9.21 Whenever F_0 is used either to control the operating cycle or to influence product release, it should be part of a complete quality assurance system and the validation and routine control subject to independent assessment by the licensing authority.

9.22 The GGMP (see paragraph 1.9) requires validation and control of equipment and processes. Any computer software used to determine the F_0 delivered to the product should also be validated and any modifications controlled.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

10. Sterilizers for unwrapped instruments and utensils

Introduction

10.1 This chapter discusses specifications for clinical sterilizers designed to process unwrapped solid instruments and utensils intended for immediate use.

10.2 The guidance given here assumes that the sterilizer is to be used to process medical devices. However, these sterilizers do not meet the essential requirements of the EU Directives discussed in Chapter 1, which do not permit the supply of unpackaged sterile medical devices.

10.3 Sterilization is achieved by direct contact of the load items with good-quality saturated steam at a preferred sterilization temperature of 134°C (see Table 4).

10.4 Sterilizers for unwrapped instruments and utensils are distinguished from other high-temperature steam sterilizers by the following features:

a. air is removed from the sterilizer by passive displacement, either downward or upward depending whether the steam is supplied externally or generated internally. These sterilizers should therefore not be used to process either wrapped instruments and utensils or unwrapped instruments and utensils with narrow lumens which could inhibit the removal of air and the penetration of steam. Such items should be processed in a porous-load sterilizer (see Chapter 8);

b. except where vacuum is used to dry the load (normally in larger, fixed sterilizers), the load is partially dried by natural evaporation after it has been removed from the chamber;

c. since the sterilized items are exposed to the air on being removed from the chamber, they are susceptible to rapid recontamination. These sterilizers are therefore suitable for clinical use only within the immediate environment in which the load items are to be used.

10.5 Where practicable, instruments and utensils should be wrapped and processed in a porous-load sterilizer.

10.6 Sterilizers for unwrapped instruments and utensils may either be transportable or fixed.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Transportable sterilizers

10.7 The majority of sterilizers are transportable (bench-top) models which are electrically heated, requiring only a 13 A socket outlet and no piped services. They are commonly used in theatre suites where there is no SSD service and in primary health care units, such as GP and dental practices.

10.8 Steam is generated within the sterilizer chamber and a supply of distilled, deionised or reverse-osmosis water is required. Tap water should not be used as it may cause scaling and chlorine dissolved in the water may corrode the chamber.

10.9 Certain machines, known as “flash” sterilizers, operate at 150°C with a holding time of a few seconds. Although they are intended for rapid sterilization of unwrapped instruments and utensils, the time saved in sterilization is lost in waiting for the load to cool. They do not conform to BS 3970 (see paragraph 10.11) and their use is not recommended.

Fixed sterilizers

10.10 Fixed sterilizers are generally discouraged, but may be installed in an operating theatre to replace existing fixed sterilizers where supply from a porous-load sterilizer is impracticable.

Standard specifications

10.11 Transportable sterilizers for unwrapped instruments and utensils should conform with the specifications in BS 3970: Parts 1 and 4 and the safety specifications in BS EN 61010: Part 2-041. A European Standard on “small” sterilizers (less than one module) is under development and will eventually supersede the relevant clauses of BS 3970.

10.12 Fixed sterilizers should meet the performance requirements of BS 3970: Parts 1 and 4.

Additional specifications

10.13 The following specifications are permitted as options to those in BS 3970: Parts 1 and 4.

Operating cycle

10.14 A transportable sterilizer should have a single operating cycle. Option A of BS 3970: Part 4 (134-138°C) is recommended for NHS use. Some sterilizers may be equipped to provide other optional operating cycles, specified by the purchaser, but the selection of the cycle should be by means of a key, code or tool not available to the operator.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Temperature recorder

10.15 A temperature recorder is optional in BS 3970: Part 4 but is recommended where documented evidence of correct functioning is required.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

11. Dry-heat sterilizers

Introduction

11.1 This chapter discusses specifications for clinical sterilizers designed to sterilise load items by exposure to hot, dry air. Such sterilizers are correctly known as “dry-heat sterilizers” and sometimes as “hot-air sterilizers” or “sterilising ovens”. They are intended to process materials such as oils, powders and some ophthalmic instruments, which can withstand high temperatures but are likely to be damaged or not sterilized by contact with steam.

11.2 The guidance given here assumes that the sterilizer is to be used to process either medicinal products or medical devices in compliance with the EU Directives discussed in Chapter 1.

11.3 Sterilization is achieved by direct contact of the load items with hot, dry air at a preferred sterilization temperature of 160°C (see Table 4).

11.4 Purchasers should be aware that, owing to the low thermal conductivity of air, it is difficult to obtain an even temperature distribution within the chamber and heat transfer from the air to the load can be very slow. A complete cycle, including assisted cooling to 80°C, takes approximately five hours for a full test load as described in Part 3 of this SHTM.

11.5 Dry-heat sterilizers are not suitable for use as drying cabinets (see BS 2648 for specifications for drying cabinets).

Standard specifications

11.6 The only British Standard covering dry-heat sterilizers was BS 3421: 1961, which has long been inadequate and is now withdrawn. There are no immediate plans for future British or European Standards covering dry-heat sterilizers. In the absence of a current standard, dry-heat sterilizers should conform to Model Engineering Specification C14 published by NHS Estates and to the safety specifications in BS EN 61010: Part 2-043.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Additional specifications

11.7 The GGMP requires dry-heat sterilizers to have the following characteristics:

a. air should be circulated within the chamber to promote a uniform temperature distribution;

b. positive pressure should be maintained inside the chamber to prevent the entry of non-sterile air;

c. any air admitted to the chamber should be passed through a bacteria-retentive filter.

12. Low-temperature steam disinfectors and low-temperature steam and formaldehyde sterilizers

Introduction

12.1 This chapter discusses specifications for clinical disinfectors and sterilizers designed to process heat-sensitive items (wrapped or unwrapped) which will withstand saturated steam at temperatures up to 80°C.

12.2 The guidance given here assumes that the sterilizer is to be used to process medical devices in compliance with the EU Directives discussed in Chapter 1. Low-temperature steam and formaldehyde (LTSF) is not listed in the GGMP as a suitable method for sterilization of medicinal products.

12.3 Disinfection is achieved by the direct contact of the load items with good-quality saturated steam at a disinfection temperature of 71°C at sub-atmospheric pressure ("LTS disinfectors"). Sterilization is achieved by contact with both saturated steam and formaldehyde gas ("LTSF sterilizers"). Sterilizers designed for LTSF will normally incorporate an LTS disinfection cycle.

NOTE: Despite their name, LTSF sterilizers are disinfectors.

12.4 Formaldehyde is a toxic gas. Exposure to formaldehyde is controlled by the COSHH Regulations 1999 and subject to the maximum exposure limits detailed in Table 1. Operational safety information is given in Part 4 of this SHTM.

12.5 LTS disinfectors and LTSF sterilizers operate for the whole of the cycle with the chamber pressure below atmospheric pressure. An air leak rate which is too small to affect the efficacy of a porous-load process may in the case of LTS and LTSF cause an unacceptable volume of air to enter the chamber. Air detectors currently available cannot reliably detect at negative pressures, so as an alternative manufacturers now include a vacuum leak monitor, set to fail the cycle at a leak rate not exceeding 5.2 mbar min^{-1} (see the vacuum leak monitor test in Part 3 of this SHTM). A vacuum leak monitor is less effective than an air detector.

12.6 Since the sterilization process is ultimately dependent on chemical action, microbiological test methods are required to confirm that sterilization conditions have been attained (see Part 3).

12.7 LTSF sterilizers require special precautions for ventilation and drainage (see Chapter 6).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Standard specifications

12.8 LTS disinfectors (or LTSF sterilizers with an LTS cycle) should conform to the specifications in BS 3970: Parts 1 and 5. LTSF sterilizers should conform to the specifications in BS 3970: Parts 1, 5 and 6 and the safety specifications in BS EN 61010: Part 2-042.

12.9 No European Standards are currently planned for LTS disinfectors or LTSF sterilizers.

Additional specifications

12.10 The following specifications for LTSF sterilizers are in addition to those given in BS 3970: Parts 1 and 6.

Room ventilation

12.11 The sterilizer manufacturer should supply the appropriate interfaces to enable the sterilizer to function with the room ventilation system as described in Chapter 6.

Local exhaust ventilation

12.12 LTSF sterilizers should be connected to a local exhaust ventilation system (LEV) to ensure that the emission of formaldehyde gas into the atmosphere does not present a safety hazard. The sterilizer manufacturer should supply the appropriate hoods and interfaces to enable the sterilizer to function with the LEV system as described in Chapter 6.

Formalin supply

12.13 The formalin reservoir within LTSF sterilizers should be installed in a sealed, recessed enclosure protected from mechanical damage. The means of attachment of the reservoir should minimise the possibility of spillage. The top of the reservoir should be no more than 1.5 m above floor level.

12.14 An indicator, visible from the front of the sterilizer, should show:

a. how much formalin has been used in the current cycle;

b. how much formalin remains in the reservoir.

Degassing facilities

12.15 A space or room should be allocated for the aeration and storage of processed loads. Load items do not normally absorb formaldehyde and providing the gas removal is satisfactory, the load may be placed in the downstream part of the ventilation flow in a designated area of the finished goods store.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Gas monitoring system

12.16 Gas detectors should be placed wherever there is a risk of people being exposed to formaldehyde. Such places would normally include both the loading area and plantroom. The detectors should be placed close to the normal working positions of personnel. The monitoring system should be set to sound a visual and audible alarm when the atmospheric concentration of formaldehyde exceeds a preset level no greater than the short-term maximum exposure limit specified in Table 1.

12.17 Interfaces with the ventilation systems will also be required as discussed in Chapter 6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13. Ethylene oxide sterilizers

Introduction

13.1 This chapter discusses specifications for clinical sterilizers designed to sterilise load items by exposure to ethylene oxide gas. Such sterilizers are commonly known as “ethylene oxide sterilizers” or “EO sterilizers”.

13.2 The guidance given here assumes that the sterilizer is to be used to process medical devices in compliance with the EU Directives discussed in Chapter 1.

13.3 EO is a highly reactive liquid and gas which is toxic, flammable and explosive. Exposure to EO is controlled by the COSHH Regulations 1999 (see Chapter 1). The safe operation of EO sterilizers requires careful consideration of all aspects of the installation and operation of equipment. Operational safety information is given in Part 4 of this SHTM.

13.4 EO sterilizers should be installed in dedicated areas which are not used for any other working purposes.

13.5 An EO sterilization process may include preconditioning and degassing procedures requiring additional equipment. Further information about preconditioning is given in paragraph 13.21 and about degassing in paragraph 13.35.

13.6 EO sterilizers have the potential to cause serious environmental pollution. Large sterilizers will require additional plant to dispose safely of exhaust products and this will add considerably to the cost. Such plant is described in paragraph 13.39. Precautions in ventilation and drainage systems are outlined in Chapter 6.

13.7 Since the sterilization process is ultimately dependent upon chemical action, microbiological test methods are required to confirm that sterilization conditions have been attained. These are described in Part 3 of this SHTM.

13.8 Purchasers of an EO sterilizer should be aware of the following points:

a. the difficulty in validating and monitoring suitable cleaning processes for loads before they are sterilized (see Part 4);

b. the difficulty in carrying out representative performance qualification tests for the wide variety of loading conditions that may be used (see Part 3);

c. the difficulty in carrying out meaningful bioburden studies on small numbers of widely differing devices to be sterilized (see Part 4);

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

d. the problems associated with determining the levels of residual EO and its reaction products when small numbers of widely differing devices are processed (see Part 3);

e. the need for specialist technical resources dedicated to the operation and maintenance of the equipment (see Part 4).

13.9 EO installations can be expensive both to buy and to run. As there are few items which need to be sterilized by EO, their provision cannot normally be justified by individual hospitals. Where there is a clear need for EO sterilization, the service should be run by a well-supported specialist unit where microbiological testing, environmental controls, degassing procedures and evaluation of residual EO in the sterilized product can be assured.

Types of sterilizer

13.10 Two types of EO sterilizer are suitable for NHS use.

Low-pressure sterilizers

13.11 These are small sterilizers, of chamber volumes around 150 litres, where the sterilant is pure EO at sub-atmospheric pressure. The gas is supplied from a single-use, disposable cartridge contained within the chamber. The cartridge limits the amount of EO in use at any one time and reduces the toxic and explosive hazards. The chamber is designed to contain the effects of an explosion of the contents of a single cartridge.

13.12 Low-pressure sterilizers are relatively cheap to install and to run, requiring no piped EO service and no gas disposal plant. The low pressure in the chamber allows pressure-sensitive equipment to be processed safely.

High-pressure sterilizers

13.13 These are large sterilizers, of chamber volume up to 500 litres, where the sterilant is EO diluted with another gas, supplied from cylinders.

13.14 The mixtures are chosen to expose the load to an EO concentration of around 500-1000 mg litre^{-1} while keeping the potential hazards to a minimum. Two gas systems are in common use:

a. EO with chlorofluorocarbons (CFCs) at pressures up to 2 bar: CFCs have traditionally been used as a diluent gas but are no longer acceptable for environmental reasons;

b. EO with carbon dioxide at pressures up to 6 bar.

13.15 Because of their larger size, high-pressure sterilizers require gas disposal plant to remove EO from the chamber exhaust (see paragraph 13.39).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Standard specifications

13.16 EO sterilizers should conform to the specifications in BS EN 1422 and the safety specifications in BS EN 61010: Part 2-042. Two types of sterilizer are specified:

a. **type A** sterilizers have operating cycles programmable by the user and may have very large chamber volumes; they are intended primarily for use in industry;

b. **type B** sterilizers have one or more preset operating cycles; the chamber volume is no greater than 1000 litres.

13.17 EO sterilizers for use in the NHS should conform to Type B. They may be either low-pressure or high-pressure systems (see paragraph 13.10).

Additional specifications

13.18 The following specifications for EO sterilizers are in addition to those given in BS EN 1422.

Room ventilation

13.19 The sterilizer manufacturer should supply the appropriate interfaces to enable the sterilizer to function with the room ventilation system as described in Chapter 6.

Local exhaust ventilation

13.20 EO sterilizers should be connected to a local exhaust ventilation system (LEV) to ensure that the emission of EO gas into the atmosphere does not present a safety hazard. The sterilizer manufacturer should supply the appropriate hoods and interfaces to enable the sterilizer to function with the LEV system as described in Chapter 6.

Preconditioning facilities

13.21 For successful sterilization the load should be at a predetermined temperature and humidity before the start of the operating cycle. This may be achieved by exposing the load to the required conditions in an environmentally controlled room or chamber. This preconditioning procedure is considered an integral part of the sterilization process. See Part 4 for more information about routine preconditioning.

13.22 Preconditioning requires either a chamber (designed to accommodate one sterilizer load) or a room (two or more loads).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13.23 Humidification should be by direct injection of low-pressure steam and should be controlled by direct measurement of relative humidity (RH) within the chamber or room. Humidifiers which operate by dispersion of water into an aerosol (such as spinning-disk humidifiers or nebulizers) are potent sources of microbial contamination and should not be used.

13.24 Provision should be made for continuous monitoring and recording of temperature and RH at locations determined as being representative of the conditions prevailing throughout the chamber or room.

13.25 The temperature and RH at which the chamber or room is controlled should be compatible with the conditions prevailing during the sterilizer operating cycle. They should be selected so that the temperature and RH of the load going into the sterilizer are neither so low that problems of long heat-up and condensation occur, nor so high that temperature control of the cycle is compromised. The uniformity of conditions should be established during validation.

Preconditioning chamber

13.26 All internal surfaces should be smooth, impermeable, durable and easily cleanable. Wherever possible internal corners should be rounded with a minimum radius of 25 mm.

13.27 Chambers constructed of metal should be of stainless steel, mild steel clad with stainless steel or nickel, or anodised aluminium. Alternatively, metal surfaces may be treated to inhibit corrosion.

13.28 The chamber should have assisted air circulation designed to provide effective airflow around all load items (whether partly or fully loaded) and to maintain uniform temperature and humidity throughout the chamber. Air entering the chamber should be filtered.

13.29 Door interlocks should be provided so that after the door has been closed it cannot be opened until the preset preconditioning time has elapsed.

Preconditioning room

13.30 The room should be segregated from assembly and packaging areas but located close to the sterilizer loading area to permit rapid transfer of the load.

13.31 Consideration should be given to cleanliness and ease of cleaning, especially in the design and location of equipment. The room should have a standard of finish similar to that of environmentally controlled areas. All internal surfaces should be smooth and free from cracks. Surface finishes should be impermeable, durable and easily cleanable. Ledges should be kept to a minimum. Wherever possible, internal corners should be rounded with a minimum radius of 25 mm. Any services required for cleaning should be provided within the room.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13.32 Corrosion of metal components may be a problem in the high-humidity conditions prevailing in the room. Uncoated metal surfaces should be either stainless steel or anodised aluminium.

13.33 The room should have assisted air circulation designed to provide effective airflow around all load items (whether the room is partly or fully loaded) and to maintain uniform temperature and humidity throughout the room. Air recirculation should incorporate a filtration system.

13.34 The door should be fitted with an audible and visual alarm set to operate if the door is left open for more than the time for which the conditions in the room can be maintained. This time should be established during validation (see Part 3 of this SHTM).

Degassing facilities

13.35 Most, if not all, materials subject to EO sterilization retain varying amounts of EO gas. The residual EO in medical devices must be reduced to a safe level, both for personnel handling the product and for the patient. The general term for this procedure is aeration. Aeration within the operating cycle is known as flushing. Aeration following the operating cycle is known as degassing.

13.36 Other compounds may also be present as reaction products of EO, for example ethylene chlorhydrin, and the concentration of these will also need to be reduced. Reference in this SHTM to reduction of EO concentration should be read as applying equally to any other toxic reaction products which may be present.

13.37 Reduction of residual EO occurs naturally as gas diffuses from the product into the surrounding air. Under normal ambient conditions this process may be very slow and significant amounts of EO may be released into the environment. For these reasons degassing by storage under ambient conditions is not recommended. Mechanical degassing should be used.

13.38 A degassing facility may be either a purpose-made aeration cabinet or a room. Some sterilizers incorporate an additional flushing stage as part of the operating cycle and this may be sufficient. Within the NHS the volume of product and the number of cycles a week will be small; for most installations a separate aeration cabinet is not normally necessary.

Disposal of EO

13.39 When an EO sterilizer is purchased consideration must be given to the method to be used to dispose of gases exhausted from the chamber. For a low-pressure sterilizer, chamber exhaust ventilation as described in Chapter 6 is adequate. For high-pressure sterilizers, however, the quantity of EO is likely to be too high to be disposed of safely without further processing.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

13.40 Five basic methods are available: water scrubbing, incineration, catalytic oxidation, reclamation and EO absorption and modification. Of these, catalytic oxidation is recommended for use in the NHS.

13.41 Catalytic oxidation oxidizes EO to carbon dioxide and water by heating the exhaust gases in the presence of a catalyst at a temperature of approximately 300°C. Maximum efficiency is in excess of 99%.

13.42 Inlet gas streams must be diluted to contain less than 1% EO to prevent significant heating of the catalyst bed. High EO concentrations may cause a runaway reaction and under these conditions, in addition to the fire and explosion hazard, any CFCs present in the gas may be degraded to give toxic products such as phosgene.

13.43 The purchase and running costs are moderate to high. Little routine maintenance is required other than periodic replacement of the catalyst bed.

13.44 Small units suitable for installation with small EO sterilizers are commercially available and present few installation problems.

Gas monitoring system

13.45 Gas detectors should be placed wherever there is a risk of people being exposed to EO. Such places would normally include the loading area, plantroom, manifold room and degassing room. The detectors should be placed close to the normal working positions of personnel. The monitoring system should be set to sound a visual and audible alarm when the atmospheric concentration of EO exceeds a preset level no greater than the short-term maximum exposure limit specified in Table 1.

13.46 Interfaces with the ventilation systems will also be required as discussed in Chapter 6.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14. Laboratory sterilizers

Introduction

14.1 This chapter discusses specifications for sterilizers ("laboratory sterilizers") used for the processing of materials and equipment to be used in clinical laboratories.

14.2 These sterilizers are not intended for the processing of medical devices or medicinal products. There is therefore no need for them to comply with the EU Directives discussed in Chapter 1.

14.3 Guidance on validation and periodic testing of laboratory sterilizers is given in Part 3 of this SHTM. Guidance on operation is given in Part 4.

Provision of laboratory sterilizers

14.4 The HSE Advisory Committee on Dangerous Pathogens recommends that laboratory sterilizers capable of making safe infected material be provided as shown in Table 11.

Table 11: Provision of laboratory sterilizers

Containment level	Provision
1	No sterilizers are required
2	A sterilizer with a make-safe cycle must be readily accessible, normally in the same building as the laboratory
3	A sterilizer with a make-safe cycle should be preferably situated within the laboratory, but one must be readily accessible in the laboratory suite
4	A double-ended sterilizer with interlocking doors with entry in the laboratory and exit in a clean area must be provided

Source: *Categorisation of pathogens according to hazard and categories of containment* (4th edition), HSE 1995.

14.5 General information on the requirements for the four containment categories can be found in the HSE document *Categorisation of pathogens according to hazard and categories of containment*, published by HMSO. Purchasers should note that the containment requirements have been given statutory force by the Control of Substances Hazardous to Health Regulations 1999.

14.6 Sufficient sterilizers should be installed to ensure that contaminated material can continue to be made safe if any sterilizer is removed from service. A cycle for the make-safe of small plastic discard (see paragraph 14.38) and a cycle for the make-safe of contained fluid discard (see paragraph 14.42) should be available at all times. The need for other cycles to be duplicated

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

will depend on the nature and volume of the work being done in the laboratory.

14.7 Where possible, at least one sterilizer should be designated solely for the processing of discard material.

14.8 Laboratory sterilizers intended to process discard material should be sited as close as possible to the area in which the discard is produced, to avoid contaminated material being transported through rooms where it would not normally be stored or handled. Laboratory sterilizers intended to process culture media should be directly accessible from the media preparation area.

14.9 The preferred type of sterilizer is a front-loading unit, recessed into a panel separating the loading area from the plantroom, as described in Chapter 5. Such sterilizers are available with a wide range of chamber sizes and operating cycles.

14.10 Sterilizers with a door at each end are essential for Containment Level 4 laboratories, though they present special problems of installation and access for maintenance.

14.11 Free-standing machines, with chambers up to 500 litres, are also available. They are either top-loading or front-loading. For top-loading sterilizers, where there may be difficulties in load handling and lifting and a hazard from hot surfaces, the practical limit is 250 litres. Multiple free-standing sterilizers are not normally cost-effective when used in centralised sterilising facilities.

14.12 Transportable sterilizers, which generate steam from an internal reservoir, may be appropriate for small laboratories.

Design considerations

14.13 A laboratory sterilizer may provide one or more operating cycles, each designed for processing a particular type of load. The number and nature of the operating cycles which can be supported by any particular machine will depend on details of its design and construction. It will depend in particular on the methods used to remove air from the chamber and load, the methods used for cooling and drying the load and the provision of thermal door locks. Purchasers should carefully consider which operating cycles they are likely to need in the future, so that the manufacturer can install the necessary hardware. Otherwise it may not be possible to add a new operating cycle to a sterilizer without expensive modification. It is not merely a matter of “reprogramming.”

14.14 The following three considerations are crucial. The cycles themselves are described in paragraphs 14.36-14.55.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Air removal

14.15 Laboratory sterilizers commonly employ one of two principles for removing air from the chamber, each of which can be implemented in several ways:

a. **passive:** steam comes in at the top of the chamber and air is forced out at the bottom (downward displacement). This is the simpler (and cheaper) method, but only suitable for loads such as sealed bottles which do not impede the removal of air from the chamber. (In certain machines, notably transportables, passive air removal may be by upward displacement.)

b. **active:** the chamber is subjected to successive pressure changes to draw air from the chamber. This is required for loads such as fabrics, glassware and other equipment where trapped air cannot reliably be removed by passive methods. The more difficult air is to remove, the more pressure pulses will be required. Active air removal is always faster than passive methods.

Cooling and drying

14.16 Where necessary, one of four cooling methods may be used:

a. **natural:** the load is allowed to cool naturally in the chamber until it reaches a safe temperature. This is the cheapest option and acceptable if lengthy cycle times are tolerable and the load is not likely to be damaged by remaining hot for long periods;

b. **dry assisted:** either cold water is circulated through the jacket or through cooling coils, or air is circulated through the chamber (with or without pressure pulsing) to accelerate the cooling process. This is faster than natural cooling;

c. **wet assisted:** the load is sprayed or deluged with coolant water. This is faster than dry assisted cooling, therefore the method of choice for products which cannot withstand long periods at high temperature, but is only acceptable for loads such as sealed bottles where the coolant cannot come into contact with the contents. It is not suitable for loads contained in discard boxes;

d. **vacuum:** the chamber is evacuated to permit the remaining heat in the load to evaporate moisture, simultaneously cooling and drying the load. This is suitable for loads which trap moisture (in general these are the same as the loads which trap air).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Thermal door locks

14.17 Laboratory sterilizers constructed to BS 2646 will have one or two door locks designed to prevent the door from being opened until the load cools to a preset temperature:

a. all sterilizers will have an interlock that prevents the door from being opened until the temperature of any fluid in the chamber and load (including condensate) has fallen below the boiling point of water at local atmospheric pressure (100°C at sea level);

b. sterilizers designed to process discard and fluid loads (cycles for make-safe of discard in large containers, sterilization of culture media, and free steaming) will have an additional interlock (a “thermal door lock”) to ensure that the door cannot be opened until the temperature of fluid in sealed containers has fallen below 80°C (see paragraph 14.26 for additional specifications). Note that this requirement will considerably lengthen the cycle time.

Standard specifications

14.18 Specification of laboratory sterilizers is covered by the various parts of BS 2646, *Autoclaves for sterilization in laboratories*, which has been radically revised in recent years:

Part 1: 1993 - Specification for design, construction and performance;

Part 2: 1990 - Guide to planning and installation;

Part 3: 1993 - Guide to safe use and operation;

Part 4: 1991 - Guide to maintenance;

Part 5: 1993 - Methods of test for function and performance.

14.19 While BS 2646 is a sound basic specification for laboratory sterilizers, the UK Health Departments recommend additional specifications which are detailed in paragraphs 14.23-14.34.

14.20 Laboratory sterilizers constructed in accordance with BS 2646 will not be suitable for processing material infected with Hazard Group 4 pathogens unless provision is made to contain and sterilise all chamber effluents before disposal. Such a sterilizer should not be operated without a full fault-and-effect analysis to ensure that the containment remains secure if a failure occurs. The advice of the Public Health Laboratory Service or the NHS in Scotland Management Executive should be sought before specifying a sterilizer for a Containment Level 4 laboratory.

14.21 BS 2646 does not cover culture media preparators. A UK Health Departments specification for these is discussed in paragraph 14.56.

14.22 A European Standard on laboratory sterilizers is in preparation but is unlikely to be published in the near future.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Additional specifications

14.23 The following specifications are additional to those required by BS 2646: Part 1. Purchasers should ensure that they are agreed with the manufacturer before any contract is made.

Instruments and controls

14.24 BS 2646: Part 1: 1993 requires only that sterilizers be fitted with a chamber temperature indicator and a chamber pressure indicator. Laboratory sterilizers for use in the NHS must have a temperature recorder and a pressure recorder, complying with the requirements of BS 3970: Part 1.

14.25 A cycle counter complying with BS 3970: Part 1 will also be required.

Thermal door-lock override

14.26 Where the sterilizer is provided with a thermal door lock designed to prevent the door being opened until the temperature of fluids in sealed containers has fallen to 80°C (14.17b), a means should be provided to override the lock during the cooling stage of the operating cycle. The override is intended for use by trained persons who wish to gain access at temperatures above 80°C to loads which will not present an explosive hazard.

14.27 The override should meet the following specifications:

a. the override switch is accessible only by means of a key, code or tool unique to the sterilizer;

b. it operates only during the cooling stage of the cycle and causes the cooling stage to terminate;

c. there is a visual indication that the override has been operated;

d. the switch resets automatically when released;

e. at the end of the cycle the door cannot be opened except by means of a key, code or tool.

14.28 Where the sterilizer is intended to be used exclusively for the make-safe of discard in small containers, compliance with paragraphs 14.27d and 14.27e may be waived with the agreement of the laboratory safety officer. In this case, the switch should reset automatically whenever a different operating cycle is selected or whenever the power supply is interrupted.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Load-temperature probe

14.29 Where the sterilizer is to be used with cycles other than the make-safe of discard, a load-temperature probe should be provided within the chamber. This is a temperature sensor attached to a flex and designed to be inserted into load items (such as bottles) to monitor the temperature during an operating cycle. The reading is displayed on a temperature recorder as described in paragraph 14.24. Means should be provided to stow the probe in a safe position within the chamber when it is not in use.

Steam generators

14.30 Where steam is supplied from a generator within the sterilizer (Types 2 and 3 of BS 2646: Part 1: 1993), condensate from the steam which comes into contact with any discard load should not be returned to the boiler.

14.31 Where the sterilizer chamber is used as a water reservoir (Type 4), the water should enter the chamber after the start of the cycle and be drained before the end of the cycle.

14.32 Reservoirs may accumulate solidified agar and should de designed so that they can be cleaned easily.

Chamber drain

14.33 The chamber drain should be designed to minimise the risk of its becoming blocked with solidified agar or similar material.

14.34 Where the temperature of the effluent is high, for example for free steaming, means should be provided to prevent vapour being discharged into the plantroom or the loading area. Further information on drainage may be found in Chapter 6.

Top-loading sterilizers

14.35 Top-loading sterilizers are difficult to load safely without the use of mechanical aids. Loading systems should be designed to protect the operator from the risk of injury caused by lifting and hot surfaces and should comply with the requirements of the Manual Handling Operations Regulations 1992 and the Lifting Operation and Lifting Equipment Regulations 1998 (see Chapter 4 and Part 1 of this SHTM).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operating cycles

14.36 BS 2646 recognises only three distinct operating cycles which it denotes as make-safe, liquids sterilization, and equipment and glassware sterilization. The range of operating cycles recommended for NHS use, and the materials they are designed to process, are described below and specified in Table 12. Where the table gives a choice of sterilization temperatures, the highest temperature should normally be specified. The performance class listed for each cycle is explained in Table 5. If heat-sensitive loads are likely to be processed, then additional lower-temperature cycles may be required. The complete set of cycles to be provided on each machine, including any non-standard cycles not shown here, should be agreed with the manufacturer before the contract is placed.

Free steaming (variable cycle)	Yes	Passive	Dry assisted	102 - 104	10

These are the most common combinations for operating cycles. Others are possible.

[a] See Table 4 for full sterilization conditions.

[b] See Table 5 for definitions of performance classes.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14.37 Operating cycles are normally automatic and preset and cannot be adjusted by the operator. For some processes, however, such as the sterilization of culture media and free steaming, it may be desirable to have a variable cycle with controls for adjusting the sterilization temperature and holding time within a preset range. This feature should normally be provided as a separate cycle.

Make-safe of small plastic discard

14.38 This cycle corresponds to the “make-safe” cycle specified in BS 2646. It is designed to sterilise infected material held in plastic containers not exceeding 50 ml. Examples of such containers include Petri dishes, specimen bottles and other small plastic items intended either for disposal or for reuse.

14.39 Although the containers would normally be unsealed, the limits on volume ensure that any fluid held in a sealed container does not present an explosion hazard when the door is opened at the end of the cycle. Glass containers and larger plastic containers should be processed with the make-safe cycle for contained fluid discard (paragraph 14.42).

14.40 If the workload is heavy, an active air removal system (paragraph 14.15b) is recommended to shorten the cycle time.

14.41 Discard boxes as specified in paragraph 14.60 will be required.

Make-safe of contained fluid discard

14.42 This cycle is a variant of the “liquids sterilization” cycle specified in BS 2646. It is designed to make-safe infected material in sealed glass containers of any size or sealed plastic containers of volume greater than 50 ml.

14.43 While essentially the same as the culture media cycle (paragraph 14.45), a sterilization temperature of 126°C is normally used to protect the glass. Lower sterilization temperatures should only be used if plastic containers are to be processed.

14.44 Discard boxes as specified in paragraph 14.60 will be required.

Sterilization of culture media

14.45 This cycle is a variant of the “liquids sterilization” cycle specified in BS 2646. It is designed to sterilise culture media in open or sealed containers.

14.46 Since culture media are normally damaged by sterilization at 134°C the maximum sterilization temperature is set at 121°C.

14.47 A variable cycle, in which combinations of sterilization temperature and holding time can be set by the operator, may be desirable for certain products and, if required, should be specified as a separate cycle.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14.48 The culture media cycle is also suitable for disinfecting unwrapped equipment such as tubing sets.

Disinfection of fabrics

14.49 This cycle is a variant of the “glassware and equipment” cycle specified in BS 2646. It is designed to disinfect (but not sterilise) fabric materials such as towels, clothing, wrapped animal bedding, and other porous materials.

14.50 If the fabrics are required to be sterile and dry at the end of the cycle, a machine complying with the performance requirements for a clinical porous-load sterilizer will be necessary (see Chapter 8).

14.51 The cycle differs from the glassware and equipment cycle (14.53) in that more pressure pulses will be required to remove air from the load.

14.52 The fabrics cycle is also suitable for sterilising empty glassware without caps and for disinfecting wrapped tubing and wrapped filters (see paragraph 14.54).

Sterilization of glassware and equipment

14.53 This cycle corresponds to the “glassware and equipment” cycle specified in BS 2646. It is designed to sterilise clean, empty glassware (without caps) and equipment such as tubing and filters. Loads must not contain any fluids.

14.54 Some microbiological filter membranes may be damaged by the rapid fluctuations in pressure used by an active air-removal system, and it may be necessary to provide a separate filter cycle.

Free steaming

14.55 This cycle is not specified in BS 2646. It is designed to melt solidified agar by exposing it to steam near atmospheric pressure. It is normally a variable cycle. If the workload is heavy, this will not be a cost-effective way of using a sterilizer and a Köch steamer may be more suitable.

Culture media preparators

14.56 Many of the problems which relate to sterilising culture media can be solved by the use of small sterilizers in which the media constituents are placed directly into the chamber, thus avoiding the use of glass containers and their attendant hazards. Since these small machines have a unique function, their design is specialised in comparison with other laboratory sterilizers and BS 2646 is not applicable.

14.57 A culture media preparator consists of two or three modules incorporated into a system designed to provide controlled preparation, sterilization, cooling and dispensing of culture media with a minimum of attention by the

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

operator. The system may also include a module which automatically stacks the completed culture plates.

14.58 The sterilizer module consists of a pressure vessel which contains the medium, surrounded by a jacket (which may itself be a pressure vessel) containing a heat transfer fluid (usually water) or separate heating elements and coils. Throughout the preparation and sterilising part of the process heat is transmitted from the jacket to the culture medium to attain a controlled temperature between 80°C and 130°C in order to dissolve the constituents and sterilise the resultant culture medium. After a predetermined time at the sterilization temperature the medium is rapidly cooled to a controlled dispensing temperature between 40°C and 60°C. Cooling is usually achieved by circulating cold water. Provision is also made for adding solutions to the sterilized cooled medium before possible reheating, cooling and final dispensing.

14.59 The sterilizer module of these systems should conform with the UK Health Departments' specifications set out in *Performance and safety specification for culture media sterilizers* (STB 3A/85/12) with the following modifications:

a. both inner and outer vessels must have a pressure relief valve; these must be dedicated safety valves set to prevent the vessel being over-pressurised and not have any other function. They must be positioned so that in the event of the valves operating the discharge will not be expelled into the immediate working area;

b. port covers should be made of a material, such as stainless steel, which will not distort under normal operating conditions.

Discard boxes

14.60 When a sterilizer intended for use with make-safe cycles is purchased, suitable boxes will need to be specified for receiving discard material, transporting it from the laboratory bench to the sterilizer, and containing the load during the sterilization process. Enough boxes to load the chamber fully should be provided.

14.61 The sterilizer manufacturer will have used a certain type of discard box in determining the cycle time. If other types are used for routine production, the cycle time may differ considerably.

14.62 The design of the box can greatly affect the overall cycle time, varying between 45 minutes and two hours when the process incorporates an active air-removal system, and between two and six hours for processes based on passive displacement. Figure 3 illustrates a typical commercially available discard box.

14.63 The box should be designed to facilitate the removal of air from the load and the penetration of steam into the load.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

14.64 The box material should be impervious, conduct heat well, be robust, resistant to puncturing, easily cleanable and able to withstand the sterilization process without damage. Stainless steel, aluminium and plastic are the most common materials:

a. stainless steel, preferably coated with polytetrafluoroethylene (PTFE), is the material of choice. Its principal advantages are resistance to distortion at sterilization temperatures, good heat transfer and “non-stick” properties;

b. aluminium is lighter than other metals but is prone to metal fatigue and cracking, and so has a shorter life expectancy;

c. plastic boxes are cheaper than those made of metal but conduct heat poorly, increasing energy consumption and lengthening cycle times. Where inserts are used to segregate solid from liquid discard, a plastic box may distort and prevent the discard or insert from being withdrawn.

14.65 Where small discard is to be made safe, the box should contain a trivet to support the load before sterilization and allow any liquids to drain to the bottom of the box during the cycle. This will make it easier to separate solid and liquid residues for disposal.

14.66 Discard should be enclosed when the box is being moved. Loose-fitting lids are satisfactory for transport within a laboratory. Alternatively, the discard material may be placed in a discard bag (see paragraph 14.67) inside an open box, providing the neck of the bag is closed. Whenever discard material is transported outside the laboratory suite, a sealed and locked lid should be fitted. Where the lid can affect the efficacy of the sterilization process, it should be opened or removed before the cycle begins and sterilized along with the box.

14.67 Bags, usually plastic, are available with identification markings for discard material. The bags are often manufactured in a material which will melt at 134°C to assist air removal. Discard bags should always be contained in a discard box and opened wide before sterilization.

Glossary

The following list of definitions has been adopted in SHTM 2010 and used in Part 2. Certain pressure terms have been modified to comply with the requirements of BS EN 764. Cross references to other terms are shown in bold type.

absolute pressure	pressure for which the zero value is associated with absolute vacuum.
aeration	a part of the **sterilization process** during which **sterilant gas** and/or its reaction products desorb from the **load** until predetermined levels are reached. See **degassing** and **flushing**.
air detector	a device used to determine that sufficient air or other **non-condensable gases** have been removed from the **chamber**.
allowable pressure	of a pressure vessel, a limit to the **operating pressure** specified for safety reasons. See **design pressure**.
automatic controller	a device that, in response to predetermined **cycle variables**, operates the **sterilizer** sequentially through the required stages of the **operating cycle**.
batch process record (BPR)	a permanent record of one or more **cycle variables recorded** during a complete **operating cycle** by instruments fitted permanently to the **sterilizer**.
biological indicator	a device, consisting of an inoculated carrier contained within a primary pack, designed to test the efficacy of an **operating cycle**.
Bowie-Dick test	a test, used mainly with porous load sterilizers, to show whether or not steam penetration into a **standard test pack** is even and rapid.
cartridge	in **EO sterilizers**, a portable, single-use, simple vessel containing **sterilant** gas under pressure from which the gas is delivered by puncturing the cartridge.
chamber	the part of the **sterilizer** in which the **load** is placed.
chamber exhaust ventilation (CEV)	a ventilation system designed to extract gas from the **chamber** of an **EO sterilizer** supplied from a **cartridge**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

chamber furniture	shelves, pallets, loading trolleys and other fixed or movable parts that support the **load** within the **chamber**.
chamber temperature	the lowest temperature prevailing in the **chamber**.
chemical indicator	a device designed to show, usually by change of colour, whether specified values of one or more **cycle variables** have been attained.
clinical sterilizer	a **sterilizer** designed to process **medical devices** or **medicinal products** to be used in the clinical care of patients.
commissioning	the process of obtaining and documenting evidence that equipment has been provided and installed in accordance with the equipment specifications and that it functions within predetermined limits when operated in accordance with the operational instructions.
conditioning	in **EO sterilizers**, the treatment of a **load** within the **operating cycle**, but prior to **sterilization**, to attain a predetermined temperature and humidity throughout the load.
contained fluid discard	discard material held in sealed glass containers or sealed plastic containers of volume greater than 50 ml (see **small plastic discard**).
cooling stage	the period of the **operating cycle**, after the **holding time** has been completed, during which the **load** remains in the **chamber** while the load cools to a safe temperature.
culture media preparator	a specialised **laboratory sterilizer** designed for the **sterilization** and dispensing of culture media.
cycle complete	recognition by the **automatic controller** that the preset values for the **cycle variables**, necessary for a successful **operating cycle**, have been attained and that the sterilized **load** is ready for removal from the **chamber**.
cycle variables	the physical properties, for example time, temperature, pressure, humidity and gas concentration, that influence the efficacy of the **operating cycle**.
dedicated steam supply	a supply of steam produced by a generator for the exclusive use of a **sterilizer** or group of sterilizers.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

degassing	1. in **LTSF** and **EO sterilizers**, an **aeration** procedure in which **sterilant** gas and its reaction products are desorbed from the **load** by defined treatment outside the **sterilizer** after completion of the **operating cycle**. 2. a pre-heating treatment of boiler feed-water to reduce the amount of **non-condensable gases** in the steam supply.
design pressure	of a pressure vessel, the pressure chosen for the design calculations. See **operating pressure**, **allowable pressure**.
discard	laboratory material which is, or may be, infected by micro-organisms and is to be made safe before disposal.
discard bag	a bag, usually of plastic, designed to receive solid **discard** material before being placed in a **discard box** for processing by a **make-safe** cycle.
discard box	a box designed to contain discard material for processing by a make-safe cycle.
disinfection	a process used to reduce the number of viable micro-organisms in a **load** but which may not necessarily inactivate some viruses and bacterial spores.
disinfector	an apparatus designed to achieve **disinfection**.
double-ended sterilizer	a **sterilizer** in which there is a door at each end of the **chamber**.
dry-heat sterilizer	a **clinical sterilizer** designed to sterilise **loads** by exposure to hot dry air near atmospheric pressure.
dryness value	a dimensionless quantity, approximating to the dryness fraction, derived to determine whether steam is of the correct dryness for **sterilization** purposes. A dryness value of 1.0 represents dry **saturated steam**.
EO sterilizer	a **clinical sterilizer** designed to sterilise **loads** by exposure to **ethylene oxide** gas or EO gas mixtures.
equilibration time	the period which elapses between the attainment of the **sterilization temperature** in the **chamber** and the attainment of the sterilization temperature in all parts of the **load**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

ethylene oxide (EO)	**sterilant** gas used to sterilise items that would be damaged by exposure to heat or moisture. Chemical formula CH_2CH_2O.
F_O	a quantity, measured in minutes, used to determine the efficacy of an **operating cycle** and equivalent to a continuous period at a temperature of 121°C.
fail-safe	an attribute of **sterilizer** design whereby failure of any component or its associated services does not create a safety hazard.
fault	the recognition by the **automatic controller** that the preset **cycle variables** for the **operating cycle** have not been attained and that **sterilization** or **disinfection** has been jeopardised.
flash sterilizer	a device designed to achieve **sterilization** by exposing the **load** to a very high temperature steam for a few seconds.
fluid sterilizer	a **clinical sterilizer** designed to sterilise fluids in sealed containers by exposure to **high-temperature steam** under pressure.
flushing	in **LTSF** and **EO sterilizers,** an **aeration** procedure by which remaining **sterilant** gas is removed from the **load** within the **chamber** by the passage of air or other inert gas.
formaldehyde	**sterilant** gas used in combination with **low-temperature steam** to sterilise items that would be damaged by exposure to **high-temperature steam.** Chemical formula HCHO. Also known as methanal.
formalin	formaldehyde Solution BP. A 38% aqueous solution of **formaldehyde** stabilised with 10% w/v ethanol, commonly used as the primary material for generating formaldehyde gas.
free steaming	a process, used in **laboratory sterilizers,** in which the **load** is exposed to steam near atmospheric pressure.
free-standing	of a **sterilizer,** installed in a room which is not separated into a **plantroom** and a **loading area**.
full load	a specified **load,** used in thermometric tests, to represent the maximum size and mass of load which the **sterilizer** is designed to process.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

gas exposure time	in **EO sterilizers,** the time for which the **chamber** is maintained at the specified temperature, gas concentration, pressure and humidity.
gauge pressure	pressure equal to the difference between the **absolute pressure** and local atmospheric pressure.
high-temperature steam	steam at a temperature above the boiling point of water at local atmospheric pressure.
holding time	the period during which the temperature in all parts of the **chamber, load** and any coolant fluid is held within the **sterilization temperature band.** It follows immediately after the **equilibration time**.
hot-air sterilizer	see **dry-heat sterilizer**.
indicated	an indicated value is that shown by a dial or other visual display fitted permanently to the **sterilizer** (see **recorded** and **measured**).
installation checks	a series of checks performed by the contractor to establish that the **sterilizer** has been provided and installed correctly, is safe to operate, does not interfere with nearby equipment and that all connected services are satisfactory and do not restrict the attainment of conditions for **sterilization**.
installation tests	a series of tests performed by the contractor after the **installation checks** to demonstrate that the **sterilizer** is working satisfactorily.
integral steam supply	a supply of steam produced in a sterilizer **chamber** or in a generator directly connected to it. The pressure in the sterilizer chamber is equal to that in the generator.
Köch steamer	a laboratory apparatus designed to expose a **load** to steam near atmospheric pressure and commonly used for melting solidified agar.
laboratory sterilizer	a **sterilizer** designed to sterilise, disinfect or **make-safe** laboratory materials and equipment.
load	collectively, all the goods, equipment and materials that are put into a **sterilizer** or **disinfector** at any one time for the purpose of processing it by an **operating cycle**.
load item	one of several discrete containers, packs or other units that together constitute a **load**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

load-temperature probe	a movable temperature sensor fitted within the **sterilizer chamber** and designed to record the temperature inside selected **load items**.
loading area	the room or area in front of the **sterilizer** in which the operator works and from which the sterilizer is loaded and unloaded. It is commonly separated by a fascia panel from the **plantroom**.
loading condition	a specified combination of the nature and number of **load items,** the items of **chamber furniture,** and their distribution within the **chamber**.
loading factor	the average fraction of the **usable chamber space** occupied by a load during normal operation.
local exhaust ventilation (LEV)	a ventilation system designed to extract small amounts **EO** or **formaldehyde** vapour released during normal operation of a **sterilizer** and its ancillary equipment.
low-temperature steam (LTS)	steam at a temperature below the boiling point of water at local atmospheric pressure.
LTS disinfector	a clinical **disinfector** designed to disinfect **loads** by exposure to **low-temperature steam** at sub-atmospheric pressure.
LTSF sterilizer	a **clinical sterilizer** designed to sterilise **loads** by exposure to **low-temperature steam** and **formaldehyde** gas at sub-atmospheric pressure.
mains steam supply	the supply of steam produced for distribution to a range of steam-consuming equipment by an independent common boiler.
make-safe	a process, used in **laboratory sterilizers,** to reduce the microbial content of contaminated material so that it can be handled and disposed of without causing an infection hazard or environmental contamination.
master process record (MPR)	a **batch process record** obtained from a thermometric **commissioning** or **performance qualification** test and annotated to show the permitted tolerances for **cycle variables** during subsequent testing and routine production.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

measured	a measured value is that shown on a test instrument, such as a thermometric recorder or a test pressure gauge, attached to the **sterilizer** for test purposes **(see indicated** and **recorded)**.
medical device	any instrument, apparatus, appliance, material or other article, whether used alone or in combination, including the software necessary for its proper application, intended by the manufacturer to be used on human beings for the purpose of: diagnosis, prevention, monitoring, treatment or alleviation of disease; diagnosis, monitoring, treatment, alleviation or compensation for an injury or handicap; investigation, replacement or modification of the anatomy or of a physiological process; control of conception; and which does not achieve its principal intended action in or on the human body by pharmacological, immunological or metabolic means, but which may be assisted in its function by such means. (Source: EU Council Directive 93/42/EEC.)
medicinal product	any substance or combination of substances presented for treating or preventing disease in human beings or animals. Any substance or combination of substances which may be administered to human beings or animals with a view to making a medical diagnosis or to restoring, correcting or modifying physiological functions in human beings or in animals is likewise considered a medicinal product. (Source: EU Council Directive 65/65/EEC.)
module	a standard unit of **chamber** size being a rectangular box measuring 300 x 300 x 600 mm of volume 54 litres.
non-condensable gases (NCGs)	gases which cannot be liquefied by compression under the range of conditions of temperature and pressure used during the **operating cycle**.
noted	a noted value is that written down by the operator, usually as the result of observing an **indicated**, **recorded** or **measured** value.
operating cycle	the set of stages of the **sterilization** or **disinfection** process carried out in sequence and regulated by the **automatic controller.** It is synonymous with the terms “sterilization cycle” for **sterilizers** and “disinfection cycle” for **disinfectors**.
operating pressure	the pressure in the **chamber** during the **plateau period** of an **operating cycle**. See **allowable pressure**, **design pressure**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

override	a system by which the progress of the **operating cycle** can be interrupted or modified as necessary.
paraformaldehyde	a mixture of polymethylene glycols formed by the reaction of **formaldehyde** with water.
performance class	an integer, from 1 to 20, related to the total cycle time for a **sterilizer** with a **full load**.
performance qualification (PQ)	the process of obtaining and documenting evidence that the equipment, as commissioned, will produce acceptable product when operated in accordance with the process specification.
performance requalification (PRQ)	the process of confirming that the evidence obtained during **performance qualification** remains valid.
periodic tests	a series of tests carried out at daily, weekly, quarterly and yearly intervals.
personal protective equipment (PPE)	equipment, including clothing, which is intended to be worn or held by a person at work, which protects against one or more risks to his or her health and safety.
plant history file	a file containing **validation**, maintenance and other engineering records for each **sterilizer**.
plantroom	the room or area to the rear of the **sterilizer** in which services are connected and which provides access for maintenance. It is commonly separated by a fascia panel from the **loading area**.
plateau period	the **equilibration time** plus the **holding time**.
porous-load sterilizer	a **clinical sterilizer** designed to process, by exposure to **high-temperature steam** under pressure, porous items such as towels, gowns and dressings, and also **medical devices** that are wrapped in porous materials such as paper or fabrics.
preconditioning	treatment of a **load** to attain predetermined conditions, such as temperature and humidity, before the start of an **operating cycle**.
pressure ballasting	a technique used in **fluid sterilizers** by which the pressure in the **chamber** is maintained at or near to the pressure inside the **load** containers during all or part of the **operating cycle**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

pressure vessel	a collective term describing the sterilizer **chamber,** jacket (if fitted), door(s) and components that are in permanent open connection with the chamber.
priming	of a steam generator, the delivery of steam containing water in suspension due to violent boiling or frothing.
process indicator	a **chemical indicator** used to distinguish between processed and unprocessed load items.
pyrogen	a bacterial toxin that causes a rise in body temperature and which is not destroyed by steam **sterilization**.
recommissioning	a procedure to confirm that operational data established during **commissioning** remain valid.
recorded	a recorded value is that shown on the output of a recording instrument fitted permanently to the **sterilizer** (see **indicated** and measured).
revalidation	a procedure to confirm an established **validation,** consisting of **recommissioning** followed by **performance requalification**.
safety hazard	a potentially detrimental effect on persons or the surroundings arising directly from either the **sterilizer** or its **load.**
saturated steam	steam whose temperature, at any given pressure, corresponds to that of the vaporisation curve of water.
small load	a specified **load,** used in thermometric tests, to represent the minimum size and mass of load which the **sterilizer** is designed to process.
small plastic discard	**discard** material comprising or held in plastic containers not exceeding 50 ml in volume.
sterilant	an agent used to effect **sterilization,** such as steam, hot air or a sterilising gas.
sterile	condition of a **load item** that is free from viable micro-organisms. See BS EN 556 for the requirements for a **medical device** to be labelled “sterile”.
sterilization	a process undertaken to render a **load sterile**.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

sterilization conditions	the ranges of the **cycle variables** which may prevail throughout the **chamber** and **load** during the **holding time**.
sterilization process	the complete set of procedures required for **sterilization** of a **load,** including the **operating cycle** and any treatment of the load before or after the operating cycle.
sterilization temperature	minimum acceptable temperature of the **sterilization temperature band**.
sterilization temperature band	the range of temperatures which may prevail throughout the **load** during the **holding time.** These temperatures are expressed as a minimum acceptable (the **sterilization temperature)** and a maximum allowable and are stated to the nearest degree Celsius.
sterilizer	an apparatus designed to achieve **sterilization**.
sterilizer process log	a log, kept by the User, which contains records for each production cycle.
superheated steam	steam whose temperature, at any given pressure, is higher than that indicated by the vaporisation curve of water.
thermal door lock	an interlock fitted to certain **sterilizers** to prevent the door from being opened until the temperature in the **chamber** and **load** falls below a preset value.
transportable	requiring no permanent connections or installation and capable of being moved manually without mechanical assistance. Synonymous with “bench-top”.
type tests	a series of tests conducted by the manufacturer to establish the working data for a **sterilizer** type.
usable chamber space	the space inside the **chamber** which is not restricted by **chamber furniture** and which is consequently available to accept the **load**.
utilisation factor	the fraction of the open hours for which a sterilizer is available to process loads.
validation	a documented procedure for obtaining, recording and interpreting data required to show that a **sterilization process** will consistently comply with predetermined specifications.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

works tests	a series of tests to establish the efficacy of each **sterilizer** at the manufacturer's works.

Appendix 2: Information to be supplied by the manufacturer

A2.1 The following information should be supplied by the manufacturer of the sterilizer at or before the time the sterilizer is delivered.

Standards

A2.2 Statements of compliance with relevant British and European Standards and documentary evidence to demonstrate such compliance.

Instruction manual

A2.3 The manual should contain complete instructions including:

a. simplified operating instructions in a durable form suitable for fixing next to the sterilizer;

b. guidance on the types of load that may be processed in the sterilizer and their recommended packaging;

c. operational limits including design pressure, maximum permissible working pressure and maximum permissible working temperature.

Instruments and controls

A2.4 The manual should include a description of each instrument and control fitted to the sterilizer including:

a. the scale ranges of each and the limits of accuracy;

b. evidence that the calibration of each instrument has been verified and that the instrument is reading correctly within its stated limits of accuracy.

A2.5 Where an air detector is fitted, the manual should give:

a. the setting of the sensitivity of the air detector;

b. the level of the signal from the airdetector which will trigger automatic controller to abort the cycle and indicate a fault;

c. the vacuum leak rate that will cause this level to be exceeded.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Operating cycles

A2.6 The manual should give a description of each operating cycle available on the sterilizer specifying:

a. the sterilization temperatures available;

b. graphical representation of cycle variables (temperature, pressure, etc.) as a function of elapsed time for each sterilization temperature;

c. the maximum rate of change for each cycle variable;

d. the range of variation of any adjustable, preset cycle variables;

e. the cycle time and performance class for the thermometric tests for a full load described in Part 3 of this SHTM;

f. copies of the cycle records obtained during any type tests or works tests.

Services

A2.7 The manual should give a description of all the engineering services required by the sterilizer, specifying:

a. values of the fluctuating demands placed on each service during the course of a normal operating cycle;

b. the maximum and minimum safe supply pressures, temperatures and voltages.

Safety

A2.8 Safety information should include:

a. descriptions of any safety hazards that may arise in the normal operation of the sterilizer and recommended precautions to avoid them;

b. descriptions of all safety devices including their recommended settings and any means provided to override and reset them.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Chamber

A2.9 Information about the chamber should include the following:

a. the total volume of the chamber;

b. the dimensions of the usable chamber space and its capacity expressed both in litres and as an integral number of sterilization modules;

c. sufficient information to enable the user to identify, for an empty chamber:

(i) the parts of the usable chamber space that are the fastest and the slowest to attain the sterilization temperature;

(ii) the parts of the usable chamber space that are the hottest and the coolest during the sterilization holding time;

(iii) for sterilizers with a thermal door lock, the part of the usable chamber space that is the slowest to cool to a preset safe temperature (normally 80°C).

Maintenance manual

A2.10 Two copies should be provided. It should include:

a. a planned preventative maintenance programme consistent with the principles outlined in Part 4 of this SHTM together with detailed instructions for the procedures contained within it;

b. a list of any information to enable the user to identify, for an empty and testing;

c. diagrams of all electrical, steam, compressed air, water and gas systems;

d. a complete list of spare parts, indicating all parts which should be held in stock and that may require replacement during the normal working life of the sterilizer together with their likely usage rates;

e. guidance on tracing and rectifying likely causes of malfunction;

f. procedures for door safety control checks together with the sequence of operation;

g. method of calibrating the pressure, temperature and humidity indicating and recording systems.

Preface

SHTM 2010 gives guidance on the choice, specification, purchase, installation, validation, periodic testing, operation and maintenance of the following types of sterilizer in use in the National Health Service:

a. clinical sterilizers:
   (i) high-temperature steam sterilizers used for processing porous loads (including instruments and utensils wrapped in porous materials);
   (ii) high-temperature steam sterilizers used for processing aqueous fluids in sealed containers;
   (iii) high-temperature steam sterilizers used for processing unwrapped solid instruments and utensils;
   (iv) dry-heat sterilizers (hot-air sterilizers);
   (v) ethylene oxide (EO) sterilizers;

b. laboratory sterilizers:
   (i) high-temperature steam sterilizers used with one or more specialised operating cycles;
   (ii) culture media preparators

Sterilization by irradiation is not covered.

NOTE: Despite their name LTSF sterilizers are disinfectors.

This SHTM is intended primarily as a guide for technical personnel, whether specialists in sterilizers and sterilization procedures or those responsible for maintenance and testing. It is also intended for those responsible for the day-to-day running of sterilizers, and will also be of interest to supplies officers, architects, estates managers and others in both the public and private sectors.

Detailed information on the planning and design of a sterile services department, including the level of provision of sterilizers, is given in Scottish Hospital Planning Note 13; *Sterile services department*. Guidance for laboratory installations can be found in Scottish Hospital Planning Note 15; *Accommodation for pathology services*.

Although this edition of SHTM 2010 reflects established sterilizer technology, it is recognised that considerable scope exists for the utilisation of emerging technology in the management of sterilizers. This will be kept under review with the aim of introducing recommendations for such technology at the earliest opportunity so that the procedures essential for the efficient, safe and effective operation of sterilizers can be optimised.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

The sterilizers described in this SHTM may not be suitable, without modification, for safely processing articles infected with Hazard Group 4 pathogens nor agents, such as those associated with transmissible spongiform encephalopathies, which are unusually resistant to sterilization. Design considerations for sterilizers intended to process articles infected with such organisms are discussed in Part 2.

NOTE: Information about Hazard Groups may be found in the HSC document 'Categorisation of pathogens according to hazard and categories of containment' (4th edition, 1995) compiled by the Advisory Committee on Dangerous Pathogens.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

1. Introduction

General

1.1 This part of SHTM 2010 covers the validation and periodic testing of the various sterilization processes used in hospitals, laboratories and other healthcare facilities.

1.2 Terminology used in sterilization has long been inconsistent and occasionally ambiguous. This SHTM introduces a set of terms consistent with European Standards (see paragraph 1.4) which, it is hoped, will in time be adopted by sterilization workers in the NHS. The Glossary contains definitions referred to in this part. A fuller list of terms will be found in Part 5, 'Good practice guide'.

1.3 The Reference section contains full references for all the documents referred to in this part and for selected documents of which the reader should be aware. A fuller list of references relevant to sterilization will be found in Part 5.

European Standards

1.4 Part 1 of this SHTM discusses the three European Union Directives on the manufacture and supply of medical devices, active implantable medical devices and in-vitro diagnostic medical devices, which were implemented in the UK in stages from 1993 onwards. The Directives do not cover sterilization of medicinal products, as this is governed by other legislation (see Part 1).

1.5 To support the Directives, the European Committee for Standardisation (Comité Européen de Normalisation, CEN) prepared draft European Standards on operational procedures for different methods of sterilization of medical devices. Compliance with the relevant standard is considered to be a legal presumption of compliance with the sterilization requirements of the Directive it supports. The standards require that persons responsible for sterilization operate a quality system and that part of that system is validation and routine testing of the process.

1.6 The following Standards on the validation and routine control of sterilization processes are relevant to this part of SHTM 2010:

a. BS EN 550 covers ethylene oxide sterilization;

b. BS EN 554 covers all "moist heat" sterilization. This includes porous load and fluid sterilizers (except where used for medicinal products), and sterilizers for unwrapped instruments and utensils;

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

c. BS EN 556 sets out the requirements for medical devices to be labelled “sterile”.

1.7 While the guidance given here is designed to be broadly consistent with the standards, SHTM 2010 should not be regarded as a substitute for the standards themselves when ascertaining compliance with EU Directives or the UK Regulations that implement them.

Personnel

1.8 The following personnel are referred to in this part of SHTM 2010. Further information, including qualifications and areas of responsibility, can be found in Part 1.

1.9 **Management** is defined as the owner, occupier, employer, general manager, chief executive or other person of similar authority who is ultimately accountable for the sole operation of the premises.

1.10 Depending on the nature of the organisation, this role may be filled by the general manager, chief executive, laboratory director or other person of similar authority. In small, autonomous installations the user may take on this function.

1.11 The **user** is defined as the person designated by the executive manager to be responsible for the management of the sterilizer.

1.12 In a hospital the user could be a sterile services department manager, laboratory manager or theatre manager; in primary care he or she could be a general practitioner, dentist, or other health professional. Where a sterilizer is used to process medicinal products, the user is normally the production manager (see paragraph 1.20) in charge of the entire manufacturing process.

1.13 The **competent person (pressure vessels)** is defined as a person or organisation designated by management to exercise certain legal responsibilities with regard to the written scheme of examination of any pressure vessel associated with a sterilizer described in the Pressure Systems Safety Regulations 2000 (see Part 1). The shorter term “competent person” is used in this SHTM.

© Borders General Hospital NHS Trust on behalf of
NHSScotland Property and Environment Forum

1.14 The **authorised person (sterilizers)** is defined as a person designated by management to provide independent auditing and advice on sterilizers and sterilization and to review and witness documentation on validation. The shorter term “authorised person” is used in this SHTM.

1.15 A list of suitably qualified authorised persons (sterilizers) is maintained by the Institution of Healthcare Engineering and Estate Management (see Appendix 1).

1.16 The **test person (sterilizers)** is defined as a person designated by the executive manager to carry out validation and periodic testing of sterilizers, The shorter term “test person” is used in this SHTM.

1.17 The **maintenance person (sterilizers)** is defined as a person designated by the executive manager to carry out maintenance duties on sterilizers. The shorter term “maintenance person” is used in this SHTM.

1.18 The **microbiologist (sterilizers)** is defined as a person designated by the executive manager to be responsible for advising the user on microbiological aspects of the sterilization of non-medicinal products. The shorter term “microbiologist” is used in this SHTM.

1.19 The **production manager** is defined as a person designated by the executive manager to be responsible for the production of medicinal products.

1.20 The **quality controller** is defined as a person designated by the executive manager to be responsible for quality control of medicinal products with authority to establish, verify and implement all quality control and quality assurance procedures.

1.21 The **laboratory safety officer** is defined as a person designated by the executive manager to be responsible for all aspects of laboratory safety including equipment, personnel and training relating to safety issues, and ensuring compliance with safety legislation and guidelines.

1.22 An **operator** is defined as any person with the authority to operate a sterilizer, including the noting of sterilizer instrument readings and simple housekeeping duties.

1.23 The **manufacturer** is defined as a person or organisation responsible for the manufacture of a sterilizer.

1.24 The **contractor** is defined as a person or organisation designated by the executive manager to be responsible for the supply and installation of the sterilizer, and for the conduct of the installation checks and tests. The contractor is commonly the manufacturer of the sterilizer.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Safety

1.25 Extensive guidance on the safe operation of the various types of sterilizer is given in Part 4, 'Operational management'. As far as testing is concerned, normal safety precautions are adequate except in the case of sterilizers used to process infectious materials, and sterilizers using gaseous sterilants, as described below. Users are recommended to operate a permit-to-work system to ensure that such sterilizers are declared safe to work on, and that personnel working on them have documented authority to do so.

Infectious materials

1.26 All sterilizers have the potential to process infectious materials, but attention is drawn to certain laboratory sterilizers with cycles expressly designed for the routine making-safe of discard material that is or may be contaminated with pathogenic micro-organisms. Note also that laboratory sterilizers without a make-safe cycle may be occasionally used to process infected material in the event of the designated machine being out of service. The user should therefore ensure that personnel working on laboratory sterilizers wear appropriate protective clothing and are fully informed of any hazards that may be present. Further guidance may be found in the HSC document 'Safe working and the prevention of infection in clinical laboratories: model rules for staff and visitors', compiled by the Health Services Advisory Committee.

Gaseous sterilants

1.27 Low-temperature steam and formaldehyde (LTSF) sterilizers and ethylene oxide (EO) sterilizers both use toxic gases in the sterilization process. Occupational exposure to formaldehyde and EO is controlled by the Control of Substances Hazardous to Health (COSHH) Regulations (see Part 1). Maximum exposure limits are set out in the annual Guidance Note EH40, 'Occupational exposure limits', published by the Health and Safety Executive (HSE) (see References). The limits shown in Table 1 are as at 2001. These limits are statutory maxima but should not be regarded as representing a safe working exposure; employers have a legal obligation to ensure that the level of exposure is reduced so far as is reasonably practicable and in any case below the maximum exposure limit.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Table 1: Maximum exposure limits for atmospheric formaldehyde and ethylene oxide

	Short term exposure limit		Long term exposure limit	
Gas	[ppm]	[mg m^{-3}]	[ppm]	[mg m^{-3}]
Formaldehyde	2	2.5	2	2.5
Ethylene oxide	-	-	5	9.2

The short-term exposure limit (STEL) is the average over any 15-minute period.

The long-term exposure limit (LTEL) is the exposure over any 24-hour period expressed as a single uniform exposure over an 8-hour period.

COSHH does not specify a STEL for EO. In such cases the STEL is deemed to be three times the LTEL in accordance with the recommendations of the Health and Safety Executive.

(Source: HSE Guidance Note EH40 (2001)

1.28 Certain tests in this document require that the sterilant gases be replaced with a suitable non-hazardous substitute:

a. for LTSF sterilizers, the primary material for generating formaldehyde (usually formalin) should be replaced with water;

b. for EO sterilizers where the gas is supplied from cylinders, the sterilant gas should be replaced with a suitable non-toxic, non-flammable gas or gas mixture admitted to the chamber through the EO supply system (including the vaporiser). Air may be used if the system is known to be free of residual traces of EO sufficient to cause an explosive or fire hazard (see paragraph 6.54 for a specification for a suitable monitoring instrument), but nitrogen is recommended as being safe in all circumstances;

c. for EO sterilizers where the gas is supplied from cartridges contained within the chamber, no substitute is normally necessary because of the small amounts of EO present in the system. If a substitute is thought to be desirable, nitrogen cartridges may be used.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2. Testing of sterilizers

Introduction

2.1 Sterilization is a process whose efficacy cannot be verified retrospectively by inspection or testing of the product. For this reason sterilization processes have to be validated before use, the performance of the process routinely monitored, and the equipment maintained.

2.2 Means of assuring that a sterilizer is fit for its Intended purpose will include tests and checks carried out during the various stages of manufacture, after delivery, during validation and periodically thereafter. Tests will also be required before a sterilizer is returned to service after modification.

2.3 The philosophy of testing and maintenance embodies three main principles to ensure that required standards of performance and safety are attained and sustained:

a. all sterilizers are subject to a planned programme of tests to monitor their performance;

b. all sterilizers are subject to a planned programme of preventive maintenance irrespective of whether or not a preventive maintenance scheme is being operated on the premises generally;

c. expertise on all aspects of the testing of sterilizers should be available at two levels; these are represented by the authorised person (sterilizers) and the test person.

2.4 The scheduled test programmes include simple procedures undertaken by the user, as well as more complex tests undertaken by the test person to demonstrate that the equipment is functioning satisfactorily.

2.5 Schedules for installation checks, validation tests and periodic tests are presented in Chapters 3, 4 and 5, and discussed below. Where appropriate, the schedules refer to detailed test procedures described in later chapters.

2.6 Maintenance of sterilizers is dealt with in Part 4 of this SHTM.

Responsibilities for validation

2.7 Sterilizers should be commissioned on site using the procedures described in this SHTM. The purchaser, manufacturer and contractor have distinct responsibilities.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Purchaser

2.8 Management should nominate an authorised person (sterilizers) to provide advice on validation.

2.9 The test person should witness the installation checks and tests carried out by the contractor, and arrange for test loads to be supplied as required.

2.10 The test person should carry out the commissioning tests and performance qualification tests. (Some of the performance qualification tests on LTSF and EO sterilizers are the responsibility of the user.)

Manufacturer

2.11 The manufacturer should ensure that the sterilizer is designed, manufactured and tested within a quality system such as that given in BS 5750. The extent of testing will depend on whether the manufacturer has obtained a current certificate of compliance to a relevant British or European Standard by means of a type test for the particular type and size of sterilizer:

a. where a certificate is available, the manufacturer may limit the works tests to those which demonstrate compliance with the specification;

b. when a certificate is not available, such as for a one-off design, works tests should (except for the sound pressure test) include those listed as commissioning tests in Tables 2 and 3 (see Chapter 4). This option is expensive.

Contractor

2.12 The contractor (who may also be the manufacturer) should complete the installation checks and tests specified in Chapter 3 to the satisfaction of the test person before the sterilizer can be accepted for use in accordance with the contract.

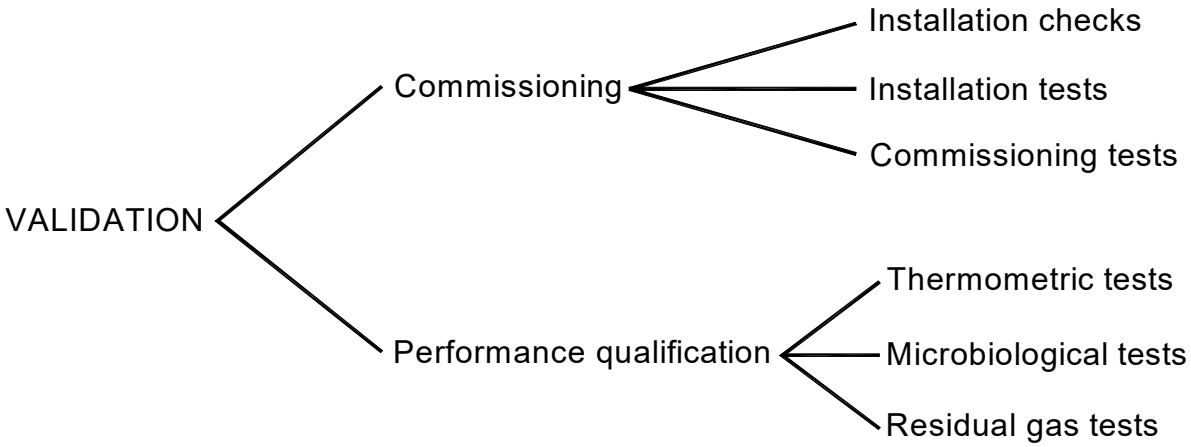
2.13 The contractor should provide the test instruments and equipment (but not the test loads, see paragraph 2.9) required for the installation checks and tests, and should satisfy the authorised person that their accuracy, calibration and condition meet the requirements for test instruments specified in Chapter 6, and that the calibration of each instrument has been checked on site and is satisfactory.

The validation process

2.14 Validation is defined as a documented procedure for obtaining, recording and interpreting the results needed to show that a process will consistently yield a product complying with predetermined specifications. Validation is considered as a total process which consists of commissioning followed by performance qualification (Figure 1).

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Figure 1: The validation process



Commissioning

2.15 Commissioning is defined as the process of obtaining and documenting evidence that the equipment has been provided and installed in accordance with its specifications, and that it functions within predetermined limits when operated in accordance with operational instructions.

2.16 Commissioning consists of a series of installation checks and installation tests (often identified as “installation qualification” and “equipment qualification”) to be carried out by the contractor, and a series of commissioning tests to be carried out by the test person.

Installation checks

2.17 On delivery of the sterilizer, the contractor should carry out the required installation checks to establish that the sterilizer has been provided and installed correctly, is safe to operate, does not interfere with nearby equipment and that all connected services are satisfactory and do not restrict the attainment of conditions for sterilization.

2.18 Ancillary equipment, such as service supplies and ventilation systems, should be checked by the contractor responsible for their installation.

2.19 The schedule for installation checks is set out in Chapter 3.

Installation tests

2.20 When the installation checks have been completed, the contractor should carry out the required installation tests to demonstrate that the sterilizer is working satisfactorily. The contractor is not required to carry out any thermometric tests unless previously specified in the contract. Any assistance required from the department in which the sterilizer is installed should be agreed between the contractor and the purchaser.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.21 If any maintenance or modification work is carried out on the steam, water or piped gas services after the installation tests have been completed, the tests should be repeated by the test person before the commissioning tests commence.

2.22 The schedule for installation tests is set out in Chapter 4.

Commissioning tests

2.23 When the sterilizer has been accepted, the test person should carry out a sequence of commissioning tests to evaluate basic performance and safety. Some of these commissioning tests are identical to those specified as installation tests, and need not be repeated if commissioning follows within seven days of the installation tests.

2.24 The schedule for commissioning tests is set out in Chapter 4.

Performance qualification

2.25 Performance qualification (PQ) is defined as the process of obtaining and documenting evidence that the equipment as commissioned will produce an acceptable product when operated according to process specification.

2.26 PQ consists of tests designed to show that sterilization conditions are attained throughout a production load. A thermometric test is sufficient for most sterilizers but an additional microbiological test is required for sterilizers using gaseous sterilants, and may be necessary for any sterilizer where loading conditions cannot be validated solely by thermometric methods.

2.27 In principle, a PQ test is required for each loading condition that the sterilizer is intended to process. In practice, a test on a single “reference load” may be valid for a range of less demanding loading conditions and in some cases, notably porous loads, the tests specified for commissioning will often provide sufficient evidence for performance qualification.

2.28 The schedule for performance qualification tests is set out with the commissioning tests in Chapter 4. Further information and detailed procedures for performance qualification are given in Chapter 8.

Documentation

2.29 Accurate and efficient keeping of records is an essential part of the management of a sterilizer. A recommended system, based on a plant history file and a sterilizer process log, is described in Part 4 of this SHTM.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Summary sheets

2.30 On the completion of the validation process, and before leaving the premises, the test person should prepare summary sheets for the user containing the results of the commissioning and PQ tests, and essential working data. At the request of the user the test person should also supply graphical representations of cycle variables obtained from the thermometric tests. The sheets should be signed by the test person and countersigned by the user to certify that the sterilizer is fit for use. Summary sheets should be kept in the sterilizer process log for ready reference by the user. A set of model summary sheets is given in Appendix 3.

2.31 At the same time the test person should provide the user with copies of any master process records (see paragraph 8.58) required for routine production.

Validation report

2.32 Within one month of the completion of the validation process the test person should prepare a full validation report. It should include the following:

a. all the data, supplied by the contractor, collected during the installation checks specified in Chapter 3 and the installation tests specified in Chapter 4, with written confirmation from the contractor that they meet the manufacturer's specifications;

b. written confirmation from the contractor that the calibration of all instruments and gauges fitted to the sterilizer has been verified;

c. all the data collected during the commissioning tests specified in Chapter 4, with written confirmation from the test person that they meet the requirements of the tests;

d. data showing the correlation between the performance of the instruments fitted on the sterilizer and the test instruments used for commissioning and performance qualification;

e. all the data collected during the performance qualification tests in the form of PQ reports (see paragraph 8.54), with written confirmation from the test person and the user and (for medicinal products) the quality controller of the loading conditions (see paragraph 8.7) which may be satisfactorily processed in the sterilizer.

2.33 If any of the data is in the form of electronic data files, the report should include copies of disks or tapes containing the data in a format agreed with the user, and a print-out of each disk or tape directory showing clearly where the data for each test are to be found.

2.34 The test person should certify that all tests and checks have been carried out and that the results are satisfactory. The microbiologist should sign the records of any microbiological tests. The complete validation report should be examined and countersigned by the authorised person.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.35 The validation report should be given to the user for the plant history file and a copy retained by the test person. Copies should be sent to the authorised person and, on request, to the quality controller and the microbiologist.

Periodic tests

2.36 After the validation process has been completed, and the sterilizer is passed into service, it is subject to a schedule of periodic tests at daily, weekly, quarterly and yearly intervals. These tests are the shared responsibility of the user and the test person.

2.37 The yearly test schedule is essentially a revalidation schedule. It provides for performance requalification (PRQ) tests to confirm that data collected during performance qualification remain valid.

2.38 The schedule of periodic tests is set out in Chapter 5.

Revalidation

2.39 Revalidation is the process of confirming that the operational data acquired during validation remain valid. It consists of recommissioning followed by performance requalification. Revalidation is required on the following occasions:

a. when modifications or engineering work are carried out which could affect the performance of the sterilizer, for example:
   (i) when a sterilizer is to be returned to service after the repair of a serious defect (see Part 4);
   (ii) when the inspection of a sterilizer pressure vessel by the competent person requires the removal of components which could affect the performance of the sterilizer (if the inspection immediately precedes a yearly test, recommissioning is not necessary);
   (iii) when the preset values of cycle variables have been modified;
   (iv) when the software in a computer control system has been upgraded or otherwise modified;

b. when the sterilizer is to be returned to service after investigation and correction of unacceptable deviations from performance data established during validation, for example:
   (i) when the pattern of a batch process record is outside the limits specified on the master process record;
   (ii) when the sterilizer fails a periodic test;

c. when there is a demand for revalidation by an authorised inspectorate or licensing authority;

d. whenever the user or authorised person advises that revalidation is necessary.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

2.40 The revalidation procedure is identical to that prescribed for the yearly tests set out in Chapter 5.

Repeat validation

2.41 On occasions, usually rare, it will be necessary to repeat the validation procedure to obtain a new set of commissioning and performance qualification data to replace the set originally obtained during validation. Repeat validation is required on the following occasions:

a. when the sterilizer is subject to modifications of such a nature that the validation data must be presumed to be no longer valid, for example:
   (i) when a sterilizer, other than a transportable, has been moved and installed at a new site;
   (ii) when a sterilizer has been dismantled or extensively overhauled or modified;
   (iii) when a new operating cycle has been introduced;
b. when revalidation or a yearly test fails to confirm the validity of the original validation data and no obvious cause can be found;
c. whenever the authorised person advises that repeat validation is necessary;
d. when there is a demand for repeat validation by an authorised inspectorate or licensing authority.

2.42 The authorised person should advise on which elements of the validation process need be repeated. For example, it will not be necessary to repeat all of the installation checks.

Types of test

2.43 Although many tests are listed in the schedules, they fall into a few basic categories as follows.

2.44 **Automatic control tests** are designed to show that the operating cycle functions correctly as evidenced by the values of the cycle variables indicated and recorded by the instruments fitted permanently to the sterilizer.

2.45 **Thermometric tests** use accurate measuring equipment to monitor temperatures and pressures independently of the instruments fitted to the sterilizer. They provide the assurance that the temperature requirements for sterilization are met:

a. thermometric tests for a **small load** are designed for two purposes. In sterilizers with an active air removal system they demonstrate that the sterilizer is capable of removing air from a small load in which air from a near-empty chamber has been retained. In cycles for fluid loads they

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

demonstrate that sufficient condensate will be collected for cooling purposes, and that the initial temperature overshoot is kept within acceptable limits;

b. thermometric tests for a **full load** are designed to show that sterilization conditions are present in a test load of specified maximum mass and of sufficient size to fill the usable chamber space. In certain circumstances they may also serve as PQ tests for loading conditions which present a lesser challenge to the operating cycle than the specified full load (see paragraph 8.7).

2.46 **Microbiological tests** are designed to show that sterilization conditions are attained where thermometric methods are inadequate, that is, for LTSF and EO sterilizers and for exceptional loading conditions in other sterilizers.

2.47 Other tests, specific to certain types of sterilizer, are designed to show that the steam supply is suitable, the sterilizer does not produce too much noise, the chamber is airtight, gaseous sterilants are not released into the environment, and safety devices are functioning correctly.

Procedure on failure of a test

2.48 A correctly installed and maintained sterilizer should have no difficulty in complying with either the validation tests or the periodic tests. As a rule, a failure of a test implies that the sterilizer is not working to specification, and it should be withdrawn from service and the failure investigated. In practice the immediate action to be taken is a matter for judgement based on the nature of the failure and experience gained in using the sterilizer. In some cases it may be acceptable for the sterilizer to continue in service under restricted operating conditions until the failure can be investigated. The authorised person and the user should agree in advance on how to handle test failures.

2.49 **It should be emphasised that the user has the ultimate responsibility for certifying that the sterilizer is fit for use.**

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3. Schedule of installation checks

Introduction

3.1 On delivery of the sterilizer the contractor should carry out the installation checks set out in this chapter and included in the contract to establish that the sterilizer has been provided and installed correctly, is safe to operate, does not interfere with other equipment and that all connected services are satisfactory and do not restrict the attainment of conditions for sterilization.

3.2 Installation checks on services and other ancillary equipment should be carried out by the contractor responsible for their installation. These checks should be completed satisfactorily before starting the checks on the sterilizer itself.

3.3 Any checks specified here which are not included in the contract should be completed by the test person before commissioning begins.

3.4 As a safety precaution, checks on LTSF sterilizers should be carried out on the LTS cycle only. Checks on EO sterilizers should be carried out using a non-hazardous substitute for the sterilant as described in Chapter 1.

Checks on ancillary equipment

3.5 Ancillary equipment should ideally be installed and commissioned before the validation procedure for the sterilizer begins. Where the checks require the sterilizer to be operating, the test person should carry them out in cooperation with the sterilizer contractor. The sterilizer contractor is not responsible for the correct functioning of services and other ancillary equipment unless agreed in the contract.

Engineering services

3.6 Check that the following requirements are met:

a. the engineering services are installed correctly, they are adequate to meet the demands of the sterilizer, and they do not leak;

b. drains remove effluent effectively when all plant in the vicinity, including the sterilizer, is connected and operating;

c. the water economy system (if fitted) operates correctly;

d. for EO sterilizers supplied from cylinders, the system complies with the requirements of Part 2, and all gas lines are free of leaks.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

Additional checks for LTSF and EO sterilizers

3.7 LTSF and EO sterilizers require further checks to the ventilation and safety systems because of the use of toxic gases.

3.8 For both LTSF and EO, check that the ventilation systems within the loading area, plantroom and manifold room meet the requirements of Part 2. Pay particular attention to the following:

a. they meet the manufacturer's specification;

b. air flow is from the operator towards the sterilizer, and air does not flow from the plantroom into the loading area;

c. exhaust systems are non-recirculating and their discharges comply with safety regulations;

d. if the air flow is insufficient to cause a minimum of 10 air changes an hour:

(i) a warning is given;

(ii) the door cannot be opened at the end of the operating cycle;

(iii) a new cycle cannot be started.

3.9 Check that the local exhaust ventilation system meets the requirements of Part 2. Pay particular attention to the following:

a. air flow is from the operator towards the sterilizer, and air does not flow from the plantroom into the loading area;

b. the rate of flow complies with that specified in Part 2;

c. the exhaust discharge complies with safety regulations specified in Part 2.

3.10 Check that the drain from the sterilizer to the drainage system is trapped, sealed and vented to a safe position, as described in Part 2.

Additional checks for EO sterilizers

3.11 Check that the local exhaust ventilation system meets the following requirements in addition to those in paragraph 3.9:

a. manual control switches are located in prominent, easily accessible positions, such as in the EO cylinder change area;

b. the system operates whenever any one of the manual switches is operated;

c. it operates automatically at the end of an operating cycle and before the door is opened;

d. it operates whenever any of the gas detectors sense that the atmospheric concentration of EO exceeds the short-term exposure limit specified in Table 1.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.12 Check that EO safety installations meet the requirements of Part 2. Pay particular attention to the following:

a. notices concerning emergency procedures, safety and restricted access are displayed in prominent positions;

b. where gas is supplied from cylinders:

(i) environmental alarm and emergency systems are installed and operate in accordance with the specification;

(ii) emergency protective equipment is provided and stored in designated areas.

Checks on the sterilizer

3.13 The following checks presume that engineering services and other ancillary equipment are functioning correctly.

Preliminary checks

3.14 After the sterilizer has been installed, check that the following requirements are met:

a. the manufacturer has supplied all the documents specified in the contract;

b. the sterilizer has been supplied and installed in accordance with the contract;

c. calibration verification certificates for the temperature and pressure instruments and controllers are supplied;

d. no defects are apparent from a visual inspection of the sterilizer;

e. all supports, bases, and fixing are secure and without imposed strain from service connections;

f. thermal insulation is in good condition and securely attached;

g. security and settings of door safety switches and door-locking components are in compliance with data provided by the manufacturer;

h. keys, codes or tools required to operate locked controls are supplied and operate satisfactorily. Each key, code or tool unlocks only the control for which it is intended, and cannot unlock controls on other sterilizers in the vicinity;

i. loading trolleys and other aids are effective and safe in use.

© Borders General Hospital NHS Trust on behalf of NHSScotland Property and Environment Forum

3.15 Check that the electrical equipment on the sterilizer is correctly connected to the electrical service. Carry out the following electrical tests:

a. insulation resistance;

b. phase sequence (for three-phase installations);

c. polarity;

d. bonding and earth continuity;

e. emergency stop.

Functional checks

3.16 During an operating cycle with an empty chamber, check that the following requirements are met (several cycles may be necessary to complete all the checks):

a. the selection of automatic or manual control is by key, code or tool. When the controller is in manual mode, the automatic control is inactivated. When the controller is in automatic mode, the manual control is inactivated;

b. under automatic control, steam, compressed air, formaldehyde or EO cannot be admitted into the chamber, and the operating cycle cannot start, until the door is locked and sealed. Under manual control, the operator can advance the cycle only sequentially through each stage. Any stages designed to remove formaldehyde or EO from the chamber and load cannot be circumvented;

c. throughout the cycle, indicated and recorded steam, water, air and gas pressures are within the limits specified by the manufacturer;

d. throughout the cycle, there are no leaks of steam, water, air, gas or effluent;

e. there is no evidence of interference to or from other equipment connected to the same services;

f. there is no evidence of electromagnetic interference to or from other equipment;

g. operation and readings of all instruments appear satisfactory, including return to zero (this may not be achievable with combined pressure and vacuum gauges);

h. the temperature of surfaces routinely handled by the operator does not exceed that specified in Part 2;

i. the effluent temperature does not exceed that specified in Part 2.

3.17 At the end of a cycle check that the following requirements are met:

a. the door opening system cannot be operated until the chamber vent valve is open, and the chamber pressure is within 200 mbar of atmospheric;

b. door retaining parts cannot be released until the seal between the door and chamber has been broken, and the chamber is effectively vented to atmospheric pressure;

c. the door interlock system is either fail-safe or is fitted with at least two independent interlocks. Failure of one interlock, or any one service, does not allow the door to be opened when conditions within the chamber would cause a hazard, for example, pressure in excess of 200 mbar, unacceptable level of sterilant gas, or temperature of fluid in sealed containers above 80°C (glass) or 90°C (plastic);

d. for EO sterilizers, the operating cycle automatically returns to either the gas removal stage or the flushing stage if the door has remained sealed for more than 15 minutes after the admission of air;

e. the automatic controller has operated in accordance with the specification.

Response to external faults

3.18 It is necessary to check that the sterilizer reacts correctly and safely when exposed to a number of external fault conditions, that is, a safety hazard is not created and a false indication of cycle complete is not obtained. During each stage of an operating cycle, check the response of the sterilizer to the following simulated faults (where appropriate to the type of sterilizer):

a. operation of the emergency stop button;

b. power failure;

c. steam pressure too low;

d. steam pressure too high;

e. water pressure too low;

f. compressed air pressure too low;

g. failure of sterilant gas supply (LTSF and EO);

h. failure of room ventilation (LTSF and EO).

4. Schedule of validation tests

Introduction

4.1 Installation tests are carried out by the contractor to demonstrate compliance with specifications, and may be repeated by the test person if required. Commissioning and performance qualification tests are carried out by the test person.

4.2 The schedules for the tests are set out for each type of clinical sterilizer in Table 2 and for laboratory sterilizers in Table 3. Each test is cross-referenced to a detailed description of the test procedure in a later chapter. The tests should be carried out with the sterilizer at normal working temperature (a warming-up cycle may be needed) and completed in the order shown.

4.3 The laboratory machine known as a Köch steamer is not listed here. Where it is used primarily for melting agar, validation tests are not required. Where it is to be used for the disinfection of a product, the thermometric tests prescribed in Table 3b for the culture media cycle should be followed.

4.4 The calibration of thermometric test equipment should be checked before and after the thermometric tests as described in paragraphs 6.32-39.

4.5 In principle, performance qualification tests should be carried out after the commissioning tests have been completed. However, for sterilizers with an active air removal system, thermometric PQ tests may be performed while the sensors used in the commissioning tests are still in place and before any final vacuum leak test. This is provided for in the schedules. Where tests on EO sterilizers require EO gas to be in the chamber, however, sensors should either be removed from the chamber or else disconnected from the recorder and the wires grounded to the body of the sterilizer (see note (d) to Table 2f).

4.6 Chapter 8 describes general procedures for conducting performance qualification tests and generating master process records.

Table 2: Schedule of validation tests for clinical sterilizers

Table 2a: Validation tests for porous load sterilizers

		Ref
	Installation tests – contractor	
1.	Vacuum leak test	11.2
2.	Verification of calibration of sterilizer instruments	6.32
3.	Automatic control test	12.1
	Commissioning tests – test person	
1.	Steam non-condensable gas test	9.4
2.	Steam superheat test	9.20
3.	Steam dryness test	9.30
4.	Vacuum leak test	11.2
5.	Vacuum leak test (temperature and pressure sensors connected)	11.2
6.	Automatic control test	12.1
7.	Verification of calibration of sterilizer instruments*	12.2
8.	Chamber wall temperature test	13.3
9.	Air detector performance test for a small load	11.45
10.	Air detector performance test for a full load	11.53
11.	Thermometric test for a full load	13.15
12.	[Load dryness test]*	13.25
13.	Thermometric test for a small load	13.7
14.	[Load dryness test]*	13.25
15.	Thermometric test for a small load (to check consistency with test 13)	13.7
	Performance qualification tests (see below)	
16.	Vacuum leak test (sensors removed)	11.2
17.	Air detector function test	11.60
18.	Bowie-Dick test for steam penetration	13.3
19.	[Sound pressure test]	10.1
	Performance qualification tests – test person	
1.	Thermometric tests for performance qualification as required by the user[a]	8.13
2.	Hospital load dryness check	13.25

* May be done at the same time as the preceding test.
[ ] Optional test, to be done at the user's discretion.
a. Not normally required for loads processed in a sterile services department (SSD) (see paragraph 8.7).

2.	Microbiological tests for performance qualification as required by the user[d]	18.49
3.	Environmental gas tests*	8.37
	Performance qualification test – user	
1.	Tests for degassing time	8.46

* May be done at the same time as the preceding test.
[ ] Optional test, to be done at the user's discretion.
a. Required only where the sterilizer operates above atmospheric pressure.
b. Required only where a circulating fan is fitted. Instrumentation is used to demonstrate that pressures and flows specified by the manufacturer are obtained.
c. May be omitted if test data are provided by the manufacturer.
d. To avoid risk of sparking, tests using EO gas should not be done while temperature sensors are in the chamber. Providing safe operating procedures are not compromised, it may be acceptable to disconnect the sensors from the recorder and ground the wires to the body of the sterilizer.
